# Abstraction

*Internet is growing in a fast manner. It covers a wider range of human activities nowadays. This growth leads to great opportunities for doing business online. For this reason, we built this online traveling agency to practice real life E-commerce. In this report, we will summarize the work done in this semester and state the improvement made on the projects since the last report. First of all, there will be an overview of the whole project, and then the facilities provided by TravelNet such as online shopping and flight reservation will be described. After that, actual implementation and system architecture will be introduced. CORBA integration with TravelNet for containing distributed components is also an important new part to be mentioned. TravelNet is cooperated with a secure payments system for credit cards and a micropayments system for store-value cards. Their communication mechanism will be described and a performance measurement on payment will also be conducted also. Finally, a conclusion will be given.*

# Chapter1.Introduction

## ObjectiveandOverviewofTravelNet

TherearemanycompaniesthatexpandtheirbusinessontotheInternetforselling product,promotingtheirproductsandprovidingservices.Thiskindofbusinessnotonly opensanewwayforbusinessbutalsoprovidegreatconvenienceforcustomers.The mainobjectiveofthisprojectistodevelopsuchanE-commerce systemthatis similar to reallifeandcanfulfilltheactualneedsofthesociety.

TravelNetprovidesmostofthecommontypeofservices,whichisprovidedinreality, theyareprovidinginformation(TravelGuides,HotelInformation),services(Flight Reservation)andproducts(OnlineShop).Aswhatcustomersneedisaninteractive service-providingsite,Webserversshouldbecapableofhandlingdynamiccontentwith respecttoclientrequests,so serversideprogramming,backendinformationretrievaland dynamicWebpagesgenerationisnecessary.InTravelNet,WemakeuseofJava ProgrammingLanguagewithJavaServletandJavaServerPagetofulfilltheseneeds.

## Chapter2.TravelNetFacilities

### 2.1.Introduction

TravelNet, similar to other traveling agencies, provides a number of convenient functions to users so they can enjoy their travel without spending a lot of effort. Services included flight search and reservation, online accessory shop, hotel information and travel guides. Before using these services, a user must register to be our member, so register and login services for membership is also provided.

Below is the main page of TravelNet, users can access these services through a click on the links.

Figure2.1.TravelNetMainPage

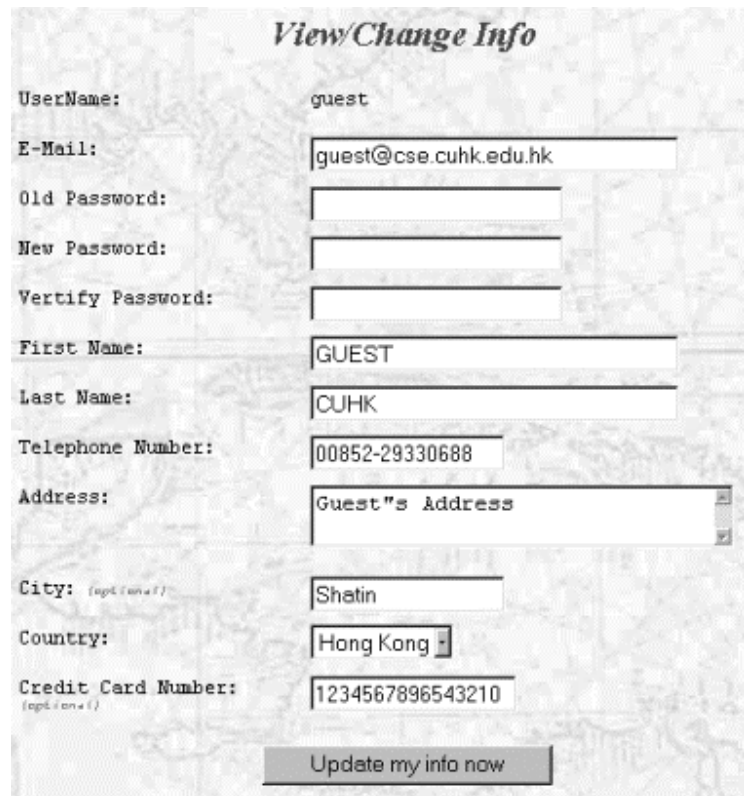

Figure2.23.Updatepersonalinformation

## 2.3 Flight Search and Reservation

Flight search is one of the most significant features of TravelNet. It had been enhanced a lot since the last semester. Now not only the single flight search, but also round trip flight search. In addition, itinerary management and flight ticket reservations system is now available.

### Flight Search

In single flight search, users are allowed to consult the airlines' databases with users requirement and make reservation on the search result. The system requires user to input some basic elements on the search. The basic elements of queries include the departure and arrival cities, the departure date, the types of flight (one way/round trip), the class of service (first class/business class/economy class), the age category of the ticket (below 12/adult/above 65). Possible additional requirement include the exact range for departure time, the choice on fare (e.g. is there any penalties for refund of tickets), the airline company, etc. Usually, the optional requirement help to lower the size of the search result while the basic method is also provided to enhance the flexibility of the search. These search options are flight company and change penalty. In round trip flight search, the available options are similar except on more return date and time. Round trip is always cheaper than 2 single flights so this flight search is useful for those people who had already planned their trips specifically.

The screenshot shows a web interface for flight search. At the top, there is a logo with a plane icon and the word 'FLIGHTS' in a stylized font. Below the logo, the text 'One Way Search' is displayed. The form is divided into four numbered sections:

- 1. Where and when do you want to travel?**
  - 'Select the city from the list'
  - 'From:' dropdown menu with 'Hong Kong' selected.
  - 'To:' dropdown menu with 'Hong Kong' selected.
  - 'Departing: (Month-Day-Year)' with 'Jan', '1', and '1999' selected.
  - 'Departure Time:' dropdown menu with 'Not Specific' selected.
- 2. Who is going on the trip?**
  - 'Please choose the appropriate age group for the ticket holder'
  - 'Adults (age 12 to 64)' selected.
- 3. Do you have any preferences?**
  - 'Class:' dropdown menu with 'Economy' selected.
  - 'Type: (leave it UNCHECKED for lower price ticket if it is not necessary)'
    - No change penalties after purchase.
  - 'Airline:' dropdown menu with 'Not Specific' selected.
- 4. Start the search?**
  - 'Search the result to show:'
    - Lowest price tickets
    - All possible choices
  - 'Search NOW!' button
  - 'Reset all fields' button

Figure 2.31. Flight Search

All these selectable fields are combo boxes. These boxes reduce the typing error and provide easier selection. Even those people who are not familiar with flight information can still get what they want from these selection in these boxes. After results have been displayed, the user can select any of them and add to their own itinerary.

As a sample result as shown on the right. A user can select one of the flight which is more suitable to him/her and add it to itinerary by clicking the button on the bottom left corner.

Figure2.32.Searchresult

## Itinerarymanagement

Figure2.41.TravelShopmainpage

## ShopBasket

After user has found a product he/she is interested in, he/she may add it to the basket by clicking the "Add to Basket" button. Users may also change the color they desire and the quantity they want.

Figure 2.42. Adding an item to basket

In the basket interface, you can drop any item from your basket by selecting the item to drop then click the Update Basket Button. Afterwards, it will be refreshed and updated.

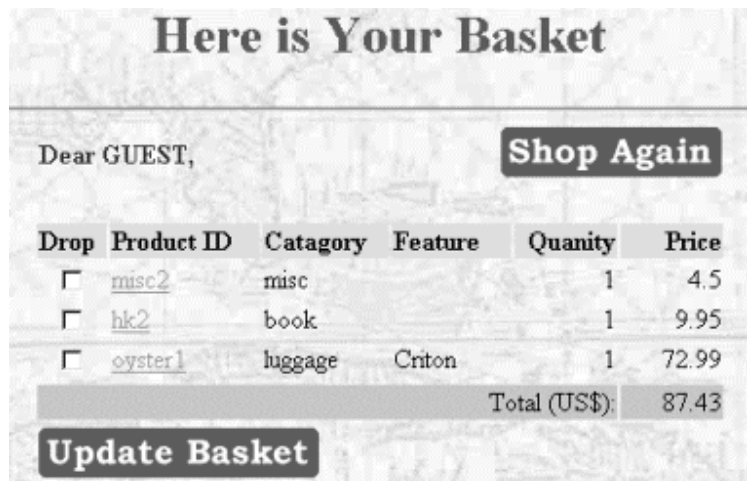

Figure 2.43. Displaying Shop Basket

### ShopPayment

Different from flight reservation, users can pay for their selected stuffs in the shop basket not only by credit card but also MONDEX card. As the items sold in TravelShop is not too expensive, we can make use of Internet micro payment method to provide a more secure and convenient way for our customers to pay their bills.

For MONDEX payment, user should ready their card into the reader when they hit the link. After that the client will connect to MONDEX payment server and start the payment. For credit card payment, they have to type in the correct information before they checkout. Information like type of card, name of card holder, card number and expire date is necessary. For both payment methods, upon a successful payment, an acknowledgement will be given, then TravelNet will carry on to the post payment processes.

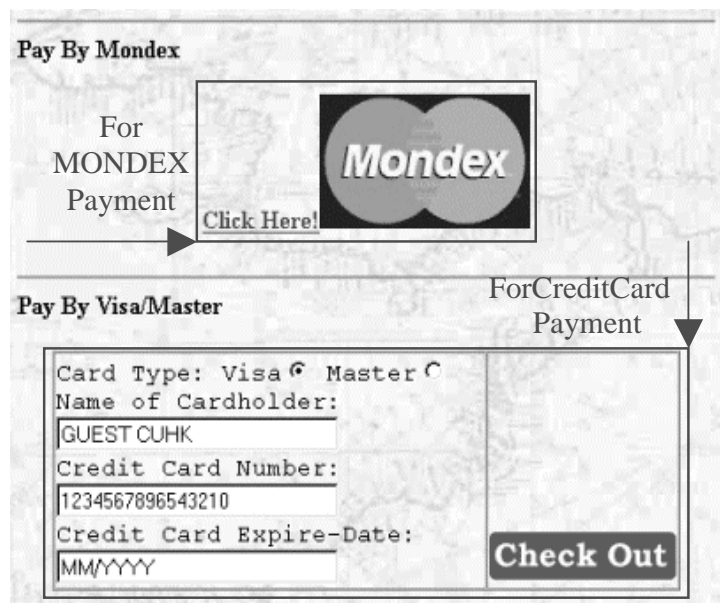

Figure 2.44. Payment Screen

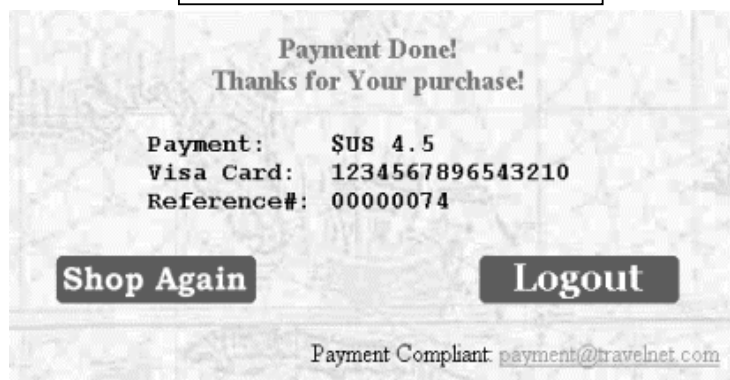

Figure 2.45. Payment Done

## 2.5.HotelInformation

Hotel is an essential part for any travel, so TravelNet includes some useful information for the hotels of the Asian cities that TravelNet targeted on. The cities included Beijing, Hong Kong, Tokyo, Seoul, Shanghai, Taipei and Singapore. Users can easily browse the information of the hotels by some click on the hotel information main page. Hotel reservation is not available since our project time is limited and the mechanism is more or less similar to that of flight reservation, so we miss that out.

This snapshot on the right shows a sample hotel information page of TravelNet. Information includes description, location, room, rates and facilities of a hotel. Also some images of the hotel will be posted in the page. Users can still make a reservation request to the hotel, but TravelNet will just direct the request to the specified hotel.

Figure 2.51. Hotel Information Main Page

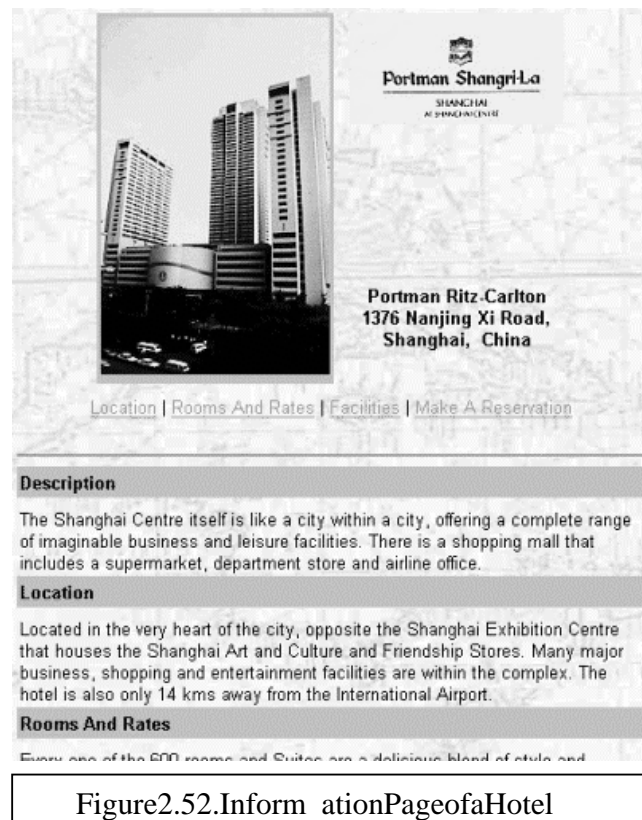

Figure 2.52. Information Page of a Hotel

## 2.6.TravelGuides

Itwillbeveryconfusingifatravelerdoesn't knowmuchabouttheinformationofthe places.TravelNettravelguideswillprovide usersacompleteoverviewofthetargeted countriesi.e.China,Japan,Korea,Singapore, Taiwan.Informationlike basicdescriptionof thecities, mapofthecities,introductionof somefamousspot,transportation andthe currency.

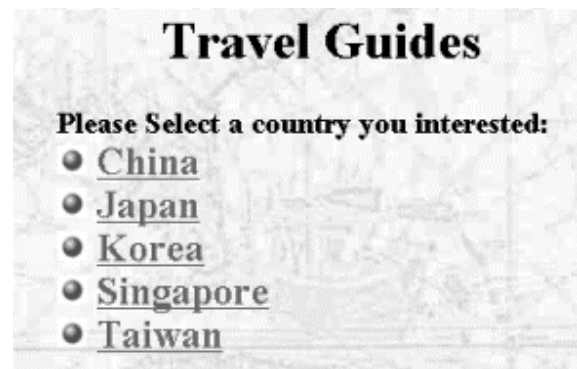

Figure2.61.TravelGuidesMainPage

## 2.7.OnlinePayment

AsmentionedbeforeonlinepaymentisaessentialpartofTravelNet.Flightreservation andshopcheckoutneedspayment.Wehadalreadyincorporatedwithtwotypesof Internetpayment,oneisthetraditionalcreditcardpaymentandtheotherisaneewmicro paymentmethodbyMONDEXcard.Wewilldescribethemechanismofthesepayment methods.AlsothecommunicationbetweenthesepaymentsserversandTravelNetwillbe statedinchapter5.

# Chapter3.SystemArchitecture

## 3.1.Introduction

Inthischapter,theoverallarchitectureofTravelNetwillbeshown.Component connectionswillbedescribedabstractlyinordertogiveaconceptualideaofhow TravelNetwork.Detaildesignwillbeprovidedinthenextchapter.Besides,theold modelwillalsoillustratedasacomparisonofmajorchanges.

## 3.2.SystemArchitectureOverview

### 3.2.1PreviousCentralizedSystem

BelowdescribetheoldsystemarchitectureOfTravelNet.Mostoftheprocessesare directdatabaseaccess,datamanipulationandgeneratingresponse.Thesystemincludes securityconcernonInternetconnection(SSL)eventhoughitlacksnearlyreallife paymentsystem.

3.2.1 Previous Centralized System (cont')

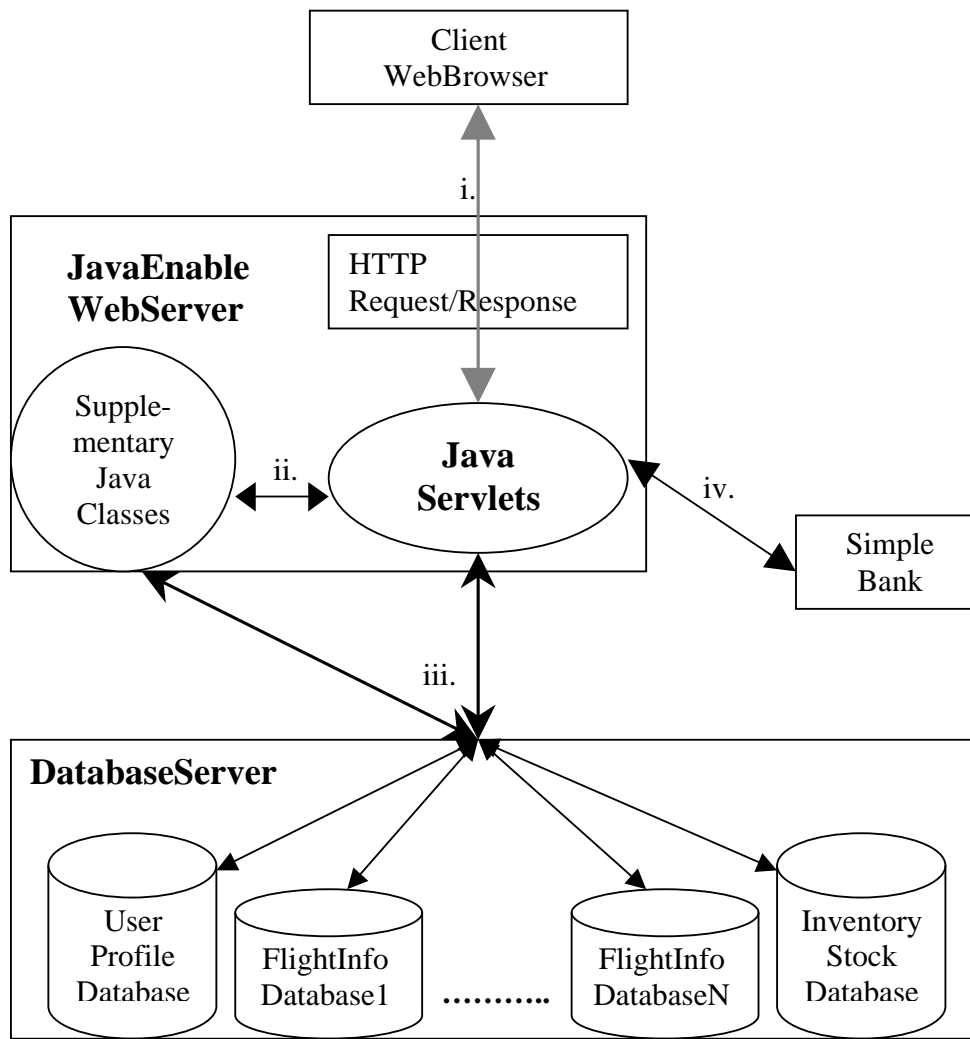

Figure3.21. System architecture of previous system

**Components description:**

- ◆ *Client Web browser* : Client of TravelNet with an HTTP Web browser that supports SSL connection.
- ◆ *Java enable Web server* : TravelNet Web server which is capable of running Java programs, Java Servlets and Java Server Pages for handling client requests
- ◆ *Java Servlets* : In TravelNet most of the application logic will be programmed inside it such as database connection and generating dynamic Web pages.
- ◆ *Simple Bank* : A very simple prototype of a bank to simulate credit card transaction.

- ◆ *Database Server* :It consists of a collection of database tables. Tables included TravelNet user profile, flight database of a number of airlines, inventory stock database for TravelShop.
  - ◆ User Profile database -It stores all TravelNet user's profile (username, password, name, address, etc.)
  - ◆ Flight Information database -each database represents an airline company database (so it should not be centralized). It stores the information like price, flight detail, classes and plane information.
  - ◆ Inventory Stock database -The data of the products sold in TravelShop will be stored in it.

Data flow descriptions:

- i. Client will use a web browser to access the web services provided by TravelNet Web server. Data/Requests send from client to server will be encrypted on a Secure Socket Layer (SSL). Web server will generate response page according to client request and send back to client browser.
- ii. Although Java Servlets can carry out all the application logic by itself, for reusability of components, we can build some classes for some common purposes.
- iii. Database access is essential for client requests, such as user management, flight searches and stock management. Java programs can access most of the databases system by JDBC. For this Java Servlets and Java classes can query the database for client requests and provide the necessary information.
- iv. At the end of 1<sup>st</sup> semester, we cannot obtain any secure payments server to incorporate with TravelNet, so we simulate a very simple one to handle credit card payment. When user checkout from TravelShop, it will invoke a checkout Servlet and update the bank database for the credit value of the credit card for checkout.

3.2.2 Current system with distributed components

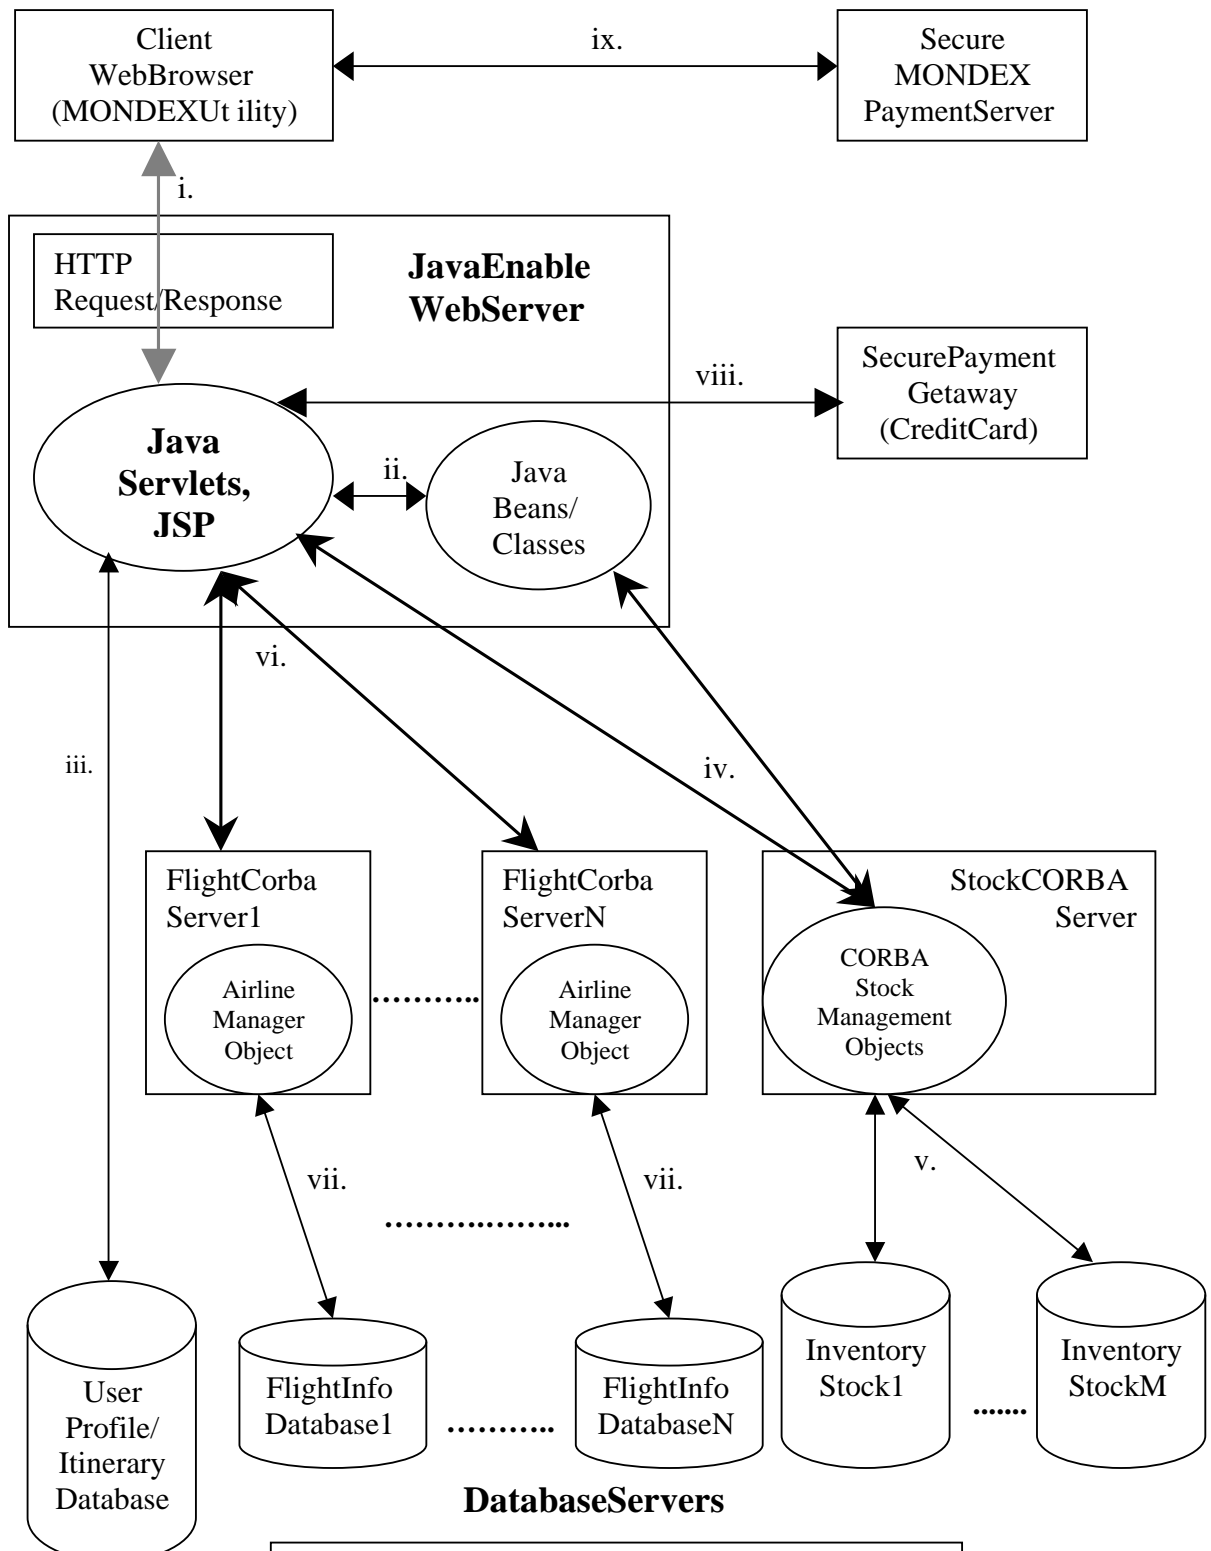

Figure 3.22. System Architecture of current system

### 3.2.2Currentsystemwithdistributedcomponents(cont')

Thecurrentsystemismuchmorecomplexthanbefore.Withsecurepayment systemsand distributedcomponentsaddedtothepreviousystem,it becomesmorerealisticandmodular.Nowwearegoingtoshowthedetailed flowofdataofthesystem.

#### **Componentsdescription:**

- ◆ *ClientWebbrowser* -ClientofTravelNetwithanHTTPWebbrowserthatsupport SSLconnection.FortheuseofMONDEX,clientmustbeequippedwithMONDEX hardwareandssoftware.
- ◆ *JavaenableWebserver* -TravelNetWebserverwhichiscapableofrunningJava programs,JavaServletsandJavaServerPages(JSP)forhandlingclientrequests
- ◆ *JavaServlets* :InTravelNetmostoftheapplicationlogicwillbeprogrammedinsideit suchasdatabaseconnectionandgeneratingdynamicWebpages.
- ◆ *Javabeansandclasses* -TheseJavamodulesprovidereusablefunctionstofulfillthe requests.JavaServerpagesmakeuseofbeansforprocessing,sothattheapplication logiccanbeseparatedfromwebdesign
- ◆ *UserProfiledatabase* -ItstoresallTravelNetuser'sprofile(username,password, name,address,etc.).Besides,itineraryofuserwillbestored inprofiledatabasealso.
- ◆ *FlightCORBAserver* - Eachserverwillmanageasingle(oronenumberof)airline managerobject.Queryofanyairlineinformationmustthroughtheairlinemanagers. ThesesimilarobjectsaredistributedbyanumberofCORBAserver .
- ◆ *FlightInformationdatabase* -Eachdatabaserepresentsanairlinecompanydatabase (soitshouldnotbecentralized).Itstorestheinformationlikeprice,flightdetail, classesandplaneinformation.
- ◆ *StockCORBAserver* - ACORBAserverthanmanagethest ockCORBAobjects. Eachobjectwillmanageastockdatabase,forupdatingandaccessinginformation. Anyrequesttothedatabasemustmakeuseofthemanagerobjectofthestockserver.

- ◆ *InventoryStockdatabase* -Eachdatabasestoresacategoryofproduct, like luggage. This stock database is different from the previous design, since the database is distributed by categories.
- ◆ *SecurePaymentGateway* - It is a secure payments system for credit card which is developed by a post-grad student. Credit card payment request will be handled by this system.
- ◆ *MONDEXPaymentServer* -MONDEX is a common smart card system for international use. The server is maintained by the Center of Innovation and Technology. The server allows MONDEX card for a payment over the Internet.

#### Dataflow description

- i. Client will use a web browser to access the web services provided by TravelNet Web server. Data/Requests send from client to server will be encrypted on a Secure Socket Layer (SSL). Web server will generate response page according to client request and send back to client browser.
- ii. Java Servlets will probably call some classes for processing some functions and Java Server Pages can make use of Java bean to handle some application logic.
- iii. All process related to user profile access will connect to the TravelNet users' database. These access include login, update profile, etc.
- iv. When a server application needs the stock data from databases, it will request the stock manager in the stock CORBA server using the interface provided by this object.
- v. Stock manager manages all the stock managing module of an inventory database of a specific category. According to the requests from web server, Stock manager will consult stock module to retrieve data from database.
- vi. When a flight related query/request is made from client, Web server will request the airline manager that reside on different machines for the desired information. Actual database is abstracted from the interface provided.
- vii. An airline manager can connect to their responsible database, data will be retrieved from the database according to the request from the interface.
- viii. If a check out or reservation process with a credit card payment is going to carry out, a message of encrypted (by payment server public key) request will be sent out. A

payment result acknowledgment message will be encrypted (by TravelNet's public key) and send back to merchant. Servlet will then process the result and generate output.

- ix. This connection is between Mondex client machine and Mondex payment Server. Payment plugin collect enough information of a payment from TravelNet Web server, then it request the payment server directly for a payment process. After payment is done, the result will be return to the client. The Mondex user will pass the payment result back to TravelNet and let it to verify the payment result.

## Chapter 4. System Design

### 4.1. Development tools

#### 4.1.1 Java

Java is an object-oriented language similar to C++, but simplified to eliminate language features that cause common programming errors. Java source code are compiled into a format called bytecode, which can then be executed by a Java interpreter. Compiled Java code can run on most computers because a Java interpreter and runtime environment, known as Java Virtual Machine which exist on most of the operating system.

It has a comprehensive set of classes for easier programming. Portability and structural object oriented approach make it suitable for large scale cross platform applications. The main reasons for selecting Java as a development tool are the easy integration with CORBA and the advantages for web applications.

#### 4.1.2. Java Servlet and JSP

Java Servlet is a well-defined Java package that bring great convenience to web applications. It is a server-side component that is platform and protocol independent. Servlets can be used to extend the functionality of a Java-enabled Web server. Servlet can be imagined as a faceless applet. Servlets are loaded and invoked by the Web server in much the same way that applets are loaded and invoked by Web browsers.

The HTTP Servlets replace the traditional CGI programming in a more convenient and efficient way. We can write pure Java language to handle web browser requests. As it is pure Java programming, all the advantages of Java will still be retained.

#### 4.1.2CORBA

CORBA allows applications to communicate with one another no matter where they are located or who has designed them. CORBA was introduced by Object Management Group (OMG) and defined the Interface Definition Language (IDL) and the Application Programming Interfaces (API) that enable client/server object interaction within a specific implementation of an Object Request Broker (ORB).

The ORB is the middleware that establishes the client-server relationships between objects. Using an ORB, a client can transparently invoke a method on a server object, which can be on the same machine or across a network. The ORB intercepts the call and is responsible for finding an object that can implement the request, pass it the parameters, invoke its method, and return the results. The client does not have to be aware of where the object is located, its programming language, its operating system, or any other system aspects that are not part of an object's interface. In so doing, the ORB provides interoperability between applications on different machines in heterogeneous distributed environments and seamlessly interconnects multiple objects systems.

The nature of CORBA meets our needs in distributing the system components. Airline companies agreed with a common CORBA interface, different airline companies can have different approaches on their own platform, database design and programming language used. Airline objects should reside on different machines so performance should be better than run all airline searches on a single machine.

##### **4.1.3.1.URL Namings services**

URL Naming Services is provided by Borland Visibroker 4.0. It is a simple mechanism that lets a server object associate its IOR with a URL in the form of a string in a file.

Client programs can then locate the object using the URL pointing to the file containing the stringified URL on the web server. The URL Naming Services supports any URL scheme that Java runtime supports, such as http.

IOR stands Interoperable Object Reference. It represents a reference to a CORBA object in the form of a string. By obtaining this string, the URL Naming service can help a client to resolve the reference to the object. This service will be used for the CORBA object reference for TravelNet.

## 4.2.DatabaseDesign

### 4.2.1.UserProfileDatabase

- **USER\_PROFILE:**

This database stores all necessary information of TravelNet users. Credit card number is not a compulsory field because it is not secure to store the credit card number in the database.

Name	Type	Nullity	Integrity
USERNAME	VARCHAR2(12)	NOTNULL	PRIMARYKEY
EMAIL	VARCHAR2(30)	NOTNULL	
PASSWORD	VARCHAR2(20)	NOTNULL	
FIRSTNAME	VARCHAR2(20)	NOTNULL	
LASTNAME	VARCHAR2(20)	NOTNULL	
TELENUM	VARCHAR2(15)	NOTNULL	
ADDRESS	VARCHAR2(90)	NOTNULL	
CITY	VARCHAR2(15)		
COUNTRY	VARCHAR2(5)		
CREDITNO	VARCHAR2(16)		

- **TRANSACTION\_RECORD:**

Payment transactions will be recorded in here. For later reference or complain from users. The second field will be stored as credit card number for credit card payment and MONDEX payment ID for MONDEX payment.

Name	Type	Nullity	Integrity
TRANS_NO	NUMBER(38)	NOTNULL	PRIMARYKEY
CARD_NO/ MONDEXPID	VARCHAR2(16)	NOTNULL	
AMOUNT	FLOAT(126)	NOTNULL	>0
TRANS_TIME	DATE	NOTNULL	

#### 4.2.2.InventoryStockDatabase

- **LUGGAGE\_STOCK:**

Inventory stock of luggage will be stored in this database. It reveals the actual stock of TravelShop.

Name	Type	Nullity	Integrity
PRODUCT_ID	VARCHAR2(10)	NOTNULL	PRIMARYKEY
PRICE	FLOAT(126)	NOTNULL	>0
STOCK	NUMBER(38)	NOTNULL	>0

- **BOOK\_STOCK:**

Inventory stock of books will be stored in this database. It reveals the actual stock of Travel Shop.

Name	Type	Nullity	Integrity
PRODUCT_ID	VARCHAR2(10)	NOTNULL	PRIMARYKEY
PRICE	FLOAT(126)	NOTNULL	>0
STOCK	NUMBER(38)	NOTNULL	>0

- **MISC\_STOCK:**

Inventory stock of miscellaneous products will be stored in this database. It reveals the actual stock of TravelShop.

Name	Type	Nullity	Integrity
PRODUCT_ID	VARCHAR2(10)	NOTNULL	PRIMARYKEY
PRICE	FLOAT(126)	NOTNULL	>0
STOCK	NUMBER(38)	NOTNULL	>0

### 4.2.3. AirlineCompaniesDatabases

- **FLIGHT\_INFO**

A database stores all the flights operated by the Airline Company .

Name	Type	Nullity	Integrity
FLIGHT_NUM	VARCHAR2(6)	NOTNULL	PRIMARYKEY
SRC_PLACE	VARCHAR2(3)	NOTNULL	
DEST_PLACE	VARCHAR2(3)	NOTNULL	
D_TIME	TIME	NOTNULL	
A_TIME	TIME	NOTNULL	
AIRCRAFT	VARCHAR2(4)	NOTNULL	

- **FLIGHT\_SCHEDULE**

A database for weekly schedule of specific flights

Name	Type	Nullity	Integrity
FLIGHT_NUM	VARCHAR2(6)	NOTNULL	PRIMARYKEY
SUN	VARCHAR2(1)	NOTNULL	
MON	VARCHAR2(1)	NOTNULL	
TUE	VARCHAR2(1)	NOTNULL	
WED	VARCHAR2(1)	NOTNULL	
THU	VARCHAR2(1)	NOTNULL	
FRI	VARCHAR2(1)	NOTNULL	
SAT	VARCHAR2(1)	NOTNULL	

- **FARE\_INFO**

A database stores the fare list of each class of tickets in terms of one -way flights and round-trip flights.

Name	Type	Nullity	Integrity
FLIGHT_NUM	VARCHAR2(6)	NOTNULL	PRIMARYKEY
OW_FCLASS	FLOAT(10)	NOTNULL	>0
OW_BCLASS	FLOAT(10)	NOTNULL	>0
OW_ECLASS	FLOAT(10)	NOTNULL	>0
RT_FCLASS	FLOAT(10)	NOTNULL	>0
RT_BCLASS	FLOAT(10)	NOTNULL	>0
RT_ECLASS	FLOAT(10)	NOTNULL	>0

- **PLANE\_SIZE**

A database stores the capacity of each plane of 3 classes of service (first class/business class/economy class).

Name	Type	Nullity	Integrity
AIRCRAFT	VARCHAR2(4)	NOTNULL	PRIMARYKEY
FCLASS	NUMBER(3)	NOTNULL	
BCLASS	NUMBER(3)	NOTNULL	
ECLASS	NUMBER(3)	NOTNULL	

- **TICKET**

A database stores the capacity of each plane of 3 classes of service (first class/business class/economy class).

Name	Type	Nullity	Integrity
FLIGHT_ID	VARCHAR2(6)	NOTNULL	PRIMARYKEY
DDATE	DATE	NOTNULL	PRIMARYKEY
FCLASS	NUMBER(3)	NOTNULL	
BCLASS	NUMBER(3)	NOTNULL	
ECLASS	NUMBER(3)	NOTNULL	

- **USER\_ITINERARY**

A database which stores the sold ticket for internal usage.

Name	Type	Nullity	Integrity
TICKET_NUM	VARCHAR2(12)	NOTNULL	PRIMARYKEY
FLIGHT_NUM	VARCHAR2(6)	NOTNULL	
NAME	VARCHAR2(40)	NOTNULL	

**\*Note:** The above is the database schema for each airline company. Since it is not available to have multiple databases for our use, we simply simulate the situation by appending code as a prefix to the database table to represent the ownership of the table. For example, the code for Cathay Pacific Airways is CX, so all the tables that belong to the company are started with CX\_, like CX\_TICKET and so on.

stockbeanwillusetheCORBAinterfaceofthest ockobject,whichisresponsibleforthe  
inventorystockofthecategoryoftheitemtobeselected.Aftertherequestofstockbean  
hadfinished,itwillbeacknowledged.Uponthestatusofstock,theshopbasketwillbe  
updated.Forremovinganitem,it simplyupdatesthesessionvalue.

If a user wants to checkout the items in the shop basket they have to choose the way for checkout (Credit card & MONDEX card). For MONDEX payment, user will connect to Payment Server directly. For Credit Card payment, TravelNet will be act as a middleman between the Payment Server and user. For both payment methods, upon a successful Payment, post payment process will be carried out and an acknowledgement page will be generated.

Shop Basket will not be stored in database. It will only be stored for a login session.

### 4.3.3. Post Payment Process

After payment is done, the responding change of stock will be updated through the stock bean again (quantity of sold items is deduced from database). Some other things have to be recorded for reference, they are the delivery log and transaction record. Delivery log keeps the items to be delivered and transaction record is used for future reference of payment problems.

## **4.4. Stock Management**

### 4.4.1. Mechanism

Stock is managed by a CORBA object resides on a machine other than the Web server machine. As mentioned before a Java bean is responsible for resolving reference of this object and invoke the method for access stock database indirectly. The IOR of this CORBA object is placed on another web server. Stock bean resolve the reference by obtain this IOR.

The interface of stock CORBA object provides 2 main methods. They are checking the price of an item and ordering an item. In the following subsection, we will describe the interface in more detail.

#### 4.4.2.CommunicationInterface

##### ◆ **StockManagerInterface**

```
interface StockMgr{  
    Stock open(in string name);  
};
```

This interface will return a stock object of a specified category. For example, a luggage stock management object. When the requested object is not instantiated, an instance of this interface will be created and be resided on the CORBA server then the reference of it will be returned. When the requested object had already existed, a reference of this object will be returned.

##### ◆ **CategoryStockInterface**

```
interface Stock {  
    float check_price(in string pid, in long quantity)  
    raises (out_of_stock, internal_error);  
    boolean order(in string pid, in long quantity) raises  
    (internal_error);  
    boolean reset() raises (internal_error);  
};
```

This interface represents a stock manager of a specific category. It provides 3 methods for maintaining the stock.

Check price method will return the price of the item of this category when the item stock is enough otherwise an out\_of\_stock exception will be raised.

Order method will first check the stock of the requested item, if the quantity is enough a true value will be returned and the stock value will be updated. If there is not enough stock, a false will be returned.

A reset function is provided for the stock to reset to default values.

All of the methods above will raise an internal exception when there is some non-recoverable error happens.

## 4.5.ItineraryManagementDesign

Itinerary of every TravelNet user will be stored in a database. The facilities provided are similar to a shopping basket. User can add a flight to an itinerary from search results or remove a flight from the itinerary. Different from a shopping basket, an itinerary update is directly done on the database but not on the user session. This is to ensure the consistency of the itinerary because a user can log off for quit the Web browser anytime, then we have to handle this inconsistency problem if an update is made on the session first. A Java class is developed to handle the update of the itinerary database. In the itinerary database, a unique ticket number is used to identify a ticket. Meanwhile, the flight number and the name of the ticket holder will also be stored.

## 4.6.FlightSearchandReservation

### 4.6.1.Mechanism

TravelNet provides a number of ways to search for a flight. Single flight search, round trip search and direct query. Airline manager is developed for each airline for them to serve their client independent of each other. TravelNet will collect all information from these airline managers of different company and display them to the user in response to their request.

Airline manager class is responsible for resolving the reference of the CORBA airline service objects. Search parameters from user will be passed to the methods provided by CORBA airline manager objects. Result will be returned to the Servlets that handle the response page to the user. Result will be formatted and printed on the Client browser.

Based on these search results, user can select one of the flights and add it to an itinerary.

He/She can keep updating the itinerary by searching for a new flight or adding a specific flight.

After a user has confirmed on a flight, he may then reserve it. The process handles client request will be connected to a CORBA airline service again and to reserve that flight ticket.

For reserving a flight, payment process will be executed first then a booking request will be issued to the airline service object. The availability of that flight of the corresponding class will be reduced in the database. As the airline service object informs TravelNet that the flight is reserved, this flight item will be removed from the itinerary.

## 4.6.2.CommunicationInterface

### ◆ **Airline Service Interface**

```
string query_all(in string serv_type, in string src_place,
                in string dst_place, in string seat_class,
                in string dweekday, in long mindt,
                in long maxdt, in string rweekday,
                in long minrt, in long maxrt,
                in string dept_date, in string retr_date)
    raises (internal_error);
string query_one(in string flight_num,
                in string serv_type, in string seat_class)
    raises (internal_error);
boolean is_flight_exist(in string flight_num,
                       in string weekday, in string seat_class)
    raises (internal_error);
boolean is_seat_avail(in string flight_num,
                     in string dept_date, in string seat_class)
    raises (internal_error);
string book(in string serv_type, in string holder_name,
            in string dept_fnum, in string dept_date,
            in string dept_seat_class, in string retr_fnum,
            in string retr_date, in string retr_seat_class)
    raises (internal_error);
```

Query\_all will carry out a full search of the airline database according to the search options (parameters). It is used for a single flight search. For a round trip, we just do a single search twice and give a discount on the total of two flights. In fact, the query result will be quite complex. The easiest way to return it back to the client is to concatenate the result into a string with a specific format.

Is\_flight\_exists is called to check whether this flight exists, a Boolean true will return if flight exists otherwise a false will be returned. Similar to this, is\_seat\_available is provided to check whether these seats are available for this flight and seat class.

Book function of this interface allows client to book a flight. A unique ticket ID in a form of string will be returned for successful booking, otherwise an null string will be returned.

### 4.6.3.PerformanceComparison

We had conducted a performance comparison on CORBA and non-CORBA version for One-way flight search and round-trip reservation time (in ms). The results are as below:

Experiment 1: One-way flight search between Hong Kong and Taipei

Run	Distributed version	non-distributed version
1	19010	13139
2	15883	11146
3	16364	11878
Average	17086	12054

Experiment 2: Round-trip flight reservation between Hong Kong and Beijing

Run	Distributed version	non-distributed version
1	5668	5819
2	5828	4877
3	5734	5051
Average	5743	5249

It shows that performance of distributed version will not be better than that of non-distributed version. Distributed components have other advantages that are essential for such an application.

Location of airline manager object is transparent to the online traveling agent, even the machine host is down, and it can be migrated to another host without the notice of agency.

Meanwhile, it is not practical that a machine to be uncharged in such a large database. In

case of this server is down, the whole system will be down also (single point failure), so distribute it can provide a better fault tolerance.

The performance measurement above just shows the scenario of single user, if the number of users increased, a performance bottleneck will appear in a centralized system.

The performance would be very poor and server may be down easily because of overloading.

### 4.7. WebSiteMap

There is not much difference in the appearance of TravelNet, so the site map is more or less similar to the previous one. The updates are Hotel information and Booking of Flights.

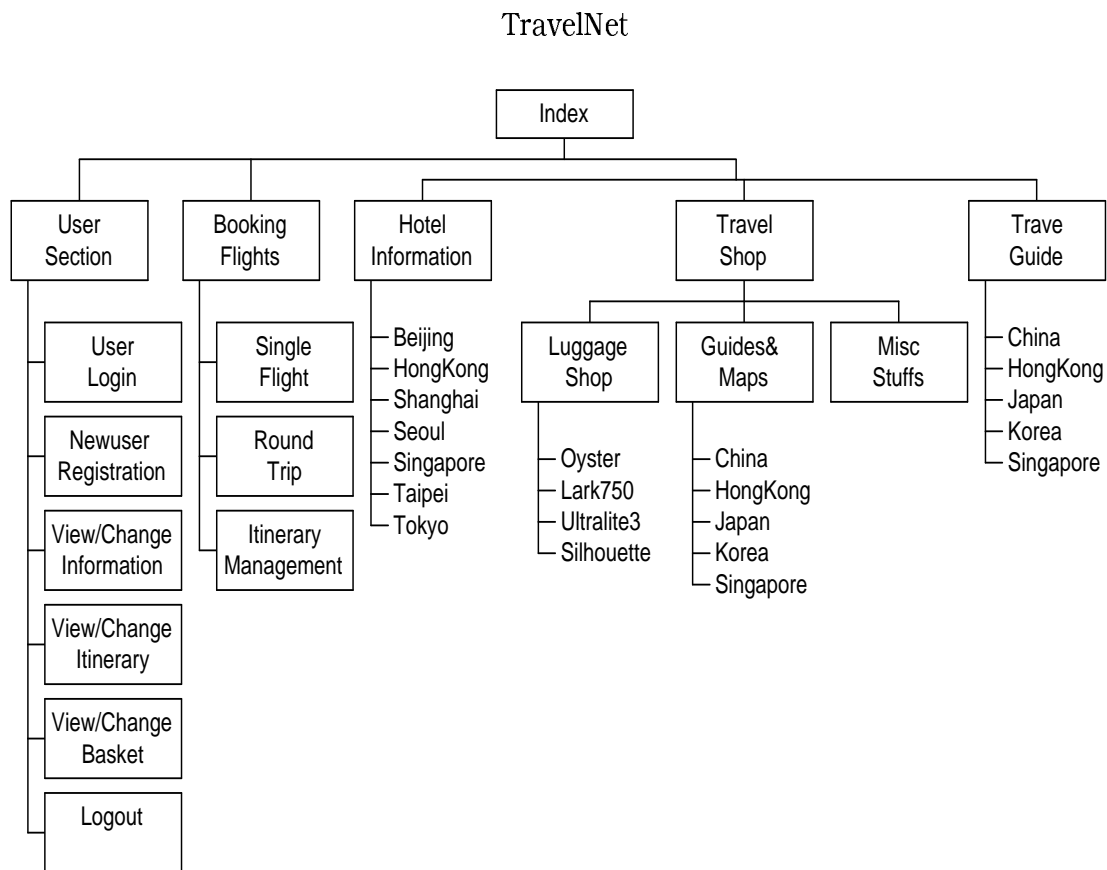

Figure 4.71. Websitemap of TravelNet

## 4.8. Security Concerns

TravelNet as an online E-commerce application, it needs customers to provide some confidential personal information to make a transaction done. One of the most important information is credit card number. Besides, name, telephone, address etc. are necessary for an Web application to provide services to them. That means these essential information must be able to send securely in order to make E-commerce exist in real life. One of the most common protocols used nowadays is SSL (Secure Socket Layer).

### 4.8.1. SSL Introduction

SSL is the Transmission Control Protocol/Internet Protocol (TCP/IP) that governs the transport and routing of data over the Internet. Other protocols, such as the HyperText Transport Protocol (HTTP), Lightweight Directory Access Protocol (LDAP), or Internet Messaging Access Protocol (IMAP), run on top of TCP/IP in the sense that they all use TCP/IP to support typical application tasks such as displaying web pages or running email servers.

The basic idea of Netscape on security is that the programming for keeping your messages confidential ought to be contained in a program layer between an application (such as a web browser or HTTP) and the Internet's TCP/IP layers. The SSL protocol runs above TCP/IP and below higher-level protocols such as HTTP or IMAP. It uses TCP/IP on behalf of the higher-level protocols, and in the process allows an SSL-enabled server to authenticate itself to an SSL-enabled client, allow the client to authenticate itself to the server, and allow both machines to establish an encrypted connection.

Netscape's SSL uses the public and-private key encryption system from RSA, which also includes the use of a digital certificate. These capabilities address fundamental concerns about communication over the Internet and other TCP/IP networks:

⇒ *SSL server authentication* allows a user to confirm a server's identity. SSL-enabled client software can use standard techniques of public-key cryptography to check that a server's certificate and public ID are valid and have been issued by a certificate

authority(CA)listedintheclient'slistoftrustedCAs.Thisconfirmationmightbe importantiftheuser,forexample,issendingacreditcardnumberoverthenetwork andwantstocheckthereceivingserver'sidentity.

⇒ *SSLclientauthentication* allowsaservertoconfirmuser'sidentity.Usingthesame techniquesasthoseusedforserverauthentication,SSL-enabledserversoftwarecan checkthataclient'scertificateandpublicIDarevalidandhavebeenissuedbya certificateauthority(CA)listedintheserver'slistoftrustedCAs.Thisconfirmation mightbeimportantiftheserver,forexample,isabankssendingconfidentialfinancial informationtoacustomerandwantstochecktherecipient'sidentity. However, this functionisnotusedasitisnotacommonpracticeforeveryusertoapplyforaclient certificatebeforeusingourservice.WejustuseouruseraccountsysteMforthis purpose.

⇒ *EncryptedSSLconnection* requiresallinformationsentbetweenaclientandserver tobeencryptedbythesendingsoftwareanddecryptedbythereceivingsoftware,thus providingahighdegreeofconfidentiality.Confidentialityisimportantforboth parties toanyprivatetransaction.Inaddition,alldatasentoveranencryptedSSL connectionisprotectedwithamechanismfordetectingtampering --that is,for automaticallydeterminingwhetherthe datahasbeenalteredintransit.

SSLcomesintwostrengths,40-bitand128-bit,whichrefertothe lengthofthe"session key"generatedbyeveryencryptedtransaction.Thelongerthekey,themoredifficultitis tobreaktheencryptioncode.

#### 4.8.2SSLinTravelNet

Due to its reliable and popular, we decided to use this as our protocol for server authentication. There is no other way for us to provide encryption for Web communication on browsers.

Since a number of web servers and the major web browsers (e.g. Netscape and Internet Explorer) have already supported SSL, the major thing for us to use SSL is to get a server certificate and a fixed IP machine for the web servers such that we can use it to apply for a digital certificate for the web server. On the other hand, client side authentication is not yet popular on the Internet, so we just limited the authentication on the TravelNet server. Once the machine is settled, we have applied a trial certificate from Entrust Technologies, which is an international CA. Trial version of the certificate works just the same as the commercial one except its valid period is shorter. The key length of this certificate is 40-bit. Although it doesn't give the maximum security, that's enough for our purpose as the use of 128-bit is the same as 40-bit key.

After installation of the certificate into the web server, the SSL connection is ready to use. In our system, we just need to refer our code (html) for form submission by https, which is a syntax of calling SSL through URL. An indication of the SSL enabled connection is by a small lock icon in the browser.

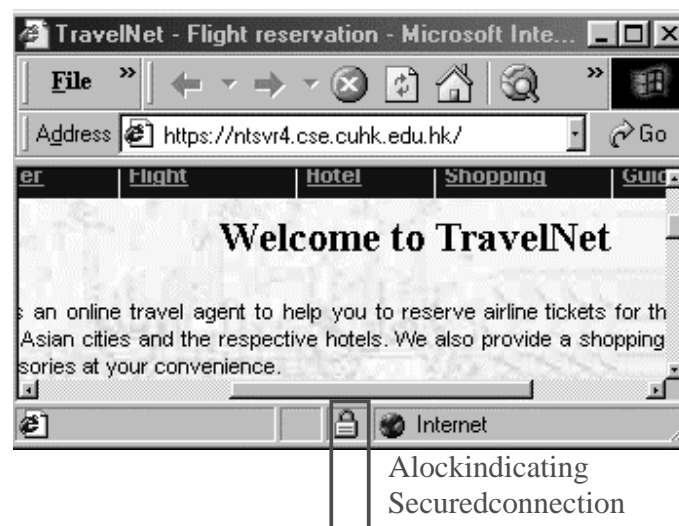

Figure 4.8.2. TravelNet on SSL Connection

# Chapter 5. Payment Methods

## 5.1. Introduction

E-Commerce can't be developed if there is no secure payment methods. People who pay for the services provided by online company must be sure that they pay for their service without the risk of losing more money than the service worth. Moreover, it's unacceptable that their payment information is stole by illegal users so that those people can buy things on the Net without paying bills. When there is no trusted service for customers, they will not join into these E-commerce activities. Providing a secure payment method is a must.

Eventhough it seems risky for Internet payment, there is nothing that's any risk at all. Credit cards and smart cards can also be used illegally when someone stole it from your purse. The probability of your cards are being stolen is greater than that of your cards information are being leaked to hackers.

In this session, we are going to describe two payment methods that used by TravelNet. They are credit card payment and smart card payment. By integrating these payment methods into TravelNet, it looks more realistic and complete.

## 5.2. Secure Payment Method on Credit Card

Credit card is the most common way for Internet Payment. Almost everyone has one and money can be credited to service provider on the card information is approved. Due to this convenience, anyone who gets the card information can shop online without getting authorized by the card owner. This situation is unacceptable. The most effective way to secure the card information, that is being sent on the Net, is encrypting it.

TravelNet had made use of a payment system proposed by a post-graduate student of CUHK. It's secured by using a public-private key encryption for encoding information. In the following subsection, we will describe in detail on its system architecture, performance and security level.

### 5.2.1.SystemArchitecture

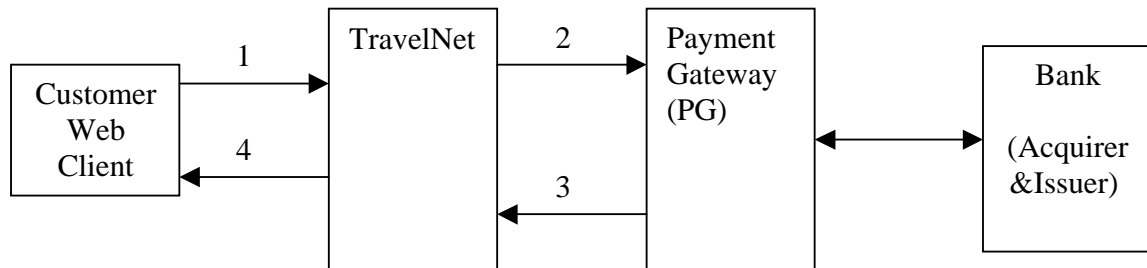

Figure5.2.11:CreditCardPaymentArchitecure

1. The customer first goes to the TravelNet homepage and browses products, and puts these selected goods into a virtual shop basket. After the customer finishes choosing the products, the payment process is triggered by clicking a checkout button on the show basket user interface. A secure connection between the customer and the TravelNet is established using SSL protocol for communications. The customer then enters personal information and credit card information into the browser. In addition, the product information and the total amount will be included in the message, which is sent to the TravelNet. The message content (M1) in this step is
2. Upon the receipt of message M1, the TravelNet can get the desired item listing and credit card information of the customer. The merchant then requests payment authorization and validation of credit card from cardholder's financial institution by composing a message (M2) which consists of the customer's personal and credit card information, together with the total amount and the merchant's name (TravelNet). This message will be encrypted by the merchant's private key to serve as an authentication. A header, which contains the merchant identification number and a number, denoting the payment option the customer chose, is attached to the message. The whole message is encrypted with the payment gateway's public key to prevent eavesdropping and message tampering.
3. When the PG receives the message (M2) from the TravelNet, the PG first uses the private key to decrypt the message to get a decrypted message and a header. The PG will notice the message is sent by a specific merchant (TravelNet) but only the

merchant's public key and decrypt the header message. Next, PG will communicate with the issuer (the bank issue customer's credit card) and the acquirer (the bank where TravelNet account resides) through an existing banking network, which is assumed secure. After the PG receives the response from the issuer and the acquirer, the PG will compose a message (M3) including the response (whether the credit card is valid and the purchase is within the credit limit) and a receipt to the merchant for record purposes. It is then encrypted by the PG's private key for authentication. In addition to the message, the PG's certificate is adhered to the message. The whole message is encrypted by the merchant's public key for privacy and security purpose

4. Upon the receipt of the PG's message, the merchant will decrypt the message using the private key and then using PG's public key to obtain the original message. After checking the result, the merchant will compose an non-encrypted message (M4) to inform the customer if the purchase is successful or not. The message will be displayed as an html document for the customer. Since TravelNet only support server authentication, M4 will not be encrypted. Meanwhile the content inside M4 need not be contained any private information, as customer already knows it.

### 5.2.2 Security Concerns

For a system to be secure from potential attacks, it should handle the attacks on eavesdropping, message tampering and masquerading. TravelNet and the payment system are secure from those attacks.

⇒ Eavesdropping: Attackers cannot see the contents of the message (M1) transferred from client browser to TravelNet server on the personal information throughout the payment process. The customer's information is encrypted by the SSL protocol. The TravelNet payment request message (M2) sent to PG is encrypted by the PG's public key. Besides, the acknowledgement message (M3) sent back to the TravelNet from PG is encrypted by the TravelNet's public key. Hence, no one can understand the message except the one who owns the corresponding private key for message decryption.

- ⇒ Message tampering: Any encrypted message cannot be tampered with, since it will not be possible to decrypt it after it has been changed. By using message digests, a digitally signed message cannot be tampered with. In M2 and M3, for example, digitally signed messages are used to prevent message tampering attacks.
- ⇒ Masquerading: TravelNet system gets a server certificate from a trust third party for authentication purpose. Masquerading is consequently prevented on the system. Moreover, messages are authenticated with a digital signature to prevent masquerading. As a digital signature uses an owner's private key, no other people own the private key except the owner.

### 5.2.3. Performance Measurement

We had conducted an experiment on the performance of the payment gateway (PG) with TravelNet. In our experiments, the server always allows concurrent users to request a payment and all the requests can be executed concurrently. In TravelNet, however, we can specify the type of execution scenario, either sequential or concurrent. For a single request, the total checkout time in TravelNet is between 1.7 seconds and 2 seconds. The time could be as long as 10 seconds in the worst scenario. To filter out noises, we perform 5 executions to obtain the average time measure for each data point in every experiment. The performance measurement is based on two different models: Multiple-threaded model and single-threaded model.

In the multiple-threaded model, requests are processed in parallel. Each request will obtain only a portion of the server resources, which is inversely proportional to the number of requests. For example, when there are 10 concurrent users' requests, each client process will be on the average 10 times slower than each executing alone, as each of them only grasps 10% of the server resources. The time of overlapping processes will consequently be longer. There is also an extra task-switching overhead that is very significant when the number of tasks becomes large. As displayed in Figure 5.2.31, the payment process time increases as the number of concurrent users increases. We can also see in Figure 5.2.31 that the total payment process time is divided into two parts: time spent on the Merchant client and time spent on the Payments system server. In terms of

theportion oftimespentforthetotalcheckoutprocess,paymentservercontributesover 80%.

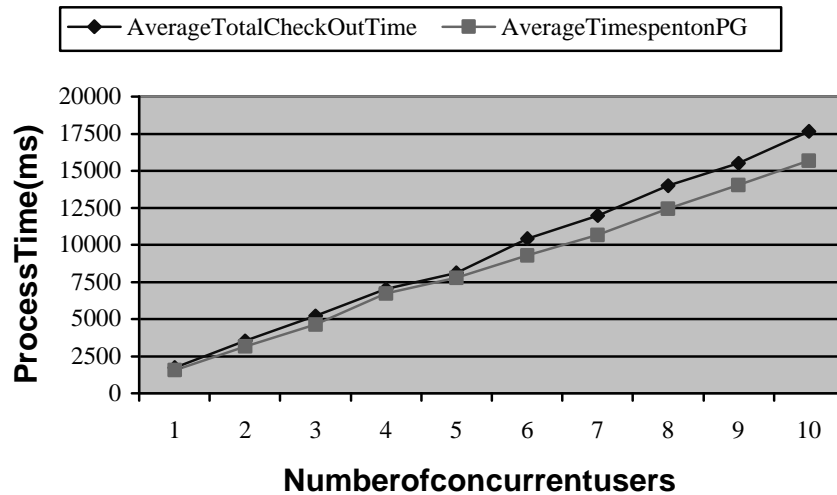

Figure.5.2.31:PaymentTransactionTimeinMultiple -ThreadedModel

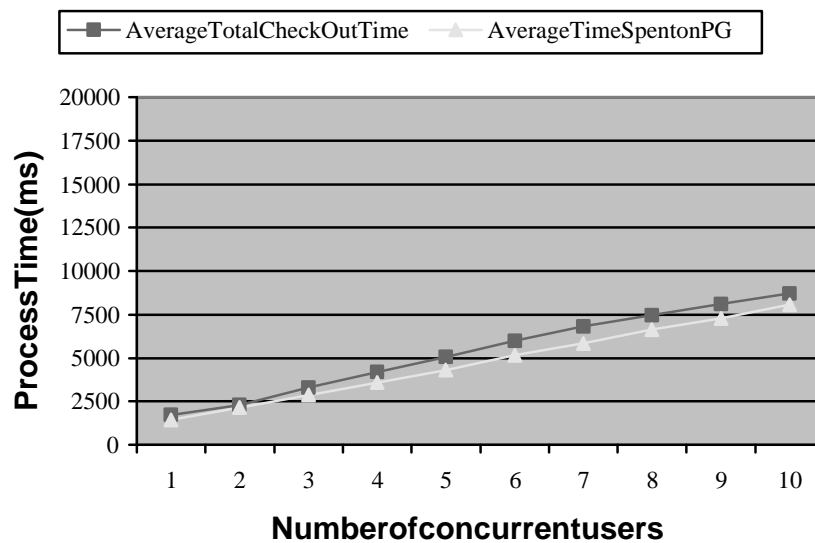

Figure.5.2.32:PaymentTransactionTime inSingle -ThreadedModel

Inthesingle -threadedmodel,TravelNetclientsrequestinafirst -come-first-servemanner. Everyrequestwaitsforallthepreviousrequeststobefinishedbeforeitcangainaccessto theserverresources.Figure5.2.32showsth eaveragetotalprocesstimeandthetime spentonPGforthesingle -threadedmodel.Asacomparison,wecanseefromFigure 5.2.33thatitsaverageprocesstimeismuchshorterthanthatofthemultiple -threaded

model. The main reason is due to database resource conflict for the multiple -threaded model when the multiple concurrent processes access the PG, which currently has only one merchant, namely, TravelNet. As the PG server resources have to be shared among the multiple requests, the requests will hold resource (e.g., lock data item) and compete with each other, thus delaying the complete time. In the single -threaded model, server resources are not shared among the requests and only a task -switching time is necessary between each request. As the response time is quite important in such an interactive application, the single -threaded model behaves better than the multiple -threaded model. It is noted, however, that if we have multiple merchants in the PG, which handles different requests within independent merchants, the multiple -threaded model would be significantly improved.

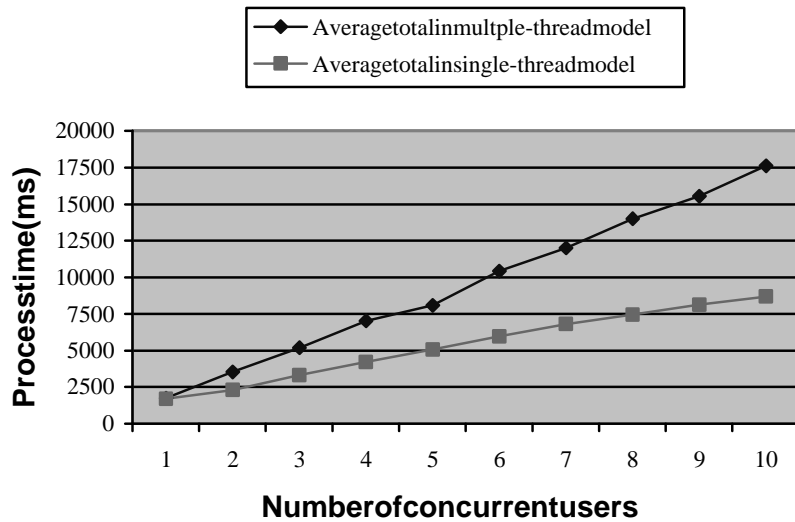

Figure.5.2.33: A Comparison for Single -Threaded and Multi -Threaded Model

For a better performance for TravelNet, we decided to use a Single -Threaded model for TravelNet's checkout policy for credit card.

The payment processing time can be divided into two parts as well: the time required to perform cryptography algorithms (including message encryption and decryption), and the time required to transmit messages and handle payments. Figure 5.2.34 shows the comparison on the payment processing time on the PG regarding the overhead due to cryptography. We found that when the number of concurrent users increases, the gap

showing the difference on the processing time between using cryptographic algorithms and without using them becomes larger. This overhead indicates that for a more secure payments system, there is a tradeoff on the time to handle payment transactions. This tradeoff is quantitatively provided in TravelNet for a detailed analysis.

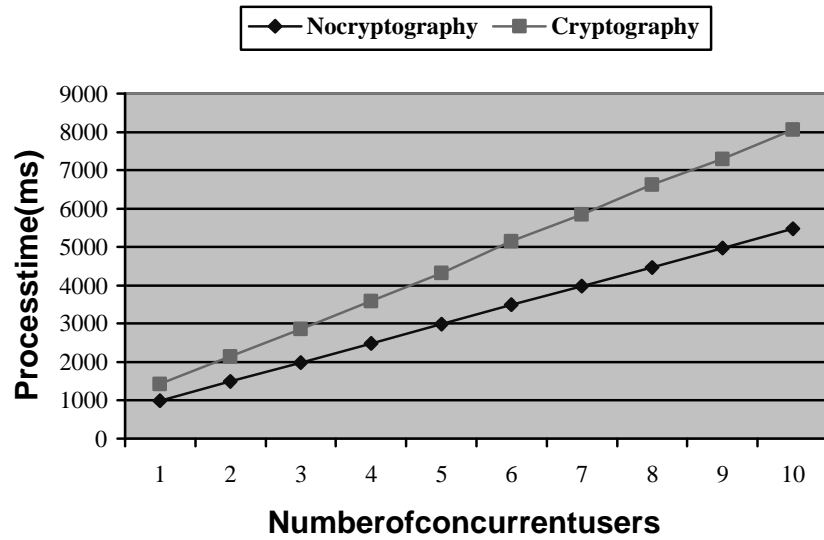

Figure.5.2.34:Single -ThreadedModelonthePaymentTransactionTimeonPG

### 5.3. MicroPayment Method

Smartcards becoming more and more popular over Internet payments since it is convenient and more secure. Mondex is some of the most famous store -value smartcard in the market. On the Mondex card, there is a microprocessor embedded on it. This microcomputer has been programmed to function as an "electronic purse". The electronic purse can be loaded with value, where it is stored until it is used as payment for goods or services at retailers or service outlets or transferred to another Mondex Card, by inserting the Card into a card reader. The electronic purse can also be locked using a personal code so that only the card's owner can access the value on it.

We met the golden chance that there is a joint project between the Center of Innovation and Technology of CUHK and the Mondex developing company for the testing of Mondex in a medium size community, CUHK campus. A Mondex payment server is ready to use in our computer science department, and we had obtained the equipment that is necessary for accessing this server and can have a try on actual Mondex payment on the Internet. We integrate it into TravelNet so as to provide micro -payment services.

#### 5.3.1. System Architecture

##### **A Brief Description**

The concept is as follows.

1. The consumer checks out at the TravelNet, the merchant prepares and signs the payment request, and gives it to the consumer.
2. The consumer goes to the payment server and submits the payment request.
3. The payment server verifies the signature of the payment request. If it is correct, it proceeds with the payment.
4. The payment is completed, Payment Server prepares and signs the payment result, and gives it to the consumer.
5. The consumer goes to the merchant again and submits the payment result.
6. The merchant verifies the signature of the payment result. If it is correct, it proceeds with the post -payment processing.

## ThePaymentFlow

The figure below shows the flow of a Mondex payment using digital signature.

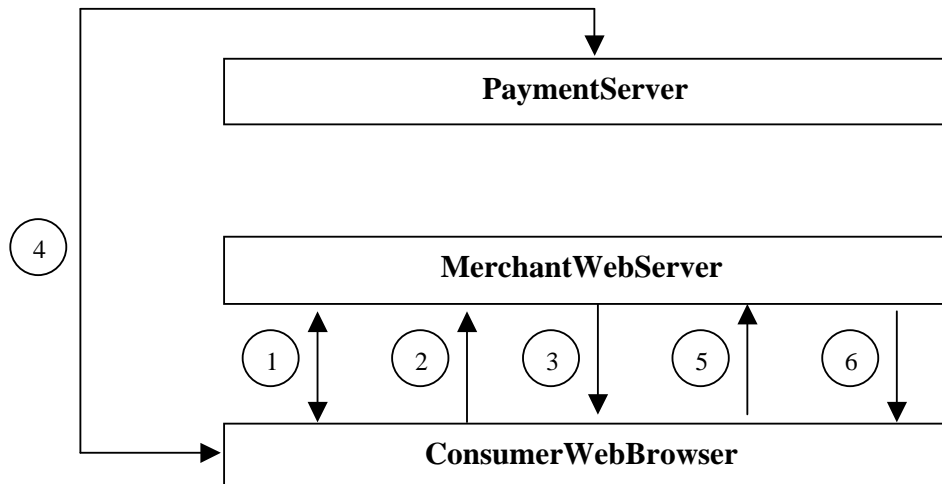

Figure 5.3.11. The Mondex Payment Flow Using Digital Signature

1. Shopping. A consumer reaches a TravelNet and logged in, he or she either interacts with the TravelNet shopping system or selects the desired products. After they selected the desired products, he/she wants to pay for the service charge, for example to pay for the electric bill.

All the items selected will be displayed in the shop basket of TravelNet. After the customer had confirmed to buy the items in the shop basket then they can issue a checkout operation to start the payment.

2. Confirm the payment. From the payment confirm webpage, the consumer selects one of the available payment methods, which can be Visa, Master and Mondex. Finally the consumer presses the Confirm Payment button to confirm the payment on Mondex.
3. Upon requesting a checkout by Mondex, a server program will be run and it does the followings:
  - (i) Check whether the state of payment is valid.
  - (ii) Construct the payment request from database.

- (iii) Sign the payment request using the Mondex Merchant utility library provided by the developer.
  - (iv) Construct a webpage embedding the Consumer Mondex Payment plugin program reference and the corresponding plugin input arguments, and send it to the consumer. The plugin arguments contain the payment request and the merchant's signature on the payment request.
4. The customer plugin connects to Payment Server and starts the payment. Upon the consumer receiving the webpage containing the plugin reference, the plugin is invoked. The plugin connects to the payment server via SSL. It authenticates the Payment Server and then submits the payment request to it. Payment Server first verifies the signature of the request, then queues it up; and eventually the Mondex payment between a merchant Mondex card and the consumer Mondex card begins. Finally, the result of payment will be signed by Payment Server and sent to the consumer plugin.

Figure 5.3.11. A snapshot of plugin

5. Submit the payment result. The consumer plugin calls another processing Servlet from TravelNet, say Result, to submit the signed payment result received from Payment Server.
6. Deliver the post-payment webpage. The Result program first verifies the signature of Payment Server using the library provided. If it is correct, it does the post-payment processing and responds as a webpage to the consumer. It sends a webpage containing the payment result and reference number to the consumer.

### 5.3.2.MondexClientEquipment

EveryMondexclientwillhavealightweightcardreadercallediReader(figure5.3.22).It mustbepluggedintothemachinethatisusedforbrowsingInternetforshopping. Besides,adriveroftthisdeviceshouldalsoobeinstalled.Acusomermanagementcon sole program(figure5.3.21)isavailableforcustomtomangehisMondexcardandkeep trackofpaymentRecords.Inthisprogram,userscanalsoanthecurrencytodisplay, lockingthecardandcheckingthecardstatus.

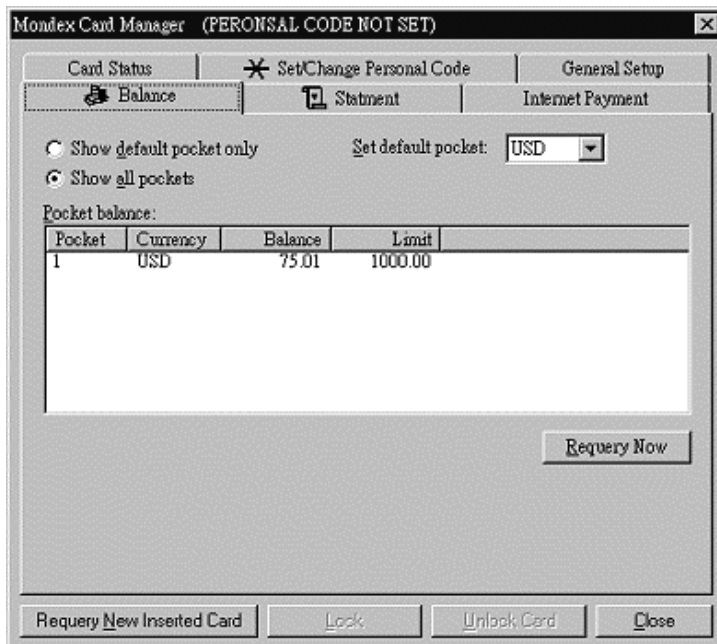

Figure5.3.21.Mondxemanagementprogram

Figure5.3.22.iReader

### 5.3.3.TheBenefits

#### **Eliminate thecommunicationbetweenthemerchantandthePaymentServer**

It saves the processing power and communication bandwidth on both the Payment Server and the merchant web server on establishing the SSL connections since client will directly call a plug-in to connect to payment server and process payment.

#### **More convenient shopping**

For the use of credit card, customer has to fill in detailed information and send it over the Internet. This process seems troublesome and customer will naturally worry about the security of the payment. By Mondex, all the client has to do is insert the card properly then issue a start operation on payment. This sounds more easy and convenient.

#### **Favor non credit -card-holder**

Not everyone owns a credit card for shopping on Internet since applying for a credit card has some restrictions like age and income. Mondex Card favors those who have no credit card. They can still enjoy the convenience provided by now a day's technology.

#### **Limited value**

Mondex cards have a maximum stored value limit. Even an unlocked card has been stolen by others, the maximum lost in monetary value will be at most the maximum value of a Mondex card.

### 5.5.4.SecurityConcerns

#### **Replay of messages**

Since the consumer acts as the middle party on delivering the payment request and payment result between the merchant and the Payment Server, it is possible that the consumer captures the payment request or result and re-submits them later in order to get any benefits or interrupt the merchant's service. Both the Payment Server and Content Servers should be designed to detect and eliminate any replayed payment requests or results.

#### **Detection of Replayed Payment Request in Payment Server**

To detect the replayed payment request, the principle is to make each payment request *unique*. Payment ID is not adequate, because the same payment ID may be used in payment resume. To achieve that, each payment request will have a GMT timestamp appended. The timestamp is generated by the merchant and specified in the plug-in parameters. The timestamp is signed, so any change to it will be detected. Hence,

PaymentIDtogetherwiththeGMTtimestampwillusedtoidentifyapaymentin PaymentServer.

PaymentServerwillkeepahistoryofthereceivedpaymentrequests.Itwillcheck againsteachincomingpaymentwiththehistorytodetectifanyreplayedrequest. Howeveritisnotfeasibletokeepeachreceivedpaymentrequestinhistoryormemory duetolimitedsystemresources.Therefore,PaymentServerwillfirstcheckifthe time stampismatchedwiththecurrenttime.Sincethereistimedifferenceinthemerchant webserverandthePaymentServer,atoleranrangeoftimedifferencesay2hoursis introduced.Ifthereceivedpaymentrequestisoutsidethisrangeoftime,itisrejected.If itiswithinthetimerange,itwillbecheckedagainstthehistory.Sothehistoryneeds onlytocontain2hoursofpaymentrequest.Thehistoryofpaymentrequestwillalsobe savedtodiskandbereadbackwhenPaymentServerisrestartednexttime .Thetolerant timedifferenceisconfigurable.

### **DetectionofReplayedPaymentResultinContentServer**

Todetectthereplayedpaymentresult,theGMTtimestampfromthepaymentrequest willbeputinthepaymentresultssendingtoContentServer.Therefore,providedthe ContentServerisdesignedtouseboththePaymentIDandtheGMTtimestamppto identifyapayment,thereplayedpaymentresultcanbedetected.

## Chapter6.Conclusion

WehavesuccessfullyfinishedacompleteE-commerceapplication,with sophisticated servicesandpaymentmethods.Besidessomeexternalqualities,wealsodevotelotsof effortsonthomodularandstructuraldeigns.

Inthelastterm,TravelNetcontainanumberofservices,theyincludedmembership management,TravelShop,s implesingleflightsearchandsometravelguides.Theyare developedincentralizedmannerandalltheaccessofdatabaseisdirectlyfromServlets process,whichalsohandletheoutputlayout.Creditcardpaymentissimulatedbysimple databaseaccess.Mostoftheeffortlasttermspentontestingandinvestigatingsome suitablesoftwaretools,WebsecurityandhardwareforfurtherdevelopmentofTravelNet. That'swhyTravelNetseemsincompleteandprematureinthatstagebutweprepareda goodbaseforustodevelopabettersysteminthecomingterm.

Inthisterm,weconcentrateondistributingsystemcomponentsandpaymentmethods incorporation.ForamoremodulardesignonWeblayoutdesignandprocesscomponent, wemakeuseoftheconceptofJavabean andJavaServerPage.CORBAintegrationfor distributedcomponentsisanothermajorenancementofTravelNet.CORBAFlight managersandCORBAstockmanagersaredevelopedandrundwithTravelNetina distributedmannerforabetterperformanceandtolerance.Bytheway,weaddsome moreserviceslikemoreflightsearchoption,reservation,itinerarymanagerandhotel information.

PaymentmethodsareagreatadvancementofTravelNet.Whencombinedwithcredit cardpaymentandMondexpayment,itmakesTravelNetmorerealistic.Especiallyfor Mondexpayment,wecangaintheexperienceofthemechanismofreallifemicro paymentsystem.

Asaconclusion,itisarewardingprojectforusandtheeffortwepaidonthisisauseful experiencethatwegainforustodevotetotheE-society.

# Appendix

## A. Software

- ⇒ **JavaAPI1.1.8** : Javaisanobject -orientedlanguage,whichispoplarallaround theworldtoday.Becauseofitsportability,itgrowsalongwiththeInternetrelated technologies.ItscompleteandrobustAPIbringspro grammerandsoftware developeraconvenientdevelopingenvironment.Sinceitisslowerthannative programminglanguage,Javaisnotsuitableforlowlevelprogrammingorreal timeprocessing.Ontheotherhand,itisperfectfornetworkingapplication programming.
- ⇒ **JavaServletAPI** : ServletsaretheJavaplatformtechnologyofchoicefor extendingandenhancingWebservers.Servletsprovideacomponent -based, platform-independentmethodforbuildingweb -basedapplications,withoutthe performancelimitatio nsofCGIprograms.
- ⇒ **JavaServerPage** :ItusesaformatsimilartoHTMLtags.Itincludesspecialtags forincludingJavascriptlets.Directusageofcomponentbeanshelptoseparate webdesignandapplicationlogic.JSPwillbecompiledtoJavaobjectcode and canbestartserviceonJavaenableWebServer.
- ⇒ **WindowsNTServer4.0withIIS4.0:** WindowsNTServerisaquitecommon commercialproductMicrosoftWindowsNTServer4.0isamultipurpose operatingsystem specializedonServeroperations .IISisaco mmonWebserver forNTservers.ItsupportsSSLserverauthenticationandcapabilityofaddnew moduleforWebservices.
- ⇒ **Oracle8i:** Apopulardatabaseserver.TravelNetmakeuseofthisDBMSasdata storage.Oracle8i,thedatabaseforInternetcomputing,c hangestheway informationismanagedandaccessedtomeetthedemandsoftheInternetage, whileprovidingsignificantnewfeaturesfortraditionalonlinetransaction processing(OLTP)anddatawarehouseapplications.Itprovidesadvancedtoolsto manage alltypesofdatainWebsites,butitalsodeliverstheperformance, scalability,andavailabilityneededtosupportverylargedatabase(VLDB)and mission-criticalapplications.

- ⇒ **ServletExec2.2** :ServletExecisaServletengine.Itisahigh -performance, reliable,inexpensivewebapplicationserverandServletenginethatimplements theJavaServletAPIandJavaServerPages(JSP)standards,componentsofthe Java2Platform,EnterpriseEdition(J2EE)suiteofstandardsdefinedbySun Microsystems.Servlet Execrunsonallmajorwebserverandoperatingsystems.
- ⇒ **BorlandVisibroker4.0:** VisiBrokerisacompleteCORBA2.3ObjectRequest Broker(ORB)thatsupportsthedevelopment,deployment,andmanagementof distributedobjectapplicationsacrossavariety ofhardwareplatformsand operatingsystems.InadditiontoVisiBroker(theORB),threeothercomponents areavailablewiththisproduct.Theyinclude
- NamingService
  - EventService
  - Gatekeeper
- ⇒ **MondexMerchantUtility:** Autilityprovideafunctionforme rchanttosigna paymentrequestandverifyapaymentresult.Thisistheessentialfunctionfor Mondexpayment.

## B. Hardware

- ⇒ **WebContentServer:** PentiumII300MHz,96 -MBmemory.Amid -endmachine isneededforawebservertohandlerequestsconcurrentlyesp eciallyoursystem requesthandlerisJavaServlet.APentium2300MHzisjustmeetourdemand.It isaserverwithastaticInternetaddress.TheInternetnameis ntsvr4.cse.cuhk.edu.hk.
- ⇒ **CORBAServer:** AnumberofSunUltraworkstations,128 -MB,100Mbps - networkspeedwithUnixOperatingSystem.Aniceenvironmentfordistributed network.
- ⇒ **MondexiReader,TestCard:** Testcardhasacertainvalueinsidefortesting purposenoactualvalue.IReaderisadeviceforreadingdatafromMondexCards. Thisdevicewil lbeconnectedtoaCOMportofamachine.

### C. Client Requirement

- ⇒ **Netscape3.0+orInternetExplorer4.0+:** TravelNetclientonlyneedsasimple webbrowser.ItisrecommendedthatclientbrowserisSSLenablebecausethe clientwillsubmitcriticalinformati onthroughtheInternet.Thisunprotected transmissionisveryinsecure.Ifinformationisbeinghacked,hackermayusethis informationforillegalshopping.
- ⇒ **Mondexcustomerplugin:** Apluginprogrammushavetobeinstallintheclient machine.Itwillb einvokedwhenaMondexpaymentisissuedfrommerchant.
- ⇒ **MondexiReader:** UsedtoreadandprocesswithModexcard.
