# MATH1050 Exercise 3 (Answers and solution)

## 1. Solution.

- (a) Let  $\zeta$  be a complex numbers. We have  $\zeta \overline{\zeta} = (\operatorname{Re}(\zeta) + i\operatorname{Im}(\zeta))(\operatorname{Re}(\zeta) i\operatorname{Im}(\zeta)) = (\operatorname{Re}(\zeta))^2 + (\operatorname{Im}(\zeta))^2 = |\zeta|^2$ .
- (b) Let z, w be complex numbers. Suppose  $w \neq 0$ .  $\frac{z}{w} = \frac{z\bar{w}}{w\bar{w}} = \frac{z\bar{w}}{|w|^2}$ .

## 2. Solution.

Let z, w be complex numbers.

(a)  $|zw|^2 = (zw)\overline{(zw)} = zw\overline{z}\overline{w} = (z\overline{z})(w\overline{w}) = |z|^2|w|^2$ . Since  $|z| \ge 0$ ,  $|w| \ge 0$  and  $|zw| \ge 0$ , we have |zw| = |z||w|.

(b) Suppose  $z \neq 0$  and  $w \neq 0$ , and  $\theta, \varphi$  are respective arguments of z, w. Then  $z = |z|(\cos(\theta) + i\sin(\theta))$  and  $w = |w|(\cos(\varphi) + i\sin(\varphi))$ . Therefore

$$zw = [|z|(\cos(\theta) + i\sin(\theta))][|w|(\cos(\varphi) + i\sin(\varphi))] \\ = |z||w|[(\cos(\theta)\cos(\varphi) - \sin(\theta)\sin(\varphi)) + i(\sin(\theta)\cos(\varphi) + \cos(\theta)\sin(\varphi))] \\ = |zw|(\cos(\theta + \varphi) + i\sin(\theta + \varphi)).$$

### 3. Solution.

Let 
$$\omega = \frac{\sqrt{3} + i}{2}$$
.  
(a)  $\omega^2 = \frac{1 + \sqrt{3}i}{2}, \ \omega^3 = i, \ \omega^{11} = \frac{\sqrt{3} - i}{2}, \ \omega^{12} = 1$ .  
(b)  $\sum_{k=0}^{2230} \omega^{k+1} = \omega \sum_{k=0}^{2230} \omega^k = \omega \cdot \frac{1 - \omega^{2231}}{1 - \omega} = \omega \cdot \frac{1 - \omega^{-1}}{1 - \omega} = -1$ .

#### 4. Solution.

Let a, b, c be real numbers. Suppose  $a^2 + b^2 + c^2 = 1$  and  $c \neq 1$ . Define  $z = \frac{a+bi}{1-c}$ 

(a) 
$$|z|^2 = z\bar{z} = \frac{a+bi}{1-c} \cdot \frac{a-bi}{1-c} = \frac{a^2+b^2}{(1-c)^2} = \frac{1-c^2}{(1-c)^2} = \frac{1+c}{1-c}.$$
  
(b) We have  $|z|^2 = \frac{1+c}{1-c}.$   
Then  $c = \frac{|z|^2 - 1}{|z|^2 + 1} = \frac{z\bar{z} - 1}{z\bar{z} + 1}.$   
Since  $z = \frac{a+bi}{1-c}$ , we have  $\operatorname{Re}(z) = \frac{a}{1-c}$  and  $\operatorname{Im}(z) = \frac{b}{1-c}.$   
Therefore  $a = (1-c)\operatorname{Re}(z) = \left(1 - \frac{z\bar{z} - 1}{z\bar{z} + 1}\right) \cdot \frac{z+\bar{z}}{2} = \frac{z+\bar{z}}{z\bar{z} + 1}$   
Also,  $b = (1-c)\operatorname{Im}(z) = \left(1 - \frac{z\bar{z} - 1}{z\bar{z} + 1}\right) \cdot \frac{z-\bar{z}}{2i} = \frac{z-\bar{z}}{i(z\bar{z} + 1)}.$ 

#### 5. Solution.

(a) Suppose z, w are complex numbers.

Then  $|z + w|^2 = |z|^2 + |w|^2 + z\bar{w} + \bar{z}w$ . Also,  $|z - w|^2 = |z + (-w)|^2 = |z|^2 + |-w|^2 + z\overline{(-w)} + \overline{z}(-w) = |z|^2 + |w|^2 - z\overline{w} - \overline{z}w.$ Then  $|z+w|^2 + |z-w|^2 = 2|z|^2 + 2|w|^2 + z\bar{w} + \bar{z}w - z\bar{w} - \bar{z}w = 2|z|^2 + 2|w|^2$ .

(b) i. Suppose r, s, t are complex numbers.

1. Suppose r, s, t are complex numbers. Then  $|2r - s - t|^2 = |(r - s) + (r - t)|^2 = 2|r - s|^2 + 2|r - t|^2 - |(r - s) - (r - t)|^2 = 2|r - s|^2 + 2|t - r|^2 - |s - t|^2$ . Similarly,  $|2s - t - r|^2 = 2|s - t|^2 + 2|r - s|^2 - |t - r|^2$  and  $|2t - r - s|^2 = 2|t - r|^2 + 2|s - t|^2 - |r - s|^2$ . Therefore  $|2r - s - t|^2 + |2s - t - r|^2 + |2t - r - s|^2 = 3(|s - t|^2 + |t - r|^2 + |r - s|^2)$ . ii. Let  $\zeta, \alpha, \beta$  be complex numbers. Suppose  $\zeta^2 = \alpha^2 + \beta^2$ . Then  $(\zeta + \alpha)(\zeta - \alpha) = \zeta^2 - \alpha^2 = \beta^2$ . We have

We have

$$\begin{aligned} (|\zeta + \alpha| + |\zeta - \alpha|)^2 &= |\zeta + \alpha|^2 + |\zeta - \alpha|^2 + 2|\zeta + \alpha||\zeta - \alpha| \\ &= 2|\zeta|^2 + 2|\alpha|^2 + 2|(\zeta + \alpha)(\zeta - \alpha)| \\ &= 2|\zeta|^2 + 2|\alpha|^2 + 2|\beta^2| \\ &= 2|\zeta|^2 + 2|\alpha|^2 + 2|\beta|^2 \end{aligned}$$

Modifying the above argument (by interchanging the roles played by  $\alpha$  and  $\beta$ ), we have  $(|\zeta + \beta| + |\zeta - \beta|)^2 = 2|\zeta|^2 + 2|\beta|^2 + 2|\alpha|^2$ .

Therefore  $(|\zeta + \alpha| + |\zeta - \alpha|)^2 = (|\zeta + \beta| + |\zeta - \beta|)^2$ . Note that  $|\zeta + \alpha| + |\zeta - \alpha| \ge 0$  and  $|\zeta + \beta| + |\zeta - \beta| \ge 0$ . Then  $|\zeta + \alpha| + |\zeta - \alpha| = |\zeta + \beta| + |\zeta - \beta|$ .

#### 6. Solution.

Let  $z \in \mathbb{C}$ . Suppose 4|z+1| = |z+16|. Then  $16(z+1)(\overline{z}+1) = 16(z+1)\overline{(z+1)} = 16|z+1|^2 = |z+16|^2 = (z+16)\overline{(z+16)} = (z+16)(\overline{z}+16)$ .

Now  $16(z\overline{z} + z + \overline{z} + 1) = z\overline{z} + 16z + 16\overline{z} + 16^2$ .

Therefore  $15z\overline{z} = 15 \cdot 16$ . We have  $|z|^2 = z\overline{z} = 16$ . Hence |z| = 4. z lies on the circle with centre at 0 and radius 4.

Write  $\mu = 1 + i$ ,  $\nu = 3 - i$ .

(a) Note that  $\frac{\mathsf{Im}(\nu) - \mathsf{Im}(\mu)}{\mathsf{Re}(\nu) - \mathsf{Re}(\mu)} = \frac{-1 - 1}{3 - 1} = -1.$ Let  $\eta \in \mathbb{C}$ .

 $\eta$  lies on the ('infinite') straight line joining  $\mu, \nu$ 

 $\begin{array}{ll} \mathrm{iff} & \mathsf{Im}(\eta) - \mathsf{Im}(\mu) = \frac{\mathsf{Im}(\nu) - \mathsf{Im}(\mu)}{\mathsf{Re}(\nu) - \mathsf{Re}(\mu)} \cdot (\mathsf{Re}(\eta) - \mathsf{Re}(\mu)) \\ \mathrm{iff} & \mathsf{Im}(\eta) - 1 = (-1) \cdot (\mathsf{Re}(\eta) - 1) \\ \mathrm{iff} & \mathsf{Re}(\eta) + \mathsf{Im}(\eta) - 2 = 0 \end{array}$ 

(b) Consider the curve C on the Argand plane defined by the equation  $|z - \mu| = |z - \nu|$ .

i. Let  $\zeta \in \mathbb{C}$ . Note that

$$\begin{aligned} |\zeta - \mu|^2 &= (\zeta - \mu)\overline{(\zeta - \mu)} = \zeta \bar{\zeta} - \bar{\mu}\zeta - \mu \bar{\zeta} + \mu \bar{\mu} = |\zeta|^2 - (1 - i)\zeta - (1 + i)\bar{\zeta} + 2\\ |\zeta - \nu|^2 &= (\zeta - \nu)\overline{(\zeta - \nu)} = \zeta \bar{\zeta} - \bar{\nu}\zeta - \nu \bar{\zeta} + \nu \bar{\nu} = \zeta \bar{\zeta} + (-3 - i)\zeta + (-3 + i)\bar{\zeta} + 10. \end{aligned}$$

We have

$$\begin{split} |z-1-i| &= |z-3+i| \quad \text{iff} \quad |z-1-i|^2 = |z-3+i|^2 \\ &\text{iff} \quad (2+2i)\zeta + (2-2i)\bar{\zeta} - 8 = 0 \\ &\text{iff} \quad 2(\zeta + \bar{\zeta}) + 2i(\zeta - \bar{\zeta}) - 8 = 0 \\ &\text{iff} \quad \frac{1}{2}(\zeta + \bar{\zeta}) - \frac{1}{2i}(\zeta - \bar{\zeta}) - 2 = 0 \\ &\text{iff} \quad \mathsf{Re}(\zeta) - \mathsf{Im}(\zeta) - 2 = 0 \end{split}$$

ii. The equation of the 'infinite' straight line  $\ell$  joining  $\mu, \nu$  is given by  $\operatorname{Re}(z) + \operatorname{Im}(z) - 2 = 0$  with unknown z in the complex numbers.

The curve C is a straight line whose equation is given by  $\operatorname{Re}(z) - \operatorname{Im}(z) - 2 = 0$  with unknown z in the complex numbers. The slope of  $\ell$  is -1, and the slope of C is 1. Therefore the lines  $\ell$ , C are perpendicular to each other.

The slope of  $\ell$  is -1, and the slope of C is 1. Therefore the lines  $\ell, C$  are perpendicular to each other  $\ell$  and C intersect each other at the point 2.

Note that  $|2 - \mu| = \sqrt{2} = |2 - \nu|$ . Hence 2 is the mid-point of the line segment joining  $\mu, \nu$ .

It follows that C is the perpendicular bisector of the line segment joining  $\mu, \nu$ .

## 8. Answer.

z = 2 or z = 4 + 2i.

**Remark.** The curve described by the equation |z - 2 - 2i| = 2 is the circle with centre 2 + 2i and radius 2. It is tangent to the real axis at 2 and the imaginary axis at 2i.

The curve described by the equation |z - 4 + 2i| = |z - 2i| is the 'infinite' straight line which perpendicularly bisects the line segment joining 4 - 2i and 2i.

The latter passes the point 2, which lies on the former, and by symmetry (and perpendicularity), passes through the point 4 + 2i on the former.

#### 9. Answer.

(a) 2+2i, 4i (b)  $\sqrt{2}$  (c) -1+i

**Remark.** The curve described by the equation |z - 2i| = 2 is the circle with centre 2i and radius 2. It is tangent to the real axis at 0.

The curve described by the equation |z - 4 - 4i| = |z| is the 'infinite' straight line which perpendicularly bisects the line segment joining 4 + 4i and 0.

They intersect each other at the points 2 + 2i and 4i only.

Because  $(S_{\alpha,r})$  has exactly two solutions, the curve  $|z - \alpha| = r$ , which describes the circle with centre  $\alpha$  and with radius r, must pass through the points 2 + 2i and 4i, no matter which values  $\alpha$ , r take. Then by symmetry,  $\alpha$  lies on the 'infinite' straight line which is the perpendicular bisector for the line segment joining 2 + 2i and 4i.

#### 10. Solution.

Let  $\omega$  be a complex number. Suppose  $|\omega| = 1$  and  $\operatorname{Im}(\omega) \ge 0$ . Further suppose  $\omega^2 + \frac{5}{\omega} - 2$  is purely imaginary. There exists some  $\theta \in \mathbb{R}$  such that  $\omega = |\omega|(\cos(\theta) + i\sin(\theta))$ . Since  $|\omega| = 1$ , we have  $\omega = \cos(\theta) + i\sin(\theta)$ . Then  $\omega^2 = \cos(2\theta) + i\sin(2\theta)$  and  $\frac{1}{\omega} = \bar{\omega} = \cos(\theta) - i\sin(\theta)$ . Then  $\omega^2 + \frac{5}{\omega} - 2 = (\cos(2\theta) + 5\cos(\theta) - 2) + i(\sin(2\theta) - 5\sin(\theta))$ Since  $\omega^2 + \frac{5}{\omega} - 2$  is purely imaginary, we have  $0 = \operatorname{Re}\left(\omega^2 + \frac{5}{\omega} - 2\right) = \cos(2\theta) + 5\cos(\theta) - 2 = 2\cos^2(\theta) + 5\cos(\theta) - 3$ . Then  $(2\cos(\theta) - 1)(\cos(\theta) + 3) = 0.$ Therefore  $\cos(\theta) = \frac{1}{2}$  or  $\cos(\theta) = -3$ . The possibility ' $\cos(\theta) = -3$ ' is rejected. Then  $\cos(\theta) = \frac{1}{2}$ . Therefore  $\sin(\theta) = \frac{\sqrt{3}}{2}$  or  $\sin(\theta) = -\frac{\sqrt{3}}{2}$ . Since  $\operatorname{Im}(\omega) \ge 0$ , we have  $\operatorname{Im}(\omega) = \sin(\theta) = \frac{\sqrt{3}}{2}$ . Therefore  $\omega = \cos(\theta) + i\sin(\theta) = \frac{1}{2} + \frac{\sqrt{3}}{2}i$ . 11. Answer.

(a) 1

(b) *Hint*. Be aware that 
$$|\lambda| = 1$$
 and  $\overline{\lambda} = \frac{1}{\lambda}$ . Also be aware that  $\lambda^2 = \cos(2\alpha) + i\sin(2\alpha)$ .

(c) -

## 12. Solution.

- i. Let z be a complex number. (a) Note that  $|z|^2 - |\mathsf{Re}(z)|^2 = |z|^2 - (\mathsf{Re}(z))^2 = (\mathsf{Im}(z))^2 \ge 0.$ Then  $|z|^2 \ge (|\mathsf{Re}(z)|)^2$ . Note that  $|z| \ge 0$  and  $|\mathsf{Re}(z)| \ge 0$ . Therefore  $|z| \ge |\mathsf{Re}(z)|$ 
  - Suppose  $|z| = |\operatorname{Re}(z)|$ . Then  $(\operatorname{Im}(z))^2 = 0$ . Therefore  $\operatorname{Im}(z) = 0$ . Hence z is real.
  - Suppose z is real. Then  $z = \operatorname{Re}(z)$ . Therefore  $|z| = |\operatorname{Re}(z)|$ .
  - ii. Let z be a complex number. Define  $w = -i\hat{z}$ . We have  $w = -i(\operatorname{Re}(z) + i\operatorname{Im}(z)) = \operatorname{Im}(z) - i\operatorname{Re}(z)$ . Then  $\operatorname{Re}(w) = \operatorname{Im}(z)$  and  $\operatorname{Im}(w) = -\operatorname{Re}(z)$ . We have  $|z| = |-iz| = |w| > |\mathsf{Re}(w)| = |\mathsf{Im}(z)|$ . Equality holds iff w is real. The latter holds iff z is purely imaginary.
- (b) Let u, v be complex numbers.

By the result in part (a),  $|\mathsf{Re}(u\overline{v})| \le |u\overline{v}| = |u||\overline{v}| = |u||v|$ .

- Suppose  $|\mathsf{Re}(u\bar{v})| \leq |u||v|$ . Then, by the result in part (a),  $u\bar{v}$  is real.
  - \* (Case 1.) Suppose v = 0. Then  $0 \cdot u + 1 \cdot v = 0$ , and  $0, 1 \in \mathbb{R}$  with  $1 \neq 0$ .
  - (Case 2.) Suppose  $v \neq 0$ .
  - Write  $p = |v|^2$ ,  $q = -u\bar{v}$ . Note that  $p, q \in \mathbb{R}$ , and  $p \neq 0$ .
  - We have  $pu = |v|^2 u = u\overline{v}v = -qv$ . Then pu + qv = 0.
- Suppose there exist some  $p, q \in \mathbb{R}$  such that pu + qv = 0 and p, q are not both zero. Without loss of generality, assume  $p \neq 0$ . Write r = -q/p. We have u = rv. Then  $\mathsf{Im}(u\bar{v}) = \mathsf{Im}(rv\bar{v}) = \mathsf{Im}(r|v|^2) = 0$ . Therefore  $u\bar{v}$  is real. Hence  $\mathsf{Re}(u\bar{v}) = |u||v|$ .

#### i. Let z, w be complex numbers. (c)

Then |z|Since |z|

and

$$\begin{aligned} (|z| + |w|)^2 - |z + w|^2 \\ &= |z|^2 + |w|^2 + 2|z||w| - (z + w)\overline{(z + w)} = |z|^2 + |w|^2 + 2|z||w| - (z + w)(\overline{z} + \overline{w}) \\ &\vdots \\ &= |z|^2 + |w|^2 + 2|z||w| - (|z|^2 + |w|^2 + 2\operatorname{Re}(z\overline{w})) \\ &= 2(|z||w| - \operatorname{Re}(z\overline{w})) \ge 2(|z||w| - |\operatorname{Re}(z\overline{w})|) \ge 0. \end{aligned}$$
Then  $|z + w|^2 \le (|z| + |w|)^2$ .  
Since  $|z + w|, |z|, |w|$  are all non-negative, we have  $|z + w| \le |z| + |w|$ .  
Note that  $|z + w| = |z| + |w|$  iff  $(\operatorname{Re}(z\overline{w}) = |\operatorname{Re}(z\overline{w})|$  and  $|\operatorname{Re}(z\overline{w})| = |z||w|)$ .  
• Suppose  $|z + w| = |z| + |w|$ .  
Then  $\operatorname{Re}(z\overline{w}) = |\operatorname{Re}(z\overline{w})|$  and  $|\operatorname{Re}(z\overline{w})| = |z||w|$ .  
Since  $|\operatorname{Re}(z\overline{w})| = |z||w|$ , by the result in part (b), there exist some real numbers  $p, q$  such that  $pz + qw =$   
and  $p, q$  are not both zero.  
Without loss of generality, assume  $p \neq 0$ .  
Define  $s = p^2$  and  $t = -pq$ . Note that  $s > 0$ .

0

We have  $sz = p^2 z = -pqw = tw$ .

Since  $\operatorname{Re}(z\bar{w}) = |\operatorname{Re}(z\bar{w})|$ ,  $\operatorname{Re}(z\bar{w})$  is a non-negative real number.

Now  $0 \leq s \operatorname{Re}(z\bar{w}) = \operatorname{Re}(sz\bar{w}) = \operatorname{Re}(tw\bar{w}) = \operatorname{Re}(t|w|^2) = t|w|^2$ . Since  $|w|^2 \geq 0$ , we have  $t \geq 0$ .

• Suppose there exist some non-negative real numbers s, t such that sz = tw and s, t are not both zero. Without loss of generality, assume s > 0.

We have z = tw/s. Then  $z\overline{w} = \frac{t}{s}|w|^2 > 0$ .

Therefore  $\operatorname{\mathsf{Re}}(z\bar{w}) = \frac{t}{\varsigma} |w|^2 = |\operatorname{\mathsf{Re}}(z\bar{w})|.$ 

Note that sz - tw = 0. Then by the result in part (b), we have  $|\operatorname{Re}(z\overline{w})| \le |z||w|$ . Hence  $(\operatorname{Re}(z\overline{w}) = |\operatorname{Re}(z\overline{w})|$  and  $|\operatorname{Re}(z\overline{w})| = |z||w|)$ . Therefore |z + w| = |z| + |w|.

ii. Suppose u, v are complex numbers.

We have  $|u| = |(u - v) + v| \le |u - v| + |v|$ . Then  $|u| - |v| \le |u - v|$ .

We also have  $|v| = |u + (v - u)| \le |u| + |v - u| = |u| + |u - v|$ . Then  $|u| - |v| \ge -|u - v|$ .

Therefore  $-|u - v| \le |u| - |v| \le |u - v|$ . Hence  $||u| - |v|| \le |u - v|$ .

||u| - |v|| = |u - v| iff (|u| = |u - v| + |v| or |v| = |u| + |v - u|).

- Suppose ||u| |v|| = |u v|. Then |u| = |u - v| + |v| or |v| = |u| + |v - u|. Without loss of generality, assume |u| = |u - v| + |v|. Then there exist some non-negative real numbers s, t such that s(u - v) = tv and s, t are not both zero. Define h = s and k = s + t. Note that h, k are non-negative real numbers. If s = 0 then t > 0 and k = s + t > 0. If t = 0 then h = s > 0. Hence h, k are not both zero. We have hu = su = (s + t)v = kv.
- Suppose there exist some non-negative real numbers h, k such that hu = kv and h, k are not both zero. Without loss of generality, assume  $|u| \ge |v|$ .

We have h|u| = |hu| = |kv| = k|v|. Then  $h \le k$ . Since  $h \ge 0$  and  $k \ge 0$  and h, k are not both zero, we have  $k \ge 0$ .

Define s = h and t = k - h. Then s > 0, and  $t \ge 0$ .

We have su = hu = kv = (k - h)v + hv = tv + sv. Then s(u - v) = tv. Therefore by the result in part (c.i), we have |u| = |(u - v) + v| = |u - v| + |v|. Hence |u - v| = |u| - |v| = |u| - |v|
