Actin cytoskeleton is the major player in mechanisms driving multiple forms of cell motility. Actin filaments cooperating with numerous actin-binding proteins are able to form distinct types of higher order structures: networks and bundles, which are designed for carrying out various functions. One of important actin functions is generation of pushing force for protrusion of a leading edge of motile cells. Lamellipodia and filopodia are the two major protrusive organelles utilized by different cells for leading edge protrusion. Even though both are driven by actin polymerization, lamellipodia and filopodia have strikingly different structural design and use different sets of actin-binding proteins. Lamellipodia, which are broad, flat protrusions are filled with a branched network of actin filaments, which propagates through cycles of dendritic nucleation, elongation, capping, and depolymerization of actin filaments. Filopodia, which are thin cellular processes, contain a tight bundle of parallel actin filaments, which elongates at the tip and depolymerizes from the rear.

Although basic models for the leading edge protrusion have been formulated, many questions remain about the molecular design of the protrusive machinery and specific roles of individual molecules. Our approach is to analyze molecular architecture of actin cytoskeleton during protrusion and correlate these data with live cell behavior. Recent progress in understanding the molecular mechanisms of actin-based protrusion will be presented.

**R1 2 Active Polar Gels: A Paradigm for Cytoskeletal Dynamics.**
FRANK JULICHER, *Max Planck Institut für Physik Komplexer Systeme, Nöthnitzer Str. 38, 01187 Dresden, Germany*

The cytoskeleton of eucaryotic cells is an intrinsically dynamic network of rod-like filaments. Active processes on the molecular scale such as the action of motor proteins and the polymerization and depolymerization of filaments drive active dynamic behaviors while consuming chemical energy in the form of a fuel. Such emergent dynamics is regulated by the cell and is important for many cellular processes such as cell locomotion and cell division. From a general point of view the cytoskeleton represents an active gel-like material with interesting material properties. We present a general theory of active viscoelastic materials made of polar filaments which is motivated by the the cytoskeleton. The continuous consumption of a fuel generates a non- equilibrium state characterized by the generation of flows and stresses. Our theory can be applied to experiments in which cytoskeletal patterns are set in motion by active processes such as those which are at work in cells. It can also capture generic aspects of the flows and stress profiles which occur during cell locomotion.

**R1 3 Elasticity, adhesion and actin based propulsion.***
AJAY GOPINATHAN,† *University of California Santa Barbara*

When a cells crawls, its shape re-organizes via polymerization and depolymerization of actin filaments. The growing ends of the filaments are oriented towards the outside of the cell, and their polymerization pushes the cell membrane forwards. The same mechanism comes into play when the bacterial pathogen Listeria monocytogenes infects a cell. The bacterium hijacks the host cell's actin machinery to create an actin network (the actin comet tail) that propels the bacterium through cells and into neighboring cells. We propose a mechanism for how polymerization gives rise to motility that incorporates the effects of inhomogeneous polymerization. We treat the actin comet tail as an elastic continuum tethered to the rear of the bacterium. The interplay of polymerization and tethering gives rise to inhomogeneous stresses calculated with a finite element analysis. We quantitatively reproduce many distinctive features of actin propulsion that have been observed experimentally, including stepped motion, hopping, tail shape and the propulsion of flat surfaces.

**R1 4 Fluorescent Speckle Microrheology.**
MARGARET GARDEL, *The Scripps Research Institute*

The actin cortex is the dense shell of actin filaments between the cell membrane and the cytoplasm maintaining and regulating cell shape. It is one of the principal determinants of cell mechanical properties, whose spatiotemporal modulations play a central role in processes that involve architectural dynamics of a cell, such as cell migration, division and morphogenesis. However, the exact mechanism of cortical actin elasticity regulation itin vivo is still unresolved. We present a high-resolution and molecularly specific assay of itin vivo cortical actin elasticity, fluorescent speckle microrheology. Speckles originate when fluorescent actin is randomly incorporated into the network along with abundant endogeneous non-fluorescent actin, leading to high spatial variations of the local fluorophore density; high-density areas appear as diffraction-limited spots (speckles) upon high-resolution imaging. Speckles act as fiduciary marks of the network and can be used to directly image strain fluctuations, in contrast to classical microrheology techniques using imbedded probes. When tracking positional fluctuations of actin speckles in cells without convective network flow with subpixel precision, we find that the displacements of neighboring speckles are spatially correlated. Their correlation function decays as 1/r with interspeckle distance r, which is consistent with theoretical predictions for strain field decay in a 3D continuous viscoelastic medium. On the basis of these results, we use the amplitude of the correlation function to measure viscoelastic properties of the actin network. Due to high intracellular speckle densities and their homogeneous distribution throughout the cell, this approach yields much higher spatial resolution than other microrheology techniques, which is validated using itin vitro actin networks. Thus, this assay allows us to map intracellular actin cortex elasticity with micron resolution, and to relate intracellular heterogeneities of elasticity to heterogeneities in other dynamic cellular parameters.

**16:54**
**R1 5 Nonlinear Elasticity in Biological Gels.**
CORNELIS STORM, *University of Leiden*

The mechanical properties of soft biological tissues are essential to their physiologic function and cannot easily be duplicated by synthetic materials. Unlike simple polymer gels, many biological materials including blood vessels, mesentery tissue, lung parenchyma, cornea and blood clots, stiffen as they are deformed, or strained. Stiffening under deformation allows tissues to be compliant at small strains and strengthen at larger deformations that could threaten tissue integrity. The molecular structures and design principles responsible for this non-linear elasticity are unknown. I will outline a molecular theory that accounts for strain-stiffening in a range of molecularly distinct gels formed from cytoskeletal and extracellular proteins and reveals universal stress-strain relations at low to intermediate strains. The input to this theory is the force-extension curve for individual semi- flexible filaments and the assumptions that networks composed of them are isotropic and that their elastic response is affine. The theory shows that systems of filamentous proteins arranged in an open crosslinked meshwork invariably stiffen at low strains without requiring a specific architecture or multiple elements with different intrinsic stiffness.

## SESSION R2: FRACTIONAL QUANTUM HALL SYSTEMS
**Wednesday Afternoon, 15 March 2006; Ballroom III, Baltimore Convention Center at 14:30**
**Horst Stormer, Columbia University, presiding**

**14:30**
**R2 1 New physics in the second Landau Level.**
GABOR CSATHY, *Princeton University*

Clean two-dimensional electron systems subjected to perpendicular magnetic fields have a long history of revealing exotic ground states. A large number of these states are only possible in the presence of electron-electron interactions. Two notable examples of such collective ground states are the fractional quantum Hall liquids of the first two Landau levels and the electronic solids called the stripe and bubble phases forming beyond the first Landau level. These two classes of phases are simultaneously present and hence compete in the second Landau level. This talk will highlight our latest results on the evolution of the states of the second Landau level as the magnetic field is tilted away from the direction perpendicular to the sample. The challenging task of cooling to millidegree temperatures and in-situ tilting in this low temperature environment is achieved with a hydraulically driven rotator equipped with sintered Silver heat exchangers mounted onto the nuclear demagnetization stage of a dilution refrigerator. We found that the bubble states are rapidly destroyed with tilt and argue that such a behavior is consistent with the formation of an electronic solid. Furthermore, the well developed $\nu = 2+1/5$ and $2+4/5$ liquids are found to be driven insulating while the $2+1/3$ and $2+2/3$ states survive to the largest tilt angles accessible. The simplest interpretation of the rapid evolution of these states is that bubble phases melt into a classical Hall gas and the $\nu = 2+1/5$ and $2+4/5$ liquids solidify with tilt. Our data suggest that spin interaction plays an important role in the formation of these phases. In particular, we surmise that the bubble phases are not fully spin-polarized but most likely have a substantial antiferromagnetic order. These bubble phases could be first examples of antiferromagnetically ordered solids in a single layer two-dimensional electron system. This work was done in collaboration with J.S. Xia, C.L. Vicente, E.D. Adams, N.S. Sullivan, D.C. Tsui, H.L. Stormer, L.N. Pfeiffer, and K.W. West.

**R2 2 How free are composite fermions? An inelastic light scattering perpective.**
YANN GALLAIS, *Dept. of Physics and Dept. of Appl. Phys. & Appl. Math, Columbia University, New York*

The presentation is focused on the study of spin excitations in the regime of the Fractional Quantum Hall Effect (FQHE) to probe composite fermion interactions. The spin excitations are observed by inelastic light scattering methods. The composite fermion picture is appealing because the FQHE of strongly interacting electrons in 2D becomes the Integer Quantum Hall Effect of nearly-free composite fermions. Recent inelastic light scattering experiments show that the study of spin excitations of composite fermion quasiparticles offers unique venues to address the question: how free are composite fermions? Our experiments are conducted in the filling factor range $2/7<\nu<2/5$. We measured low energy spin-flip excitations of composite fermions in which orientation of spin and composite fermion Landau level quantum number change simultaneously. The filling factor dependence of the spin-flip excitation intensity displays a striking non-monotonic behavior as the occupation of composite fermion Landau levels are changed. This occurs when the filling factor moves above and below $\nu = 1/3$. We find remarkable behaviors that are attributed to the strong impact of residual

composite fermion interactions. The breakdown of the non-interacting composite fermion picture seen in our experiments seems to manifest quasiparticle condensations that in magneto-transport experiments are interpreted as the FQHE of composite fermions. *The work was done in collaboration with Jun Yan, T.H. Kirschenmann, C.F. Hirjibehedin, I. Dujovne, A. Pinczuk, B.S. Dennis, L.N. Pfeiffer and K.W. West.

**15:42**
**R2 3 Exotic Excitations of Composite Fermions.**
MICHAEL PETERSON, *University of California Santa Cruz*

The low-energy physics of the fractional quantum Hall effect (FQHE) is marked by the emergence of weakly correlated quasiparticles called composite fermions that are qualitatively distinct from the original strongly correlated electrons. A composite fermion (CF) is an electron bound to an even number of quantum mechanical vortices of the many-body wave function where the number of vortices characterizing the CF is called its flavor. Inelastic light scattering has played a crucial role in understanding the different types of excitations in the FQHE regime. While the lowest energy neutral excitations are accurately described as single CF particle-hole pairs, other types of interesting higher energy excitations are possible. We describe two such excitations. (i) Composite fermion flavor changing excitations (Peterson and Jain, PRL 93, 046402(2004), Wojs and Quinn, Philos. Mag. B 80, 1405(2000)): The lowest energy excitations are such that the flavor of the excited CF remains constant. We show that, in addition, there is a new class of excitations where the excited CF loses some of its vortices, i.e., it changes its flavor. Further, we suggest that these flavor changing excitations are relevant to the experimental observation of Hirjibehedin *et al. (PRL, 91, 186802(2003)) of co-existing excitation modes of differently flavored CFs in the filling factor range* $1/3 > \nu \geqslant 1/5$. (ii) Electronlike CF excitations (Jain and Peterson, PRL 94, 186808(2005)): We show that the electron is not irretrievably lost in the FQHE regime. In particular, we find that the electron (hole) couples to a complex high energy bound state of CF quasiparticles (holes). Experimental consequences of this complex bound state will be discussed.

**16:18**
**R2 4 A proposal for measuring fractional charge and statistics in fractional quantum Hall states through noise experiments.**
EUN-AH KIM, *Stanford Institute for Theoretical Physics*

Quasiparticles of fractional quantum Hall (FQH) fluids are predicted to be finite energy vortices carrying fractional charge and fractional statistics. These properties reflect the non-trivial topological order which characterizes each FQH state as a distinct phase. However, strong evidence for fractional statistics has remained an open experimental challenge. We propose a three-terminal ''T-junction'' as an experimental setup for directly detecting fractional charge and statistics of fractional quantum Hall quasiparticles via cross current noise measurements. Through a careful non-equilibrium calculation of the quantum noise in the T-junction setup for FQH Jain states, we showed that the cross current correlation (noise) can be written in a simple form with all the statistics dependence captured in a factor of $\cos\theta$ in one of two contributions, where the statistical angle $\theta$ is defined by the phase gained by a two quasiparticle wave function upon exchange. By analyzing these two contributions for different parameter ranges that are experimentally relevant, we demonstrated that the noise at finite temperature reveals signatures of generalized exclusion principles, fractional exchange statistics and fractional charge. We also predicted that the vortices of Laughlin states exhibit a ''bunching'' effect, while higher states in the Jain sequences exhibit an ''anti-bunching'' effect.

**16:54**
**R2 5 Phonon Absorption Experiments on Composite Fermions.**
FRITZ SCHULZE-WISCHELER, *Institut für Festkörperphysik, Universität Hannover, Appelstraß e 2, 30167 Hannover, Germany*

We present a time-resolved phonon absorption technique as an efficient tool to investigate the properties of the fractional quantum Hall effect (FQHE). We interpret our data within the Composite Fermion (CF) picture of the FQHE, were the CF quasiparticles are constructed by attaching two magnetic flux quanta $\phi_0$ to each electron. As a result, the CFs at filling factor $\nu$ and electron density $n$ experience only an reduced magnetic field $B^* = B - 2\phi_0 n$, so that they behave in $B^*$ in analogy to electrons in the magnetic field $B$ and form Landau levels of CFs with effective filling factor $p = \nu/1 - 2\nu$ in particular. In a first set of experiments, we measure phonon excitation gaps in the FQH regime for various filling factors and find that the measured gaps can be well described in the framework of Landau-level transitions of CFs involving no spin flip [1]. We are able to deduce the CF mass $m^*(10T) = 0{,}5m_0$ from these transitions. We apply the same model to energy gaps which we deduce from transport experiments. These gaps are transitions from one level to another reduced by disorder. Here, spin flip are allowed. From results near the crossing of two levels, we were able to deduce the g-factor of CFs [2]. A second set of phonon absorption experiments focuses on the specific heat $C$ of the 2DES at various filling factors $\nu$ [3]. Here, we find an exponential dependence $C \propto (1/T)^2 exp(-\Delta/T)$ on

temperature $T$ if the 2DES is in a state with an energy gap $\Delta$. At $\nu = 1/2$, where the external magnetic field is fully cancelled by the gauge field, we find a linear temperature dependence as expected for a Fermi sea of CFs.

## SESSION R3: LATERAL SPIN TRANSPORT
**Wednesday Afternoon, 15 March 2006; Ballroom I, Baltimore Convention Center at 14:30**
**Chia-Ling Chien, Johns Hopkins University, presiding**

**14:30**
**R3 1 Spin injection, diffusion and detection in lateral spin valves.**
YI JI, *Materials Science Division and Center for Nanoscale Materials, Argonne National Lab*

Metallic heterostructures involving ferromagnetic metals (FM) and non-magnetic metals (NM) offer very rich spintronic phenomena, such as giant magnetoresistance and spin-transfer torque. Recently, new interests have been found in heterostructures that feature lateral variation of materials. The motivation originates from the possibility of lateral integration of future spintronic devices and the advantage of extra degrees of freedom in controlling spin accumulation offered by lateral structures. In this work, we demonstrate non- local spin injection and detection in lateral spin valves. A lateral spin valve consists of a NM nanowire connected with two FM electrodes, one as the spin injector and the other as the spin detector. The measurement configurations are arranged in such a way that the current injection circuit and voltage detection circuit are separated, and so are the charge current and the spin current. A pure spin current without charge flow can be obtained in lateral spin valves, and the detected spin signal exhibits very large percentage change. The spin accumulation in lateral spin valves strongly depends on the spin diffusion length of the NM and the injection polarization of FM/NM interface, both of which can be determined by measuring a series of spin valves with different injector detector separations. We have determined the spin diffusion lengths and injection polarizations for Py/Au/Py and Co/Cu/Co lateral spin valves, fabricated by different techniques. The differences of these quantities in two systems will be discussed. This work is done in collaboration with Axel Hoffmann, Sam Jiang, John Pearson, and Sam Bader, and supported by U.S. DOE Office of Basic Energy Science-Materials Science under contract No. W-31- 109-ENG-38.

**15:06**
**R3 2 Dynamics of lateral magnetoelectronic thin-film nanostructures.**
GERRIT BAUER, *TU Delft*

Hybrid nanostructures made from ferromagnetic and normal metals come in two main flavors: perpendicular multilayer nanopillars and lateral thin film devices. Current-induced magnetization dynamics have until now mainly been studied in perpendicular structures. However, lateral devices have several advantages compared to perpendicular ones, such as relative ease to study multi-terminal configurations and to directly observe the magnetic order parameter. In this talk I will discuss the magnetization dynamics of lateral thin-film structures in the framework of magnetoelectronic circuit theory. The research has been done in collaboration with Xuhui Wang, Yaroslav Tserkovnyak, Arne Brataas, Bart van Wees, Axel Hoffmann, and Teruo Ono.

**15:42**
**R3 3 Spin-polarized tunneling and spin diffusion in sub-micron lateral spin-transistors.***
SERGIO O. VALENZUELA, *Physics Department, Harvard University, Cambridge MA 02138, USA*

Much effort has been devoted to understand how the electron spin is transferred through interfaces and to identify the fundamental processes that suppress the spin polarization. Spin- transistors with the Johnson and Silsbees geometry are a unique tool to study these phenomena. In these devices, a spin- polarized current is injected into a non-magnetic metal using a tunnel junction in combination with a ferromagnet (FM), which acts as a spin source. The polarized current results in non- equilibrium spin populations in the non-magnetic metal, which are detected as voltages using a second FM. Fabricated aluminum- based devices with spin transresistances as high as 2 Ohm allow us to study spin-flip scattering mechanisms and spin-polarized tunneling. The tunneling polarization at zero bias is compared with the one estimated with the Meservey and Tedrow technique in the same sample. In addition, as the spin-transistor measurements can be extended to finite voltages and high temperatures, new valuable information is obtained on the character and polarization

of the electrons that tunnel out of or into the ferromagnetic source. Surprisingly, the polarization is found to be strongly bias-dependent and asymmetric around zero bias. The origin of these phenomena is analyzed.

*In collaboration with D.J. Monsma, M. Tinkham, C.M. Marcus and V. Narayanamurti.

**16:18**
**R3 4 Spin-torque effects due to pure spin currents in lateral geometries.**
YOSHICHIKA OTANI, *ISSP University of Tokyo*

Spin injection into the ferromagnetic materials induces a spin torque due to the spin angular momentum transfer between the conduction electron spin and the localized magnetic moment. The magnetization reversal of a nano-scale ferromagnet thereby takes place when the spin polarized current is injected into it. This has been demonstrated using metallic nanopillar devices consisting of magnetic multilayered systems with the spin polarized current flowing perpendicular to the plane. The spin torque mentioned above is known to be proportional to the spin current density. Therefore not the charge current causing the Joule heat but the spin current is essential to realize efficient magnetization reversal due to the spin torque. Thus non-local spin injection technique is employed to realize such a reversal. Here we discuss our resent results on the magnetization reversal due to non-local spin injection into a nano-scale ferromagnetic particle in a lateral ferromagnetic/nonmagnetic hybrid device [1].

## SESSION R4: IONIC, DIPOLAR AND H-BONDING POLYMERS
**Wednesday Afternoon, 15 March 2006; 308, Baltimore Convention Center at 14:30**
**Sanat Kumar, Rensselaer Polytechnic Institute, presiding**

**14:30**
**R4 1 Solvent-induced changes in the structure and rheology of polyelectrolyte solutions.**
VICTOR BREEDVELD, *Georgia Institute of Technology*

By integrating microfluidics and particle tracking microrheology, we have constructed a dialysis cell for microrheology, which provides unique opportunities for studying the dynamics of microstructural changes induced by changes in solvent composition. Such experiments are virtually impossible with mechanical rheometers. The concept and design of the microdialysis cell will be discussed, and data will be presented on the structural and rheological response of polyelectrolyte solutions to changes in ionic strength. Sulphonated polystyrene is a water-soluble polymer and its molecular conformation in solution strongly depends on ionic strength of the solution. It will be shown that quantitative measurements of transient solution viscosity during solvent exchange can be performed with the new dialysis cell. Experiments were also performed on amphiphilic block copolypeptide (BCP) hydrogels, which self-assemble into fibrillar structures due to a subtle balance between attractive and repulsive intermolecular forces. Electrostatic repulsion between the hydrophilic L-lysine blocks plays a key role. Therefore, changes in ionic strength have a significant effect on the self-assembled local structure and mechanical properties of the BCP gels, as was previously observed in rheometer experiments. Microrheology in the dialysis cell provided a much more complete picture, revealing the occurrence of microscopic phase separation upon the addition of salt. For example, in a K160L40 lysine-leucine block copolypeptide, the motion of tracer particles in the hydrogel is homogeneous in DI water. After the addition of salt, microrheology reveals the co-existence of populations of freely moving and immobilized particles. The changes in local microstructure were found to be reversible when the ionic strength of the solution was lowered again. Data will be presented on the dynamics of the morphological and rheological changes of various block copolypeptide hydrogels.

**15:06**
**R4 2 Theoretical Modeling of Hydrogen Bonded and Metal-Ligand Associating Polymers.***
ELENA DORMIDONTOVA, *Department of Macromolecular Science and Engineering, Case Western Reserve University, Cleveland, Ohio 44106; E-mail:eed@case.edu*

Applying analytical modeling in combination with Monte Carlo simulations we have studied the association behavior and properties of two types of supramolecular polymers employing 1) hydrogen bonded and 2) metal-ligand associative motifs. In the first case association between the hydrogen bonded arrays results in numerous donor-acceptor interactions between the complementary end groups of linear oligomers leading primarily to formation of linear chains or rings. Similar architectures of self-assembled polymers can also be obtained by reversible 1:2 complex formation between metal ions (such as Zn(+2), Cd(+2), Co (+2), etc.) and ligands of end-functionalized oligomers. In this case the association is strongly influenced by metal- ligand ratio. We analyze the chain-ring equilibrium and study the influence of the strength

and type of association, rigidity of the complex and solution composition on the degree of association and the average molecular weight of the supramolecular polymers. For metal ions (such as La(+3), Nd(+3), Eu(+3), etc) capable of 1:3 complex formation with the ligands, self-assembly results in reversible polymers of more complex architecture, in particular a reversible network (in the percolation limit). Since the coordination sites of the metal possess unequal reactivity (having different energies of association with the first, second and third ligand) and due to the cooperativity of binding, network formation is influenced by different factors such as metal/ligand ratio, oligomer length and concentration. Predictions of an analytical model based on the equilibrium among different associating species and classical percolation theory compare favorably with simulation results for gel fraction and average molecular weight. Simulation results and theoretical predictions will be compared with available experimental data.

**15:42**
**R4 3 Soultion assembly of charged block copolymers and block copolypeptides.***
DARRIN POCHAN, *University of Delaware*

By considering peptidic or charged, synthetic polymers in the materials self-assembly design process, one can take advantage of inherently biomolecular attributes; intramolecular folding events, secondary structure stabilized by hydrogen bonding, and electrostatic interactions; in addition to more traditional self-assembling molecular attributes such as amphiphilicty, to define hierarchical material structure and consequent properties. The solution assembly behavior of two charged block copolymers will be discussed. First, diblock copolypeptides consisting of a hydrophilic, charged block and a hydrophobic block were designed to self-assemble due to their amphiphilic nature. The defined helical secondary structure of the leucine hydrophobic block forces these molecules to form a membraneous local nanostructure. However, diverse materials, ranging from rigid hydrogel, vesicle suspension, or hexagonal single crystal, can be formed depending on assembly pathway. Second, synthetic triblock copolymers with charged corona blocks can be assembled in dilute solution with multivalent organic counterions to produce complex micelle structures such as toroids and discs. Nanostructure can be tuned with different concentrations or molecular volumes of organic counterion. Transmission electron microscopy, small-angle neutron scattering, multiphoton confocal microscopy, dynamic light scattering, and atomic force microscopy results will be discussed.

*This work supported by the Division of Materials Research and Chemical Transport Systems of the NSF.

**16:18**
**R4 4 Water Solubility of Polymers with Salt: The Hofmeister Series.**
PAUL CREMER, *Texas A&M University*

We have designed temperature gradient microfluidic devices that allow high throughput, low sample volume assays to be performed on the folding of thermoresponsive polymers and proteins. These macromolecular systems are insoluble at high temperatures, but become hydrated and unfold as the temperature is decreased in a process analogous to the cold denaturation of proteins. Our assays enable highly precise measurements to be made rapidly of the physical behavior of the polymers. The device is specifically used to obtain data on poly (N-isopropylacrylamide) and alpha-elastin at multiple concentrations in the presence of a variety of ions. The results indicate that the folding process follows the Hofmeister series. This series, which dates back to 1888, is a rank ordering of anions and cations based upon their ability to salt-out or salt-in proteins. It had been historically believed that ions affect macromolecule solubility indirectly through their interactions with bulk water. This idea has been largely disproved by a variety of characterization techniques over the last decade. A new theory to explain the mechanism of the Hofmeister effect, however, still needs to be developed. Microfluidic assays in combination with vibrational sum frequency spectroscopy allowed us to develop a model based solely on the direct interaction of the ions with a macromolecule and its first hydration shell. In fact, the protein folding properties can be related to a few simple factors: an ion's hydration entropy, its effect on the surface tension of an aqueous interface, and its ability to interact directly with binding sights on a protein.

**16:54**
**R4 5 Polyelectrolyte effects in polymers for lithography.**
VIVEK PRABHU, *Polymers Division, National Institute of Standards and Technology*

The transformation of a solid-like film into a solution upon exposure to a miscible solvent is a complex process involving sluggish kinetic pathways associated with the slow transport of the liquid into the film and the evolution of the thermodynamic driving forces during the course of the dissolution process. In complex materials such as polymers, this process occurs in stages from the transformation of the glassy or crystalline film into a swollen state, followed at longer times by the final dissolution of the film. Dissolving polyelectrolyte films exhibit additional complexities in their dissolution dynamics over uncharged polymer films. Interfacial charge density, the dielectric constant of the medium, ionic strength and valence influence the phase behavior of charged polymers thus affecting their dissolution behavior. The dissolution mechanism can be tailored for different applications, for instance the microelectronics industry utilizes the selective dissolution of one component enabling lithographic pattern formation. We present neutron reflectivity and quartz crystal

microbalance results to address polyelectrolyte effects in thin films such as the counterion distribution, quasi-equilibrium swelling and kinetics. V.M. Prabhu, R.L. Jones, E.K. Lin, W-L Wu. ''Polyelectrolyte effects in model photoresist developer solutions.'' J. Vac. Sci. and Tech.B, 21, 1403 (2003). V.M. Prabhu, B.D. Vogt, W-L. Wu, J. Douglas, E. Lin, S. Satija, D. Goldfarb, and H. Ito. ''Direct measurement of the counterion distribution within swollen polyelectrolyte films'' Langmuir Letter, 21, 6647 (2005).

## SESSION R5: PATHS FROM ACADEMICS TO EMPLOYMENT

**Wednesday Afternoon, 15 March 2006; 309, Baltimore Convention Center at 14:30**
**John L. Orrell, Pacific Northwest National Laboratory, presiding**

**14:30**
**R5 1 AIP Statistics on Physics Employment Trends.**
ROMAN CZUJKO, *American Institute of Physics*

This talk provides a statistical overview of the employment trends for physicists. The work done by physics bachelors, masters, and PhDs is qualitatively different. This talk will describe the career paths commonly pursued by recent physics graduates at each degree level and will illustrate how these trends have changed over time. It will discuss the indicators that point to both the strengths and weaknesses of the current job market for physicists. The paper will include a discussion of recent reports that claim that American students are avoiding science and engineering. It will conclude with a discussion of the pro's and con's of recent calls for dramatic increases in U.S. degree production in the sciences.

**15:06**
**R5 2 Industry Job Hunting for PhDs.**
BERNARD SILBERNAGEL, *ExxonMobil Research & Engineering Co.*

The industrial environment presents opportunities and challenges that are significantly different from those in academia. The research problems encountered are often complex and the solutions are generally sought by teams of researchers with a variety of skills from different disciplines. An important criterion for a new researcher in industry is that they be able to represent their area of competency on such a team. In most instances, hiring decisions are based on a reasonable compatibility of the candidate's skills and the needs of the research area, but the supposition is that the individual will evolve with time and with changing assignments. Important attributes for the candidate are solid technical strength in their area of expertise, good ''peripheral vision'' of science and technology in proximate and more remote areas, and a willingness to adapt to changes in the direction of the project. In contrast to academia, there are a variety of career paths for the industrial scientist, including a long-term participation in research and development, migration into the more practical aspects of the business (such as problem-solving or technical liaison) or management. Initially, it will probably not be apparent which of these paths is the most desirable and, in fact, a person may be involved with more than one during the course of their career. Each of these paths, or a combination of them, can be extremely satisfying and rewarding.

**15:42**
**R5 3 Government Positions for Physicists.**
DAVID SEILER, *National Institute of Standards and Technology*

There are a number of government agencies that employ physicists in a wide variety of jobs – from student internships to post docs to full time staff positions. You can do real, creative, fore-front physics or pursue a wide range of leadership positions. The possibilities are almost unlimited and so is the impact your work can have on the government, academia, and industry. So how do you go about finding a government job? What qualities or abilities are deemed valuable? What are the advantages and disadvantages to working in the government? I will bring some personal experiences and observations from working in the government (one year as a rotator at the National Science Foundation in the Division of Materials Research and almost 18 years at the National Institute of Standards and Technology, both as a Group Leader and a Division Chief) to bear on these questions and more. Prior to my government career I was a physics professor pursuing research and teaching in academia.

**16:18**
**R5 4 Aiming for Professorship at a Research University.***
CHRISTOPHER J. STANTON, *University of Florida*

In this talk, I will discuss and provide guidance on how to prepare and approach applying for an academic faculty position at a research oriented university as a first time professor. First I will discuss what is expected of a beginning faculty member at a research university. Next I will cover what you should be doing as a postdoc to enhance the chances of a finding a research position at a university. Finally I will go over all aspects of the job search process. Topics that will be discussed include: 1) preparing your CV, research and teaching statements, and cover letter, 2) getting letters of recommendation, 3) preparing for the interview, 4) the ''Job Talk,'' 5) following up the interview, 6) negotiating the start-up package, and finally 7) accepting or rejecting an offer. Throughout the talk, I will try to emphasize what the ''search committee'' as well as the department is looking for in a successful candidate and some pitfalls to avoid in the process.

**R5 5 Teaching and Research at Undergraduate Institutions.**
SHILA GARG, *The College of Wooster*

My own career path has been non-traditional and I ended up at a primarily undergraduate institution by pure accident. However, teaching at a small college has been extremely rewarding to me, since I get to know and interact with my students, have an opportunity to work with them one-on-one and promote their intellectual growth and sense of social responsibility. One of the growing trends at undergraduate institutions in the past decade has been the crucial role of undergraduate research as part of the teaching process and the training of future scientists. There are several liberal arts institutions that expect research-active Faculty who can mentor undergraduate research activities. Often faculty members at these institutions consider their roles as teacher-scholars with no boundary between these two primary activities. A researcher who is in touch with the developments in his/her own field and contributes to new knowledge in the field is likely to be a more exciting teacher in the classroom and share the excitement of discovery with the students. At undergraduate institutions, there is generally very good support available for faculty development projects in both teaching and research. Often, there is a generous research leave program as well. For those who like advising and mentoring undergraduates and a teaching and learning centered paradigm, I will recommend a career at an undergraduate institution. In my presentation, I will talk about how one can prepare for such a career.

## SESSION R6: U. S. WOMEN IN PHYSICS: AN INTERNATIONAL PERSPECTIVE
**Wednesday Afternoon, 15 March 2006; 310, Baltimore Convention Center at 14:30**
**Kimberly Budil, Lawrence Livermore National Laboratory, presiding**

**14:30**
**R6 1 An International Perspective on Women in Physics.**
ARIEL MICHELMAN-RIBEIRO, *BU / NIH*

The 1$^{st}$ International Union of Pure and Applied Physics (IUPAP) Conference on Women in Physics, held in 2002 in Paris, France, highlighted a number of issues facing women physicists around the world. A second conference was held in May 2005 in Rio de Janeiro, Brazil, with the goal of examining the progress made since the last conference and also to provide an opportunity for the delegates to present their research, both physics research and gender-related research, and to make contacts for future collaborations. The conference was attended by 145 delegates from 42 countries, including a very diverse delegation of 22 women and men from the U.S. The conference was organized by the Working Group on Women in Physics of IUPAP, which is charged with making recommendations to IUPAP on how to attract, retain, and increase the participation of women in physics at all levels. The conference included a round table discussion on ''Research Funding and Women in Physics,'' several plenary talks, a poster session on women in physics in each country, a poster session on research by individual delegates, and discussion groups on six topics including attracting girls into physics, launching a successful career, getting women into leadership, improving the institutional climate, learning from regional differences, and balancing family and career. Conference proceedings have been published that include research abstracts, summaries from the discussion groups, articles on the plenary talks, and papers from each country on the status of women in physics in their country (proceedings can be found at http://proceedings.aip.org/proceedings/confproceed/795.jsp). This talk will discuss the U. S. delegation and their country paper on the situation for women in physics in the U.S. as well as highlights from the information presented by the delegates from other nations. The outcomes of the 2002 conference will be described briefly and then the signs of progress noted in 2005 will be summarized.

**15:06**
**R6 2 What Works for Women in Undergraduate Physics? Learning from Different Institutions.***
BARBARA L. WHITTEN, *Colorado College*

The participation of women in physics has increased in recent years, but the percentage of women receiving bachelor's degrees in physics is still less than half that in mathematics or chemistry. The undergraduate years have been identified as the biggest ''leak.'' With a team of women physicists, I have been studying undergraduate physics departments to learn what makes some departments female-friendly. An informal and supportive department culture is the most important factor we have identified. There are many elements that make up a female-friendly culture, and different kinds of institutions—small colleges, universities, women's colleges, and HBCUs—all have important ideas to contribute. I will discuss what these different institutions have to tell us about recruiting and retaining women in the undergraduate physics major.

**15:42**
**R6 3 Women Physicists of Color Achieving at the Intersection of Race and Gender.**
K. RENEE HORTON, *University of Alabama*

As minority women physicists, we stand at the intersection of race and gender. We are physicists to be sure, but we are also women of Native, African and Hispanic descent. We are colleagues, mothers, sisters, and wives, as are our white counterparts, but our experiences cannot be distilled to only gender or race. As Prudence Carter and Scott Page remind us, women of color emerge from the interaction between race and gender.[1] This distinction is important since most researchers who study American women's participation in science focus exclusively on the participation of white American women. Of those who acknowledge the existence of non-white women, most do so by disclaiming the exclusion of women of color because the numbers are so small or the experiences are different from white American women. There are some important differences however. While American women are 15 percent of all scientists and engineers, black American women are 60 percent of all black scientists and engineers. Yet less than 3 black women and 3 Hispanic women earn PhDs each year, out of about 1100. As Rachel Ivie and Kim Nies Ray point out, ''Minority women especially represent a great, untapped resource that could be drawn on to increase the size of the scientific workforce in the U.S.''[2] Donna Nelson's study of diversity in science and engineering faculties further finds that there are no female black or Native American full professors.[3] In physics, there are no black women professors and no Native American women professors at all. Despite such a bleak picture, there is hope. Of the 18 departments that award at least 40 percent of bachelor's degrees to women, 7 are Historically Black Colleges and Universities. Black women are earning degrees from HBCUs at rates above equity, and many singles and firsts at predominantly white institutions continue to persevere despite the obstacles.

**R6 5 Interacting in the Smog Factors that Shape Faculty Attitudes and Beliefs about Race and Inclusion.**
APRIEL K. HODARI, *The CNA Corporation*

Many faculty members realize that we must interact productively with diverse colleagues and students, and we must find ways to benefit from the talents of all members of our intellectual community. Put simply, we must aim for the ceiling rather than the floor. This means that we approach our work informed that engaging diversity in our classrooms will increase our success and the success of itall our students. But in physics, it is often difficult to measure and address diversity issues because doing so is not perceived as central to our discipline. To address this apparent disconnection, we present some ideas on race [1] and inclusion [2] within the context of the physics instruction. Specifically, we speak to how university faculty might use inclusive pedagogy in physics education research and curriculum. Our goal here is to open a frank dialogue and present concrete avenues to explore as you create activities that serve your classroom best. Tatum, Beverly Daniel. (2004). **Herbert Levine, University of California, San Diego, presiding**

**14:30**
**R7 1 Evolutionary ecology of E. coli metapopulations in patchy landscapes.***
JUAN KEYMER, *Princeton University*

Spatial ecology and metapopulation biology are essential features of natural populations. Extinction of local populations, the colonization of new suitable habitat patches (metapopulation dynamics) as well as the creation and destruction of local habitats (patch dynamics) are basic components of the evolutionary process shaping life-history strategies. As Darwin liked to put it ''the zoology of archipelagoes.'' The role of spatial structure have been shown to be important for both, persistence and coexistence. However, the spatial ecology of microbial metapopulations have rarely been observed nor exploited technologically. We use nano and micro fabrication technology to build a spatially explicit (dynamic) landscape of habitat patches (the metapopulation chip) and a (UV) laser-based disturbance regime (patch dynamics). By building upon the theory of metapopulations in dynamic landscapes, we build fitness landscapes by linking patch dynamics to fluorescent patterns coming from molecular markers in the cell culture. We use landscape ecology and metapopulation biology to generate selective forces that can be used for evolutionary design of microorganisms.

**15:06**
**R7 2 Life has Evolved to Evolve.***
MICHAEL DEEM, *Rice University*

Concomitant with the evolution of biological diversity must have been the evolution of mechanisms that facilitate evolution, due to the essentially infinite complexity of protein sequence space. We describe how evolvability can be an object of Darwinian selection, emphasizing the collective nature of the process. Rapid or dramatic environmental change leads to selection for greater evolvability. The selective pressure for large scale genetic moves, such as DNA exchange, becomes increasingly strong as the environmental conditions become more uncertain. These results demonstrate that evolvability is a selectable trait and allow for the explanation of a large body of experimental results. Many observations within evolutionary biology, heretofore considered evolutionary happenstance or accidents, are explained by selection for evolvability. As specific examaples, we discuss evolution within the immune system and evolution of drug resistant microrganisims.

**15:42**
**R7 3 Can Evolution Be Understood Quantitatively?***
DANIEL S. FISHER, *Harvard University*

Although the underlying laws and mechanisms of biological evolution have been known for a long time, little is understood about the time scales of evolutionary processes. This talk will focus on quantitative questions about evolutionary dynamics and on the potential for progress on intermediate time-scale issues via combinations of microbial experiments and theory. A recent experiment on one of these will be presented. Some basic questions about long time-scale processes will also be raised, and potential roles of abstract models in sharpening these and advancing understanding addressed briefly.

**16:54**
**R7 5 Genome Evolution in the 21st Century.**
JAMES SHAPIRO, *University of Chicago*

Assume no previous theories about genetics and evolution. What conclusions would we draw from molecular data (e.g. genome sequences)? We start from basic principles of cellular information processing: cells behave cognitively using signal transduction networks; signal transduction involves weak noncovalent interactions; allosteric properties of biomolecules; multivalent storage of information in DNA sequences and nucleoprotein complexes; inertness of naked DNA. Genome informatics thus requires formation of nucleoprotein complexes. Complex formation requires generic repeated signals in the DNA; repetition also permits cooperativity to stabilize weak interactions. DNA is a functional structural component of nucleoprotein complexes, not a passive data tape. Specificity in DNA nucleoprotein complex formation involves combining multiple generic signals and/or sequence recognition by small RNAs. Novel combinations of generic signals and coding sequences arise in genomes by iteration and rearrangement. Cells possess natural genetic engineering functions that actively restructure DNA molecules. These internal DNA remodeling functions act cognitively in response to internal and external inputs. They operate non-randomly with respect to (1) the types of new structures produced and (2) the regions of the genome modified. Whole genome sequence data increasingly documents the historical role of natural genetic engineering in evolutionary changes. Basic principles of cellular molecular biology and DNA function lead to a complex interactive systems view of genome organization. This view incorporates different DNA components found in sequenced genomes. Regulated cellular natural genetic engineering functions permit genomes to serve as Read-Write information storage systems, not just Read-Only memories subject to accidental change. These 21st Century conclusions are most compatible with a systems engineering view of the evolutionary process.

**SESSION R8: MONOLAYERS, MEMBRANES & MICROEMULSIONS**
**Wednesday Afternoon, 15 March 2006**
**314, Baltimore Convention Center at 14:30**
**Mark Bowick, Syracuse University, presiding**

**14:30**
**R8 1 Theory of Myelin Coiling** JUNG-REN HUANG, THOMAS WITTEN, *University of Chicago* We propose a new model to explain coiling of myelins composed of fluid bilayers. This model allows the bilayer cylinders of a myelin to be non-coaxial and the bilayer lateral tension to vary from bilayer to bilayer. Our calculations suggest that a myelin would bend or coil to lower its free energy when the bilayer lateral tension is sufficiently large. The proposed coiling mechanism is in a sense similar to the classical Euler buckling of a thin elastic rod subject to axial compression. The analysis of a simple two-bilayer case shows that a bilayer lateral tension of about 1 dyne/cm can easily induce coiling of myelins of typical lipid bilayers. This model signifies the importance of bilayer lateral tension in determining the morphology of myelinic structures.

**14:42**
**R8 2 Curvature condensation and twinning in an indented elastic shell** MOUMITA DAS, ASHKAN VAZIRI, *Harvard University* ARSHAD KUDROLLI, *Clark University* L. MAHADEVAN, *Harvard University* We study the formation of a localized geometrical defect and its evolution in an elastic shell using a combination of experiment and numerical simulation. We find that as a symmetric localized indentation on a semi-cylindrical shell increases, there is a transition from a global mode of deformation to a localized one which leads to the condensation of curvature along a parabolic crease along the line of symmetry. Further indentation leads to a twinning phenomena wherein the crease bifurcates into two defects that move apart on either side of the line of symmetry. We present a simple theory to explain the main features of the experiments and numerical simulations.

**14:54**
**R8 3 Anomalous persistence of a pinch in a pipe** L. MAHADEVAN, A. VAZIRI, M. DAS, *Harvard University* The response of low-dimensional solid objects combines geometry and physics in unusual ways, exemplified in structures of great utility such as a tubular shell that is ubiquitous in nature and technology. Here we provide a particularly surprising consequence of this confluence of geometry and physics in tubular structures: the anomalously large persistence of a localized pinch in an elastic pipe whose effect decays very slowly as an oscillatory exponential with a persistence length that scales as $R^{3/2}/t^{1/2}$, diverging as the thickness of the tube vanishes. The result is more a consequence of geometry than material properties, and is thus equally applicable to carbon nanotubes and cytoskeletal microtubules as it is to aircraft fuselages and geological plates, with a number of consequences, some of which we consider.

**15:06**
**R8 4 Crystalline order on the paraboloid** LUCA GIOMI, MARK BOWICK, *Syracuse University* We describe an experimental and theoretical investigation of crystalline order on a two-dimensional paraboloid. In contrast to the sphere, the paraboloid exhibits both variable Gaussian curvature and a boundary. Both these features must be treated for a thorough theoretical understanding. A macroscopic model of a parabolic crystal can be obtained in the laboratory by assembling a single layer of soap bubbles on the surface of a rotating liquid, thus extending the classic work of Bragg and Nye on planar arrays of soap bubbles.

**15:18**

**R8 5 Elastic Stiffness of Grain Boundary Scars and Dislocation Dynamics** HOMIN SHIN, MARK BOWICK, *Syracuse University* We analytically calculate the stiffness of finite-length grain boundaries (scars) on a spherical crystal within the continuum elasticity theory. The scar is composed of an isolated disclination with $+1$ topological charge together with a finite number of dislocations. We determine the elastic free energy of a single finite-grain boundary scar by considering interacting defects, such as Disclination-Disclination (D-D), Disclination-dislocation (D-d), and dislocation-dislocation (d-d). The harmonic potential binding dislocations to the scar is obtained by determining the free energy of a single dislocation perturbed away from its equilibrium position. The elastic spring constants so obtained are compared to experimental data on dislocation dynamics [1]. We conclude with some comments on interstitial dynamics. [1] Lipowsky, P., Bowick, M. J., Meinke, J. H., Nelson, D. R. and Bausch, A. R., Nature Mater. 4, 407-411 (2005).

**15:30**

**R8 6 Membrane Nano-Structures: The Three Tether Junction** OLIVER RUEBENACKER, *University of Connecticut* GREG HUBER, *University of Connecticut* Tethers are robust cylindrical nanostructures of lipid bilayer membranes, including biomembranes. They can be easily produced in experiments and can be found in and on cells. Tethers are useful for probing the mechanical properties of membranes, because the radius of a tether is small enough to make the bending stiffness of the membrane relevant. In an experiment, a glass bead was attached to a tether and pulled with a laser tweezer leading to the formation of a three tether junction. I will present a theory explaining the observed force-displacement relationship and simulation results of the shape of the three tether junction.

**15:42**

**R8 7 Toward a multi-scale simulation of lipid bilayer systems** TAISUKE SUGII, SHU TAKAGI, YOICHIRO MATSUMOTO, *The University of Tokyo* In numerical simulations of lipid bilayer systems, it has become important to treat the membrane molecules (e.g., lipids, proteins, and drug molecules) explicitly for designing medical drugs and for developing drug delivery systems. However, it is difficult to apply straightforwardly a microscopic simulation technique such as the molecular dynamics method to the large-scale bilayer systems, because the length and the time scales of these systems are very large compared to the scales of the molecules. The authors take two approaches for this problem. First, we use the dissipative particle dynamics method and the coarse grained molecular dynamics method in addition to the standard molecular dynamics method. The results are compared with the molecular-dynamics results and experimental data. Secondly we use a molecular dynamics and continuum hybrid simulation method. In this method, the region near the membrane is computed by an atomistic-simulation method and the solvent region is computed by a continuum-simulation method. (In our study, the coarse grained molecular dynamics was used for the atomistic region.) The validity and availability of this later approach will be discussed.

**15:54**

**R8 8 Influence of the size of interacting domains on the diffusion of nano-particles** FLORIAN RÜCKERL, CARSTEN SELLE, JOSEF KÄS, Single particle tracking (SPT) is widely used for investigating the diffusion of proteins in cell membranes. However, short lifetime and the blinking of fluorescent tracers make it difficult to obtain sufficient data on the interactions with the inhomogeneities of the membrane. Langmuir lipid monolayers provide control over obstacle size and the corresponding interaction energy since their condensed domains within liquid phases exhibit a net dipole moment. The diffusion of a stable, negatively charged latex bead in the coexisting liquid phase, with a dipole moment anti parallel to the one of the domain, was observed by SPT. The interaction energy was obtained by Boltzmann statistics of the tracking data. The electric field of the monolayer domains varies with domain size. Its distance dependence can principally change from $E \sim 1/r^3$ for a single dipole to $E \sim 1/r$ for large domains ($R > 10m$). The influence of this change on the particle diffusion was investigated by Monte Carlo simulations. The analysis shows that the particles are stronger trapped at the domain border of smaller domains and that a change from two to one dimensional diffusion occurs. Recently, we also started analogous experiments using red blood cells and vesicles as biomembrane mimics.

**16:06**

**R8 9 Control of domain formation and budding in multicomponent bilayer membranes** KURT A. SMITH, ANNA C. BALAZS, *University of Pittsburgh* Phase separation in fluid bilayer membranes, of lipids or block copolymers, can lead to a budding transition when line tension between the two phases comes to dominate the bending rigidity of the membrane. This leads to a nearly spherical bud connected to the membrane by a small neck. We examine the role of molecular architecture and composition on this shape transformation. Specifically we consider the inclusion of twin-tail amphiphiles which lower the free energy of the system by segregating to the interface between the two phases. Such additives can be used to lower the surface tension, thus controlling the critical size at which buds form. In addition they stabilize the neck when budding does occur, by acting essentially as stitches, thereby increasing the energy needed to detach the bud from the membrane. Using dissipative particle dynamics we are able to simulate the dynamics of large mebrane patches over relevant time scales.

**16:18**

**R8 10 Ordering by collapse: Two-dimensional crystallization of hydrophobic dimers by folding Langmuir monolayers*** DAVID VAKNIN, *Ames Laboratory, Iowa State Univerisity* WEI BU, *Ames Laboratory, Iowa State Univerisity* ALEX TRAVESSET, *Ames Laboratory, Iowa State Univerisity* Synchrotron X-ray studies of arachidic-acid monolayers compressed to the collapse region, beyond their densely packed molecular area, reveal that the resulting structures are stable and exhibit a surprising degree of order. Different structures, depending on whether the monolayer is spread on pure water or on $CaCl_2$ solutions, are identified. On pure water the collapsed monolayer forms a stable crystalline trilayer, with acyl-chain packing practically identical to the 3D crystal structure of fatty acids. For monolayers spread on $Ca^{2+}$ solutions, the collapse regime consists of an inverted bilayer with the hydrophobic tails in contact with the water surface and the calcium ions bridging the polar heads. The inverted bilayer structure possesses a well ordered crystalline slab of calcium-oxalate-monohydrate

intercalated between two acyl-chains. We discuss the implications of our findings to recent reports on dewetting of water near hydrophobic surfaces, on the formation of super-lattice structures by ions beneath a monolayer, and the relevance to certain biological processes.

*The MUCAT sector at the APS, through Ames Laboratory, and the use of the APS are supported by U.S. DOE, Basic Energy Sciences under Contracts Nos. W-7405-Eng-82 and W-31-109-Eng-38, respectively.

**16:30**

**R8 11 Mechanical Properties of an Actin Filament Network Monolayer*** ROBERT WALDER, MICHAEL DENNIN, *U. C. Irvine Department of Physics and Astronomy* ALEX LEVINE, *UCLA Department of Chemistry and Biochemistry* Actin filament networks present a model system to study the mechanical properties of semi-rigid polymer networks. Because they are a network, the filaments can display behavior that deviates from continuum elasticity theory on sufficiently short length scales, resulting in interesting nonlinear response of the system to applied stresses and strains. We have developed a Couette (concentric cylinders) style apparatus to study monolayers of actin confined to the air-water interface. This talk will present results characterizing the response of the monolayer to continuous and step-wise strains. We will report on measurements of the viscosity of the actin network, as a macroscopic characterization, and on tracking of particles embedded in the network. The particle tracking is used to probe local displacements of the network in response to applied strain. We will report on tests of the predicted transition between affine and non-affine displacements as a function of cross-linking density.

**16:42**

**R8 12 Shape Selection in Self-Assembled Chiral Membranes: New Mechanism Based on the Flexoelectric Effect** ZHAO LU, ROBIN SELINGER, JONATHAN SELINGER, *Liquid Crystal Institute, Kent State University* Many biological materials self-assemble into chiral microstructures such as cylindrical tubules and helical ribbons. A chiral elastic theory proposed by Selinger et al., based on the elastic properties and chirality of amphiphilic lipid molecules, has been successful in explaining the formation of tubules and helical ribbons. Recently, an experiment has shown that achiral lipid molecules can also form chiral microstructures. This challenges the previous theory based on molecular chirality. Toward understanding this problem, we develop a new model for membrane shape selection based on the flexoelectric effect. We investigate this model through both analytical calculations and dissipative particle dynamic simulations on tethered membranes.

**16:54**

**R8 13 Bile Salt Mediated Growth of Reverse Wormlike Micelles in Nonpolar Liquids** SHIH-HUANG TUNG, YI-EN HUANG, SRINIVASA RAGHAVAN, *Department of Chemical and Biomolecular Engineering, University of Maryland, College Park, MD 20742* We report the growth of reverse wormlike micelles induced by the addition of a bile salt in trace amounts to solutions of the phospholipid, lecithin in nonpolar organic solvents. Previous recipes for reverse wormlike micelles have usually required the addition of water to induce reverse micellar growth; here, we show that bile salts, due to their unique ''facially amphiphilic'' structure, can play a role analogous to water and promote the longitudinal aggregation of lecithin molecules into reverse micellar chains. The formation of transient entangled networks of these reverse micelles transforms low-viscosity lecithin organosols into strongly viscoelastic fluids. The zeroshear viscosity increases by more than five orders of magnitude, and it is the molar ratio of bile salt to lecithin that controls this viscosity enhancement. The growth of reverse wormlike micelles is also confirmed by small-angle neutron scattering (SANS) experiments on these fluids.

**17:06**

**R8 14 Mesoscopic simulations of binary mixtures and microemulsions using a stochastic, particle-based algorithm** ERKAN TUZEL, *School of Physics and Astronomy, University of Minnesota* GUOAI PAN, THOMAS IHLE, DANIEL KROLL, *Department of Physics, North Dakota State University* Particle-based simulation techniques provide an attractive alternative to traditional methods for the coarse-grained modeling of a fluctuating solvent. A particularly appealing algorithm introduced by Malevanets and Kapral[1], called Stochastic Rotation Dynamics, describes a fluid with an ideal gas equation of state. The algorithm has been successfully applied to study polymers, colloids, and vesicles in shear flow. Recently, this algorithm has been generalized to model fluids with non-ideal equations of state[2]. We will discuss how this can be used to study binary mixtures with a miscibility gap. Results for the demixing such as the phase diagram and measurements of interface fluctuations and the surface tension of a droplet will be shown. By tuning the ratio of surface tension and viscosity both damped and overdamped capillary waves were obtained.The coarsening of domains during spinodal decomposition is also investigated. In order to describe microemulsions, the model is further extended to include surfactant molecules. Preliminary results for the onset of emulsification will be presented. [1] A. Malevanets, R. Kapral, J. Chem. Phys. 110, 8605 (1999). [2] T. Ihle, E. Tuzel, D. M. Kroll, cond-mat/0509631; cond-mat/0511312.

**17:18**

**R8 15 On the bouncing of rigid spheres on thin polymer films** LAURENT COURBIN, ANTONIN MARCHAND, ASHKAN VAZIRI, HOWARD A. STONE, *Division of Engineering and Applied Sciences, Harvard University* We report on a study of the rebound of stainless steel spheres on thin polymer films. After the sphere is dropped it bounces off the plastic sheet and the evolution in time of the subsequent rebounds are recorded. Experiments are performed varying the sphere radius, the impact velocity, and the film tension. The variations of the contact time, the amplitude of deformation of the film, and the loss of energy of the sphere after impact, as reported via a coefficient of restitution, lead to a number of scaling relations. These results are interpreted in terms of linear and nonlinear theories of the elasticity of membranes.

**SESSION R9: IMAGING, SIGNAL DETECTION AND PROCESSING**
**Wednesday Afternoon, 15 March 2006**
**301, Baltimore Convention Center at 14:30**
**Karen Waldrip, Sandia National Laboratories, presiding**

**14:30**
**R9 1 A single pixel camera based on compressed sensing** KEVIN KELLY, *Electrical Engineering Dept., Rice University* DHARMPAL TAKHAR, JASON LASKA, MIKE WAKIN, MARCO DUARTE, BRIAN VAN OSDOL, DROR BARON, RICHARD BARANIUK, Digital micromirror devices have proven to be a commercially viable MEMs technology for the video/projector display market. Inspired by the success of this technology, we have combined a microcontrolled mirror with a single optical sensor so that it additionally acquire images, rather than merely adapt current camera technology to serve as an optical sensor. In this project, we have developed a practical image/video camera based on this concept and realized it through the use of itcompressed sensing. Our design has additional desirable properties including scalable output bit stream, variable image resolutions and video frame rates. We will also discuss the generalization of itcompressed sensing as a way of image formation for other single detector systems.

**14:42**
**R9 2 Low temperature confocal microscopy with a 4 K closed-cycle cryostat** ANGELIKA KUENG, CHRISTOPH BOEDEFELD, CHRISTIAN SCHULHAUSER, *Attocube System AG* MATTHIAS BUEHLER, JENS HOEHNE, *VeriCold Technologies GmbH* Low temperature confocal microscopy is a technique of major interest with regard to research fields ranging from material and surface science to single molecule spectroscopy. Common setups involve the use of expensive liquid helium and suffer from the lack of coarse positioning units at cryogenic temperatures. We present for the first time a highly flexible confocal microscope combined with a 4 K closed-cycle cryostat. This complete system solution enables plug-and-play high resolution confocal microscopy at low temperatures without the need of liquid helium. The low-vibration pulse tube based cryostat has been specially adapted for very low vibrations as required for applications in combination with scanning probe microscopy. The developed confocal microscope is thermally compensated guaranteeing ultra-high stability at low temperature providing at the same time very high optical resolution as will be shown in various examples. Furthermore, nanopositioning units based on the slip-stick principle allow coarse positioning over centimeters. The system allows operation at extreme conditions as high magnetic fields and high vacuum.

**14:54**
**R9 3 4Pi Spectral Self-interference Fluorescence Microscopy*** MEHMET DOGAN, *Department of Physics, Boston University* ANNA K. SWAN, *Department of ECE, Boston University* M. SELIM UNLU, *Department of ECE, Boston University* BENNETT B. GOLDBERG, *Department of Physics, Boston University* 4Pi fluorescence confocal microscopy [1] improves axial resolution, and Spectral Self-Interference Fluorescence Microscopy (SSFM) [2] provides sub-nanometer localization of fluorescent emitters in biological structures. Here we report on the construction and evaluation of a 4Pi fluorescence confocal microscope and discuss the efforts to combine the high resolution 4Pi technique with SSFM. In the 4Pi microscope, the back focal planes of two opposing high numerical aperture objectives are filled with coherent laser illumination and counter propagating spherical wave fronts form constructive interference at the common focus of two objectives, resulting in an improvement of the axial point spread function (PSF). We characterized the 3-D PSF of the microscope using fluorescent polystyrene beads and fluorescent monolayers. We measured a factor of 3 improvement of the axial PSF compared to a confocal microscope. [1] S. W. Hell et al. J. Opt. Soc.Am. A Vol. 9, No. 12, pp. 2159 (1992) [2] A. K. Swan et al. **R9 4 Enhancing Diffraction-Limited Images Using the Properties of the Point Spread Function** ALEXANDER SMALL, *Laboratory of Integrative and Medical Biophysics, National Institute of Child Health and Human Development, NIH* ILKO ILEV, *Office of Science and Engineering Laboratories, FDA* AMIR GANDJBAKHCHE, *Laboratory of Integrative and Medical Biophysics, National Institute of Child Health and Human Development, NIH* We propose a simple method for enhancing diffraction-limited microscope images, enhancing the resolution by at least a factor of two. In its simplest implementation, our algorithm is ideally suited for enhancing images obtained with near-field illumination, such as scanning probe microscopy of cells. We exploit the fact that the finite width of the point spread function introduces correlations between pixels in an image. Our method is much simpler than other methods for beating the diffraction limit, requiring no specialized equipment beyond the microscopes commonly found in biology laboratories, and only a single computational step to yield significant enhancements. We have theoretically analyzed the performance of our algorithm by generating images with point objects, and convolving those images with the point spread function (PSF) of a diffraction- limited lens. After enhancing the resulting images, we find that our method reduces the width of the PSF by a factor of two, and also yields a much steeper profile, enhancing contrast. Even when objects are too close to be resolved distinctly, our method enhances the aspect ratio of the resulting diffraction blur, clearly pointing to the existence of structure.

**R9 5 Feasibility of using Backscattered Mueller Matrix Images for Bioaerosol Detection** CHANGHUI LI,* GEORGE W. KATTAWAR,† *Texas A&M University* It has been shown that by looking at the backscattered radiance from an object illuminated by a laser beam one could effectively distinguish different morphologies from one another. However, if one wants to obtain all the information possible from elastic scattering either from a single particle or an ensemble of particles then one must use the Mueller matrix which contains all the polarization and radiance information available. In this talk, we will show that if we take advantage of the polarization information of the object, many more images related to the overall morphology as well as the internal structure of the object can be obtained. We will present images of the complete Mueller matrix to show the sensitivity of its sixteen components to both external and internal particle prop-

erties. We will also show that by using only one or two elements of this matrix one might be able to distinguish bioaerosols such as anthrax from more benign aerosols. We also show that the back-scattering Mueller images contain more information than the forward scattering ones.

**R9 6 The Role of Hyperspectral Imaging in the Visualization of Obliterated Writings** HINA AYUB, *Oak Ridge Institute for Science & Education- FBI Laboratory Research Division* DIANE WILLIAMS, *FBI Laboratory Research Division* The forensic questioned document community has encountered difficulty visualizing obliterated writing using conventional methods. Cases have been reported in which pencil obliterated by ink, and ink obliterated by ink, cannot be discerned visually. Conventional methods for visualization of obliterated writings do not adequately visualize writing when obliteration is made with the same color ink, or when graphite pencil writings are obliterated by ink. We report the use of hyperspectral imaging to successfully view obliterated writings in which a ''true black'' ink obliterated graphite as well as graphite/graphite and ink/ink obliterations. Hyperspectral imaging (HSI) is a novel optical technique in which hundreds of narrow contiguous bands, over a large range of wavelengths, can be viewed to yield a complete spectral profile at each pixel in the image. HSI has evolved as the product of conventional two-dimensional imaging and spectroscopy. The resultant image of HSI is a three-dimensional data cube, with the pixels constrained to a single plane, and the complete reflectance spectra seen along the orthogonal axis. We used three types of hyperspectral imaging systems, which provided a wavelength range spanning approximately 300-1700 nm, to visualize the obliterated writing samples. Additionally, we will present data obtained from the use of thermal imaging to successfully view obliterated writings.

**R9 7 Femto-second real-time single-shot digitizer** JASON CHOU, OZDAL BOYRAZ, BAHRAM JALALI, *Electrical Engineering Department, University of California, Los Angeles* We demonstrate a single-shot digitizer with a record 10 Tera Sample-per-Second sampling rate, an order of magnitude improvement over prior state-of-the-art. The feat is accomplished by using a photonic time stretch preprocessor which slows down the electrical waveform by a factor of 250 before it is captured by an electronic digitizer. To achieve this performance, distributed Raman optical amplification was realized in the dispersive medium that performs the time dilation. Experimentally, a 90 GHz electrical signal is digitized in real time at 100 femto-second intervals. To the best of our knowledge, this is the first femto-second real-time digitizer.

**R9 8 A photopyroelectric sensor for the high-resolution thermophysical characterization of liquid mixtures.** ANNA MATVIENKO, ANDREAS MANDELIS, *Center for Advanced Diffusion-Wave Technologies, University of Toronto* A common principle of photothermal techniques is the study of thermal wave propagation in a sample following heating by an intensity modulated laser beam. In this study, we applied the photopyroelectric thermal-wave cavity technique with the common-mode-rejection demodulation scheme to the measurements of thermal diffusivity of water-alcohol mixtures at low concentrations. The high sensitivity of the photothermal signal to the thermal diffusivity of samples relies on the exponential decay character of the thermal-wave field at a given modulation frequency. The common-mode-rejection demodulation scheme involves the launching of two unequal duration pulses over one modulation period. In this case, the lock-in amplifier output represents the difference between the response waves produced by each one of two pulses. This differential technique shows resolution at the level of 0.2% v/v of alcohol in water, the highest ever reported using thermophysical techniques. In terms of future applications the proposed system can eventually be implemented into a self-contained in-situ liquid pollution monitor.

**16:06**

**R9 9 Johnson Noise Thermometry in the range 505 K to 933 K** WESTON TEW, JOHN LABENSKI,*SAE WOO NAM, SAMUEL BENZ, PAUL DRESSELHAUS, *NIST, Boulder CO* JOHN MARTINIS, *UC Santa Barbara* The International Temperature Scale of 1990 (ITS-90) is an artifact-based temperature scale, $T_{90}$, designed to approximate thermodynamic temperature $T$. The thermodynamic errors of the ITS-90, characterized as the value of $T - T_{90}$, only recently have been quantified by primary thermodynamic methods. Johnson Noise Thermometry (JNT) is a primary method which can be applied over wide temperature ranges, and NIST is currently using JNT to determine $T - T_{90}$ in the range 505 K to 933 K, overlapping both acoustic gas-based and radiation-based thermometry. Advances in digital electronics have now made the computationally intensive processing required for JNT viable using noise voltage correlation in the frequency domain. We have also optimized the design of the 5-wire JNT temperature probes to minimize electromagnetic interference and transmission line effects. Statistical uncertainties under 50 $\mu$K/K are achievable using relatively modest bandwidths of $\sim$ 100 kHz. The NIST JNT system will provide critical data for $T - T_{90}$ linking together the highly accurate acoustic gas-based data at lower temperatures with the higher-temperature radiation-based data, forming the basis for a new International Temperature Scale with greatly improved thermodynamic accuracy.

**R9 10 Using Temperature-Dependent Phenomena at Oxide Surfaces for Species Recognition in Chemical Sensing.** STEVE SEMANCIK, DOUGLAS MEIER, JON EVJU, KURT BENKSTEIN, ZVI BOGER, CHIP MONTGOMERY, *Chemical Science and Technology Laboratory, NIST* Nanostructured films of $SnO_2$ and $TiO_2$ have been deposited on elements in MEMS arrays to fabricate solid state conductometric gas microsensors. The multilevel platforms within an array, called microhotplates, are individually addressable for localized temperature control and measurement of sensing film electrical conductance. Temperature variations of the microhotplates are employed in thermally-activated CVD oxide film growth, and for rapid temperature-programmed operation of the microsensors. Analytical information on environmental gas phase composition is produced temporally as purposeful thermal fluctuations provide energetic and kinetic control of surface reaction and adsorption/desorption

phenomena. Resulting modulations of oxide adsorbate populations cause changing charge transfer behavior and measurable conductance responses. Rich data streams from different sensing films in the arrays have been analyzed by Artificial Neural Networks (ANN) to successfully recognize low concentration species in mixed gases. We illustrate capabilities of the approach and technology in the homeland security area, where dangerous chemicals (TICs, CWSs and CWAs) have been detected at 10-100 ppb levels in interference-spiked air backgrounds.

**R9 11 2D Thermal Imaging of the Surfaces of Optoelectronic Devices by Thermoreflectance Microscopy** M. FARZANEH, D. LÜERßEN, *Mount Holyoke College, Massachusetts Institute of Technology* P. MAYER, R. J. RAM, *Massachusetts Institute of Technology* JANICE A. HUDGINGS, *Mount Holyoke College* For the last 40 years, thermoreflectance has been used to experimentally validate bandstructure calculations for semiconductor and metallic materials. The recent development of high resolution thermoreflectance microscopy as a noninvasive, 2D thermal imaging technique, based on measuring the variations of the surface reflectivity with temperature opens new avenues of probing the nanoscale properties of materials and devices. Recently, we have demonstrated that by utilizing stochastic resonance a thermal resolution of 10mK can be achieved, which exceeds the quantization limit of the camera by two orders of magnitude. Here, we report the use of thermoreflectance to characterize a photonic integrated circuit comprised of cascaded semiconductor optical amplifiers. Optical cooling of the biased amplifiers by 0.5K is observed which demonstrates the high spatial and thermal resolution achievable with stochastic resonance enhanced thermoreflectance microscopy.

**16:42**

**R9 12 Suppression of Non-Resonant Background in Broadband Coherent Anti-Stokes Raman Scattering Microscopy with Interferometry*** TAK KEE, MARCUS CICERONE, *National Institute of Standards and Technology* We demonstrate an interferometric technique for suppressing non-resonant background in broadband coherent anti-Stokes Raman scattering (CARS) microscopy. CARS microscopy has become an important biological imaging tool due to its non-invasiveness, and high spatial resolution. Our previous work on developing broadband CARS microscopy has improved the chemical specificity significantly by increasing the spectral coverage to $> 2500\ \mathrm{cm}^{-1}$ [T.W. Kee, M.T. Cicerone, Opt. Lett. **29**, 2701 (2004)]. Although CARS microscopy provides high sensitivity in the C-H stretch region of the vibrational spectrum, the signals in the Raman fingerprint region suffer from low signal-to-background ratio because of the presence of a non-resonant background due to the electronic response of the sample. Suppressing the non-resonant background signal is crucial in order to develop CARS microscopy into a powerful technique to image biochemical reactions in cells. In our approach, a broadband CARS signal with high spectral resolution interferes with another broadband CARS signal with lower spectral resolution. Fourier transform of the interferometric measurements allow the extraction of the imaginary part of the signal, which is free of the non-resonant background.

**R9 13 Digital ultrasonic pulse-echo overlap system and algorithm for unambiguous determination of pulse transit time** CRISTIAN PANTEA, DWIGHT RICKEL, ALBERT MIGLIORI, *Los Alamos National Laboratory, Materials Science and Technology (MST)-National High Magnetic Field Laboratory (NHMFL), Los Alamos, New Mexico 87545* JIANZHONG ZHANG, YUSHENG ZHAO, *Los Alamos National Laboratory, Los Alamos Neutron Scattering Center (LANSCE)-12, Los Alamos, New Mexico 87545* SAMI EL-KHATIB, *Physics Department, New Mexico State University, Las Cruces, New Mexico 88003* ROBERT LEISURE, *Colorado State University, Department of Physics, Fort Collins, Colorado 80523* BAOSHENG LI, *Mineral Physics Institute, State University of New York (SUNY) at Stony Brook, Stony Brook, New York 11794* We report an evolution of an all-digital ultrasonic pulse technique for measurements of elastic constants of solids. An unambiguous analytical procedure is described for determining the correct time delay of echoes without any need for actual echo overlap. We also provide a simple procedure for making corrections for transducer-bond-induced phase shifts. The precision of a measurement made with this system at ambient temperature exceeds one part in $10^7$ without the use of mixers, gates, time delays, and other complications normally associated with such measurements.

**17:06**

**R9 14 Application of the finite element method to resonant ultrasound spectroscopy data analysis.*** A. SUSLOV, I. DIXON, S. HEADLEY, E. DEYLE, *NHMFL, Tallahassee, FL* A. MIGLIORI, *LANL, Los-Alamos, NM.* Commercially available finite-element software is used to determine elastic moduli from experimental data acquired by resonant ultrasound spectroscopy (RUS) on an arbitrarily-shaped sample. The sample geometry must be provided in coordinate form, as well as the crystallographic symmetry and the crystallographic orientation relative to the coordinates. The algorithm has been tested on published resonance measurements obtained on rectangular parallelepipeds and cylinders of cubic, tetragonal, hexagonal and monoclinic symmetries. The results agree within expected numerical precision to the elastic constants found by other computational methods. The algorithm is much slower than the one normally implemented explicitly for RUS analysis but, for difficult-to-prepare or fragile samples such as a layered specimen prepared from several materials, moduli can be obtained without polishing or otherwise damaging the sample. Details of the model generation, meshing and optimization approach will be discussed.

**R9 15 Source distance information and frequency shifts by chirp decomposition** V. GURUPRASAD, *Inspired Research, NY* Innovative frequency shifts directly revealing the source distance of received signals are obtainable from phase spectra as follows. The phase expression for a travelling wave, $\phi = -\omega(t - r/c)$, implies increasing static phase differences $\delta\phi(r) = r\,\delta\omega/c$ between adjacent frequencies in the radiated waves. The static differences are useless for information transport and hard to measure, hence were hitherto generally ignored. Scanning the spectrum transforms them to Doppler-like shifts revealing the distance, given by the partial derivative $\delta\omega(r) = \partial\phi/\partial t|_{r,t} = \dot{\omega}r/c$, where $\dot{\omega}$ is the scanning rate, provided the signal has

nonzero bandwidth. By controlling $\dot{\omega}$, any source can now be instantly ranged or isolated, allowing separations down to 10 m at 100 m range for 10 MHz voice modulated carrier – without CDMA or power control, as described at IEEE WCNC 2005. The mechanism is also realizable by simple chirp transform, and has been verified by simulation and with acoustic signals. EM field tests are now being arranged. The results and other aspects of general physics interest will be discussed.

**R10 1 Broad-Band Sum-Frequency Generation Spectroscopy at Platinum/Solution Interfaces.***
ANDRZEJ WIECKOWSKI, *University of Illinois at Urbana-Champaign*

Vibrational Broad-Band Sum-Frequency Generation Spectroscopy (BB-SFG) is the second-generation SFG method for studying surfaces, including wet electrochemical interfaces. BB-SFG measurements, which are based upon the second-order nonlinear optical process are inherently interface specific (as is SFG) but add sensitivity and control to SFG. The electrochemical cell used for the reported measurements has an ideal configuration where the thickness of the supporting electrolyte (25 $\mu$m) is controlled by a spacer, allowing for rapid spectral acquisitions (5 $s^{-1}$) synchronized with the potential sweep at 5 mV $s^{-1}$). In the talk, simultaneous electrochemical and BB-SFG measurements will be reported for adsorption/oxidation of carbon monoxide on polycrystalline and well-ordered Pt(hkl) electrodes with both CO-free and CO-saturated electrolytes. The emphasis will be on the combination between thin layer electrochemistry (TLE) and vibrational electrode surface analysis, and on dynamics of Pt/solution interfaces probed by the CO molecule adsorption and oxidation.

**R10 2 Charge inversion at ultra-low electrolyte concentrations*** DUNCAN J. McGILLIVRAY, MATHIAS LÖSCHE, *Dept of Physics, Carnegie Mellon University & CNBT, NIST Center for Neutron Research* JENS PITTLER, *Dept of Physics, University of Leipzig, Germany* WEI BU, ALEX TRAVESSET, DAVID VAKNIN, *Ames Lab & Dept of Physics & Astronomy, Iowa State University* Synchrotron x-ray reflectivity studies of the anionic phospholipid DMPA in monolayers spread on very dilute solutions of $LaCl_3$ reveal strong adsorption of the cations at nanomolar and micromolar concentrations, and a sharp transition in cation concentration at the interface as a function of ionic strength. Using anomalous X-ray reflection we determine the number of $La^{3+}$ ions per $DMPA^-$ (surface charge density, $\sigma \approx e^-/40$ Å$^2$) over four orders of magnitude in bulk ion concentration. We find that at concentrations in the range 10–300 nM $La^{3+}$ forms a Stern layer with $\approx$ 1 $La^{3+}$/ 3 $DMPA^-$, thus neutralizing the lipid surfaces charge. At a critical bulk concentration, $C_t \approx$ 500 nM, the surface concentration of $La^{3+}$ increases steeply, up to a saturation level with $\approx$ 1 $La^{3+}$/ DMPA. The strong condensation of $La^{3+}$ above $C_t$ implies that the charge at the interface is reversed. We provide theoretical arguments that the charge reversal is facilitated by 1) strong correlations between the phosphate groups and $La^{3+}$ ions and 2) hydrogen bonding of hydroxyl groups, effectively forming the complex $La^{3+}PO_4^{2-}OH^-$.

**15:18**
**R10 3 Modeling Electrocatalysis – Electro-oxidation of Pt(111)** TIMO JACOB, MATTHIAS SCHEFFLER, *Fritz-Haber Institute, Faradayweg 4-6, D-14195 Berlin, Germany* Electrochemical reactions (such as in fuel cells) usually occur under conditions of finite temperature, pressure, and electrode potential, implying a very involved situation, possibly leading to novel surface materials. Especially the presence of an electrode potential, which results in the formation of an electric double-layer, affects the composition and structure of the electrode/electrolyte-interface. Towards a more realistic treatment of electrocatalysis we developed an appropriate theory in which the electrode of the interface is assumed to be in contact with a *bulk-electrode* reservoir (at chemical potential $\mu_{el}$) while the electrolyte is in contact with a *bulk-electrolyte* reservoir. Although we are in the process of simulating the entire electric-double layer self-consistently, the present approach already allows us to estimate the limites of the expected effects. As a first application we studied the electro-oxidation of Pt(111) by calculating the $p/T/\phi$-phase diagram. The obtained behavior, that positive electrode potentials stabilize higher oxygen coverages, is in qualitative agreement with cyclic-voltammetry experiments.

**15:30**
**R10 4 Electrochemical oxidation in solid oxide fuel cells – Where does it occur and how?** ROBERT WALKER, *Department of Chemistry and Biochemistry, University of Maryland* MICHAEL POMFRET, *Department of Chemistry and Biochemistry, University of Maryland* Electrochemical processes in solid-oxide fuel cells (SOFCs) are thought to occur at a ''triple phase boundary'' (TPB) – that junction between a conducting anode, a solid oxide electrolyte and the gas phase fuel mixture. A quanti-

tative, physical description of this boundary, however, remains elusive given difficulties associated with probing molecular species present in SOFCs under realistic operating conditions of high temperatures and reducing atmospheres. Recently, we have constructed an SOFC that has optical access to the anode assembly allowing us to probe with Raman spectroscopy the chemical intermediates present on anode and electrolyte surfaces as carbon containing fuels are electrochemically oxidized. Results show that chemistry occurs on both the anode and electrolyte surfaces as well as in the vicinity of the purported TPB. The reduced electrolyte surface is both catalytically active and, over micron distances, electrically conductive. The Ni anode shows strong evidence of adsorbed carboxylate intermediates. This talk will address mechanisms of electrochemical oxidation in SOFCs using direct and indirect experimental probes as well as the consequence of our findings for models of a well defined triple phase boundary.

**R10 5 Epitaxial Electrodeposition of Chiral Metal Oxide Films.**
JAY SWITZER, *University of Missouri-Rolla*

Chirality is ubiquitous in Nature. One enantiomer of a molecule is often physiologically active, while the other enantiomer may be either inactive or toxic. Chiral surfaces offer the possibility of developing heterogeneous enantiospecific catalysts that can more readily be separated from the products and reused. Chiral surfaces might also serve as electrochemical sensors for chiral molecules- perhaps even implantable chiral sensors that could be used to monitor drug levels in the body. Our trick to produce chiral surfaces is to electrodeposit low symmetry metal oxide films with chiral orientations on achiral substrates (see, Nature **425**, 490, 2003). The relationship between three-dimensional and two-dimensional chirality will be discussed. Chiral surfaces lack mirror or glide plane symmetry. It is possible to produce chiral surfaces of materials which do not crystallize in chiral space groups. We have deposited chiral orientations of achiral CuO onto single-crystal Au and Cu using both tartaric acid and the amino acids alanine and valine to control the handedness of the electrodeposited films. We will present results on the chiral recognition of molecules such as tartaric or malic acid and L-dopa on the chiral electrodeposited CuO. Initial work on the electrochemical biomineralization of chiral nanostructures of calcite will also be discussed.

**R10 7 How Water Meets a Hydrophobic Surface – Reluctantly and with Fluctuations** ADELE POYNOR, LIANG HONG, STEVE GRANICK, *University of Illinois at Urbana-Champaign* The details of how water meets a hydrophobic surface are still hotly debated. Here we use two independent methods, ellipsometry in the time-resolved phase-modulated mode, and surface plasmon resonance, to investigate the view that thermodynamics causes a nanometer-sized low-density layer to form adjacent to the hydrophobic solid. Strong evidence in favor of the hypothesis is found. This zone of depleted density shows large fluctuations even within the spatial (over a beam size of 10 $\mu$m) and temporal (with a time constant of 30 ms) averaging inherent in ellipsometry measurement. Statistical analysis of these noise spectra reveal a remarkable scaling with the area over which the measurements are averaged.

**16:42**
**R10 8 Diffusion, adsorption and incorporation of antifreeze glycoprotein molecules at the ice/water interface** HIROYUKI NAKAYA, SALVADOR ZEPEDA, YUKIHIRO UDA, SHUICHIRO MATSUMOTO, *Hokkaido University* ETSURO YOKOYAMA, *Computer Center, Gakushuin University* YOSHINORI FURUKAWA, *Hokkaido University* Antifreeze glycoproteins(AFGP) are known to inhibit ice crystal growth by adsorbing to the interface. But, there is no direct observation of the distribution of AFGP molecules around the interface of the growing ice crystal. In order to observe the growing ice/water interface, one-directional growth experiments of ice crystal growth were carried out in AFGP solution. AFGPs were labeled with fluorescent markers to see the distribution of AFGP molecules. We obtained video image of the distribution of AFGP molecules near the growing ice/water interface by using fluorescent microscopy. Incorporation and accumulation of AFGP molecules at the interface were clearly observed, and strongly depend on the growth rate of the ice crystal. We also observed the diffusion field of AFGP molecules from the ice interface and calculated diffusion and segregation coefficients. We found that AFGP molecules strongly adsorb to the growing ice crystal interface, and incorporate between grain boundaries, but found little evidence for incorporation into the crystal lattice. This is contrary to previous paradigms for AFGP function.

**16:54**
**R10 9 Self-oscillatory ice crystal growth in antifreeze protein (AFP) and glycoprotein (AFGP) solutions** SALVADOR ZEPEDA, HIROYUKI NAKAYA, YUKIHIRO UDA, *Hokkaido University* ETSURO YOKOYAMA, *Gakushuin University* YOSHINORI FURUKAWA, *Hokkaido University* AFPs and AFGPs allow many organisms including fish, plants and insects to survive sub-freezing environments. They occur in a wide range of compositions and structure, but to some extent they all accomplish the same functions: they suppress the freezing temperature, inhibit recrystallization, and modify ice crystal growth. A complete description of the AFGP/AFP surface mechanism as well as other ice surface phenomenon has eluded scientists primarily due to a lack of direct surface studies. We study ice crystal growth in AFGP and AFP solutions with phase contrast microscopy during free solution growth under various conditions including microgravity. Free-solution growth experiments show an anisotropic self-oscillatory growth mode of the steps and interface near the freezing temperature and enhancement of the growth rates in the c-axis. These results contradict the previous ''tight-binding'' mechanism thought to be responsible for antifreeze function. To study the effects of temperature driven convective flows on the interface kinetics, microgravity experiments were performed in a jet airplane during a parabolic flight path. Step propagation on the basal plane slows down considerably when entering the microgravity condition and reaches a critical condition just below 0.2g.

**17:06**
**R10 10 Simulation study of water/silicon oxide interface** CHRISTIAN LORENZ, SUSAN REMPE, MARK STEVENS, GARY GREST, *Sandia National Laboratories* MESFIN TSIGE, *Southern Illinois University* The interaction of water with solid surfaces plays a crucial role in many phenomena. The water-silica interface is one of the typical systems encountered in technological and natural materials. Numerous technological applications of silica were found to rely on its specific surface properties. Large scale quantum mechanics (QM) and classical molecular dynamics (MD) simulations are used to study the molecular configurations and wetting properties of water at the interface of different silicon oxide surfaces. In order to understand how the surface coverage of silanols (-SiOH) affects the wetting behavior of the silica surfaces, both crystalline ((001) $\alpha$-quartz (coverage 9.6 $nm^{-2}$) and (100) $\beta$-cristobalite (7.8 $nm^{-2}$)) and amorphous silica (5.0 $nm^{-2}$) substrates have been studied. The binding energy of the water, the number of water molecules hydrogen-bonded to the surface and the configuration of the hydrogen-bonded water molecules are determined as a function of silanol coverage from QM simulations. The number of water molecules within a monolayer and the orientation of the water molecules within the monolayer and in the bulk are determined from MD simulations. Results from two classical force fields are compared to one another and to the relevant quantities from the QM simulations. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**R10 11 Hydrogen etching and graphitization of 4H- and 6H-SiC** XUEBIN LI, ZHIMIN SONG, TIANBO LI, CLAIRE BERGER, PHILLIP FIRST, WALTER DE HEER, *Georgia Institute of Technology* Hydrogen etching and graphitization on the surfaces of 4H/6H-SiC with different off-axis angles were studied at temperatures ranging from 1300-1600$^0$C. Above 1500$^0$C, the scratches caused by polishing on the surfaces of SiC were effectively removed by the reaction with hydrogen. AFM images showed various topographies on the surfaces of 4H/6H SiC after hydrogen treatment, related to wafer type (4H or 6H), polar faces (Si- face or C-face), off-axis angles, and inherent substrate defects. Flat thin graphite films were grown by the thermal decomposition of SiC at high temperature on both C- and Si- faces of SiC in a vacuum furnace. Surface graphitization of 4H/6H SiC previously flattened by hydrogen etching was analyzed in UHV by LEED and AES, and in ambient air by AFM. Mobility of graphite films grown on the C-face of 4H-SiC ranges from 1000 to 10,000 $cm^2$/Vs. Magnetotransport of the graphite film shows 2D gas behavior, accompanying with SdH oscillations and Hall plateaus.

**R11 1 Unraveling proton accommodation in water with cluster spectroscopy.**
MARK JOHNSON, *Yale University*

We describe how argon-nanomatrix spectroscopy, implemented with broadly tunable solid state infrared laser sources, allows us to establish how water networks flex and distort to accommodate elementary aqueous species like protons and electrons. We will focus on the hydrated proton, as this charge defect accounts for charge conduction in many biological processes that occur in a hydrophobic environment. By freezing the water clusters to their minimum energy structures, sharp, characteristic bands are recovered very low in energy that reveal how the local solvent arrangement dictates the spatial extent of the excess charge delocalization.

**R11 2 Excess Electrons in Water Clusters** YING LI, *School of Physics, Georgia Institute of Technology* ROBERT BARNETT, *School of Physics, Georgia Institute of Technology* UZI LANDMAN, *School of Physics, Georgia Institute of Technology* Excess electrons in water systems are always a research topic of interest. In this talk, we will discuss the behavior and formation of the excess electrons in water cluster using DFT ab-initio simulations with a combination of quantum mechanics and molecular mechanics. System size is chosen so that the excess electrons will form a bound state rather than a surface state. Measurements will be performed to test the stability of the electron structure.

**15:18**

**R11 3 Surface-trapped excess electrons on ice** FRANCESCA BALETTO, MAL-SOON LEE,*SANDRO SCAMDOLO, *The Abdus Salam ICTP and INFM-CNR Democritos, Trieste (Italy)* Local surface trapping of excess electrons has recently been observed in large water clusters and at the ice/vacuum interface. The existence of stable surface-bound states for the excess electron may have important implications in atmospheric chemistry, electrochemistry, and radiation physics. By means of first-principles molecular dynamics we find that excess electrons induce a structural reconstruction of the ice surface on a time scale of a fraction of a picosecond [Baletto et al., PRL 95, 176801 (2005)]. Preliminary results on small neutral water clusters indicate that fast (on a picoseconds scale) structural changes occur already at the lowest atmospheric temperatures, suggesting that addition of excess electrons may lead to even more substantial structural rearrangements than those found for the ice surface.

**R11 4 Hole-filling spectroscopy of the ittrans-formanilide-$H_2O$ and tryptamine-$H_2O$ complexes: Solvent shuttling and solvent loss*** TIMOTHY ZWIER, JASPER CLARKSON, *Dept. of Chemistry, Purdue University* Studies of molecular clusters formed and cooled in a supersonic expansion offer unique opportunities to study novel types of dynamical processes under well-defined conditions. This talk will highlight recent studies in our laboratory at Purdue involving water-containing complexes with ittrans-formanilide (TFA) and tryptamine (TRA). In TFA-$H_2O$, stimulated emission pumping is used to initiate a unique type of reaction in which a single water molecule is shuttled between remote hydrogen-bonding sites on the same solute molecule. The energy barrier to isomerization is measured for shuttling the molecule in either direction. In TRA-$H_2O$ and TRA($ND_2$)-$D_2O$, infrared excitation is used to dissociate the water molecule from a flexible molecule with well-defined starting geometry. Isomer-specific product quantum yields of the TRA monomer product will be reported as a function of the XH or XD oscillator excited. The interplay between water loss and conformational isomerization of the flexible TRA molecule will be discussed.

**R11 5 Anharmonic Vibrational Spectra of Hydrogen Bonded Clusters*** SOTIRIS S. XANTHEAS, *Chemical Sciences Division, Pacific Northwest National Laboratory, 906 Battelle Boulevard, PO Box 999, MS K1-83, Richland, WA 99352* We report anharmonic vibrational spectra for a variety of hydrogen bonded clusters such as $(H_2O)_n$ and $(HF)_n$, $n$=1-5. We investigate the convergence of the hydrogen bonded frequencies with basis set and level of electron correlation and compare with the available experimental data. For this purpose we employ the correlation-consistent basis sets up to quintuple zeta (5z) quality and compute the spectra at the second order Møller-Plesset (MP2) and Coupled Cluster plus Single and Double with perturbative estimate of Triple excitations [CCSD(T)]. The correlation between the calculated elongations in the hydrogen bonding stretches and the corresponding computed/observed vibrational frequencies suggest an extension of Badger's rule for these hydrogen bonded systems.

**R11 6 Probing the Stepwise Solvation of the Sulfate Dianion: Gas Phase Infrared Spectroscopy of $SO_4^{2-} \cdot (H_2O)_n$ Clusters (n=3-24)** KNUT R. ASMIS, GERARD MEIJER, *Fritz-Haber-Institut der Max-Planck-Gesellschaft, Faradayweg 4-6, D-14195 Berlin, Germany.* GABRIELE SANTAMBROGIO, MATHIAS BRUEMMER, LUDGER WOESTE, *Institut fuer Experimentalphysik, Freie Universitaet Berlin, Arnimallee 14, D-14195 Berlin, Germany.* JIA ZHOU, DAVE T. MOORE, DANIEL M. NEUMARK, *Department of Chemistry, University of California and Chemical Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA.* Hydrated sulfate dianions are of paramount importance in diverse branches of science. However, a microscopic, molecular level understanding of the nature of the solute-solvent interaction as well as the composition of the solvation shell has not yet been achieved. Here we report the first gas phase infrared spectra of multiple charged anions in general, namely of mass-selected $SO_4^{2-} \cdot (H_2O)_n$ dianions ($n$=3-24) employing the infrared multiple photon dissociation technique in combination with radiation from the free electron laser FELIX. The infrared spectra (550-1800 $cm^{-1}$) were measured in the region of the stretching and bending modes of the sulfate core as well as characteristic intra- and intermolecular water modes, allowing an unprecedented, atomic level insight into structure of the complex as well as the nature and strength of the underlying hydrogen bonding interaction.

**16:06**

**R11 7 Effective polarizabilities of water clusters** RAMIRO MORO, ROMAN RABINOVITCH, CHUNLEI XIA, VITALY KRESIN, *University of Southern California* We report the measurement of electrical polarizabilities of water clusters [$(H_2O)_n$, n=3-18] by deflection of a supersonic beam in an inhomogeneous field. In all the clusters studied, the deflections are only towards higher fields, indicating a polarizability-like behavior. The highest polarizability per one water molecule is seen in the trimer ($7.9 \pm 0.3$ Å$^3$) and it quickly decreases for larger clusters to about 4 Å$^3$ per molecule for n=6-18. These values are large and could be explained by the addition of two parts: an intrinsic electronic polarizability plus a contribution from a permanent dipole moment responding with a Langevin-like behavior. With a cluster temperature of $\sim$ 200 K, estimated from the evaporative ensemble picture, the permanent dipole moments are $\sim$ 1-2 Debye per cluster.

**16:18**

**R11 8 Experimental Evidence for Internal Structure in Aqueous – Organic Nanodroplets*** GERALD WILEMSKI, *University of Missouri-Rolla* BARBARA E. WYSLOUZIL, *The Ohio State University and Worcester Polytechnic Institute* REINHARD STREY, *University of Cologne, Germany* CHRISTOPHER H. HEATH, *Worcester Polytechnic Institute* UTA DIEREGSWEILER, *Worcester Polytechnic Institute* The spatial distribution of species within an aerosol droplet influences how it interacts with its environment. Despite the ubiquity of multicomponent nanodroplets in natural and technological aerosols, there are no published measurements of their internal structure. In a recent paper [Wyslouzil, et. al., Phys. Chem. Chem. Phys. **8**, xxx, (2006)], we report the first experimental results for structure in aqueous organic nanodroplets based on small angle neutron scattering by high number density aerosols. For $H_2O$ – n-butanol droplets, fitting of the diffraction patterns confirms the picture of an aqueous core containing $\sim$ 3 mol% alcohol covered by a shell of densely packed alcohol molecules.

**R11 9 Imaging predissociation dynamics and energy flow pathways in vibrationally excited acetylene-HCl dimers** GUOSHENG LI, JESSICA PARR, IGOR FEDOROV, HANNA REISLER, *University of Southern California* We report photofragment imaging studies of the predissociation of acetylene-HCl dimers. The dimer is vibrationally excited by laser irradiation either in the CH asymmetric stretch mode of the acetylene subunit or in the HCl subunit. Photofragment ion images of HCl in specific rotational states are obtained from which kinetic energy release patterns are analyzed. The predissociation behavior in the two cases is different. CH stretch excitation is followed by IVR in acetylene and results in an acetylene fragment with one quantum of CC stretch excitation (in agreement with results of Roger Miller and coworkers) and a statistical rotational energy distribution. HCl excitation results in acetylene fragments with one or two quanta of bending excitation with no clear preference for a specific mode. In both cases HCl rotations are nonstatistical. The different predissociation outcomes reflect the different energy flow pathways followed in each case. Research supported by the US National Science Foundation.

**R11 10 Monte Carlo simulations of Phase Changes in Lennard-Jones nanoclusters.** SILVINA GATICA,* *Department of Physics and Astronomy, Howard University* XIAO DONG, ESTELA BLAISTEN-BAROJAS, *School of Computational Sciences, George Mason University* Monte Carlo simulations of Lennard-Jones clusters of less than 100 atoms are performed to explore the possible phase changes. The simulation is made at constant pressure and temperature. In the Monte Carlo the volume of the cluster is evaluated during the calculation in terms of the mean quadratic radius, and the reduced temperature is kept below 0.4 to avoid the evaporation of the cluster. We obtain a PV diagram and calculate the energy per particle, the radial distribution function, the coordination number and displacement function, to look for signatures of the presence of a solid-liquid-like phase change. The equilibrium structure and number of layers in the cluster at each pressure and temperature are also computed. We compare our findings with predictions of other authors.

**R11 11 Infrared spectroscopy of metal-solvent clusters: $Li(NH_3)_n$ and $Li(MeNH_2)_n$** ANDREW ELLIS, TOM SALTER, COREY EVANS, VICTOR MIKHAILOV, *University of Leicester* Mass-selected infrared spectra of the uncharged metal-solvent clusters $Li(NH_3)_n$ and $Li(MeNH_2)_n$ in the N-H stretching region have been recorded using two techniques, photodepletion spectroscopy and two-colour (IR+UV) REMPI. Infrared REMPI is the most suitable for the smaller clusters, since the energy input into the cluster by the IR photon is insufficient to cause dissociation. Our latest findings for this technique will be presented alongside computational predictions of the cluster spectra. For the larger clusters, injection of an IR photon in the N-H stretching region causes rapid dissociation and offers the opportunity to record mass-selected IR spectra by photodepletion spectroscopy. IR photodepletion spectra of $Li(NH_3)_n$ near 3 $\mu$m recorded for $n = 4$-7 show vibrational structure that points to completion of the first solvation shell at $n = 4$, with additional ammonia molecules entering a second shell in which the solvent molecules are more weakly bound to the cluster. Photodepletion spectra have also been recorded for other clusters, including $Li(MeNH_2)_n$, and the latest findings for these species will be described.

**17:06**

**R11 12 Rings, Towers and Cages in $Zn_nO_n$ Clusters** ARTHUR REBER, SHIV KHANNA, *Department of Physics, Virginia Commonwealth University, Richmond Va. 23284* JAGTAR HUNJAN, MARCELA BELTRAN, *Instituto de Investigaciones en Materiales, Universidad Nacional Autonoma de Mexico* It is shown that the transition from an elementary ZnO molecule to compact bulk wurtzite ZnO proceeds via hollow rings, towers, and cages. First principles electronic structure calculations within a gradient corrected density functional framework have been carried out to investigate the progression of geometries and electronic properties of $Zn_nO_n$ (n=2-12,15,16,21) clusters. It is shown that $Zn_nO_n$ (n=2, 3, 4, 5, 6, 7) clusters are all single, highly stable rings and that $Zn_3O_3$ is particularly stable. Starting at $Zn_8O_8$, these elementary rings begin to assemble into column structures that begin to distort at n=10. The ground states of $Zn_{12}O_{12}$, and $Zn_{16}O_{16}$ are single cages while the structure of $Zn_{11}O_{11}$, $Zn_{15}O_{15}$ and $Zn_{21}O_{21}$ can be described as barrels. The $Zn_{12}O_{12}$ cage has a high dissociation energy and a large highest occupied molecular orbital (HOMO)-lowest unoccupied molecular orbital (LUMO) gap of 2.51 eV making it a potential candidate for cluster assemblies.

**17:18**

**R11 13 On the Aluminum Cluster Superatoms acting as Halogens and Alkaline-earth Metals** DENNIS E. BERGERON, PATRICK J. ROACH, A. WELFORD CASTLEMAN, *Department of Chemistry and Physics, The Penn State University, College Park PA, 16802* NAICHE O. JONES, J. ULISES REVELES, SHIV KHANNA, *Department of Physics, Virginia Commonwealth University, Richmond VA, 23284* It is shown that a new class of super-polyhalides can be formed by combining the $Al_{13}$ super-halogen with the conventional halogen, I. Experimental reactivity studies demonstrate that the new super-polyhalides, $Al_{13}I_x^-$, exhibit pronounced stability for even numbers of I atoms.

Theoretical investigations probing the geometry and the electronic structure reveal that the enhanced stability is associated with pairs of I atoms occupying the on-top sites around the $Al_{13}^-$ core. We also demonstrate another series, $Al_{14}I_x^-$, that exhibits stability for odd numbers of I atoms. It is shown that this series can be described as consisting of an $Al_{14}I_3^-$ core upon which the I atoms occupy on-top locations around the Al atoms. The potential synthetic utility of superatom chemistry built upon these motifs will be addressed.

**17:30**

**R11 14 Induced super-halogen behavior of metal moieties in halogen-doped metal clusters** FEDOR NAUMKIN, *Faculty of Science, UOIT, Oshawa ON L1H 7K4, Canada* HOBART LEUNG, Recent studies of the $Al_{13}I^-$ cluster ion have shown negative charge localization on the aluminum core and associated this with its super-halogen character resulting from a high electron affinity EA of $Al_{13}$ (exceeding that of the I atom). The present work reports results of ab initio calculations for a similar halogen-doped metal cluster, $M_{13}X^-$. The charge is found to be localized on the $M_{13}$ core as well, even though its EA is lower than that of X. Other properties such as structure and stability for different spin-states are also investigated and compared with those for the neutral counterparts. Comparison to the corresponding smaller metal-halide species is made as well. The charge localization on the metal moieties is concluded to be associated not only with the relative EA values. An alternative, physically transparent interpretation is given, which explains the observed charge distributions on electrostatic basis. The super-halogen behavior of the metal moieties is linked to the presence of the halogen atom in the systems.

**R12 1 Electron Phonon Interaction at the Si(111)−7 × 7 Surface** I. BARKE, FAN ZHENG, A. KONICEK, R. HATCH, F.J. HIMPSEL, *Dept. of Physics, University of Wisconsin Madison, 1150 University Ave, Madison, WI 53706* In recent years, it has become possible to study the electron-phonon interaction of metals by high resolution photoelectron spectroscopy. However, virtually no such experimental information is available for the case of semiconductors. It is shown that electron-phonon interaction at the Si(111)−7 × 7 surface provides a natural explanation for the unusual band dispersion of the metallic surface states. While local density theory predicts a hole-like dispersion for the adatom bands that cross the Fermi level $E_F$, photoemission finds an electron-like band with a break in the slope at 0.1 eV below $E_F$. Such behavior follows naturally from electron phonon interaction with the surface phonon mode at $\hbar\omega = 70$ meV that dominates electron energy loss spectra. It has been assigned to adatom vibrations by molecular dynamics calculations. Two independent determinations of the electron-phonon coupling parameter from the band dispersion and the temperature dependent phonon broadening yield very similar coupling parameters around $\lambda = 1.1$.

**R12 2 Ultrafast Electron Dynamics of Silicon Surface States: Second-Harmonic Hole Burning Spectroscopy on Si(111)7x7*** JOHN A. MCGUIRE, *University of California, Berkeley* MARKUS B. RASCHKE, *Max-Born-Institut fur Nichtlineare Optik und Kurzzeitspectroscopie D-12489 Berlin, Germany* Y.R. SHEN, *University of California, Berkeley* We used second harmonic generation (SHG) as an all-optical, surface-specific probe of spectral hole-burning to measure the ultrafast dynamics of electronic excitations into the adatomU1 band of the Si(111)7x7 surface. The time-delayed SHG obtained with tunable ~ 100 fs probe pulses was measured in response to the excitation of a ~ 100 fs pump pulse at 1.54 eV. The transient holes induced by the pump corresponded to a homogeneous dephasing time as short as 15 fs. Carrier-carrier scattering was responsible for the linear dependence of the dephasing rate on pump fluence. The hole-burning spectra also reveal a strong coupling between the localized dangling-bond states and the surface phonon mode at 570 $cm^{-1}$ associated with the adatoms. The technique can be extended to measurement of electron dynamics at any interface between two centrosymmetric media accessible to light.

**R12 3 Silicon surface evolution at high temperature in UHV** VALERIAN IGNATESCU, JACK BLAKELY, *Cornell University* The step distribution, associated with the miscut of a Si wafer can be modified by controlled step flow. There are many studies of step-flow dynamics during sublimation or deposition at high temperature. In our group, atomically flat, step-free surfaces were previously obtained over areas of up to 50 by 50 microns by annealing Si samples in UHV. The surface of a normal crystal wafer does not usually show a step-terrace structure. Instead, a Czochralski Si wafer, mirror polished by chemical-mechanical polishing, has an rms roughness of 1-2 nm. A sizable thermal budget has to be used to remove this initial roughness or that induced by reactive ion etching. We report here results of the evolution of step distributions over a range of temperatures. By inducing a temperature gradient on our Si samples we were able to study the stages that occur as the surface transforms towards an atomically flat one. The samples were later reannealed to see the morphological changes that occurred on previously examined regions. We have also investigated the processes of trench formation near the walls of etched craters and of ridge development around the edges of mesas structures.

**15:06**

**R12 4 Interacting dimer rows on Si(001): Reconstructed Si(001)*** ARIEF BUDIMAN, *University of Calgary* A continuum model involving elastic interactions of dimer rows on a two-dimensional surface is presented. It produces a logarithmic stress-domain interaction energy from the obtained partition function. Using dimer rows as the building blocks of a reconstructed surface thus generalizes Alerhand and Marchenko models of the stress-domain interaction on terraces, which have been previously used to predict step- height transition on reconstructed Si(001). The double-layer step phase is determined to be more stable that the single-layer step phase for typical temperatures and miscut angles. A mixed phase region in the temperature-versus-miscut-angle phase diagram is found.

**R12 5 Gold on silicon: Can theory and experiments for Si(111)-(5x2)-Au be reconciled?** STEVEN ERWIN, *Naval Research Laboratory* CHRISTOPH SEIFERT, *Universität Duisburg-Essen, Duisburg, Germany* Since its discovery 30 years ago, the 5x2 reconstruction of Si(111) induced by 2/5 monolayer of Au has been widely studied for its unusual one-dimensional electronic properties. Despite quite detailed and consistent data from a variety of surface science techniques, there is still no structural model consistent with the constraints inferred from those data. Here we combine density-functional theory (DFT) and scanning tunneling microscopy (STM) data to systematically develop and investigate new candidate structural models. The underlying 5x2 parent reconstruction is decorated by Si adatoms, whose density is at most one adatom per two 5x2 unit cells, and at equilibrium is half of this limit. We consider first the adatom-free parent reconstruction. Starting from simple principles of dangling bonds and surface stress relief, we construct a well-defined set of chemically plausible models that can be exhaustively generated by combinatorics. Several recently proposed models for Si(111)-(5x2)-Au are examples from this set. We then consider the role of the Si adatoms. We find that their role is two-fold: to passivate dangling bonds and to dope the parent band structure. Using the complete model, detailed predictions for STM imagery and surface band structure compare favorably with experiment.

**15:30**

**R12 6 Au-Induced Reconstructions on the Si(111) Surface*** F.-K. MEN, A.-L. CHIN, *Department of Physics, National Chung Cheng University, Chia-Yi 621, Taiwan, ROC* By depositing Au onto a Si(111)-(7× 7) surface at elevated temperatures, the existence of (5× 2), ($\sqrt{3} \times \sqrt{3}$), and (6× 6) reconstructions have long been studied as a function of Au coverage. The corresponding structures however are yet to be satisfactorily determined. By using scanning tunneling microscopy (STM), we have investigated these Au-induced surface structures at LN2 temperature. With STM image quality exceeding currently published results, we are able to identify fine details in those reconstructions, which may shed new light on constructing structural models.

*Work supported by NSC, Taiwan, ROC.

**R12 7 Ab Initio Studies of Indium Diffusion on the Si(111)-7x7/Ge(111)-5x5 Surface*** D. PSIACHOS, *Dept. of Physics, Queen's University* M. J. STOTT, *Dept. of Physics, Queen's University* The mechanisms for the self-assembly of ordered arrays of indium magic clusters on the Si(111)-7x7/Ge(111)-5x5 surface have been investigated theoretically using ab initio total energy simulations. Plane wave density functional methods have enabled us to obtain the potential energy surface for one indium atom adsorbed on the Ge(111)-5x5 surface. Using these ab initio-derived energies as input, a classical molecular dynamics simulation has yielded values for the temperature-dependent, trajectory-dependent, microscopic self-diffusion coefficients of an indium atom on the Ge(111)-5x5 surface. For comparison, we also have calculated the diffusion coefficient obtained through fully ab initio molecular dynamics where we have used the non-self-consistent Harris Functional due to computational cost. Also, as a third approach, the harmonic approximation of the transition state theory has been applied and is assessed in light of the two molecular dynamics simulations. The single-atom results show promise for providing useful information on how the magic clusters on semiconductor surfaces may be formed.

**R12 8 Evolution of Si Surface Morphology under Oxygen Etching*** ALISON BASKI, *Virginia Commonwealth University* MARY WILLIS, *Virginia Commonwealth University* JONATHAN DICKINSON, *Georgetown College* We have studied the surface morphologies produced after oxygen etching of the following Si surfaces: (001), (111), (113), (5 5 12), and (112). Atomic force microscopy data show the evolution of the surface morphology as a function of dosage (50 to 400 Langmuirs) for sample temperatures from 700 to 900 [r]C and a pressure of $3x10^{-7}$ Torr. We have found that certain orientations are relatively stable against extended etching, whereas others are unstable and produce faceted morphologies. The (001), (111), and (113) surface orientations are stable and produce morphologies composed of terraces with islands caused by etching around oxide-induced pinning sites. As expected, the island density decreases as temperature increases, yielding an effective activation energy of 2 to 4 eV. High-index surfaces such as (5 5 12) and (112), however, are unstable against extended etching and produce faceted sawtooth morphologies. These sawtooths are aligned along the [110] direction and are primarily composed of the more stable (111) and (113) planes. Further studies are in progress to determine if steady-state morphologies exist at dosages above 1000 Langmuirs.

**16:06**

**R12 9 Dissociation pathways and multiple adsorption configurations of ammonia on Si(001)*** HANCHUL KIM, *Korea Research Institute of Standards and Science* OPTI NAGUAN CHUNG, SUKMIN CHUNG, *Pohang University of Science and Technology* JA-YONG KOO, *Korea Research Institute of Standards and Science* The adsorption of ammonia ($NH_3$) molecules on the Si(001) surface has been investigated by combining the scanning tunneling microscopy (STM) and the ab initio pseudopotential calculations. An $NH_3$ molecule had been known to spontaneously dissociate into $NH_2$ and H and form the so-called on-dimer configuration (OD). In OD, $NH_2$ and H bond with two Si atoms of one Si dimer. However, our study shows that there exist two distinct configurations of $NH_3$/Si(001). One is the existing model of OD, which is found to be the lowest energy state. The other is identified to be an inter-dimer configuration (ID), where $NH_2$ and H adsorb at two Si atoms at the same side of two adjacent dimers along the dimer row. The simulated STM images of OD and ID are in good agreement with experimental observations, proving the existence of two distinct adsorption configurations of $NH_3$/Si(001).

**R12 10 Desorption of Hydrogen from Si(111) by Resonant Excitation of the Si-H Vibrational Stretch Mode*** ZHIHENG LIU, *University of Minnesota* LEONARD FELDMAN, *Vanderbilt University* NORMAN TOLK, *Vanderbilt University* ZHENYU ZHANG, *Oak Ridge National Laboratory* PHILIP COHEN, *University of Minnesota* We report first measurements of non-thermal, non-electronic resonant photodesorption of hydrogen from a Si(111) surface using tunable infrared radiation. The wavelength

dependence of the desorption yield Shows a peak at 0.26 eV, the energy of the Si-H vibrational stretch mode. The corresponding excitation cross section is determined to be $2.3 \times 10^{-18}$ cm$^2$. The desorption yield is quadratic in the infrared intensity and quartic in the electric field along the Si-H bond direction. We postulate that two neighboring hydrogen adatoms, once simultaneously excited in their vibrational stretch mode, can desorb associatively at room temperature.

**R12 12 Chemical fingerprinting at the atomic level with scanning tunneling spectroscopy** KOJI S. NAKAYAMA, *Department of Materials Science and Engineering, UIUC, and IMR, Tohoku University* TOMOKO SUGANO, *Department of Materials Science and Engineering, UIUC* KENJI OHMORI, *Frederick Seitz Materials Research Laboratory, UIUC* A.W. SIGNOR, J.H. WEAVER, *Department of Materials Science and Engineering, UIUC* Atomic-scale chemical analysis has been a long-standing goal of materials characterization. It requires the ability to interrogate individual atoms and to recognize their distinguishing signatures. Scanning tunneling spectroscopy based on scanning tunneling microscopy makes it possible to map the local electronic density of states for clean surfaces and for those with adsorbates at 80 K. We have developed a protocol that allows us to obtain the spectral fingerprints of halogen atoms on Si(001), and we use those fingerprints to distinguish between adatom species for surfaces with Cl and Br mixed adsorbates. The key to the process is the energy distribution of the antibonding states that depend on the halogen species. The protocol developed here, with its emphasis on the distribution and distinction of energy states, should be applicable to other systems, and should yield new insights regarding chemical identification.

**16:54**

**R12 13 Spin echo resolved grazing incidence neutron scattering** GIAN FELCHER, SUZANNE TE VELTHUIS, PETER FALUS, *Argonne National Laboratory, Argonne IL 60439* ALEXEI VOROBIEV, JANOS MAJOR, HELMUT DOSCH, *Max Planck Institut für Metallforschung, D70569 Stuttgart Germany* Conventionally the spin-echo technique is used to encode energy transfer in neutron inelastic scattering experiments. However, spin-echo may encode the neutron momentum transfer, allowing the probing of large length scale structures without the need of a tight neutron beam collimation and resulting intensity loss. This concept has recently been successfully utilized for small angle scattering experiments in transmission geometry as well as scattering in the grazing incidence geometry at a reflectometer (EVA, Institut Laue-Langevin, Grenoble) equipped with neutron resonance spin echo circuits as well as appropriate neutron spin rotators. The tests included the measurement in transmission geometry of suspensions of polystyrene balls (1500 Å radius) as well as anodized aluminum oxide 2D gratings, as well as the measurement in reflection geometry of the characteristic lengths of assemblies of polystyrene droplets dewetted from a silicon surface. The results are guiding the design of an instrument for the Spallation Neutron Source capable of studying the structure and working of biological membranes.

**R12 14 Epitaxial growth and structure of the high-k dielectric $Pr_2O_3$ on Si(001) and Si(111)** JORG ZEGENHAGEN, LAURE LIBRALESSO, TIEN-LIN LEE, *ESRF, France* Keeping the capacitance of CMOS devices constant while shrinking further the gate dimensions requires intolerably thin $SiO_2$ layers for next generation devices. Thus, replacing $SiO_2$with a material with larger static permittivity k and matching properties is at present a very urgent task. Among others, the sesquioxide $Pr_2O_3$ is discussed as a possible candidate material. We deposited ultra thin films of $Pr_2O_3$by e-beam evaporation on atomically clean (001) and (111) surfaces. We studied the growth from the very early stages using low energy electron diffraction, scanning tunneling microscopy, Auger electron spectroscopy, grazing incidence X-ray diffraction, X-ray reflectivity and X-ray photoelectron spectroscopy. On Si(111), $Pr_2O_3$ grows pseudomorphically in the hexagonal phase. On Si(001) surface, a 0.6 nm thick layer of cubic $Pr_2O_3$ grows followed by the formation of a silicate layer on top. Growth under 10−8 mbar O2 atmosphere is needed in order to prevent Pr−silicide formation.

**R13 1 Attosecond electron wave packets.***
KENNETH SCHAFER, *Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803-4001*

Attosecond electron wave packets are created when a train of extreme ultraviolet attosecond pulses is used to ionize an atom or molecule via one photon absorption. These novel wave packets differ in several useful ways from the temporally confined electron wave packets that are made via tunnel ionization. They can, for instance, be tailored for different applications by controlling the light field that generates the attosecond pulse train. In this talk we will describe how attosecond electron wave packets can be used to study the one photon ionization process via interferometry, and their application in the study and control of strong field processes in such as harmonic generation and above threshold ionization.

**R13 2 Probing ultrafast electronic motions in atoms with the attosecond pump-probe** LEE COLLINS, SUXING HU, *Los Alamos National Laboratory* BARRY SCHNEIDER, *National Science Foundation* Through full-dimensional numerical simulations with using our recently-developed efficient and accurate parallel solver for the time-dependent Schrödinger equation, we have demonstrated that an attosecond pulse can effectively *probe* the extremely fast motion of an electronic wave packet in atoms. Pumped by a broadband femtosecond UV pulse, one electron of ground-state Helium can be launched into a superposition of low-lying excited states, thus forming a wavepacket that begins to orbit the atomic core. A time-delayed attosecond EUV pulse (probe) then ionizes the atom causing three-body breakup. Measuring either the energy sharing of the ionized electrons or the total ionization probability as a function of the time delay displays the internal motion of the excited electron. Our simulation has shown that an ultrashort Kepler period of 2 $fs$ can be followed for several cylces. This opens the prospect of a wealth of similar pump-probe experiments to examine *electronic motion.*

**R13 3 Tomographic Imaging of Molecular Orbitals Using Femtosecond Lasers.**
DAVID VILLENEUVE, *National Research Council of Canada*

I will show how we can experimentally reconstruct a single-electron orbital wave function from a simple molecule, dinitrogen. We use a seemingly unlikely technique, high harmonic generation (HHG). HHG occurs when a gas is irradiated with an intense femtosecond laser pulse. The atoms or molecules are tunnel-ionized by the laser field, and then are driven back to the parent ion within the same optical cycle. Some of these electrons recombine with the parent, and release their kinetic energy as xuv photons. The resulting spectrum covers the photon range of 10–100 eV. The radiation results from a transition from a continuum electron wave function, described as a plane wave, and the orbital from which the electron was removed, the HOMO. Thus the experiment is a measure of the transition dipole matrix elements between the single-electron orbital and a set of plane waves. By rotating the molecule in the gas phase using a second laser pulse, we can map out the matrix elements for different projections of the molecule. This data can then be inverted using a tomographic algorithm to yield an image of the orbital wave function. We will show the recovered $3\sigma_g$ orbital of $N_2$. Beyond the single active electron approximation, there are other transitions that are allowed between the HOMO and inner orbitals. This is due to the indistinguishability of the electrons. Including these exchange terms gives even better agreement between theory and experiment. Because this measurement is made with a 25 fsec laser pulse, it is now possible to perform pump-probe experiments to observe dynamic changes in the electronic structure of molecules. It may even be possible to observe *electronic* wave packet motion within an atom with attosecond resolution.

**R13 4 Coherent excitation and control of surface phonons.**
YOSHIYASU MATSUMOTO, *Institute for Molecular Science*

The excitation and control of nuclear wavepackets using tailored laser pulses have attracted a lot of interest recently and being realized mainly in gas-phase molecules. In contrast, there have been little studies on the coherent excitation and

control for adsorbates particularly on metal surfaces. This is because dephasing is substantially rapid on metal surfaces due to efficient couplings between adsorbates and metals. Recently, we have demonstrated the time-domain observation of nuclear wavepacket dynamics of monolayer adsorbate by femtosecond time-resolved second harmonic generation (TRSHG). When metal surfaces covered with alkali metal atoms are irradiated by ultrafast laser pulses, coherent surface phonon modes are excited. The formation and dissipation processes of coherent surface phonons are probed by time-resolved second harmonic generation. SHG signal intensities are enhanced by alkali atoms adsorption by various resonant transitions in the adsorbate-substrate system. However, not all resonant electronic transitions lead to the generation of coherent stretching vibrations of alkali atoms. The measurements of TRSHG traces as a function of the excitation photon energy at a fixed alkali coverage indicate that resonant transitions between adsorbate-induced surface states is responsible for the coherent vibrational motions. By carefully examining the Cs coverage dependence of the TRSHG waveform, we found that TR-SHG traces show beating structures. This indicates that the oscillatory TR-SHG traces are contributed by at least two kinds of coherent surface phonon modes: the Cs-Pt stretching mode (2.3 THz) and the Rayleigh phonon mode (2.6 or 2.9 THz, depending on the Cs coverage). We used fs pulse trains with the repetition frequencies of 2.0 - 2.9 THz that are synthesized by using a spatial-light modulator as an excitation source for the coherent phonons. By tuning the pulse train frequency, we succeed in the selective excitation of a coherent phonon mode.

**R13 5 Femtosecond microscopy of surface plasmon propagation on a silver film.*** ATSUSHI KUBO, *Department of Physics and Astronomy University of Pittsburgh, PRESTO JST* NIKO PONTIUS, *BESSY mbH* HRVOJE PETEK, *Department of Physics and Astronomy University of Pittsburgh* By using interferometric time-resolved photoelectron emission microscopy (ITR-PEEM), we investigate the dynamics of surface plasmon polariton (SPP) propagation with 0.33-fs per frame time and 40-nm spatial resolution. 10-fs phase-locked pump-probe pulse pairs with 400-nm center wavelength irradiate a silver film at 65 degree angle from the surface normal to launch a SPP wave from a line defect in the film. We image the propagation of the SPP wave through its interference with the external light field. The interference periodically modulates the total amplitude of the polarization field in silver, and thereby the two-photon photoemission current from the surface. Two-dimensional microscopic maps of the photoemission intensity at pump-probe delay $\tau_d$ are recorded by the PEEM. Sequential PEEM images taken with a delay increment step of 0.33-fs record the dynamics of SPP wave packet propagation and dissipation as a movement of the oscillatory interference pattern. The progression speed and the attenuation of the oscillatory pattern are reproduced by a simulation with the known dispersion of the complex SPP wave vector. The SPP imaging experiments demonstrate the possibility of coherent control of plasmon field in metallic nanostructures.

**R13 6 Adaptive Control of the Spatial Position of White Light Filaments in an Aqueous Solution** ROBERT LEVIS, *Temple University* GEORGE HECK, *Temple University* JOSEPH SLOSS, *Temple University* White light filamentation produced from intense laser beams represents a method to produce highly nonlinear energy deposition both spatially and temporally in the gas, liquid, or solid phase. We have demonstrated control over the spatial coordinates (position and extent) of white light filaments (supercontinuum generation) in an aqueous solution using shaped ultrafast, strong field laser pulses. These are the first experiments to achieve control of filament position through the manipulation of the spectral phase of an ultra-fast (50 fs) 800nm excitation laser pulse. A closed feedback loop employing a spatial light modulator and a genetic algorithm was used to manipulate the spectral phase of the pulses to achieve a specified filament position and length.

**R13 7 Relaxation dynamics of dissolved molecule probed by a phase locked pulse pair:$Br_2$ in Ar*** MIZUHO FUSHITANI, HEIDE IBRAHIM, MARKUS GUEHR, NIKOLAUS SCHWENTNER, *Freie Universitaet Berlin* A phase locked pulse pair-(PLPP) is a strong tool to investigate the electronic coherence of molecules. Recently, we have shown that the PLPP experiment is also applicable to dissolved molecules[1]. Here, we apply this method to the $Br_2$/Ar system and investigate relaxation dynamics in the electronically excited *B* state of $Br_2$. We observed not only laser induced fluorescence(LIF) from the *B* state but also LIF from the *A* and *A'* states which are energetically lower than the *B* state. Tuning the relative phase between PLPPs provides the various LIF ratio among those states, indicating relaxation channels which can be coherently controlled. The PLPP results will be compared with those obtained by frequency resolved excitations which give the LIF ratio resulting from all possible relaxation. [1] M. Fushitani, et al. PCCP 7 (2005) 3143.

**R13 8 Interfaces of methanol:water mixtures with an OTS-coated substrate probed by sum-frequency vibrational spectroscopy*** WEITAO LIU, LUNING ZHANG, Y. R. SHEN, *Physics Department, University of California at Berkeley* Aqueous solutions of short chain alcohols are important reagents in organic chemistry, and their physical and chemical properties at hydrophobic interfaces play key roles in many applications. To study their interfacial structures at the molecular level, we applied sum-frequency vibrational spectroscopy (SFVS) to the interfaces of methanol-water mixtures with an octyltrichlorosilane (OTS)-covered silica as model systems. From the methanol CH3 symmetric stretching mode, we deduced the interfacial coverage and orientation of methanol molecules vs. its molar concentration, and studied the hydrogen-bonding property of methanol with neighboring molecules. It appeared that methanol molecules adsorbed at the interfaces with the same average orientation at all concentra-

tions. From the dangling-OH stretching mode of water molecules, we observed the correlation between the methanol surface number density and the water free OH bonds. Ab initio calculations were used to help investigate the interfacial structures of hydrogen-bonded species.

**R13 9 Vibrational Relaxation of Anions in Nonaqueous Reverse Micelles** GERALD SANDO, JEFFREY OWRUTSKY, *Chemistry Division, US Naval Research Laboratory* Static and ultrafast infrared spectroscopy have been used to measure vibrational frequencies and vibrational energy relaxation (VER) times for high frequency bands of small ions in nonaqueous reverse micelles (RMs). Formamide RMs are stable with anionic (AOT) and nonionic surfactants. In AOT RMs, the vibrational frequencies of azide ($N_3^-$) are blue shifted, while the VER times are slower. Bulk behavior is approached as the RM size increases. The frequency-rate correlation is opposite of what is seen in bulk solvents and aqueous RMs. The effects are small in nonionic RMs because azide near surfactant headgroups resembles that in formamide, as shown by results in TGE, a model of the polar portion of the surfactant. The dynamics for $Fe(CN)_5NO^{2-}$ depend on the probe frequency because of the inhomogeneous distribution of solvation sites throughout the poorly defined interface. Ionic liquid containing reverse micelles are formed with nonionic surfactants. The VER rates of the ionic liquid anions are faster than in the bulk ionic liquids, but slower than in TGE, consistent with a mixed solvation environment of ionic liquid and surfactant.

**R13 10 Molecular quantum computation by using ultrashort intense laser pulses under the influence of non-Markovian dissipation** YUKIYOSHI OHTSUKI, *Tohoku University & JST-CREST* We numerically study molecular quantum computation by combining an ensemble of molecular states and shaped ultrashort intense laser pulses through a case study of Grover's quantum search algorithm, in which qubits are implemented in the vibrational states of I2. In the simulation, the Grover iteration is divided into two basis operations, the so-called oracle and the inversion about mean operation, which are realized by laser pulses designed by an optimal control method within the density matrix formalism. These pulses perform Grover iteration with high accuracy although the lack of extreme precision leads to a slight reduction in the population associated with the solution to the search problem. The accuracy of the Grover iteration is shown to be improved by the normalization with respect to the ''qubit population.'' The relaxation effects on the accuracy of the computation are systematically examined by using the non-Markovian master equation with phenomenological relaxation parameters. The gate pulses are designed under the influence of non-Markovian dissipation, in which the pulse design equation is solved by a newly proposed iteration algorithm.

**R16 1 Fabrication and Characterization of Bi2Te3 Nanoparticles for Thermoelectric Applications** YI MA, BED POUDEL, WENZHONG WANG, DEZHI WANG, ZHIFENG REN, *Boston College, MA* Q. HAO, H. LEE, GANG CHEN, *Massachusetts Institute of Technology* Bi2Te3 nanoparticles with diameters of 10-30 nm have been successfully synthesized via a hydrothermal method. The as-prepared nanoparticles were characterized by X-ray diffractometer (XRD, Cu Kalpha, Bruker AXS), field emission scanning electron microscope (SEM, JEOL-6340F) and transmission electron microscope (TEM/HRTEM, JEOL-2010F) equipped with an energy-disperse X-ray spectrometer (EDS). The densification of Bi2Te3 nanopowders was conducted in two ways: plasma pressure compaction (P2C) and hot pressing. The density of the as-pressed pellet sample was about 98-99 % of theoretical density (7.7 g/cm3). The Seebeck coefficient, electrical and thermal conductivities were further investigated.

**14:42**

**R16 2 Characterization and thermoelectric properties of Si-Ge nanocomposite*** DEZHI WANG, WENZHONG WANG, SHUO CHEN, JIANYU HUANG, ZHIFENG REN, *Boston College, Dept. of Physics* HOHYUN LEE, GANG CHEN, *MIT, Dept. of mechanical Engineering* MING TANG, M. S. DRESSELHAUS, *MIT, Dept. of Electrical Engineering* PAWAN GOGNA, JEAN-PIERRE FLEURIAL, *Jet Propulsion Laboratory* BRADLEY KLOTZ, *Dynamic Science, Inc.* Low dimension is one of the most promising directions to search for high-ZT thermoelectric materials. It has been predicted by theory and proved by experiments that structures such as quantum well and superlattice can increase ZT by several times vs the corresponding bulk materials. However, it is very difficult to manufacture those low dimensional structures in large scale for bulk applications. To realize those principles, we have designed and synthesized successfully a new structure so called Si-Ge nanocomposite—nano Silicon particles in SiGe alloy matrix. The Si-Ge nanocomposite was made of nano silicon and germanium particles by a unique hot-press procedure. The samples are being characterized by TEM, SEM, XRD and thermoelectric property measurements. The results will be reported in detail.

**R16 3 Prospects for nanoscale thermoelectric Bi(1-x)Sb(x) alloys** JOSEPH P. HEREMANS, *The Ohio State University, Department of Mechanical Engineering and Department of Physics* Bi(1-x)Sb(x) alloys are the materials with the highest thermoelectric figure of merit at cryogenic temperatures around 100 K. Recently, Thonhauser et al. (Appl. Phys. Lett. **85** 588 2004) calculated that heavily-doped pure Bi could be an excellent thermoelectric material at 300 K. Bi doped *p*-type with 1% Sn to a hole concentration of about $15x10^{21}cm^{-3}$ and a Fermi level 250 meV below that of the pure semimetal could reach itZT=1.44. Unfortunately, no *p*-type doping has been achieved experimentally in semimetallic Bi at room temperature, not only because of the solubility limit of Sn in Bi, but mostly because the band structure is very temperature-dependent, and the energy overlap between

conduction and valence band is much larger at 300 K than at 4 K. Two new approaches are suggested here. Firstly, one can attempt to use the model in dilute Bi(1-x)Sb(x) alloys. Secondly, one should be able to increase the power factor by adding nanoprecipitates to a Bi or Bi(1-x)Sb(x) alloy matrix, following a precipitation anneal similar to that used on PbTe:Pb by Heremans et al. (J. Appl. Phys. **98** 063703 2005). Model calculations, and the result of some preliminary experiments, will be given.

**R16 4 Quantum Confinement and Surface State Effects in the Thermopower of Bismuth Nanowires.** T.E. HUBER, *Howard University* A. NIKOLAEVA, *Academy of Sciences. Moldova* D. GITSU, *Academy of Sciences. Moldova* L. KONOPKO, *Academy of Sciences. Moldova* M.J. GRAF, *Boston College* Because of the increased density of states arising from one-dimensional confinement, it is anticipated that bismuth quantum wires will exhibit superior thermoelectric properties. Recently, angle-resolved photoemission spectroscopy (ARPES) studies have shown that Bi supports surface states that have not been considered in current models of quantum confinement. Studies of the Fermi surface, employing the Shubnikov-de Haas (SdH) method, in arrays of 30- to 80-nm bismuth nanowires partially corroborates ARPES findings. We have studied the thermopower of arrays of 50-nm Te- and Sn-doped Bi nanowires and we discuss these experimental results in terms of a Bi nanowire conduction model based on ARPES and SdH results.

**R16 5 The Order Disorder phase transition in $Zn_4Sb_3$** S. BHATTACHARYA, R.P. HERMANN, V. KEPPENS, *Department of Materials Science and Engineering, The University of Tennessee, Knoxville, TN* J. SNYDER, *Jet Propulsion Laboratory, California Institute of Technology, Pasadena, CA* T.M. TRITT, *Department of Physics, Clemson University, Clemson, SC* $Zn_4Sb_3$ has been widely investigated not only for its promise as a thermoelectric material, [1] but also for the unique transport properties it exhibits. $Zn_4Sb_3$ undergoes two distinct phase transitions (i) from $\alpha$ to $\beta$-phase at $T_C \approx$ 250 K and (ii) from $\beta$ to $\gamma$-phase at $T_C \approx$ 765 K. [2] We have performed electronic and thermal transport measurements exploring the structural phase transition at $T \approx$ 250 K from the ordered $\alpha$, to the disordered $\beta$ phase. The well-known $\alpha$ to $\beta$ phase transition manifests itself in anomalies in the resistivity, thermopower and specific heat measurements at $T \approx$ 250 K as well as a change in slope in the thermal conductivity, leading to a reduction in thermal conductivity as $Zn_4Sb_3$ changes phase from the ordered to the disordered state. Moreover, measurements of the elastic properties using resonant ultrasound spectroscopy (RUS) reveal dramatic changes at the order-disorder transition. [1] Snyder et al., Nature Materials **3**, 458-463, (2004) [2] Vuillard, G. et al., C.R. Seances, Acad. Sci., Ser. C: Sci. Chim. **263**, 1018-1021, (1966)

**R16 6 Presence of $\alpha$ phase domains in the phonon-glass thermoelectric $\beta$-$Zn_4Sb_3$ from atomic pair distribution function (PDF) analysis** H. J. KIM, E. S. BOZIN, S. J. L. BILLINGE, *Department of Physics and Astronomy, Michigan State University, East Lansing, MI 48824* S. HAILE, *Materials Science, California Institute of Technology, Pasadena, CA 91125* G. J. SNYDER, *Jet Propulsion Laboratory, 4800 Oak Grove Drive, Pasadena, CA 91109* The promisingly high ZT of $\beta$-$Zn_4Sb_3$ between 450 K and 670 K is known to be due to its exceptionally low thermal conductivity. The discovery of significant Zn interstitial disorder in $\beta$-$Zn_4Sb_3$ provides foundation for better understanding of the origin of the glass-like thermal conductivity[1]. Furthermore, it has been reported that Zn interstitial atoms become ordered in $\alpha$-phase[2]. We report on the local structural study of $\beta$-$Zn_4Sb_3$ using PDF technique, which has been successfully applied to solve the structures of crystallographically challenged materials[3,4]. Prominent diffuse scattering is found both in neutron and x-ray data. The PDF analysis suggests that the average $\beta$-structure consists of locally $\alpha$-structure like domains where Zn interstitial atoms are ordered. This provides an important local structural insight into not well understood $\alpha$ to $\beta$ order-disorder phase transition in $Zn_4Sb_3$ at 260 K. [1] G. J. Snyder et al. Nat. Mater. **3**, 458 (2004) [2] J. Nylén et al. J. Am. Chem. Soc. **126**, 16306 (2004) [3] T. Egami and S. J. L. Billinge, Underneath the Bragg peaks, Pergamon Press, Elsevier, Oxford, England, 2003 [4] S. J. L. Billinge and M. G. Kanatzidis, Chem. Commun., 749 (2004)

**R16 7 Theoretical study of thermal properties of Si clathrates*** XIAOLI TANG, JIANJUN DONG, *Physics Department, Auburn University* Pristine silicon clathrate ($Si_{136}$) is an ''expanded volume'' allotrope of Si that is metastably available at ambient conditions, and it exhibits a significant decrease in lattice thermal conductivity. We have theoretical studied vibrational, thermodynamic, and transport properties of $Si_{136}$ and compared its results with those of the ground state diamond-structured Si. The equilibrium temperature-pressure phase boundary between the two phases occurs in the negative pressure regime. Despite obvious differences in the energetics and lattice vibrational modes for the two polymorphic forms of Si, our calculations indicate that their heat capacities are quite similar. We further predict that $Si_{136}$ has a region of negative thermal expansion below T=140K. Our itab initio prediction shows that thermal expansion in the guest-free $Si_{136}$ clathrate is significantly smaller than the previously reported data of guest encapsulated clathrates. In contrast to similar thermal properties in the two phases, our calculations of lattice thermal conductivities reveal some dramatically different features in the phases. We will discuss the origin of the predicted ''oscillation'' in the current-current correlation functions.

**R16 8 Optical and thermoelectric properties of Tl-filled $CoSb_3$ skutterudites from first-principles*** IN GEE KIM, *Northwestern University* ARTHUR J. FREEMAN, Filled skutterudite antimonides have attracted much interest as a new class of thermoelectric materials.[1] We have determined the electronic structures, optical and thermoelectric propertes of Tl-filled skutterudite $CoSb_3$ by using the highly precise full-potential linearized augmented plane wave (FLAPW) method[2] within the Perdew-Burke-Ernzerhof (PBE)[3] form of the generalized gradient approximation (GGA) to density functional theory. In contrast to the small-gap semiconducting $CoSb_3$, Tl-filled $CoSb_3$ is calculated to be metallic with Tl-*sp* bands stongly hybridized with all the other elements over the entire energy region. The thermoelectric

properties, e.g. the Seebeck coefficient, are evaluated and discussed in terms of the diagonal terms of the optical matrix elements.

**R16 9 Low-temperature Thermodynamic Properties of Eu-filled Skutterudites** Y. LUAN, S. BHATTACHARYA, V. KEPPENS, *Department of Materials Science and Engineering,The University of Tennessee, Knoxville, TN 37996* D. MANDRUS, B.C. SALES, *Condensed Matter Sciences Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831* THE UNIVERSITY OF TENNESSEE COLLABORATION, OAK RIDGE NATIONAL LABORATORY COLLABORATION, It is well known that the presence of a ?rattling? atom in filled skutterudite antimonides leads to glasslike thermal properties, complemented by an unusual thermodynamic behavior that indicates the presence of low-energy vibrational modes in addition to the normal acoustic phonons. The current work focuses on a study of $EuFe_4Sb_{12}$, which combines ''rattling'' with magnetic ordering below $T_c = 90$ K. The elastic moduli have been measured as a function of temperature and magnetic field, using resonant ultrasound spectroscopy (RUS). The temperature-dependence of the elastic response is dominated by two phase transitions: the well-known magnetic ordering at 90 K, as well as a second transition at 40 K. In addition, specific heat measurements have been carried out for the same compound. Together these measurements provide us with an extensive set of data, probing the complex thermodynamic behavior of this material.

**16:18**

**R16 10 Effects of Substitution and Grain Size on the High Temperature Thermoelectric Properties of MNiSn Phases.** SLADE CULP, *University of Virginia* S. JOSEPH POON, *University of Virginia* TERRY M. TRITT, *Clemson University* NICOLETA HICKMAN, *Clemson University* BRAD EDWARDS, *Clemson University* UNIVERSITY OF VIRGINIA COLLABORATION, CLEMSON UNIVERSITY COLLABORATION, The merit of n-type Sb doped MNiSn (M=Ti, Zr, Hf) half-Heusler phase, as a promising material for use in high temperature power generation, is exhibited by large thermopower, and small, semimetallic, resistivity values. It has been observed that the level of Sb doping on the Sn site plays a fundamental role in the determining the temperature at which the material will achieve maximum thermoelectric efficiency. Meanwhile, the high thermal conductivity found in ternary MNiSn, can be reduced via mass fluctuations and strain field effects induced through substitution at the M and Ni sites. In addition, the effects of grain size modification, through supplemental synthesis techniques, on the lattice thermal conductivity will be discussed. The combination of substitutions and grain size modification in the ternary half-Heusler system results in a complex thermoelectric material with a figure of merit on the order of ZT=1.

**16:30**

**R16 11 Promising thermoelectric properties in some p-type half-Heuslers** MENG ZHU, S.J. POON, *Dept. of Physics, University of Virginia* V. PONNAMBALAM, T.M. TRITT, *Dept. of Physics and Astronomy, Clemson University* N-type half-Heuslers are well-known due to their potential thermoelectric properties, however, our study shows that p-type half-Heusler alloys can be prepared with promising values. A series of $Hf_xZr_{1-x}Co_yPt_{1-y}Sn_zSb_{1-z}$ samples have been synthesized, and thermoelectric properties have been measured. Our results show that the thermopower (S) increases and resistivity decreases in a good amount. In addition to the high power factors, thermal conductivity ($\kappa$) kept low values, which indicate that we can get promising value by optimizing the combination of elements.

**16:42**

**R16 12 Thermoelectric properties of some p-type half-Heusler alloys*** V. PONNAMBALAM, T.M. TRITT, *Dept. of Physics and Astronomy, Clemson University* MENG ZHU, S.J. POON, *Dept. of Physics, University of Virginia* We have synthesized a series of multi-component p-type half Heusler alloys by simultaneously substituting suitable elements at different crystallographic sites. Both electrical and thermal transport properties of these alloys are studied up to 1000K to evaluate their thermoelectric potential. At 300K, typical thermopower(S) and resistivity($\rho$) values are around $\sim$ 80 $\mu$V/K and $\sim$ 1m$\Omega$-cm respectively. Due to heavy substitution/doping, ($\rho$)-T behavior is similar to that of a degenerate semiconductor and the resistivity increases with increasing T with $\rho$ values in the range of few m$\Omega$-cm at 1000K. Thermopower also increases with increasing T and reaches a maximum of hundreds of $\mu$V/K at 1000K. Room temperature thermal conductivity ($\kappa$) values are about $\sim$ 4.5 W/m-K and these $\kappa$ values are low compared to those of ternary half-Heusler alloys. In well- optimized compositions, these values could improve even further.

**R16 13 Growth, structural, and transport properties of epitaxial $NaxCoO_2$ thin films** ZHIGANG MA, A. VENIMADHAV, D.A. TENNE, QI LI, A. SOUKIASSIAN, X.X. XI, D.G. SCHLOM, R. ARROYAVE, Z.K. LIU, MINHYEA LEE, *Pennsylvania State University* N.P. ONG, *Princeton University* H.P. SUN, XIAOQING PAN, *University of Michigan* Layered cobaltate $NaxCoO_2$ has attracted much attention recently due to its superconductivity and exceptionally high thermoelectric power. Here we report structural, electrical, and thermopower properties of epitaxial and topotaxial $Na_xCoO_2$ thin films on (0001) sapphire substrate. Topotaxial $Na_xCoO_2$ films were prepared by converting an epitaxial $Co_3O_4$ film to $Na_xCoO_2$by annealing in Na vapor and epitaxial $Na_xCoO_2$films were obtained by pulsed laser deposition. Structural analysis showed the films are *c*-axis oriented. For topotaxial films, annealing in different Na vapor pressures resulted in films with different Na concentrations, which showed distinct transport properties. For directly deposited epitaxial films by pulsed laser deposition, deposition parameters are found to control the Na concentration and hence the film properties. The largest thermoelectric power of the samples made by different methods is found to be similar in the range of 70-100 $\mu$V/K at room temperature.

**17:06**

**R16 14 On the Thermoelectric Properties of Layered Cobaltates*** QIANG LI, *Brookhaven National Laboratory* A study on the thermoelectric properties of layered cobaltates is presented, based on the dynamic mean field theory for strongly correlated electron systems. Electron correlation results in a crossover from coherent quasi-particle excitation at low temperature to incoherent excitation at high temperatures in cobaltates. With an extremely narrow quasi-particle bandwidth ($h\omega_c \sim$ 50 meV), the thermal destruction of Fermi-liquid occurs at the moderate crossover temperature $T_M$ ( $\sim$ 200 K), and suggests a new scaling for thermoelectric power $S$ of cobaltates ($S \sim$ kT/ith$\omega_c \sim T/T_M$) at low temperatures. At high temperatures, the dominating incoherent excitation leads to a weak temperature dependent $S$, and electric resistivity $\rho$ approaches the Mott-limit $ha/e^2 \sim$ a few m$\Omega \cdot$ cm for cobaltates, where $a$ is a lattice constant.

**R17 1 Dependence of the groundstate interband optical transition in InAs-GaSb superlattices on the width of the GaSb layers** PATRICK FOLKES, J. LITTLE, S. SVENSSON, K. OLVER, *Army Research Laboratory, Adelphi Maryland* A. AMTOUT, S. KRISHNA, *Center for High Technology Materials, University of New Mexico, Albuquerque New Mexico* We have investigated the optical characteristics of a set of InAs-GaSb superlattice structures (SLS) which have InAs layers with a fixed width of 25 Å and GaSb layers whose width varies from stucture to structure over the range 25 Å to 100 Å. Photoluminescence measurements were carried out over the range 10K – 100K on the SLS. Using photodiodes fabricated from the SLS, measurements of the photocurrent-excitation energy spectrum and the time-resolved photoconductivity were carried out at 78K. The observed dependence of the relative oscillator strength of the SLS band-edge transition on the GaSb layer width will be compared with theory[1]. The effect of defects on the the optical and transport properties of the SLS and the dependence of this effect on the GaSb layer width will be discussed.

**R17 2 Comparison of terahertz emission from N-face and In-face indium nitride thin films** GRACE CHERN, *Army Reseach Laboratory* ERIC READINGER, *Army Reseach Laboratory* HONGEN SHEN, *Army Reseach Laboratory* MICHAEL WRABACK, *Army Reseach Laboratory* CHAD GALLINAT, *University of California, Santa Barbara* GREGOR KOBLMUELLER, *University of California, Santa Barbara* JAMES SPECK, *University of California, Santa Barbara* Narrow band gap semiconductors are attractive as emitters of terahertz radiation when optically excited with femtosecond laser pulses. We present a comparison of THz emission from N-face and In-face indium nitride (InN) thin films. The InN samples are optically pumped with a 160 fs laser pulse at 800nm. The subsequent THz radiation is detected by ultrafast electro-optic sampling using a 2mm thick ZnTe crystal. The measured In-face InN films have a Hall mobility of 838 $cm^2$/Vs and 2098 $cm^2$/Vs, and the measured N-face InN samples have a Hall mobility of 645 $cm^2$/Vs and 1460 $cm^2$/Vs. For both polarities, we show an increase in THz power from InN with higher mobilities. However, THz radiation from the In-face InN sample with a Hall mobility of 2098 $cm^2$/Vs is lower in power than from the N-face InN film with a lower Hall mobility of 1460 $cm^2$/Vs. We attribute the lower THz power from In-face InN samples to lower crystalline quality of the In-face material, as determined by x-ray, TEM and photoluminescence measurements. The ratio of the defect density and the PL intensity between the In-face and N-face materials is approximately 3 and 10, respectively.

**R17 3 Electro-Optical characterization of W-structured type-II superlattice photodetectors** J.G. TISCHLER, E.H. AIFER, I. VURGAFTMAN, J.R. MEYER, *Naval Research Laboratory* C.L. CANEDY, E.M. JACKSON, *SFA Inc.* Antimonide based superlattices (SLs) have shown promise as the next generation material system for very long wave infrared focal plane arrays. In particular, we investigated n-i-p diodes with ''W-structured'' type-II SLs, consisting of repetitions of AlGaInSb/InAs/InGaSb/InAs/AlGaInSb layers such that the bulk conduction band-edges of each period forms a ''W'' pattern. The performance of such photodiodes (PDs) depends on a combination of optical and transport properties, such as the absorption coefficient and

minority carrier diffusion length. In order to optimize such devices, it is necessary to measure these properties independently. Using a combination of techniques such as transmission and photoluminescence (PL) spectroscopies, and black-body responsivity measurements, we have systematically studied and optimized our PDs. We have found that the most sensitive parameter that limits the PD performance is the carrier lifetime, making PL measurements the most sensitive characterization technique. We report PDs with up to 100% charge collection efficiency and up to 35% external quantum efficiency.

**R17 4 Recent development of terahertz wave sensing and imaging science, technology, and applications.**
X.-C. ZHANG, *Center for Terahertz Research, Rensselaer Polytechnic Institute, Troy, NY 12180 USA*

Recent advances in THz science and technology make it one of the most promising research areas in the 21st century for sensing and imaging, as well as in other interdisciplinary fields. We believe new T-ray capabilities will impact a range of interdisciplinary fields and industrial companies, including: communications, imaging, medical diagnosis, health monitoring, environmental control, and chemical and biological identification. While microwave and X-ray imaging modalities produce density pictures, T-ray imaging provides spectroscopic information within the THz frequency range. The unique rotational and vibrational responses of materials within the THz range provide information that is generally absent in optical, X-ray and NMR images. A THz wave can easily penetrate and inspect the insides of most dielectric materials, which are opaque to visible light and low contrast to X-rays, making T-rays a useful complementary imaging source in this context. Recent developments of THz wave technologies allow us to coherently control a THz wave (phase, amplitude, and directionality). I present its impacts the physics understanding and industrial applications. Examples of imaging a long distance target ( $>$ 100 meters), large scale industrial samples ( $>$ m2), or a small scale semiconductor device (a few nanometer) will be presented.

**R17 5 Self-assembled ErAs nanoislands for enhanced terahertz detection.** JOHN O'HARA, ROHIT PRASANKUMAR, *Los Alamos National Laboratory* JOSH ZIDE, ART GOSSARD, *University of California-Santa Barbara* ANTOINETTE TAYLOR, RICHARD AVERITT, *Los Alamos National Laboratory* Traditionally, THz detectors based on photoconductive (PC) antennas have utilized low-temperature grown GaAs (LT-GaAs) and radiation-damaged silicon-on-sapphire (RD-SOS) due to their fast carrier trapping times. However, the development of self-assembled ErAs nanoislands embedded in a GaAs matrix offers a particularly useful alternative for THz PC devices based on the ability to independently tune photo-excited carrier lifetimes, trap density, and dark resistance. In this work, we demonstrate enhanced THz detection using self-assembled ErAs:GaAs nanoisland structures. Three nearly identical THz PC antenna detectors are fabricated; one each on the LT-GaAs, RD-SOS, and ErAs:GaAs substrates. Their performance in a typical THz time-domain spectroscopy system is compared in terms of optical efficiency, bandwidth, and saturation behavior. Carrier lifetimes in all three substrates are also compared via pump-probe techniques.

**R17 6 Type II superlattice infrared focal plane arrays: Optical, electrical, and mid-wave infrared imaging characterization.** JOHN LITTLE, STEFAN SVENSSON, ARNIE GOLDBERG, STEVE KENNERLY, KIM OLVER, *Army Research Laboratory, Adelphi, MD 20783* TRIRAT HONGSMATIP, MICHAEL WINN, PARVEZ UPPAL, *BAE Systems, Nashua, NH 03060* We have studied the infrared optical and temperature dependent electrical properties of 320 x 256 arrays of GaSb/InAs type II superlattice infrared photodiodes. Good agreement between single-pixel and focal plane array measurements of the photon-to-electron/hole conversion efficiency was obtained, and the infrared absorption coefficient extracted from these measurements was found to be comparable to that of HgCdTe with the same bandgap as the type II superlattice. Temperature and voltage dependent dark current measurements and the voltage dependent photocurrent generated by a 300 K background scene were described well using a semi-empirical model of the photodiode. We will show high-quality images obtained from the mid-infrared focal plane array operating at 78 K.

**16:06**

**R17 7 Pulsed THz-emission and carrier concentrations in InN** RICARDO ASCAZUBI, INGRID WILKE, *Rensselaer Polytechnic Institute* WILLIAM SCHAFF, *Cornell University* InN grown on sapphire substrates with GaN or AlN buffer layers exhibits a variety of unique electronic properties for the development of brighter photo-conducting THz-radiation sources. Since InN is a narrow band gap semiconductor it is also an attractive candidate for compact and lightweight THz-spectroscopy and imaging systems based on femtosecond fiber laser operating at 1.55$\mu$m wavelength. The important properties of InN with regard to strong THz-emission are low probability of intervalley scattering and strong intrinsic electric fields near the surface. The electric fields at the InN surface are caused by a strong intrinsic electron surface accumulation. We report on THz-emission of n-type InN with carrier concentrations ranging from $10^{17}$cm$^{-3}$ to $10^{20}$cm$^{-3}$. We observe a strongly increasing THz-emission with decreasing carrier concentrations. Based on charge neutrality the dependence of THz-emission on carrier concentrations is explained by assuming an underpopulated region behind the surface accumulation layer, across which the surface field interacts with photo-injected carriers generating THz-transients. The surface state density calculated within this model agrees well data obtained by high resolution electron energy loss spectroscopy data.

**R17 8 A New All-Optical Imaging Scheme based on QWIP technology** DEBING ZENG, GANG CHEN, RAINER MARTINI, *Dept. of Physics and Engr. Physics, Stevens Institute of Technology* Infrared imaging applications have gained increasing interest over the recent decades due to favorable light propagation, night imaging as well as chemical sensing applications. However, the scalability of the existing techniques towards high resolution in the multi-megapixel range is one of the major challenges in today's IR imaging technologies. Here we present an alternative solution using an all-optical wavelength conversion scheme. QWIP has been successfully proven their potential in IR imaging applications. Yet the fundamental conversion process from IR light to electric current has been one of the major restrictions in such system. To overcome this problem we propose the use of an all-optical conversion scheme, which utilizes an interband resonant optical NIR beam to probe the electrical population of the QW structure. In this methodology the incident MIR radiation changes the occupation of the QWs, which in turn influences the NIR transmission. Hence the irradiated MIR images can be probed by spatially resolved measurement of the NIR transmission, as has been demonstrated by Nada et al. for all-optical switching purposes. In this talk we present an implementation scheme of the all-optical QWIP readout technique together with theoretical calculations of the sensitivity of the proposed device and its temperature dependence. First experimental results will be presented also. The Authors thankfully acknowledge financial support by US Army, Picatinny Arsenal.

**R17 9 A THz Microcavity with a Phononic Cavity Polariton** HADLEY LAWLER, *Naval Research Laboratory* SANJIV SHRESTA, *NIST* GAVIN BRENNEN, *NIST* Polaritons were originally considered within the context of the dielectric response of bulk systems, and its relation to the dispersion of fundamental solid-state excitations, such as excitons and optical phonons. More recently, excitonic cavity polaritons have been theoretically described and observed. These excitonic cavity polaritons represent a tunable Rabi coupling between a condensed matter excitation within a microstructure and a cavity-resonant electromagnetic mode. Like excitons, optical phonons possess well-characterized cross-sections with the electromagnetic field, but at lower energies and larger length and time scales. We present theory relevant to a phononic cavity polariton, discuss the prospects for the observation of such a system, and detail our progress toward the prediction of the Rabi coupling's variation with tunable parameters. While susceptibility-type measurements are a possible route for the detection of such a system, we emphasize the possibility of measuring the Rabi oscillation directly in the time domain using ultrafast lasers.

**16:42**
**R17 10 Interplay between plasmon and current due to terahertz radiation** DANHONG HUANG, *USAF Research Lab (VSSS)* CASEY RHODES, *The Johns Hopkins University* PAUL ALSING, DAVE CARDIMONA, *USAF Research Lab (VSSS)* A unique structure composed of a half-space of air and a semi- infinite n-doped bulk GaAs covered by a heavily-n-doped InAs conducting interface sheet is proposed to explore the physics behind the interplay between a transverse sheet current, evanescent modes, and a longitudinal field in the bulk. The presence of the 3D and 2D plasma waves and the sheet current enables the longitudinal and transverse electromagnetic oscillations to couple in directions both perpendicular and parallel to the conducting sheet. We derive a spatially-nonlocal dynamic theory in order to determine the effects of the longitudinal 3D plasma-wave excitation, transverse sheet current and 2D plasma waves, and evanescent modes on the enhancement of a transmitted near-E-field with an electromagnetic wave incident on our proposed structure. For p-polarized incident field, we find one sharp dip and a broad peak in the transmitted near-E-field due to absorption by the longitudinal 3D plasma wave and its coupling to the transverse sheet current.

**16:54**
**R17 11 Submicron Material Characterization Using Terahertz Scanning Near-Field Microscopy** HOU-TONG CHEN, ANTOINETTE TAYLOR, RICHARD AVERITT, *Los Alamos National Lab* FEDERICO BUERSGENS, ROLAND KERSTING, *University of Munich* The recent development of the apertureless terahertz scanning near-field optical microscope (THz-SNOM) allows for submicron spatial resolution [1] and enables a broad variety of novel applications in material characterization. The basic mechanism is that a metallic probe allows for mapping of the THz permittivity of a surface. In this contribution, we report on measurements of microscopic scale charge carrier distributions and dielectric contrast with sub-micrometer resolution in various material systems and structures using THz-SNOM. We have identified a novel imaging mechanism in terms of a configurational resonance [2], which contrasts the widely accepted scattering model at visible and near-infrared frequencies. [1] H.-T. Chen, et al., Appl. Phys. Lett. **83**, 3009 (2003). [2] H.-T. Chen, et al., Phys. Rev. Lett. **93**, 267401 (2004).

**R18 1 Quantum Dephasing and Decoherence in Carbon Nanotubes: Role of Electron-Phonon coupling.** STEPHAN ROCHE, *CEA*

In this talk, the role of electron-phonon coupling on quantum transport is addressed in clean and disordered carbon nanotubes. Defects and impurities are modelled by static disorder, whereas dynamic disorder is driven by the time-dependent vibrations of carbon atoms, that impact on the electronic overlap matrix coupling. On the basis of the Kubo framework in the coherent regime, the conductance scaling properties in the weak localization regime are explored, and from the incorporation of the superimposed effect of acoustic phonon modes phonon, the energy-dependent coherence

length and coherence times will be derived, following a phenomenological perspective. Additionally, the strong disturbance of the electronic structure due to optic modes is analyzed, and shown to strongly alter the conductance scaling behaviour of both metallic and semiconducting otherwise clean nanotubes. Consequences for the high-bias regime of nanotubes-based field effect transistors and limitations of semi-classical focus will be discussed.

**R18 2 Combined electrical transport and STM of carbon nanotubes** B.J. LEROY, I. HELLER, V.K. PAHILWANI, C. DEKKER, S.G. LEMAY, *Kavli Institute of Nanoscience, Delft University of Technology* We have performed simultaneous electrical transport and scanning tunneling spectroscopy measurements on suspended carbon nanotubes. By combining these two measurement techniques we are able to probe the electronic states involved in transport through the nanotube. The spectroscopy shows peaks due to Coulomb blockade, which split and change energy as a function of the source-drain voltage across the nanotube. These peaks track the Fermi level of the source and drain electrodes. Unexpectedly, the strength of the peaks also depends on position along the tube.

**15:18**

**R18 3 Role of electronic excitations in ion collisions with carbon nanostructures.*** DAVID TOMANEK, *Michigan State University* YOSHIYUKI MIYAMOTO, *NEC Corporation* ARKADY KRASHENINNIKOV, *Helsinki University of Technology* We study the effect of electronic excitations during collisions of protons with $sp^2$ bonded carbon nanostructures by performing molecular dynamics simulations. To obtain microscopic insight into the collision process in real time, we combine time-dependent density functional calculations for electrons with molecular dynamics simulations for ions, and compare the results to molecular dynamics simulations in the electronic ground state. The simulations for protons colliding with carbon nanotubes and graphite are performed in the interesting range of impact energies of tens to hundreds of eV, corresponding to ion velocities covering a broad range around the Fermi velocity of the target, $v_F = 8 \times 10^5$ m/s. In agreement with the binary collision approximation, we find only negligible deviations from Born-Oppenheimer dynamics for projectile velocities well below the Fermi velocity. Our results establish validity limits for the Born-Oppenheimer approximation, and also the threshold energy for sputtering of carbon nanotubes and graphite.

**R18 4 Electrical conducting and breakdown behaviors of multiwall carbon nanotubes under different contact modes** SHUO CHEN, J.Y. HUANG, S.H. JO, Z.Q. WANG, D.X. HAN, *Boston College* G. CHEN, M. DRESSELHAUS, *MIT* Z.F. REN, *Boston College* We have carried out electrical transport property studies of individual multiwall carbon nanotubes while viewing the structural changes in-situ inside a high resolution transmission electron microscope. Two types of contact have been tested: end-contact with all layers contacted with the electrodes, and side-contact with only the outmost layer contacted with the electrodes. We found that in some cases electrical breakdown takes place in the innermost layer under both contact modes with a simultaneous current drop, which indicates that under high bias voltage, each layer carries a current even there is no direct contact with the electrodes. Eexperimental evidence shows that the temperature can reach around 3000 °C during breakdown, so the inter-layer conducting could be induced by strong electric field or by thermal excitation.

**15:42**

**R18 5 Distinct properties of single-wall carbon nanotubes with sidewall chemical functionalization** JIANPING LU, HYOUNGKI PARK, *Univ. of North Carolina at Chapel Hill* JIJUN ZHAO, *Washington State University* itAb initio calculations reveal distinct electronic properties associated with side wall functionalization of SWNTs. The metallic tubes are found to be more reactive than the semiconducting ones. The hybridization between the addend and the tube induces unique impurity states near the Fermi level. For semiconducting tubes the state is localized near the functionalized site with a characteristic length of 15 Å. In contrast, the impurity state is extended and acts as a strong scattering centre in metallic tubes. This effect greatly hinders the ballistic transport of electrons along the metallic nanotubes. The characteristic dependence of the electronic states and the conductance on functional molecules provides possible pathways for chemical sensor applications and the band structure engineering.

**15:54**

**R18 6 Effects of sidewall functionalization on the conducting properties of SWNTs** HYOUNGKI PARK, *Univ. of North Carolina at Chapel Hill* JIJUN ZHAO, *Washington State University* JIANPING LU, *Univ. of North Carolina at Chapel Hill* We investigated the conducting properties of sidewall functionalized SWNTs with a finite addend concentration. Robust differences are found between monovalent and divalent addends. For monovalent addition a small number of addends can significant disrupt the ballistic conductance of nanotubes near the Fermi level. As the addend concentration increases the conductance rapidly decreases and approaches zero at addends to C ratio around 25%. In contrast, divalent addends have only weak effects on the conducting properties and the nanotube quantum conductance remains above 1 even for addend concentration as large as 25%. These differences can be attributed to the formation of impurity state near the Fermi level for monovalent addition, while divalent addends create impurity states far away from the Fermi level.

**16:06**

**R18 7 Theory of scanned-gate microscopy of carbon nanotubes and nanowires** MATTHEW ZHANG, MISHA FOGLER, *UCSD* We model theoretically a scanned-gate microscopy experiment where a Coulomb-blockaded metallic carbon nanotube (nanowire) is probed by an AFM tip. The tip modifies the charge of the nanotube via an electrostatic coupling. The amount of induced charge can have a complicated dependence on the position and the voltage of the tip in a realistic experimental situation where several screening gates and nearby stray charges may be present, which may obscure the interpretation of the results. We demonstrate that such difficulties can be significantly reduced in the geometry where a nearby backgate screens the electrostatic interactions making them short-range. We show that it is then possible to calculate and simply distinguish among different con-

tributions to the induced charge. Combining the above electrostatic modelling with many-body bosonization methods we demonstrate that the presence of the tip causes an oscillatory shift in the Coulomb blockade peak positions. We show that the amplitude and the phase of this shift can be used to study the spin-charge separation and Luttinger-liquid effects in one-dimensional wires.

**16:18**

**R18 8 Re-entrant semiconducting behavior of zigzag carbon nanotubes on substitutional doping by oxygen dimers** SEUNG-HOON JHI, *Department of Physics, POSTECH* The electronic structures of carbon nanotubes doped with oxygen dimers are studied using the *ab initio* pseudopotential density functional method. The fundamental energy gap of zigzag semiconducting nanotubes exhibits a strong dependence on both the concentration and configuration of oxygen dimer defects that substitute for carbon atoms in the tubes and on the tube chiral index. For a certain type of zigzag nanotube when doped with oxygen dimers, the energy gap is closed and the tube becomes semimetallic. At higher oxygen-dimer concentrations the gap reopens, and the tube exhibits semiconducting behavior again. The change of the band gap of the zigzag tube is understood in terms of their response to the strains caused by the dimer substitutional doping.

**16:30**

**R18 9 Modulated conduction in single-walled carbon nanotubes using covalently bound chromophore functionalities** JASON SIMMONS, *Department of Physics* TYLER MARK, *Department of Chemical Engineering* GUANGDE CHEN, *Department of Chemistry* VICTORIA CAMPBELL, PADMA GOPALAN, *Department of Materials Science & Engineering* MARK ERIKSSON, *Department of Physics, University of Wisconsin - Madison* Carbon nanotube hybrid materials are widely studied in order to leverage the exceptional thermal and electronic properties for a number of applications. We demonstrate an optically active nanotube-hybrid material by covalently functionalizing single-walled nanotubes with an azo-based chromophore. Upon UV illumination, the conjugated chromophore functionality undergoes a cis-trans isomerization, breaking the conjugation and modulating the conductance of individual functionalized nanotubes. Though there is most likely no direct charge transfer between the chromophore and the nanotube, the isomerization results in a charge redistribution near the nanotube, modifying the local electrostatic environment and causing the change in conductance. Further, the conductance change is reversible; indicating that the chromophore functionalized nanotubes can be used as reversible photo-switches.

**16:42**

**R18 10 Electron Transport in Carbon Nanotubes with Superconducting Contacts** ALEXANDER MAKAROVSKI, GLEB FINKELSTEIN, *Duke University, Department of Physics* We report on our measurements of electron conductance in single-walled carbon nanotubes contacted by superconducting leads. We study the proximity effect induced by the superconducting contacts at temperatures below the transition temperature of the leads. Excess differential conductance (way above the ballistic limit of $4e^2/h$ for a single-wall nanotube with normal contacts) and subgap Andreev reflection peaks are observed.

**16:54**

**R18 11 Superconductivity in entirely end-bonded multi-walled carbon nanotubes** JUNJI HARUYAMA, IZUMI TAKESUE, NAOKI KOBAYASHI, *Aoyama Gakuin University* SHOHEI CHIASHI, SHIGEO MARUYAMA, *Tokyo University* TOSHIKI SUGAI, HISANORI SHINOHARA, *Nagoya University* One-dimensional (1D) systems face some obstructions that may prevent the emergence of superconductivity(SC), e.g., 1.a Tomonaga-Luttinger liquid (TLL), 2.Peierls transition, and 3.Low density of states due to VHSs. A carbon nanotube (CN) is one of the best candidates for investigating a possibility of 1D SC and its interplay with such obstructions. Only two groups have experimentally reported SC in ropes of single-walled CNs (SWNTs) and very thin SWNTs [1] to date. In addition, those interplay with 1D phenomena have never been clarified. Some theoretical papers also predicted strong correlation between TLL states and SC for SWNT ropes and importance of electron-phonon interaction for thin SWNTs [2]. Here, we report that entirely end-bonded multi-walled CNs (MWNTs) can show SC with the $T_c$ as high as 12K [3] (about 50-times larger than $T_c$ in former of [1]). We find that emergence of this SC and its interplay with TLL states are highly sensitive to junction structures of Au electrode/MWNTs. Only MWNTs with optimal numbers of electrically activated shells realized by the entire end-bonding can allow the SC due to intershell effects. 1. M. Kociak, et al., PRL 86, 2416 (2001); Z. K. Tang, et al., Science 292, 2462 (2001), 2. J.Gonzalez, PRL 88, 076403 (2002); R.Barnett, et al., PRB 71, 035429 (2005), 3. J.Haruyama et al., PRL Accepted

**R18 12 Zero-bias anomaly and possible superconductivity in single-walled carbon nanotubes** JIAN ZHANG, ALEXANDER TSELEV, YANFEI YANG, KYLE HATTON, PAOLA BARBARA, *Department of Physics, Georgetown University, Washington, DC 20057* SERHII SHAFRANIUK, *Physics and Astronomy Department, Northwestern University, Evanston IL 60208* We report measurements of field-effect transistors made of isolated single-walled carbon nanotubes contacted by superconducting electrodes. For large negative gate voltage, we find a dip in the low-bias differential resistance. Surprisingly, this dip persists well above the superconducting transition temperature of the electrodes, indicating that it is not caused by superconducting proximity effect from the electrodes. This conclusion is supported by measurements on carbon nanotubes contacted by normal electrodes showing similar features. One possible explanation is superconductivity in the nanotubes.

**17:18**

**R18 13 Shell filling and excited states in a fully tunable double quantum dot on a carbon nanotube** SAMI SAPMAZ, CAROLA MEYER, PIOTR BELICZYNSKI, PABLO JARILLO-HERRERO, LEO KOUWENHOVEN, *Kavli Institute of Nanoscience Delft* We have realized fully controllable and tunable nanotube quantum dots defined with electrostatic top-gates. Using three electrostatic top-gates we have made a NT double dot. Clear honeycomb patterns are observed in the charge stability diagram as a function of two independent side-gates. Furthermore, for the first time we have observed discrete excitations at finite bias. The origin of these excitations is discussed. The central top-gate is used to control the coupling between the two NT dots. Controlling electron interactions in a molecular system is important for many applications such as for example quantum computation.

**14:30**
**R19 1 Theory of Spin Hall Effect in GaAs.**
HANS-ANDREAS ENGEL, *Harvard University*

In the spin Hall effect, an electric current in a system with spin-orbit coupling induces a transverse spin current which leads to non-equilibrium spin accumulation near sample boundaries. Generating and manipulating non-equilibrium spin magnetization by electric fields is one of the most desirable goals of semiconductor spintronics, because electric fields have potentialities for accessing individual spins at nanometer scales. In this talk, I review the different spin-orbit coupling mechanisms in direct gap semiconductors and the implications of these mechanisms for the spin Hall effect. In particular, we recently developed a theory that accounts for spin-orbit coupling at charged impurities. This coupling leads to itextrinsic spin currents that contain skew scattering and side jump contribution [1]. Applying our theory to bulk n-GaAs, without any free parameters, we find spin currents that are in reasonable agreement with recent experiments by Kato et al. [2]. Also, such contributions are important for p-doped GaAs. Furthermore, we analyzed the effect of itintrinsic spin-orbit coupling in the presence of anisotropic impurity scattering, and found that, somewhat surprisingly, an electrical field can lead to a bulk magnetization component itperpendicular to both the spin-orbit field and an external magnetic field. These works have been done in collaboration with B.I. Halperin, E.I. Rashba, and A.A. Burkov. [1] H.-A. Engel, B.I. Halperin, and E.I. Rashba, Phys. Rev.Lett. **95**, 166605 (2005). [2] Y.K. **R19 2 Spin Hall Current Induced Edge-Spin Accumulation in Two-Dimensional Electron and Hole Systems** KENTARO NOMURA, *Department of Physics, University of Texas at Austin* JAIRO SINOVA, NIKOLAI SINITSYN, TOMAS JUNGWIRTH, JOERG WUNDERLICH, BERND KAETSNER, ALLAN MACDONALD, In spintronic devices, spin densities have traditionally been generated by external magnetic fields, circularly polarized light sources, or by spin injection from ferromagnets. Recently there has been considerable interest in a new strategy in which edge spin densities are generated electrically via the spin Hall effect. We have performed numerical studies on spin transport in two-dimensional systems with various spin-orbit interactions including both intrinsic and extrinsic effects. We find that the spin Hall current strongly depends on the character of the spin-orbit interactions. We address the relation between bulk spin currents and edge spin accumulations, and compare our results with recent experimental observations. K. Nomura, J. Sinova, N. A. Sinitsyn, A. H. **15:18**
**R19 3 Spin Hall effect in p-type semiconductors in magnetic fields** MEHDI ZAREA, SERGIO ULLOA, *Ohio University* We calculate the spin Hall conductivity driven by Rashba spin-orbit interaction in *p*-type two-dimensional semiconductors in the presence of a perpendicular magnetic field. For a highly confined quantum well the eigenstates and eigenvalues of the system, described by a *k*-cubic Rashba term for heavy holes, can be described by Landau spinor states, as in the *k*-linear case [1]. The contribution of the interband transitions to the Kubo-Greenwood formula gives the density-dependent *conventional* spin Hall conductivity, which approaches its universal value $\sigma^{z}_{xy} = 9e/8\pi$ for weak spin-orbit coupling and low Fermi energies, in agreement with previous work. However, two intraband contribution terms cancel this effect, resulting in *zero* conventional spin Hall conductivity. Adding the torque dipole contribution to the definition of spin current, we also study the *effective* spin conductivity. This is shown to be proportional to the total magnetization plus surface terms which exactly cancel it for small spin-orbit coupling. The fact that both effective and conventional spin Hall conductivities vanish is unexpected, especially as one expects the intraband transitions to evolve into vertex corrections for low magnetic fields. Supported by NSF-NIRT. [1] M. Zarea and S. E. Ulloa Phys. Rev. B 72, 085342 (2005).

**R19 4 Non-linear charge and spin Hall effect caused by insulating or charged disks in a two dimensional electron gas** DAVID SCHMELTZER, HSUAN-YEH CHANG, *City College of New York* We show that a time depend electric field in the presence of static vortices caused by insulating regions induces a non-linear time average Hall effect without breaking time reversal symmetry. A time dependent electric field will induce a time dependent Lorentz force in the presence of static vortices of size *D* giving rise to a Hall voltage in a two dimensional electronic gas. The origin of the vortices are insulating regions which cause the electronic wave function to vanish. This theory can explain the recent experiment in a two dimensional GaAs/AlGaAs dot with insulating disks. In this experiment, a driving microwave field in the y-direction has been applied and a DC voltage has been measured in the x-direction. When the insulating disks are replaced by charged disks, we suggest that the Aharonov-Casher effect will induce a spin-Hall effect.

**R19 5 The Helical Liquid and the Edge of Quantum Spin Hall Systems** CONGJUN WU, *Kavli Institute for Theoretical Physics, UCSB* B. ANDREI BERNEVIG, SHOU-CHENG ZHANG, *Physics Department, Stanford University* The edge states of the recently proposed quantum spin Hall systems constitute a new symmetry class of one-dimensional liquids dubbed the ''helical liquid,'' where the spin orientation is determined by the direction of electron motion. We prove a no-go theorem which states that a helical liquid with an odd number of components cannot be constructed in a purely 1D lattice system. In a helical liquid with an odd number of components, a uniform gap in the ground state can only appear when the time-reversal (TR) symmetry is spontaneously broken by interactions. On the other hand, a correlated two-particle backscattering term by an impurity can become relevant while keeping the TR invariance. We further study the Kondo effect in such a liquid which exhibits new features in the structure of the screening cloud.

**15:54**

**R19 6 ''Spin-orbit'' susceptibility in the quantum spin Hall systems** SHUICHI MURAKAMI, *Department of Applied Physics, University of Tokyo* There are two classes of insulators showing the spin Hall effect. One is a spin Hall insulator such as PbTe while the other is a quantum spin Hall system. They are distinguished by an absence or presence of edge states. To study such insulators showing the spin Hall effect, we construct a spin analog of the Středa formula. We use the conserved spin current as proposed by Zhang et al.[cond-mat/0503505], thereby the resulting Středa formula becomes quite simple (i.e. without any $\dot{\mathbf{s}}$ terms). As a result, the spin Hall conductivity for band insulators is proportional to a ''spin-orbit'' susceptibility, representing a response of the orbital magnetization to the Zeeman field (or equivalently a response of the spin magnetiation to the orbital magnetic field). We apply the result to real systems such as $Bi_{1-x}Sb_x$, because in insulating $Bi_{1-x}Sb_x$ the diamagnetic susceptibility is largely enhanced due to the spin-orbit coupling.

**16:06**

**R19 7 Stability of the quantum spin Hall effect with disorder and interactions** CENKE XU, JOEL MOORE, *University of California Berkeley* The stability to interactions and disorder of the quantum spin Hall effect (QSHE) proposed for time-reversal-invariant 2D systems is discussed. The QSHE requires an energy gap in the bulk and gapless edge modes that conduct spin-up and spin-down excitations in opposite directions. When the number of Kramers pairs of edge modes is odd, certain one-particle scattering processes are forbidden due to a topological $Z_2$ index. However, two particle scattering processes can localize the edge modes and destroy the QSHE: the region of stability for both classes of models (even or odd number of Kramers pairs) is obtained explicitly. For a single Kramers pair the QSHE is stable to weak interactions and disorder, while for two Kramers pairs it is not; however, the two-pair case can be stabilized by *either* finite attractive or repulsive interactions. We also discuss a mechanism to generate 1D localized states in magnetic semiconductors. These states are localized by the domain wall between two opposite ferromagnetic orderings. The total number of these localized states can be expressed in terms of a real space topological number. The existence of these localized states can result in a quantum spin Hall effect as well as a quantum charge Hall effect.

**16:18**

**R19 8 Mesoscopic Spin Hall effect** PHILIPPE JACQUOD, *University of Arizona* INANC ADAGIDELI, *University of British Columbia* We focus on the mesoscopic spin Hall effect in ballistic microstructures. Using an extension of Landauer-Buttiker formalism, we calculate the average and variance of spin Hall conductance using the semiclassical approximation as well as Random Matrix theory. We compare these calculations to numerical simulations. We show in particular that the diagonal contribution corresponding to the classical (spin)conductance vanishes. However, interference corrections lead to a finite spin-Hall conductance. This conductance depends crucially on whether the system is regular or chaotic.

**16:30**

**R19 9 The pseudospin degree of freedom and dynamics in degenerate bands** QIAN NIU, *The University of Texas at Austin, Austin, TX 78712* DIMITRIE CULCER, *Advanced Photon Source, Argonne National Laboratory, Argonne, IL 60439 and Department of Physics, Northern Illinois University, De Kalb, IL 60115* Carriers in degenerate bands possess an additional degree of freedom, which may be regarded as a pseudospin. In a wave- packet picture, along with the center of mass motion in crystal momentum and real space, one must also take into account the probability amplitudes, which characterize the inter-band dynamics. The additional degree of freedom introduces nontrivial non-Abelian corrections to the carrier dynamics. These corrections include non-Abelian Berry curvature terms and a non-Abelian correction to the group velocity. For the four- band Luttinger model we will demonstrate that, under the action of an electric field, coherent wave-packet evolution leads to separation of up and down spins, discussing the role of the pseudospin in this process. We find that the helicity in the four band model can be expressed in terms of the pseudospin and is not conserved in an electric field. In addition, we will discuss the role of the pseudospin in determining the Landau levels in the Luttinger Hamiltonian by semiclassical quantization.

**16:42**

**R19 10 Transport Equations and Spin-Charge Propagating Mode in a Two Dimensional Hole Gas with Spin-Orbit Coupling** TAYLOR HUGHES, ANDREI BERNEVIG, *Stanford University* YAROSLAW BAZALIY, *IBM Almaden Research Center* SHOU-CHENG ZHANG, *Stanford University* We find that the spin-charge motion in a strongly confined two-dimensional hole gas (2DHG) supports a propagating mode with cubic dispersion apart from the diffusive mode due to momentum scattering. Propagating modes seem to be a generic property of systems with spin-orbit coupling. Through a rigorous Keldysh approach, we obtain the transport equations for any system with spin-orbit coupling that can be represented using spin- 1/2 matrices. We specialize to the 2DHG and analyze the behavior of the hole spin relaxation time, diffusion coefficients, and spin-charge coupled motion. We also confirm the value of the spin Hall conductivity in the ballistic regime and discuss the viability of the propagating mode.

**16:54**

**R19 11 Spin-orbit coupling and Zeeman splitting of holes in GaAs nanostructures grown in [113] direction** TAISUKE MINAGAWA, YULI LYANDA-GELLER, *Department of Physics, Purdue University* We have calculated the anisotropic spectrum, g-factor and spin- orbit interactions for hole carriers in GaAs quantum wells grown in direction [113], and quantum wires and

quantum dots confined to such quantum wells. We have developed a simple analytical approach for calculations of spectra of holes confined to nanostructures within the Luttinger Hamiltonian scheme, which allows us to compute the wave functions and energies without invoking admixtures of ''light'' and ''heavy'' holes perturbatively. We have identified the dominant spin-orbit interaction terms and discuss their effects on dynamics of holes in external magnetic and electric fields. We have also calculated spin relaxation and dephasing times for 2D holes quantized along [113] direction.

**17:06**

**R19 12 Spin-orbit induced spin precession in 2D hole systems** DIMITRIE CULCER, *Advanced Photon Source, Argonne National Laboratory, Argonne, IL 60439 and Department of Physics, Northern Illinois University, De Kalb, IL 60115* CHRISTIAN LECHNER, *Institut fuer Theoretische Physik, Universitaet Regensburg, D-93040 Regensburg, Germany* ROLAND WINKLER, *Advanced Photon Source, Argonne National Laboratory, Argonne, IL 60439 and Department of Physics, Northern Illinois University, De Kalb, IL 60115* It is well known that two-dimensional hole systems are characterized by an effective spin 3/2. Recently it was shown that the spin density matrix for such spin-3/2 systems can be decomposed into a sequence of multipoles which has important contributions from higher-order multipoles beyond the ones known for electron systems [1]. We will show that these multipoles can precess even in the absence of a magnetic field if strong spin-orbit interactions are present. Particularly simple and enlightening expressions for the spin polarization and higher order multipoles emerge in certain geometries. We will discuss an experimental setup in which this precession can be observed and investigate promising spintronics applications. [1] R. Winkler, Phys. Rev. B 70, 125301 (2004)

**17:18**

**R19 13 A Luttinger Hamiltonian is not enough** M.C. CHANG, C.P. CHUU, Q. NIU, *University of Texas at Austin* In the study of spintronics, it is important to understand carrier transport in multiple energy bands, such as in the conduction or valence bands in semiconductors. Such bands are often described by effective Luttinger Hamiltonians, derived from k.p perturbation and symmetry considerations. A closely related case is the Pauli Hamiltonian, which suppose to give an effective description for the upper Dirac bands in the non-relativistic limits. Here we show that such an effective Hamiltonian alone is not really sufficient. Various Berry phase type corrections must be supplemented to give proper description of electron charge and spin dynamics.

**SESSION R20: FOCUS SESSION: MULTIFERROICS III: PEROVSKITES**

**Craig Fennie, Rutgers University, presiding**

**14:30**

**R20 1 Multiferroicity of $BiMnO_3$ reexamined from first principles.** TATSUYA SHISHIDOU, TAMIO OGUCHI, *ADSM, Hiroshima University* $BiMnO_3$ is believed to show both ferromagnetic and ferroelectric orders. In contrast to its robustly confirmed ferromagnetism, only one experimental group has succeeded in observing ferroelectric hysteresis loop[1]. Another group has reported small magnetocapacitance effect around the ferromagnetic Curie temperature[2]. Using first-principles scalar-relativistic full-potential linear augmented plane wave (FLAPW) method and adopting the experimental lattice data, we have given several significant insights on physical properties of $BiMnO_3$ [3]. Further extended results will be shown in this talk. With including spin-orbit interaction, possible directional coupling between the polarization and magnetization will be discussed together with magnetocrystalline anisotropy. Results of structual optimization based on the first-principles atomic forces will be presented to verify its ferroelectricity. Possible doping effect will also be explored. [1] A. Moreira dos Santos *et al.*, Solid State Commun. **122** 49 (2002). [2] T. Kimura *et al.*, Phys. Rev. B **67** 180401(R) (2003). [3] T. Shishidou, N. Mikamo, Y. Uratani, F. Ishii, and T. Oguchi, J. Phys.: Condens. Matter **16** S5677 (2004).

**14:42**

**R20 2 Orbital order, ferromagnetism, and ferroelectricity of $BiMnO_3$ and related compounds** CHANHO YANG, TAEYEONG KOO, YOON HEE JEONG, *Dept of Physics, POSTECH* Multiferroic materials, where ferroelectricity and magnetism coexist, have been actively studied. This class of materials would offer a large application potential for new devices taking advantage of two coupled degrees of freedom based on local off-centered distortion and electron spin. Although most often the magnetic state in coexistence with ferroelectricity is antiferromagnetic, $BiMnO_3$ is an interesting exception with the simultaneous existence of ferromagnetism and ferroelectricity. However, the transition temperatures are in great disparity with $T_{FE} = 770$ K and $T_{FM} = 105$ K, and consequently its ME coupling is not large. In this talk, we will report on three aspects of $BiMnO_3$: (1) Long range ordering of 3d-orbital of $Mn^{3+}$ ions and its influence to the ferromagnetism and ferroelectricity (2) How to create a system to induce a large inter- property coupling by modifying $BiMnO_3$ (3) How to obtain a material with a large inter-coupling at room temperature

**14:54**

**R20 3 Magnetic Ferroelectrics Bi,Pb-3*d* Transition Metal Perovskites** MASAKI AZUMA, KAZUHIDE TAKATA, TAKASHI SAITO, YUICHI SHIMAKAWA, MIKIO TAKANO, *Inst. Chem. Res., Kyoto Univ.* SEIJI NIITAKA, *Mag. Res. Lab., RIKEN* ALEXEI BELIK, *ICYS, NIMS* SHINTARO ISHIWATA, *Dept. Appl. Phys., Waseda Univ.* Magnetic ferroelectrics attract much attention because of the possible application for the memory device and the fascinating coupling between magnetic and dielectric properties. A classical way to obtain a magnetic ferroelectric is to locate $Bi^{3+}$ or $Pb^{2+}$ ions and a magnetic transition metal ion on A and B sites of perovskite structure. The $6s^2$ lone pair and the strong covalent character of Bi(Pb)-O bonds stabilize a noncentrosymmetric distorted structure. For example, $BiFeO_3$ and $BiMnO_3$ are established antiferromagnetic and ferromagnetic ferroelectrics, respectively. We have studied structure, magnetic and electric properties of $BiMO_3$ with $M$=Cr, Co and Ni and $PbVO_3$ stabilized by high-pressure synthesis. $BiCrO_3$ is an antiferromagnetic ferroelectric with $BiMnO_3$ type structure. $BiCoO_3$ and $PbVO_3$ are found to have tetragonal $PbTiO_3$ type structures with expected polarizations of $\sim 100 \mu C/cm^2$. $BiNiO_3$crystallizes in a triclinic structure

where disproportionation into $Bi^{3+}$ and $Bi^{5+}$ takes place. We have also succeeded in preparing a designed ferromagnetic ferroelectric double provskite $Bi_2NiMnO_6$. In this compound, NaCl type ordering of $Ni^{2+}$ ($e_g^1$) and $Mn^{4+}$ ($t_{2g}^3$) leads to ferromagnetism with $T_C$=140 K.

**15:06**

**R20 4 Dielectric, magnetic, magneto-optical and nonlinear optical properties of ferroelectric ferromagnetic semiconductor $BiMnO_3$ from first-principles calculations** GUANG-YU GUO,* HAI-QING LIN, *Department of Physics, Chinese University of Hong Kong, Shatin, Hong Kong* $BiMnO_3$ is a biferroic (ferroelectric and ferromagnetic) semiconductor, and hence a member of the family of multiferroic materials. In order to gain a full understanding of its interesting properties such as biferroic behavior, we have calculated from first-principles the electronic structure, exchange coupling, linear and non-linear optical susceptibilities as well as magneto-optical Kerr rotation of $BiMnO_3$. The calculations are based on density functional theory with generalized gradient approximation plus on-site Coulomb correlation (GGA+U). The all-electron full potential linearized augmented plane wave (FLAPW), frozen core full potential projector augmented wave (PAW), and also all-electron tight-binding linear muffin-tin orbital methods (TB-LMTO) are used. In this contribution, we will present and analyze the obtained exchange coupling parameters, magneto-optical Kerr rotation spectra, dielectric constants and second-harmonic generation coefficients.

**R20 5 Properties and superlattice for multiferroics $BiMnO_3$.*** C.Q. JIN, Z.H. CHI, H. YANG, R.C. YU, S.M. FENG, F. Y. LI, *Institute of Physics, Chinese Academy of Sciences* Single-phase multiferroics $BiMnO_3$ceramic was synthesized via high-pressure high-temperature technique. Microstructure modification accompanied by emergence of superlattice due to electron-beam irradiation was observed wherein by means of ED and HRTEM. Magnetic evaluation manifesting a unique ferromagnetic phase transition at 103 K has corroborated our speculation that as-prepared BiMnO3 ceramic is free of polymorphism at room temperature. Furthermore, magnetization versus temperature ($M - T$) characterization combined with itin situ variable temperature powder X-ray diffraction (XRD) and dielectric constant versus temperature ($\varepsilon$-T) spectrum scanning confirmed that as-prepared $BiMnO_3$ specimen exhibits simultaneous occurrence of ferromagnetism and ferroelectricity below its ferromagnetic Curie temperature ($T_M$)of 103 K.

**R20 6 Structural Investigations of Bi-containing, multiferroic thin films using Second Harmonic Generation** ERNST KNOESEL, S.E. LOFLAND, K.F. McDONALD, C.J. MEETING, *Rowan University* M. MURAKAMI, M. ARANOVA, I. TAKEUCHI, *University of Maryland* The intensity and polarisation of the bulk second harmonic generation (SHG) from thin films depends critically on the second-order susceptibility tensor, which in turn is strongly influenced by the crystal structure of the film. Multiferroic $BiMO_3$ (M=Fe,Cr) thin films were grown epitaxially as thin films on varies substrates with changing orientations. We have found a substantial bulk SHG signal from of these materials and performed comparative magnetic field and temperature dependent studies. The implication with respect to crystal structure, magnetic phase transitions and multiferroic properties are discussed.

**15:42**

**R20 7 Multiphase Formation In Bi based Multiferroic Thin Films: Structural Change And Strain Relaxation*** SUNG HWAN LIM, MAKOTO MURAKAMI, SHIGEHIRO FUJINO, MANFRED WUTTIG, ICHIRO TAKEUCHI, LOURDES G. SALAMANCA-RIBA, *University of Maryland, College Park* WENDY LYNN SARNEY, *Army Research Laboratories, Adelphi, Maryland* Bi based multiferroic epitaxial thin films like, Bi-Fe-O and Bi-Mn-O were grown on $SrTiO_3$(001) substrates by pulsed laser deposition under various oxygen partial pressures (0.1 – 20 mTorr) and thickness (35 – 500 nm). The structural properties of impurity phases in these systems were characterized by transmission electron microscopy, x-ray diffraction, and energy dispersive x-ray spectroscopy. In the Bi-Fe-O system growth at oxygen partial pressures lower than 5 mTorr gives rise to the formation of the canted antiferromagnetic phase, $\alpha$-$Fe_2O_3$ with a columnar structure in a matrix of $BiFeO_3$. Simultaneously, ferromagnetic phase, $\gamma$-$Fe_2O_3$ precipitates with plate-like structure in the $\alpha$-$Fe_2O_3$ matrix. Similarly, $Mn_3O_4$ impurity phase forms in the Bi-Mn-O system when the films are grown at low oxygen partial pressure. In Bi-Fe-O film, the friction of $\gamma$-$Fe_2O_3$ enhances the magnetic properties of the film, while $\alpha$-$Fe_2O_3$ reduces the compressive stress in $BiFeO_3$ due to its smaller volume compared to that of $BiFeO_3$. We also report structural and magnetic properties of $BiCrO_3$ thin film, a new multiferroic material.

**R20 8 Dichroism and order parameter coupling in $BiFeO_3$ Films** MIKEL BARRY, T. ZHAO, F. ZAVALICHE, M.P. CRUZ, Y.H. CHU, R. RAMESH, *University of California, Berkeley* A. SCHOLL, A. DORAN, *Advanced Light Source, Lawrence Berkeley National Laboratory* $BiFeO_3$ is an attractive material because it is a possible multiferroic and lead-free replacement for ferroelectric memory cells and piezoelectric sensors and actuators. We are probing the possibility of coupling between ferroelectricity and antiferromagnetism in epitaxial thin films of this system. X-ray linear dichroism based PEEM images were obtained using a high spatial resolution photoelectron emission microscope (PEEM). This combination of XLD and PEEM provides high spatial resolution along with elemental and chemical specificity and surface sensitivity. A Piezoforce microscope (PFM) was used to switch the ferroelectric state in micron-sized regions of the film, which were subsequently probed using temperature dependent PEEM measurements. Temperature dependent structural measurements were carried out to probe the changes in the ferroelectric order parameter with temperature. We observe a strong change in XLD as the temperature is raised to and beyond the Neel temperature. We will present the results of our approaches to decouple the XLD responses that arise from purely the structural distortion (i.e., due to ferroelectricity) and that arising from the antiferromagnetic state, as well as the results of the coupling experiments. This work is supported by an LBL-LDRD program and by the ONR under a MURI program.

**R20 9 Systematic investigation of multiferroic properties of $(Bi_{1-x}Sm_x)FeO_3$ and $(Bi_{1-x}La_x)FeO_3$ thin films using composition spreads** MAKOTO MURAKAMI, *University of Maryland* V. NAGARAJAN, *University of New South Wales* A. VARTHARAJAN, *University of New South Wales* S. FUJINO, *University of Maryland* M. WUTTIG, *University of Maryland* I. TAKEUCHI, *University of Maryland* $BiFeO_3$ and its room temperature multiferroic properties have attracted much attention. However, it is generally believed that its magnetic and ferroelectric properties have not been unambiguously established. There have been some reports of A-site substituted $BiFeO_3$ aimed at improving its properties. In this study, we report on synthesis and multiferroic properties of La and Sm modified $BiFeO_3$ thin films. In particular, in order to systematically study these systems, we fabricated composition spread thin films of $(Bi_{1-x}Sm_x)FeO_3$ and $(Bi_{1-x}La_x)FeO_3$ ($x=0\sim 1$) on $SrTiO_3$ and $LaAlO_3$ substrates using combinatorial pulsed laser deposition. Several structural transitions were found in the middle of the spreads in both systems using x-ray microdiffraction. In $(Bi_{1-x}La_x)FeO_3$, the structure was found to change from rhombohedral to paramagnetic phase at about 20% of $BiFeO_3$. Ferroelectric properties and magnetic properties of the spreads were mapped using piezoforce microscopy and scanning SQUID microscopy. We report on the effect of the structural transitions on their multiferroic properties. This work was supported by NSF MRSEC DMR 0520471 and ONR.

**16:18**

**R20 10 Scanning probe imaging of coexistent ferroelectricity and ferromagnetism in thin films of room temperature multiferroics.** V.R. PALKAR, S.C. PURANDARE, J. JOHN, S. GOHIL, S. BHATTACHARYA, *Tata Institute of Fundamental Research, Mumbai-5, India* DEPARTMENT OF CONDENSED MATTER PHYSICS AND MATERIALS SCIENCE COLLABORATION, Scanning probe imaging methods, both piezoresponse and magnetic force types, are used to study domain patterns in thin films of room temperature multiferroics. The results demonstrate coexistence of the two order parameters in microscopic scale and rules out macroscopic phase separation. Furthermore, a tapping mode technique is shown to yield information of both order parameters allowing simultaneous observation of both types of domain structures. Prospects of imaging possible coupling between the two order parameters, as seen in bulk measurements, will be discussed.

**16:30**

**R20 11 The Nanostructure Formation and Growth Evolution of Ferroelectric/Ferromagnetic $BiFeO_3$-$CoFe_2O_4$ Thin Films*** SHENG YU YOUNG, LOURDES G. SALAMANCA-RIBA, *Materials Science and Engineering Department, University of Maryland, College Park* HAIMEI ZHENG, *Materials Science and Engineering Department, University of California Berkeley* We have investigated the mechanism of the self-assembly of $BiFeO_3$-$CoFe_2O_4$ (BFO-CFO) ferroelectric/ferromagnetic thin film nanostructures using high-resolution transmission electron microscopy. We discuss the formation of the CFO columnar structure during the deposition process. The BFO-CFO thin films were deposited on $SrTiO_3$ (001) single crystal substrates using pulsed laser deposition at a substrate temperature of 700 $^oC$ and deposition rate of around 5nm/min. In the early stages of growth, CFO domains form with dome like island shape and are covered by a BFO layer. After approximately 10 mins of continuous deposition, the nanocomposite rearranges and diffusion dominates to form a self-assembly of faceted CFO columns that extend to the surface of the film. These columns show pyramidal-like faceted shape and are embedded in the BFO matrix. A few atomic layers of BFO lie at the interface between the CFO columnar structures and the substrate. This layer helps relax the misfit strain between CFO and STO. The magnetic properties of the nanocomposite samples will also be presented.

**16:42**

**R20 12 Electrical and Magnetic Properties of $Pb(Zr,Ti)O_3/CoFe_2O_4$ Composite Thin Films** NORA ORTEGA, S. MAJUMDER, P. BHATTACHARYA, R.S. KATIYAR, *University of Puerto Rico* P. DUTTA, M.S. SEEHRA, A. MANIVANNAN, *West Virginia University* Composite thin films made of ferroelectric and ferromagnetic materials are the potential candidates for sensors, data storage, and transducers due to possible manipulation of magnetic properties by electric field and vice versa. In this work, we have fabricated $Pb(Zr,Ti)O_3-CoFe_2O_4$ (PZT-CFO) multilayer thin films using pulsed laser deposition on $Pt/TiO_2/SiO_2/Si$ substrates at 400 °C and post annealed at 650°C using rapid thermal annealing (RTA) process. The X-ray diffraction studies revealed the growth of the perovskite PZT and the spinel CFO in two separated phases in the composite films. The dielectric constant ($\varepsilon_r$) of PZT-CFO multilayer showed strong frequency dispersion with an order of magnitude decrease in the frequency range of 1kHz to 1MHz. Similar decrease in $\varepsilon_r$ was also observed with decrease of temperature from 300 to 150 K. The remanent polarization ($P_r$) of the film (23 $\mu C/cm^2$) was also reduced to 1 $\mu C/cm^2$with decrease in the temperature (at 100 K). The magnetic measurements in the composite thin films showed the saturation magnetization ($M_s$) to be 9 emu/cm$^3$ at room temperature that increased to 38 emu/cm$^3$ at 5 K.

**R20 13 Quantum Monte Carlo calculations of $BiScO_3$ ferroelectric well-depths*** HENDRA KWEE, *College of William and Mary* HENRY KRAKAUER, *College of William and Mary* SHIWEI ZHANG, *College of William and Mary* The perovskite (1-x) $BiScO_3$-x $PbTiO_3$ alloy has been reported as having a large piezoelectric properties.[1] Density functional theory (DFT) using local density approximation (LDA) predicts an extraordinarily large ferroelectric well depths (about 1.2 eV) of the end point compound $BiScO_3$.[2] We perform quantum Monte Carlo calculations on $BiScO_3$ to calculate these well depths. In our QMC method,[3] the two-body terms coming from electron-electron interactions are decoupled using a Hubbard- Stratonovich transformation. The ground state is obtained from projection of an initial trial wave function by random walks in Slater determinant space. To control the sign/phase problem, a trial Slater determinant is used, which in our calculations is taken directly from the DFT calculations. We find in the QMC calculation large finite-size effects in the primitive cell, on the order of a few eV. We study these finite-size effects and explore several schemes to reduce them.

**R20 14 Magnetic and structural properties of $CeO_2$ nanoparticles*** PRASANTA DUTTA, SUSMITA PAL, MOHINDAR SEEHRA, *West Virginia University* G. TURPIN, R. ERNST, *University of Utah* CONSORTIUM COLLABORATION, Nanoparticles of cerium oxide, $CeO_2$, have potential applications in catalysis, fuel cells, microelectronics etc [1]. In this work, we have investigated the magnetic and structural properties of 10%$CeO_2$ supported on $SiO_2$ aerogel with a BET surface area $\approx$ 700 $m^2$/g. X-ray diffraction (XRD) studies show cubic $CeO_2$ as the dominant phase with particle size $\approx$ 3 nm. Temperature variation (2K – 350K) of the magnetic susceptibility $\chi$ shows Curie-type variation with the Curie constant C = 5.9 $\times$ $10^{-5}$ emu K/g Oe. In electron magnetic resonance (EMR) studies from 5 K to 300 K at 9.28 GHz, an EMR line at g $\approx$ 2.1 with linewidth $\Delta$H $\approx$ 100 Oe is observed for T $<$ 40 K. Since $Ce^{4+}$ in $CeO_2$ is diamagnetic, we tentatively suggest that the observed Curie variation of $\chi$ and the EMR line [2] are due to paramagnetic $Ce^{3+}$ present in oxygen-lean $CeO_2$ nanoparticles. From the magnitude of C, the concentration of $Ce^{3+}$ is estimated to be $\approx$ 3 %. Further studies are in progress. [1]. S. Sathyamurthy et al, Nanotechnol. 16, 1960 (2005). [2]. D. Schaniel et al, Phys. Rev. B 70, 144410 (2004).

**R21 1 Large-scale pattern formation in active particles suspensions: From interacting microtubules to swimming bacteria.***
IGOR ARANSON, *Argonne National Laboratory*

We consider two biological systems of active particles exhibiting large-scale collective behavior: microtubules interacting with molecular motors and hydrodynamically entrained swimming bacteria. Starting from a generic stochastic microscopic model of inelastically colliding polar rods with an anisotropic interaction kernel, we derive set of equations for the local rods concentration and orientation. Above certain critical density of rods the model exhibits orientational instability and onset of large-scale coherence. For the microtubules and molecular motors system we demonstrate that the orientational instability leads to the formation of vortices and asters seen in recent experiments. Similar approach is applied to colonies of swimming bacteria itBacillus subtilis confined in thin fluid film. The model is formulated in term of two-dimensional equations for local density and orientation of bacteria coupled to the low Reynolds number Navier-Stokes equation for the fluid flow velocity. The collective swimming of bacteria is represented by additional source term in the Navier-Stokes equation. We demonstrate that this system exhibits formation of dynamic large-scale patterns with the typical scale determined by the density of bacteria.

**R21 4 Stress-induced reversal of flagellar propulsion: an ingredient of quorum polarity of *Bacillus subtilis****
L. CISNEROS, C. DOMBROWSKI, R.E. GOLDSTEIN, J.O. KESSLER, *University of Arizona* Recent experiment have shown large-scale dynamic coherence in suspensions of the bacterium *B. subtilis*, characterized by quorum polarity – the collective parallel swimming of cells. To probe mechanisms leading to quorum polarity, we study the response of individual *B. subtilis* cells to steric stress brought on by swimming into a micron-sized spatial constriction. Careful visualization shows that cells can fully reverse their swimming direction at spatial constrictions without turning the cell body. This property, termed ''flippancy,'' is quantified by measurements of the inward and outward swimming velocities, accelerations and decelerations, and docking times. The asymptotic inward and outward swimming speeds far from the constriction show near perfect correlation, implying that the propelling flagella flip, and that ''forwards'' and ''backwards'' are dynamically indistinguishable, as with *E. coli*. Implications for the collective dynamics are discussed.

**R21 5 Effects of nonlinear membrane elasticity on capsule recovery*** ANDRES GONZALEZ-MANCERA, CHARLES EGGLETON, *UMBC* The recovery of a capsule from an initially deformed shape is considered. The problem is solved numerically for a capsule made of an incompressible liquid surrounded by a thin elastic membrane using the Boundary Integral Method. Elastic membranes with different constitutive models providing a wide range of behaviors at large deformations (strain-hardening, strain-softening and linear elastic) were considered. The results suggest that the recovery process is dominated by the isotropic dilatation modulus. The recovery process from small deformations was seen to be nearly independent of the membrane constitutive model. Recovery from large deformations was highly dependent on the constitutive model and the initial geometry of the capsule. Analysis of the recovery from large deformations demonstrated that the process is modulated by the tangential component of the elastic traction, $\backslash F_t$, acting on the membrane. This component of the traction was seen to either favor or oppose the recovery depending on the constitutive equation used to model the elastic membrane. The differences in the recovery process can be used to identify the best model for a particular capsule based on features observed during the recovery process.

**R21 6 Balancing energy input and viscous dissipation in the Zooming BioNematic*** J.O. KESSLER, *U. Arizona* R.E. GOLDSTEIN, *University of Arizona* R. CORTEZ, *Tulane U.* Beyond a concentration threshold, populations of the swimming bacteria *Bacillus subtilis* form a phase (the Zooming BioNematic=ZBN) comprising intermittent domains of co-aligned cells all swimming in the same direction. Collectively generated hydrodynamic forces between bacteria, the cells' ability to flip flagella, thereby changing swimming polarity, and their tendency to swim upstream into a collectively generated current are fundamental interactions leading to the ZBN. But how does the ZBN generate dynamic patterns, similar to ones at $Re \gg 1$? The energy put into the fluid by the swimming organisms overwhelms viscous damping, as demonstrated by a new dimensionless ratio $Bs$, analogous to $Re$ but replacing the numerator by a measure of bacterial energy input. The magnitude of $Bs$ is estimated via the Navier-Stokes equations, considering individual bacteria at moderate concentration, and entire domains at high. $Bs$ is proportional to the bacterial concentration, and in both of those regimes, $Bs \gg 1$. Remarkably, unlike the Reynolds number, $Bs$ is independent of viscosity.

**R21 7 Multicellularity and the Functional Interdependence of Motility and Molecular Transport*** C. SOLARI, S. GANGULY, J.O. KESSLER, R. MICHOD, R.E. GOLDSTEIN, *U. of Arizona* Benefits, costs and requirements accompany the transition from motile totipotent unicellular organisms to multicellular organisms having cells specialized into reproductive (germ) and vegetative (sterile soma) functions such as motility. In flagellated colonial organisms such as the volvocalean green algae, organized beating by the somatic cells' flagella yields propulsion important in phototaxis and chemotaxis. It has not been generally appreciated that for the larger colonies, flagellar stirring of boundary layers and remote transport are fundamental for maintaining a sufficient rate of metabolite turnover, one not attainable by diffusive transport alone. We describe experiments that quantify the role of advective dynamics in enhancing productivity in germ-soma differentiated colonies. First, experiments with suspended deflagellated colonies of *Volvox carteri* show that forced advection improves productivity. Second, Particle Imaging Velocimetry of fluid motion around colonies reveals flow fields with very large characteristic velocities $U$ extending to length scales comparable to the colony radius $R$. For a typical metabolite diffusion constant $D$, the Peclet number $Pe = 2UR/D \gg 1$, indicative of the dominance of advection over diffusion, with striking augmentation at the cell division stage.

**R21 8 Flagella-Driven Flows Circumvent Diffusive Bottlenecks that Inhibit Metabolite Exchange*** MARTIN SHORT, CRISTIAN SOLARI, SUJOY GANGULY, JOHN KESSLER, RAYMOND GOLDSTEIN, *University of Arizona* THOMAS POWERS, *Brown University* The evolution of single cells to large and multicellular organisms requires matching the organisms' needs to the rate of exchange of metabolites with the environment. This logistic problem can be a severe constraint on development. For organisms with a body plan that approximates a spherical shell, such as colonies of the volvocine green algae, the required current of metabolites grows quadratically with colony radius whereas the rate at which diffusion can exchange metabolites grows only linearly with radius. Hence, there is a bottleneck radius beyond which the diffusive current cannot keep up with metabolic demands. Using *Volvox carteri* as a model organism, we examine experimentally and theoretically the role that advection of fluid by surface-mounted flagella plays in enhancing nutrient uptake. We show that fluid flow driven by the coordinated beating of flagella produces a convective boundary layer in the concentration of a diffusing solute which in turn renders the metabolite exchange rate quadratic in the colony radius. This enhanced transport circumvents the diffusive bottleneck, allowing increase in size and thus evolutionary transitions to multicellularity in the Volvocales.

**R21 9 Measurement of Flow Patterns and Dispersion in the Human Airways*** FRANK E. FRESCONI, AJAY K. PRASAD, *Department of Mechanical Engineering, University of Delaware* A detailed knowledge of the flow and dispersion within the human respiratory tract is desirable for numerous reasons. Both risk assessments of exposure to toxic particles in the environment and the design of medical delivery systems targeting both lung-specific conditions (asthma, cystic fibrosis, and chronic obstructive pulmonary disease (COPD)) and system-wide ailments (diabetes, cancer, hormone replacement) would profit from such an understanding. The present work features experimental efforts aimed at elucidating the fluid mechanics of the lung. Particle image velocimetry (PIV) and laser induced fluorescence (LIF) measurements of oscillatory flows were undertaken in anatomically accurate models

(single and multi-generational) of the conductive region of the lung. PIV results captured primary and secondary velocity fields. LIF was used to determine the amount of convective dispersion across an individual generation of the lung.

**R21 10 On small insect flight – A two-dimensional study** PAULO FERREIRA DE SOUSA, *New Mexico State University* Small insect flight is characterized by very small Reynolds numbers and relatively simple wing motions. In this study, a two-dimensional approximation of small insect flight is calculated with a newly developed high-order immersed boundary incompressible Navier-Stokes flow solver. The simulated motion of the model wing is a simplification of the flight of Drosophila melanogaster, and was done in line with previous experimental and numerical simulations available in the literature. Calculations were carried out until a time-periodic steady-state was achieved. Changes in lift generation and vortex dynamics are studied for Reynolds numbers spanning two orders of magnitude, in order to accurately find the critical Re number above which flapping flight is possible. Above the critical Reynolds number, vortices are alternately shed during translation. Below the critical Reynolds number, vortices are formed but not shed during translation, creating two attached and almost identical vortices. This transition is significant because, below it, an important mechanism of lift generation no longer applies, effectively indicating a lower bound for insect flight to occur.

**16:54**
**R21 11 Wake characteristics of a model ornithopter** ALFREDO JUAREZ, *New Mexico State University* JACOB HARLOW, *New Mexico State University* JAMES ALLEN, *New Mexico State University* PAULO FERREIRA DE SOUSA, This paper details unsteady wake measurements from a model Ornithopther flying in a wind tunnel at representative flight conditions. Testing over a range of Strouhal number, 0.1-0.3, shows that the unsteady wake is composed of coherent vortical structures that resemble vortex rings. A single ring is formed in the wake of each wing during one wing beat. Momentum balance from velocity field measurements are reconciled with unsteady lift and drag measurements from a drag balance.

**17:06**
**R21 12 Vertical hovering of a symmetric flapping model** MAKOTO IIMA, TATSUO YANAGITA, *Hokkaido University* We study the motion of a model equipped with flapping wings under the influence of gravity (external force). This model moves in a two-dimensional fluid according to the hydrodynamic force generated by vortices separated from its wings. As a result of the interaction between the vortices and the wings, the model moves steadily in a direction against the gravity. Moreover, hovering, i.e., a steady flight staying in a particular position, can be achieved here by the effective use of vortex structures enhancing the hydrodynamic force that supports the model against gravity. The system exhibits a transition from the state with hovering to a state where hovering is impossible, as the model parameters are changed.

**R22 1 Magnetic Viruses: Utilizing Self-Assembly for Biomedical Applications.***
AXEL HOFFMANN,† *Materials Science Division, Argonne National Laboratory*

Magnetic nanoparticles coated with biochemical surfactants have emerged recently as an important component for enabling many biological and medical applications. We implemented a biotemplating approach to create such magnetic nanoparticles by utilizing native protein capsid shells derived in high yield from the T7 bacteriophage virus.[1] The magnetic nanoparticles are grown via bio-mineralization reactions inside of hollowed-out capsids that retain their original chemical recognition properties. The resultant ''magnetic viruses'' are uniform in geometry, physical properties, and biochemical functionality. This makes these viruses ideally suited for many biomedical applications among which we investigated specifically a novel sensing scheme for target recognition based on Brownian relaxation.[2] For this scheme we use the *ac*-susceptibility of the functionalized magnetic nanoparticles suspended in liquid. Upon binding the target of interest to the particles, their Brownian relaxation time is modified, which is readily detected by a change of the frequency dependence of the magnetic susceptibility. This scheme has several advantages; (i) it requires only one binding event for sensing; (ii) there is a useful signal both in the absence and presence of the target; (iii) the signal contains information

about the size of the target besides the biochemical affinity; and (iv) since the binding modifies the magnetic susceptibility of the magnetic particles there is no need for removing unbound labels.

**R22 2 Atomic model for the exchange bias in Fe/FePt(110) alloy** CHANYONG HWANG, W. KIM, *Korea Research Institute of Standards and Science* J.S. PARK, Y.P. LEE, *Department of Physics and q-Psi, Hanyang University* S.C. HONG, *Department of Physics, Ulsan University* Fe overlayers on top of Pt(110) surface have been studied using STM and SMOKE. Based on our atom-resolved STM data, we have shown the atomic model for the growth of this system. One of the interesting system is the one grown at elevated temperature. In this case, Fe-Pt surface alloy is formed on top of Pt(110) surface. This surface alloy still maintains the lattice constant of Pt substrate and reveals to be an antiferromagnet. In addition to the field cooling upon additional Fe layers, our first principles calculation clear shows the antiferromagnetic order. For the unified picture of the exchange bias phenomena, we need an atomically resolved antiferromagnetic surface and we will present the possible mechanism of this exchange bias in our system.

**15:18**
**R22 3 Competing Mechanisms in Asymmetric Magnetization Reversal in Exchange Biased Bilayers*** OLEG PETRACIC,† ZHI-PAN LI, IVAN K. SCHULLER, *Physics department, University of California, San Diego, La Jolla* A systematic micromagnetic simulation is performed to investigate the asymmetric magnetization reversal in exchange bias bilayers. When the unidirectional anisotropy is comparable with the uniaxial anisotropy of the ferromagnet, we found that the descending branch is dominated by rotation while the ascending one is dominated by domain wall motion. When the unidirectional anisotropy is large enough, the magnetization reversal occurs through FM incomplete domain walls parallel to the interface. This results in a larger transverse component in the ascending branch, opposite to the previous mechanism. These two mechanisms coexist and compete for intermediate unidirectional anisotropies and lead to very delicate situations in particular when a magnetic field misalignment and interfacial inhomogeneity are involved. The results are able to explain some of the confusion in the present study of the asymmetric reversal mechanisms.

**R22 4 Magnetization Precession in Interlayer Exchange-Coupled Thin Films*** STEVEN MICHALSKI, JIAN ZHOU, RALPH SKOMSKI, NIKOLAY POLUSHKIN, ROGER KIRBY, *Department of Physics and Astronomy and Center for Materials Research and Analysis, University of Nebraska-Lincoln, 68588-0111, Lincoln, NE* We have studied the static and fast dynamic magnetic properties of exchange-coupled magnetic layers using both magneto-optical measurements and conventional magnetometry. The samples studied include [Co/Pt] multilayers with perpendicular magnetic anisotropy (PMA) coupled via a variable thickness intervening Cu (Pt) layer to a Co (Sm-Co) layer with in-plane magnetic anisotropy. Such systems should exhibit a wide variety of magnetic configurations, permitting control of magnetic properties through control of exchange strength and PMA. The hysteresis loops show direct evidence of ferromagnetic exchange coupling. We report here the results of magnetization precession measurements using a femtosecond laser in a pump-probe experiment with direct optical excitation. For the samples studied so far, we observe only one precession frequency for a given applied magnetic field, rather than the expected two, but the frequency varies with the thickness of the coupling layer as expected. Our results are interpreted in terms of an LLG model which includes PMA and variable exchange coupling.

*Work supported by NSF-MRSEC, W. M. Keck Foundation and CMRA

**15:42**
**R22 5 Exchange coupling in multilayers with perpendicular magnetic anisotropy** JIAN ZHOU, RALPH SKOMSKI, STEVEN MICHALSKI, ROGER KIRBY, DAVID SELLMYER, *Department of Physics and Astronomy and CMRA, University of Nebraska, Lincoln, NE 68588* Recently much attention has been paid to the interlayer exchange coupling (IEC) through nonmagnetic layers, for especially certain applications. In this work we investigate the interlayer exchange coupling through Cu or Pt spacer layers between two magnetic phases with perpendicular or in-plane anisotropy. $(Pt5Å/Co3Å)_3$ layers with perpendicular magnetic anisotropy (PMA) are exchange-coupled to an in-plane anisotropic Sm-Co 30Å layer through a Pt spacer. The competing anisotropies and IEC in the system yield a spin-reorientation transition behavior with a varying Pt thickness. We also have studied $(Pt5Å/Co3Å)_3$ layers which are exchange-coupled to $(Co3Å/Pt5Å)_3$ through a Cu spacer. Transition from single phase hysteresis to two-phase behavior indicates a reducing IEC between the PMA layers with increasing Cu thickness. Both model calculations and micromagnetic simulations show that interlayer exchange

coupling is essential in calculating the hysteresis, and indicate how the interlayer coupling can be tuned by changing the spacer thickness. *This research is supported by DOE, NSF-MRSEC, the W. M. Keck Foundation, and CMRA.

**R22 6 Spin Dynamics in Exchange Biased Co/FeMn Bilayers*** JEFFREY PARKER, MUN CHAN, MELISSA HAUGEN, BRUCE BOLON, CHRIS LEIGHTON, PAUL CROWELL, *University of Minnesota* We report a study of the spin dynamics in exchange biased Co/FeMn bilayers using time resolved Kerr microscopy (TKRM) with sub-nanosecond resolution. Samples were prepared via UHV dc magnetron sputter deposition onto a $Si/SiO_x$ substrate at room temperature in an applied field of 300 Oe. Deposition of a 30nm Cu buffer layer allowed for (111) textured growth of the subsequent Co/FeMn layers. In all samples the Co thickness was held constant at 6nm, while the FeMn thickness, t, was varied between 0 and 20nm. In accordance with previous work we found a room temperature critical thickness of the FeMn layer of approximately 3.5nm and a broad peak in the coercivity at this thickness. For low FeMn thickness a noticable asymmetry occurs in the magnetization hysteresis loops only for temperatures below the blocking temperature. TRKM is used to probe the dynamic response of the magnetization to fast magnetic field pulses. The different reversal mechanisms on either side of the hysteresis loop were probed by both the static and dynamic magnetization of the films as a function of temperature (between 40 and 450 K), and applied field.

**R22 7 Exchange Bias in $Fe_xNi_{1-x}F_2$/Co Bilayers*** MIYEON CHEON, ZHONGYUAN LIU, DAVID LEDERMAN, *Multifunctional Materials Laboratory, Dept of Physics, West Virginia University* $FeF_2$ is an ideal antiferromagnet with a tetragonal rutile crystal structure and a strong uniaxial magnetic anisotropy along the *c*-axis ([001] direction). $NiF_2$ also shares the rutile crystal structure with similar lattice parameters, but its magnetic anisotropy causes spins to be in the $a - b$ plane, resulting in a weak ferromagnetism due to a small tilting of the antiferromagnetic sublattices. Because several theories predict that exchange bias should be a strong function of the magnetic anisotropy in the antiferromagnet, the $Fe_xNi_{1-x}F_2$/Co bilayer system provides a framework whereby this can be studied experimentally. We have grown several single-crystalline $Fe_xNi_{1-x}F_2$50 nm thick films on $MgF_2$ (110) substrates via molecular beam epitaxy with *x* varying between 0 and 1.0. We will report on the exchange bias as a function of Fe concentration in the alloy.

*Supported by NSF grant DMR-0400578.

**R22 8 Dynamics of Spontaneous Magnetization Reversal in Exchange Biased Bilayers*** ZHI-PAN LI, CASEY W. MILLER, IGOR V. ROSHCHIN, IVAN K. SCHULLER, *Physics Department, UC San Diego, La Jolla, CA 92093* We observe a temperature-driven magnetization reversal of a ferromagnet (FM= Ni, Co) magnetization under a constant magnetic field, when it is exchange biased by an antiferromagnet (AF=$FeF_2$). We attribute this phenomenon to the competition of the AF interfacial coupling and the FM Zeeman energy. This striking behavior allows us to investigate the AF dynamics through the FM reversal behavior. We found that the magnitude of FM reversal for a given cooling field strongly depends on the cooling speed, and the wait time around the Néel temperature. This shows the magnetic viscosity of the AF around its phase transition temperature. Moreover, by thermal cycling, the FM exhibits successive spontaneous reversal. This thermal training effect further points to high energy barriers resulting in slow dynamic processes of the system.

**R22 9 Exchange bias measurements of epitaxial magnetic oxide exchange bias bilayers.** XIANGLIN KE, LAND BELENKY, CHANG-BEOM EOM, MARK RZCHOWSKI, *University of Wisconsin-Madison* NIRT TEAM, It has been shown in epitaxial bilayers that antiferromagnetic exchange coupling exists at atomically abrupt interfaces between ferromagnetic oxides $La_{0.67}Sr_{0.33}MnO_3$ and $SrRuO_3$ [1,2]. We have grown the bilayers on (001) $SrTiO_3$ substrates by pulsed laser deposition with atomic layer control. By analyzing the in-plane magnetization loops of the LSMO layer, and the total magnetization of the (frozen) SRO layer, we determine the exchange field of the bilayer and the domain structure of the $SrRuO_3$ biasing layer as a function of cooling field. This data shows evidence for domain walls both parallel and perpendicular to the interface. We support this conclusion with a simple energy minimization including contributions from the interfacial exchange, dipole interaction with the cooling field, domain wall energies, and magnetostatic energy. We also pattern the samples with e-beam and x-ray lithography techniques. Size effect on coercivities of both LSMO and SRO electrodes and exchange bias in the bilayers will be discussed. [1] X. Ke, M. S. Rzchowski, L.J. Belenky, C. B. Eom, Appl. Phys. Lett, **84**, 5458 (2004). [2] X. Ke, L.J. Belenky, C. B. Eom, M. S. Rzchowski, J. Appl. Phys. **97**, 10K115 (2005).

**R22 11 Effects of coupling on domain structure of [Pt(6Å)/Co(4Å)]$_3$/NiO($t_{NiO}$)/[Co(4Å)/Pt(6Å)]$_3$ multilayers with oscilla-**

**tory coupling*** ANDREW BARUTH, S.H. LIOU, S. ADENWALLA, *Department of Physics and Astronomy and Center for Materials Research and Analysis, University of Nebraska, Lincoln, NE 68588* D.J. KEAVNEY, *Advanced Photon Source, Argonne National Laboratory, Argonne, IL 60439* Multilayered structures of Pt(6Å)/Co(4Å)$]_3$/NiO($t_{NiO}$)/[Co(4Å)/Pt(6 Å)$]_3$ show oscillatory exchange coupling between the two Co/Pt layers [1]. One possible mechanism for the exchange coupling may be via the propagation of canted NiO spins at the interface, an effect that can reproduce the oscillatory coupling [2] and that has been seen using X-ray Magnetic Circular Dichroism [3]. Domain images on virgin samples taken with XMCD-PEEM and MFM reveal a direct correlation between domain size and absolute coupling strength. The coupling strength was varied by changing both NiO and Pt thicknesses. MFM images show that the coupling in both FM and AFM coupled samples occurs domain by domain. FM domains form within the AFM domain wall due to a slight relative shift of the domains in the upper and lower multilayers. These FM regions contain visible stripes corresponding to opposite net magnetizations in the domain wall. [1] Phys. Rev. Lett. 91, 037207 (2003) [2] Phys. Rev. Lett. 92, 219703 (2004) [3] Phys. Rev. B 70, 224423 (2004)

**R22 13 Ferromagnetism of CoAl(100) induced by oxidation at 300 K** VOLKER ROSE, *Center for Nanoscale Materials (CNM), Argonne National Laboratory* KLAUS BRUEGGEMANN, RUDOLF DAVID, HARALD IBACH, *Institute for Surfaces and Interfaces (ISG 3), Research Center Juelich, Germany* In situ magneto-optical Kerr effect measurements were performed to investigate the magnetic behavior of CoAl(100) upon oxidation at room temperature. As an ideal $Co_{50}Al_{50}$ crystal is known to be paramagnetic at room temperature, our studies show a transformation into a ferromagnetic phase during increasing exposure to $O_2$. Oxidation of CoAl(100) at 300 K leads to the growth of an amorphous $Al_2O_3$ film [1], causing a Co excess at the metal/oxide interface that is sufficient to provide ferromagnetism. Annealing of the oxidized sample brings about a drastic increase of the coercive field, generated by diffusion of Al into the Co film. But, after annealing at 550 K, the ferromagnetism vanishes completely. [1] V. Rose, V. Podgurski, I. Costina, R. Franchy, Surf. Sci 541 (2003) 128.

**R23 1 Nanomagnetic Simulations of Recording Media.***
THOMAS SCHREFL, *University of Sheffield*

The optimization of ultra-high density recording systems requires the joint simulation of the recording head, the data layer and the soft underlayer. This talk presents micromagnetic simulations of recording processes in perpendicular and patterned media. The numerical technique for the multiscale simulation combines the finite element method with an accelerated boundary method. The use of hierarchical matrices and FFT methods significantly speeds up the computation time for the magnetostatic interactions between the head and the data layer. In addition to dynamic magnetization processes, energy barriers of recording media are calculated using a nudged elastic band method. The rise time of the write field was found to depend significantly on vortex motion in the pole tip of the head. The shortest field rise time was obtained for intermediate values of the Gilbert damping constant. Under the influence of the write field, magnetization reversal in composite perpendicular media occurs by the nucleation and expansion of reversed domains. However, thermally activated switching in composite media shows reversal by quasi-uniform rotation. Therefore it is possible to keep a high energy barrier while reducing the switching field in composite media, where a soft magnetic layer is exchange coupled to the hard magnetic layer. The energy barrier of composite media was calculated as a function of the applied

field. The results show that the extrapolation of barriers measured at high fields underestimates the zero-field energy barrier. The calculated energy barrier of an island of a patterned media is smaller than the anisotropy constant times the island volume. This result shows that thermally activated magnetization reversal in patterned islands is non-uniform. The energy barrier of a square island with a size of only 20 nm was found to be 17% lower than the barrier expected for uniform rotation.

**R23 2 Magnetization Dynamics in Ultrahigh-Density Magnetic Recording*** R. SKOMSKI, J. ZHOU, D. J. SELLMYER, *Department of Physics and Astronomy and Center for Materials Research and Analysis, University of Nebraska, Lincoln, NE* Thermally activated magnetization reversal is a key consideration in the development of magnetic recording materials with ultrahigh densities. We consider the onset of magnetization reversal (nucleation) and describe the magnetization by a Langevin model, where the magnetization dynamics is realized by random thermal forces. The exchange, anisotropy, and Zeeman energies are expanded into powers of a small perpendicular magnetization component, and the dynamics reduces to a time-dependent superposition of normal modes. In the Stoner-Wohlfarth (SW) model, the approach reproduces the Arrhenius-Néel-Brown law $\tau = \tau_o \exp(E_a \backslash k_B T)$ with an approximate energy barrier $E_a$ and a particle-size dependent constant $\tau_o$. The same is true for the micromagnetic approach, where the local micromagnetic parameters such as $K_1(\mathbf{r}) = < K_1(\mathbf{r})>$ give rise to nonuniform magnetization modes in inhomogeneous and interacting particles. However, both the coercivity $H_c$ and the energy barrier $E_a$ are smaller than the SW predictions. A further reduction of $H_c$ and $E_a$ is obtained by taking into account local anisotropy fluctuations of the type $< K_1(\mathbf{r})^2 > - K_1(\mathbf{r})^2$. This reduction corresponds to fluctuating energy barriers, and establishes a particle-shape and materials-dependent upper limit to energy barriers in very small particles.

*This research is supported by NSF MRSEC, DOE, INSIC, and CMRA.

**15:18**

**R23 3 Experimental determination of switching field distributions in perpendicular and patterned recording media** ANDREAS BERGER, *Hitachi Global Storage Technologies* BYRON LENGSFIELD, YOSHIHIRO IKEDA, OLAV HELLWIG, ERIC FULLERTON, We have developed and applied a magnetometry method for the measurement of intrinsic switching field distributions in magnetic recording media [1]. The method is based upon a comparison between the major loop and a set of recoil loops, which start at a certain distance $\Delta M$ away from saturation. Hereby, we measure the applied field difference $\Delta H$ between the recoil loops and the major loop at identical M-values. By simultaneously analyzing complete $\Delta H(M, \Delta M)$-data sets, we gain a refined measure of the entire switching field distribution $D(H_S)$. We studied the reliability of this method by means of micromagnetic modeling and find it to be robust and precise in reproducing the input parameters. In particular, the method is rather insensitive to inter-granular exchange coupling up to a certain threshold value. Also, a self-consistency check of the methodology was developed. An existing polar-MOKE setup was adapted to allow for $\Delta H(M, \Delta M)$-data acquisition, which enables a non-destructive sample characterization that is also compatible with the disk shape of recording media. Measurements on perpendicular and patterned recording media were made and results were compared to recording performance tests. [1] A. Berger, B. Lengsfield, Y. Ikeda, Y. H. Xu, and E. E. Fullerton, IEEE Trans. MAG **41**, 3178 (2005)

**R23 4 Simulations Of Nanomagnet Clusters With Perpendicular Uniaxial Anisotropy For Multilevel Data Storage** QIJUN XIAO, *Umass, Amherst, Physics Dept.* ROBERT KROTKOV, *Umass, Amherst, Physics Dept.* MARK TUOMINEN, *Umass, Amherst, Physics Dept.* UMASS, AMHERST, PHYSICS DEPT. TEAM, Digital data storage technology generally relies on a binary storage paradigm. In this work we explore a different scheme that exploits the stepwise, itmultilevel total magnetization of a small cluster of interacting nanomagnets. The magnetization of a cluster can be resolved more easily than that of a single nanomagnet, due to the larger lateral size. Micromagnetic simulations, based on the Landau-Lifshitz-Gilbert (LLG) equation with parameters representative of $Co_3Pt$, reveal that magnetostatic interactions within a cluster produce a rich multilevel magnetic response, each level providing a stable remanent magnetization state. This work describes simulations used to investigate a multilevel data storage unit based on a hexagonal cluster of interacting uniaxial single domain nanomagnets. The accessibility and stability of the discrete magnetization states are studied. The switching properties of the nanomagnet clusters can be tuned by modifying the geometry, providing the ability to engineer desirable magnetic properties.

**15:42**

**R23 5 Magnetic properties of nanosized systems, discrete and continuum approaches*** PATRICIO VARGAS, DAVID LAROZE, *Universidad Santa Maria* In this work we present results obtained with a scaled Monte Carlo technique in two systems: The first one is the system proposed at the NIST web page and known as the $\mu$MAg Standard Problem No 3. There, the system is a perfect cube made of a magnetic material, with uniaxial anisotropy and the problem is to find the critical edge length at which the magnetic vortex structure and the most uniform arrangement of magnetization (the so-called flower state) are of equal energy. The second system is a study of the reversion process in an ideally soft magnetic nanowire of cylindrical shape, (diameter of 60nm and 1$\mu$m length) at room temperature. By calculating magnetic energies, using continuum and exact methods, in a simple one dimensional discrete system, we show that the

usual scaling technique used in some micromagnetic models breaks down at the nanometer scale.

**15:54**

**R23 6 Micromagnetism in the ultrathin limit** DANILO PESCIA, OLIVER PORTMANN, MATTHIAS BUESS, ALESSANDRO VINDIGNI, ANDREAS VATERLAUS, *Laboratory for Solid State Physics, ETH Zurich* CHRISTIAN HORST BACK, *Institut für Experimentelle und Angewandte Physik, Universität Regensburg,* We derive some results concerning the static and dynamic micromagnetic behavior of magnetic elements in the ultrathin limit. In this limit, a most remarkable, shape-independent, logarithmic correction of the magnetostatic energy appears, produced by the long-range character of the dipolar interaction. Apparently unrelated phenomena such as the pinning of the precessional motion at some of the boundaries of a thin magnetic element, the non-pinning at other boundaries and a multi-to-single-domain transition in ultrathin elements with perpendicular magnetization have a common origin: the logarithmic correction.

**16:06**

**R23 7 Magnetic properties of coupled Gd/Pd/Ni thin films** ILIR ZOTO, GARY MANKEY, *MINT Center, Department of Physics, University of Alabama* Transition metal-rare earth bilayers might allow magnetizations higher than that available from transition metal if the strong exchange interactions of the transition metal layer could be used to raise the Curie temperature of an adjacent, high moment rare earth layer. Literature suggested for a ferromagnetic interaction in the Ni-Gd bulk alloys and an increased moment at room temperature when Gd layer is deposited onto thin Co and permalloy films. Recently, we found that Ni/Gd bilayers couple antiferromagnetically at the interface. Adding a spacer layer could change the coupling behaviour. Here, a study of a Gd(15nm)/Pd(tnm)/Ni(10nm) trilayer is presented with t varying from 0.5 to 2.5nm. The hysteresis loops were measured with VSM in the temperature range 5-250K. A Stoner-Wolfarth model simulates the hysteresis loops through the minimization of the energy of the following expression:

$$E = -M_1 H t_1 \cos(\theta_1) - M_2 H t_2 \cos(\theta_2) + K_1 t_1 \sin^2(\theta_1) + K_2 t_2 \sin^2(\theta_2) + J_1 \cos(\theta_1 - \theta_2) + J_2 \cos^2(\theta_1 - \theta_2)$$

where $J_1$ and $J_2$ are the bilinear and biquadratic coupling constants. The simulated loops are in good agreement with the experimental results and confirm the antiferromagnetic coupling of Ni and Gd layers for $t < 2.5$nm and the disappearance of the coupling for $t > 2.5$nm.

**16:18**

**R23 8 Influence of the antiferromagnet spin structure on exchange bias.** R. MORALES,*ZHI-PAN LI, *Physics Department, University of California San Diego, La Jolla, CA, USA* J. M. ALAMEDA, *Departamento de Física, Universidad de Oviedo, Oviedo, Spain* IVAN K. SCHULLER, *Physics Department, University of California San Diego, La Jolla, CA, USA* The exchange bias phenomenon (EB) is known by a shift of the hysteresis loop along the magnetic field axis ($H_{EB}$). In ferromagnet/antiferromagnet (FM/AF) thin films EB originates from the exchange interaction between FM and AF spins at the interface. Therefore, some theoretical models consider the EB as a purely interfacial phenomenon, but some experimental results are incompatible with these models. In this work we investigate the influence of an internal AF spin structure on EB. FM1/AF/FM2 trilayers have been prepared with disimilar FM1 and FM2 coercivities, so the sample can be cooled down below the AF Néel temperature with parallel or antiparallel FM magnetizations. It has been observed that $H_{EB}$ changes drastically from the parallel to the antiparallel cooling configuration for AF thicknesses $t_{AF} < 200$nm while it hardly varies for $t_{AF} > 300$nm. This result demonstrates that the internal spin structure of the AF is a key point to the understanding of EB. Work supported by US-DOE and European Marie-Curie-OIF.

**R23 9 First-principles study on the magnetic and structural properties of Fe-Co alloys*** DANGXIN WU, PING LIU, QIMING ZHANG, *The University of Texas at Arlington* RUQIAN WU, *University of California, Irvine* $Fe_xCo_{1-x}$ alloys with different compositions are investigated using first-principles methods, FLAPW and PAW, based on density functional theory. The structural geometries of the alloys were optimized at a given composition by PAW method implemented in VASP. The initial structures were fcc and hcp for Co-rich systems, and bcc for Fe-rich systems. The formation energies were then calculated and the stability of the alloys was studied. For those systems with lower symmetries and favorable formation energies, the magnetic properties, such as the saturated magnetization and the magnetocrystalline anisotropy, were carefully studied using the FLAPW method.

**R23 10 Magnetic depth profile of $La_{0.7}Ca_{0.3}MnO_3$/$YBa_2Cu_3O_{7-\delta}$ trilayers** S.G.E. TE VELTHUIS, A. HOFFMANN, *Argonne National Laboratory, Argonne, IL* V. PEÑA, D. ARIAS, C. LEON, J.L. MARTINEZ, J. SANTAMARIA, *Universidad Complutense de Madrid, Spain* M.R. FITZSIMMONS, B.J. KIRBY, *Los Alamos National Laboratory, Los Alamos, NM* M. VARELA, *Oak Ridge National Laboratory, Oak Ridge, TN* Recent experiments showed magnetoresistance in excess of 1000% in epitaxial tri- layers containing highly spin polarized $La_{0.7}Ca_{0.3}MnO_3$ (LCMO) manganite and high Tc superconducting $YBa_2Cu_3O_{7-\delta}$ [1]. This large magnetoresistance originates from spin imbalance due to the injection of spin polarized carriers. In a series of trilayers, with varying LCMO layer thickness, polarized neutron reflectometry has determined the detailed magnetization depth profile. For trilayers exhibiting a strong magnetoresistance, differences in the magnetization profiles of the two LCMO layers is observed, providing a mechanism for antiferromagnetic alignment during the magnetization reversal process. Obtained details of the magnetization at the interfaces lead to a better understanding of these variations. [1] V. Peña *et al.*, Phys. Rev. Lett **94** (2005) 057002.

**SESSION R24: BLOCK COPOLYMER APPLICATIONS**
**Wednesday Afternoon, 15 March 2006**

**14:30**
**R24 1 Catalysts from Block Copolymers** DAVID DURKEE, *Univ. of California-Berkeley* NITASH BALSARA, *Univ. of California-Berkeley* ALEXIS BELL, *Univ. of California-Berkeley* Homogeneous catalysts are widely used to catalyze chemical reactions in the liquid phase; however, the separation of the reactants and products from such a catalyst can be difficult and often limits their use in practice. For this reason there has been considerable interest in the heterogenization of homogeneous catalysts. The use of polymers for this purpose has been particularly attractive because of the availability of a wide range of polymeric structures and methods for catalyst incorporation. Our novel approach for heterogenizing homogeneous catalysts that involves the use of microphase separated block copolymers. Block copolymers are synthesized from a crosslinkable monomer that forms a supporting gel upon crosslinking, an organometallic monomer that is catalytically active, and a depolymerizable block that can be removed to form mass transfer pathways, or pores. When placed in a solvent, the polymer gel swells to facilitate transport of the reactants to the active centers and the transport of products from these centers. This is functionally similar to the synthesis of mesoporous siliceous materials created by an amphiphilic, structure-directing agent. However, in this system, placement of the catalyst site is also controlled by self-assembly.

**14:42**
**R24 2 Thermally Crosslinkable Diblock Copolymer Templates** JULIE LEISTON-BELANGER, THOMAS RUSSELL, *University of Massachusetts- Amherst* ERIC DROCKENMULLER, *IBM Almaden Research Center* CRAIG HAWKER, *University of California- Santa Barbara* The ability to create robust nanoporous templates using polymeric thin films is important for such applications as nanofabrication and selective filtration. Thermally crosslinkable diblock copolymers based on benzocylcobutene chemistry were synthesized that could be used to this end. Poly[(styrene-stat-benzocyclobutene)-b-(D,L-lactic acid)] (PSBCB-b-PLA) was made using living free radical and ring-opening polymerization techniques. This diblock copolymer was shown to microphase separate into a cylindrical morphology that could be stabilized by heating. The minor PLA component was then removed using base to create a nanoporous crosslinked template that was 30 nm thick, with pores about 14 nm in diameter. These nanoporous templates resisted pore collapse when subjected to harsh thermal and solvent conditions. Since the base degradation of PLA produces hydroxyl groups along the pore walls, the ability to access these groups, in conjuction with the thermal and solvent resistance, opens a wide range of organic reaction possibilities.

**14:54**
**R24 3 Ordered Hexagonal Arrays of Holes with 40 nm Period by Shear Alignment of Diblock Copolymer Bilayers** JOSE VEDRINE, DOUGLAS ADAMSON, RICHARD REGISTER, *Princeton University* THOMAS PICKTHORN, *Oxford University* PAUL CHAIKIN, *New York University* An ordered hexagonal array of holes was fabricated by shear-aligning a molten bilayer film of a sphere-forming diblock copolymer in a nitrogen atmosphere. The block copolymer consisted of a polystyrene (PS) matrix and polyisoprene (PI) spheres, and was spin-coated onto a Si substrate prior to shearing. The top layer of microdomains in the bilayer was removed via a nonselective fluorine-based reactive ion etch (RIE). The PI spheres in the remaining bottom layer were then degraded with ozone to produce a PS mask with an ordered array of voids. The voids were transferred into the Si substrate by RIE, producing a dense array of holes approximately 20 nm wide and spaced 40 nm apart. This bilayer shearing procedure allows for the production of hole arrays with excellent long-range orientational order and few grain boundaries, which are unachievable by shearing a single-layer film. In addition, Au was evaporated onto the array, yielding a film of Au with regular perforations having a 40 nm period.

**15:06**
**R24 4 Reversible Nanostructures Assembled from Amphiphilic Block Copolymers** CHEN XU, XUEFENG FU, MICHAEL FRYD, BRADFORD WAYLAND, KAREN WINEY, RUSSELL COMPOSTO, *University of Pennsylvania* We present a novel route to assemble perpendicular cylinders by converting an asymmetric diblock copolymer from poly(styrene-b-tert butyl acrylate) (PS-b-PtBA) to poly(styrene-b-acrylic acid) (PS-b-PAA) using an auto-catalytic reaction. Upon exposing films of PS-b-PAA to water, PAA cylinders constrained by the continuous, glassy PS phase protrude 10 nm above the surface and swell laterally to form mushroom caps, rendering the entire surface hydrophilic. The swelling dynamics of the PAA mushrooms is captured by a two-stage mechanism, where domain growth is controlled by super case II diffusion of water into PAA followed by the slow relaxation of the PAA chains. Upon partial drying in air, the mushroom collapses as stretched hydrophilic chains relax, which results in nanometer depression in the center of each cap. The nanostructures revert to their initial dimensions and area fractions upon complete drying, demonstrating reversibility of swelling. This finding provides a new route to fabricate stimuli-responsive materials for sensors, microactuators, and microfluidic devices.

**15:18**
**R24 5 Patterned mesoporous media via 3-D replication in supercritical Carbon dioxide.** SIVAKUMAR NAGARAJAN, THOMAS RUSSELL, JAMES WATKINS, *University of Massachusetts, Amherst* JOAN BOSWORTH, PETER BUSCH, DETLEF SMILGIES, CHRISTOPHER OBER, *Cornell University* Mesoporous metal oxide films having cylindrical channels oriented normal to the surface have generated intense interest due to their potential use as sensors, catalysts and detection devices. Further, the ability to pattern these mesostructured films makes it versatile to generate mesoporous materials with precisely controlled geometries and morphologies. Here we describe a novel route to mesoporous silica films with perpendicular nanochannels prepared by the 3-D replication of block copolymer templates in supercritical carbon dioxide. Templates comprised of poly(alpha-methyl styrene) cylinders oriented normal in the matrix of poly (hydroxy styrene) having trace amounts of acid catalyst was in-

fused with solutions of silica precursor in sc $CO_2$ to selectively deposit silica within the matrix. Calcination yielded the porous silica arrays. The phase selective deposition was enabled by segregation of acid catalyst into hydrophilic matrix. Substitution of acid catalyst with photo sensitive acid generators facilitates to pattern the mesoporous films, which could potentially have applications in microfluidic devices and low-dielectric constant layers for microelectronic devices.

**15:30**

**R24 6 Ordered Nanostructured Carbon Generated from Pyrolyzed Polymer Precursors inside Anodic Aluminum Oxide Template** JIUN-TAI CHEN, KYUSOON SHIN, JULIE LEISTON-BELANGER, MINGFU ZHANG, THOMAS RUSSELL, *Polymer Science and Engineering Department, University of Massachusetts Amherst* Various carbon structures were generated by using polystyrene-block-polyacrylonitrile (PS-b-PAN) as carbon precursors in the nanopores of anodic aluminum oxide (AAO) membranes. PS-b-PAN block copolymers were drawn into nanopores of AAO by capillary force. By using different annealing temperatures, block copolymer nanotubes or nanorods can be generated. The morphologies of PS-b-PAN inside the nanopores were induced by structural frustration and interfacial interactions and were investigated by transmission electron microscopy. After stabilization and pyrolysis of the carbon precursors, the morphologies were retained and various carbon structures can be obtained. The carbon structures were found to be amorphous by Raman spectroscopy and x-ray diffraction.

**15:42**

**R24 7 Soft molding to align cylindrical nanodomains of block copolymers*** HIDEAKI YOKOYAMA, LEI LI, *AIST* Block copolymers are a class of materials that self-assemble into ordered periodic nanostructures. However, we often find that such spontaneous self-assembly ends up with disappointing randomly oriented polygrain structures, which limit the application of the nanodomains. Soft molding is a unique technique to transfer topological pattern with a soft mold, which permits a conformal contact with surfaces. A soft mold with a periodic topological pattern is embossed on the block copolymer thin films. The soft molding not only replicates the topological pattern to the block copolymer thin films but also induces microscopic flow in block copolymer thin films and controls the orientation of cylindrical domains. We fabricated a single layer of $3 \times 10^5$ parallel cylindrical nanodomains over an area of 1 cm $\times$ 1 cm.

**15:54**

**R24 8 Nanopatterning of Viruses and Proteins Using Microphase Separated Block Copolymers** ARTHUR CRESCE, *University of Maryland, Dept. of Materials Science and Engineering* ANGELA LEWANDOWSKI, WILLIAM BENTLEY, PETER KOFINAS, *University of Maryland, Dept. of Chemical and Biomolecular Engineering* Diblock copolymers containing nickel ions have been prepared that are capable of selectively adsorbing histidine-tagged green fluorescent protein (hisGFP), and also binding tobacco mosaic virus (TMV). A block copolymer of norbornene and norbornene dicarboxylic acid was synthesized using ring-opening metathesis polymerization. A 400/50 block ratio achieved a spherical microphase-separated morphology with roughly 20 nm diameter dicarboxylic acid spheres. The spherical phase was exposed to nickel ions in solution, templating the formation of nickel nanoparticles. This process gave a nickel-loaded diblock copolymer film whose surface was used to chelate his-GFP. Fluorescence spectroscopy and TEM confirmed the presence of the protein on the polymer surface. A sulfonated triblock copolymer was loaded with nickel ions using a similar solution-doping procedure. The morphology of this copolymer was lamellar, and its sulfonated block was loaded with nickel ions. TEM studies revealed the presence of the virus on the surface of the copolymer and showed that the bond between the TMV and the polymer surface can withstand severe detergent washes.

**16:06**

**R24 9 Surface Directed Assembly of Viral Monolayers** S. WARGACKI, R. NAIK, D. PHILLIPS, *Air Force Research Laboratory* M. FRANCIS, *University of California, Berkley* V. WARD, *University of Otago* E. THOMAS, *Massachusetts Institute of Technology* R.A. VAIA, *Air Force Research Laboratory* The facile two-dimensional fabrication of micron-scale patterns of ordered-nanoscale structures on flexible substrates has numerous broad implications, including sacrificial templates for further assembly, deposition or material removal. Previous examinations of block-copolymer assembly on micron-scale patterns with topological and/or chemical relief have demonstrated the ability to not only dictate the larger superstructure of the surface but also to impact the local nano-scale self-assembly and defect stability via confinement. These processes are examined with respect to the surface directed assembly of colloidal particles, specifically rod-like Tobacco Mosaic Virus (TMV) and iscohoderhal viruses it-Wiseana Iridovirus (WIV) and MS2. The unique surface chemistry and shapes provide a complement to traditional colloidal building-blocks. Initially, high throughput processing by convective self assembly (CSA) with orthogonal temperature gradients is combined with chemical modification of Silicon surfaces via soft-lithography to determine the key processing parameters for monolayer assembly. The impact of the viral shape (rod v. iscohodra) as well as the critical range of enthalpic interactions between the virus and substrate that control in-plane order and pattern formation will be discussed.

**16:18**

**R24 10 Guided Molecular Self-Assembly of Block Copolymer and Nanoparticles** SHAN ZOU, *Department of Chemistry, University of Toronto* GILBERT WALKER, *Department of Chemistry, University of Toronto* Block copolymers form a variety of ordered structures on nanometer length scales, allowing them to serve as an ordered matrix for nanoparticles which add functionality to the composite. The result is an ordered array of nanoparticles with potential applications including magnetic storage media, photonic crystals, or high-surface-area catalysts. Here we demonstrate the molecular self-assembly of diblock copolymers and cadmium selenide based nanoparticles. In thin films, nanoparticles assemble into one of the ordered pattern domains formed by the diblock copolymers on Si substrates. Ideas for directing the individual particles to different locations normal to the surface will be discussed.

**16:30**

**R24 11 Effect of Casting Solvent on the Morphology of Block Copolymer / Maghemite Nanoparticle Mixtures** KOOKHEON CHAR, MOON JEONG PARK, *Seoul National University* We investigate the effect of casting solvent on the morphology of block copolymer / magnetic nanoparticle (NP) mixtures. Monodisperse maghemite NPs with surfaces modified with oleic acids

have been synthesized and PS-b-PI, PS-b-PB, PS-b-PEO, and PS-b-P4VP, diblock copolymers showing cylindrical morphology were used as structure-directing matrices for the NPs. Four different solvents, hexane, toluene, THF, and CHCl3 were used to prepare film specimens by static casting and the interaction between mesophase-forming copolymers and nanoparticles, which can be tuned by casting solvent, leads to remarkably different hybrid morphology. With casting with good solvent for both blocks, with the increase in NP concentration, domains of NP aggregates were observed while the NPs were selectively incorporated into the minor domains of block copolymer under selective solvent condition. The interplay between magnetic NPs and block copolymers was also tested with different size of magnetic NPs and also with different molecular weight of block copolymers. In order to characterize the structural change of block copolymers associated with different NP loadings small- angle x-ray scattering was performed and the structural information is in good agreement with transmission electron microscopy images and differential scanning calorimetry results.

**16:42**
**R24 12 2-D Hierarchical Structure of Block Copolymer / Bionanoparticle Complexes** DONGSEOK SHIN, *University of Massachusetts, Amherst* THOMAS RUSSELL, *University of Massachusetts, Amherst* The morphology of complexes made of poly(styrene-b-N-methyl-4- vinylpyridinium iodide) (PS-P4VPMeI) and horse spleen ferritin was investigated. A polymer film was casted on a substrate then was immersed in a protein solution to allow for protein adsorption. After rinsing the sample with deionized water and drying, the specimen was placed in a mixed vapor of benzene and water. This solvent annealing technique has allowed us to get the final morphology of the complex at ambient condition. At low loading of ferritin, the morphology of the block copolymer was conserved and the ferritin was localized at the microdomains of the minor component (P4VPMeI). As the loading of ferritin increased, the microdomains containing ferritin particles grew in size and elongated in shape. Eventually, the micordomains occupied by ferritin were connected and formed closed loops at high loading of ferritin. However, in the area enclosed with the loops, the morphology of the block copolymer itself was maintained. As a result, we were able to get a hierarchical structure by incorporating bio-nanoparticles into block copolymer thin films.

**16:54**
**R24 13 Effect of Interacting Nanoparticles on the Ordered Morphology of Block Copolymer / Nanoparticle Mixtures** MOON JEONG PARK, YU JIN KANG, KOOKHEON CHAR, *Seoul National University* We investigate the effect of hard additives, i.e., magnetic nanoparticles (NPs), on the ordered morphology of block copolymers by varying NP concentration. In order to characterize the structural change of block copolymer associated with different NP loadings, small-angle x-ray scattering and transmission electron microscopy were performed. Monodisperse maghemite NPs with surfaces modified with oleic acids have been synthesized and PS-b-PI diblock copolymers showing cylindrical morphology were used as structure-directing matrices for the NPs. With the increase in NP concentration, domains of NP aggregates were observed. It is surprising to note that regular lattice-like aggregates with maghemite NPs induce an intriguing morphological transformation from the hexagonal cylinders to the body-centered cubic spheres via undulated cylinders of block copolymers, which does not show such order-order transition without NPs. The interplay between magnetic NPs and block copolymers was also tested with different size of magnetic NPs and also with different molecular weight of PS-b-PIs. We also demonstrate the preferred orientation of anisotropic microdomains of PS-b-PI, which is known to be difficult to orient by applying electric or magnetic field. This result could add more flexibility in structural control and orientation of block templates opening up new applications in the future.

**17:06**
**R24 14 Magnetic Properties of Ni Nanoparticles Dispersed in Polystyrene-Isoprene-Polystyrene Triblockcopolymers** MIRCEA CHIPARA, *Indiana University* YOU QIANG, *University of Idaho* LINFENG GUO, *Indiana University* AMINIAN HOSSEIN, *Umicore* JEFFREY M. ZALESKI, *Indiana University* SY-HWANG LIOU, *University of Nebraska* Polymer based magnetic nanocomposites were obtained by dispersing Ni nanoparticles within polystyrene-isoprene-polystyrene block copolymers. High power sonication (500 W) was used to obtain an uniform dispersion of magnetic nanoparticles. The dependence of the magnetic properties of these nancomposite materials as a function of Ni concentration (from 0 % Ni to about 25 % Ni) and temperature (in the range 100 K to 500 K) was analyzed. The agglomeration of Ni nanoparticles above the glass transition of the hard phase was observed. The process is irreversible. The agglomeration of nanoparticles is triggered by the fast decrease of diffusion coefficients above the glass transition temperature of the hard phase. Such large changes of magnetic properties triggered by the elastic properties of the matrix were not yet been reported. Ferromagnetic resonance data on Ni based composites in the temperature range 100 to 500 K confirmed the agglomeration of Ni nanoparticles and supported the irreversible character of this modification. Additional magnetic data were obtained by SQUID, VSM, and AFM (with magnetic tips).

**17:18**
**R24 15 Penetrant Diffusion in a SEBS Triblock Copolymer by Pulse Field Gradient NMR** ALAN JONES, *Clark University* MARCUS GIOTTO, ALANA CANFIELD, GUOXING LIN, *Clark University* Solid triblock copolymers can serve as the basis for membranes in such applications as separations and fuel cells. Diffusion of a low molecular weight penetrant in such a membrane is strongly affected by the morphology. The effect of the morphology on the translational motion of the penetrant can be directly assessed by pulse field gradient NMR measurements. The rotational and translational motion of 2,2,4-trimethylpentane (TMP) in a SEBS triblock will be characterized by NMR. TMP is primarily soluble in the rubbery EB phase of the SEBS triblock so that this phase then acts as the conductive component of the membrane.

**SESSION R25: ADHESION AND VISCOELASTICITY IN POLYMER THIN FILMS**
**Wednesday Afternoon, 15 March 2006**
**322, Baltimore Convention Center at 14:30**
**Karen Winey, University of Pennsylvania, presiding**

**14:30**
**R25 1 QCM Studies of Polymer Gel Spreading in Liquid Environments** FRANK NUNALEE, BRUCE LEE, PHILLIP MESSERSMITH, KENNETH SHULL, *Northwestern University* Adhesion of polymer gels to substrates is a complicated phenomenon, particularly if the system is submerged in a liquid. Establishment

of mechanical contact hinges upon the details of the gel's surface structure. In many cases, the polymeric component of the gel is shielded by a segregated solvent layer. These issues have important implications for those interested in soft, adhesive materials for biological applications. In this investigation, we utilize the surface sensitivity of the quartz crystal microbalance (QCM) to study the spreading behavior of polymeric liquids and gels on a rigid surface while submerged in a liquid medium. While the QCM has been used extensively to study adsorption by exploiting its sensitivity to material properties in the direction normal to the crystal's electrodes, few studies have utilized the QCM's ability to sense changes in loading in the plane of the electrodes. We propose equations to describe the predicted response of the QCM to a generalized viscoelastic material spreading at the QCM surface at the expense of the surrounding liquid medium. Several experimental examples are given in order to support the validity of the proposed equations, including situations where the spreading material is a Newtonian liquid, a polymer solution, or a polymer gel.

**14:42**

**R25 2 Frictional properties of hydrophobic nanopatches in different solvents.** MATTEO CASTRONOVO, *University of Trieste, Trieste, Italy* ROBERT HUDEJ, *Synchrotron Trieste, Trieste, Italy; International School for Advanced Studies (ISAS), Trieste, Italy* DENIS SCAINI, MARTINA DELL'ANGELA, *Synchrotron Trieste, Trieste, Italy; Department of Physics, University of Trieste, Trieste, Italy* LOREDANA CASALIS, *Synchrotron Trieste, Trieste, Italy* GIACINTO SCOLES, *Synchrotron Trieste, Trieste, Italy; International School for Advanced Studies (ISAS), Trieste, Italy; Princeton University, Princeton, NJ* Controlling friction at the micro- and nano-scale is of crucial importance, especially in applications as micromachines. In order to develop new ways of controlling friction, it is extremely important to understand how friction depends on the atomic structure of the interface. Using nanografting, an AFM-assisted lithographic technique, we correlated frictional properties of alkanethiols with hydrophobic termination (CH3) and of alkenethiols with hydrophilic termination (OH) on the same surface in water and in 2-butanol, using the same tip. In 2-butanol friction on C11OH is higher than on the C18 patch since OH groups on the SiO2 AFM tip surface interact more strongly with OH groups on C11OH than with CH3 groups on C18. In water, due to the strong interactions between the OH groups, the solvent molecules form an ordered layer on OH terminated SAM, which can be penetrated by the AFM tip only at relatively high applied forces.

**14:54**

**R25 3 Viscoelastic behavior of PDMS thin films with POSS nanofillers** WEN YIN, JIANJUN DENG, JOHN R. HOTTLE, HYONG-JUN KIM, ALAN R. ESKER, *Department of Chemistry (0212), Virginia Tech, Blacksburg, VA, 24061* Blends of amphiphilic poly(dimethylsiloxane) (PDMS) and a model polyhedral oligomeric silsesquioxane (POSS) nanofiller, trisilanolisobutyl-POSS, have been studied via the Wilhelm plate technique and surface light scattering (SLS). The surface pressure – surface concentration isotherms indicate that as the weight percentage of POSS increases in the blend systems, the collapse pressure of PDMS. SLS results reveal that increasing film's POSS content increases the dilational modulus of the PDMS thin films. This system is ideal for studying how nanofillers affect the viscoelastic behavior of polymer thin films at an attractive surface.

**15:06**

**R25 4 Modified Side-Chain Liquid Crystalline Polymer Thin Films as Low Adhesion Surfaces** HARIS RETSOS, *E.S.P.C.I., PARIS, Lab PPMD* DAEWON LEE, *School of Chem & Bio. Engr., Seoul National University, Seoul, Korea* COSTANTINO CRETON, *E.S.P.C.I., PARIS, Lab PPMD* KOOKHEON CHAR, *School of Chem. & Biol. Engr., Seoul National University, Seoul, Korea* The adhesive properties of side-chain liquid crystalline block copolymer thin films against soft acrylic pressure-sensitive-adhesive layers have been investigated with the probe method. Since the structure of the thin films varies from crystalline to liquid crystalline or to fully isotropic state as a function of temperature, we investigated the effect of annealing temperature of the interface on the adhesive properties. All the layers displayed very low adhesion at room temperature but above the crystalline to LC transition temperature, this low adhesion property disappears, presumably due to the reorganization of interfacial structure. To avoid this reconstruction, the 14C alkyl side-chains were modified by the incorporation of $SO_2$ groups that experience the dipole-dipole interactions and provide remarkable temperature stability to the crystalline phases. We further investigated the influence of the position and the kind of polar group in the side-chains on the structural and adhesion properties of those block-copolymers.

**15:18**

**R25 5 Polydispersity Effects on Polymer-Polymer Welding.** ANNA BARNETTE, RICHARD WOOL, IAN McANINCH, *Dept Chemical Engineering, Univ Delaware* During polymer-polymer welding, it is generally accepted that molecular weight distribution $\phi$(M) and its polydispersity (PD) affects the weld strength and required welding times. However, current welding models do not adequately address the role of PD coupled with interdiffusion Reptation dynamics, entanglement connectivity and relations between the fractal interface structure and strength, which would allow the optimal selection of the molecular weight distribution $\phi$(M). A computer simulation was developed to predict the microscopic effects of PD on welding and the results are compared with experiments on model blends of monodisperse polystyrenes (PS). The validity of the model was tested using Double Cantilever Beam PS samples that were first wetted below, and then welded for various times t, above the glass transition temperature. Wedge cleavage fracture testing determined that the weld strength $G_{1c}$ reached the maximum strength G* at an interfacial penetration contour length of 240 kDa corresponding to M* = 8 $M_c$. The simulations and experiments for monodisperse interfaces yielded $G_{1c}(t) = G^*[t/\tau]^{1/2}$where the welding time behaved as $\tau \sim$ M, and $\tau$ was less than the Reptation time $T_r \sim M^3$. For polydisperse samples, the time exponent of $.5ex1\mathrm{ker}n - .1em/\mathrm{ker}n - .15em.25ex2$ decreased empirically with increasing PDI and the welding times were related to various moments of $\phi$(M) and increased with increasing PDI until a PDI of approximately 12 was reached. The welding times for strength development are much shorter than the welding times for maximum fatigue resistance.

**R25 6 Lubrication by glycoprotein brushes.** BRUNO ZAPPONE, *UCSB* MARINA RUTHS, *UMass Lowell* GEORGE W. GREENE, *UCSB* JACOB ISRAELACHVILI, *UCSB* Grafted polyelectrolyte brushes show excellent lubricating properties under water and have been proposed as a model to study boundary lubrication in biological system. Lubricin, a glycoprotein of the synovial fluid, is considered the major boundary lubricant of ar-

ticular joints. Using the Surface Force Apparatus, we have measured normal and friction forces between model surfaces (negatively charged mica, positively charged poly-lysine and aminothiol, hydrophobic alkanethiol) bearing adsorbed layers of lubricin. Lubricin layers acts like a versatile anti-adhesive, adsorbing on all the surfaces considered and creating a repulsion similar to the force between end-grafted polymer brushes. Analogies with polymer brushes also appear from bridging experiment, where proteins molecules are end-adsorbed on two opposing surfaces at the same time. Lubricin 'brushes' show good lubricating ability at low applied pressures ($P < 0.5$MPa), especially on negatively charged surfaces like mica. At higher load, the adsorbed layers wears and fails lubricating the surfaces, while still protecting the underlying substrate from wearing. Lubricin might thus be a first example of biological polyelectrolytes providing 'brush-like' lubrication and wear-protection.

**R25 7 Understanding Polymer Adhesion: Calculations of Adsorption of Organic Molecules onto Si and $SiO_2$ Surfaces** KAREN JOHNSTON, RISTO NIEMINEN, *Helsinki University of Technology* The adhesion of polymer films onto metal and oxide materials is important for many industrial and technological applications. It is therefore essential to understand the underlying structure and bonding of the polymer and the surface. The aim of this research is to seek methods to improve polymer adhesion by using a multiscale approach. The first step involves the use of density functional calculations to understand the atomic-scale structure and bonding of polymers on surfaces. I will present first-principles results for the adsorption of benzene and related molecules on Si and $SiO_2$ surfaces. I will then discuss how this information will be incorporated into larger scale methods, such as Kinetic Monte Carlo or coarse-graining techniques. This research is supported by a grant from the Finnish Technology Development Agency (TEKES).

**15:54**

**R25 8 Differential pressure experiment to probe adhesive interactions in thin films** ANNY FLORY, DAVID BRASS, KENNETH SHULL, *Department of Materials Science and Engineering, Northwestern University* In our laboratory we have developed a highly sensitive experiment which allows the measurement of very weak adhesive interactions between interfaces joined together by specific bonds. In the experiment, we place a membrane across a glass tube and use a syringe pump to apply a pressure difference across the membrane. The membrane is then inflated into contact with a glass substrate or the quartz disk of a quartz crystal resonator that is functionalized as desired and is immersed in an aqueous environment. A Langmuir layer is placed at the interface between air and water providing the modification of the surface chemistry of the membrane. The asymmetric Laplace equation is used to derive the energy release rate (G) from the experimental results. The advantage of this method is that specific and weak adhesive interactions as the ones encountered in biological systems can be accessed but also that the approach can be extended to measurement of very strong adhesive interactions such as those in synthetic gels. In this discussion, the validity of the method will be presented through results obtained on adhesive interactions between various model systems.

**16:06**

**R25 9 Capillary wave dynamics on viscoelastic polymer thin-films: Monolayers and bilayers** MARK HENLE, ALEX LEVINE, *Department of Chemistry and Biochemistry, University of California, Los Angeles* We investigate the capillary wave dynamics of supported polymeric thin-films both at the free surface and at the buried polymer/polymer interface in a bilayer system. Recent XPCS experiments (J. Lal, private communication) on such systems suggest that the decay rate of the coupled capillary waves at the free surface and at the buried interface are remarkably independent of the in-plane wavevector. In order to understand this phenomenon, we present the results of continuum hydrodynamic calculations of the capillary wave dynamics on supported monolayers and bilayers of both Newtonian and viscoelastic fluids. We find that the experimentally observed wavevector dependence of the capillary-wave decay rate can be accounted for by treating one or both of the polymers as a viscoelastic fluid with a single stress-relaxation time. We also investigate the effect of a finite slip length at either the polymer/polymer interface or the polymer/substrate interface.

**16:18**

**R25 10 Molecular recoiling forces in ultra-thin films of long entangled polymer chains** ARNOLD CHANG-MOU YANG, TONY MING-HSUN YANG, SEN-YEN HOU, YU-LUN CHANG, *Department of Material Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan* Molecular recoiling force stemmed from non-equilibrium chain conformation was found to play a very important role in the dewetting stability of polymer thin films. Correct measurements and inclusion of this molecular force into thermodynamic consideration are crucial for analyzing dewetting phenomena and nanoscale polymer chain physics. This force was measured using a simple method based on contour relaxation at the incipient dewetting holes. The recoiling stress was found to increase dramatically with molecular weight and decreasing film thickness. The corresponding forces were calculated to be in the range from 9.0 to 28.2 mN/m, too large to be neglected when compared to the dispersive forces ( $\sim$ 10 mN/m) commonly operative in thin polymer films. This work is supported by Air Force (AFOSR-04-4074) and National Science Council of Taiwan.

**R25 11 The Effect of Nanobubbles on Microcantilever Bending** SANGMIN JEON, *Pohang University* RAMYA DESIKAN, *University of Tennessee* FANG TIAN, THOMAS THUNDAT, *Oak Ridge National Laboratory* Nanomechanical cantilevers are very small and extremely sensitive force and mass sensors. Here, we report on the impact of the vertical component of surface energy on microcantilevers when nanobubbles form on their surfaces. Young's equation, which is commonly used to determine the contact angle of liquid drops on a solid surface, ignores the vertical component of the surface energy. Despite this force being extremely small and its effect on the solid can be ignored, it plays a significant role for flexible surfaces such as microcantilevers. A gold-coated silicon microcantilever and a dodecanethiol coated silicon microcantilever were used to detect real-time formation of nanobubbles on their surfaces when exposed to air-rich water. As air nanobubbles form on the surfaces of the cantilever, the cantilever undergoes bending and we relate this to the vertical compo-

nent of surface energy in Young's equation. This implies that the vertical component of the surface tension should be considered for flexible solid surfaces, and the formation of nanobubbles should be avoided when cantilevers are used as sensors to avoid artifacts.

**16:42**
**R25 12 Measuring local viscoelastic properties of complex materials with atomic force microscopy** PAULA WOOD-ADAMS, WENSHENG XU, *Concordia University* Tapping mode atomic force microscopy is a technique to measure the topography and properties of surfaces involving a micro-cantilever with a tip at one end that is excited into an oscillation near its resonance frequency. The cantilever-tip assembly is positioned vertically such that the tip touches the surface at the bottom of its down-stroke and then scanned over the surface. The oscillation of the cantilever is affected by the topography of the surface, the local surface properties and the feed back controller which maintains the amplitude of the oscillation at a fixed set point value. The vertical movements needed to maintain constant oscillation amplitude are used to draw the topography image and the phase lag of the oscillation relative to the excitation force is used to draw the phase image. The phase lag is sensitive to local mechanical properties under certain experimental conditions and we have found that by using silicon as an internal standard reference surface we can unambiguously relate the phase lag to local viscolastic properties of a polymeric material. We have built a model describing this relation, validated the model with experimental data and finally inverted it such that it can be used to determine local properties. This allows us to measure high frequency local viscoelastic properties on length scales as small as several nanometers. This technique works well for relatively compliant polymer surfaces with a shear modulus less than about 1 GPa. Funding Provided by the Taiho Kogyo Tribology Research Foundation.

**16:54**
**R25 13 The kinetics of the reaction of telechelics at a soft interface by neutron reflectivity** J. KEVIN RICE, HELEN JI, MARK DADMUN, JIMMY MAYS, *University of Tennessee* The aim of this study is to gain a fundamental understanding of the kinetics of the in- situ formation of blocky copolymer molecules at a soft, immiscible polymer interface by the reaction of telechelic polymers across that interface. The resultant interfacial morphology that is formed from this reaction is also studied. Specular neutron reflectivity measurements were made after various annealing times on bilayer PS/PMMA samples, each of which contains dPS telechelics in one layer and monochelic PMMA in the other. Three reactive chain-end pairs were studied: epoxy-amine, epoxy-carboxylic acid, and amine-anhydride. After sufficient annealing of each system, an interfacial layer forms between the PS and PMMA that contains triblock copolymer formed by the reaction of the telechelics and the reactive PMMA chains. The thickness of this interfacial modifier layer, as well as the roughness between the matrix layers, increases with annealing time. Several molecular weights of the telechelics were studied and results relating the time evolution of the blocky copolymer volume fraction at the interface to interfacial excess, as well as interfacial coverage and reaction rate constants will be discussed.

## SESSION R26: FOCUS SESSION: COUNTERION DYNAMICS IN CHARGED BIOPOLYMER SYSTEMS

**R26 1 Counterion liquids between biological polyelectrolytes.**
GERARD WONG, *University of Illinois at Urbana-Champaign*

Electrostatic interactions between charged surfaces in water are dominated by counterion behavior. For example, repulsion between like-charged objects are due to the osmotic pressure of compressed counterions, and attraction between oppositely-charged objects are due to the entropy gain of counterion release. In systems with strong electrostatic interactions, mean field theories break down and counterion correlations and dynamics become important. To explain counterintuitive phenomena such as like-charge attraction between polyelectrolytes, exotic models such as counterion Wigner lattices were proposed, but no experimental comparisons at sufficient spatial resolution exist. Using inelastic x-ray scattering, the spatiotemporal correlations of counterions that mediate binding between charged polymers have been measured in aqueous solution down to molecular length-scales. We find that these ions are hierarchically organized into a dense, strongly correlated liquid that exhibits an acoustic-like phonon mode. The excitation spectra at high wave-vector Q reveal unexpected dynamics due to ions interacting with their ''cages'' of nearest neighbors. The measured speed of sound and collective relaxation rates in this liquid agree well with simple model calculations.

**R26 2 Bjerrum Pairing Correlations at Charged Interfaces*** ALEX TRAVESSET, DAVID VAKNIN, *Iowa State University and Ames Lab* Electrostatic correlations play a fundamental role in aqueous solutions. In this letter, we identify transverse and lateral correlations as two mutually exclusive regimes. We show that the transverse regime leads to binding by generalization of the Bjerrum pair formation theory and point out that this purely electrostatic correlation becomes dominant for strongly charged interfaces. We compare our theoretical predictions with different experiments on charged membranes and Langmuir monolayers and find good agreements. We contrast our approach with existing theories in the strong coupling limit and on charged modulated interfaces and discuss different scenarios leading to charge reversal and equal-charge attraction by macro-ions.

**R26 3 Charged Polymers in Electric Fields.**
ROLAND NETZ, *Technical University Munich*

Charged polymers in solution are considered under the action of external electric fields. An electric field acts simultaneously on charged groups of the polyelectrolyte and on mobile counterions. As a result, charges are displaced and a dipole moment is produced, which leads to stretching and orientation of the polymer parallel to the external field. On the the other hand, hydrodynamic effects favor a perpendicular orientation of stiff polymers with respect to the external field, which is related to the phenomenon of anomalous birefringence. By performing hydrodynamic simulations, the relation between the electrophoretic mobility and the non-equilibrium perturbation of the polymer structure is investigated which results from a competition between electro-friction effects when counterions glide along the polymer backbone and coupling between hydrodynamic and elastic forces. Friction effects are more pronounced when polymers are confined, for example when they move through pores or when they adsorbed at surfaces.

**R26 4 Migration of DNA on electrically inhomogeneous surfaces** ERIC PETERSEN, *Harvard College* BINGQUAN LI, VLADIMIR SAMUILOV, XIAOHUA FANG, JONATHAN SOKOLOV, MIRIAM RAFAILOVICH, *Dept. of Materials Science and Engineering, Stony Brook University* Surface electrophoresis of kilo-bp DNA on electrically inhomogeneous surfaces was studied. The surfaces were produced by stamping micropatterns of gold strips onto silicon wafers using the Whitesides microcontact printing technique. Simulations of the field distribution on the surface revealed regions of very high field strength localized at the Au/Si interface. As a result, both electrophoretic and dielectrophoretic forces contribute to the movement of DNA on the surface. The mobility of DNA across the patterned surface was measured via laser induced fluorescence detection with an electric field oriented normal to the strips in the plane of the surface. The interaction of DNA with the surface was imaged with a confocal microscope in laser scanning mode with a CCD camera. Results indicate the measured mobility of DNA on a chemically micropatterned surface depends on the period size of the gold striped pattern relative to the contour length of the DNA molecule and the persistence length of the chain relative to the size of the electric field disturbance at the Au/Si interface. Consequentially, surface separation of DNA of different size and flexibility is possible.

**R26 5 Evidence for High Conductivity in the Pili of Geobacter sulfurreducens: ''Nano-wires'' in a Prokaryotic Electron Transport Chain?*** KEVIN D. MCCARTHY, *Dept. of Physics and Dept. of Microbiology, UMass* GEMMA REGUERA, TEENA MEHTA, JULIE S. NICOLL, *Dept. of Microbiology, UMass* XINYU WANG, *Dept. of Phyics, UMass* MARK T. TUOMINEN,[†] DEREK R. LOVLEY, *Dept. of Microbiology and The Geobacter Project, UMass* We discuss results of Conducting-Probe Atomic Force Microscopy (CP-AFM) applied to the nanoscopic filamentary pili of the prokaryote Geobacter sulfurreducens. (G. Reguera, et al., Nature **435**, 1038, 2005) The apparently high cross-axis conductivity of this bacterial membrane protein complex, along with evidence of its necessity for respiratory reduction of insoluble Fe(III) deposits in nature, points to the possibility of a novel role for the pili protein complex in the electron transport chain of a prokaryote: as a kind of ''nano-wire'' for conduction of electrons to Fe(III) oxides. CP-AFM and itin vivo genetic engineering experiments supporting the ''nano-wire'' hypothesis are presented.

**R26 6 Dynamical Transition of the Protein Observed in Terahertz Dielectric Response** JING-YIN CHEN, JOSEPH KNAB, ANDREA MARKELZ, *Physics Department, University at Buffalo, SUNY, Buffalo, NY 14260* Temperature dependent measurements (10 K – 296 K) were made of the terahertz dielectric response of oxidized and reduced cytochrome C (CytC) buffer solutions using THz time domain spectroscopy (THzTDS) (0.12-2.0 THz). The imaginary part of the index ($\kappa$) for both ferri and ferro CytC solutions increases linearly with temperature at low temperatures and then strongly increases near 200 K with a plateau at 250 K. The change of $\kappa$ for ferroCytC between 200 K and 250 K is nearly half that of ferriCytC. The result is consistent with

Mossbauer measurements; however THzTDS measures motions in the significantly shorter time range, 0.5 – 8 ps. These are the first measurements of the transition in the THz range and put constraints on allowed mechanisms. The agreement with polarizability insensitive Mossbauer supports that the dramatic increase in the THz dielectric response with oxidation we reported for CytC films (Phys Rev E 72, 040901 (2005)) results mainly from a large increase in the low frequency vibrational density of states. Work was supported by NSF Career PHY-0349256, and NSF IGERT DGE0114330.

**16:30**

**R26 7 Terahertz dielectric response dependence on protein melting and hydration** YUNFEN HE, J.R. KNAB, *Physics, University at Buffalo, SUNY* B. SHAH, *Chem. Eng., Rutgers University* A.G. MARKELZ, *Physics, University at Buffalo, SUNY* Hydration is critical for protein structure stability and flexibility. The hydration dynamics of denatured proteins necessarily plays a significant role in protein folding/unfolding and aggregation. We previously reported the observation of a transition in the THz dielectric response for native state hen egg white lysozyme (HEWL) with hydration. As hydration increases the response slowly increases until at 0.25h (gm water/gm protein) the absorbance and index sharply increase. The frequency range is associated with structural vibrational modes and the hydration level coincides with the filling of the first solvation shell. We present recent THz hydration dependence results as a function of denaturing. The THz absorption coefficient is nearly independent of denaturation while the index of refraction significantly decreases compared to native state and has a stronger frequency dependence with a peak appearing near 0.5 THz. Most significantly the hydration transition at 0.25h is still present for the denatured samples, suggesting the net itbound water content is nearly identical to the native state.

**16:42**

**R26 8 Inorganic Surface and Structure Adhesion of Amino Acids and Peptides** LARUE DUNKLEBERGER, ROBERT WILLETT, LOREN PFEIFFER, *Bell Laboratories, Lucent Technologies* Interactions at the interface of biological molecules and inorganic materials are an open question in materials science; understanding these hybrid interfaces at the molecular level can have extensive basic and practical implications. In an extensive set of measurements we have systematically examined the adhesion of amino acids to a series of inorganic surfaces used in semiconductor devices. Peptides comprised of each of the twenty amino acids were exposed in solution to surfaces including metals, insulators, and semiconductors. Significant differential adhesion to the various surfaces is observed over the complement of amino acids, with adhesion determined largely by the amino acid side-chain charge. Mapping of adhesion findings for the amino acids versus materials in multiple solutions has been accomplished, in addition to examination of concentration and pH dependence. These results provide an empirical basis for building peptide to inorganic surface structures. In this vein, we have designed inorganic nano-structures using molecular beam epitaxy that are shown to selectively bind to prescribed primary peptide sequences. The inorganic structures fabricated here are shown to be able to discriminate between peptides with differences of only two to four amino acids. This surprising specific differential adhesion in both open surfaces to varied amino acids and in nanoscale structures to peptides is examined for the physical processes at play.

**16:54**

**R26 9 Interactions between the HIV-TAT transduction domain and cell membranes** ABHIJIT MISHRA, *University of Illinois, Department of Materials Science and Engineering* GERARD WONG, *University of Illinois, Department of Materials Science and Engineering, Department of Physics, Department of Bioengineering* Biologically active molecules such as proteins and oligonucleotides can be transduced into cells with high efficiency when covalently linked to a Protein Transduction Domain (PTD), such as the TAT domain in the HIV virus. All PTDs have a high content of basic amino acids resulting in a net positive charge. Electrostatic interactions between cationic PTDs and the negatively charged phospholipids that constitute the plasma membrane are likely to be responsible for peptide uptake, but no detailed structural studies exist. We compare membrane structures induced by the cationic TAT domain and those induced by other cationic polypeptides as a function of membrane composition using synchrotron x-ray scattering, and examine possible mechanisms of the anomalous transduction.

**17:06**

**R26 10 Temperature Effects on Threshold Counterion Concentration to Induce Aggregation of fd Virus** QI WEN, JAY TANG, *Brown University* We seek to determine the mechanism of like-charge attraction by measuring the temperature dependence of critical divalent counterion concentration ($C_c$) for the aggregation of fd viruses. We find that an increase in temperature leads to a decrease in the dielectric constant ($\varepsilon$) of the solvent, thus causing $C_c$ to decrease. At a constant $\varepsilon$, $C_c$ is found to increase as temperature increases. The effect of $T$ and $\varepsilon$ on $C_c$ is combined to that of one parameter: Bjerrum length ($l_B$). $C_c$ decreases exponentially as $l_B$ increases. The exponential decay of $C_c$ suggests that entropic effect of counterions plays an important role at the onset of bundle formation.

**17:18**

**R26 11 Ion Distribution around DNA: Can Transitions Be Observed?** KURT ANDRESEN, LISA KWOK, XIANGYUN QIU, HYE YOON PARK, JESSICA LAMB, LOIS POLLACK, *Cornell University* The spatial distribution of counterions that reduce or neutralize the charge of biopolymers is fundamentally important in determining how these polymers interact with each other and with their surroundings (i.e. with charged surfaces). We will discuss recent anomalous small-angle x-ray scattering (ASAXS) experiments that quantify the distribution of ions around DNA strands in solution. This counterion atmosphere has been studied as a function of a variety of experimental conditions, including those known to lead to structural transitions of the biopolymer.

**SESSION R27: MANY-BODY/STRONGLY CORRELATED**

**R27 1 Density Matrix Renormalization Group algorithm on intersecting chains** HAIHUI GUO, STEVEN WHITE, *University of California, Irvine* Systems of intersecting chains are interesting both from a fundamental viewpoint and because of their potential use in nanoscale devices. Here, we will introduce a new density

matrix renormalization group algorithm to perform calculations on intersecting chains systems. The new DMRG algorithm greatly reduces the number of states kept per block to roughly $\sqrt{m}$ compared with the alternative ''non-local'' approach. We present results on 3-chain Heisenberg $S = 1$ system with two geometries, one with a single site in the center of junction, the other with three sites in the center of junction.

**14:42**

**R27 2 Finite-temperature density matrix renormalization using an enlarged Hilbert space** ADRIAN E. FEIGUIN, *Microsoft Research* STEVEN R. WHITE, *University of California, Irvine* We apply a generalization of the time-dependent DMRG to study finite temperature properties of several quantum spin chains, including the frustrated $J_1 - J_2$ model. We discuss several practical issues with the method, including use of quantum numbers and finite size effects. We compare with transfer-matrix DMRG, finding that both methods produce excellent results.

**14:54**

**R27 3 DMRG meets NRG*** ANDREAS WEICHSELBAUM, *Arnold Sommerfeld Center (LMU), Munich, Germany* FRANK VERSTRAETE, *Institute for Quantum Information, Caltech, Pasadena, US* ULRICH SCHOLLWÖCK, *Institut für Theoretische Physik C, RWTH-Aachen, Germany* J. IGNACIO CIRAC, *Max-Planck-Institut für Quantenoptik, Garching, Germany* JAN VON DELFT, *Arnold Sommerfeld Center (LMU), Munich, Germany* We present a unified framework of renormalization group methods, including Wilson's numerical renormalization group (NRG) and White's density-matrix renormalization group (DMRG), within the language of matrix product states. This allows to improve over Wilson's NRG for quantum impurity models by a variational method optimal in this framework. We illustrate it for the single-impurity Anderson model; moreover we use a variational method for evaluating Green's functions. The proposed method is more flexible in its description of off-resonance spectral properties, opening the way to time-dependent, out-of-equilibrium impurity problems. It also substantially improves computational efficiency for one-channel impurity problems, suggesting *linear* scaling of complexity for *n*-channel problems.

**15:06**

**R27 4 Strong Coupling Polaron in 2D in Terms of the Bethe-Salpter Equation** RUSSELL SELVA, YURIY MALOZOVSKY, *Southeastern Louisiana University* We consider the formation of polaron in two dimensions in terms of the Bethe-Salpeter equation. We develop the perturbation diagram approach to the electron-phonon interaction problem and show that the series of the ladder diagrams lead to the well-known Bethe-Salpeter equation. We evaluate the self-energy of the polaron. We show that even in the case of the weak electron-phonon interaction there at least one bound state exists for the polaron in two dimensions. We consider the formation of the polaron for the interaction of an electron both with acoustic and optical phonons. We have found the existence of the strong coupling polaron in both cases.

**R27 5 Collective fields in the functional RG for fermions: Vacuum expectation values and spontaneous symmetry breaking** FLORIAN SCHUETZ, PETER KOPIETZ, *Institut fuer Theoretische Physik, Universitaet Frankfurt, Max-von-Laue Strasse 1, 60438 Frankfurt* We discuss partial bosonization of interacting electron systems by a Hubbard-Stratonovich transformation and derive the functional renormalization group equations for the one-line-irreducible vertices of the resulting coupled field theory containing fermionic and collective bosonic fields. We analyze different choices of the cutoff in either the fermionic or the bosonic propagator. Recently,we have shown that for the Tomonaga-Luttinger model a purely bosonic cutoff can be combined with Ward identities to solve a whole hierarchy of flow equations and to reproduce the exact solution for the single particle Green's function known from bosonization [1]. Here, we generalize our approach to include the possibility that some bosonic components of the field have a finite vacuum expectation value. The system of flow equations is then modified and supplemented by a flow equation for the vacuum expectation value of the field. For bosonic fields describing fluctuations in the zero-sound channel, the vacuum expectation value of the zero mode is closely related to the fermionic density, which can be exploited to calculate the compressibility. By using a cutoff in the free bosonic propagator, the renormalization group flow can be set up to systematically yield corrections to the self-consistent Hartree approximation. [1] F. Schuetz, L. Bartosch, and P. Kopietz, Phys. Rev. B 72, 035105 (2005)

**15:30**

**R27 6 Ab initio Anderson impurity approach to x-ray absorption spectra of transition metal complexes*** DANIEL L. COX, *Department of Physics, University of California, Davis, CA 95616* ARND HUBSCH, *Max-Planck-Insitut für Physik komplexer Systeme, Nöthnitzer Str. 38, 01187 Dresden, Germany* MONTIAGO X. LABUTE, *Theoretical Biology and Biophysics, Los Alamos National Laboratory, Los Alamos, NM 87545* We present a generic Anderson impurity approach to transition metal molecules that allows to study correlation effects beyond the usual electronic structure calculations. Here, first principle density functional theory calculations (using SIESTA) are employed to determine the parameter of the model Anderson impurity Hamiltonian. We use the Lanczos algorithm to diagonalize the model Hamiltonian within a restricted set of basis states that is built up in the spirit of of the Gunnarsson Schönhammer trial wave function for heavy fermion compounds. The presented approach is applied to the K-edge x-ray absorption spectra of the valence tautomer molecule $Co(3,5\text{-}DTBSQ)_2(phen)$.

**15:42**

**R27 7 Anomalous tunneling of bound pairs in crystal lattices** PAVEL KORNILOVITCH, *Hewlett-Packard Company* VLADIMIR BULATOV, A novel non-perturbative method of solving scattering problems for bound pairs on a lattice is developed. Two different break- ups of the Hamiltonian are employed to calculate the full Green operator and the wave function of the scattered pair. The calculation converges exponentially in the number of basis states used to represent the non-translationinvariant part of the Green operator. The method is general and applicable to a variety of scattering and tunneling problems. As the first application, the problem of pair tunneling through a weak link on a one-dimensional lattice is solved. It is found that at the momentum values close to $\pi$ the pair tunnels

much easier than one particle, with the transmission coefficient approaching unity. This anomalously high transmission is a consequence of the existence of a two-body resonant state localized at the weak link. [V.L. Bulatov and P.E. Kornilovitch, Europhys. Lett. **73**, 352 (2005).]

**15:54**

**R27 8 Non-Markovian dynamics on one-dimensional quantum lattices** MICHAEL ZWOLAK,* *California Institute of Technology* Recently ideas from Quantum Information have sparked a number of advances in the simulation of interacting quantum lattice systems. Vidal first proposed a method, dubbed the Time Evolving Block Decimation (TEBD) algorithm, to simulate real-time dynamics of pure states on one-dimensional lattices. [1] Subsequently this method was extended to the simulation of mixed states, including real-time dynamics governed by a Markovian master equation and construction of thermal states. [2] These methods scale linearly in the system size, enabling relatively large lattices to be studied. We present a more general extension of the TEBD algorithm which allows one to simulate non-Markovian master equations within the Born approximation. This method scales quadratically with the system size. We demonstrate the method with examples of spins and fermions. We also discuss applications to systems driven out of equilibrium by external reservoirs. [1] G. Vidal, Phys. Rev. Lett. 91, 147902 (2003); 93, 040502 (2004). [2] M. Zwolak, G. Vidal, Phys. Rev. Lett. 93, 207205 (2004).

**R27 9 Exotic excitations with fractional charges on frustrated lattices** ERICH RUNGE, *Technische Universität Ilmenau* FRANK POLLMANN, PETER FULDE, *Max-Planck-Institut für Physik komplexer Systeme* Geometrical frustration of lattices can lead to a macroscopic degeneracy in the classical limit and thus to many interesting physical effects. In spin systems these are e.g. translational invariant spin liquid ground states and deconfined spinons. In contrast to magnetic properties, one began only recently to explore the charge degrees of freedom on frustrated lattices. For the systematic study of charge degrees of freedom, we consider a model of spinless Fermions with nearest-neighbor hopping $t$ and Coulomb repulsion $V$. Quantum fluctuations reduce the classical ($t = 0$) macroscopic degeneracy. For the strongly correlated limit $V \gg |t|$, it has been predicted that an added electron can decay into two mobile quasi-particles, leading to fractional charges of $e/2$ in 2D and 3D systems. For a deeper understanding of these charge degrees of freedom we calculated numerically the properties of static and dynamic charges on the 2D checkerboard lattice. We find evidence for a weak confinement between two fractional charges leading to excitations with very large spatial extend. Furthermore, we argue that the fractional charges are probably deconfined on the 3D pyrochlore lattice.

**R27 10 Making an analogy between a multi-chain interaction in Charge Density Wave transport and the use of wave functionals to form S-S' pairs.** ANDREW BECKWITH, First, we show through a numerical simulation that the massive Schwinger model used to formulate solutions to CDW transport in itself is insufficient for transport of soliton-antisoliton (S-S') pairs through a pinning gap model of CDW transport. We show that a model Hamiltonian with Peierls condensation energy used to couple adjacent chains (or transverse wave vectors) permits formation of S-S' pairs which could be used to transport CDW through a potential barrier.Previously, we have argued that there are analogies between this construction and the false vacuum hypothesis used for showing a necessary and sufficient condition for formation of CDW S-S' pairs in wavefunctionals. Here we note that this can be established via either use of the Bogomil'nyi inequality or an experimental artifact which is due to use of the false vacuum hypothesis to obtain a proportional 'distance' between the S-S' charge centers.

**R27 11 Localized component method for few-body scattering and bound state calculations*** VLADIMIR ROUDNEV, *Kansas State University* A modification of Faddeev equations which admits a very effective computational scheme is proposed. The method allows to perform precise calculations of bound states and scattering in few-body systems. For the systems having loosely bound subsystems the method can reduce the computation time by an order of magnitude. We illustrate the method by calculating bound states and scattering of three atoms with a simple model interaction. We also report results for systems of noble gas atoms with realistic interactions.

**R27 12 Equilibrium technique applied to strongly correlated electron transport in steady-state nonequilibrium*** JONG HAN, *State University of New York at Buffalo* We present a quantum algorithm of nonequilibrium steady-state transport within the equilibrium formalism. Current-carrying nonequilibrium ensemble is constructed by the Boltzmann factor $\exp[-\beta(\hat{H} - \hat{Y})]$ using the bias operator $\hat{Y}$ which imposes the boundary condition of different chemical potentials in source-drain reservoirs of electronic device. In the limit of non-interacting quantum dot systems, the mapping of a nonequilibrium to an effective equilibrium system can be explicitly shown to reproduce the Landauer-Büttiker formula. The equilibrium formulation is successfully applied to the strongly correlated transport of the Kondo regime, with the anomalous Kondo peak at small voltage bias and incoherent inelastic transport at high bias. This demonstrates that the numerical tools developed in equilibrium theory, such as quantum Monte Carlo, exact diagonalization, or renormalization group methods, can be applied in nonequilibrium and complement the existing theories based on nonequilibrium Greens function technique.

**R27 13 Cluster Impurity Solver for LDA+DMFT Calculations** QUAN YIN, SERGEY SAVRASOV, *University of California, Davis* CA 95616 TEAM, We report the electronic structure calculations of strongly correlated systems such as Mott Insulators, using the LDA+DMFT method. LDA+DMFT is a combination of the Density Functional Theory and the Dynamical Mean Field Theory featuring both the one-electron approximation and the many-body treatment for electrons, which is suitable for any ratio of coulomb repulsion over band width, and all computations are self-consistent. In the process of solving the Anderson Impurity Model for DMFT, several solvers with different accuracy were used and their results are compared. This presentation will focus on our most recently developed cluster solver and its applications.

**17:06**
**R27 14 Many-body Co-tunneling in Coupled Quantum Dots** CAROLYN YOUNG, *McGill University* MICHAEL HILKE, *McGill University* We developed a new formalism which allows us to study co-tunneling events in coupled quantum dot structures. By generalizing the non-equilibrium Green's function (NEGF) method for the case of N-particle Green's functions, we are able to calculate the many-body self-energy associated with semi-infinite leads. This formalism can be used to calculate the co-tunneling contribution to the differential conductance of various structures, such as parallel- and serial-coupled quantum dots, as well as Aharonov-Bohm interference devices.

**R28 1 Unraveling Biological Design Principles Using Engineering Methods: The Heat Shock Response as a Case Study.**
HANA EL-SAMAD, *Biochemistry and Biophysics, QB3, UC San Francisco*

The bacterial heat shock response refers to the mechanism by which bacteria react to a sudden increase in the ambient temperature. The consequences of such an unmediated temperature increase at the cellular level is the unfolding, misfolding, or aggregation of cell proteins, which threatens the life of the cell. To combat such effects, cells have evolved an intricate set of feedback and feedforward mechanisms. In this talk, we present a mathematical model that describes the core functionality of these mechanisms. We illustrate how such a model provides valuable insight, explaining dynamic phenomena exhibited by wild type and mutant heat shock responses, corroborating experimental data and guiding novel biological experiments. Furthermore, we demonstrate, through the careful control analysis of the model, several design principles that appear to have shaped the feedback structure of the heat shock system. Specifically, we itemize the roles of the various feedback strategies and demonstrate their necessity in achieving performance objectives such as efficiency, robustness, stability, good transient response, and noise rejection in the presence of limited cellular energies and materials. Examined from this perspective, the heat shock model can be decomposed, both conceptually and mathematically, into functional modules. These modules possess the characteristics of more familiar modular structures: sensors, actuators and controllers present in a typical technological control system. We finally point to various theoretical research challenges inspired by the heat shock response system, and discuss the crucial relevance of these challenges in the modeling and analysis of many classes of systems that are likely to arise in the study of gene regulatory networks.

**R28 2 Network growth models and genetic regulatory networks*** JOSHUA SOCOLAR, DAVID FOSTER, *Duke University, Durham, NC* STUART KAUFFMAN, *Institute for Biocomplexity and Informatics, University of Calgary* We study a class of growth algorithms for directed graphs that are candidate models for the evolution of genetic regulatory networks. The algorithms involve partial duplication of nodes and their links, together with innovation of new links, allowing for the possibility that input and output links from a newly created node may have different probabilities of survival. We find some counterintuitive trends as parameters are varied, including the broadening of indegree distribution when the probability for retaining input links is decreased. We also find that both the scaling of transcription factors with genome size and the measured degree distributions for genes in yeast can be reproduced by the growth algorithm if and only if a special seed is used to initiate the process.

**R28 3 Bistability of the naturally induced lactose utilization system of Escherichia coli** JELENA STAJIC, MICHAEL WALL, *Los Alamos National Laboratory* In the absence of the preferred sugar glucose, lactose utilization machinery in the bacterium E. coli is activated. The genetic circuit responsible for this response, lac operon, has been observed to exhibit bistability when induced by an artificial inducer, TMG. Here we investigate conditions under which bistability might be observed in response to lactose. The aim of our study is to establish whether the natural system exhibits bistability, as is often assumed despite the lack of experimental support.

**15:30**
**R28 4 Origins of sloppiness in biological models.** JOSHUA WATERFALL, FERGAL CASEY, RYAN GUTENKUNST, *Cornell University* KEVIN BROWN, *Harvard University* CHRISTOPHER MYERS, JAMES SETHNA, *Cornell University* Models of biological networks such as those involved in signal transduction, development, and the cell cycle routinely contain dozens of parameters. Even if high quality data on the dynamics of every form of every chemical species were available for such networks, some parameter combinations would be orders of magnitude more constrained than other combinations – a feature we term sloppiness. In order to understand this shared, possibly universal, behavior we turn to mathematically well-defined classes of models – multiple linear regression, sums of polynomials and sums of exponentials. The origins of sloppiness turn out to have nothing to do with how much data is available or how many parameters a model has, but are instead the scale of description at which a model is constructed

and how the parameters of the model map to the data. Thus describing a cloud of points by a plane, the core of linear regression, is not sloppy while describing complex biological networks by the biochemical reactions, just as fitting sums of exponentials or polynomials, is unavoidably sloppy.

**15:42**
**R28 5 Function Constrains Topology.** CHAO TANG, *University of California at San Francisco* WENZHE MA, QI OUYANG, *Center for Theoretical Biology, Peking University* In the biological world, intimate relations between function and form are well established on the macroscopic and the microscopic scales. However, on the ''mesoscopic'' scales, to what extend the function of a system and the organization of its parts are related? In this talk, I will present a case study of the segmentation polarity gene network in Drosophila. The function of this network is to stabilize the segmentation pattern of gene expression during the development. We found that although there are numerous networks which can perform the function, the requirement for the function to be robust severely constrains the network's topology. The network selected by nature is among the most robust topological classes. Furthermore, I will show that the knowledge of viable topologies can be used to help identify ''missing'' links in the network.

**R28 6 Stability tuned: An analysis of a gene network with counteracting feedback loops*** MURAT ACAR, ATTILA BECSKEI, ALEXANDER VAN OUDENAARDEN, *MIT* On induction of cell differentiation, distinct cell phenotypes are encoded by complex genetic networks. Here we explore the key parameters that determine the stability of cellular memory by using the yeast galactose-signalling network as a model system. This network contains multiple nested feedback loops. Of the two positive feedback loops, only the loop mediated by the signal transducer Gal3p is able to generate two stable expression states with a persistent memory of previous galactose consumption states. A negative feedback through the inhibitor Gal80p reduces the strength of the core positive feedback. Despite this, a constitutive increase in the Gal80p concentration tunes the system from having destabilized memory to having persistent memory. A model reveals that fluctuations are trapped more efficiently at higher Gal80p concentrations. Indeed, the rate at which single cells randomly switch back and forth between expression states was reduced. These observations provide a quantitative understanding of the stability and reversibility of cellular differentiation states. (For more information: Nature 435, 228-232 (2005)).

**R28 7 Parameters of the proteome evolution from the distribution of sequence identities of paralogous proteins** KOON-KIU YAN, *Stony Brook University* JACOB AXELSEN, *Compexity Lab, Niels Bohr Institute, Denmark* SERGEI MASLOV, *Brookhaven National Laboratory* The evolution of the full repertoire of proteins encoded in a given genome is driven by gene duplications, deletions and modifications of amino-acid sequences of already existing proteins. The information about relative rates and other intrinsic parameters of these three basic processes is contained in the distribution of sequence identities of pairs of paralogous proteins. We introduced a simple mathematical framework that allows one to extract some of this hidden information. It was then applied to the proteome-wide set of paralogous proteins in H. pylori, E. coli, S. cerevisiae, C. elegans, D. melanogaster and H. sapiens. We estimated the stationary per-gene deletion and duplication rates, the distribution of amino-acid substitution rate of these organisms. The validity of our mathematical framework was further confirmed by numerical simulations of a simple evolutionary model of a fixed-size proteome.

**R28 8 Differentiation at the single cell level: Slow, noisy, and out of control.**
GUROL SUEL, *California Institute of Technology*

Transient differentiation allows genetically identical cells to generate dynamical phenotypic diversity in a homogeneous environment. In Bacillus subtilis, competence is a transient state associated with the capability for DNA uptake from the environment. Individual genes and proteins underlying differentiation into the competent state have been elucidated, but it is unclear how these genes interact dynamically in individual cells to control both entry into competence and return to vegetative growth. Here we show that transient differentiation can be understood in terms of excitable behavior of the underlying genetic circuit. Using quantitative fluorescence time-lapse microscopy, we directly observed the activities of multiple circuit components simultaneously in individual cells. We analyzed the resulting data in terms of a mathematical model. A core module containing positive and negative feedback loops controls both entry into, and exit from, the competent state. Reengineering the competence network to bypass the negative feedback loop specifically blocks exit from competence converting the excitable system into a bistable one. These results show that a simple genetic circuit combines stochastic and deterministic elements to support transient differentiation through excitability.

**R28 10 Quantitative study of gene regulation mediated by small RNA** EREL LEVINE, THOMAS KUHLMAN, *Center for Theoretical Biological Physics, UCSD* ZHONGGE ZHANG, *Division of Biological Sciences, UCSD* TERENCE HWA, *Center for Theoretical Biological Physics, UCSD* The role of small regulatory RNAs (sRNA) in controlling many pathways in bacteria has been highlighted in recent years. Small RNAs have been found in regulating the response of E. Coli to various stress conditions, frequently by destabilizing the mRNA molecules of their target. Here we describe quantitatively the unique properties of this mode of regulation. We characterize - both theoretically and experimentally - the expression of a sRNA-regulated reporter, under different regulatory signals and genetic backgrounds. Our analysis predicts the existence of two regimes of gene expression, separated by a sharp transition: When the transcription rate of the sRNA exceeds that of its targets, we expect very low level of protein synthesis, with fluctuations strongly suppressed. However, when the sRNA transcription rate becomes lower than that of its target, a proportional fraction of target transcripts are expected to be stable, leading to protein expression. In the context of stress response, our results suggest a ''stress-relief'' mechanism, where gradual response is evoked only once a ''tolerance threshold'' is exceeded. We also characterized an intriguing coupling effect between the mRNA levels of different genes, arising from their shared regulatory sRNA. Such coupling may be used by the cell to create a hierarchy of responses to changes in regulatory signals.

**R28 11 Quantitative Dissection of a Bacterial Promoter: Cooperativity, Sensitivity, and Combinatorial Control*** THOMAS KUHLMAN, *Center for Theoretical Biophysics, UCSD* ZHONGGE ZHANG, MILTON SAIER, *Division of Biological Sciences, UCSD* TERENCE HWA, *Center for Theoretical Biophysics, UCSD* E. coli's lac promoter offers a possibility of confronting system-level properties of transcriptional regulation with the known biochemistry of the molecular constituents and their mutual interactions. We repeated a previous study [Setty et al, PNAS 100: 7702-7 (2003)] by removing several extraneous factors which modulated expression of the itlac promoter. Through characterization of the promoter activity for key mutants and using thermodynamic modeling, we account for the control of the lac promoter in terms of known interactions. We reveal how the sensitive response to inducers arises from the accumulation of several weakly cooperative interactions, and depict how the activator CRP plays a dual role as the enhancer and sensitizer of repression by assisting LacI-mediated DNA looping.

**R29 1 The Impact of Cholesterol on Lateral Organization in a Three-Species Non-Equilibrium Model of a Biomembrane** ANDREW P. PARADIS, SUSAN R. McKAY, SAMUEL T. HESS, *Department of Physics and Astronomy, University of Maine, Orono, Maine 04469-5709* Experimentally, cholesterol strongly influences many biological functions in cells. This study examines the mechanisms by which cholesterol affects membrane organization using a simple non-equilibrium model with exo- and endocytosis events. Three species, representing cholesterol, saturated and unsaturated lipids, move and interact on a two dimensional triangular lattice, simulated using a Metropolis algorithm. Interaction energies among the three species are adjustable, as are the rate and size of simulated endo- and exocytosis events. These events keep the system substantially out of equilibrium and yield a striped pattern comparable to those seen experimentally [1]. [1] Baumgart T, Hess ST, and Webb WW. Nature. 2003 Oct 23;425(6960):821-4.

**14:42**
**R29 2 Lipid Bilayers and Titanium: Controlling Surface Adsorption** LINDA S. HIRST, *MARTECH, Dept. of Physics, Florida State University* EMILY PARKER, NOEL C. MacDONALD, *Dept of Mechnical & Environmental Engineering, University of California, Santa Barbara* CYRUS R. SAFINYA, *Materials Dept. University of California, Santa Barbara* Used extensively for implants, titanium is relatively inert in the body, and considered a biocompatible metal. We have investigated the interactions of cationic lipid mixtures with a highly polished bulk $TiO_2$ surface and report the observation of an interesting cationic lipid tubule phase stabilized in 2D on the $TiO_2$ surface. This phase is distinct from the bulk tubule phase observed in some mixtures as the tubules form a network with small mesh size and appear to be more flexible. Cationic lipid vesicles were formed under various salt conditions and deposited on the $TiO_2$ surface via vesicle absorption, then observed with fluorescence microscopy. In certain mixtures, bulk tubule phases were observed. When deposited on glass the bulk tubule phase became unstable and bilayers gradually formed on the glass surface. However, deposition of the same cationic mixtures on $TiO_2$ resulted in the formation of a 2D network of lipid tubules on the surface. The network, although pinned to the surface remained fluid in nature, as confirmed by FRAP experiments. The tubules appear to be only weakly attracted to the $TiO_2$ and this may explain their stability on the surface.

**14:54**

**R29 3 Growth and Morphology of Solid-like Domains in Binary Giant Lipid Vesicles** PAUL BEALES, *University of Edinburgh* VERNITA GORDON, ZHIJUN ZHAO, STEFAN EGELHAAF, WILSON POON, *University of Edinburgh* Giant lipid vesicles are important, optically-resolvable, model systems for studying physical phenomena in biomembranes and have important applications as technological containers in the engineering of novel soft materials. Giant vesicles containing two different lipid components are well-mixed in the fluid phase; as the temperature is lowered phase separation occurs between fluid and solid-like phases. We observe this phase separation using confocal fluorescence microscopy. The varied domain morphologies have previously been assumed to result from interplay between line tension and the elastic properties of the bilayer. However, we find that the domain morphology can be understood from the structure of the solid-like phase: the molecular scale lipid organization determines the mesoscopic domain shape analogous to how unit cell symmetries determine the shape of three-dimensional crystals. We also show that the domains grow by a non-equilibrium mechanism that is well-know to occur in alloys. Slow diffusion in the solid-like phase results in a compositional gradient within these domains.

**15:06**

**R29 4 Laser Tweezer Deformation of Giant Unilamellar Vesicles** CORY POOLE, *University of Maryland* JOZSEF MESZAROS, KUMAR SENTHIL, WOLFGANG LOSERT, *University of Maryland* In an aqueous solution phospholipid bilayers self-assemble to form a closed surface which is called a vesicle. Vesicles have been studied extensively due to their relevance as a model for biomembranes as well as their practical uses for chemical containment and transport. We use a holographic optical tweezer array to study the mechanical response of giant unilamellar vesicles to applied stresses. By producing vesicles with encapsulated silica microspheres we use the tweezers to indirectly manipulate vesicled. Two or more spheres are used to stretch the vesicle membrane and subsequently the vesicle relaxes back to an equilibrium shape. These deformations are imaged at millisecond temporal resolution with spatial resolution on the order of 20 nm, and characteristic time and length scales of the relaxation are calculated. Further we are able to directly deform the membrane by pulling on the fluid utilizing an index of refraction mismatch between the inside and outside of the vesicle. We image the vesicle and extract the vesicle shape. Fourier analysis is used to track the vesicle as it returns to equilibrium after being stretched. We compare these deformations to preliminary data on deformations due to polymerization induced on both the inside and outside of vesicles.

**R29 5 Nanoscale characterization of solid-supported phospholipid multilayer films*** WILFRED NGWA, ANDREW GAO, TANIA CUBANO, KEZHENG CHEN, ALOK SAHGAL, WEILI LUO, *Department of Physics, University of Central Florida* Using atomic force microscopy (AFM) and the auxiliary molecular force probe (MFP) technique, we have studied the structure and nanomechanical response to nano-indentation of multilayered films of dioleoylphosphatidylcholine (DOPC) films prepared by solution spreading, spin-coating and capillary methods. Estimates for the Young's modulus for the different methods are found to be similar for sufficiently thick films. Our results demonstrate that previously reported estimates for the Young's modulus of adsorbed vesicles and lipid bilayers (membranes) by scanning probe techniques are ostensibly affected by the coupling of the substrate. Failure and self-healing of multilamellar lipid membranes is discussed.

*This work is partially supported by NSF NIRT 0103587.

**R29 6 A quasi-elastic neutron scattering study of the stabilization of freeze-dried cholesterol-containing DPPC liposomes by trehalose** V. GARCIA SAKAI, *NIST Center for Neutron Research* M. DOXASTAKIS, A.S. REDDY, J. DE PABLO, *Dept. Chem. Eng. University of Wisconsin* J.K. MARANAS, *Dept. Chem. Eng., Penn State University* The dissacharide trehalose has been employed extensively as a dehydroprotectant for stabilizing phospholipidic membranes, as a result of its ability to lower the gel-to-fluid phase transition temperature [Tm] of phospholipids. Upon rehydration of the membrane in the presence of trehalose, the transition is prevented and cell leakage is avoided. We use quasi-elastic neutron scattering [QENS] on selective deuterated samples to probe the dynamics of both the heads and tails of freeze-dried liposomes in the presence and absence of trehalose. The dynamics of the lipid tails are responsible for the melting transition, which is significantly lowered in the presence of the sugar. The mobility of the head-group is directly associated with the mobility of the sugar. In the current work, we add cholesterol to the liposomes. Cholesterol, abundant in mammalian cell membranes and embedded in the bilayer structure due to its hydrophobic nature, is added to the liposomes. QENS measurements on the stabilization by trehalose on cholesterol-containing liposomes are presented. At temperatures lower than Tm the mobility of the tails is greatly reduced by cholesterol, but the addition of trehalose has little effect dynamics. At temperatures above the transition though, the mobility of the tails is only slightly reduced, but the addition of trehalose leads to a large decrease in dynamics.

**15:42**

**R29 7 A Density Functional Theory Study of the Non-local Correlations between Nucleic Acid Base Pairs** VALENTINO R. COOPER, TIMO THONHAUSER, DAVID C. LANGRETH, *Rutgers University* The interactions of nucleic acid bases are fundamentally important in determining the behavior and structure of biologically important molecules such as DNA and RNA. However, the stacking of nucleic acid bases in a strand of genetic material involves significant van der Waals forces, which are often inaccurately represented or too expensive to compute in many modern theoretical methods. In this paper, we use Density Functional Theory (DFT) with a non-local van der Waals correlation functional[1] to study the stacking interactions of nucleic acid base pairs. This method correctly and seamlessly accounts for the long-range interactions present among isolated fragments through a density-density interaction formula. Since this technique is implemented within DFT it has the advantage of being able to draw on the speed, efficiency and accuracy of this *ab initio* method.

**15:54**

**R29 8 Low Temperature Orbital Paramagnetism in B-DNA** MICHAEL J. HARRISON, *Michigan State University* A planar model of B-DNA has been developed that exhibits orbital paramagnetic properties at zero temperature. The paramagnetism is nonlinear in applied field and has a maximum several times the

magnitude of diamagnetism per particle in a 2DEG. The model depends on the assumption that approximately 1% of the pi-stack electrons in B-DNA are suffiffiently delocalized and have wave functions that permit them to move coherently parallel to the helix axis, and extend several diameters perpendicular to its axis. The theoretical results closely represent recent experimental data [1]. 1. S. Nakamae, et. al., Phys. Rev. 94, 248102-1 (2005)

**16:06**

**R29 9 Kinetic Modelling of Transcription Elongation** DAIBHID O'MAOILEIDIGH, *Rutgers University* VASISHT TADIGOTLA, *Rutgers University* ANIRVAN SENGUPTA, *Rutgers University* VITALY EPSHTEIN, *New York University Medical Center* RICHARD EBRIGHT, *Rutgers University* EVGENY NUDLER, *New York University Medical Center* ANDREI RUCKENSTEIN, *Rutgers University* Transcription is the first step in gene expression and it is at this stage that most of genetic regulation occurs. The enzyme RNA polymerase (RNAP) walks along DNA creating an RNA transcript at a highly non-uniform rate. We discuss how many non-intuitive features of the system may be experimentally and physically motivated and present first a model, which agrees qualitatively with a host of experimental evidence. We also examine intrinsic pauses where it is thought that the RNAP will move backwards along the DNA template without changing the length of the RNA transcript. We describe a simplified kinetic scheme for the recovery of intrinsic pauses with the same degree of predictive power as our thermodynamic model (presented separately). The separation of timescales between the movement of the RNAP and global changes in the RNA secondary structure is seen to be crucial for the function of RNAP. This is essentially a model of a Brownian ratchet where RNAP executes a 1D random walk in a sequence dependent potential over a range determined by the co-transcriptional RNA fold for each transcript length

**16:18**

**R29 10 Understanding spontaneous sharp bending of DNA** CHONGLI YUAN, ELIZABETH RHOADES, LYNDEN ARCHER, *Cornell University* Gene expression often requires the interplay of two distant genetic regions and thus sharp bending of DNA is essential for gene functioning. Contrary to the conventional thinking that the bending of DNA strand below its persistent length was essentially facilitated by DNA binding proteins, Widom's group recently demonstrated, using cyclization assay, that such kind of sharp bending can be spontaneously formed (Mol. Cell, 2004, 355). Two models were referred in the original work to explain this ''enhanced'' flexibility of short DNA strand, namely, the melted single- and double-bubble models. To elucidate the detailed mechanism behind the DNA sharp bending, DNA molecules containing single- and double-melted bubbles was synthesized by introducing non Watson-Crick base pairs to the DNA backbone. Time resolved fluorescence energy transfer was used as the major tool to evaluate the bending stiffness of afore mentioned short DNA strand. The effect of bubble size, number and position on the DNA stiffness was independently evaluated. The energetic penalty of forming the locally melted structure was determined using other individual experiments. These results not only clarify the physical origin of the previously observed cyclizability of short DNA strand but also help to interpret the cyclization data of DNA molecules of wider size ranges.

**16:30**

**R29 11 The role of stacking interactions in the folding dynamics of DNA hairpins** MARTA SALES-PARDO, *Northwestern University* JON WIDOM, *Northwestern University* LUIS AMARAL, *Northwestern University* To gain a deeper insight into cellular processes such as transcription and translation, one needs to uncover the mechanisms controlling the configurational changes of nucleic acids. As a step toward this aim, we present here a novel mesoscopic-level computational model that provides a *new window* into nucleic acid dynamics. We validate the model by studying DNA hairpins, single-stranded molecules with two complementary segments (''stems'') linked by a non-complementary ''loop.'' Our model reproduces experimental observations and enables us to monitor the configurational dynamics of hairpins, providing clear evidence of a ''zipping'' process in the closing toward the native configuration. In addition, our model allows us to demonstrate that there is a preferred zipping pathway for folding which is both the most frequent and the fastest way for the hairpin to fold. Most importantly, our model allows us to tune the importance of the different interactions in the nucleotides and uncover the role of stacking interactions as the driving force in the zipping dynamics.

**16:42**

**R29 12 Thermodynamic Model of Transcription Elongation** VASISHT TADIGOTLA, *Rutgers University* DAIBHID O'MAOILEIDIGH, *Rutgers University* ANIRVAN SENGUPTA, *Rutgers University* VITALY EPSHTEIN, *New York University Medical Center* RICHARD EBRIGHT, *Rutgers University* EVGENY NUDLER, *New York University Medical Center* ANDREI RUCKENSTEIN, *Rutgers University* We present a statistical mechanics approach to the prediction of backtracked pauses in prokaryotic transcription elongation derived from structural models of the transcription elongation complex (TEC). Our algorithm is based on the thermodynamic stability of TEC along the DNA template calculated from the sequence dependent free-energy of DNA-DNA, DNA-RNA and RNA-RNA base pairing associated with (a) the translocation and size fluctuations of the transcription bubble; (b) the changes in the DNA-RNA hybrid; and (c) the changes in the RNA folding free-energy. The calculations involve no adjustable parameters apart from a cutoff used to discriminate paused from non-paused complexes. When applied to 100 experimental pauses in transcription elongation by E. coli RNA polymerase on ten DNA templates the approach produces highly statistically significant results. Transcription elongation is an inherently kinetic process and a simplified kinetic model with the same predictive power is presented separately.

**16:54**

**R29 13 The role of telomere dynamics in aging and cancer** KRASTAN BLAGOEV, EDWIN GOODWIN, *Los Alamos National Laboratory* Telomere length changes are far more dynamic than previously thought. In addition to a gradual loss of $\sim$ 100 base pairs per telomere in each cell division, losses as well as gains may occur within a single cell cycle. We are investigating how telomere exchange, extension, and deletion affect the proliferative potential of telomerase-negative somatic cells. Experimental techniques are being devised to detect dynamic telomere processes and quantify both the frequency and length changes of each. In parallel, a ''dynamic telomere model'' is being used that incorporates telomere dynamics to study how the telomere size distribution evolves with time. This is an essential step towards understanding the role that telomere dynamics play in the normal

aging of tissues and organisms. The model casts light on relationships not otherwise easily explained by a deterministic ''mitotic clock,'' or to what extent the shortest initial telomere determines the onset of senescence. We also expect to identify biomarkers that will correlate with aging better than average telomere length and to shed light on the transition to unlimited growth found in telomerase-negative tumor cells having the ALT (alternative lengthening of telomeres) phenotype, and to evaluate strategies to suppress the growth of these tumors.

**17:06**

**R29 14 Optical Investigation of the Phases of Liquid Crystals of Nanoscale Duplex DNA** GIULIANO ZANCHETTA, *U. of Milano, Italy* MICHI NAKATA, *U. of Colorado* TOMMASO BELLINI, *U. of Milano, Italy* NOEL CLARK, *U. of Colorado* Polymeric DNA chains are known to exhibit chiral nematic and hexagonal columnar LC phases. Recently we found that even very short duplex DNA oligomers 6-basepairs (bp) to 20-bp in length also form nematic and columnar phases depending on the concentration of DNA. To investigate the structure of those phases, we used depolarized transmission light microscopy (DTLM) to probe texture and measure birefringence, and optical interferometry to measure DNA concentration. These observations show a chiral nematic and two distinct columnar phases in the short oligomer duplexes. We will discuss the structure of these phases and present data correlating their occurance with solution conditions and with the detailed base pair configuration and the ends of the oligomers, showing that, for example, unpaired bases at the ends of the oligomers tend to suppress the LC phases. Work supported by NSF MRSEC Grant DMR 0213918 and NSF Grant 0072989.

**SESSION R30: POLYMER NANOCOMPOSITES**
**Wednesday Afternoon, 15 March 2006**
**327, Baltimore Convention Center at 14:30**
**Alamgir Karim, National Institute of Standards and Technology, presiding**

**14:30**

**R30 1 Bridging, Steric Stabilization, Aggregation and Phase Separation in Polymer Nanocomposites** JUSTIN B. HOOPER, KENNETH S. SCHWEIZER, *University of Illinois* The polymer reference interaction site model theory is employed to study the potential of mean force (PMF) between nano-sized spherical particles in a dense polymer melt. A simple monomer-filler attractive potential is used to probe the competition between packing entropy and interfacial enthalpic effects. As interfacial cohesion increases the nanoparticle organization varies from contact depletion aggregation, to well dispersed sterically stabilized behavior corresponding to a thermodynamically stable polymer coating, to tightly bridged particles. Near linear scaling of the PMF with particle/monomer size asymmetry ratio is found, and the spatial range of the interfacial attraction is crucial in determining particle organization. Spinodal demixing calculations suggest two types of phase separated states and a miscibility window. The latter is rapidly destroyed as particle size and/or interfacial attraction strength increase. The presence of bound polymer layers in miscible nanocomposites is predicted to result in microphase separation like features in the collective polymer structure factor.

**14:42**

**R30 2 Glass transition behavior of polystyrene/silica nanocomposites.*** YUPING XIE, SUDEEPTO SEN, SANAT KUMAR, *Rensselaer Polytechnic Institute* AMITABH BANSAL, *GE* GE COLLABORATION, The change in thermomechanical properties of nano-filled polymers is of considerable scientific and technological interest. The interaction between the nanofillers and the matrix polymer controls the nanocomposite properties. We will present the results from recent and ongoing DSC experiments on polystyrene/silica nanocomposites. Polystyrene of different molecular weights (and from different sources) and silica nanoparticles 10-15 nm in diameter (both as received from Nissan and surface modified by grafted or physisorbed polystyrene) are being used to process the nanocomposites. We are studying trends in the glass transition behavior by changing the matrix molecular weights and the silica weight fractions. Recent data indicate that the glass transition temperature can both decrease and increase depending on the polymer-nanofiller combination as well as the thermal treatment of the nanocomposites prior to the DSC runs.

*Thanks to NSF for support.

**14:54**

**R30 3 Molecular model for the rheology of polymer nanocomposites** CATALIN PICU, ALIREZA SARVESTANI, *Rensselaer Polytechnic Institute* In this work we develop a molecular model for the rheology of entangled monodisperse homopolymers filled with nanoparticles at low filling volume fraction. This research is the continuation of our ongoing effort towards establishing a connection between the macroscopic time-dependent behavior of polymer nanocomposites and their molecular structure. The model is developed based on insight gained from molecular simulations, regarding the structure and dynamics of polymeric chains confined between nanoparticles. These simulations provide physically relevant parameters for the rheological model. The model accounts for reptation, chain stretch and contour length fluctuations. It also accounts for the short-range energetic interactions between polymers and fillers. Its predictions are compared with experimental data. The rheological model is implemented in a FEM package to simulate nanocomposite processing.

**15:06**

**R30 4 Comparison of the Glass Transition Temperature (Tg)-Confinement Effect in Real and Model Polymer Nanocomposites.** JOHN M. TORKELSON, PERLA RITTIGSTEIN, LINDA J. BROADBELT, RODNEY D. PRIESTLEY, *Northwestern University, Evanston, IL 60208* Addition of nanoparticles to polymers leads to enhancement of Tg when attractive interactions (e.g., hydrogen bonding) are present at the nanoparticle-polymer interface. Nanoparticle concentration and dispersion play major roles in determining the Tg enhancement. Unfortunately, characterization of dispersion by transmission electron microscopy is difficult and tedious. Here we show by determination of the Tg-confinement effect in ''model'' polymer-silica nanocomposites (NCs), i.e., a polymer film of known thickness with two silica substrates supporting both sides of the film, that it is possible to characterize the effect of interparticle spacing on Tg and the approximate interparticle spacing in real polymer-silica NCs. Studies of model poly(2-vinyl pyridine) (P2VP)-silica NCs with 200-900 nm interlayer spacing reveal that a significant Tg enhancement is observed at a 500-nm interlayer spacing and that the Tg enhancement exceeds 20 K at a 200-nm interlayer spacing. Studies of model poly(methyl methacrylate) (PMMA)-silica NCs exhibit lesser Tg changes at

smaller interlayer spacing. By comparison of Tg enhancements in real and model NCs, a 5 K Tg enhancement in a 0.4 vol% silica-PMMA NC relates to a 100-130 nm interparticle spacing while a 10 K Tg enhancement in a 4 vol% silica-P2VP NC relates to a 300 nm interparticle spacing.

**15:18**

**R30 5 Polymer-Nanoparticle Interfacial Interactions in Polymer Nanocomposites: Confinement Effects on Glass Transition Temperature and Suppression of Physical Aging.** PERLA RITTIGSTEIN, JOHN M. TORKELSON, *Northwestern University, Evanston, IL 60208-3120* Confinement effects on glass transition temperature (Tg) and physical aging are measured via fluorescence in polystyrene (PS), poly(methyl methacrylate) (PMMA) and poly(2-vinyl pyridine) (P2VP) nanocomposites (NCs) containing 10-15 nm diam. silica nanospheres or 47 nm diam. alumina nanospheres. At 0.1-10 vol% nanofiller, Tgs can be enhanced or depressed relative to neat, bulk Tg or invariant with nanofiller content. For alumina NCs, Tg increases relative to bulk Tg by as much as 16 K in P2VP, decreases by as much as 5 K in PMMA, and is invariant in PS. These results are explained by wetted P2VP-nanofiller interfaces with attractive interactions, non-wetted PMMA-nanofiller interfaces, and wetted PS-nanofiller interfaces lacking attractive interactions, respectively. The presence of wetted or non-wetted interfaces is controlled by choice of solvent; silica/PMMA NCs exhibit Tg enhancements or reductions relative to bulk Tg when films are made from methyl ethyl ketone or acetic acid solutions, respectively. A factor of 10 reduction of physical aging rate relative to that of neat P2VP is shown in a 4 vol% alumina/P2VP NC. Hence, a strategy for achieving non-equilibrium, glassy polymer systems that are nearly stable to physical aging is to incorporate well-dispersed nanoparticles possessing attractive interfacial interactions with the polymer.

**15:30**

**R30 6 Relaxation and Glass Transition in Confined and Filled Polymers.** VLADIMIR DOLIDZE, EDWIN ARROYO, MANUEL RIVERA, FOUAD ALIEV, *University of Puerto Rico* We report the results of the investigations of the influence of confinement and filling of polymers with nanosize aerosil particles on the glass transition and dynamics of the $\alpha$- and the $\beta$-relaxation processes in poly(octylmethacrylate) (POMA) by dielectric spectroscopy dynamic light scattering and differential scanning calorimetry. The polymer was synthesized directly in pores of the porous glass matrix with interconnected and randomly oriented pores with an average pore size of 100 nm by free radical polymerization of the monomer. Both the $\alpha$- and the $\beta$- processes were observed in confined polymer. We found that confinement is resulted in the reduction of the glass transition temperature $T_g$ of the polymer. This change in $T_g$ was mainly due to the existence of a developed pore wall-polymer interface and difference in the dynamic behavior of polymer in the surface layers compared to that in the bulk. The random structure of the host media was less important. Variations of size of filling particles and their concentration are helpful in understanding of relaxation properties at polymer – solid interface as well as a role of surface interactions in glass transition.

**15:42**

**R30 7 Directed Assembly of Nanoparticle Arrays using Block Copolymer Templates** HUIMAN KANG, *Department of Chemical and Biological Engineering and Center for Nanotechnology, University of Wisconsin, Madison 53706, USA*. ANDREW N. MANGHAM, *Department of Chemistry, University of Wisconsin, Madison 53706, USA*. MARK P. STOYKOVICH, *Department of Chemical and Biological Engineering and Center for Nanotechnology, University of Wisconsin, Madison 53706, USA*. ROBERT J. HAMERS, *Department of Chemistry, University of Wisconsin, Madison 53706, USA*. PAUL F. NEALEY, *Department of Chemical and Biological Engineering and Center for Nanotechnology, University of Wisconsin, Madison 53706, USA*. CdSe nanoparticles, functionalized with tetradecyl phosphonic acid (TDPA), were synthesized so as to preferentially segregate into the polystyrene (PS) domains of polystyrene-itblock-poly(methyl methacrylate) (PS-*b*-PMMA). Nanocomposites, composed with ternary blends (PS-*b*-PMMA/PS/PMMA) and CdSe, could be directed to assemble into defect-free and registered periodic and non-regular structures on chemically patterned substrates. The location of nanoparticles in the PS differs depending on the blend composition and the commensurability between the chemical surface pattern and the bulk lamellar period of the composite and can be interpreted in terms of the interplay between the phase behavior of the composite systems and surface and interfacial interactions. CdSe nanoparticle arrays, replicating the block copolymer patterns, were obtained by removing the polymer using $O_2$ plasma.

**15:54**

**R30 8 Surface segregation of silver nanoparticles in the in-situ synthesized Ag/PMMA nanocomposites.** RANJAN D. DESHMUKH, RUSSELL J. COMPOSTO, *Materials Science and Engineering, University of Pennsylvania* Silver nanoparticles were synthesized in-situ, by thermal decomposition of (1,1,1,5,5,5 Hexafluoroacetylacetonato)silver(I), Ag(hfac), precursor at 185 $^{o}$C, in thin films of Poly(methyl methacryalate), PMMA. Rutherford backscattering spectrometry, RBS, was used to observe and quantify the silver distribution along the thickness of the sample. Strong surface segregation of nanoparticles to the polymer surface and substrate was observed in PMMA thin films by RBS and also confirmed by cross-sectional transmission electron microscopy (TEM). Surface segregation mechanism has been attributed to simultaneous thermal decomposition and diffusion of precursor to polymer surface and substrate. It has been shown that the particles present near the surface could be initially exposed and then are eventually covered by the polymer leading to particle sinking as observed by TEM. Atomic force microscopy (AFM) showed bigger nanoparticles and wider size distribution on increasing the nanoparticle loading from 5 to 20-wt %. UV/Visible spectroscopy on PMMA/Ag nanocomposite films showed plasmon resonance peaked at 422 nm due to the presence of silver nanoparticles.

**16:06**

**R30 9 Selective Metallization of Well Aligned PS-*b*-P2VP Block Copolymers in Thin Films and in Confined Geometries** JAMES D. SIEVERT, JAMES J. WATKINS, THOMAS P. RUSSELL, *University of Massachusetts - Amherst* Well aligned, microphase-separated structures of styrene-2-vinylpyridine block copolymers are being used as templates for macromolecule-metal nanocomposites. These composites are either prepared as thin films or confined in nanoporous aluminum oxide membranes. Under optimal conditions, templates are prepared as thin films or confined nanorods and metallized without disturbing the ordered structure. We have developed a procedure that deposits metal within the polymer using supercritical carbon dioxide-soluble metal precursors. The use of supercritical carbon dioxide allows

for selective metallization of the polymer at or below the glass transition, without disrupting the morphology. In addition, similar procedures have been investigated using metal salts and acids. Using these techniques, metals and metal-sulfides including silver, gold, platinum and zinc sulfide have been selectively deposited.

**16:18**

**R30 10 Static and Dynamic Neutron Scattering Studies of Polystyrene-Silica Nanocomposites.*** SUDEEPTO SEN, YUPING XIE, SANAT KUMAR, *Rensselaer Polytechnic Institute* DEREK HO, VICTORIA GARCIA-SAKAI, *National Institute of Standards and Technology* RPI/NIST COLLABORATION, Studies of polymer chain conformation and dynamics in the presence of nanofillers are critical in the context of the mechanical properties of polymer nanocomposites. We will present the results from recent and ongoing SANS experiments on polystyrene-silica nanocomposites containing polystyrene matrices of different molecular weights and silica nanofillers (10 – 15 nm in diameter) over a range of weight fractions. Preliminary neutron backscattering fixed-window scans of these nanocomposites indicate a similarity between the dynamics of the nanocomposites and thin polystyrene films in the sub-glass region. These results and results from ongoing backscattering experiments will also be discussed.

*NSF-NSEC

**16:30**

**R30 11 Structure and properties of poly(methyl methacrylate) (PMMA)-fullerene ($C_{60}$) nanocomposites** JAMIE KROPKA, *Department of Chemical Engineering, The University of Texas at Austin* PETER GREEN, *Department of Material Science and Engineering, Applied Physics, Macromolecular Science and Engineering, University of Michigan* We examined the rheological and dynamical mechanical (DMA) properties of PMMA-$C_{60}$ nanocomposite materials with relatively low concentrations of $C_{60}$, 0.1-5wt%. Decreases of the glass transition temperature ($T_g$), $\sim 7\ ^oC$, were observed in samples with 0.5 and 1 wt% $C_{60}$. The decreases in $T_g$ are connected to decreases of the longest relaxation time measured for the system. The plateau modulus of the composites was enhanced relative to the homopolymer but did not increase monotonically with $C_{60}$ concentration. The relative changes of the relaxation time, the plateau modulus and $T_g$ cannot be explained by the Doi-Edwards model and appear to be connected to the distribution of the nanoparticles, as determined by electron microscopy.

**16:42**

**R30 12 Self-Corralling of nanorods under electric fields.** SURESH GUPTA, QINGLING ZHANG, TODD EMRICK, THOMAS RUSSELL, *Polymer Science and Engineering department, University of Massachusetts, Amherst* Orienting semiconductor nanorods normal to a surface is highly desirable for applications including photovoltaic, spintronics, etc. We have achieved this using solutions of mixture of alkane-covered CdSe nanorods with PMMA by solvent evaporation under an electric field. The electric field aligns the nanorods parallel to the field lines whereas incompatibility between the PMMA and alkane ligands causes a phase separation that tends to segregate the nanorods. This phase separation generates line tension that further compacts the packing of nanorods. Furthermore the nanorods are being synthesized that are covered with photoactive polymer such as poly (3-hexyl thiophene). This may lead to enhancement in efficiency of organic-inorganic heterojunction photovoltaic devices.

**16:54**

**R30 13 Theoretical and Experimental Studies of New Polymer-Metal High-Dielectric Constant Nanocomposites** VALERIY GINZBURG, MICHAEL ELWELL, KYLE MYERS, ROBERT CIESLINSKI, SARAH MALOWINSKI,*MARK BERNIUS, *The Dow Chemical Company* High-dielectric-constant (high-K) gate materials are important for the needs of electronics industry. Most polymers have dielectric constant in the range $2 < K < 5$; thus to create materials with $K > 10$ it is necessary to combine polymers with ceramic or metal nanoparticles. Several formulations based on functionalized Au-nanoparticles ($R \sim 5$ - 10 nm) and PMMA matrix polymer are prepared. Nanocomposite films are subsequently cast from solution. We study the morphology of those nanocomposites using theoretical (Self-Consistent Mean-Field Theory [SCMFT]) and experimental (Transmission Electron Microscopy [TEM]) techniques. Good qualitative agreement between theory and experiment is found. The study validates the utility of SCMFT as screening tool for the preparation of stable (or at least metastable) polymer/nanoparticle mixtures.

*Present address: Instron Corp., Norwood MA

**17:06**

**R30 14 Epoxy-silica composites for micro-electronic applications: effect of filler** HYUKSOO LEE, *Samsung Electro-mechanics Co.* MYEONGHO HONG, CHOONKEUN LEE, ILSANG MAENG, JAECHOON CHO, SANGMOON LEE, JEONGBOK KWAK, SEUNGHYUN RA, The epoxy composites filled with silica fillers having various amounts and sizes were prepared and a detailed study of the structure-property relationships of the resulting composites is reported. Scanning electron microscopy (SEM), thermomechanical analyzer (TMA), rheological behavior, and stress-strain analysis were used to evaluate the epoxy-silica composite morphology and physical properties. The stiffness and thermal expansion were improved with increasing filler amount. Whereas, the ductility decreased significantly as the filler content increased. Scanning electron micrographs of fractured composites revealed that the dispersion of the filler in the matrix is highly dependent on the size and amount of fillers and has a strong effect on the mechanical, thermal, and rheological properties of the composites. The processibility of the composites for micro-electronic applications such as printed circuit board (PCB), is briefly discussed.

**17:18**

**R30 15 Quantum dots tailored with water soluble conjugated polymer** JUN XU, *Materials Science and Engineering Department, Iowa State University* JOSEPH SHINAR, *Physics and Astronomy Department, Iowa State University* ZHIQUN LIN, *Materials Science and Engineering Department, Iowa State University* Placing the conjugated polymer (CP) in direct contact with the quantum dot (QD) offers advantages over cases where QD aggregation dominates. Such quantum dot- conjugated polymer nanocomposite (QD-CP) possesses a well-defined interface, thereby significantly promoting the charge or energy transfer between these two components. Here we demonstrate an approach to graft water soluble, negatively charged conjugated polymer, MPS-PPV from CdSe QD surfaces. The conjugation length of the MPS-PPV is adjustable by varying the ratio of co-solvents used. The photophysical properties of the nanocomposites in nanoscopic confined geometries are studied.

**SESSION R31: PROPERTIES OF CARBON NANOTUBES**
**Wednesday Afternoon, 15 March 2006**
**328, Baltimore Convention Center at 14:30**
**Nicola Marzari, Massachusetts Institute of Technology, presiding**

**14:30**
**R31 1 Neon adsorption on single walled carbon nanohorns*** V. KRUNGLEVICIUTE, K. LASK, A. D. MIGONE, *Southern Illinois University* B. BULLER, T. BEATTIE, U. VENKATESWARAN, *Oakland University* We present results for Ne adsorbed on single walled carbon nanohorns (SWNHs) purchased from NanoCraft, Inc. The as-received SWNHs were characterized with Raman spectroscopy. The spectra show two peaks attributable to the D and G-bands, with the G-band exhibiting a shoulder in contrast to a single Lorentzian peak reported in the literature. A portion of the SWNHs was sonicated in methanol for twenty minutes and heated under vacuum at 60oC for 12 hours (this treatment was followed to produce ''nanohorn- paper''). Full adsorption isotherms were measured on this sample between 22 and 31 K, and low coverage isotherms were measured between 40 and 49 K. Neon measurements were also performed at 31 K on a sample of SWNHs that was not subjected to the methanol treatment, for comparison. We found no difference between the results obtained on these two sets of samples. We will also present isotherm data on SWNHs that were heated to 520 K under vacuum.

*This work was supported by the NSF through grant DMR-0089713 (ADM) and DMR-0104176 (UV).

**14:42**
**R31 2 Carbon nanotube − metal cluster bond strengths: implications for catalytic growth.** PETER LARSSON, *Condensed Matter Theory Group, Physics Department, Uppsala University, Box 530, SE-751 21, Uppsala, Sweden* FENG DING, *Rice University, ME & MS Department, Houston, TX 77005* J. ANDREAS LARSSON, *Tyndall National Institute, Lee Maltings, Prospect Row, Cork, Ireland* ARNE ROSEN, *Physics Department, Goteborg University, SE-412 96, Goteborg, Sweden* RAJEEV AHUJA, *Condensed Matter Theory Group, Physics Department, Uppsala University, Box 530, SE-751 21, Uppsala, Sweden* KIM BOLTON, *Physics Department, Goteborg University, SE-412 96, Goteborg, Sweden* Catalysts play a crucial role in the production of carbon nanotubes (CNTs). Although a lot of experimental effort has been devoted to finding metals and alloys to optimize CNT growth, the importance of the CNT-metal interactions at the microscopic level are not well understood. Previous simulations based on analytic force fields indicate that a critical role of the catalyst particle is to maintain an open end of the growing CNT, and that sufficiently strong CNT-metal bond strengths are required for this criterion to be met. Here we report CNT-metal bond strengths obtained from density functional theory for a variety of metal clusters. In agreement with the simulations, these calculations reveal that CNT interactions with metals used for production (e.g., Fe and Ni) are stronger than for other metals (e.g. Au). These bond strengths are also compared to the C-C bond energies that form when a cap forms at the end of the growing CNT.

**14:54**
**R31 3 Uncatalyzed Etching of Single Walled Carbon Nanotubes on Surfaces** SEAN PHEASANT, VALERIE MOORE, ROBERT HAUGE, RICHARD SMALLEY, *Rice University* Aside from burning, the only way single walled carbon nanotubes (SWNTs) have been etched is with the use of a catalyst nanoparticle at high temperatures in an oxidative or reducing atmosphere. The catalyst is a particle close in size to the diameter of the nanotube, and is usually composed of iron, molybdenum, nickel or cobalt, or a combination of these metals. The catalyst operates at the ends of the SWNTs, where it dissociates molecules from the atmosphere on its surface, and combines them with carbon atoms from the tube to form a gas. It has been found that SWNTs can be oxidatively etched with CO2 at a high temperature (900°C) in the absence of catalyst particles. The reverse of the Boudard reaction occurs at high temperatures to produce two molecules of CO from a molecule of CO2 and a C atom. When the ends of the tubes are closed, no etching is observed, indicating that only the open ends of the tubes can be attacked by CO2 and not the sidewalls. Experiments were done on both SiO2 and highly oriented pyrolytic graphite (HOPG). Results suggest the tubes etch faster on HOPG than they do on the oxide surface.

**15:06**
**R31 4 Defects in carbon nanotubes** RODRIGO G. AMORIM, ANTÔNIO J. R. DA SILVA, A. FAZZIO, *Instituto de Física, Universidade de São Paulo* ALEX ANTONELLI, *Instituto de Física ''Gleb Wataghin,'' UNICAMP* It is a consensus that defects can alter in a significant way the mechanical properties of carbon nanotubes. We here will investigate, using ab initio total energy density functional theory calculations, some defects and their properties, such as: 1) an interstitial carbon atom right besides a vacancy that can connect tubes in bundles or in multiwall nanotubes; 2) two vacancies that can connect tubes in bundles; 3) a variety of configurations for two vacancies in one nanotube, and how their energies vary with separation. In particular, we will compare the formation energies of the 5-8-5 and 555-777 two-vacancy defects as a function of nanotube diameter.

**15:18**
**R31 5 Electroabsorption of Single-Walled Carbon Nanotubes*** W. JOSHUA KENNEDY, Z. VALY VARDENY, *University of Utah* We have measured the electric field modulated absorption (EA) of single-walled carbon nanotubes (SWNT) isolated in a poly-vinyl alcohol matrix (PVA). The derivative-like structure of the EA indicates that the low energy absorption bands are excitonic in origin. We report the voltage, temperature, and polarization dependence of the EA spectrum. Additionally, the sensitivity of the EA spectrum to the energy levels of the SWNT allows us to use EA spectroscopy to observe shifts in the absorption bands of our sampleS induced by various external fields that are difficult to resolve using CW techniques. Several examples will be discussed.

*Supported in part by the DOE

**15:30**
**R31 6 Phases of Ethane Adsorbed on Purified HiPco Single Walled CarbonNanotubes.** DINESH RAWAT, ALDO MIGONE, *Department of Physics, Southern Illinois University* We have measured adsorption isotherms of ethane on purified HiPco SWNTs for coverages in the first layer. We wanted to investigate the existence of different phases for ethane as a function of coverage on this substrate, and to compare the results to those on planar graphite. We measured isotherms at 103, 110,150,

160, and 165K. We used the low-coverage isotherm data to obtain an estimate for the binding energy of ethane on the SWNTs; we found a value of 363 meV for this quantity. This binding energy value is 1.81 times greater than the corresponding one for this quantity on planar graphite. We have also determined the coverage dependence of isosteric heat of adsorption for ethane using the results for isotherms obtained at above-mentioned temperatures. This work was supported through a grant from NSF, DMR#0089713, and by the Materials Technology Center of SIUC.

**15:42**

**R31 7 Single Electron Effects in a Carbon Nanotube Electromechanical Oscillator** AREND VAN DER ZANDE, *LASSP Cornell University* RENA ZIEVE, *Department of Physics, UC Davis* VERA SAZONOVA, PAUL MCEUEN, *LASSP Cornell University* We have fabricated suspended, doubly clamped, carbon nanotube (NT) transistors to investigate the low temperature coupling between mechanical vibration of the NT and single electron effects. At low temperatures of 0.3K to 4.2K, the NT behaves as a quantum dot. The NT quantum dot displays Coulomb oscillations in the conductance by sweeping a gate voltage. Mechanical vibrations are induced in the NT by applying a high frequency AC voltage relative to the gate [1]. The nonlinear conductance of the Coulomb oscillations can be used as a mixer to detect the NT's own motion. We find that the mechanical resonances of the NT are influenced by the Coulomb oscillations. We observe a dip in the resonance frequency and a dip in the quality factor as the gate voltage is swept through a Coulomb oscillation. We attribute these dips to the forces on the NT from the hopping of single electrons on and off the NT as it moves with respect to the gate. [1] V. Sazonova, Y. Yaish, H. Ustunel, D. Roundy, T.A. Arias, and P.L. McEuen, Nature 431, 284-287 (2004)

**15:54**

**R31 8 Anharmonic effects in carbon nanotubes: from thermal expansion to phonon lifetimes** N. BONINI, N. MOUNET, N. MARZARI, *Department of Materials Science and Engineering, MIT, Cambridge, MA, USA* M. LAZZERI, F. MAURI, *Institut de Minéralogie et Physique des Milieux Condensés, Paris, France* We study anharmonic effects in carbon nanotubes using a combination of density-functional theory and density-functional perturbation theory. In particular, we investigate thermal expansion and phonon lifetimes, which are key quantities that govern mechanical and transport properties in these systems. The thermal expansion coefficients are calculated from a minimization of the vibrational free energy in the quasi-harmonic approximation. Our results show that carbon nanotubes contract both in the axial and radial directions at low and room temperature and expand at higher temperatures. The role of different phonon modes in the thermal contraction is discussed together with their Grüneisen parameters. Anharmonic phonon lifetimes are evaluated from the cubic terms in the interatomic potential, using density-functional perturbation theory and the $2n+1$ theorem. Finally, we discuss the possibility of estimating anharmonic effects using downfolding from graphene.

**16:06**

**R31 9 Raman Spectroscopy of Carbon Nanotubes under Axial Strain** RAJAY KUMAR, *University of Southern California* HAO ZHOU, *University of Southern California* STEPHEN CRONIN, *University of Southern California* We measure the Resonance Raman spectra of individual carbon nanotubes under axial strain. A combination of atomic force microscopy (AFM) and lithography is used to produce strains in nanotubes ranging from 0.1% to 5%. The vibrational and electronic energies of the nanotubes are found to be very sensitive to strain. The D, G and G' band Raman modes are observed to downshift with strain indicating elongation, and hence weakening, of the carbon-carbon bonds. The intensities of the Raman modes are also observed to change as a function of strain, indicating a strain-induced shifting of the electronic subbands. A tight-binding model is presented to explain the changes observed in the Raman intensity in accordance with the Resonance Raman equation.

**16:18**

**R31 10 Synthesis and Raman characterization of Nitrogen doped single walled carbon nanotubes.** ADALBERTO ZAMUDIO, ANA-LAURA ELIAS, *IPICYT, Mexico* FEDERICO VILLALPANDO-PAEZ, *MIT, USA* JULIO A. RODRIGUEZ-MANZO, EDUARDO CRUZ-SILVA, HUMBERTO TERRONES, *IPICYT, Mexico* TAKUYA HAYASHI, Y.A. KIM, HIROYUKI MURAMATSU, MORINOBU ENDO, *Shinshu University, Japan* MILDRED S. DRESSELHAUS, GENE DRESSELHAUS, *MIT, USA* MAURICIO TERRONES, *IPICYT, Mexico* We report the production of macroscopic amounts of long strands consisting of SWNT doped with nitrogen, using a CVD approach. We performed series of experiments varying the concentration of the nitrogen precursor in the solution, from 0.01% to 26 % by weight. The materials were characterized using scanning electron microscopy (SEM), transmission electron microscopy (TEM), high resolution TEM, and Raman Spectroscopy. We will describe the changes in the Raman spectra caused by the nitrogen content using of different laser lines. First principle calculations on the electronic and vibrational properties of the doped SWNTs with N will also be presented.

**16:30**

**R31 11 Raman spectra and thermal stability analysis of 0.4 nm freestanding single-walled carbon nanotubes** JIAN TING YE, ZI KANG TANG, *Department of Physics and Institute of Nano Science and Technology, Hong Kong University of Science and Technology* SEMICONDUCTOR CLUSTER TEAM, Thermal stability of ultra-small 0.4 nm single-walled carbon nanotubes is studied by means of Raman scattering measurement under vacuum. The 0.4 nm SWNTs are very stable when they are confined inside the channels of the AFI crystal. When these SWNTs are extracted from the channels into free space, however, they become thermally unstable because of the strong curvature effect. All three structures of the 0.4 nm-sized SWNTs are destroyed between 730 to 790 K, a temperature range much lower than that of large-sized SWNTs. The (5,0) tube is only destroyed after temperature reaches 790 K and seems slightly stabler than the other two structures: the (3,3) and (4,2) tubes.

**16:42**

**R31 12 Effect of Magnetic Field in Carbon Nanotubes** YURIY MALOZOVSKY, ANDREW KINCHEN, *Southeastern Louisiana University* We study the effect of magnetic field in the armchair carbon nanotubes (CNT). We model the carbon nanotube as a tubule with electrons confined to the surface of the tubule by an attractive delta-function potential. We derived the dynamic pair interaction potential between two electrons in the tubule in the presence of magnetic field. Dispersion of plasma modes at differ-

ent values of angular momentum, and single-particle excitations in the presence of the magnetic field are derived as well. The self-energy part due to the interaction of an electron with plasma modes in magnetic field is also discussed.

**16:54**

**R31 13 Low-energy dark discharge growth of ultra-thin aligned carbon nanofibers for field emitter and optical antenna arrays*** YANG WANG, *Boston College* K. KEMPA, *Boston College* Z. F. REN, *Boston College* DEPT. OF PHYS., BOSTON COLLEGE TEAM, We show experimentally the applicability of using a dc low-energy dark discharge state to grow aligned carbon nanofibers with diameters of less than 10 nm and directly on polyimide and transparent conducting oxides without buffer layers. The average discharge current density used can be 2-3 orders of magnitude lower than that in a typical plasma-enhanced chemical vapor deposition (PECVD), so that the plasma heating and etching effects are greatly alleviated, leading to lower growth temperatures and higher substrate compatibility. The nanofibers grown by dark discharges exhibit similar optical antenna effects to those grown by PECVD methods, and their diameter and density can be reduced to achieve good field emission properties.

*Financial supports from US Army Natick Soldier Center and National Science Foundation are acknowledged.

**17:06**

**R31 14 Electronic and transport properties of carbon-based atomic chain structures** R. TUGRUL SENGER, ENGIN DURGUN, *Bilkent University* SEFA DAG, *Oak Ridge National Laboratory* SEFAATTIN TONGAY, *University of Florida* SALIM CIRACI, *Bilkent University* Our first-principles calculations show that monatomic chains of carbon have high cohesive energy and axial strength, and are stable even at high temperatures. Pure carbon chains are metallic, and periodic compounds of carbon with transition- metals exhibit half-metallic properties where the electronic spins are fully polarized at the Fermi level. Finite-length carbon atomic chains capped with single transition metal atoms constitute the ultimately small spin-valve systems with high magnetoresistive ratios. In all these structures the electronic, magnetic and transport properties show interesting variations depending on the number of carbon atoms being odd or even. [1] S. Tongay, R.T. Senger, S. Dag, and S. Ciraci, Phys. Rev. Lett. **93**, 136404 (2004). [2] R. T. Senger, S. Tongay, S. Dag, E. Durgun, and S. Ciraci, Phys. Rev. B **71**, 235406 (2005). [3] S. Dag, S. Tongay, T. Yildirim, E. **R32 1 Multi-scale Modeling of Thermal-Electromechanical Response of Piezoelectric Thin Film** LIMING XIONG, *The George Washington University* JAMES LEE, *The George Washington University* YOUPING CHEN, *The George Washington University* YAJIE LEI, This study aims at understanding and improving the properties of the piezoelectric thin films through numerical simulation. On the basis of first principle calculation, empirical inter-atomic potential is obtained by fitting to the lattice parameters, energy surface and phonon dispersion relation. Both traditional MD simulation and a new atomistic multi-scale field theory are employed to simulate the material behavior of piezoelectric thin films under thermal, electrical and mechanical loading. Results are well agreed with each other between MD simulation and the newly developed field theory. Meanwhile, it is found out that the newly developed field theory is more efficient in studying nonequilibrium phenomenon, high temperature and high pressure working conditions for thin films. Size effects, thermal conductivity, failure process and material behavior in harsh environments for the thin films are investigated, which provide us with scientific information for the design and optimization of industrial application.

**R32 2 Multi-scale Simulations of $SiO_2$ Systems I: Classical and Hybrid Simulations*** CHAO CAO, YAO HE, HAI-PING CHENG, *University of Florida* Classical MD simulations show that bulk and nano-wire silica glass exhibit completely different stress-strain curves. A typical bulk sample breaks almost instantaneously while a nano-wire sample usually breaks ''gradually.'' A further simulation on nano-wire sample surrounded by water molecule shows that the stress-strain curve is not affected very much by the presence of water molecules. However, from previous quantum calculations (by Du et. al), one would believe that the water molecules do affect the fracture of silica a lot. Therefore, multi-scale simulations on a simple model $SiO_2$ chain are performed and compared with classical simulations on the same system to investigate mechanisms underlying the inconsistency. The multi-scale simulation is also compared with a full quantum calculation in our second talk.

**14:54**

**R32 3 Multiscale Simulation of SiO2 II: Quantum Simulations*** YAO HE, CHAO CAO, HAI-PING CHENG, *University of Florida* To investigate effects of external stress and the influence of water molecules on the energetic stability of low dimension silica systems, we have performed ab initio molecular-dynamics simulations as well as hybrid classical/quantum simulations of SiO2 chains. These silica chains are formed by edge-sharing two-rings. We present strain dependent interactions of silica-water systems at room temperature. Our investigations provide qualitative and quantitative descriptions of the reaction processes. We have also compared these ab initio results with results obtained from our multiscale simulations method, in which the quantum region is embedded in a classical region.

**R32 4 Dissipation of Mechanical Energy in Carbon Nanotube-based Mechanical Devices.**
PAUL TANGNEY, *The Molecular Foundry, Lawrence Berkeley National Laboratory*

The creation of functional mechanical devices at the nanoscale is a major goal of nanoscience, and multiwalled carbon nanotubes (MWCNT) are promising materials for constructing such devices. The large disparity between the strengths of intralayer and interlayer interactions in MWCNTS allows for smooth relative motion of concentric tubes. Some simple mechanical elements such as linear and rotational bearings have already been constructed from MWCNTs by exploiting this feature [1]. However, little is known about the dominant mechanisms for dissipation of mechanical energy at the nano scale, and devices based on MWCNTs are both technologically important and useful as test systems for theoretical investigations. In this talk, atomistic simulations of some simple MWCNT-based mechanical systems will be presented. It is shown that reducing the dimensions of a device can have a strong impact on phononic friction. The small masses of nanotubes relative to the forces between them means that relative velocities can be comparable to and larger than atomic thermal velocities. In this regime, theories based on a quasi-adiabatic response of atoms to the relative motion of nanotubes fail and simulations reveal a strong and complex velocity dependence of friction [2]. Large edge to surface ratios mean that edges can play an important role in energy dissipation and for concentric nanotubes of length 10s of nm, the ends of the nanotubes have been shown to dominate sliding friction [2]. These and other important features of friction in nanotube-based devices will be discussed and illustrated with the results of molecular dynamics simulations. This work was supported by the NSF Grant No. DMR04-39768 and U.S. DOE Contract No. DE-AC03-76SF00098. [1] J. Cumings and A. Zettl, Science 289, 602 (2000); A. M. **R32 5 Elastic properties of SiC nanoscopic wires** MAXIM MAKEEV, *NASA Ames Research Center, MS 229-1, Moffett Field, CA 94035* MADHU MENON, *Department of Physics and Astronomy, University of Kentucky, Lexington, KY 40506* DEEPAK SRIVASTAVA, *NASA Ames Research Center, MS 229-1, Moffett Field, CA 94035* Mechanical properties of crystalline and amorphous SiC nanowires have been investigated using molecular dynamics simulations with the Tersoff bond-order interatomic potential. The crystalline and a-SiC nanowires of different diameters were studied under tension/compression, torsion, and bending. The bending and torsion rigidities are found to be strongly dependent on the wire size. This is unlike the Young's modulus computed from uniaxial loading curves. Atomistic relaxations effects near the thresholds of structural stability are investigated for the four employed load types. The mechanical properties of crystalline SiC nanowires are compared with a-SiC wires of the same radii.

**R32 6 Simulation Studies of Mechanical Properties of Novel Silica Nano-structures** KRISHNA MURALIDHARAN, JOAN TORRAS COSTA, SAMUEL B. TRICKEY, *University of Florida* QTP NANOROD TEAM, Advances in nanotechnology and the importance of silica as a technological material continue to stimulate computational study of the properties of possible novel silica nanostructures. Thus we have done classical molecular dynamics (MD) and multi-scale quantum mechanical (QM/MD) simulation studies of the mechanical properties of single-wall and multi-wall silica nano-rods of varying dimensions. Such nano-rods have been predicted by Mallik et al. to be unusually strong in tensile failure. Here we compare failure mechanisms of such nano-rods under tension, compression, and bending. The concurrent multi-scale QM/MD studies use the general PUPIL system (Torras et al.). In this case, PUPIL provides automated interoperation of the MNDO Transfer Hamiltonian QM code (Taylor et al.) and a locally written MD code. Embedding of the QM-forces domain is via the scheme of Mallik et al. Work supported by NSF ITR award DMR-0325553.

**R32 7 On The Nonlinear Mechanics of Carbon Nanocones Using The Consistent Atomic-scale Finite Element Method** ARASH MAHDAVI, *Penn State, Department of Mechanical and Nuclear Engineering* ERIC MOCKENSTURM, *Penn Sate, Department of Mechanical and Nuclear Engineering* In the present work, a new multiscale modeling technique called the Consistent Atomic-scale Finite Element (CAFÉ) method is introduced. Unlike traditional approaches for linking the atomic structure to its equivalent continuum, this method directly connects the atomic degrees of freedom to a reduced set of finite element degrees of freedom without passing through an intermediate homogenized continuum. As a result, there is no need to introduce stress and strain measures at the atomic level. The Tersoff-Brenner interatomic potential is used to calculate the consistent tangent stiffness matrix of the structure. In this finite element formulation, all local and non-local interactions between carbon atoms are taken into account using overlapping finite elements. In addition, a consistent hierarchical finite element modeling technique is developed for adaptively coarsening and refining the mesh over different parts of the model. This process is consistent with the underlying atomic structure and, by refining the mesh, molecular dynamic results will be recovered. In contrast with most other multiscale methods, there is no need to introduce artificial boundaries for coupling atomistic and continuum regions. The applicability of the method is shown with several examples of deformation of carbon nanocones subjected to different loads and boundary conditions.

**R32 8 Nanocrystalline Domain Formation as a Strain Relaxation Mechanism in Ultra-Thin Metallic Films** M. RAUF GUNGOR, DIMITRIOS MAROUDAS, *University of Massachusetts, Amherst* In this presentation, we report results for the atomistic mechanisms of strain relaxation over a wide range of applied biaxial tensile strain (up to 17%) in free standing Cu thin films based

on isothermal-isostrain molecular-dynamics simulations. After an elastic response at low strain ( $<$ 2%), plastic deformation occurs through ductile void growth accompanied by emission of screw dislocations from the void surface, as well as emission of threading dislocation loops from the film's surface. At strain levels below 8%, expansion of the plastic zone around the void during void growth is the major strain relaxation mechanism. At higher levels of applied strain ( $>$ 8%), a practically uniform distribution of dislocations is generated in the metallic thin film, which mediates the transformation of the initially single-crystalline film structure to a nanocrystalline one. Furthermore, void growth is inhibited as the dislocations emitted from the void surface are pinned by the simultaneously generated network of defects in the nanocrystalline material.

**16:30**

**R32 9 New and exotic self-organized patterns for modulated nanoscale systems** ELIANA ASCIUTTO, CHRISTOPHER ROLAND, CELESTE SAGUI, *North Carolina State University* The self-organized domain patterns of modulated systems are characteristic of a wide variety of chemical and physical systems, and are the result of competing interactions. From a technological point of view, there is considerable interest in these domain patterns, as they form suitable templates for the fabrication of nanostructures. We have analyzed the domains and instabilities that form in modulated systems, and show that a large variety of new and exotic patterns – based on long-lived metastable or glassy states – may be formed as a compromise between the required equilibrium modulation period and the strain present in the system. The strain results from topologically constrained trajectories in phase space, the effectively preclude the equilibrium configuration.

**16:42**

**R32 10 Studies of elastic and plastic deformation of nanostructured materials: A continuum approach** MIKKO HAATAJA, *Princeton University* PETER STEFANOVIC, *McMaster University* NIKOLAS PROVATAS, *McMaster University* Nanostructured materials can have physical and mechanical properties that are strikingly different from their corresponding bulk counterparts. Consequently, unraveling the physical mechanisms that give rise to their behavior at the atomic scale is essential in order to exploit and harness their unique properties. From a theoretical perspective, capturing dynamic phenomena across very long time scales with direct atomistic simulation methods (e.g., Molecular Dynamics [MD]) becomes a very challenging task due to inherent time scale limitations. Here we present a continuum field theory approach for modeling both elastic and plastic deformations, free surfaces, and multiple crystal orientations in systems with both hexagonal and cubic symmetry in two spatial dimensions. The model is based on a free energy for the local, temporally coarse-grained atomic density, which is minimized by spatially periodic structures. Hence, it incorporates, by construction, both elastic phenomena as well as defects in the form of, e.g., vacancies, dislocations, and grain boundaries. Furthermore, its dynamics is constructed such that it incorporates both diffusive and elastic relaxation phenomena. By introducing a variable elastic time scale, we are able to maintain mechanical equilibrium while simulating microstructural evolution on time scales well beyond those accessible by conventional atomistic MD simulation methods.

**R32 11 Van der Waals forces between nanoclusters: importance of many-body effects** HYE-YOUNG KIM, JORGE SOFO, *Physics Department, The Pennsylvania State University, University Park, PA* DARRELL VELEGOL, *Chemical Engineering Department, The Pennsylvania State University, University Park, PA* MILTON COLE, *Physics Department, The Pennsylvania State University, University Park, PA* AMAND LUCAS, *Physics Department, University of Namur, Begium* Van der Waals (VDW) interactions between nanoclusters have been calculated using a self-consistent, coupled dipole method. The method accounts for all multi-body (MB) effects and can be used to calculate dispersion interaction energies between nanoclusters of arbitrary shape. Comparison is made between the exact potential energy, V, and the values obtained with two alternative methods: $V^{(2)}$, a sum of two-body interactions, and $V^{(2)} + V^{(3)}$, the sum of 2-body and 3-body interactions. For some clusters and orientations, $V^{(2)}$ is close to the exact result. In other situations, MB effects can be large. For all cases considered here, the 3-body term alone does itnot accurately represent the MB contributions to V. MB contributions are especially important for shape-anisotropic clusters.

**R32 12 Average speeds and durations of pulsed plane waves transmitted through chiral sculptured thin films** JOSEPH GEDDES, AKHLESH LAKHTAKIA, *Penn State University* We computed, with a finite-difference algorithm, the durations and average speeds of pulsed, ultrashort, optical plane waves transmitted through chiral sculptured thin films (STFs). Chiral STFs are assemblages of parallel nanohelixes affixed to a substrate; the helixes possess diameters of 10–300 nm, lengths of micrometers, and pitches that can be engineered during the fabrication via physical vapor deposition. We modeled the chiral STFs as continuously nonhomogeneous, anisotropic dielectric materials which are either linear or exhibit a Kerr-type nonlinearity. We computed the equivalent, root mean square, and correlation durations of the transmitted pulses and found that these quantities tend to increase with decreasing carrier wavelength, though there is an exception to this trend when the linear film exhibits the circular Bragg phenomenon. Increasing nonlinearity also tends to increase the durations of transmitted pulses. We computed the average peak speed, center-of-energy speed, and correlation speed of the pulsed plane wave and found that these speeds tend overall to increase with carrier wavelength but decrease with increased nonlinearity. Our results will have application in the design of optical pulse shaping devices.

**17:18**

**R32 13 Approximate Approach to Multi-Dimensional Tunneling in Solids** MARIO ANCONA, *Naval Research Laboratory* For reasons of tractability elastic tunneling within or from solids is typically treated with one-dimensional or quasi-one-dimensional approximations. In this presentation methods for analyzing multi-dimensional solid-state tunneling that maintain physical fidelity yet remain computationally efficient are discussed. After a brief review of the microscopic EBK approach, the discussion focuses on a macroscopic form of quantum transport theory whose equations are most easily understood via analogies with gas dynamics and electron optics. Various analytical implications of the theory are derived and numerical illustrations are provided.

**R33 1 Scanning Probe Applications to the Adhesive, Tribological and Rheological Properties of Materials.**
JACK E. HOUSTON, *Sandia National Laboratories*

Scanning probes are finding expanding application to the local analysis of a broad range of materials properties. I will discuss studies of adhesion, tribology and rheology applied to a range of materials using Interfacial Force Microscopy (IFM), a scanning force-probe technique distinguished by its use of a quantitative and mechanically stable force-feedback sensor. This unique sensor enables the force to be recorded as two interfaces approach, make contact, deform and separate making possible an accurate evaluation of the development of the adhesive bond and its failure. Thus, the nature of the adhesive bond, e.g., van der Waals, electrostatic, covalent, etc., can be established and the total adhesive energy measured quantitatively. Lateral forces can also be measured enabling direct observation of the interfacial friction force as a function of the normal force. These advantages will be illustrated with examples involving: (1) the interaction of a tip and substrate functionalized with self-assembled monolayer films having various combinations of chemically distinct end groups, as well as the interaction involving polymer surfaces, (2) the viscous properties of adventitious water adsorbed on various tip and substrate materials and (3) a quantitative, local rheological analysis of an extreme example of a viscoelastic material. These examples clearly demonstrate the intimate relationship between interfacial bond strength and the mechanical properties of the contact in determining overall adhesive strength. In addition, they dramatically demonstrate the weak correlation between the maximum adhesive force upon contact separation (the so called ''pull-off force'') and the quantitative work of adhesion. The assumptions required to make this correlation strong are seldom valid in ''real'' contact situations. Sandia is a multi-program laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the U.S. Department of Energy's National Nuclear Security Administration under Contract DE-AC04-94AL85000.

**R33 2 Sub-micron void structure during spallation fracture*** JAMES BELAK, JOHN KINNEY, MUKUL KUMAR, *Lawrence Livermore National Laboratory* J. ILAVSKY, *Advanced Photon Source* LYLE LEVINE, *National Institute of Standards and Technology* Samples of single and poly-crystal aluminum were shocked to incipient spallation fracture and recovered on the LLNL light gas gun. Previously, we analyzed the void structure in these samples using 3D x-ray tomography. Here, we extend this analysis to sub-micron length scales using ultra-small-angle scattering (USAXS and USANS). The USANS data overlaps in length-scale with the tomography data. The data displays novel power law scaling and a Guinier region suggesting a mean size for sub-micron voids of 60nm. These results will be compared to direct numerical simulation using molecular dynamics.

**R33 3 Dislocation Compression and Recovery Mechanisms in Shock-Recovered Al Single Crystals from White Beam Diffraction*** R. BARABASH, G. ICE, *ORNL* J. BELAK, M. KUMAR, *LLNL* J. ILLLAVSKY, *APS* A spatially resolved diffraction method with a sub-micron beam is applied to characterize both the dislocation structure and strain gradients in shock-recovered samples of Al (123) single crystal. Complementary OIM and SEM analysis were performed. The microbeam-Laue diffraction reveals several distinct zones located at different depths under the shock front. Pronounced streaking of Laue images are observed in the zones close to the front and back surface, consistent with a single slip mode. The portion of geometrically necessary dislocations reduces with depth while the portion of statistically stored dislocations increases. The Al sample was shocked to incipient spallation fracture and the Laue diffraction in the region of void formation shows a peculiarly complicated shape. To get a better understanding of the reasons for such a complex shape, 3D depth resolved measurements were performed. These measurements showed that in the central region alternating local lattice rotation takes place. This is due to the inhomogeneous plastic deformation surrounding each void. The density and organization of dislocations is presented as a function of depth under the shock front as well as comparison to SEM on the same samples. *This work was performed by DOE, at LLNL under Contract W-7405-Eng-48, at ORNL under the Contract DE-AC05-00OR22725 and at APS under Contract No. W-31-109-ENG-38.

**15:30**
**R33 4 Multiscale Simulations of High-Temperature Fracture in Silicon** NOAM BERNSTEIN, *Naval Research Lab* We simulate the effects of temperature on the dynamic fracture process in silicon. We use a dynamically coupled method that combines tight-binding at the crack tip with empirical potentials far from the tip in a molecular dynamics (MD) simulation.[1] This method has been shown to give brittle fracture at low temperatures, in agreement with experiment.[1] Here we present simulations of fracture at high temperatures, about 1000 K. These simulations are carried out in a strip geometry, and are relatively long and well equilibrated. There is no evidence that the velocity gap closes at these temperatures, at least not on the MD time scale. Fluctuations manifest themselves in the spontaneous nucleation of defects at

the crack tip. We discuss the nature and evolution of the defects, and their possible relation to the sharp brittle-to-ductile transition observed in silicon. [1] N. Bernstein and D. Hess, MRS Proc. vol. 653 (2001); – Phys. Rev. Lett. vol. 91 (2003).

**15:42**
**R33 5 Fracture scaling in columnar cornstarch** LUCAS GOEHRING, STEPHEN MORRIS, *University of Toronto* We have studied fracture spacing in desiccated cornstarch slurries, which exhibit columnar jointing. This fracture process creates long hexagonal pillars, and is famous for causing spectacular geologic features such as the Giants Causeway. The columnar pattern is formed as a planar network of cracks pass through a cooling or drying body. Even in simple 2D shrinkage fracture experiments it can be difficult to explain the spacing between cracks, however, in this case it is generally believed that the crack spacing depends on the average crack advance rate. Using computerized feedback, we controlled the desiccation rate of starch slurries. Continuous measurements of sample mass were converted into estimates of crack position and crack advance rate. After drying, direct measurements of crack spacing were made throughout the sample by cutting up the colonnade. With a constant crack advance rate, the jointing selects a particular scale after a transient coarsening. The selected scale does not uniquely depend on the final crack advance rate, but rather shows a type of memory inherited from its transient initiation. We present our investigations into this scaling, and how it depends on the fracture advance rate.

**15:54**
**R33 6 Reversible Rupture of a Two-Dimensional Alkane Crystal*** SHISHIR PRASAD, ALI DHINOJWALA, *The University of Akron* We present the first study of the rupture of a surface frozen monolayer of alkane (nonadecane) by oscillating an air bubble in its disordered melt. The two-dimensional (2D) crystal breaks abruptly at the start of every expansion and contraction cycle and recovers rapidly back to its original structure in a fraction of a second. This is unlike our experience of watching glass sheets or solids break due to the fast recovery times after the rupture of 2D crystals. The strength of this 2D crystal is determined by the presence of defects or grain boundaries and it is a strong function of temperature and rate of change in (surface) area. These results have important consequences in understanding the role of defect-mediated mechanical properties in crystals, colloids, glasses, granular materials, and fluids in confined geometries.

**16:06**
**R33 7 Spontaneous curvature cancellation in forced thin sheets** TAO LIANG, THOMAS WITTEN, *Department of Physics, University of Chicago* We report numerically observed spontaneous vanishing of mean curvature on a developable cone made by pushing a thin elastic sheet into a circular rim [1]. The mean curvature is seen to drop by nearly two orders of magnitude in a narrow zone near this rim, independent of thickness of the sheet, the supporting radius and the amount of deflection. Several variants of developable cone are studied to examine the necessary conditions that lead to the vanishing of mean curvature. It is found that the presence of appropriate amount of radial stress is necessary. The d-cone geometry somehow produces the right amount of radial stress to induce just enough radial curvature to cancel the conical azimuthal curvature. In addition, the circular symmetry of supporting rim plays an important role. When the supporting ring is elliptical, the radial curvature overcompensates the azimuthal curvature near the minor axis and undercompensates near the major axis. Our numerical finding is verified by a crude experiment using reflective plastic sheets. We expect this finding to have broad importance in describing the general geometrical properties of forced crumpling of thin sheets. [1] Cerda et al, Nature 401, 46 (1999)

**16:18**
**R33 8 Elasticity and gravity competing in a 2D system** P. MELLADO, *Johns Hopkins University* A. CONCHA, *Johns Hopkins University* We propose a minimal model for studying the consequences of the competition between elasticity and gravity on a surface. The model describes a cylindrically symmetric membrane composed of an elastic substrate and a stiff crust that experience a gravitational field directed radially inward. Under certain conditions an instability that breaks the initial symmetry can appear. When a stretching energy for the crust is introduced and an appropriate geometrical constraint on the system is imposed, an exotic periodic pattern forms. We provide an analytical solution to the model and show that while the stretching energy is responsible for the periodic pattern, faults in the stiff crust emerge generically when elasticity and gravity are competing. Possible implications in geology are discussed.

**16:30**
**R33 9 Development of First and Second Generation Fractures** MARTIN FERER, *National Energy Technology Laboratory and West Virginia University* DUANE SMITH, *U. S. Department of Energy, National Energy Technology Laboratory* In fractured reservoirs, one often finds a first generation of nearly parallel fractures and a second generation of fractures approximately perpendicular to the first-generation fractures. We have developed a simple blocks and springs model to study how the first generation fractures affect the development of the second generation. In the model, a layer of squares is connected to a substrate by spring-like shear forces, and each square is connected to its neighbors by intra-layer spring-like shear and tensile forces, of randomly chosen strengths. First the substrate gradually expands in the x direction generating stresses on the layer, which cause the failure of some of the intra-layer springs. Stopping this expansion at a maximum value X, we have the first generation of fractures. Then the substrate gradually expands in the y direction to a maximum value, Y, producing the second generation of fractures. During these expansions, we determine the length distribution of the first and the second generation fractures. Comparing the two distributions shows how the first-generation fractures affect the development of the second-generation fractures. After expansion has stopped, we determine the size (number of broken bonds) of each fracture, the maximum linear extent of each fracture, and the distributions of each.

**16:42**
**R33 10 Growing Fractures Using Iterated Conformal Maps.** H.G.E. HENTSCHEL, *Emory University* We will describe how iterated conformal mapping techniques can be used to grow fractures computationally and investigate their geometric characteristics as well as stress distributions. We will describe the similarities and differences between Mode I, II, and III fracturing patterns. Iterated conformal mapping techniques allows an efficient and accurate solution of the Lame equations without resorting to lattice models and for calculating the fracture roughness exponent.

**14:42**
**R34 2 Multifractal particle distribution in compressible turbulence on a free surface.*** WALTER GOLDBURG, MAHESH BANDI, *Department of Physics and Astronomy, University of Pittsburgh* JOHN CRESSMAN, *Krasnow Institute, George Mason University* The distribution of particles in compressible turbulence on a free surface is inhomogeneous. The floaters flee regions of fluid up-wellings and cluster into ridge-like structures near fluid down-wellings. The concentration of floaters is measured on the surface of a large tank of turbulently stirred water. The multifractal structure of the clusters is reflected in the moments of particle concentration. The results are compared with recent work of Bec et al. [J. Bec, K. Gawedzki and P. Horvai, Phys. Rev. Lett., 92, 224501 (2004)] conducted on synthetic velocity fields that follow the compressible Kraichnan model.

*This work is supported by the NSF under Grant No. DMR-0201805.

**14:54**
**R34 3 Velocity and Scalar intermittency in restricted Euler dynamics** YI LI, CHARLES MENEVEAU, *Johns Hopkins University* A long standing problem in turbulence is to predict the intermittency from Navier-Stokes equation. Recently, by adopting a Lagrangian point of view and using the restricted Euler dynamics, we derived a simple nonlinear dynamical system, called advected delta-vee system, for the time evolution of longitudinal and transverse velocity increments, from which we showed that the non-Gaussian tails in turbulence originate from the inherent self-amplification of longitudinal velocity increments, and cross amplification of transverse velocity increments. Here, after reviewing previous results, the analysis is generalized to the increments of a passive scalar. A simple nonlinear equation is derived for the time evolution of scalar increments. The equation is coupled to the advected delta-vee system through the squeezing effect of the longitudinal velocity increment. Numerical integration of the equations starting from Gaussian initial conditions shows rapid development of non-Gaussian tails in the PDF of scalar increments, suggesting the system captures important trends in the original Navier-Stokes and scalar transport dynamics.

**15:06**
**R34 4 How Gaussian is the Velocity Gradient Tensor at Large Scales in Hydrodynamic Turbulence?** LAURENT CHEVILLARD, YI LI, CHARLES MENEVEAU, *The Johns Hopkins University, Baltimore, MD.* Fully developed turbulent flows exhibit a continuous range of exited scales, from the finest (dissipative range) towards the integral scale where energy is injected. Many theoretical approaches use the assumption that at large scales the fluctuations display Gaussian statistics. This has also been repeatedly confirmed based on measurements of longitudinal velocity increments in the Eulerian framework and temporal velocity increments in the Lagrangian framework. When the separation is comparable to integral scales of the flow, the PDFs of these velocity increments display Gaussian statistics, in contrast to the elongated tails and non-Gaussian statistics at smaller scales. Motivated by recent insights gained from Restricted Euler dynamics, we examine the statistics of the full velocity gradient tensor and several of its invariants relevant to the transfer of energy from large to small scales. Using Direct Numerical Simulations, we study the coarse-grained and band-pass Eulerian velocity gradient tensor. Among other features, we show that even at the integral length scale, the gradient statistics deviate from Gaussianity.

**15:18**
**R34 5 Quantum Fluid Mechanical Theory of Turbulence** DAVID DROSDOFF, ALLAN WIDOM, *Northeastern University* YOGENDRA SRIVASTAVA, *Northeastern University, INFN, University of Perugia* Turbulence has been called the last great unsolved problem of classical physics. The difficulty of solving the turbulence problem classically (even with the help of recent large scale computer simulations) may be that the problem is not classical. Turbulence will here be described as due to the non-commuting nature of the components of the Landau quantum fluid velocity field. The formation of fractal dimensional regions of quantum vortex strings in fully developed turbulence will be discussed along with the implied Kolmogorov scaling functions.

**15:30**
**R34 6 Counter-gradient transport in the atmospheric boundary layer** CHERYL KLIPP, *US Army Research Laboratory* Counter-gradient transport in turbulent flows, also called negative viscosity, has been theorized and observed over the past century at a variety of spatial scales. More than one mechanism may be responsible for the process of transferring momentum from slower moving fluid to faster moving fluid depending on the scale of the flow and other flow properties. Horizontal divergence is presented as a possible mechanism for counter-gradient momentum transport observed in the atmospheric boundary layer.

**15:42**
**R34 7 LES Simulations of Pulsed Gas Jets.** JONATHAN ANDERS, *Purdue University* VINICIO MAGI, *Purdue University* JOHN ABRAHAM, *Purdue University* The study of pulsed jets is motivated by their applications which include increasing mixing, enhancing heat transfer, and controlling flow separation and vortex structures. This work investigates the interaction between gas jet pulses in the near-field using large eddy simulation (LES). LES employing the constant coefficient Smagorinsky model is compared to Reynolds-averaged Navier-Stokes (RANS) simulations with a two-equation k-$\varepsilon$ model. RANS predictions indicate faster penetration of subsequent jet pulses caused by the mean flow field from the first pulse, and do not show enhanced mixing due to residual turbulence. LES of the jet near-field includes development

of the head vortex ring and transition to turbulence in the jet. LES of the pulsed gas jet predicts interaction of the head vortex with residual turbulence from an earlier pulse. The dominant effect of the mean flow field and the accelerated penetration seen in RANS predictions are not evident in the LES results.

**R34 8 Vortical structures in a flume** R. GURKA, *Dept. of Mech. and Mat. Engr., Univ. of Western Ontario* A. LIBERZON, *Inst. of Hydromechanics and Water Resources Mgmt., ETH Zurich, Switzerland* G. HETSRONI, *Faculty of Mech. Engr., Technion, Israel* We report the results of statistical spatial characterization of coherent structures in turbulent boundary layer in a flume. The characterization approach is based on the proper orthogonal decomposition (POD) of vorticity, elucidating large-scale coherent patterns in a turbulent boundary layer. The method was successfully applied to the two- and three-dimensional experimental data extracted from particle image velocimetry (PIV), and multi-plane stereoscopic PIV (XPIV) respectively, and the three-dimensional data from direct numerical simulation (DNS) in a channel flow. The large-scale structure was obtained by using linear combination of POD eigenmodes of vorticity. POD allows for methodological analysis of the properties of the educed structure in the different measurement planes (orthogonal in the case of 2D PIV and parallel in the case of XPIV) and in the different cross-sections of the DNS data. Based on the statistical approach we suggest a conceptual model of large-scale coherent structures in a turbulent boundary layer flow that incorporates the experimental and the numerical results. The proposed conceptual model is a spiral vortical structure attached to the wall and expanding in both the spanwise and the wall-normal directions. Its shape resembles a funnel structure and a 'double-cone eddy' concept. The relationship of the model to the structures in the near wall region is presented.

**16:06**

**R34 9 Single-point Velocity Statistics** YONGGUN JUN, X.L. WU, *University of Pittsburgh* The single-point (SP) velocity statistics is investigated in forced and decaying two-dimensional turbulence in a flowing soap film. It is shown that the probability distributin functions (PDF) in both cases deviate from a Gaussian distribution, which is normally anticipated in turbulent fluid flows. In the forced turbulence case, the tail of the SP velcoty PDF decays faster than Gaussian and can be correlated with the forcing statistics on small sclaes. In the decaying turbulence case, the SP velocity PDF evolves from a sub-Gaussion to a super- Gaussian behavior as a function of decaying time. In all times, however, the locally averaged vorticity distribution remains approximately Gaussian. While our forcing data may be explained by the instanton model put forward by Falkovich et al., the decaying turbulence data remain unexplained by theory.

**16:18**

**R34 10 Coherent Structures in Decaying Two-Dimensional Turbulence** MICHAEL RIVERA, *Los Alamos National Laboratory* MICHAEL TWARDOS, ROBERT ECKE, We revisit the matter of coherent structures, such as vortices, and their role in decaying two-dimensional turbulence. These experiments take place in an electromagnetically forced stratified layer within a square container with no slip boundaries and a linear dissipation with the container bottom. Results relating the energy and enstrophy of the bulk flow with the number and strength of coherent vortices are compared with earlier numerical and experimental work.

**16:30**

**R34 11 Multiscale Distribution of Energy Transfer in Two Dimensional Turbulence** MICHAEL TWARDOS, MICHAEL RIVERA, ROBERT ECKE, In two dimensional turbulence, the mechanisms responsible for energy transfer to larger scales are not well understood. We present results from an experimental system consisting of a square meter of electromagnetically driven thin salt water layer that is used to investigate this inverse energy cascade. A filter technique applied to high resolution velocity fields is used to understand scale to scale energy transfer. An extension of this technique determines the contribution of energy transfer across a given length scale from smaller scales. Expanding the subgrid coupling terms allows for some speculation of the energy transfer mechanisms.

**16:42**

**R34 12 Statistical Properties of 2 Dimensional Turbulence in a Finite Box** COLM CONNAUGHTON, *Center for Nonlinear Studies, Los Alamos National Laboratory* MISHA CHERTKOV, *Theoretical Division, Los Alamos National Laboratory* VLADIMIR LEBEDEV, *Landau Institute for Theoretical Physics* IGOR KOLOKOLOV, *Landau Institute for Theoretical Physics* In the standard statistical theory of two dimensional hydrodynamics forced at some intermiediate scale, two cascades are produced. Energy flows to large scales, producing Kolmogorov's $k^{-5/3}$ spectrum at small $k$ and enstrophy flows to small scales to produce Kraichnan's $k^{-3}$ spectrum at large $k$. If we consider turbulence in a finite box in the absence of large scale dissipation, the inverse cascade eventually reaches the size of the box and the cascade is blocked. This leads to accumulation of energy in the largest modes, a process which can be qualitatively thought of as a non-equilibrium condensation process. The ''condensate'' in this case is a coherent, large scale vortex dipole. We investigate how the system passes through a series of distinct regimes, leading to the emergence of this large scale structure. We show how it affects the scaling properties of two-dimensional turbulence and explain how the presence of very strong vortices leads to an apparent modification of the small scale statistical properties of the inverse cascade.

**16:54**

**R34 13 Direct Numerical Simulations of Turbulent Flow in a Wavy Channel** LUO WANG, KOSTAS HOUSIADAS, ANTONY BERIS, *University of Delaware* A spectrally preconditioned biconjugate gradient algorithm (Bi-CGSTAB) has been developed that enabled us to perform high accuracy (spectral) efficient Direct Numerical Simulations (DNS) of Newtonian turbulent flow in an undulating channel geometry. The DNS of have been performed in a channel geometry involving a single sinusoidal solid wavy wall with amplitude/half width ratio of 0.1 and a wave length of 2. Two different friction Reynolds numbers have been investigated, $Re_\tau$=160 and 220 corresponding to mean Reynolds numbers (based on the channel half width) 1800 and 2480, respectively. The computational domain used was 10x2x5 along the streamwise, shearwise and spanwise direction respectively, with spectral resolutions ranging from 160x257x64 to 320x385x128. The nu-

merical results compare well against Hudson's measurements (Hudson, Ph.D. Thesis, UIUC 1993). In addition, the DNS results allowed us to investigate in detail various turbulence statistics and the vorticity structure and its influence from the wall undulation.

**R34 14 Non-Boussinesq effects on heat transport in turbulent Rayleigh-Bénard convection of gases*** DENIS FUNFSCHILLING, *UCSB* GUENTER AHLERS, *UCSB* In turbulent Rayleigh-Bénard convection large temperature differences often are used in order to reach very high Rayleigh numbers. This can lead to a breakdown of the Boussinesq approximation which assumes temperature-independent fluid properties. We presents quantitative measurements of non-Boussinesq (NB) effects on the heat transport obtained by using Ethane gas at a mean temperature of 40°C and pressures up to 40 bars. At the largest temperature differences of about 40°C, where the top of the sample approached the vapor-liquid saturation curve, the Nusselt number was **increased** above the Boussinesq value by several percent. This contrasts with NB effects in liquids[1] where the heat transport is reduced below the Boussinesq value.

**R34 15 Lattice Boltzmann studies of drag reduction in turbulent channel flow with polymers.** ALEXANDER KARPIKOV, *Yale University* S.A. ORSZAG, K.R. SREENIVASAN, Massive drag reduction in turbulent flow by dilute addition of polymers has long been a challenging problem in fluid dynamics. In order to study this problem here we use the Lattice Boltzmann method (LBM) to simulate turbulent channel flow. A polymer model, which is macroscopically equivalent to the FENE-P model, is included in LBM to represent polymers. Drag reduction with polymers was observed in the simulations. Although such drag reduction has been demonstrated in laboratory experiments, the mechanisms are not yet clear. In order to understand these results we investigated the role of dilute polymers on Kelvin-Helmholtz instability in the much simpler turbulent mixing layer. Our simulations of the mixing layer show that polymers produce a stabilizing effect and suppress momentum transport due to fluctuating velocity components. The simulations of these two systems together provide a clearer picture of the interaction between polymers and coherent structures in the near-wall region of the turbulent flow and shed light on the mechanism of drag reduction. The addition of polymers primarily modifies turbulent bursts in channel flow, and this phenomenon has several features in common with the effect of polymers on Kelvin-Helmholtz instability in the mixing layer.

**R36 1 Time-Dependent Density Functional Calculations for Optical Excitations in Nanoscale Materials.*** IGOR VASILIEV, *New Mexico State University*

Optical properties play a crucial role in our understanding of the electronic structure of nanoscale materials. Despite significant progress in the development of computational methodologies, first principles calculations for optical excitations in nanomaterials remain extremely difficult. While the ground-state electronic structure formalism is relatively well established, calculations for excited states present major challenges to theoretical methods traditionally employed by condensed matter physics and quantum chemistry. This talk focuses on recent advances in a computational technique based on time-dependent density functional theory (TDDFT). Within the TDDFT method, electronic transition energies and oscillator strengths are obtained in the framework of linear response theory by solving a frequency-dependent equation for the dynamic polarizability. The linear-response TDDFT formalism is applied to compute the excitation energies and absorption spectra for a variety of nanoscale systems, including molecules, atomic clusters, semiconductor quantum dots, functionalized carbon nanotubes, and nanotube-polymer composites. The TDDFT approach is compared to other first principles computational methods for excited states and discussed in terms of accuracy, efficiency, and computational cost.

**R36 2 Quantum Monte Carlo Calculations of Excitations in Hydrogenated Germanium Clusters** JORDAN VINCENT, *Physics Dept. at UIUC* JEONGNIM KIM, *NCSA/MCC at UIUC* RICHARD MARTIN, *Physics Dept. at UIUC* Quantum Monte Carlo (QMC) calculations are presented for energies of ground and excited states of Ge atom and hydrogen passivated closed-shell molecules and clusters: GeH4, Ge2H6, Ge5H12, Ge10H16 and Ge29H36. We compare the results for excitations with previous QMC and time-dependant Density Functional Theory (TDDFT) done for the corresponding Silicon clusters [1,2]; in particular; we find that preliminary results for lowest excitation enregy of Ge29H36 5.08[29]eV is lower than the gap 5.4eV reported for Si[2]. Core-valence partitioning for Ge is implemented by replacing the core-states with a Hartree-Fock pseudopotential plus a Core Polarization Potential (CPP)[3]. Core-valence correlation

treated by the CPP is shown to be essential for accurate atomic energies and significant for the molecules, but smaller in the clusters. [1] Porter et. al., PRB 64, 035320 (2001). [2] Williamson et. al., PRL 89, 196803 (2002). [3] Shirley and Martin, PRB 47, 15413 (1993)

**R36 3 Ab initio X-Ray Absorption Fine Structure Cumulants*** F. VILA, J.J. REHR, *University of Washington* H.H. ROSSNER, H.J. KRAPPE, *Hahn-Meitner-Institut* Theoretical calculations of vibrational effects in x-ray absorption spectra typically employ semi-phenomenological models, e.g. empirical force constants or correlated Debye or Einstein models. Instead we introduce an efficient and generally applicable ab initio approach based on electronic structure calculations of the dynamical matrix together with the Lanczos recursion algorithm [1] and relations between the cumulants. The approach yields 1) the thermal expansion coefficients (first cumulant of the vibrational distribution function); 2) correlated Debye-Waller factors (second cumulants) and 3) anharmonic contributions (third cumulants). Results are presented for crystalline (Cu, Au, Ge, GaAs) and molecular ($GeCl_4$, $C_6H_6$) systems. Our results for the Debye-Waller factors agree well with experiment. [1]H.J. Krappe and H.H. Rossner, Phys. Rev. B**70**, 104102 (2004).

**R36 4 Real Space Multiple-Scattering Calculations of Optical Properties*** M.P. PRANGE, J.J. REHR, A.L. ANKUDINOV, *U. of Washington* J.A. SOININEN, *U. of Helsinki* We present a method for *ab initio* calculations of the dielectric function which is applicable for periodic and non-periodic materials alike. Our approach is a generalization to finite momentum transfer of that implemented in the real space multiple-scattering code FEFF8 and is the real-space analog of the KKR method. The approach includes self-consistent potentials, an energy dependent self-energy and screened core-hole effects. The method yields the dynamic structure factor $S(\vec{q},\omega)$ over a broad spectrum from the optical to x-ray energies, and in the long-wavelength limit, yields various optical constants. Results for several materials are presented and compared with experiment.

**R36 5 Ab initio Quasiparticle Self-Energies and X-ray spectra*** J. KAS, M. PRANGE, A. SORINI, J.J. REHR, *U. of Washington* Present calculations of inelastic losses in x-ray spectra typically employ semi-empirical or highly simplified models, such as the plasmon-pole self-energy, which are only semi-quantitative for near edge spectra. Here we present an efficient *ab initio* approach applicable to general materials, starting from a real-space multiple-scattering calculation of the dielectric function,[1] which is fit to a multiple-pole model with of order $10^2$ poles. This yields multiple-pole GW self-energies, and hence related quantities such as inelastic mean free paths (IMFP). The approach leads to improved amplitudes and phases for core-level x-ray spectra up to photo-electron energies of order $10^3$ eV. Results for the IMFP are found to be in good agreement with experiment and with other approaches.[2,3]

**R36 6 Isolating symmetry components of the Mg and Al DOS using momentum-transfer dependent Inelastic X-ray Scattering** TIM FISTER, *Physics Department University of Washington, Seattle WA* GERALD SEIDLER, JOHN REHR, ALEKSI SOININEN, *University of Helsinki* JULIE CROSS, ALBERT MACRANDER, *Advanced Photon Source, Argonne National Labs* We have used the non-resonant inelastic x-ray scattering (NRIXS) from core electrons to measure the dynamic structure factor of the Mg and Al L-edges for momentum transfers ($q$) ranging from 0.8 10.1$Å^{-1}$. Changing $q$ alters the measured energy loss spectrum by allowing new, dipole-forbidden transitions to different symmetry final states. Here, we highlight the connection between dynamic structure factor and the projected components of the density of states (ldos) using a modified version of FEFF that incorporates multipole transitions. In addition to itab initio theoretical agreement with the observed $q$-dependence, we present preliminary efforts toward obtaining an experimentally-derived ldos.

**R36 7 Metal-metal nanolayered structures for generation of hard x-ray radiation** PETER SHKOLNIKOV, *ECE Department, SUNY at Stony Brook* ALEXANDER KAPLAN, ALEXANDER POKROVSKY, *ECE Department, Johns Hopkins University* Our new research effort is aimed at developing a new X-ray source for medical applications, using low-energy electrons. Generation of intense narrow-band X-ray transition radiation (TR) by few-MeV electrons traversing solid multilayer structures, initially proposed for by us $\sim$ 1 keV photons, changes dramatically at energies of interest to medicine, 30-50 keV, because of significant changes in dielectric constants. In particular, the choice of the materials for the multilayer target proposed by us for soft X- ray generation, is no longer applicable. In particular, our original approach was based on choosing a layer of a high-Z material as a ''radiator'' with a chosen $K$-shell transition, and the layer of low-Z material as a neutral ''spacer.'' However, in the 30-50 keV range, TR spectra with such pairs show a spectral $dip$, not a peak,at the chosen $K$-shell. Our new theoretical investigations have shown that the optimal spacer now, as a rule, should have higher Z than the radiator. One example of such combination is Mo/Ag; we predict that its X-ray TR spectrum contains a strong, 1% wide peak at the K-edge of Mo, $\sim$ 20 KeV. We present our recent theoretical results of the subject, as well as our experimental results for the Mo/Ag target.

**16:18**

**R36 8 Optical conductivity of granular metals** YEN LEE LOH, *Purdue University* VIKRAM TRIPATHI, *Cambridge University, UK* Arrays of metallic grains, which can be fabricated in a number of ways, exhibit interesting behavior in many properties due to the interplay between tunneling and Coulomb blockade effects. One such property is the AC conductivity, which can be measured using optical reflectivity techniques. We present here a calculation of the AC conductivity of a regular granular array. For this purpose we have found it necessary to generalize the Ambegaokar-Eckern-Schön (AES) model to include polarization fluctuations as well as charge fluctuations. In contrast to the DC conductivity, which is determined by inter-grain charge transfer and obeys an Arrhenius law at low temperature, we show that the AC conductivity is dominated by a resonance peak for intra-grain polarization oscillations, which has a power-law tail at low frequencies. Although the resonance frequency agrees with the classical prediction, the resonance width depends on quantum mechanical tunneling and Coulomb blockade parameters, in addition to intra-grain impurity scattering. This additional damping is due to inelastic cotunneling of polarization fluctuations to neighbouring grains.

**R36 9 Probing by transport the single-particle energy spectrum up to high energy of one quantum dot with the ground state of an adjacent weakly coupled quantum dot to examine the behavior of magnetic-field induced two- and three-level crossings** DAVID AUSTING, *National Research Council of Canada* GOULIN YU, JAMES GUPTA, MAREK KORKUSINSKI, GEOFFREY AERS, NATIONAL RESEARCH COUNCIL OF CANADA TEAM, We investigate high bias single electron resonant tunneling through sub-micron gated AlGaAs/InGaAs/AlGaAs/InGaAs/AlGaAs triple barrier structures for which the tunnel coupling energy between the two quantum dots is very weak ( $< 0.1$meV). The two quantum dot ''disks'' in the vertical diatomic artificial molecule located in the circular device mesa can be almost circular or elliptically deformed. In either case, assuming the lateral confining potential to be strictly parabolic, one would expect the single-particle states of one quantum dot to evolve with magnetic field in a very distinct and recognizable way, and that all energy level crossings are real crossings. We find, however, particularly for two quantum dots with an elliptical deformation ratio of about 4/3, numerous anti-crossings (levels split by up to about 1meV in energy) as well as crossings when two or three levels meet in the spectrum. We show the measured spectrum, attempt to classify the crossing and anti-crossing behavior, and offer possible explanations for this intriguing behavior.

**16:42**

**R36 10 Anomalous electronic transport features in a lateral quantum dot array sample** WEI PAN, R.G. DUNN, J.L. RENO, J.A. SIMMONS, *Sandia National Laboratories* D. LI, S.R.J. BRUECK, *CHTM, University of New Mexico* We will present in this talk experimental results obtained in a lateral quantum dot array sample, with a pitch size of $\sim$ 350 nm and a designed dot size of $\sim$ 150nm. The starting material is a high quality quantum well with the two-dimensional electron gas buried 200 nm below the surface. The quantum dot array is defined by a Ti/Au metal grid, which was fabricated using the interferometric lithograph and lift-off techniques. Around zero magnetic field, a pronounced positive magnetoresistance is observed, which can be explained by the semi-classical model of magnetic breakdown. The so-called commensurability oscillations together with the usual Shubnikov-de Hass oscillations are also observed. Surprisingly, in a pure DC measurement of longitudinal resistance, an anomalous resistance spike is clearly seen. The magnetic field position of this resistance spike depends on the amplitude of applied DC bias ($V_{ds}$) between source and drain, and shows roughly a $1/V_{ds}$ dependence. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**R36 11 Polarization and orientation effects on energy transfer in semiconductor nanocrystals.*** AMEENAH N. AL-AHMADI, SERGIO E. ULLOA, *Ohio University* We study the effect of the orientation factor on coherent energy transfer from a donor to an acceptor quantum dot. We calculate the polarization of the acceptor dot as a function of incident light polarization in resonance with different donor levels. We demonstrate that the measurement of the acceptor polarization can be used to obtain information on the relative orientation between the donor-acceptor pair. We use the density matrix to study the dynamics of the luminescence polarization of the QDs in the Lindblad approximation [1]. We use a realistic model of the exciton levels and the oriented dipole transition of each level to predict the importance of the orientation factor on the energy transfer in semiconductor nanocrystals. We consider the band edge fine structure of the exciton in the QDs based on an effective mass description with eight exciton levels [2]. Our results show strong dependence of the polarization of the acceptor dot on the relative orientation between the donor-acceptor pair and the specific donor state under excitation. [1] A.N. Al-Ahmadi and S.E. Ulloa, Phys. Rev. B 70, 201302(R) (2004). [2] Al.L. Efros and M. Rosen, Ann. Rev. Mater. Sci. 30, 475 (2000).

**R36 12 Energy relaxation and phonon bottleneck in semiconductor quantum dots** SERGUEI GOUPALOV, *Los Alamos National Lab* We show explicitly that the so-called phonon bottleneck in energy relaxation in semiconductor quantum dots arises as a limiting case of a more general model originally due to Huang and Rhys [S.V.Goupalov, Phys. Rev. B **72**, 073301 (2005)]. Therefore, the restrictions on the energy relaxation imposed by the phonon bottleneck are much less fundamental than it is commonly believed. We calculate temperature dependence of the non-radiative multiphonon transition rate within the properly corrected Huang-Rhys model and discuss other models where the phonon bottleneck is circumvented in connection with recent experiments on epitaxial and colloidal quantum dots.

**17:18**

**R36 13 Spectroscopic studies of $Fe_3O_4$ nanocrystals** LAYRA REZA, *Physics Department, University of Texas at El Paso* FELICIA MANCIU, *Physics Department, University of Texas at El Paso* YUDHISTHIRA SAHOO, *Institute for Lasers, Photonics and Biophotonics, State University of New York at Buffalo* We have used IR spectroscopy to study the temperature dependence of optically active phonon modes of $Fe_3O_4$ nanocrystals, to obtain information about the possible Verwey transition, which is usually manifested in bulk material. The samples were synthesized by

colloidal chemistry. The crystallinity and sizes were examined by transmission electron microscopy (TEM) and X-ray diffraction. The TEM pictures show an average size of 6-8 nm for $Fe_3O_4$ nanocrystals. Samples for the IR studies were prepared in the form of pellets, by embedding them in a polycrystalline CsI matrix. The temperature dependence ($10K < T < 300K$) IR transmission results exhibit a frequency increase upon decreasing the temperature for the infrared-active phonons around 360 $cm^{-1}$ and 574 $cm^{-1}$, but without notable anomalies around the critical temperature (120K) as compared to those previously observed in a single $Fe_3O_4$ crystal. The appearance of a fine structure at low temperatures could account for the lifting of the degeneracy of the phonon modes. This splitting is associated with the degree of the distortion of the symmetry of the system.

**R37 1 Conductance Through Single Organometallic Molecules.***
HAROLD U. BARANGER, *Duke University*

We have undertaken ab initio calculations of the conductance and I-V curve of a variety of single molecules bridging two metallic leads. The method adopted is a non-equilibrium Green function (NEGF) approach to transport combined with density functional theory (DFT) calculations for the electronic structure. A principal motivation comes from experiments in the U. Maryland group [1]: they showed that a molecule containing a ferrocene moiety conducts nearly perfectly, in striking contrast to the severely impaired conduction through all fully conjugated but non-metallic molecules. Our calculations show that, indeed, there is a transmission resonance at the Fermi energy of the leads connected to the iron atom in the molecule. However, the comparison of theory and experiment also points to significant weaknesses caused by approximations in the standard NEGF+DFT approach. Thus, on a much simpler system—a H atomic chain—we carry out much improved calculations involving exact exchange, hybrid functionals, and the optimized effective potential method. These provide a cautionary illustration of the kind and magnitude of errors in the standard approach. Finally, emboldened by our success with the ferrocene-containing molecule, we turn to developing a true molecular spintronics based on cobaltocene moieties (spin 1/2). A simple molecule with a single cobaltocene provides a spin filter; we demonstrate a spintronic switch and spin valve using a dicobaltocene molecule [2]. [1] S.A. Getty, et al. (groups of M.S. Fuhrer, and L.R. Sita), PRB 71, 241401(R) (2005). [2] R.Liu, S.-H. Ke, H.U. Baranger, and W. Yang, Nano Lett. 5, 1959 (2005).

**R37 2 Negative differential resistance (NDR) of ferrocenyl-alkanethiolate on the Au (111) surface** SHUCHUN WANG, *NC State U.* WENCHANG LU, QINGZHONG ZHAO, JERRY BERNHOLC, With the rapidly growing interest in the development of molecular electronics, the resonant tunneling diode (RTD) becomes an attractive molecular device goal due to its utility in switching logic and simplicity in integration. Molecular systems displaying Negative Differential Resistance (NDR) and resonant tunneling show great potential as RTDs. In a recent experiment, self-assembled monolayers (SAMs) of ferrocenyl-alkanethiolate on gold show clear molecular NDR, but its mechanism has not been identified. We report first-principles studies of electronic transport in such SAMs by the non-equilibrium Green functions method. The calculated I-V characteristics show strong NDR at both positive and negative biases, which are in good agreement with the experimental results. We find that the ferrocene group acts like a quantum dot and that the resonant coupling between its HOMO and the gold leads is responsible for the NDR features. Such molecules could lead to novel RTDs in nanoscale molecular devices.

**R37 3 Exploring the lead dependence of single-molecule conductance from first principles: The case of $H_2$ molecular junctions** K.H. KHOO, *Dept of Physics, UC Berkeley* J.B. NEATON, *The Molecular Foundry, LBNL* STEVEN G. LOUIE, *Dept of Physics, UC Berkeley, The Molecular Foundry, LBNL* Although the transport properties of several single-molecule junctions have now been reported, only a few studies have systematically examined the sensitivity of the junction conductance to the choice of metallic contacts. Recent break-junction experiments have revealed significantly lower conductance for $H_2$ molecular junctions when Pt leads were replaced with Pd,[1,2] suggesting a dramatic difference in electronic coupling between the molecule and lead. In this work, we examine this coupling directly by computing the conductance of $H_2$ with several different metallic contacts using an itab-initio scattering state approach[3] based on density functional theory. We find that by substituting Pt with Pd leads, the low-bias electron transport crossesover from a ballistic to an off-resonance tunneling regime, leading to a conductance smaller than unity in agreement with experiments. The extent to which substituting different leads may be used to tune the transport properties of this and other simple single-molecule junctions will be discussed. This work was supported by the NSF Grant No. DMR04-

39768 and U.S. DOE Contract No. DE-AC03-76SF00098. [1] R.H.M. Smitit et al., Nature (London) **419**, 906 (2002). [2] Sz. Csonkait et al., Phys. Rev. Lett. **93**, 016802 (2004). [3] H.J. Choi, M.L. Cohen and Steven G. Louie, to be published.

**R37 4 Electronic level alignment at metal-molecule interfaces from first principles*** JEFFREY B. NEATON, *The Molecular Foundry, LBNL* MARK S. HYBERTSEN, *Department of Applied Physics and Applied Mathematics and Center for Transport in Molecular Nanostructures, Columbia University* STEVEN G. LOUIE, *The Molecular Foundry, LBNL and Department of Physics, UC-Berkeley* Electronic transport through nanoscale molecular junctions critically depends on the energetic alignment of frontier molecular states with the contact Fermi levels. In this work, a first-principles Greens function approach is used to explore how frontier molecular energy levels are modified at metal-molecule interfaces. The electronic structure of a model interface, benzene on graphite (0001), is computed using the GW approximation for the electron self-energy operator. Upon adsorption on the surface, the benzene HOMO-LUMO gap is predicted to be 7.2 eV, substantially reduced from its calculated gas-phase value of 10.5 eV, and slightly smaller than its computed solid-phase gap of 7.5 eV. This decrease is attributed to the change in the electronic correlation energy of the frontier states in different environments. Comparison with a classical image interaction provides a quantitative measure of the contribution of the molecule-substrate coupling to the gap narrowing of the molecule.

**R37 5 Is a molecule a quantum wire or a quantum dot?** BHASKARAN MURALIDHARAN, *School of Electrical and Computer Engineering, Purdue University, West Lafayette, IN 47907* AVIK W. GHOSH, *Dept. of Electrical and Computer Engineering, University of Virginia, Charlottesvile, VA 22904* SUPRIYO DATTA, *School of Electrical and Computer Enginnering, Purdue University, West Lafayette, IN 47907* We address an important issue regarding the appropriate transport regime for molecular conduction. A typical transport calculation employs the Non Equilibrium Green's function (NEGF) transport scheme coupled with an appropriate self consistent field (SCF) method. This implies that the molecule is treated as a ''quantum wire,'' usually applicable when contact couplings are much larger than other energy scales involved. However, there exists a whole class of experimental data whose qualitative features depart significantly from the ones usually explained using the above approach. We show that these features can be naturally addressed by adopting a Coulomb Blockade (CB) approach used in ''quantum dot'' transport. This involves description of the molecule in its many-body space. Our analysis in the many-body space of a prototypical molecule explains the non-trivial features commonly observed in low temperature molecular conduction experiments. Hence, we point out the inadequacy of SCF approaches towards a concrete description of molecular conduction which should involve both quantum chemistry and transport in the many-body space of the molecule.

**R37 6 Constrained LDA ab-initio calculation of screening of charging energy in C60** JAY SAU, JEFFREY NEATON, K.H. KHOO, *Department of Physics UC Berkeley* HYOUNG CHOI, *Department of Physics, Yonsei University* STEVEN LOUIE, MARVIN COHEN, *Department of Physics UC Berkeley* Recent measurements and theoretical calculations of the electronic properties of C60 on metal substrates have shown that the electron-electron repulsion parameter U, which determines the coulomb blockade transport properties, is strongly screened in the presence of a metal susbtrate. Since standard Density Functional Theory calculations treat this charging energy in a mean field sense, it ignores the discreteness of the charge on the C60 that is critical to coulomb blockade. To account for the effect of the screened U in transport experiments we calculate the charging energy of C60 in a few environments using a constrained LDA approach and explore the implications for coulomb blockade transport phenomena. This work was supported by National Science Foundation Grant No. DMR04-39768 and by the Director, Office of Science, Office of Basic Energy Sciences, Division of Material Sciences and Engineering, U. S Department of Energy under Contract No. DE-AC03-76SF00098. Computational resources have been provided by DOE at the National Energy Research Scientific Computing Center(NERSC)

**16:06**

**R37 7 Physical manifestation of the Kohn-Sham energy gap in tunneling currents** XIAOGUANG ZHANG, *Oak Ridge National Laboratory* ZHONG-YI LU, *Institute of Theoretical Physics, Chinese Academy of Science* SOKRATES S. PANTELIDES, *Department of Physics and Astronomy, Vanderbilt University* Density-functional theory in the Kohn-Sham (KS) approximation yields accurate ground-state properties of molecules and solids. The KS energy gap, however, is much smaller than the gap obtained from experiments that entail electronic excitations. Here we point out that the zero-bias differential resistance of metal-insulator-metal structures is a ground state property and demonstrate that the KS gap, which is a feature of the ground-state KS Hamiltonian, acts as the effective tunnel barrier. The theory is validated by three sets of available data for the resistance of $SiO_2$ films as a function of film thickness.

**16:18**

**R37 8 Semiconductor/Molecule Transport Junctions: An Analytic Form For The Self-Energies** VLADIMIRO MUJICA, *Research Professor* MARK RATNER, *Professor* We have derived an approximate analytic expression for the spectral density of a simple model of a semiconductor/molecule junction. The semiconductor is considered as a tight-binding one-dimensional chain with periodic boundary conditions, and either bond or site-energy, alternation to mimic a two-band system. Using the simplest representation for an atomic or molecular site we obtain a spectral density whose main physical and mathematical features are independent of the alternation pattern. In this contribution, we show applications of our model to the description a variety of junctions where the relative position of the energy levels involved is changed.

**16:30**

**R37 9 Ab initio study of inleastic transport in molecular electronic devices** NIKOLAI SERGUEEV, *University of Texas at Austin* ALEX DEMKOV, *University of Texas at Austin* One of the most important issues of conduction at nano-scale concerns the effects of atomic vibration. Interaction between electrons and vibrational excitations in nanoelectronic devices has become the problem to solve in order to advance the research field of nanoelectronic theory. Understanding these effects is crucial for predicting device performance. In this talk, we present a method based on Density Functional Theory and Nonequilibrium Green's functions formalism for the calculation of tunneling current and conductance in molecular electronic devices in the presence of electron-phonon interaction. Using self-consistent Born approximation, we can determine the phonon self-energy, the electron Green's function, the electronic density matrix and the electronic Hamiltonian within equal footing of our formalism. As an example, we present numerical results obtained for several molecular electronic devices and show that only few molecular vibrational excitations seem to have an effect on the inelastic tunneling.

**16:42**

**R37 10 Microscopic Current Flow Patterns in Nanoscale Quantum Point Contacts** NA SAI, NEIL BUSHONG, *University of California, San Diego* RYAN HATCHER, *Vanderbilt University* MASSIMILIANO DI VENTRA, *University of California, San Diego* Transport in nanoscale conductors has been studied extensively mainly using the stationary scattering approach. However, the dynamical nature of transport, and in particular, the flow patterns of the microscopic current through a nanoscale junction, have remained poorly understood. We apply a novel time-dependent transport approach [1], which combines closed and finite geometries with time-dependent density functional theory,to study current flow patterns in nanoscale quantum point contacts [2]. The results of both atomistic and jellium calculations show that surface charges form dynamically at the junction-electrode interfaces in both abrupt and adiabatic junctions. The curr ent exhibits some characteristics of a classical hydrodynamic liquid but also displays unique patterns arising from the interaction with the surface charges. We also investigate the effect of the flow velocity, charge density, and lattice structures on the electron dynamics. If time permits we also discuss the effects of the viscosity of the electron liquid [3]. Work supported by DOE (DE-FG02-05ER46204). [1] M. Di Ventra and T.N. Todorov, J. Phys. Cond. Matt. 16, 8025 (2004). [2] N. Bushong, N. Sai and, M. Di Ventra, Nano Lett. (in press). [3] N. Sai, M. Zwolak, G. Vignale, and M. Di Ventra, Phys. Rev. Lett. 94, 186810 (2005 ).

**16:54**

**R37 11 Electron transport in molecular devices** SIMONE PICCININ, *Princeton Univeristy - Department of Chemistry* RALPH GEBAUER, *ICTP - Trieste (Italy)* ROBERTO CAR, *Princeton University - Department of Chemistry* We present an application of a recently proposed quantum-kinetic scheme for non equilibrium transport properties in nanoscale systems, based on a Liouville-master equation for the reduced density operator and combined with a Density Functional Theory description of the electronic structure [1,2]. The systems studied are the well known benzene-dithiol sandwiched between two gold electrodes and the gold quantum point contact. The results we obtain are in general agreement with previous theoretical works and with recent experimental measurements. We analyze the spatial distribution of the current density and the effect of geometrical distortions on the transport properties.

## SESSION R38: SUPERCONDUCTIVITY—OPTICAL SPECTROSCOPY OF CUPRATES: IR HALL EFFECT

**Wednesday Afternoon, 15 March 2006**
**341, Baltimore Convention Center at 14:30**
**John Cerne, University at Buffalo, SUNY, presiding**

**14:30**

**R38 1 Strong correlation effects in the IR Hall Effect in the cuprates: an overview*** H.D. DREW, *University of Maryland* The Hall Effect at infrared frequencies provides a sensitive probe of strong interaction effects in strongly correlated metals. Experimental results show that the strong interaction effects inter the Hall conductivity and the optical conductivity differently in the cuprates [1,2,3]. For hole doping the Hall angle at mid IR frequencies is nearly simple Drude but with a scattering rate that is nearly frequency dependent in contrast to the optical conductivity [1]. The Hall frequency is in good agreement with ARPES results at optimal doping but increases rapidly for underdoped samples in contrast to expectations from ARPES [1,2]. The electron doped cuprates show evidence for density wave gap excitations and are non Drude-like even outside the density wave regime of doping and temperature [3]. A recent theoretical analysis based on the exchange of magnetic excitations that includes vertex corrections in the conductivity appears to account for many of these observations [4]. [1] DC Schmadel, et al., cond-mat/0510793. [2] L Shi, et al., cond-mat/0510794. [3] A Zimmers, et al., cond-mat/0510085. [4] H Kontani, cond-mat/0507664.

**R38 2 Significant Role of Current Vertex Correction in Optical Conductivity of Strongly Correlated Systems.** SEIICHIRO ONARI, HIROSHI KONTANI, *Nagoya University, Japan* Based on the microscopic Fermi liquid theory, we study DC and AC transport phenomena in strongly correlated systems. We take the current vertex correction (CVC), which is called the backflow in the phenomenological Fermi liquid theory, into account correctly to satisfy the conservation laws. In the vicinity of the antiferromagnetic (AF) quantum critical point (QCP), various transport coefficients show striking deviations from the Fermi liquid-type temperature dependences due to the CVC. Moreover, we find that the frequency dependence of the CVC gives rise to striking deviations of the optical conductivities from the conventional extended-Drude-type functions, when systems is close to the AF-QCP. We explain the important effect of the CVC on the temperature- and frequency-dependences of $\sigma(\omega)$ and $\sigma_{xy}(\omega)$ in strongly correlated systems.

**14:54**

**R38 3 Theory of Optical Conductivity and Hall Conductivity in High-Tc Superconductors** HIROSHI KONTANI, *Nagoya University, Japan* We study AC conductivities in high-Tc cuprates, which offer us significant information to determine the true ground states. We take the current vertex correction (CVC) into account correctly to satisfy the conservation laws in terms of the fluctuation-exchange (FLEX) approximation. The significant role of the CVC on the optical Hall conductivity, $\sigma_{xy}(\omega)$, is confirmed in the presence of strong antiferromagnetic (AF) fluctuations. This fact leads to the failure of the relaxation time approximation (RTA). As a result, experimental highly unusual behaviors, (i) prominent $\omega$ and temperature dependences of the optical Hall conductivity and the optical Hall coefficient, $R_H(\omega)$, and (ii) a simple Drude form of the optical Hall angle, $\theta_H(\omega)$, for a wide range of $\omega$, are satisfactorily reproduced. In conclusion, both DC and AC transport phenomena in (slightly under-doped) high-Tc cuprates can be explained comprehensively in terms of a nearly AF Fermi liquid, without assuming an exotic ground state.

**15:06**

**R38 4 The mid-infrared Hall effect in optimally-doped $Bi_2Sr_2CaCu_2O_{8+\delta}$*** DON SCHMADEL, *Department of Physics, University of Maryland, College Park, Maryland 20742 USA* GENDA GU, *Department of Physics, Brookhaven National Laboratory, Upton, New York 11973 USA* H.D. DREW, *Department of Physics, University of Maryland, College Park, Maryland 20742 USA* Heterodyne polarometry is used to measure the frequency dependence in the mid IR from 900 to 1100 cm$^-$1 and temperature dependence from 35 to 330 K of the normal state Hall transport in single crystal, optimally doped $Bi_2Sr_2CaCu_2O_{8+\delta}$. The results show a simple Drude behavior in the Hall conductivity $\sigma_{xy}$ which stands in contrast to the more complex, extended Drude behavior for the longitudinal conductivity $\sigma_{xx}$. The mid IR Hall scattering rate $\gamma_{xy}$ increases linearly with temperature and has a small, positive, projected intercept at $T = 0$. The longitudinal scatter rate, in contrast, is much larger and exhibits very little temperature dependnece. The Hall frequency indicates a carrier mass which is 6.7 times the band mass and which decrease slighly with increasing frequency. These disparate behaviors are consistent with calculations based on the fluctuation-exchange interaction using current vertex corrections (H Kontani, cond-mat/0507664).

*This research was partially supported by the NSF under Grant No. DMR-0303112.

**15:18**

**R38 5 Infrared Hall effect in underdoped and optimally doped $La_{2-x}Sr_xCuO_4$*** LINGYUN SHI, D. SCHMADEL, H.D. DREW, *University of Maryland, College Park, MD 20742* I. TSUKADA, Y. ANDO, *Materials Science Research Laboratory, CRIEPI, Tokyo, Japan* We report a study of magneto-optical properties in the mid-infrared region of a series of $La_{2-x}Sr_xCuO_4$ samples with hole doping level ranging from severely underdoped ($x = 0.03$) to optimally doped ($x = 0.15$). The Faraday rotation and circular dichroism are measured in a magnetic field of 8 Tesla and in a temperature range between 30K and 300K. The doping and temperature dependence of infrared Hall angle is found to be consistent with a simple Drude model. A significant increase of Hall frequency is observed when the hole doping level is reduced from optimal doping, which is consistent with a drastic reduction of the volume of Fermi surface in the underdoped sample. These results are similar to results of an earlier study of underdoped YBa2Cu3O6+x [L. B. Rigal, et al., Phys. Rev. Lett. 93,137002 (2004)]. Both experiments will be compared with theoretical models of the IR Hall effect.

*The support of NSF grant DMR-0303112 is acknowledged

**15:30**

**R38 6 Far IR Hall Angle Measurements on Single Crystal $Bi_2Sr_2CaCu_20_{8+x}$.*** GREGORY JENKINS, D.C. SCHMADEL, H.D. DREW, *Physics Department, University of Maryland, College Park, MD 20742* GENDA GU, *Department of Physics, Brookhaven National Laboratory, Upton, NY 11973* The far-infrared complex Hall angle was studied in thin optimally doped single crystal $Bi_2Sr_2CaCu_20_{8+x}$ as a continuous function of temperature from 25 to 300 K and at a discrete set of frequencies in the range of 25 cm$^{-1}$ to 175 cm$^{-1}$ using a heterodyne technique. The real part of the inverse Hall angle obeys a temperature power law, $T^n$, where n = 1.65 which is consistent with the dc-value. For the three frequencies below 90 cm$^{-1}$, the Hall frequency is a constant in temperature and frequency to within 20% from $T_C$ up to room temperature. The Hall mass of 2.5 $m_e$ in reasonable agreement with the values found in far IR optical measurements 3.0 $m_e$, ARPES dispersion results along the $(\pi, \pi)$ nodal direction (2.9 $m_e$), and mid IR Hall measurements (2.8 $m_e$) where $m_e$ is the bare electron mass. These results will be compared with theoretical predictions.

*The support of NSF through grant DMR-0303112 is acknowledged.

**15:42**

**R38 7 Infrared Hall Effect in the electron-doped high $T_c$ cuprate $Pr_{2-x}Ce_xCuO_4$** A. ZIMMERS, *Center for Superconductivity Research, Department of Physics, University of Maryland, College Park, Maryland 20742, USA* L. SHI, D. C. SCHMADEL, *Department of Physics, University of Maryland, College Park, Maryland 20742, USA* W. M. FISHER, R. L. GREENE, *Center for Superconductivity Research, Department of Physics, University of Maryland, College Park, Maryland 20742, USA.* H. D. DREW, *Department of Physics, University of Maryland, College Park, Maryland 20742, USA* We have performed infrared Hall measurements ($\sigma_{xy}$) as a function of temperature, frequency (950-1100 cm$^{-1}$) and wide doping range of $Pr_{2-x}Ce_xCuO_4$. Previous measurements have shown that electron-doped materials present clear evidence for a gap in the $\sigma_{xx}$ spectrum [1] and the DC Hall effect [2] for samples below both a critical doping of $x_c \sim 0.17$, a characteristic temperature $T_W$ and an energy $\omega_W$. Our results lend further support to a density wave state in underdoped PCCO. However, these results demonstrate that $\sigma_{xy}$ exhibits strong deviations from the extended Drude model in contrast to its success for $\sigma_{xx}$ in overdoped $Pr_{2-x}Ce_xCuO_4$ and in hole-doped cuprates. The work at University of Maryland was supported by NSF grants DMR-0352735 and DMR-0303112. [1] A. Zimmers *et al.*, Europhys. Lett., **70** (2), 225 (2005). [2] Y. Dagan *et al.*, Phy. Rev. Lett. **92**, 167001 (2004).

**15:54**

**R38 8 Extended frequency dependence of the infrared Hall Effect in electron-doped high $T_c$ cuprate $Pr_{2-x}Ce_xCuO_4$** M. HOUSEKNECHT, G. ACBAS, M.-H. YANG, J. CERNE, *Physics Dept., Univ. at Buffalo, SUNY, Buffalo, NY* A. ZIMMERS, L. SHI, D.C. SCHMADEL, R.L. GREENE, H.D. DREW, *Physics Dept., Univ. of Maryland, College Park, MD* Although the infrared longitudinal conductivity $\sigma_{xx}$ in $Pr_{2-x}Ce_xCuO_4$ can be modeled using a Drude model which includes density wave (DW) excitations at low temperatures and low doping concentrations (Zimmers, PRB 2004), the infrared Hall conductivity $\sigma_{xy}$ exhibits behavior (Zimmers, cond-mat/0510085) that is not consistent with this model even outside of the DW phase. By measuring the rotation and ellipticity of the polarization of transmitted light through a sample in magnetic fields up to 7 T, the infrared Faraday angle is determined in the 115 to 366 meV (930-3000 $cm^{-1}$) energy range. The Faraday angle is closely related to the Hall angle and $\sigma_{xy}$, which provide a sensitive test of the many-body interactions that could lead to deviations from Drude behavior. Three samples with doping levels of $x = 0.12$, 0.15 and 0.18 are probed at temperatures ranging from 50 K to 300 K. Non-Drude behavior is observed in the Faraday angle, which also changes sign as a function of frequency and temperature from electron-like to hole-like as expected from the hole-like underlying Fermi surface. Supported by the Research Corporation Cottrell Scholar Award (UB), NSF CAREER Award (UB), NSF DMR-0352735 (UMCP) and NSF DMR-0303112 (UMCP).

**16:06**

**R38 9 Raman scattering study of low energy charge dynamics in the normal state of $Pr_{2-x}Ce_xCuO_{4-\delta}$** G. BLUMBERG, B. S. DENNIS, *Bell Labs, Lucent Technologies* M. M. QAZILBASH, R. L. GREENE, *Center for Superconductivity Research, University of Maryland, College Park* Some of the normal state properties of the electron-doped (n-doped) superconducting cuprates $R_{2-x}Ce_xCuO_{4-\delta}$(R = La, Pr, Nd, Sm) are different from those of the hole-doped (p-doped) cuprates. In the n-doped cuprates at optimal doping (x = 0.15) the dc resistivity is a quadratic function of temperature whereas in the p-doped cuprates it is linear in temperature. The charge carriers in p-doped cuprates are holes whereas in the n-doped cuprates both electronlike and holelike carriers exist near optimal doping; the electronlike carriers reside near ( $\pm \pi$/a, $\pm \pi$/4a) and ( $\pm \pi$/4a, $\pm \pi$/a) regions and the holelike carriers reside near ( $\pm \pi$/2a, $\pm \pi$/2a) regions of the Brillouin Zone. We have performed temperature and doping dependent Raman scattering study in the normal state of the n-doped superconducting cuprate $Pr_{2-x}Ce_xCuO_{4-\delta}$. Using polarized light we have isolated the low energy dynamics of the electronlike and holelike carriers. We compare Raman data in the $B_{1g}$ and $B_{2g}$ channels to dc resistivity and discuss the implications.

**16:18**

**R38 10 Theory of Low-Temperature Hall Effect in Electron-Doped Cuprates*** JIE LIN, *Columbia University* ANDREW MILLIS, *Columbia University* A mean field calculation of the $T \rightarrow 0$ limit of the Hall conductance of electron-doped cuprates such as $Pr_{2-x}Ce_xCuO_{4+\delta}$ is presented. The data are found to be qualitatively consistent with the reconstruction of the Fermi surface expected upon density wave ordering. The magnitude of the density wave gap is found to be large. The Hall resistance exhibits a nonanalyticity at the quantum critical point for density wave ordering, but the amplitude of the anomaly is found to be unobservably small. The quantum critical contribution to $R_H(B)$ is determined. Quantitative discrepancies between calculation and data remain, suggesting that the experimental doping is not identical to the *Ce* concentration *x*.

**16:30**

**R38 11 Infrared Hall effect measurement of correlated metal $Na_{0.75}CoO_2$*** E.J. CHOI, *Department of Physics, Univ. of Seoul, 130-743, Korea* A. ZIMMERS, *Department of Physics and Center of Superconductor Research, University of Maryland, College Park, MD 20742* L. SHI, A. SOUSHKOV, H.D. DREW, J.H. CHO, *Department of Physics, Pusan National University, Pusan, Korea* $Na_xCoO_2$ has a layered Co-O plane where Co ions form a triangular bonding block in contrast with the square Cu moments of HTSC Cu-O plane. With varying x, the compound exhibits rich phases like superconductivity (x=0.3, $H_2O$ intercalted), charge-ordering (x=0.5) and Curie-Weiss metal (x$\sim$ 0.7). $Na_xCoO_2$ thin film (x=0.75) was grown on $SrTiO_3$ substrate using PLD method. Resistivity and dc-Hall effect show same temperature dependence as those of single crystal. We studied ac Hall effect by measuring the complex Faraday rotation $\theta_F$ at infrared frequency (1100 $cm^{-1}$) for 30K$>$ T$<$ 300K and in magnetic fields up to 8 Tesla. As T decreases, real part of $\theta_F$ shows a slop change where dRe($\theta_F$)/dT from negative to positive sign at T=100K. At the same T, Im($\theta_F$)shows a dispersive structure. This anomaly comes from $\sigma_xy$ while $\sigma_xx$ is monotonic with T. Possible origin of the unusual infrared Hall conductivity sigma$_xy$ is considered in terms of spin density wave, Na-ordering, and electronic Kagome lattice.

**R38 12 Magneto-optical studies of high-$T_c$ cuprates in 33 Tesla** S.V. DORDEVIC, *The University of Akron* A. GOZAR, I. BOZOVIC, C.C. HOMES, G.D. GU, W. SI, *Brookhaven National Lab* Y.J. WANG, *National High Magnetic Field Laboratory* We will report results of our magneto-optical studies of high- $T_c$ cuprates in high magnetic field. An optimally doped LSCO thin film with thickness of 78 nm and $T_c$ = 41 K was studied in transmission geometry with magnetic field of 33 Tesla. The measurements have been performed in the mid-IR part of the spectrum, and at temperatures both below and above Tc. In addition, several other cuprates families, such as YBCO, Bi2212, LBCO and NCCO, have been studied in reflection geometry, with magnetic field of 18 Tesla applied perpendicular to $CuO_2$ planes. In all studied samples we find extreme insensitivity of optical properties to external magnetic field. The results will be discussed in the context of existing theoretical models.

**16:54**

**R38 13 c-axis magneto optics and vortex dynamics of underdoped YBCO** A.D. LAFORGE, K.S. BURCH, *University of California, San Diego* W.J. PADILLA, *Los Alamos National Laboratory* KOUJI SEGAWA, YOICHI ANDO, *Central Research Institute of Electric Power Industry, Japan* D.N. BASOV, *University of California, San Diego* c-axis reflectance measurements have been carried out on high quality single crystals of $YBa_2Cu_3O_x$ at two dopings, x = 6.65 and x = 6.75, with magnetic fields oriented both parallel and perpendicular to the $CuO_2$ plane. Fields applied parallel to the plane induced several interesting effects at temperatures below the superconducting transition, in-

cluding a strong suppression of superfluid density and the appearance of a new mode at frequencies below the Josephson plasma resonance (JPR). This mode is field-dependent both in magnitude and position, shifting to higher energies with increasing field. Here it is analyzed within several models of vortex dynamics, including that of Tachiki, Koyama, and Takahashi. Application of fields perpendicular to the plane creates a shift in the JPR frequency, as predicted by the TKT model.

**SESSION R39: SUPERCONDUCTIVITY—SODIUM COBALTATE**

**R39 1 Charge-fluctuation excitations in $Na_{1/3}CoO_2 \cdot yH_2O$*** O.D. RESTREPO(1), A.G. EGUILUZ(1), *University of Tennessee and CMSD,ORNL (2)* K.-W. LEE, J. KUNES, W.E. PICKETT(3), *University of California, Davis* We report a theoretical study of the electron-hole excitation spectrum of the hydrated superconductor $Na_{1/3}CoO_2 \cdot yH_2O$. We use a paramagnetic LDA ground state as our starting point, and calculate the dynamical density-response function using time- dependent density-functional theory. Our results are compared with calculations for the parent compound $Na_{1/3}CoO_2$ and with recent electron-energy loss spectroscopy (EELS) experiments reported by H. X. Yang et al. (PRB 72, 075106 (2005)). Interestingly, the dielectric function obtained from our ab-initio calculations differ appreciably, in the key spectral region, from the one extracted from the experimental loss function by H. X. Yang et al. In fact, our dielectric function shows better qualitative correspondence with the loss data; this finding highlights the relevance of ab-initio calculations for the study of the experimental manifestation of the electronic structure. The physics of the prominent peaks in the loss spectra is discussed; we identify signatures of the underlying electronic structure in the hydrated compounds. *DOE-CMSN PCSCS collaboration. (1) Supported by NSF ITR-DMR 0219332 (2) Managed by UT-Battelle for the U.S. DOE under contract DE- AC05-00OR22725. (3) Supported by DOE Grant DE-FG03-01ER45876

**14:42**
**R39 2 Charge and Spin Ordering in Insulator $Na_{0.5}CoO_2$: Effects of Correlation and Symmetry** KWAN-WOO LEE, WARREN PICKETT, *University of California, Davis* The discovery by Takada and coworkers of superconductivity in $Na_{0.3}CoO_2 \bullet 1.3 H_2O$ near 5K has led to extensive studies of the rich variation of properties in the $Na_xCoO_2$ system ($0.2 \leqslant x \leqslant 1$), which has a triangular lattice of Co sites and a layered structure. In addition, specifically at $x=0.5$, the system has been observed to undergo a charge disproportionation ($2Co^{3.5+} \rightarrow Co^{3+} + Co^{4+}$) and metal-insulator transition at 50 K, while the rest of the phase diagram is metallic. We will present results of studies of charge disproportionation and charge- and spin-ordering in insulating in $Na_{0.5}CoO_2$, applying ab initio band theory including correlations due to intra-atomic repulsion. Various ordering patterns (zigzag and two striped) for four-Co supercells are analyzed before focusing on the observed ''out-of-phase stripe'' pattern of antiferromagnetic $Co^{4+}$ spins along charge-ordered stripes. This pattern relieves frustration and shows distinct analogies with the cuprate layers: a bipartite lattice of antialigned spins, with axes at 90° angles. Substantial distinctions with cuprates are also discussed, including the tiny gap of a new variant of ''charge transfer'' type within the Co 3*d* system. [1] K. Takada et al., Nature **422**, 53 (2003). [2] M. L. Foo et al., Phys. Rev. Lett. **92**,247001 (2004). [3] K.-W. Lee, J. Kunes, P. Novak, and W. E. Pickett, Phys. Rev. Lett. **94**, 026403 (2005). **14:54**
**R39 3 Ab Initio Study on Na Ordering and its Relation to the Electronic/Magnetic Properties of P2-NaCoO2 Thermoelectrics** YING SHIRLEY MENG, *Massachusetts Institute of Technology* ANTON VAN DER VEN, *University of Michigan* MARIA CHAN, *M.I.T.* GERBRAND CEDER, *M.I.T.* The unusual electronic properties of NaxCoO2 make it a material of considerable interest. The system displays an unusual combination of high Seebeck coefficient and low metallic resistance. NaxCoO2 is also an interesting material on which to test our fundamental knowledge of mixed valence transition metals. NaxCoO2 is a mixed valence system with a fraction of x Co4+ and (1- x) Co3+ ions. Because of the high mobility of Na and large vacancy concentration, Na-vacancy ordering is likely in NaxCoO2. This ordering breaks the symmetry on the Co sublattice and may assist in charge ordering of Co3+ and Co4+. Mixed Co3+/Co4+ systems tend to display rich physics as they are often close to spin transitions and metal insulator transitions. In this study, we use both standard Density Functional Theory (DFT) in the Generalized Gradient Approximation (GGA) as well as GGA+U calculations to investigate the possible Na-vacancy and charge-ordered structure of P2-NaxCoO2 throughout the sodium composition range. We have identified new ground state structures at Na concentrations 0.11, 0.75 and 0.80. We have also found a strong coupling between the Na-vacancy ordering and Co3+/Co4+ charge ordering in the system. Such knowledge is crucial for understanding the thermoelectric properties of this material and similar mixed valence oxides.

**15:06**
**R39 4 Electron Correlation and Fermi Surface Topology of $Na_xCoO_2$** SEN ZHOU, *Boston College* MENG GAO, *Boston College* HONG DING, *Boston College* PATRICK LEE, *Massachusetts Institute of Technology* ZIQIANG WANG, *Boston College* The electronic structure of $Na_xCoO_2$ revealed by recent photoemission experiments shows important deviations from band theory predictions. The six small Fermi surface pockets predicted by LDA calculations have not been observed as the associated $e_g'$ band fails to cross the Fermi level for a wide range of sodium doping concentration $x$. In addition, significant bandwidth renormalizations of the $t_{2g}$ complex have been observed. We show that these discrepancies are due to strong electronic correlations by studying the multi-orbital Hubbard model in the Hartree-Fock and strong-coupling Gutzwiller approximation. The quasiparticle dispersion and the Fermi surface topology obtained in the presence of strong local Coulomb repulsion are in good agreement with experiments.

**15:18**

**R39 5 Systematic doping evolution of quasiparticle mode and Fermi surface topology in $NaxCoO_2$** DONG QIAN, *Department of Physics, Princeton University* A.V. FEDOROV, ZAHID HUSSAIN, *Advanced Light Source, Lawrence Berkeley National Laboratory* R.J. CAVA, *Department of Chemistry, Princeton University* N.L. WANG, *Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences* M.Z. HASAN, *Department of Physics, Princeton University* We have carried out a detailed and systematic state-of-the-art photoemission study of $NaxCoO_2$ over a wide range of doping. The Fermi velocity is found to be weakly anisotropic and small leading to a strongly suppressed quasiparticle bandwidth as a universal behavior in all dopings. No surface state or Ruthanate-type reconstruction is observed. Systematic studies show that the 2-D Fermi-surface area evolves according to the Na doping count only below x=0.5. The measured Fermi surface topology near superconducting Na doping kinematically allows for commensurate fluctuations (charge or lattice) as potential competing instabilities. The temperature evolution of quasiparticles will be discussed in addition.

**15:30**

**R39 6 Correlation Effects and Magnetism in $Na_xCoO_2$** MENG GAO, SEN ZHOU, HONG DING, ZIQIANG WANG, *Boston College* Correlation effects are known to be important for the electronic structure and the Fermi surface topology of $Na_xCoO_2$ [ref to prl of Zhou et al.]. Here we study magnetic properties of $Na_xCoO_2$ based on the multi-orbital Hubbard model for the cobalt $t_{2g}$ electrons in weak and strong coupling limits using Hartree-Fock and Gutzwiller approximations. Both commensurate and incommensurate magnetic order is considered. We present the phase diagram in the parameter space of local Coulomb repulsion and Hunds rule coupling for different sodium doping concentrations. The interplay between the correlation effects and Fermi surface nesting on the magnetic properties will be discussed.

**15:42**

**R39 7 Thermal Expansion Measurements of the Antiferromagnetic Transition in $Na_xCoO_2$ Single Crystals (x=0.75 and 0.80)*** C. A. M. DOS SANTOS, *Departamento de Engenharia de Materiais - FAENQUIL and Montana State University* J. J. NEUMEIER, R. K. BOLLINGER, *Montana State University* Y.-K. YU, *NIH National Center for Biotechnology Information* R. JIN, D. MANDRUS, *Oak Ridge National Laboratory* Thermal expansion, heat capacity and magnetic susceptibility measurements of $Na_xCoO_2$ (x=0.75 and 0.80) single crystals are reported. The results show second-order antiferromagnetic transition near $T_N = 22$ K. The high-resolution thermal expansion measurements, performed with a fused quartz dilatometer cell in both basal plane and c-axis directions, reveal strong anisotropy that is attributed to the hexagonal structure. Above and below $T_N$, the thermal expansion coefficients and specific heat measurements exhibit λ-like peaks which are similar to those reported for other antiferromagnetic compounds. Analysis of the critical behavior for both samples will be discussed.

**15:54**

**R39 8 Specific-heat study for the coupling between two superconducting order parameters in $Na_xMn_zCo_{1-z}O_2yH_2O$.** C.P. SUN, *Dept. of Physics, Natl. Sun Yat Sen University, Taiwan* J. -Y. LIN, *Inst. of Physics, Natl. Chiao Tung University, Taiwan* C.L. HUANG, *Dept. of Physics, Natl. Sun Yat Sen University, Taiwan* C.-J. LIU, J.S. WANG, *Natl. Changhua University of Education, Taiwan* H.D. YANG, *Dept. of Physics, Natl. Sun Yat Sen University, Taiwan* The substitution of Mn doping into the Co site, has been confirmed by the Mn *L*-edge XANES and EXAFS spectra, is performed by the specific-heat measurement with and without magnetic field. Due to the possible coexistence of isotropic and nodal-line gap, the two superconducting order parameters should exhibit different $T_c$ suppression rate by the doping impurity. Without field, two anomalies are seen below $T_c$, $\sim$ 4 K determined from magnetization, may be caused by different superconducting contributions due to the impurity effect and then merge into one under higher magnetic field ( $\sim$ 1T). Schottky effect needs to be taken into account in the normal state.

**16:06**

**R39 9 Transport Properties and X-ray Absorption Spectroscopy in Layered Cobaltate $Na_xCoO_2$ thin films** W. J. CHANG, *Department of Electrophysics, National Chiao Tung University* J. Y. JUANG, J.-Y. LIN, *Institute of Physics, National Chiao Tung University* C. M. LEE, C.-M. HUANG, J. M. CHEN, C.-H. HSU, $Na_xCoO_2$ ($x \sim 0.7$) thin films ( $\sim$ 200 nm) were fabricated on sapphire (0001) substrates via lateral diffusion of sodium into $Co_3O_4$ (111) epitaxial films. From the results of x-ray diffraction and in-plane resistivity it$\rho_{ab}$, the single phase and the metallic behaviors of these $Na_xCoO_2$ films were identified, and consisting with the results of single crystals [1] and Ohta's films [2]. The anomalous Hall effect and the magnetoresistance were also measured in $Na_xCoO_2$ thin films. In addition, the O 1*s* x-ray absorption spectra of thin films show different anisotropy to those of single crystals. The electronic structures of $Na_xCoO_2$ single crystals and thin films will be discussed to investigate the splitting of $e_g$ and $t_{2g}$ states in Co 3*d* bands of $Na_xCoO_2$ thin films. *This work was supported by the National Science Council of Taiwan, under Grant Nos. NSC-94-2112-M-009-006. [1] Maw Lin Foo et al., Phys. Rev. Lett. **92**, 247001 (2004). [2] Hiromichi Ohta et al., Crystal Growth & Design **5**, 25 (2005).

**R39 10 Variational Monte Carlo study of pairing symmetries of Na0.3CoO2.1.3H2O*** RUI FAN, YONG-QIANG WANG, HAI-QING LIN, *Institute of Theoretical Physics and Physics Department, The Chinese University of Hong Kong, Hong Kong, China* To investigate possible pairing symmetries of Na0.3CoO2.1.3H2O, we study the single band extended Hubbard model on triangular lattice with variational Monte Carlo method. For the on site s-wave, the extended s-wave, the d-wave, the f-wave and the extended-f wave parings, we use the corresponding BCS type mean field wave functions with Jastrow factors as our trial wave functions. We found that in a suitable parameters region, the extended f-wave pairing is stabilized by the nearest-neighbor Coulomb interaction V. In order to further investigate the true ground state of this system we use the constrained path Monte Carlo (CPMC) method to calculate different correlation function in the ground state.

**R39 11 Band Structures, Fermi Surface Topology and Superconductivity in $Na_xCoO_2 \cdot yH_2O$: Effects of the trigonal $CoO_6$ distortion** MASAHITO MOCHIZUKI, MASAO OGATA, *Department of Physics, University of Tokyo* In the recently discovered Co-oxide superconductor $Na_xCoO_2 \cdot yH_2O$, the edge-shared $CoO_6$ octahedra are trigonally contracted along the *c*-axis in the $CoO_2$-plane. We study how this $CoO_6$ distortion affects the magnetic properties and superconductivity in this compound by analyzing the multiorbital Hubbard model using the fluctuation-exchange approximation. It is shown that through generating the trigonal crystal field, the distortion pushes the Co $e_g'$ bands up and consequently gives rise to the hole-pocket Fermi surfaces, which have been predicted in the band calculations. As the distortion increases, the hole pockets are enlarged and the ferromagnetic fluctuation as well as the pairing instability increases, which is in good agreement with recent NQR results.

**16:42**

**R39 12 Photoemission study on core levels of NaxCoO2** JIHUA MA, *Department of Physics, Boston College, Chestnut Hill, MA 02467* HONGBO YANG, *Condensed Matter Physics & Material Science Department, Brookhavan National Laboratory, Upton, NY 11973* ZHIHUI PAN, *Department of Physics, Boston College, Chestnut Hill, MA 02467* A.V. FEDOROV, *Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA 94720* R. JIN, B.C. SALES, D. MANDRUS, *Condensed Matter Science Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831* HONG DING, *Department of Physics, Boston College, Chestnut Hill, MA 02467* A Comprehensive study on Na 2p and Co 3p core levels of NaxCoO2 is carried out by photoemission. A surface component of Na 2p core level is found. By comparing the surface state and bulk state at different emission angles, different photon energies and different doping levels, we not only extract the electron escape length in this system, but also discover other interesting features.

**16:54**

**R39 13 Determination of $t_{2g}$ Complex in $Na_xCoO_2$ by Angle-Resolved Photoemission Spectroscopy** HONGBO YANG, *Brookhaven National Laboratory* JIHUA MA, ZHIHUI PAN, *Boston College* ALEXEI FEDOROV, *Lawrence Berkeley National Laboratory* JONGYIN JIN, BRIAN SALES, DAVID MANDRUS, *Oak Ridge National Laboratory* ZIQIANG WANG, HONG DING, *Boston College* A systematic investigation on $t_{2g}$ complex in $Na_xCoO_2$ is carried by ARPES. By taking advantage of the matrix element effect, we recover and trace the dispersion of all three $t_{2g}$ bands for different Na concentration ($x = 0.3 \sim 0.7$). The dispersion ''kink'' we observed before is found to be cause by the hybridization between $a_{1g}$ and $e_g'$ bands. This band hybridization forms a narrow band near the Fermi level, which causes a large mass renormalization. The width of the non- hybridized bands is about half of the one predicted by LDA calculations, which is possibly due to the correlation effect.

**17:06**

**R39 14 Possible coexistence of *s*-wave and unconventional pairing in hydrated $Na_xCoO_2$: a new insight from impurity effects*** JIUNN-YUAN LIN, Y.-J. CHEN, *Institute of Physics, National Chiao Tung University, Hsinchu 300, Taiwan* C.-J. LIU, J.-S. WANG, *Department of Physics, National Changhua University of Education, Changhua 50007, Taiwan* C. P. SUN, H. D. YANG, *Department of Physics, National Sun Yat Sen University, Kaohsiung 804, Taiwan* S. W. HUANG, *Department of Electrophysics, National Chiao Tung University, Hsinchu 300, Taiwan* J. M. CHEN, J. M. LEE, J. F. LEE, D. G. LIU, *National Synchrotron Radiation Research Center, Hsinchu 300, Taiwan* Impurity effects on $T_c$ were known to provide indispensable information in many novel superconductors. To shed light on the symmetry of the superconducting order parameter in hydrated $Na_xCoO_2$, the Mn doping effects have been studied. X-ray absorption spectroscopy reveals that the doped Mn impurities occupy the Co sites and have a valance close to 4+. Impurity scattering by Mn is in the unitary limit that, however, does not lead to strong $T_c$ suppression. This absence of the strong impurity effects on $T_c$ is not consistent with the simple picture of a sign-changing order parameter. For reconciliation among all existing experiments, the model of coexistence of *s*-wave and unconventional pairing is proposed.

**R39 15 Effect of heavy water intercalation in sodium cobaltate.** CINZIA METALLO, *University of Tennessee* TAKESHI EGAMI, *University of Tennessee, Oak Ridge National Laboratory* THOMAS PROFFEN, *Los Alamos National Laboratory* DAVID MANDRUS, *Oak Ridge National Laboratory* BRIAN SALES, *Oak Ridge National Laboratory* RONGYING JIN, *Oak Ridge National Laboratory* Superconductivity in the hydrated compound $Na_xCoO_2yH_2O$ (x=0.35, y=1.3) is directly related to water intercalation. Nevertheless, so far, no clear explanation of the effect of water on the superconducting mechanism has been given. Here we present our study on deuterated sodium cobaltate $Na_xCoO_2yD_2O$ (x=0.35, y=1.4) at two different temperatures, T=15K, 100K. Neutron diffraction data were analyzed using the PDF technique. The PDF of $Na_xCoO_2yD_2O$ was compared with the PDF of heavy water. The diffraction spectra at both temperatures show a weak D-D correlation, and a pronounced D-O correlation. The weakened D-D correlations imply that the dynamics of the hydrogen bond is modified. This increases the dielectric response, and may enhance the electron-phonon coupling. Our results suggest a modification of the geometry of the heavy water molecules inserted in Na $_xCoO_2$, and subsequently a possible active role of water in setting the superconducting state.

**R40 2 Generating Spin Echoes in Dipolar Solids with $\pi$-Pulses: More is Different** DALE LI, *Yale University Department of Physics* YANQUN DONG, *Yale University Department of Physics* RONA RAMOS, *Yale University Department of Physics* ANATOLY DEMENTYEV, *Yale University Department of Physics* SEAN BARRETT, *Yale University Department of Physics* NMR spin echo measurements of $^{13}C$ in $C_{60}$, $^{89}Y$ in $Y_2O_3$, and $^{29}Si$ in Silicon are shown to defy conventional expectations when more than one $\pi$-pulse is used. Multiple $\pi$-pulse echo trains may either freeze-out or accelerate the dipolar decay of the signal, depending upon $\pi$-pulse phase, which suggests a connection to quantum dynamical decoupling and the formation of quantum Zeno subspaces. Exact quantum calculations (without a spin bath) reveal an intrinsic cause for these coherent phenomena: the dipolar coupling has a many-body effect during any real, finite pulse.

**15:18**
**R40 3 From Large to Small Spin Systems: Exploring Many-body Effects in NMR** YANQUN DONG, *Department of Physics, Yale University* DALE LI, *Department of Physics, Yale University* RONA RAMOS, *Department of Physics, Yale University* SEAN BARRETT, *Department of Physics, Yale University* NMR multi-pulse spin echo measurements on different nuclei and different samples show a dramatic Pulse Sequence Sensitivity (PSS): the multiple pi-pulse echo trains may either freeze out or accelerate the dipolar decay of the signal depending upon pi pulse phase. Finite-pulse spin simulations on small spin systems (7 spins) also show a tiny PSS. We propose that the dramatic PSS in experiments may be due to many-body effects during the finite pi pulses. If this is the case, the PSS should be less in small spin systems. This idea can be tested by performing spin echo experiments on small spin systems. The liquid crystal 5CB has a nematic phase, which enables the molecules to act like isolated spins systems in NMR. Since each molecule has 19 $^1H$ spins, this is an attractive system for our test. I will present experimental results on 5CB, and discuss their implication on our model.

**15:30**
**R40 4 Observation of Anomolously Long-Lived Spin Echoes in a Dense Dipolar Spin System** RONA RAMOS, YANQUN DONG, DALE LI, SEAN BARRETT, *Yale University, Department of Physics* Continuing the investigation of anomolously long-lived spin echoes found in multipulse $^{29}Si$ NMR experiments, similar proton NMR experiments were performed on adamantane ($C_{10}H_{16}$, a molecular solid that tumbles about its fcc lattice sites). In contrast to the dilute dipolar silicon samples from previous experiments [A.E. Dementyev, D. Li, K. MacLean, S.E. Barrett, Phys. Rev. B 68, 153302 (2003).], adamantane presents a densely populated, strongly coupled proton spin system in which to probe the basis of this puzzle. Despite these changes, this phenomenon, which defies conventional NMR theory, still remains. This talk will discuss the results of these experiments and its impact on our current understanding of this behavior.

**15:42**
**R40 5 Numerical modeling of the central spin problem using the spin coherent states P-representation** V.V. DOBROVITSKI, *Ames Laboratory and Iowa State University, Ames IA 50011* K.A. AL-HASSANIEH, E. DAGOTTO, *Oak Ridge National Laboratory, Oak Ridge TN, and University of Tennessee, Knoxville TN 37831* B.N. HARMON, *Ames Laboratory and Iowa State University, Ames IA 50011* We analyze decoherence of a central spin coupled to a spin bath (the central spin problem). Theoretical understanding of this process is important for many experiments, such as the recent study of decoherence of the electron spin by the nuclear spins in a quantum dot. To investigate the important non-perturbative decoherence regimes, we developed an efficient mean-field-based method for modeling the spin-bath decoherence. The method is based on the P-representation for the central spin density matrix, which is very useful in quantum optics, but has not been widely applied to quantum many-spin systems. In contrast with the standard time-dependent mean field theory, our method gives excellent agreement with the exact solution. We demonstrate performance of the method for longitudinal and transversal relaxation at different external fields. In particular, by modeling the quantum systems with up to 16000 bath spins, we make controlled predictions for the slow long-time decoherence of the central spin. We thank L. Glazman, M. Lukin, A. Polkovnikov, and J. Taylor for helpful discussions. This work was supported by NSA, ARDA, ARO, and NSF.

**15:54**
**R40 6 The sensitive electrical detection of spin coherence with pulsed electrically detected magnetic resonance** CHRISTOPH BOEHME, *University of Utah, Physics Department, 115 S 1400 E Suite 201, Salt Lake City, Utah 84112-0830, USA* KLAUS LIPS, *Hahn-Meitner-Institut Berlin, Abteilung Siliziumphotovoltaik, 12489 Berlin, Germany* We present a pulsed electrically detected magnetic resonance experiment which allows the very sensitive observation of the coherent evolution of localized electron spins in semiconductors. The experiment takes advantage of spin selection rules of electronic transport transitions which exist for tunneling through localized states of a 20 nm thick disordered silicon buffer layer between a crystalline silicon wafer and an 80 nm thick ZnO surface layer. When coherent spin states of defect pairs are prepared by means of pulsed electron spin resonance, the singlet

content (= the projection of density matrix onto the singlet state) of these states is directly proportional to the additional charge which is transmitted by the interface. Experimental data and the sensitivity limits of this spin measurement technique will be presented. The applicability of this for the readout of silicon based spin quantum information concepts is discussed.

**16:06**

**R40 7 Polarization Requirements for Ensemble Implementations of Quantum Algorithms with a Single Bit Output** BRANDON ANDERSON, *University of Texas at Dallas* DAVID COLLINS, *Bucknell University* We compare the failure probabilities of ensemble implementations of quantum algorithms which use pseudo-pure initial states, quantified by their polarization, to those of competing classical probabilistic algorithms. Specifically we consider a class algorithms which require only one bit to output the solution to problems. For large ensemble sizes, we present a general scheme to determine a critical polarization beneath which the quantum algorithm fails with greater probability than its classical competitor. We apply this to the Deutsch-Jozsa algorithm to determine the critical polarization.

**16:18**

**R40 8 Optimizing quantum gate fidelities using energy-optimal control*** SONIA SCHIRMER, *Univ. of Cambridge* Optimal control theory offers a promising framework for optimizing essential tasks in quantum computing from quantum state preparation to the implementation of quantum gates. It is applicable to a wide variety of systems from atoms and ions to quantum dots, different control mechanisms from all-optical to all-electronic, and allows implementation constraints and dissipation to be accommodated. Most existing approaches focus on the exact implementation of (unitary) quantum gates in a particular model and aim to optimize gate operation times subject to certain assumptions such as arbitrarily fast local operations, weak (inter-qubit) coupling and decoherence, etc. We consider a different paradigm for optimal control focussing on optimizing the overall gate fidelity for a desired gate and fixed gate operation time subject to physical and experimental contraints (including dissipative effects), which may be more appropriate for some systems such as electronically-controlled systems with non-weak, always-on inter-qubit coupling. We discuss the basic framework and illustrate the results using calculations for model systems.

**16:30**

**R40 9 Exact solution of qubit decoherence models by a transfer matrix method.** DIU NGHIEM, *UW-Madison* ROBERT JOYNT, *UW-Madison* QUANTUM COMPUTING UW-MADISON TEAM, A new method for the solution of the behavior of an enesemble of qubits in a random time-dependent external field was found. In this method the forward evolution in time is governed by a transfer matrix whose eigenvalues determine the various decoherence times. The method provides an exact solution in cases where the noise is piecewise constant in time. It can apply to a realistic model of decoherence of electron spins in semiconductors as well. Results are obtained for the non-perturbative regimes of the models, and we see a transition from weak relaxation to overdamped behavior as a function of noise anisotropy.

**16:42**

**R40 10 Quantum kinetics of dynamical decoupling** LEONID P. PRYADKO, *University of California, Riverside* PINAKI SENGUPTA, *University of Southern California* In an ideal world, coherent control could be made perfect by running infinitely fast sequences of infinitely short pulses. In practice, in each system there are obvious spectral limitations. There is also a large-time limit set by decoherence due to environment coupling. Altogether, this makes pulse shape and sequence design an extremely complicated optimization problem. A systematic way to approach this problem is to consider a cumulant expansion of the evolution operator, treating the strong control fields exactly. The cumulants give the expansion of the effective Hamiltonian in powers of the system Hamiltonian. The locality of the cumulant expansion ensures that the classification by sequence order remains meaningful even for large systems. The corresponding calculation can be done efficiently by constructing a time-dependent perturbation theory expansion on small clusters [1]. Intuitively, refocusing should also remain effective in the presence of low-frequency environment, as long as the parameters of the system Hamiltonian are varying slowly compared to the refocusing period $\tau$. A systematic study of this effect will be presented, based on the Floquet analysis of the non-Markovian quantum kinetic (master) equation for the open multi-qubit system in the presence of continuous refocusing fields exact up to 2nd order in the cumulant expansion [2]. [1] P. Sengupta and L. P. Pryadko, Phys. Rev. Lett. **95**, 037202 (2005). [2] L. P. Pryadko and P. Sengupta, quant-ph/0510001 (2005).

**16:54**

**R40 11 Enhanced Convergence and Robust Performance of Randomized Dynamical Decoupling** LEA SANTOS, LORENZA VIOLA, *Dartmouth College* Dynamical decoupling methods consist of repetitive sequences of control operations, whose net effect is to coherently modify the natural target dynamics to a desired one. In addition to standard deterministic schemes, randomized decoupling strategies have been recently introduced. Here, we exhibit clear evidence of the benefits of randomization in reducing the effects of undesirable couplings. For control systems which are either time-varying or require decoupling cycles involving a large number of operations, we find that simple randomized protocols offer superior convergence and stability as compared to high-level deterministic designs, including combinatorial and concatenated methods. We also show how significant improvements may be achieved for long interaction times by combining deterministic and stochastic features into new hybrid decoupling schemes.

**17:06**

**R40 12 Resurrection of Schrödinger Cat** JAE-SEUNG LEE, ANATOLY KHITRIN, *Department of Chemistry, Kent State University, Kent, Ohio 44242-0001* The most striking difference between quantum and classical systems is the ability of quantum objects to be in a superposition state. A system in a superposition of macroscopically distinct states (italive and itdead states of the ''Schrödinger cat'') would demonstrate highly unusual behavior. Cat states are the central elements in recent proposals on high-precision spectroscopy, amplified quantum detection and measurement. Quantum decoherence is the major obstacle in building practical devices which could revolutionize high-precision measurements or information processing. Here we experimentally demonstrate that quantum state of a system can be recovered after the state is destroyed by uncontrollable natural decoherence. The physical system used in this experiment is a cluster of seven

dipolar-coupled nuclear spins of single-labeled $^{13}$C-benzene oriented in liquid crystal. After decoherence of the cat state, superposition of states with all spins up (alive) and all spins down (dead), information stored in a single ancillary spin ($^{13}$C) is used to bring the protons subsystem into the italive state, while the excess entropy produced by decoherence is transferred to the ancillary spin.

**17:18**

**R40 13 Statistical performance of ensemble quantum computers in search algorithms** DAVID COLLINS, TOMASZ KOTT, *Physics and Astronomy Department, Bucknell University* We consider the statistical performance of ensemble quantum computers applied to search algorithms. In particular we consider algorithms implemented on pseudo pure initial states and determine the initial polarization required so that the quantum algorithm outperforms classical probabilistic competitors in terms of failure probabilities.

**R41 1 High-quality Thin Single-Crystal Y2O3 films Grown on Si (111)** C.-W. NIEH, W.-C. LEE, Z.-K. YANG, Y.-J. LEE, PEN CHENG, T.-D. LIN, M. HONG, *Dept. Mat. Sci. Eng., Natl Tsing Hua U, Taiwan* J. KWO, *Dept. of Phys., Natl Tsing Hua U, Hsinchu, Taiwan* C.-H. HSU, *Natl Synchrotron Rad. Res. Ctr, Taiwan* High-quality nano thick ( $\sim$ 3nm) single-crystal Y2O3 films have been MBE-grown epitaxially on Si (111) despite a 2% lattice mismatch. Studies carried out by x-ray diffraction, x-ray reflectivity, and cross-sectional HRTEM show the excellent structural properties. In-situ RHEED was used to monitor the growth quality, showing a sharp pattern of a (4x4) reconstruction. The strong oscillations of x-ray reflectivity and Pendellosung fringes surrounding the Y2O3 diffraction peaks point out that the film surfaces and the oxide/Si interfaces are atomically sharp and uniform. A record small FWHM of 0.01 degree in rocking scans was observed at Y2O3 (444), indicating the excellent quality of the nano films. The films are well aligned with the substrate with an orientation relationship of Si (111) // Y2O3 (111), and an in-plane expitaxy of Si [-110]// Y2O3 [-101]. In the thickness range of microelectronics applications, the nano Y2O3 layers have achieved a degree of perfection rarely observed in heterostructures of oxide/semiconductor.

**14:42**

**R41 2 Comparison of the Surface Structures of SrTiO3 (100) and BaTiO3 (100).** D. LI, *University of Pennsylvania* M. NIKIFOROV, DAWN BONNELL, While much research has been focused towards understanding the atomic structures on SrTiO3 surfaces, controversy still remains over the origin of the reconstructions. This talk will provide a rational description of the driving forces for previously observed and newly observed reconstructions on the (100) surface and compare these to analogous structures that occur on BaTiO3 (100). The degree to which the potential for ferroelectric ordering influences surface reconstruction will be discussed.

**14:54**

**R41 3 Coverage and bonding of thin, buried epitaxial $SrTiO_3$ on Si(100)** LENA FITTING, *Applied and Engineering Physics, Cornell University* VENUGOPALAN VAITHYANATHAN, *Department of Material Science and Engineering, Pennsylvania State University* MELANIE JONES, *Applied and Engineering Physics, Cornell University* DARRELL G. SCHLOM, *Department of Material Science and Engineering, Pennsylvania State University* DAVID A. MULLER, *Applied and Engineering Physics, Cornell University* $SrTiO_3$ can be used as a buffer layer for the growth of perovskite oxide heterostructures, opening up possibilities for the incorporation of novel materials into existing Si-based technology. While these layers have been studied during growth, a serious question for such thin layers is if their structure remains unaltered after they have been overgrown. Here, we present results of thin $SrTiO_3$ films grown on Si(100). Scanning transmission electron microscopy (STEM) of the buried structures shows the formation of islands and a non-uniform coverage of the first few monolayers after capping with a-Si. The island size increases if the $SrTiO_3$ film is grown on a $SrSi_x$ seed. An important question that arises is the existence of oxygen vacancies at the interface between the oxide and the substrate. Oxygen deficiency leads to a doping of the empty Ti 3d band in bulk $SrTiO_3$ with electrons, thereby inducing a metallic phase as the Ti formal valence changes from 4+ to 3+. Using electron energy loss spectroscopy in a STEM the Ti valence across the interface is probed on the atomic scale.

**15:06**

**R41 4 Structure of $SrTiO_3$ thin films grown on Si*** C. STEPHEN HELLBERG, *Naval Research Lab* KRISTOPHER ANDERSEN, *Naval Research Lab* Although $SrTiO_3$ films on Si have been extensively studied, the structure of the interface is not yet known. We present first-principles density-functional calculations of the energetics of the numerous proposed structures for the interface. We find that the energetically favored structure is one that has not been previously considered. The structure is consistent with x-ray and TEM probes of the interface. We discuss the implications of the interface for device applications.

**15:18**

**R41 5 Band offsets of $SrTiO_3$ thin films grown on Si*** KRISTOPHER ANDERSEN, C. STEPHEN HELLBERG, *Naval Research Laboratory* $SrTiO_3$ is a promising material to replace $SiO_2$ as the gate dielectric in metal-oxide-semiconductor field-effect transistors (MOS-FETs). The advantage of $SrTiO_3$ is its large dielectric constant: an order of magnitude greater than other promising oxides. However, the negligible conduction band offset found experimentally for heterostructures of $SrTiO_3$ (001) grown on Si (001) limits the usefulness of $SrTiO_3$ in devices because of leakage current. Here we present first-principles calculations on $Si/SrTiO_3$ heterostructures and investigate ways to modify the band offsets. Experimentally motivated structures are considered,

and the effects of dopants and defects on the electronic structure are quantified.

**R41 6 COBRA Studies of Ultrathin Ferroelectric Oxide Films*** CODRIN CIONCA, *Applied Physics, University of Michigan* D.P. KUMAH, *Applied Physics, University of Michigan* C-B EOM, *Materials Science and Engineering, University of Wisconsin-Madison* D-M KIM, *Materials Science and Engineering, University of Wisconsin-Madison* Y. YACOBY, *Racah Institute of Physics, Hebrew University, Jerusalem, Israel* D.A. WALKO, *Advanced Photon Source, Argonne National Laboratory* R. CLARKE, *Applied Physics, University of Michigan* We used Coherent Bragg Rod Analysis (COBRA) and x-ray synchrotron radiation to investigate the structure of epitaxial thin films of $PbTiO_3$ deposited by sputtering on $SrTiO_3$ substrates. The measurements were performed under different electric field conditions, including the presence of conducting electrodes. The data analysis reveals details of the atomic displacements in different layers and shows subtle variations as a function of distance from the interface. The effects of symmetry breaking at the substrate-film interface are discussed.

*Use of the Advanced Photon Source was supported by the U. S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. W-31-109-Eng-38 and Grant No. DE-FG02-03ER46023.

**R41 7 Ferroelectricity in Ultrathin Perovskite Films.*** STEPHEN STREIFFER, *Argonne National Laboratory*

The ferroelectric phase transition in ultrathin perovskite films is exquisitely sensitive to strain and to compensation of depolarizing fields arising from divergences in polarization at interfaces. However, in most experiments there is significant uncertainty in the degree of compensation by internal or external space charge (even for electroded thin films), or by the formation of domain structures that minimize depolarization energy. This in turn affects interpretation of size effects in thin films, as depolarization contributions are film thickness dependent. Here we will describe our work utilizing in-situ synchrotron x-ray scattering to study the phase transition and equilibrium 180[r] domain structure in fully coherent, epitaxial $PbTiO_3$ thin films deposited onto $SrTiO_3$ and $SrRuO_3/SrTiO_3$ substrates by metalorganic chemical vapor deposition. We will show that we can control the degree of top interface compensation by controlling the gas environment in our deposition and analysis system, and monitor this via details of the 180[r] stripe domain pattern that forms for $PbTiO_3$ on insulating $SrTiO_3$. Furthermore, we will demonstrate that compensation can be accomplished at the ferroelectric film surface by adsorption of molecular or ionic species, in contrast to electronic mechanisms that occur in the presence of a conducting electrode. Exploitation of this for novel devices or templating techniques may be possible, both through chemical control of polarity and through polarization control of ionic adsorption.

*This work was performed in collaboration with the ANL MSD In-Situ Studies Team and the A. Rappe group (U. Penn).

**R41 8 Interface effect to the nanoscale ferroelectricity** CHUN-GANG DUAN, *Department of Physics and Astronomy, University of Nebraska, Lincoln, Nebraska, 68588* RENAT F. SABIRIANOV, WAI-NING MEI, *Department of Physics, University of Nebraska, Omaha, Nebraska 68182* SITARAM S. JASWAL, EVGENY Y. TSYMBAL, *Department of Physics and Astronomy, University of Nebraska, Lincoln, Nebraska 68588* Recent experimental results demonstrate that in thin films ferroelectricity persists down to film thickness of a few unit cells. This finding opens an avenue for novel electronic devices based on ultrathin ferroelectrics, but also raises questions about factors controlling ferroelectricity and the nature of the ferroelectric state at the nanoscale. Here we report a first-principles study of $KNbO_3$ ferroelectric thin films placed between two metal electrodes, either $SrRuO_3$ or Pt. We show that the bonding at the ferroelectric-metal interface imposes severe constraints on the displacement of atoms, destroying the bulk tetragonal soft mode in thin ferroelectric films. This does not, however, quench local polarization. The critical thickness for the net polarization of the $KNbO_3$ film we found are about 1 nm for Pt and 1.8 nm for $SrRuO_3$ electrodes.

**R41 9 Ferroelectric properties of nm-scale barium and lead titanate films** Y. -H. TANG, M. -H. TSAI, *National Sun Yat-Sen University, Kaohsiung 80424 Taiwan* The first-principles calculations of the total energies of nm-scale barium titanate ($BaTiO_3$) and lead titanate ($PbTiO_3$) films with respect to the off-center Ti ion displacement, $d_{Ti}$, have been carried out to understand ferroelectric properties of these films. Since the driving force of ferroelectricity is the attractive total dipole-dipole interactions associated with the collective off-center displacements of the transition metal ions in the octahedrons [1], the ferroelectric properties of nm-scale films is expected to be different from those of thick films because of the drastic reduction of the number of available dipoles. Thus, it is interesting to know whether the nm-scale films retain ferroelectricity. The calculated total energies as a function of $d_{Ti}$ along the (110) direction show a potential well at about 0.17 and 0.15Å for $BaTiO_3$ and $PbTiO_3$, respectively. By symmetry, the potential well is the same for $-d_{Ti}$. The existence of double potential wells is a characteristic of ferroelectricity. Thus, the total energy result shows that nm-scale $BaTiO_3$ and $PbTiO_3$ films retain ferroelectricity and resultant dipoles are parallel with the films. [1] M. –H. Tsai**, Y. –H. Tang**, and S. K. Dey, J. Phys.: Condens. Matter **15**, 7901 (2003).

**16:42**
**R41 10 Effects of surface layer composition in stabilizing thin film ferroelectrics** ALEXIE KOLPAK, *University of Pennsylvania* ANDREW RAPPE, *University of Pennsylvania* Using first-principles density functional theory calculations, we explore the ramifications of chemically altering the properties of the metal/ferroelectric interfaces in thin film ferroelectric capacitors. We show that a 3 unit-cell-thick $BaTiO_3$ film with $SrRuO_3$ electrodes has a stable, bulk-like polarization when the surface BaO layers are replaced with PbO, in contrast to the unmodified $SrRuO_3/BaTiO_3$ film which only begins to support a small polarization at 8-unit cell thickness. At the other extreme, BaO surface layers completely suppress polarization in $PbTiO_3$ films even with Pt electrodes, which have been shown to stabilize a large bulk-like polarization in unaltered one unit-cell-thick $PbTiO_3$ films. Our results show that in addition to screening by the metal electrodes, the atomic structure and the work functions of the ferroelectric surface layers play key roles in determining stability. Furthermore, our work suggests that particular properties can be achieved in ferroelectric thin films through a combination of chemical surface modification and judicious choice of ferroelectric and electrode materials.

**R41 11 Visable-Deep UV Dielectric Functions and Electronic Band Structure of Lead Zirconate Titanate Thin Films** HO-SUN LEE, T.D. KANG, *Kyung Hee Univ.* Y.S. KANG, S.-J. CHO, H. MORKOC, *Virginia Commonwealth Univ.* J. LI, S.-H. WEI, *NREL* P.G. SNYDER, *Univ. of Nebraska, Lincoln* We measure pseudodielectric functions in the visible-deep ultraviolet spectral range of $Pb(Zr_xTi_{1-x})O_3$ (x=0.2, 0.56, 0.82) (PZT), $Pb_{0.98}Nb_{0.04}(Zr_{0.2}Ti_{0.8})_{0.96}O_3$, $Pb_{0.91}La_{0.09}(Zr_{0.65}Ti_{0.35})_{0.98}O_3$, and $Pb_{0.85}La_{0.15}Ti_{0.96}O_3$ films. Using a parametric optical constant model, we estimate the dielectric functions ($\varepsilon$) of the perovskite oxide thin films. Taking the second derivative of the fitted layer dielectric functions and using the standard critical point model, we determine the parameters of the critical points. In the second derivative spectra, the lowest band gap energy peak near 4 eV is fitted as a double peak for annealed PZTs due to perovskite phase. As-grown PZTs have mainly pyrochlore phase and the lowest band gap peak is fitted as a single peak. We also examine the effect of dopants La and Nb, which substitute at Pb and Zr (Ti) sites, respectively. We found three band gaps $E_a$ ( $\sim$ 3.9eV),$E_b$ ( $\sim$ 4.5 eV) and $E_c$ ( $\sim$ 6.5eV) in the order of increasing energy. The E a and Eb band gap energies were not sensitive to Zr composition. We discuss the change of critical point (CP) parameters for PZTs in comparison to the band structure calculations based on local−density−approximation. The near−constancy of the lowest band gap energy independent of Zr composition is consistent with the band calculations.

**R41 12 Electrostatics of superlattices by first principles** XIFAN WU, OSWALDO DIÉGUEZ, KARIN RABE, DAVID VANDERBILT, *Rutgers University* A complete theory of epitaxial perovskite superlattices requires an understanding of both epitaxial strain effects and of electrostatic boundary conditions. Here, focusing on the latter issue, we have carried out first-principles calculations of the nonlinear dielectric properties of short-period $BaTiO_3/SrTiO_3$ and $PbTiO_3/SrTiO_3$ superlattices having the in-plane lattice constant of $SrTiO_3$. In particular, we have mapped the energy $E$ vs. polarization $P$ for these superlattices, and for the parent bulk materials, by extending the $E(P)$ mapping algorithm of Diéguez and Vanderbilt to handle strain relaxation in the $c$-direction. We then test whether the superlattice results can be understood quantitatively in terms of the $E(P)$ information for the bulk materials and similar information on the interfaces. We reformulate the theory in terms of the electric displacement field $D$ (since this is uniform throughout the superlattice) and the corresponding internal energy $U(D)$, and investigate how to model $U(D)$ in terms of ab-initio derived bulk and interface information. We stress that once the $U(D)$ is obtained for a given superlattice, all the electrostatic properties, both linear and non-linear, can be predicted.

**17:18**
**R41 13 Epitaxial strain effects from first principles** CLAUDE EDERER, NICOLA SPALDIN, *Materials Department, University of California, Santa Barbara* Epitaxial strain can substantially enhance the spontaneous polarizations and Curie temperatures of ferroelectric thin films compared to the corresponding bulk materials. In this work we use first principles calculations to calculate the effect of epitaxial strain on the spontaneous polarization of the ferroelectrics $BaTiO_3$, $PbTiO_3$, and $LiNbO_3$, and the multiferroic material $BiFeO_3$. We show that the epitaxial strain dependence of the polarization varies considerably for the different systems, and in some cases is in fact very small. We discuss possible reasons for this different behavior, and show that the effect of epitaxial strain can easily be understood in terms of the piezoelectric and elastic constants of the unstrained materials. Our results provide a computational tool for the quantitative prediction of strain behavior in ferroelectric thin films.

**R42 1 Multiphase Equations of State for Materials with Solid-Solid and Solid-Liquid Phase Transitions.** CHRISTOPHER ROBINSON, *AWE plc*

Many materials undergo a solid-solid phase transition where the crystal structure changes with a change in pressure or temperature. In addition materials melt, which is another phase transition. Across a phase boundary there are discontinuities in density and internal energy (latent heat). Although the volume change is small, even a small volume change may cause significant effects. For example under shock loading a phase transition may cause the shock to split into two distinct shocks. The equation of state (EoS) of a material with a phase transition may be modelled by determining the EoS

for each individual phase separately. The phase that exists at any pressure and temperature is the phase with the lowest Gibb's free energy. Then the phase boundaries between phases are the loci of points in the pressure/temperature plane where two phases have the same Gibb's free energy. Along a phase boundary the EoS may be determined by assuming that the material consists of a mixture of two phases. Then the EoS in the mixed-phase region is completely determined by the EoS of the single phases. It can be shown that the bulk sound speed always falls when passing from a single-phase region into a mixed-phase region. Therefore, under isentropic compression through a phase boundary a shock will form. When implementing the EoS into hydrocodes an iterative method may be used to determine the solution to the equations: An initial guess is made of which phases exist at the required specific volume and internal energy and then the pressure, temperature and mass fractions are calculated. If the chosen phases have the lowest Gibb's free energy the solution has been found, otherwise another guess of the stable phases is made, and the iteration is repeated.

**R42 2 First-principles study of high-pressure phase transitions in $Si_3N_4$*** BIN XU, JIANJUN DONG, *Physics Department, Auburn University* HAROLD STOKES, *Brigham Young University* DORIAN HATCH, *Brigham Young University* We have performed a systematic theoretical study of phase transitions in $Si_3N_4$ at high-pressure. We calculated the Gibbs free energies of the ground state $\beta$ phase and the high-pressure $\gamma$ phase at various temperatures and pressures based on the first- principles density functional theory and the statistical quasi-harmonic theory. The thermal equations of state and the Clapeyron slope of the $\beta$-to- $\gamma$ transition at high-pressure are determined and compared with available experimental data. In addition to the recently discovered high- pressure $\gamma$-phase, we predict a new high-pressure phase of hexagonal symmetry. This new high-pressure phase is likely to exist metastably at the high pressure itand room temperature, and it is associated with a non Å-point soft phonon distortion. The structural and elastic properties and the stability condition of this predicted metastable high-pressure phase will be discussed.

**R42 3 Pressure-induced B1-to-B2 phase transition in $AgSbSe_2$*** EUNJA KIM, RAVHI KUMAR, ANDREW CORNELIUS, MALCOLM NICOL, *Department of Physics and High Pressure Science and Engineering Center, University of Nevada, Las Vegas, NV 89154* We have investigated the pressure-induced B1-to-B2 phase transitions in $AgSbSe_2$. High pressure x-ray diffraction experiments clearly show that the process starts at 20 GPa and completes at 55 GPa. Our density-functional calculations are in good agreement with the experiment and confirm the B1 to B2 transition which is similar to $AgSbTe_2$. The possible intermediate structure for B1-to-B2 transition in $AgSbSe_2$ occurring at 21-54 GPa is under investigation. Its similarity and difference to $AgSbTe_2$ will be discussed in this study.

**R42 4 High Pressure-Induced Phase Transition In $\beta$-$Ga_2O_3$: in situ Synchrotron X-Ray Diffraction Studies up to 70 Gpa*** KRISTINA E. LIPINSKA-KALITA, *Center for Nanoscale Device Research, Dept. of Electrical and Computer Eng. University of Nevada Las Vegas* PATRICIA E. KALITA, *High Pressure Science and Engineering Center, Dept. of Physics, University of Nevada Las Vegas* RUSSELL J. HEMLEY, *Geophysical Lab. Carnegie Institution of Washington, Washington DC* CEDRIC L. GOBIN, *High Pressure Science and Engineering Center, Dept. of Physics, University of Nevada Las Vegas* A renewed interest in $\beta$-$Ga_2O_3$ has arisen since it has potential applications in optoelectronic devices. We performed itin situ synchrotron radiation x-ray diffraction studies in a diamond anvil cell on $\beta$-$Ga_2O_3$ on compression up to 70 GPa and on successive decompression. The pressure-evolution of x-ray diffraction patterns was consistent with a low-to-high density phase transition. A thermodynamically stable it$\beta$-$Ga_20_3$ phase was converted into the it$\alpha$-$Ga_20_3$ phase, which is unstable at ambient conditions. The effect of hydrostatic and non-hydrostatic compression conditions on the evolution of the phase transition was also investigated in compression and decompression cycles. This work is the first report of high-pressure investigations of $Ga_2O_3$ on compression up to 70 GPa.

**R42 6 Fermi surface nesting and pre-martensitic softening in V-Nb system under high pressure*** ALEXANDER LANDA, JOHN KLEPEIS, PER SODERLIND, BABAK SADIGH, *Lawrence Livermore Nationa Laboratory, Livermore, CA 94550* IVAN NAUMOV, *University of Arkansas, Fayetteville, AR 72701* OLEG VELIKOKHATNYI, *Carnegie Mellon University, Pittsburgh, PA 15213* LEVENTE VITOS, ANDREI RUBAN, *Royal Institute of Technology, SE-10044, Stockholm* First-principles total energy calculation based on the exact muffin-tin orbital and full potential linear muffin-tin orbital methods were used to calculate

the equation of state and shear elastic constants of bcc V, Nb, and the $V_{95}Nb_{05}$ disordered alloy as a function of pressure up to 6 Mbar. We found a mechanical instability in $C_{44}$ and a corresponding softening in $C'$ at pressures $\sim$ 2 Mbar for V. Both shear elastic constants show softening at pressures $\sim$ 0.5 Mbar for Nb. Substitution of 5 at. % of V with Nb removes the instability of V with respect to trigonal distortions in the vicinity of 2 Mbar pressure, but still leaves the softening of $C_{44}$ in this pressure region. We argue that the pressure induced softening in the shear elastic constants of V and Nb can be attributed simultaneously to three different electronic structure peculiarities, namely to the Fermi Surface nesting, electronic topological transition, and the band Jahn-Teller effect.

**R42 7 Pressure-Induced Antifluorite-to-Anticotunnite Phase Transition in Lithium Oxide** AMY LAZICKI, *University of California at Davis, Lawrence Livermore National Laboratory* CHOONG-SHIK YOO, *Lawrence Livermore National Laboratory* WILLIAM EVANS, *Lawrence Livermore National Laboratory* WARREN PICKETT, *University of California, Davis* RICHARD SCALETTAR, *University of California, Davis* Using synchrotron angle-dispersive x-ray diffraction (ADXD) and Raman spectroscopy on samples of $Li_2O$ pressurized in a diamond anvil cell, we observed a reversible phase change from the cubic antifluorite ($\alpha$, Fm3m) to orthorhombic anticotunnite ($\beta$, Pnma) phase at 50( $\pm$ 5) GPa at ambient temperature. This transition is accompanied by a moderate volume collapse of 5.4 ( $\pm$ 0.8)% and large hysteresis upon pressure reversal ($P_{down}$ at $\sim$ 25 GPa). Contrary to a recent study, our data suggest that the high-pressure $\beta$-phase ($B_o$ = 188 $\pm$ 12 GPa) is substantially stiffer than the low-pressure $\alpha$-phase ($B_o$ = 90$\pm$ 1 GPa). A relatively strong and pressure-dependent preferred orientation in $\beta$-$Li_2O$, resulting in changes diffraction intensities, is observed. The present result is in accordance with the systematic behavior of antifluorite-to-anticotunnite phase transitions occurring in the alkali-metal sulfides. This work has been supported by LLNL, University of California, under the auspices of the U.S. DOE under Contract No. W-7405- ENG-48 and by the Stockpile Stewardship Academic Alliances Program under grant DOE DE-FG03-03NA00071, and by the NSF(ITR 031339) at UCD.

**R42 8 Novel Features in the Mixed-Valence State of TmTe at High Pressure: A Resonant Inelastic X-ray Scattering Study** IGNACE JARRIGE, YONG CAI, HIROFUMI ISHII, NOZOMU HIRAOKA, CHIEN-TE CHEN, *National Synchrotron Radiation Research Center, Taiwan* JEAN-PASCAL RUEFF, *Synchrotron Soleil, France* SEAN SHIEH, *National Cheng Kung University, Taiwan* CHING-PAO WANG, *National Cheng Kung University, Taiwan* TAKESHI MATSUMURA, *Tohoku University, Japan* Using resonant inelastic x-ray scattering, the mixed-valence state of TmTe under pressure is accurately determined up to 10.6 GPa. A remarkable interplay between electronic, magnetic and structural properties in TmTe under pressure is inferred throughout the considered pressure range. A nearly linear correlation is found between the pressure dependences of the valence and the volume in the metallic regime of TmTe. In the framework of the RKKY theory, the pressure dependence of the valence is found to explain both the steady decrease of the ferromagnetic state with increasing pressure in the 2-6 GPa range and the formation of the antiferromagnetic state above 6 GPa.

**16:30**

**R42 9 Elastic Stability Analysis of the Structural Response of Cubic Crystals to Hydrostatic Loading** HADRIAN DJOHARI, *Department of Chemical Engineering, University of Massachusetts, Amherst, MA 01003-3110* FREDERICK MILSTEIN, *Departments of Materials and Mechanical Engineering, University of California, Santa Barbara, CA 93106* DIMITRIOS MAROUDAS, *Department of Chemical Engineering, University of Massachusetts, Amherst, MA 01003-3110* We report results of systematic elastic stability analyses in metallic crystals based on isobaric molecular-dynamics simulations that capture the mechanical, geometric, and kinetic aspects of instabilities induced under hydrostatic loading. Our analysis emphasizes bifurcations in the crystal structural response as the applied load is varied and atomic pattern formation characteristics beyond the instability onset. Results are presented for various cases of structural evolution under hydrostatic loading for model crystals that have a cubic lattice structure at equilibrium, including crystals with structural heterogeneities such as internal nanovoids and free surfaces. The corresponding structural responses range from inhomogeneous structural transitions to fracture through decohesion and voiding. The observed instabilities are thermally activated and associated with vanishing or diminishing combinations of elastic moduli.

**R42 10 Dynamic Strength of Metals at High Pressure and Strain Rate.** THOMAS LORENZ, *Lawrence Livermore National Laboratory*

A new approach to materials science at very high pressures and strain rates has been developed on the Omega laser, using a ramped plasma piston drive. A laser drives an ablative shock through a solid plastic reservoir where it unloads at the rear free surface, expands across a vacuum gap, and stagnates on the metal sample under study. This produces a gently increasing ram pressure, compressing the sample nearly isentropically. The peak pressure on the sample, diagnosed with VISAR measurements, can be varied by adjusting the laser energy and pulse length, gap size, and reservoir density, and obeys a simple scaling relation.[1] This has been demonstrated at OMEGA at pressures to 200 GPa in Al foils. In an important application, using in-flight x-ray radiography, the material strength of solid-state samples at high pressure can be inferred by measuring the reductions in the growth rates (stabilization) of Rayleigh-Taylor (RT) unstable interfaces. RT instability measurements of solid of Al-6061-T6 [2] and vanadium, at pressures of 20-100 GPa, and strain rates of $10^6$ to $10^8$ $s^{-1}$, show clear material strength effects. Modelling results for two constitutive strength models – Steinberg-Guinan and Preston-Tonks-Wallace, show enhanced dynamic strength that may be correlated with a high-strain-rate,

phono-drag mechanism. Data, modeling details and future prospects for this project using the National Ignition Facility laser, will be presented. [1] J. Edwards et al., Phys. Rev. Lett., **92**, 075002 (2004). [2] K. T. Lorenz et al., Phys. Plasmas **12**, 056309 (2005). **R42 11 Atomistic simulations of quasi-static and shockwave loading of HMX crystals** THOMAS SEWELL, EUGENIO JARAMILLO, *Los Alamos National Laboratory* ALEJANDRO STRACHAN, *Purdue University* We have recently undertaken non-equilibrium molecular dynamics studies to aid our understanding of dynamical processes in the high explosive HMX, in particular the inelastic, anisotropic response of crystalline HMX subjected to quasi-static and shock loading. The same force field used by Sewell and co-workers in preceding simulations of HMX equilibrium properties is employed for the present research. The overarching goal of this work is to provide information that can serve as a foundation in basic science for the formulation of improved mesoscale constitutive models for the constituent materials in selected energetic formulations. The medium-term scientific challenge that stands as a prerequisite to this larger objective is to carefully identify, characterize, and quantify the dominant mechanisms of localization and dissipation in such materials, under a variety of prescribed quasi-static and dynamic loading scenarios. The focus of the present talk will be the shock response of structurally perfect, but properly thermalized, $\alpha$-HMX crystal shocked in the (100) direction, with specific discussion of results for loading below the hugoniot elastic limit, in the two-wave elastic-plastic region, and for overdriven shocks.

**R43 1 Interference between fluctuating condensates** EHUD ALTMAN, *Weizmann Institute* ANATOLI POLKOVNIKOV, *Boston University* EUGENE DEMLER, *Harvard University* Two independent Bose condensates that are released from their traps and let to overlap produce a sharp interference pattern. How does this picture change if each condensate lacks true long range order? As an example we consider the interference between a pair of one dimensional interacting Bose liquids at low temperature. We show that the average fringe contrast scales as a universal function of the system size that depends only on the Luttinger parameter. Moreover the full distribution of the fringe contrast changes with interaction strength and lends information on high order correlation functions. We also demonstrate that the interference between two-dimensional condensates at finite temperature can be used as a direct probe of the Kosterlitz-Thouless transition.

**14:42**
**R43 2 Bose-Einstein Condensation in low dimensionality*** KWANGSIK NHO, D.P. LANDAU, *Center for Simulational Physics, University of Georgia* Using path integral Monte Carlo simulation methods[1], we have studied properties of Bose-Einstein Condensates harmonically trapped in low dimemsion. Each boson has a hard-sphere potential whose core radius equals its corresponding scattering length. We have tightly confined the motion of trapped particles in one or more direction by increasing the trap anisotropy in order to simulate lower dimensional atomic gases. We have investigated the effect of both the temperature and the dimemsionality on the energetics and structural properties such as the total energy, the density profile, and the superfluid fraction. Our results show that the physics of low dimensional bosonic systems is very different from that of their three dimensional counterparts[2]. The superfluid fraction for a quasi-2D boson gas decreases faster than that for both a quasi-1D system[3] and a true 3D system with increasing temperature. The superfluid fraction decreases gradually as the two-body interaction strength increases although it shows no noticable dependence for both a quasi-1D system and a true 3D system. [1] K. Nho and D. P. Landau, Phys. Rev. A. **70**, 53614 (2004). [2] N. D. Mermin and H. Wagner, Phys. Rev. Lett. **22**, 1133 (1966); P. C. Hohenberg, Phys. Rev. **158**, 383 (1967). [3] K. Nho and D. Blume, Phys. **R43 4 One Dimensional Gas of Bosons with Feshbach Resonant Interactions*** VICTOR GURARIE, *University of Colorado* We present a study of a gas of bosons confined in one dimension with Feshbach resonant interactions, at zero temperature. Unlike the gas of one dimensional bosons with non-resonant interactions, which is known to be equivalent to a system of interacting spinless fermions and can be described using the Luttinger liquid formalism, the resonant gas possesses novel features. Depending on its parameters, the gas can be in one of several regimes. In the most interesting of them, it is equivalent to a Luttinger liquid at low density only. At higher density its excitation spectrum develops a

minimum, similar to the roton minimum in helium, at momenta where the excitations are in resonance with the Fermi sea. As the density of the gas is increased further, the minimum dips below the Fermi energy, thus making the ground state unstable. At this point the standard ground state gets replaced by a more complicated one, where not only the states with momentum below the Fermi points, but also the ones with momentum close to that minimum, get filled, and the excitation spectrum develops several branches.

**R43 5 QMC study of the 1D boson Hubbard model with a superlattice potential** VALY ROUSSEAU, MARCOS RIGOL, *University of California, Davis* FRÉDÉRIC HÉBERT, *Institut Non Linéaire de Nice* DANIEL AROVAS, *University of California, San Diego* GEORGE BATROUNI, *Institut Non Linéaire de Nice* RICHARD SCALETTAR, *University of California, Davis* We use QMC simulations to explore the phase diagram of the Bose-Hubbard model with an additional superlattice potential. We first analyse the hard-core limit where an exact analytic treatment is possible, and then use QMC to solve the soft-core case and find the insulator/superfluid phase diagram as a function of potential strength and filling. These results are relevant to the behavior of cold atoms in optical superlattices which are beginning to be achieved experimentally.

**15:30**

**R43 6 Quantum coherence of Hard Core Bosons and Fermions in one dimensional quasi-periodic potentials: superfluid, Mott and glassy phases** ANA MARIA REY, *ITAMP, Harvard-Smithsonian Center of Astrophysics, Cambridge, MA, 02138.* INDUBALA I SATIJA, *Dept. of Physics, George Mason University, Fairfax, VA, 22030* CHARLES W CLARK, *NIST, Gaithersburg MD, 20899* We use Hanbury- Brown-Twiss interferometry (HBTI) to characterize and contrast the different quantum phases exhibited by hard core bosons (HCBs) and ideal fermions confined in a one-dimensional quasi-periodic potential. In addition to the Bose-glass, superfluid and Mott insulator phases characteristic of interacting disordered bosons, we show the quasi-periodic potential induces a cascade of Mott-like band insulator transitions triggered by the fermion-type statistics of HCBs. A comparative study of the fermion model shows that except for a sign difference, HCB and fermion interferometric patterns coincide in the localized phases. In the extended phase, however, fermions behave quite differently; their correlation functions reflect some of the multifractal properties characteristic of the metal-insulator transition. When plotted as a function of the filling factor, their quasi-momentum distribution displays an Arnold tongue-like structure and the HBTI peak intensity follows a step-like pattern which resembles a devil's staircase at the onset of the localization transition.

**15:42**

**R43 7 Bose/Anderson glass and re-entrant superfluidity in strongly correlated bosons in a disordered optical lattice** TOMMASO ROSCILDE, IGNACIO CIRAC, *Max-Planck-Institut fuer Quantenoptik - Germany* We investigate the one-dimensional Bose-Hubbard model in presence of a random bimodal on-site chemical potential, modeling strongly correlated bosons in an optical lattice in presence of a second species of bosons randomly frozen in the minima of the optical potential [U. Gavish and Y. Castin, Phys. Rev. Lett. 95, 020401 (2005)]. Making use of quantum Monte Carlo simulations, we investigate both the strongly and the weakly interacting regime. In the strongly interacting case, superfluidity is found to be robust against disorder, due to effective screening of the disorder potential. Close to commensurate filling disorder is seen to promote superfluidity vs. Mott insulating behavior, leading to re-entrant superfluid order. Moreover the presence of disorder introduces a disordered Anderson-glass phase for small interparticle repulsion and a Bose-glass phase for large repulsion, separated by the superfluid phase. Clear signature of these phases are observed on realistic sizes ( $\sim$ 60 lattice sites) making the above scenario amenable to experimental realization.

**15:54**

**R43 8 Bogoliubov Excitations and Superfluidity in a Kronig-Penney Potential*** IPPEI DANSHITA, *National Institute of Standards and Technology, Gaithersburg, MD 20899, USA* SUSUMU KURIHARA, *Department of Physics, Waseda University, Ohkubo, Shinjuku-ku, Tokyo 169-8555, Japan* SHUNJI TSUCHIYA, *Dipartimento di Fisica, Universita di Trento, and Istituto Nationale per la Fisica della Materia, I-38050 Povo, Italy* We study the elementary excitations of Bose-Einstein condensates in a Kronig-Penney potential. We solve the Bogoliubov equations analytically and obtain the band structure of the excitation spectrum. We show that the excitation spectrum is phononlike at low energies. It is found that the anomalous tunneling of low-energy excitations is crucial to the phonon dispersion, which is directly connected to the superfluidity of the condensate.

**16:06**

**R43 9 Atomic Josephson Vortex*** VITALIY KAUROV, ANATOLY KUKLOV, *CSI, CUNY* We show that atomic Josephson vortices [1] in a quasi-1D atomic junction can be controllably manipulated by imposing a tunneling bias current created by a difference of chemical potentials on the atomic BEC waveguides forming the junction. This effect, which has its origin in the Berry phase structure of a vortex, turns out to be very robust in the whole range of the parameters where such vortices can exist [2]. Acceleration of the vortex up to a certain threshold speed, determined by the strength of the Josephson coupling, results in the phase slip causing switching of the vorticity. This effect is directly related to the interconversion [1], when slow variation of the coupling can cause transformation of the vortex into the dark soliton and vice verse. We also propose that a Josephson vortex can be created by the phase imprinting technique and can be identified by a specific ittangential feature in the interference picture produced by expanding clouds released from the waveguides [2]. [1] V. M. Kaurov, A. B. Kuklov, Phys. Rev. A 71, 11601(R) (2005). [2] V. M. Kaurov, A. B. Kuklov cond-mat/0508342

**347, Baltimore Convention Center at 14:30**
**J. Sarrao, Los Alamos National Laboratory, presiding**

**14:30**

**R44 1 Hidden magnetism and quantum criticality in the heavy fermion superconductor $CeRhIn_5$*** J.D. THOMPSON, T. PARK, F. RONNING, *Los Alamos National Laboratory* H.Q. YUAN, M.B. SALAMON, *University of Illinois* R. MOVSHOVICH, J.L. SARRAO, *Los Alamos National Laboratory* We report the dependence on pressure and magnetic field of the specific heat and electrical resistivity of the pressure-tuned heavy-fermion superconductor $CeRhIn_5$. Above a critical pressure, where long-range antiferromagnetic order (AFM) abruptly disappears, application of a field brings back magnetism inside the superconducting state. As a function of pressure at low temperatures, the set of fields required to induce magnetism defines a line of quantum-phase transitions that separates a phase of coexisting AFM and SC from a purely unconventional superconducting phase. This quantum-transition line and the upper critical field boundary, above which superconductivity is suppressed, merge at a quantum tetracritical point where another quantum-phase boundary separates magnetically ordered and disordered normal phases. The quasiparticle mass diverges as this normal-state quantum boundary is approached, and crossing it produces a change in the Fermi-surface volume [1]. [1] H. Shishido et al., J. Phys. Soc. Jpn. **74**, 1103 (2005).

**14:42**

**R44 2 NMR Studies of $CeCoIn_5$ below 1K** N. CURRO, B.-L. YOUNG, R. URBANO, R. MOVSHOVICH, J. SARRAO, *Los Alamos National Laboratory* We present new NMR data in the normal and superconducting states of $CeCoIn_5$ below 1K and in fields up to 12T. The temperature dependence of the Knight shift anomalies exhibited by the Co and the two In sites is field dependent in the normal state, and may be related to the presence of a field-tuned quantum critical point. The spectra and relaxation rates exhibit dramatic changes in the superconducting and Fulde-Ferrell-Larkin- Ovchinnikov states.

**14:54**

**R44 3 Hall Effect under pressure in CeCoIn5*** S. SINGH, *MPI for Chemical Physics of Solids, 01187 Dresden, Germany* C. CAPAN, *Dept. of Physics and Astronomy, LSU, Baton Rouge, Louisiana 70803, USA* S. WIRTH, M. NICKLAS, A. GLADUN, *MPI for Chemical Physics of Solids, 01187 Dresden, Germany* H. LEE, Z. FISK, *Dept. of Physics, UC Davis, California 95616, USA* J. F. DITUSA, *Dept. of Physics and Astronomy, LSU, Baton Rouge, Louisiana 70803, USA* F. STEGLICH, *MPI for Chemical Physics of Solids, 01187 Dresden, Germany* Important deviations from Landau Fermi Liquid theory are observed in many rare-earth compounds known as heavy fermion compounds. These anomalies can be ascribed to the presence of a quantum critical point (QCP) separating two different ground states in the phase diagram of these compounds. A quantum phase transition is a continuous ground state transformation driven by quantum fluctuations. In this context, CeCoIn5, a recently discovered heavy fermion superconductor, has been at the focus of intensive investigations. In this material, thermodynamic and transport properties point to a field-tuned QCP, whose origin remains elusive. At ambient pressure, this QCP is close to the superconducting upper critical field, and a Sn-doping study has failed to separate the two. We present new results on Hall Effect under pressure in a single crystal CeCoIn5 and discuss the origin of the QCP and its evolution with pressure.

**15:06**

**R44 4 Far-Infrared Properties of $CeCoIn_5$*** G.V. SUDHAKAR RAO, S. OCADLIK, F.S. RAZAVI, M. REEDYK, *Brock University* C. PETROVIC, *Brookhaven National Laboratory* Measurements of the optical response of far-infrared radiation on single crystals of heavy fermion superconductor $CeCoIn_5$ have been made at various temperatures from 0.5 K to 2.5 K using a step-and- integrate Martin-Puplett type polarizing interferometer. An energy gap-like structure reminiscent of that observed in antiferromagnetic Cr was observed below 12 $cm^{-1}$ in the superconducting state. The size of this gap feature reduces with the increase of temperature to the normal state. This observation suggests the possibility of the role of magnetic excitations in pairing the electrons in the superconducting state.

*Work at Brock University was supported by Natural Sciences and Engineering Research Council (NSERC) of Canada.

**15:18**

**R44 5 Is quantum criticality relevant to upper critical field ($H_{c2}$) scaling in the heavy-fermion compound $CeRhIn_5$?*** TUSON PARK, JOHN L. SARRAO, JOE D. THOMPSON, *Los Alamos National Laboratory* We report disparate forms of upper critical field ($H_{c2}$) scaling below and above a critical pressure $P_{c1}$, where long- range antiferromagnetic order (AFM) abruptly disappears in the pressure-tuned heavy-fermion superconductor $CeRhIn_5$. For $P > P_{c1}$, $h_{c2} = H_{c2}/H_{c2}(T = 0\ \mathrm{K})$ shows normal two- fluid type scaling with $t = T/T_c$, i.e., $h_{c2} = (1 - t^2)(1 - at^2)$, where $T_c$ is superconducting transition temperature at zero field and a is a fitting parameter. In this regime, the Maki parameter $\alpha$, a measure of Pauli limiting effects, is large, suggesting that an inhomogeneous superconducting state (FFLO) may be observable. For $P < P_{c1}$, in stark contrast, $h_{c2}$ linearly increases with decreasing $t$ down to $t = 0.1$ and the specific heat discontinuity $\Delta C/C_N$ at $T_c$ is much smaller than the BCS value (=1.43). These observations manifest the interplay between superconductivity and antiferromagnetic fluctuations that exist in the vicinity of $P_{c1}$.

*Work at Los Alamos was performed under the auspices of the U.S. Department of Energy.

**R44 6 $\mu$SR measurement of the superconducting penetration depth in aged $PuCoGa_5$** R. H. HEFFNER, K. OHISHI, W. HIGEMOTO, T. ITO, *Japan Atomic Energy Agency* G. D. MORRIS, *TRIUMF, Canada* M. J. FLUSS, *LLNL, USA* D. E. MACLAUGLIN, L. SHU, *U. C. Riverside, USA* E. D. BAUER, J. L. SARRAO, *LANL, USA* The superconductor $PuCoGa_5$ possesses a relatively high critical temperature ($T_c$ = 18.5 K), a moderate mass enhancement (Sommerfeld coefficient $\cong$ 80 mJ/mol-$K^2$) and exhibits behavior consistent with spin-fluctuation-induced d-wave superconductivity [1]. It is also radioactive, with its dominant ra-

dioisotope $^{239}$Pu having a half-life of 2.4 x $10^4$ yrs. We report $\mu$SR measurements of the temperature and field dependence of the magnetic field penetration depth $\lambda$(T,H) in a 400 day-old sample of $PuCoGa_5$ ($T_c$ = 15 K), and compare these results to data obtained on the same sample approximately one year earlier. In 600 Oe applied field both measurements show a linear low-temperature behavior for $\lambda(T) - \lambda(0) = bT$ for $T/T_c < 0.5$ with the same coefficient b. The magnitude of $\lambda$(0) in the aged sample has increased by a factor of about 1.8. The results are discussed in terms of the effects of radiation damage on the postulated d-wave superconducting order parameter. [1] J. L. Sarrao et al., Nature 420, 297 (2002); N. J. Curro et al., Nature 434, 622 (2005).

**15:42**

**R44 7 NMR investigation of Sn-doped $CeRhIn_5$** R. R. URBANO, N. J. CURRO, E. D. BAUER, D. MIXSON, J. L. SARRAO, J. D. THOMPSON, We have studied the local environment of the In(1) sites in the paramagnetic (PM) and antiferromagnetic (AFM) states of the heavy fermion compound $CeRhIn_{5-x}Sn_x$ ($0.0 \leq x \leq 0.4$) using Nuclear Magnetic Resonance (NMR) and Nuclear Quadrupole Resonance (NQR) measurements. The AFM state can be continuously suppressed by Sn doping such that the Neel temperature $T_N$ goes to zero at $x_c \cong 0.4$. $^{115}$In NQR data in the PM state reveal that the suppression of $T_N$ as a function of $x$ is accompanied by a frequency shift and a broadening of the line. We also report spin-lattice relaxation rate $T_1^{-1}$ as a function of $x$ and $T$.

**15:54**

**R44 8 In-plane Torque Measurement on $CeCoIn_5$ Single Crystals*** T. HU, H. XIAO, C. C. ALMASAN, *Kent State University* T. A. SAYLES, M. B. MAPLE, *University of California, San Diego* We report in-plane torque measurements on single crystals of the heavy fermion superconductor $CeCoIn_5$ performed in the normal state at 1.9, 3, 6, and 10 K, as a function of angle and applied magnetic field. The measurements at constant angle were done in sweeping the magnetic field up to 14 T. The measured torque has a reversible and an irreversible component, with the former larger than the latter. The reversible component can be expressed as $\tau_{rev}(\theta) = \tau_2 sin2\theta + \tau_4 sin4\theta$ ($\theta$ is the angle between the applied field and the a-axis of the crystal), which is typical of systems with long range magnetic order. However, it has been reported that the heavy fermion superconductor $CeCoIn_5$ has no long range magnetic order, but only short range antiferromagntic fluctuations. The temperature and magnetic field dependence of the coefficients $\tau_2$ and $\tau_4$ will be discussed. The torque vs field curves at fixed angles show De-Hass Van-Alphen effect at temperatures as high as 10 K. The possible reasons behind this will also be discussed.

**16:06**

**R44 9 NMR Study of the Possible FFLO State in $CeCoIn_5$** V. F. MITROVIĆ, *Brown University, Providence, RI* M. HORVATIĆ, C. BERTHIER, *GHMFL, Grenoble, France* G. KNEBEL, G. LAPERTOT, J. FLOUQUET, *SPSMS, CEA, Grenoble, France* We report nuclear magnetic resonance (NMR) measurements of the heavy-fermion superconductor $CeCoIn_5$ in the vicinity of the superconducting critical field $H_{C2}$ for a magnetic field applied perpendicular to the $c$ axis. A possible inhomogeneous superconducting state, Fulde-Ferrel-Larkin- Ovchinnikov (FFLO), is stabilized in this part of the phase diagram. In 11 T applied magnetic field, we observe clear signatures of the two phase transitions. We show that a higher temperature transition is clearly associated with the transition to the homogeneous superconducting state. The low temperature phase cannot be characterized by a simple FFLO state, viewed as a stack of static, and spatially well separated, superconducting and normal regions. Alternative explanations of the nature of the low temperature phase are discussed.

**16:18**

**R44 10 Angular Dependent Torque Measurements on $CeCoIn_5$ Single Crystals*** H. XIAO, T. HU, C. C. ALMASAN, *Kent State University* T. A. SAYLES, M. B. MAPLE, *University of California, San Diego* Angular dependent torque measurements were performed on single crystals of $CeCoIn_5$ heavy fermion superconductor ($T_{c0}$ = 2.3 K) in the temperature $T$ range 1.9 K $\leq T \leq$ 20 K and magnetic fields $H$ up to 14 T. Large paramagnetic effect is found in the normal state due to magnetic moment of the magnetic ion $Ce^{3+}$. Torque measurements in the mixed state were also performed. The torque curves show sharp hysteresis peaks at $\theta = 90^o$ ($\theta$ is the angle between $H$ and the $c$ − axis of the crystal), a result of intrinsic pinning of vortices. The anisotropy $\gamma \equiv \sqrt{m_c/m_a}$ in the mixed state was determined from the reversible part of the vortex contribution to the torque signal using Kogan's model [Phys. Rev. B **38**, 7049 (1988)]. The anisotropy $\gamma$ decreases with increasing magnetic field and temperature. The fact that $\gamma$ is not a constant points towards a multiband scenario in this heavy fermion material.

**16:30**

**R44 11 Penetration Depth Studies of Tin Doped $CeCoIn_5$** DANIEL VANDERVELDE, *University of Illinois Urbana-Champaign* H.Q. YUAN, *University of Illinois Urbana-Champaign* M.B. SALAMON, *University of Illinois Urbana-Champaign* E.D. BAUER, *LANL* N. HUR, *LANL* F. RONNING, *LANL* M.J. GRAF, *LANL* J.D. THOMPSON, *LANL* J.L. SARRAO, *LANL* R. MOVSHOVICH, *LANL* The heavy fermion superconductor $CeCoIn_5$ has attracted much attention recently. Its high $T_C$ ( $\sim$ 2.3K), nearby antiferromagnetic phases, and evidence of line nodes in the superconducting gap indicative of a d-wave order parameter have made it an interesting topic of study. Here we present measurements of the AC magnetic field penetration depth ($\Delta\lambda$(T)) undertaken on the same material, but with an impurity doping of Sn ($CeCoIn_{5-X}Sn_X$) at three concentrations x=0.03, x=0.06, and x=0.09. Our findings support the assertion that $CeCoIn_5$ is a nonlocal, d-wave superconductor, but that as impurity concentration is increased, scattering quickly becomes the dominant mechanism. All data was modeled as a quadratic, scattering-dominated temperature dependence that crosses over to a linear regime reminiscent of the pure sample at a temperature $^1$T*. The observed value of T* increases with the concentration of impurities as is predicted in the impurity model by Hirschfield and Goldenfeld ($T^* \sim \sqrt{n_i}$). [1] This dependence on the concentration of a nonmagnetic impurity adds further confirmation of the d-wave nature of the superconducting state. [1] P.J. Hirschfield and N. Goldenfeld, Phys Rev. B **48**, 4219 (1993)

**16:42**

**R44 12 Gap structure of heavy-fermion superconductor CeIrIn5 from heat transport** HAMIDEH SHAKERIPOUR, *Physique Department, Université de Sherbrooke* S.Y. LI, N. DOIRON-LEYRAUD, LOUIS TAILLEFER, C. PETROVIC, *Brookhaven National Laboratory* We present measurements of the in-plane and out-plane thermal conductivity of heavy-fermion superconductor CeIrIn5 down to temperatures approaching Tc/10, throughout the vortex state. We use the observed anisotropy in residual linear term and response to a magnetic field to shed light on the nodal structure of the superconducting gap. We compare our results to existing theoretical calculations and discuss the possibility of multi-band superconductivity, observed recently in the related material CeCoIn5 [1]. [1] M.A. Tanatar et al., Phys. Rev. Lett. 95, 067002 (2005).

**16:54**

**R44 13 Non-local Magnetic Field-tuned Quantum Criticality in Cubic $CeIn_{3-x}Sn_x$ ($x = 0.25$)** NEIL HARRISON, ALEJANDRO SILHANEK, MARCELO JAIME, VICTOR FANELLI, CRISTIAN BATISTA, *Los Alamos National Laboratory* TAKAO EBIHARA, KOJI TEZUKA, *Shizuoka University* We show that antiferromagnetism in lightly Sn-doped $CeIn_3$ terminates at a critical field $\mu_0 H_c = 38 \pm 1$ T. Electrical transport, specific heat and magnetization measurements reveal that $m^*$ does not diverge, suggesting that cubic $CeIn_3$ is representative of a critical spin-density wave (SDW) scenario, unlike the local quantum critical points observed in lower-symmetry systems such as $CeCu_{6-x}Au_x$ and $YbRh_2Si_{2-x}Ge_x$. The existence of a maximum in $m^a st$ at a lower field $\mu_0 H_x = 30 \pm 1$ T may be interpreted as a field-induced crossover from local moment to SDW behavior as the magnitude of the antiferromagnetic order parameter falls below the Fermi bandwidth.

**17:06**

**R44 14 Correlation induced phase transition in fcc Pu** SHAOPING CHEN, *Los Alamos National Laboratory* The density functional theory calculations (GGA+U) of fcc Pu indicate that as the Hubbard on-site Coulomb repulsion U increases the fcc Pu system goes through a sharp phase transition. Accompanying this transition are sharp drops of the bulk moduli, and large values and even negative values of pressure derivatives of the bulk moduli. Some evidence of these effects were consistent with current experimental observations.

**17:18**

**R44 15 Phonon mechanisms for structural phase transitions in Pu** AVADH SAXENA, TURAB LOOKMAN, R.C. ALBERS, *Los Alamos National Laboratory* CONDENSED MATTER THEORY TEAM, As a function of temeprature, pressure and alloying (Ga or Al) plutonium undergoes a series of structural transitions. Based on crystallography and symmetry we identify possible phonon mechanisms for various phase transitions. Coupling of shuffle modes corresponding to the specific phonons (primary order parameter) to the relevant strain tensor components (secondary order parameter) we develop Ginzburg-Landau free energies for some of the important structural transitions such as $\delta \rightarrow \alpha$ (FCC to simple monoclinic), $\delta \rightarrow \beta$ (FCC to side centered monoclinic) and $\beta \rightarrow \alpha$ (side centered monoclinic to simple monoclinic). We use these free energies to explore certain parts of the Pu phase diagram and relate to experimental structural and thermodynamic data such as specific heat and thermal expansion for the cases available. We also enumerate the orientational relationships between parent and product phases in these transitions.

**SESSION R45: STRONG CORRELATION IN METALS: MOTT TRANSITION**

**R45 1 The metal-insulator transition in vanadium dioxide explored by optical methods** M.M. QAZILBASH, K.S. BURCH, D.N. BASOV, *University of California - San Diego* B.G. CHAE, H.T. KIM, *Basic Research Lab, ETRI, Daejeon, Korea* The nature of the metal-insulator transition (MIT) in vanadium dioxide ($VO_2$) remains a matter of debate. At the center of the debate is the relative importance of electron-electron correlations to the MIT. We study the MIT with spectroscopic ellipsometry on $VO_2$ films grown on sapphire substrates, and determine the optical constants in the insulating and metallic states from 50 meV to 5.5 eV. The changes in the optical constants with temperature in the metallic state have been tracked from 360 K up to 500 K. The redistribution of spectral weight in the real part of the optical conductivity as a result of the MIT will be discussed with emphasis on the changes to the interband transitions. This work has been supported by Department of Energy Grant No.DE-FG03-00ER45799.

**14:42**

**R45 2 First-order metal-insulator transition not accompanied by the structural phase transition observed in $VO_2$-based devices** HYUN-TAK KIM, BYUNG-GYU CHAE, BONG-JUN KIM, YONG-WOOK LEE, SUN-JIN YUN, KWANG-YONG KANG, *ETRI in Korea* An abrupt first-order metal-insulator transition (MIT) is observed during the application of a switching pulse voltage to $VO_2$-based two-terminal devices. When the abrupt MIT occurs, the structural phase transition (SPT) is investigated by a micro- Raman spectroscopy and a micro-XRD. The result shows that the MIT is not accompanied with the structural phase transition (SPT); the abrupt MIT is prior to the SPT. Moreover, any switching pulse over a threshold voltage of 7.1 V for the MIT enabled the device material to transform efficiently from an insulator to a metal. The measured delay time from the source switching pulse to an induced MIT pulse is an order of 20 nsec which is much less than a delay time of about one msec deduced by thermal model. This indicates that the first-order MIT does not occur due to thermal. We think this MIT is the Mott transition. (New J. Phys. 6 (1994) 52 (www.njp.org), Appl. Phys. Lett. 86 (2005) 242101, Physica B 369 (2005. December) xxxx)

**14:54**

**R45 3 Terahertz spectroscopy of the metal insulator transition in vanadium dioxide** DAVID HILTON, *Los Alamos National Laboratory* ROHIT PRASANKUMAR, *Los Alamos National Laboratory* ANDREA CAVALLERI, *Oxford University* SYLVAIN FOURMAUX, *Universite du Quebec* JEAN-CLAUDE KIEFFER, *Universite du Quebec* ANTOINETTE TAYLOR, *Los Alamos National Laboratory* RICHARD AVERITT, *Los Alamos National Laboratory* We employ terahertz spectroscopy to study the metal-insulator phase transition in vanadium dioxide ($VO_2$). We measure the terahertz frequency conductivity in the metallic phase that has a real conductivity of 1000 $\Omega^{-1}cm^{-1}$ and a negligible imaginary conductivity. The observed conductivity dynamics are consistent with a photoinduced transition in spatially inhomogeneous regions of the film, followed by a thermally driven transition to the maximum conductivity.

**15:06**

**R45 4 The role of dimers in the metal-insulator transitions in $VO_2$ and $Ti_2O_3$** T.C. KOETHE, J. GEGNER, Z. HU, C. SCHÜßLER-LANGEHEINE, H. ROTH, T. LORENZ, *II. Physikalisches Institut, Universität zu Köln, Germany* F. VENTURINI, N.B. BROOKES, *ESRF, Grenoble, France* W. REICHELT, *Institut für Anorganische Chemie, TU Dresden, Germany* L.H. TJENG, *II. Physikalisches Institut, Universität zu Köln, Germany* The nature of the metal-insulator-transition (MIT) in $VO_2$ has been subject of debate for a long time. Recently the scenario of an orbital assisted MIT has been proposed on the basis of the dramatic change of the orbital occupation as observed by soft-X-ray absorption spectroscopy measurements.[1] We present the results of our bulk sensitive photoemission study on the MIT in $VO_2$ using high quality single crystals. We observe a huge transfer of spectral weight across the MIT, supporting recent LDA+DMFT cluster calculations.[2] To investigate the possible role of dimers herein, we also studied the insulating phase of $Ti_2O_3$. Here we clearly observe a double peak structure which can be taken as a characteristic for the presence of dimers.

KOROTIN, *Institute of Metal Physics, Ekaterinburg, Russia* V. I. ANISIMOV, *Institute of Metal Physics, Ekaterinburg, Russia* H. H. HSIEH, *Chung Cheng Institute of Technology, Taoyuan, Taiwan* H.-J. LIN, *National Synchrotron Radiation Research Center, Hsinchu, Taiwan* C. T. CHEN, *National Synchrotron Radiation Research Center, Hsinchu, Taiwan* D. I. KHOMSKII, *II. Physikalisches Institut, Universität zu Köln, Germany* L. H. TJENG, *II. Physikalisches Institut, Universität zu Köln, Germany* We found direct experimental evidence for an orbital switching in the V 3*d* states across the metal-insulator transition in $VO_2$. We have used soft-x-ray absorption spectroscopy at the V $L_{2,3}$ edges as a sensitive local probe, and have determined quantitatively the orbital polarizations. These results strongly suggest that, in going from the metallic to the insulating state, the orbital occupation changes in a manner that charge fluctuations and effective band widths are reduced, that the system becomes more 1-dimensional and more susceptible to a Peierls-like transition, and that the required massive orbital switching can only be made if the system is close to a Mott insulating regime.

**R45 6 X-ray Absorption Fine Structure Study of the Metal-Insulator Transition in Cr Doped $V_2O_3$*** A.I. FRENKEL, *Yeshiva University* D. PEASE, J. BUDNICK, P. SHANTHAKUMAR, T. HUANG, *University of Connecticut* N. ABITBOL, *Yeshiva University* P. METCALF, *Purdue University* We have applied the polarized x-ray absorption fine structure (XAFS) spectroscopy to study the series of $(V_{1-x}Cr_x)_2O_3$ where x ranges from 0 to 0.052. At room temperature, the metal-insulator transition (MIT) between paramagnetic metal 1 (PM-1) and paramagnetic insulator (PI) phases occurs as $x$ exceeds 0.01. At elevated temperatures, the second PM phase (PM 2) sets in the metallic samples ($x < 0.01$). We have obtained V K-edge and Cr K-edge spectra for the samples in the PM1, PM2 and PI phases at different concentrations (from 0.00365 to 0.0052) and temperatures (from 300 K to 673 K). V K-edge X-ray absorption near-edge structure (XANES) data show systematic changes across varies phase boundaries, both temperature and dopant-driven. Polarized Cr K-edge and V K-edge XANES and extended XAFS (EXAFS) data demonstrate, for the first time, that Cr enters the $V_2O_3$ lattice substitutionally, at all concentrations. Contrary to the Cr K-edge, the changes in the V K-edge XANES across the metal-insulator transition are strongly anisotropic. X-ray diffraction (XRD) and temperature dependent XANES and EXAFS results of Cr and V data will be discussed in terms of the possible percolative nature of the MIT in this system.

**R45 7 Nonequilibrium dynamical mean-field theory near the Mott transition** VOLODYMYR TURKOWSKI, JAMES FREERICKS, *Physics Department, Georgetown University, Washington, D.C. 20057* VELJKO ZLATIC, *Institute of Physics, Bijenicka c.46, P.O.B. 304, HR-10001, Zagreb, Croatia* We exactly calculate the non-equilibrium properties of the Falicov-Kimball model in an external electric field by using a recently developed non-equilibrium dynamical mean-field theory formalism [1,2]. In particular, we analyze the time-dependence of the electrical current in cases with different values of the on-site Coulomb interaction, when the system is in the metallic and in the insulating phases. The most interesting properties take place when the interaction energy is close to the metal-insulator transition value. The dynamics of the Bloch oscillations of the electrical current and the long time steady state nonlinear response are analyzed in detail. [1] J.K.Freericks, V.M.Turkowski, V. Zlatic, To be published in ''Proceedings of the 2005 Users Group Conference, IEEE Computer Society.''; cond-mat/0511061; [2] V.M. Turkowski, J.K. Freericks, Submitted to Phys. Rev. B; cond-mat/0511063.

**15:54**

**R45 8 Symmetry of Photoexcited States in Two-Dimensional Mott Insulators** TAKAMI TOHYAMA, *Institute for Materials Research, Tohoku University* The charge gap in Mott insulators is a consequence of strong electron correlation represented by large on-site Coulomb interaction. The correlation induces novel phenomena in terms of the interplay of charge and spin degrees of freedom. In this study, we examine symmetry of photoexcited

states with two photoinduced carriers in two-dimensional Mott insulators by applying the numerically exact diagonalization method to finite- size clusters of a half-filled Hubbard model in the strong- coupling limit [1]. The symmetry of minimum-energy bound state is found to be *s*-wave, which is different from a $d_{x^2-y^2}$ wave of a two-hole pair in doped Mott insulators. We demonstrate that the difference is originated from an exchange of fermions due to the motion of a doubly occupied site. Correspondingly large-shift Raman scattering across the Mott gap exhibits a minimum-energy excitation in the $A_1$ (*s*-wave) channel. We discuss implications of the results for the Raman scattering and other optical experiments. [1] T. Tohyama, cond-mat/0508519.

**16:06**

**R45 9 GW+DMFT Electronic Structure Calculations in Mott Insulators: Application to NiO** NIKOLAY ZEIN, *RRC ''Kurchatov Institute'' Moscow* SERGEY SAVRASOV, *University California, Davis* GABRIEL KOTLIAR, *University of Rutgers, NJ* We discuss the nature of Mott insulator ground state in transition metal oxides using newly developed GW+DMFT approach[1], which permits to join advantages of model (Hubbard-like) and density functional (LDA) calculations. The gap in LDA calculated antiferromagnetic state is usually much smaller than in experiment. Pure GW calculations increase the gap[2],but also cannot reproduce the paramagnetic insulating state. In GW +DMFT approach, without any fitting parameters, we calculate electronic structures of both antiferromagnetic and paramagnetic insulating states. We discuss relative position of d-metal and p-oxygen states,problems of renormalization of both electronic states near Fermi level and effective interaction at small energies, changes in static interaction under development of the gap in the paramagnetic state, effect of nearly filled bands on the value of self-energy correlation contribution. [1] N.E.Zein, S.Savrasov, G.Kotliar cond-mat/0511064 [2] S.V.Faleev, M.van Schilfgaarde, T.Kotani Phys.Rev.Lett. 93, 126406(2004)

**16:18**

**R45 10 Dynamical Mean Field Study of the Mott Transition on the Triangular Lattice Employing the Quantum Monte Carlo Technique** KARAN ARYANPOUR, RICHARD T. SCALETTAR, WARREN E. PICKETT, *Department of Physics, UC DAVIS* ALEXANDRU MACRIDIN, MARK JARRELL, *Department of Physics, Uinversity of Cincinnati* We present results on the Mott transition on the triangular lattice with nearest neighbor hopping employing the Dynamical Mean Field Theory (DMFT) and the Quantum Monte Carlo (QMC). DMFT and QMC can yield the critical value of electron-electron interaction U as a function of temperature T for the metal-insulator transition. By using the Maximum Entropy (MaxEnt) method, we calculate the Density of States (DOS) for a variety of U and T values. The formation of an Abrikosov-Suhl resonance peak in the intermediate coupling regime and a Mott gap in the strong coupling regime is observed. In addition, we discuss the behavior of the magnetic moment as a function of U and T.

**16:30**

**R45 11 First principles many-body approach to electron gas** PING SUN, *Rutgers University* GABRIEL KOTLIAR, *Rutgers University* We describe a first principles approach of constructing low energy, effective lattice model for the electron gas in a continuum of 2 and 3 spatial dimensions. The effects of the higher energy, unoccupied states are taken into account through virtue particle-hole excitations which screen the effective interactions at low energies. Using this effective model we obtain the correct order of magnitudes of the average inter- electron distance ($R_s$) at which the metal-insulator transition happens in 2d and 3d.

**16:42**

**R45 12 Effects of interorbital hopping on orbital fluctuations and metal-insulator transitions.** YUN SONG, *Department of Physics, Trent University* LIANG-JIAN ZOU, *Insititute of Solide State Physics, Chinese Academy of Sciences* We study the effects of inter-orbital hopping on orbital fluctuations and Mott-Hubbard metal-insulator transition (MIT) in the two-orbital Hubbard model within the extended linearized dynamical mean-field theory. By mapping the model onto an effective model with different bandwidths through the canonical transformation, we find that at half filling, the increases of the inter-orbital Coulomb interaction U′ and the Hund's coupling *J* drive the MIT, and the critical $J_c$ for MIT increases with the lift of the inter-orbital hopping integral $t_{ab}$. Meanwhile at quarter filling and in the strong correlation regime, the system without $t_{ab}$ exhibits MIT with the decreasing of *J*, and favors the orbital liquid ground state. However, the system transits from metal to insulator with the increasing of $t_{ab}$, accompanied with the rising of the orbital order parameter. These results show the important role of the inter-orbital hopping in the orbital fluctuation and orbital ordering.

## SESSION R46: ELECTRONIC AND OPTICAL PROPERTIES OF SEMICONDUCTORS: FIRST PRINCIPALS

**Wednesday Afternoon, 15 March 2006**
**349, Baltimore Convention Center at 14:30**
**Hai Ping Cheng, University of Florida, presiding**

**14:30**

**R46 1 Sequential Oxidation of Gallium Oxide Clusters—A First-Principles Study** S. GOWTHAM, *Michigan Technological University* AURORA COSTALES, *Universidad de Oviedo, Spain* RAVINDRA PANDEY, *Michigan Technological University, USA* The structural and electronic properties of gallium oxide lusters ($Ga_3O_n$; $n = 4 - 8$) are studied under the framework of density functional theory, with respect to sequential oxidation. The focus is on changes induced by the addition or removal of an electron from the neutral species as well as similarities/differences between aluminum oxide clusters of the same size. Lowest energy isomers in case of neutral clusters were found in doublet electronic state, and except for $Ga_3O_4^-$, $Ga_3O_4^+$, and $Ga_3O_5^-$, all ionized clusters were found in triplet electronic state. We observed that both addition and removal of an electron from the neutral cluster leads to significant changes in the structure of the lowest energy isomer, apart from altering the sequence of other low-lying geometries. Structural resemblance to corresponding alumina clusters is limited to a few cases while we predict new results for others. Binding energy remains almost constant throughout the oxidation process, with values for ionized systems bracketing the neutral ones. All clusters considered in this study are found to be stable against fragmentation via O and $O_2$ channels. Analysis of vibrational fre-

quencies confirms the tendency of $Ga_3O_6^+$ , $Ga_3O_7$ and $Ga_3O_8$ to form O-O bonds. HOMO-LUMO gap values show an oscillatory trend while calculated values of electron affinity and ionization potential are in good agreement with the corresponding values for alumina clusters.

**14:42**

**R46 2 Density Functional Band Gaps of AlAs** HUA JIN, GUANGLIN ZHAO, DIOLA BAGAYOKO, *Southern University and A&M College* We present results of ab-initio, self-consistent calculations of electronic properties of AlAs in the zinc-blende structure. Our non-relativistic calculations employed the generalized gradient approximation (GGA) of density functional potential and Bagayoko, Zhao and Williams (BZW) implementation of the linear combination of atomic orbitals (LCAO) formalism. Our calculated indirect band gaps at the X gand L points are 2.15 eV and 2.38 eV, respectively, in excellent agreement with experimental values. The calculated direct gap at $\Gamma$ is 25% smaller than the experimental one. This discrepancy may be due to experimental difficulties in the determination of this gap and it is also possibly due to the fact that it is not the fundamental one and hence may not be described by a ground state calculation. We also present calculated total and partial density of states and the electron effective mass at the bottom of the conduction band at the $\Gamma$gpoint. This work was funded in part by the Department of the Navy, Office of Naval Research (ONR, Grant No. N00014-05-1-0009), NASA (Award Nos. NCC 2-1344 and NAG 5-10253), and by the National Science Foundation (Award No. HRD 0000272). The authors are indebted to Dr. S. Hasan for his excellent technical support with the computing facilities.

**14:54**

**R46 3 The band gap of InN and ScN: A quasiparticle energy study based on exact-exchange density-functional theory** PATRICK RINKE, MATTHIAS SCHEFFLER, *Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin - Germany* ABDALLAH QTEISH, *Yarmouk University, Irbid - Jordan* JÖRG NEUGEBAUER, *MPI für Eisenforschung, Düsseldorf - Germany* The group-IIIA nitride InN and the group-IIIB nitride ScN have recently received increased attention in the field of opto-electronics and optical coatings. Due to the difficulty of growing clean samples, however, the size of their band gap has not been well established, yet. We have recently shown, that quasiparticle energy calculations in the $G_0W_0$ approximation based on density-functional theory (DFT) calculations in the exact-exchange (EXX) approach yield band gaps in very good agreement with experiment for GaN and II-VI compounds [1]. For wurtzite InN our approach predicts a gap of 0.7 eV, suggesting an intrinsic value at the lower end of the experimentally observed range [2]. For ScN there exists a longstanding controversy if the material is a semimetal or semiconductor, which has only very recently been resolved in favor of the latter. Our calculations for rocksalt ScN predict an indirect band gap of 0.9 eV in good agreement with recent experimental findings [3]. [1] P. Rinke *et al.*, New J. Phys. **7**, 126 (2005) [2] W. Walukiewicz *et al.*, J. Crystal Growth **269**, 119 (2004) [3] A. A. Al-Brithen *et al.*, Phys. Rev. B **70**, 045303 (2004)

**15:06**

**R46 4 Calculated, Optical Proprieties of Wurtzite InN** DIOLA BAGAYOKO, HUA JIN, GUANGLIN ZHAO, *Southern University and A&M College* PHYSICS DEPARTMENT TEAM, We report the results of ab-initio calculations of the dielectric function of wurtzite indium nitride (w-InN). These optical properties are derived from ab-initio energy bands obtained with a local density function approximation (LDA) potential in the Bagayoko, Zhao, and Williams (BZW) implementation of the linear combination of atomic orbital (LCAO) formalism. We practically reproduced the measured, dielectric function (Superlattices and Microstructures 36, 591-597, 2004) at energies up to 6 eV. This agreement is not limited to major peaks; it also includes the fine structures of the shoulders. Indubitably, these findings vindicate density functional theory, in general, and the local density approximation (LDA), in particular, for the correct description of properties of semiconductors – provided the basis-set and variational effect, inherently associated with most calculations, is avoided with the first-principle BZW approach. This work was funded in part by the Department of the Navy, Office of Naval Research (ONR, Grant Nos. N00014-05-1-0009 and N00014-4-1-0587), NASA (Award Nos. NCC 2-1344, NAG 5-10253, and NNG 05G146G), and the National Science Foundation (Award No. HRD 0503362).

**15:18**

**R46 5 Predictions of Electronic and Optical Properties of Cubic InN** LASHOUNDA FRANKLIN, HUA JIN, G. L. ZHAO, DIOLA BAGAYOKO, *Southern University and A&M College* We present theoretical predictions of electronic, optical, and related properties of cubic indium nitride (c-InN). We utilized a local density functional approximation (LDA) potential and the linear combination of atomic orbitals (LCAO) in our ab-initio, self-consistent calculations that implemented the Bagayoko, Zhao, and Williams (BZW) method. The predicted band gap is 0.65 eV at a theoretical, equilibrium lattice constant of 5.017 Å. We discuss other predictions for the structural and optical properties of c-InN, including the bulk modulus, electron effective masses, and the calculated dielectric function. This work was funded in part by the Department of the Navy, Office of Naval Research (ONR, Grant Nos. N00014-05-1-0009 and N00014-4-1-0587), NASA (Award Nos. NCC 2-1344, NAG 5-10253, and NNG 05G146G), and the National Science Foundation (Award No. HRD 0503362).

**15:30**

**R46 6 Band offsets of semiconductor heterostructures : dependence on density functionals*** AMITA WADEHRA, RICHARD G. HENNIG, JOHN W. WILKINS, *Department of Physics, Ohio State University, Columbus, OH 43210* GUSTAVO E. SCUSERIA, *Department of Chemistry, Rice University, Houston, TX 77005* There is an increasing interest in In-based heterostructures for HEMT. Predictions of band offsets could speed up the development process of these devices. We assess various exchange-correlation potentials including hybrid functionals such as HSE[1] to analyze electronic properties and structural energetics of such systems. We calculate the band gaps and band offsets of InAs heterostructures such as InAs/InAlAs and InAs/InAsP. We also show a comparison of the structural energies for interfaces and site substitutions obtained by using different functionals. An accurate estimation of these properties is crucial for their application in the manufacture and performance of novel semiconductor devices.

**15:42**

**R46 7 All-Electron *GW* Approximation in the Augmented-Plane-Wave Basis-Set Limit*** CHRISTOPH FRIEDRICH, ARNO SCHINDLMAYR, STEFAN BLÜGEL, *Forschungszentrum Jülich, Germany* TAKAO KOTANI, *Arizona State University, Tempe, USA* The *GW* approximation for the electronic self-energy is known to yield quasiparticle band structures in very good agreement with experiment, but almost all codes so far rely on the pseudopotential approach, which restricts the range of materials that can be treated efficiently. In addition, the adequacy of the pseudopotential approximation for quasiparticle calculations has recently come under debate. We have developed an alternative implementation within the full-potential linearized augmented-plane-wave (FLAPW) method. As possible errors resulting from the linearization of the basis set are frequently overlooked, we here investigate the influence on the *GW* self-energy correction. A systematic improvement is achieved by including additional local orbitals defined as second and higher energy derivatives of solutions to the radial scalar-relativistic Dirac equation, which constitute a natural extension of the FLAPW basis set. Within this approach we can systematically reduce the linearization error and reach the exact augmented-plane-wave basis-set limit. While the electronic self-energy and the quasiparticle energies benefit from the better description of the unoccupied states, the resulting band gaps remain relatively unaffected.

*We acknowledge financial support from the Deutsche Forschungsgemeinschaft through the Priority Program 1145.

**15:54**

**R46 8 Electronic transport in dilute GaAs:N** GEOFFREY STENUIT, STEPHEN FAHY, *Tyndall National Institute, Cork, Ireland* Plane-wave pseudopotential-based DFT (density functional theory) are used to determine the electronic properties (band structure, effective mass and energy gap) of dilute GaAs:N with substitutional nitrogen concentration $x = 1 - 3\%$.Calculations are performed using LDA (local density approximation) for the exchange-correlation functional and applied to large supercells (more than 64 atoms) to achieve the dilute limit. Scattering cross-section, as well as the mobility are derived from the nitrogen concentration dependence of the band gap in GaAsN. The effects of an $N_2$ split interstitial substitution on the electronic properties are also discussed. Finally, the presence of a localized nitrogen state in such material is also studied within this ab initio framework.

**16:06**

**R46 9 Electronic band structure, crystal structure and phonons of $ZnSiN_2$*** TULA R. PAUDEL, WALTER R. L. LAMBRECHT, *Case Western Reserve Univ* $ZnSiN_2$ is an interesting alternative to GaN. Its crystal structure is derived from the wurtzite structure of GaN by a particular ordered subsitution of the Ga atoms by Zn and Si in such as way that each N is coordinated with two Si and two Zn atoms. Electronic structure calculations were performed with two different approaches, the plane-wave ultrasoft pseudopotential approach and the full-potential linearized muffin-tin orbital method both using the local density approaximation (LDA). The structure was fully optimized. The relaxation consists primarily of the N atom finding its optimum position inside its nearest neighbor tetrahedron by making a shorter Si-N and longer Zn-N bond. An indirect LDA band gap of about 3.4 eV is obtained. Thus a gap larger than for GaN is expected. Calculations of the phonons at the center of the Brillouin zone are in progress using the linear response approach. A comparison with ZnGeN2, which was studied earlier, [W. R. L. Lambrecht et al. Phys Rev. B 72, 155202 (2005)] will be presented.

**16:18**

**R46 10 Electronic and magnetic properties of Cu-doped ZnO** ANDREIA LUISA DA ROSA, LUNMEI HUANG, RAJEEV AHUJA, *Uppsala University, Dept. of Physics, Box 530, SE-75121, Uppsala, Sweden* Diluted magnetic semiconductors have attracted attention in the past years, since they open the possibility for new devices with integrated magnetic, electronic and optical functionality. Among possible candidates ZnO is especially attractive, since it is a wide band gap material and is also piezoelectric. On the other hand, Cu and its oxides are non-magnetic, so magnetism coming from Cu clusters or precipitates can be ruled out. Although some experimental results confirm room temperature ferromagnetism in Cu-doped ZnO, other works have reported its absence. In this work we use first-principles calculations to study Cu-doped ZnO for various Cu concentrations. The total energy differences were computed for parallel and antiparallel arrangements of the Cu spins to determine whether Cu-doped ZnO has a ferromagnetic or anti-ferromagnetic ground state. We found that Cu-doped ZnO has a ferromagnetic ground state for all calculated concentrations. We also found that the exchange coupling between the Cu atoms is short ranged. We suggest that the strong hybridization between the Cu-3*d* and O-2*p* states is responsible for mediating the ferromagnetic interaction between the Cu atoms.

**16:30**

**R46 11 Computational band-gap engineering in wide-gap MgO-ZnO alloys** R. MATT LEONE, GUS L. W. HART, *Dept. Physics & Astronomy, Northern Arizona University* Wide-gap semiconducting materials are extending critical applications in high temperature/power electronics and optoelectronics such as with the continued advancement of blue to ultraviolet LEDs and lasers. MgO-ZnO alloys have been increasingly investigated due to their UV luminescence from 150-400 nm, 3.3-7.8 eV. We have developed a first-principles model Hamiltonian that predicts band gaps of cubic MgO-ZnO alloys for any superlattice type or atomic configuration. First-principles band gap energies were used as input to construct an Ising-like cluster expansion, and the cluster types used were determined using a novel genetic algorithm. The itdesign of specific wide-gap MgO-ZnO alloy superlattices for desired target band gaps is now possible with this resultant model Hamiltonian.

**16:42**

**R46 12 Electronic Structure and Vibrational spectra of $C_2B_{10}$ Based Clusters and Films*** L. L. BOYER, KYUNGWHA PARK, M. R. PEDERSON, *Naval Research Laboratory* W. N. MEI, X. C. ZENG, S. BULUSU, ELLEN DAY, SHIREEN ADENWALLA, *University of Nebraska* SEAMUS CURRAN, JAMES DEWALD, *New Mexico State University* Semiconducting boron carbide films can be used to detect neutrons and convert energy of associated nuclear reactions directly into electrical current. Such films were prepared by removing hydrogen from the

three polytypes of $C_2B_{10}H_{12}$ (carborane) deposited on various surfaces. Results from Raman scattering measurements on these films will be presented and compared with results of calculations for clusters. The electronic structure, total energy and vibrational properties of carborane molecules and $C_2B_{10}$ clusters calculated using density functional theory are reported. Computed vibrational spectra for carborane molecules are found to be in close agreement with previously published measured spectra taken on carborane solids. Eleven vibrationally stable $C_2B_{10}$ clusters have been identified and their relative energies, HOMO-LUMO gaps and vibrational properties will be discussed. Good agreement with the experimental Raman spectra is achieved from theoretical spectra computed using a Boltzmann distribution of the six lowest energy free-clusters.

**17:45**
**T7 1 The Hydrophobic Effect ab initio.**
JE-LUEN LI, *Princeton University*

We employ fully quantum-mechanical molecular-dynamics simulations to evaluate the force between two methanes dissolved in water, as a model for hydrophobic association. A stable configuration is found near the methane-methane contact separation, while a shallow second potential minimum occurs for the solvent-separated configuration. The strength and shape of the potential of mean force are in conflict with earlier classical-force-field simulations but agree well with a simple hydrophobic burial model which is based on solubility experiments. Examination of solvent dynamics reveals stable water cages at several specific methane-methane separations.

**18:21**
**T7 2 Hydrophobic Effects as Seen in Lattice Models.**
BENJAMIN WIDOM, *Cornell University*

A class of lattice models incorporating the thermodynamic mechanism of hydrophobicity is defined and its properties derived. The models are equivalent to Ising models in a field. The solvent-mediated part of the potential of mean force between a pair of hydrophobic solute molecules is obtained from the pair correlation function of the underlying one-component lattice gas. The models yield a testable relation between the strength of the hydrophobic attraction between

solute molecules and the free energy of solvation of a single one. The properties of the models are obtainable analytically in Bethe-Guggenheim approximation. The local energy density in the solvent is obtained as a function of the distance from an inserted solute. As a consistency check, this energy density, when summed over the lattice, is found to satisfy the required thermodynamic relation between the total energy change due to the solute molecule and the temperature dependence of the solubility.

**18:57**
**T7 3 Hydrophobicity at small and large length scales.**
DAVID CHANDLER, *University of California, Berkeley*

This lecture is about the statistics of density fluctuations for liquids at thermodynamic states close to liquid-vapor coexistence. Theoretical and simulation results on the length scale dependence of this statistics will be described and used to explain hydrophobic solvation, hydrophobic forces of assembly and kinetics of hydrophobic collapse. Several issues concerning so-called ''drying'' near extended hydrophobic surfaces will be addressed, and biophysical implications will be discussed.

**19:33**
**T7 4 Modeling water, hydrophobic interactions, and polymer collapse.**
THOMAS TRUSKETT, *The University of Texas at Austin*

Small and large nonpolar solutes exhibit qualitatively different hydration thermodynamics. The former are naturally accommodated into bulk water via equilibrium density fluctuations, while the latter require the formation of a macroscopic solute-water interface. Although there has been significant progress on the theory of lengthscale-dependent hydration, there are still many open questions concerning how various thermodynamic parameters (e.g., pressure, additive concentration, and pH) impact the crossover between small and large solute behavior. Similarly, there is confusion over whether hydration of small, intermediate, or large lengthscales dominate in various biological self-assembly processes. In this talk, I discuss recent theoretical progress on understanding how solution conditions affect the crossover between small and large solute hydration phenomena and how simulation/theory of the collapse of hydrophobic polymers can provide new insights into the relevance of hydrophobic interactions at different lengthscales.

## SESSION T50: PERSPECTIVES ON OUR ENERGY FUTURE
**Wednesday Evening, 15 March 2006; Grand Salon V, Marriott Waterfront Hotel at 19:30**

**19:30**
**T50 1 TBD.**
STEVEN KOONIN, *Chief Scientist for BP*

This abstract was not submitted electronically.

**20:06**
**T50 2 Physics, Physicists, and Our Energy Future.**
PATRICIA DEHMER, *Office of Basic Energy Sciences, U.S. Department of Energy*

Abundant energy is intimately linked with global stability, economic prosperity, and quality of life. However, even with aggressive conservation and energy efficiency measures, the projected increase of the Earth's population accompanied by rapid technology development and economic growth is projected to double the demand for energy by mid century and more than triple the demand by the end of the century. The reserves of fossil fuels that currently account for 85% of U.S. energy will fall far short of demand over the long term, and their use is associated with environmental contaminants ranging from greenhouse gases and toxic gases to particulates. Our energy challenges cannot be met by incremental improvements to existing technologies. Transformational changes and disruptive technologies will be required to provide clean, reliable, economic solutions. As in the past, many of these changes will likely come from fundamental research in the physical sciences. How we approach the problem as a Nation and how we respond as a community of scientists will determine our success.

**SESSION U1: SPIN LIQUIDS AND SUPERCONDUCTIVITY NEAR THE MOTT TRANSITION**

**U1 1 Spin Liquid States in the Hubbard Model: Implications for Organics.***
PATRICK LEE, *Department of Physics, MIT*

We formulate a U(1) gauge theory of the Hubbard model in the slave-rotor representation. From this formalism it is argued that spin liquid phases may exist near the Mott transition in the Hubbard model on triangular and honeycomb lattices at half filling. The organic compound $\kappa$-(BEDT-TTF)$_2$Cu$_2$(CN)$_3$ is a good candidate for the spin liquid state on a triangular lattice. We predict a highly unusual temperature dependence for the thermal conductivity of this material.

*Sung-Sik Lee and P.A. Lee, Phys. Rev. Lett. **95**, 036403.

**8:36**
**U1 2 Spin liquid and superconductivity in two-dimensional organic charge transfer salts.**
JOERG SCHMALIAN, *Iowa State University*

We introduce and analyze a variational wave function for quasi two-dimensional organic salts containing strong local and nonlocal correlation effects. We find an unconventional superconducting ground state for intermediate charge carrier interaction, sandwiched between a conventional metal at weak coupling and a spin liquid at larger coupling. Most remarkably, the excitation spectrum is dramatically renormalized and is found to be the driving force for the formation of the unusual superconducting state.

**9:12**
**U1 3 Anomalous superconductivity near the Mott transition.**
ANDRE-MARIE TREMBLAY,* *Universite de Sherbrooke*

High-temperature superconductivity appears near an antiferromagnetic Mott insulating phase and a normal phase with a pseudogap. It was suggested early on by Anderson that the strong-coupling limit of the Hubbard model should contain the main physics. It is only recently that we have begun to have access to sufficiently accurate algorithms and powerful enough computers to begin to extract the main features of the phase diagram of high-temperature superconductors from the Hubbard model in a nearly quantitative manner. In this talk, the zero temperature phase diagram of the two-dimensional Hubbard model is discussed based on several ''quantum cluster'' approaches, mainly Variational Cluster Perturbation Theory [1] and Cellular Dynamical Mean Field Theory [2], that shall be introduced. The overall ground state phase diagram of the high-temperature superconductors as well as the asymmetric one-particle excitation spectra for both hole- and electron-doping are reproduced. The d-wave order parameter is found to assume a dome shape as a function of doping and to scale like the magnetic exchange coupling J for U comparable to the bandwidth. We stress the features of superconductivity that are non-BCS like due to the proximity to the Mott insulator. In stark contrast with BCS theory, the superconducting gap can decrease monotonically at the same time as the d-wave order parameter increases away from half-filling. Also, d-wave superconductivity is driven by a lowering of kinetic energy instead of potential energy, in conformity with experiments on cuprates. The pseudogap [3-5] and results of other approaches will also be briefly touched upon. [1] David Sénéchal, P.-L. Lavertu, M.-A. Marois, and A.- M.S. Tremblay, Phys. Rev. Lett. **94**, 156404 (2005). **U1 4 The origin of the pseudogap in the high Tc superconductors.**
HERB A. MOOK, *Center for Neutron Scattering and the Condensed Matter Sciences Division, Oak Ridge National Laboratory*

The origin of the pseudogap is one of the most important questions in high Tc superconductors. The idea of circulating currents as being responsible for the pseudogap will be considered and various current paths through the Cu-O plane examined in the light of recent neutron scattering experiments.

**10:24**
**U1 5 Polarized Neutron Diffraction to discover symmetry breaking in pseudogap region of Y(123)-Cuprate.**
PHIIPPE BOURGES, *Laboratoire Léon Brilllouin, CEA-Saclay*

One of the leading issues in high-$T_C$ superconductors is the origin of the pseudogap phase in underdoped cuprates. Using polarized elastic neutron diffraction, we identify a novel magnetic order in the $YBa_2Cu_3O_{6+x}$ system*. The observed magnetic order preserves translational symmetry as proposed for orbital moments in the circulating current theory of the pseudogap state (see C.M. Varma, at http://fr.arxiv.org/abs/cond-mat/0507214). To date, it is the first direct evidence of an hidden order parameter characterizing the pseudogap phase in high-$T_C$ cuprates. * B. Fauqué, Y. Sidis, V. Hinkov, S. Pailhès, C.T. Lin, X. Chaud and P. Bourges, at http://fr.arxiv.org/abs/cond- mat/0509210.

## SESSION U2: QUANTUM MAGNETS IN HIGH MAGNETIC FIELDS
**Thursday Morning, 16 March 2006; Ballroom III, Baltimore Convention Center at 8:00**
**Igor Zaliznyak, Brookhaven National Laboratory, presiding**

**8:00**
**U2 1 Spinons, Solitons, and Breathers in Quasi-One-Dimensional Magnets.***
COLLIN BROHOLM, *Johns Hopkins University*

By scattering neutrons from coordination polymer magnets, we contrast the effects of a uniform and a staggered magnetic field on the quantum critical state of a spin-1/2 chain. In a partially magnetized state of copper pyrazine dinitrate (CuPzN) we find bounded spectral continua indicating that neutrons scatter from spin-1/2 quasi-particle pairs [1]. The complex boundaries including an incommensurate soft spot result from a field induced shift in the Fermi points for these quasi-particles. The measurements indicate that the magnetized state of CuPzN remains quantum critical. Copper benzoate [2] and $CuCl_2$2(dimethylsulfoxide) (CDC) [3] differ from CuPzN in that there are two spins per unit cell along the spin chain. Rather than continuous spectra, we find resolution limited gapped excitations when these materials are subject to high fields. So with two spins per unit cell, an applied field can drive the spin-1/2 chain away from criticality. The explanation for this effect was provided by Affleck and Oshikawa. The alternating coordination environment induces a transverse staggered field and spinon binding. The quantum sine-Gordon model is the relevant low energy field theory and it predicts soliton and breather excitations at specific energies and wave vectors that we compare to the experiments. We shall also compare a complete measurement of the dynamic spin correlation function for CDC in a field to exact diagonalization results for a spin-1/2 chain with a staggered and uniform magnetic field [4]. **U2 2 Ordering and Excitations in the Field-Induced Magnetic Phase of $Cs_3Cr_2Br_9$.**
BEATRICE GRENIER, *CEA-Grenoble*

$Cs_3Cr_2Br_9$ is an interesting example of interacting spin-dimer system. As in other isotropic antiferromagnets such as Haldane or alternating chains and ladders, the ground state in zero field is a total spin singlet separated from the excited triplet by an energy gap. In a magnetic field $H$, a phase transition occurs at a critical field $H_{c1}$, where the gap to the lowest component of the Zeeman-split triplet closes. Above $H_{c1}$, field-induced magnetic order (FIMO) for spin components perpendicular to $H$ is induced by inter-dimer or inter-chain couplings. The FIMO transition may be considered as a Bose-Einstein Condensation. $Cs_3Cr_2Br_9$ differs from other dimer systems currently studied (*e.g.* PHCC, $TlCuCl_3$) in two main ways: each $Cr^{3+}$ ion of the dimer has spin 3/2 rather than 1/2 for Cu-based systems and the arrangement of the dimers is hexagonal. This gives rise to anisotropy and frustration in a 3D lattice, respectively. The possibility of studying the magnetic ordering and the spin dynamics in a FIMO with sufficient detail to bring out features of frustration and anisotropy motivated the present neutron scattering study in $Cs_3Cr_2Br_9$.* Two field orientations have been exploited, perpendicular and parallel to the easy axis **c** (direction of the dimers). First, I present the diffraction study: the FIMO displays large hysteresis incommensurability, showing the importance of frustration. The impact of anisotropy is seen in the magnetic structure, whose nature strongly depends on the field direction. Second, I focus on spin dynamics: it

quantifies the presence of anisotropy and shows its crucial role on the energy gap at $H_{c1}$, which is measurably open or not, depending on whether $H$ is perpendicular or parallel to **c**. Third, an explanation is proposed for the large value of the gap at higher field: it involves the mixing of higher order states (itextended-FIMO), reflected by the absence of magnetization plateaus. Comparison with the sister $Cs_3Cr_2Cl_9$ compound provides a test of this hypothesis. *B. Grenier et al., Phys. Rev. Lett. **92**, 177202 (2004).

**9:12**
**U2 3 Quantum phase transitions in integer spin chains.**
ANDREY ZHELUDEV, *Oak Ridge National Laboratory*

High field inelastic neutron scattering experiments on the $S=1$ bond-alternating 1D antiferromagnet NTENP, the anisotropic $S = 1$-chain Haldane-gap compound NDMAP and the isotropic ''composite'' Haldane spin chain IPA-$CuCl_3$ [T. Masuda *et al.*, cond-mat/0506382] reveal key differences in the spin dynamics of these distinct types of quantum spin liquids. In modest applied fields the spectra of NDMAP [A. Zheludev *et al.*, Phys. Rev. Lett. **88**, 077206 (2002)] and IPA-$CuCl_3$ feature three sharp stable gap excitations. In contrast, in NTENP the highest mode is anomalously weak at $H = 0$ and rapidly broadens and vanishes when the field is turned on. Above the critical field of 1D Bose condensation of magnons and long-range ordering NDMAP retains a triplet of massive long-lived excitations [A. Zheludev *et al.*, Phys. Rev. B **68**, 134438 (2003)]. In IPA-$CuCl_3$ only two sharp gap excitations persist, with possibly an additional gapless mode. In NTENP only one sharp excitation branch is observed in this regime [Hagiwara *et al.*, Phys. Rev. Lett. **94**, 177202 (2005)], but there is new evidence of low-lying excitation continua. Work at ORNL was carried out under DOE Contract No. DE-AC05-00OR22725.

**9:48**
**U2 4 High-field ESR and thermodynamic studies of uniform and bond-alternating $S=1$ spin chains.**
MASAYUKI HAGIWARA

Recently, field-induced phenomena in quantum spin systems have attracted considerable interest. Gapped one-dimensional (1D) spin systems with a spin value $S=1$ subject to an external magnetic field strong enough to close the gap ($H_c$) are driven into a new phase. Spin excitations in this field-induced phase have been studied by experiments on a uniform S=1 antiferromagnetic spin chain $Ni(C_5H_{14}N_2)_2N_3(PF_6)$, alias NDMAP and a bond-alternating one $Ni(C_9H_{24}N_4)NO_2(ClO_4)$, alias NTENP. We performed high-field and multi-frequency ESR experiments at 1.5 K on these compounds and observed gapped excitations above $H_c$. Two or three excitation modes were observed depending on the field direction in NDMAP and only one excitation in NTENP. These results are consistent with those obtained by inelastic neutron scattering experiments in a magnetic field. Both compounds exhibit the long-range order (LRO) at a magnetic field above $H_c$ and a low temperature. Observed gapped excitations are very different from those expected from a conventional spin-wave theory in the LRO state. For NDMAP, observed branches satisfactorily agree with those analyzed by a phenomenological field theory. The difference of observed gapped excitations between NDMAP and NTENP can be explained by an interaction with a low-lying two magnon continuum at $q=\pi$ that is present in a bond-alternating chain but absent in a uniform one. When an antiferromagnetic spin chain with $S=1$ has an XY or Heisenberg symmetry, the phase above $H_c$ is critical and its low-energy physics is described by a Tomonaga-Luttinger liquid (TLL), which is characterized by a gapless $k$-linear energy dispersion with an incommensurate $k_0$ and a spin correlation having an algebraic decay. NTENP has nearly an XY symmetry and a linear temperature($T$) dependence of the specific heat ($C_{mag}$) was observed for the magnetic field parallel to the chain above $H_c$ in a temperature region above that of the LRO state. The ratio $C_{mag}/T$ increases as the magnetic field approaches $H_c$ from above and is in good agreement with the prediction of the $c=1$ conformal field theory, providing a conclusive evidence for a TLL in a gapped quasi-1D antiferromagnet.

**10:24**
**U2 5 Anisotropic Haldane-gap chains in a magnetic field.**
FABIAN ESSLER, *University of Oxford, UK*

We consider quasi one dimensional spin-1 Heisenberg chains with crystal field anisotropy in a uniform magnetic field. We determine the dynamical structure factor in various limits and obtain a fairly complete qualitative picture of how it changes with the applied field. In particular, we discuss how the width of the higher energy single magnon modes depends on the field. We consider the effects of a weak interchain coupling. We discuss the relevance of our results for neutron scattering experiments on the quasi-1D Haldane-gap compound NDMAP.

**SESSION U3: NANOMECHANICAL ARCHITECTURE OF STRAINED THIN FILMS**

**U3 1 Precise semiconductor nanotubes and nanocorrugated quantum systems: concept, fabrication and properties.**
VICTOR PRINZ, *Institute of Semiconductor Physics, Siberian Branch of Russian Academy of Sciences*

Physics and technology of several new classes of nanostructures, namely, variously shaped semiconductor, metal, dielectric and hybrid nanoshells, are overviewed. Previously, we discoved that ultrathin epitaxial heterofilms (down to two monolayers in thickness in the case of InGaAs/GaAs) can be controllably released from substrates and rolled up under the action of internal stresses into various cylindrical micro- and nanotubes, scrolls, rings, helices, etc. [1]. In this way, nanotubes with minimum diameter of 2-nm can be obtained. The fabricated nanoshells offer much promise as building blocks for nanoelectronic and nanomechanic devices, their fabrication technology being fully compatible with the well-established integrated-circuit technology [2]. Experimental and theoretical results concerning the quantum processes in the fabricated micro - and nanoshells are reported, including ballistic and tunnel transport in bent waveguides, magnetotransport, bending-induced formation of deep quantum wells and quantum dots molecules [3]. New results on the formation of spatially periodic nanostructures, nanocorrugated systems, shells with 1-nm minimum radius of curvature, building blocks for nanodevices and new nanocomposite materials are described. The present report outlines the cornerstone stages in the development of this fabrication technology for semiconductor and metal nanoobjects, including: directional rolling of films, super-critical drying of nanoshells, passivation of electron states in them, etc. Benefits offered by the new approach in the creation of 3D ordered nanoobject arrays, as well as challenges met in the development of the original nano- and molecular technology are discussed.

**U3 2 Nanomechanical Architecture of Strained Bi-layer Thin Films: From Design Principles to Fabrication.**
FENG LIU, *University of Utah*

Controlled and consistent fabrication of different classes and shapes of nanostructures (as opposed to simply stochastic self-assembly) will be a requirement if nanotechnology expects to achieve its promised impact on society. We illustrate by both theory and computation the design principles of an emerging nanofabrication approach based on the itnanomechanical architecture of strained bi-layer thin films, which are further confirmed by experiments through fabrication of a variety of nanostructures, including nanotubes, nanorings, nanodrills, and nanocoils. This approach demonstrates the possibility of fabricating nanostructures with an unprecedented level of control over their size, geometry, and uniformity, based on ita priori designs. It possesses also an unparallel level of versatility for making nanostructures with combinations of different materials. By combined multi-scale modeling and simulations from first-principles calculation, to molecular dynamics simulation, and to continuum mechanics modeling, we demonstrate how mechanical bending of nanoscale thin films differs from that of macroscopic thin films. For example, we show that surface stress will even play a more dominant role than misfit strain in bending a film that is down a few monolayers thick. *This work is supported by DOE and NSF.

**9:12**
**U3 3 Nonochannel networks, light emission and waveguidung of micro- and nanotubes, and ultra-compact coils.**
OLIVER G. SCHMIDT, *Max-Planck-Institut fuer Festkoerperforschung, Heisenbergstr. 1, D-70569 Stuttgart, Germany*

Quite generally, thin solid films can be partially released from a substrate surface by selective underetching and form into various 3D micro- and nano-objects [1-3]. Here, we show that such released layers form into complex nanochannel networks, which can be fluid-filled and emptied within fractions of a second. Furthermore, we demonstrate that single material layers roll-up into micro- and nanotubes. In particular, we show that all-Si tubes can be fabricated. Quantum emitters such as InAs/GaAs quantum dot heterostructures are integrated into the wall of rolled-up microtubes, and we study the emission and the waveguiding properties of such ''quantum dots in a tube'' [4]. Finally, metal/semiconductor bilayers are rolled up into microtubes. This technique opens the way to realize and integrate ultra-compact coils, transformers and capacitors on a single chip [5]. I am grateful to my collaborators Y. Mei, R. Songmuang, C. Mendach, C. Deneke, D. Thurmer, F. Cavallo, and A. Rastelli (all Max-Planck-Institut fuer Festkoerperforschung Stuttgart, Germany). [1] O. **U3 4 Fabrication and Applications of Tubular Semiconductor Membranes.***
ROBERT BLICK, *University of Wisconsin-Madison*

We present transport measurements on curved semiconductor membranes. The aim is to investigate geometric potentials in low dimensional electron systems. We have conducted first studies on topography dependant electron transport in complete tubes, using built in strain between lattice mismatched semiconductors. We will discuss the processing details in SiGe and InGaAs strained layers. Initial studies reveal two regimes of electron transport which are probed by a varying perpendicular magnetic field. At low magnetic field, we see an increase in electron scattering along curved regions due to an increase in electron scattering. At high magnetic field, we find a linear increase in resistance of the curved region as compared to planar regions. Finally, we will give an outlook into possible applications in nano-electromechanical systems.

**U4 1 Step and Flash Imprint Lithography.***
GRANT WILLSON, *The University of Texas*

Step and Flash Imprint Lithography has been recognized as a potentially low cost, high resolution patterning technique. Most of the published development work has been directed toward tool design and processing techniques. This work will be reviewed. There remains a tremendous opportunity and need to develop new materials for specific SFIL applications. An overview of relevant materials-related development work for SFIL lithographic applications will be presented. Material requirements for SFIL patterning for the sub-50 nm integrated circuit regime are discussed along with proposed new imprint applications, such as imprintable dielectrics that are targeted for use as on chip insulation layers.

**U4 3 Directed assembly of block copolymer containing materials on chemically nanopatterned substrates: A platform for two and three-dimensional nanofabrication.**
PAUL NEALEY, *University of Wisconsin*

Directed assembly often refers to fabrication strategies that involve the organization of one or more materials on substrates through specific interactions with patterned activated regions. Based on engineered interfacial interactions between lithographically-defined chemically nanopatterned substrates and block copolymer thin films, the domain structure of the films can be directed to assembly into defect free periodic and non-regular structures over large areas, with each structure registered with the underlying substrate. Advantages of integrating self-assembling materials into the lithographic process, particularly for the fabrication of nanoelectronic devices, include sub 1 nm control over feature dimensions, reduced line edge roughness, and the opportunity to scale the approach to pattern at dimensions of 10 nm and below. Exciting opportunities exist to extend the use of self-assembling materials in conjunction with two-dimensionally (2D) patterned activate surfaces for the fabrication complex three-dimensional (3D) materials. Arrays of functional nanoparticles, for example, can be directed to assemble using block copolymer/particle nanocomposites or in a hierarchical process using chemically functional polymers followed by in situ particle synthesis. 3D bicontinuous morphologies in which the two phases of the assembly are readily addressable, a geometrically complex structure, can be created using materials that normally form lamellae and directing them to assemble on chemically patterned surfaces consisting of square arrays of spots. The principal concept of this work is that high value added 3D structures can be created from simple 2D templates, retaining the lithographic properties of perfection and registration for applications where input and output connections to the structures are required.

**9:48**
**U4 4 Probing the 3-Dimensional Structure of Nanomanufactured Materials using CD-SAXS.**
RONALD JONES, *NIST Polymers Division*

The realization of routine nanofabrication will demand new measurement platforms capable of probing the size, shape, internal morphology, and chemical uniformity of structures ranging from nanometers to 100's of nanometers in size. Traditional microscopies such as scanning electron microscopy and atomic force microscopy are often limited to exposed surfaces and are challenged to probe internal morphologies and structures with complex 3-dimensional shapes. We have developed a platform for non-destructive characterization of repeating nanostructures or nanostructured materials applicable to a wide range of sizes (5 to 500 nm) and materials (polymers, ceramics, and metals). Critical Dimension Small Angle X-ray Scattering (CD-SAXS) utilizes a relatively high energy, collimated x-ray beam to probe the dimensions, shape, and homogeneity of nanostructures fabricated on substrates such as silicon or quartz with sub-nm precision. CD-SAXS is capable of non-destructive measurements in real time during fabrication, providing insight into a wide range of fabrication methods. We demonstrate the wide ranging capabilities of CD-SAXS using recent data from structures created with photolithography, nanoimprint, and self-assembly. Patterns are characterized in terms of their average width, height, sidewall angle, and chemical uniformity. In addition, the distribution in orientation is quantified for self-organized systems, providing insights into the factors controlling defects. Finally, the technique is demonstrated for complex systems involving pattern directed self-assembly, such as in nanoimprinted block copolymers. In these systems, confinement between a mold and substrate prevent conventional imaging during fabrication. Real time data are used to elucidate the evolution of nanometer scale structures within 100 nm scale cavities.

**10:24**
**U4 5 Characterization of Materials for Nanoscale Lithography.**
WILLIAM HINSBERG, *IBM Almaden Research Center, San Jose CA*

Current state-of-the-art semiconductor devices are fabricated at dimensions below 100 nm and industry planning anticipates that devices at the 20 nm scale will be in production a decade from now. The sizes of the component molecules of typical polymeric photoresists are of this same magnitude, and due to this convergence of scales and intrinsic materials limitations, the formation of high fidelity relief images at these dimensions will be a significant challenge. We summarize here the materials issues that must be addressed to enable the practical application of nanoscale photolithography, and describe instrumentation and methods we have developed that allow their suitability for such use to be assessed by characterizing basic materials properties.

## SESSION U5: LOW TEMPERATURE PHYSICS, A HISTORICAL PERSPECTIVE
**Thursday Morning, 16 March 2006; 309, Baltimore Convention Center at 8:00**
**George O. Zimmerman, Boston University, presiding**

**8:00**
**U5 1 Low Temperature Physics at Yale in the late 30's through the early 50's.**
ROBERT WHEELER, *Yale University, Dept. of Applied Physics*

The low temperature program at Yale was initiated by C. T. Lane (1904-1991) in the fall of 1937 when he was appointed to the teaching staff as an instructor in the department of Physics. Following his doctorate from McGill in 1929 he investigated the magnetic susceptibilities of ''soft'' metals supported by the National Research Council of Canada, the Commissioners of the 1851 Exhibition and a Sterling Fellowship at Yale. Arranged by Louis McKeehan, with $5000 from the new George Sheffield research fund, he started the construction of a Kapitza type helium liquefier. The machine was largely completed in the fall of 1939, yet liquid helium was not made until early December 1940 due to the need for extensive on line purification of the gas. Returning in 1945 from war research, Lane and Henry A. Fairbank (Ph.D 1944) continued the metals work along with new thrusts into Second Sound, properties of helium$^3$ impurities in liquid helium and starting in the 50's on rotating He II. In 1933 both Lane and Onsager were awarded Sterling Fellowships, which initiated a stimulating experimental-theoretical exchange continuing until they both retired. The best-known example was the rediscovery at Yale of the de Haas–van Alphen effect, previously observed only in bismuth, in zinc; where upon Onsager and his students provided new insights into our understanding of the Fermi surface of metals. With the development of new instrumentation one observed vast changes in experimental style during this period. The evolution of the production of liquid helium from Lane's device though the Collins machine to the commodity business of today now makes experiments of huge size and importance possible.

**8:36**
**U5 2 Rotating Superfluids.**
RUSSELL DONNELLY, *University of Oregon*

Rotation of a fluid, particularly studying phenomena affected by Coriolis forces, plays a significant role in nearly all branches of fluid dynamics. Quantum fluids are no exception, as evidenced by remarkable devices such as ''Rota'' in Helsinki. This talk concerns the early days of rotating superfluids, starting long before superfluid helium-3 appeared on the scene. I will attempt to describe some of the early experiments, how the apparatus was designed, and what the experiments revealed. There has been so much activity in this area, I will discuss mostly experiments in my own fields of interest. Time will not permit an exhaustive review of this fascinating subject.

**9:12**
**U5 3 Fritz London's Legacy at Duke University.**
HORST MEYER, *Duke University*

When $^3$He became available in small quantities after WWII Fritz London, Professor at Duke University since 1939, became very interested in its properties in the liquid and solid phases, as contrasted with those of $^4$He. His influence and that of his colleague Walter Gordy led to the appointment of William Fairbank in 1952, who was able to verify experimentally the prediction on the Fermi degeneracy of liquid $^3$He below 1K, a few weeks before London's death in 1954. With his students and associates, Fairbank carried out a number of important experiments which became classics, several of which will be described. At Duke he also started planning other experiments inspired by London's predictions. After W. Fairbank's departure for Stanford in 1959, further research on liquid and solid $^3$He and $^3$He-$^4$He mixtures was carried out by his successors at Duke University and some of the results in the sixties will be briefly described.

**9:48**
**U5 4 Liquid Helium 3 and Solid Helium at Yale and Beyond.**
D.M. LEE, *Laboratory of Atomic and Solid State Physics, Cornell University*

Many of the foundations of low temperature physics in the latter half of the twentieth century were built at Yale University under the leadership of Professor Cecil T. Lane who came to Yale in 1932 and Henry A. Fairbank who obtained his Ph.D. at Yale in 1944 under Lane's guidance. This discussion will mainly treat the contributions of Henry Fairbank and his students during the period between 1954 and 1963, when Henry Fairbank left Yale to become chairman of the Physics Dept. at Duke University. Following World War II small amounts of helium three became available to low temperature experimenters. Henry Fairbanks graduate students were provided with the opportunity to investigate second sound in dilute and later concentrated mixtures of helium three in superfluid helium four. These measurements showed strong effects of the phase separation in helium 3-helium 4 mixtures previously discovered in the laboratory of William Fairbank (a student of Lane and a brother of Henry Fairbank). As more helium three became available, studies of pure helium three were performed, including measurements of the thermal conductivity, the density and the specific heat. Early evidence for the melting curve minimum was found. The main emphasis in this work was to search for Fermi liquid behavior. Much of the later work in this area was performed by the group of John Wheatley at the University of Illinois. In studies of solid helium four at Yale, a surprising observation was made. Hitherto it had been thought that hcp was the stable phase throughout the low temperature part of the phase diagram. It was found via ultrasound experiments that a small silver of bcc solid existed at the lowest pressures. While this author was a graduate student at Yale, Henry Fairbank pointed out to him the possibility of cooling helium three via adiabatic compression from the liquid into the solid phase. (Pomeranchuk Cooling). A brief discussion is given of the use of this technique in the discovery of superfluid helium 3 by Osheroff, Richardson and the author at Cornell.

**U6 1 LDA+U Based Studies of Electronic, Vibrational and Spectroscopic Properties of Solids.***
STEVEN G. LOUIE, *University of California at Berkeley and Lawrence Berkeley National Laboratory*

The LDA+U method is a physically motivated approach that attempts to incorporate the effects of important orbital-specific local Coulomb interactions in strongly correlated electron systems while retaining the simplicity of local density approximation (LDA) calculations for real materials. In this talk, we discuss several applications of this method within the ab initio pseudopotential planewave framework. For transition metal oxides, the appropriate inclusion of the effects of onsite Coulomb U significantly alters their electronic structure leading to better agreement with experiment for quantities such as the nature of the electronic state, structural parameters, magnetic moments, phonon frequencies, etc. We have also studied the effects of doping on the electronic, magnetic, and structural properties of $NaxCoO_2$. Undoped $CoO_2$ is a metal with a high density of states at the Fermi level within LSDA, but a charge transfer insulator within LSDA+U. It is found that, due to a strong interaction between the doped electrons and the other Co d electrons, the calculated electronic structure is sensitively depended on the doping level. Finally, we discuss the use of LDA+U results as a starting mean-field solution for calculation of the electron self energy and quasiparticle excitations within the GW approximation.

**U6 2 LDA+*U* applied to oxide and nitride wide-band-gap semiconductors.***
ANDERSON JANOTTI, *University of California, Santa Barbara*

Nitride and oxide semiconductors have important technological applications, but the theoretical understanding of their properties is hampered by the shortcomings of density functional theory (DFT) in the local density approximation (LDA). In particular, DFT-LDA underestimates the binding energy of the semicore *d* states, leading to poor descriptions of quantities such as band offsets and deformation potentials. In this work we calculate the electronic and structural properties of wurtzite MgO, ZnO, and CdO, and discuss their similarities and dissimilarities with the corresponding nitrides AlN, GaN, and InN. We treat the semicore *d* states of Zn, Cd, Ga, and In explicitly as valence states in a pseudopotential framework, and improve the description of electron-electron interactions in these narrow bands by including an on-site Coulomb interaction through the LDA+*U* method. We propose a novel approach to calculate the parameter *U*, based on first-principles calculations for atoms. The approach is general and could be extended to other semiconductors and insulators where semicore *d* states play a fundamental role in the description of electronic and structural properties. The LDA+*U* approach systematically improves the LDA band gap by indirectly acting on both the valence-band maximum and conduction-band minimum. We investigate the effects of the on-site Coulomb interaction on lattice parameters, band structure, absolute deformation potentials, and band lineups. Finally we discuss how results based on LDA and LDA+*U* can be used to calculate defect transition levels and formation energies that can be directly compared with experiment.

**U6 3 First-principles calculations of electronic structure and spectra of strongly correlated systems: the LDA+U method.**
ALEXANDER LICHTENSTEIN, *University of Hamburg*

Realistic approach to the electronic structure of complex materials which contains correlated d- or f- electrons will be discussed. The density functional theory within the local spin density approximation have been highly successful for electronic structure calculations and zero temperature magnetic properties of non-correlated systems. We investigate some failures of the LDA-scheme for the charge, spin and orbital ordering in transition metal compounds. General formulation of the LDA+U method which takes into account local Coulomb correlations for the d-shell of transition metals ions in the crystal within the mean-field approximation will be presented. The LDA+U scheme describe well the antiferromagnetic Mott insulators, rare-earth and actinide systems. Electronic structure, spin and orbital moments and lattice distortions of transition-metal compounds are investigated in the framework of rotationally invariant LDA+U method. Starting from conventional LDA+U scheme the different ways to go beyond the mean-field approximation which includes in effects of the spin- and charge-fluctuations will be analyzed. Dynamical mean field theory (DMFT) in combination with the first-principle LDA scheme (LDA+DMFT) is a good starting point for calculation of the quasi-particle spectrum for metallic transition metal systems. Recent progress in analysis of the metal-insulator transition for complex transition metal oxides and calculations of the spectral function for itinerant magnetic systems will be discussed.

**9:48**
**U6 4 Disproportionation, Metal-Insulator Transition, and Critical Interaction Strength in $Na_{1/2}CoO_2$.***
JAN KUNES, *University of California Davis*

Spontaneous breaking of symmetry is one of the key concepts of solid state physics related to phase transitions. Charge/spin density wave, or charge/spin ordering if the propagation vector is commensurate, are notorious examples of broken symmetry. The charge disproportionation in $Na_{0.5}CoO_2$ is the main theme of the present work. The results of LDA+U calculations will be presented, exhibiting a charge disproportionation transition at $U \approx 3$eV. $Na_xCoO_2$ attracted considerable attention mainly due to superconductivity of its hydrated form $Na_{0.3}CoO_2.1.3H_2O$ [1]. Besides the superconductivity $Na_xCoO_2$ exhibits several intriguing properties throughout its phase diagram, such crossover from Pauli-like to Curie-Weiss susceptibility at $x=0.5$, spin-density wave around $x=0.7$ or several phase transitions for $x=0.5$ including metal-insulator transition, charge ordering and magnetic ordering [2]. The $Na_xCoO_2$ lattice consists of triangular $CoO_2$ layers separated by Na layer. The mobility of Na ions and fractional occupation of Na sublattice provides an additional complication. Using LDA+U functional within FPLO [3] bandstructure method we have performed series of supercell calculations allowing for breaking of the symmetry between different Co sites. We have found that for large enough, but physically realistic, values of the on-site Coulomb interaction U the Co sublattice disproportionates into sites with formal valencies $Co^{4+}$ and $Co^{3+}$. We have found that at the same time a gap opens in the excitation spectrum. Details of the bandstructure across the transition as well as the driving forces of the transition in the LDA+U mean field picture will be discussed. [1] K. **U6 5 A consistent, linear-response approach to LDA+U.**
MATTEO COCOCCIONI, *Department of Materials Science and Engineerig, MIT*

Hubbard U-correction to LDA or GGA has proven very effective in describing several strongly-correlated systems for which these approximations to DFT otherwise fail. Constrained DFT or semiempirical approaches have been often used to compute the Hubbard U. I introduce here an alternative scheme to evaluate the effective electronic interaction in a fully consistent way. This approach is based on the linear response of the system under consideration to a potential shift acting on the localized orbitals of the correlated sites. Using the occupations of these orbitals as the relevant electronic degrees of freedom we compute the on-site electronic coupling as the difference between the inverse of the bare and of the fully-interacting response matrices. The U computed in this way thus corresponds to the effective, atomically-averaged kernel of the Hartree-exchange-correlation interaction, in agreement with the second quantization expression of the ''+U'' energy functional. In this way the strength of the ''+U'' correction is evaluated from the same DFT scheme we aim to correct so that LDA+U becomes a consistent non-parametric method, with no need for semiempirical evaluations of the effective coupling. With this approach we successfully studied the structural, electronic, chemical and electrochemical properties of several transition-metal compounds. Examples will include minerals in the Earth's interior[1], cathode materials for next-generation lithium batteries[2] and metal-organic complexes [3]. [1] M. Cococcioni and S. de Gironcoli, PRB (2005). [2] F. Zhou, M. Cococcioni, A. C. Marianetti, D. Morgan and G. Ceder, PRB (2004). [3] H. J. Kulik, M. Cococcioni, D. Scherlis and N. **U7 2 Maskless Electron-beam and Optical Lithography.**
HENRY I. SMITH, *Dept. Electrical Engineering and Computer Science, Massachusetts Institute of Technology*

Mask-based lithography is ideal for high-volume manufacturing because it enables enormous data transfer rates. In manufacturing, the high cost of masks and lithography tools can be amortized over large numbers of products. However, for low-volume manufacturing, research and the exploration of novel applications of lithography, maskless lithography systems have significant cost and convenience advantages. Scanning-electron-beam lithography (SEBL) systems are widely used in research and some low-volume manufacturing. They suffer from well known problems of pattern-placement accuracy, slow writing speed and, in some cases, substrate damage. Strategies for circumventing these

problems will be described. A maskless optical-lithography system, called zone-plate-array lithography (ZPAL), has recently been demonstrated that achieves high throughput by the parallel operation of 1000 diffractive-optical lenses [www.lumarray.com]. The performance of ZPAL will be described and compared to SEBL. Also, novel nonlinear strategies for pushing the resolution of ZPAL to feature sizes comparable to those achieved by SEBL will be described.

**9:12**
**U7 3 Ion Beam Patterning at the Nanometer Scale.**
JOHN BAGLIN, *IBM Almaden Research Center*

Due to the absence of diffraction limitations, the extensive available process parameter space, and the prospects for one-shot imposition of a projection-reduced master mask pattern, ion beam patterning appears to offer a viable path to large-scale manufacturing of devices and systems based on nanoscale features, while offering robustness, flexibility, high quality of image definition and high throughput. We will review a variety of process variables, and the strategies by which they can be optimized for a specific application, in terms of resolution of the smallest features, minimal proximity effects, minimal edge effects, minimal statistical noise, high dimensional stability and pattern registration, and minimal effects on underlying layers. We use SRIM and other simulations of ion interactions to model the effects of ion species, energy, fluence and beam current density, and their impact on the choice of mask structure and type of photoresist where appropriate. We consider the application of the ions to pattern photoresist layers, or to locally modify the topography of polymer films, or to locally activate surfaces for selective adsorption. We also consider options for in-situ growth of 3D nanoscale features. Direct modification of the interfaces of thin film structures, and local ballistic disordering will also be discussed. Experimental demonstrations of low energy ion beam patterning with $<$ 40 nm resolution will include contact mask patterning of thin films of various polymers, and patterning of high-anisotropy magnetic multilayers for high storage density disk drive applications.

**9:48**
**U7 4 Atomic Image Projection Electron Beam Lithography.***
KI-BUM KIM, *Seoul National University*

While we are approaching to the nanotechnology era, as was proposed by Richard Feynman in 1959, our main concern still lies in how one can controllably manufacture and utilize nanometer scale features. The top-down approaches, most notably, lithography based techniques still have the problem of throughput although it has been successfully demonstrate to make features with the size less than 10 nm. The bottom-up approaches, either utilizing chemical vapor deposition process to make carbon nanotube or wet-chemical process to make size controllable quantum dots and rods, still have the limitation of extending it to many different types of materials and also delivering them on a wafer size substrate to make nanodevices. In this talk, we will propose a novel electron beam lithography technique to make nanometer scale features. The novelty of this process lies in the fact that one can utilize the crystalline lattice image commonly observed by the high resolution transmission electron microscopy as an ultimate mask to generate nanometer scale patterns. Using this technique, we demonstrate that down to 45 nm pitch size can be resolved on hydrogen silsesquioxine (HSQ) e-beam resist material. The patterns are formed on Si substarte with the dot size of about 30 nm and the line size of about 25 nm. This technique can be extend to define less than 10 nm size features only if the suitable resist is developed.

**10:24**
**U7 5 Diblock Copolymers for Nanoscale Patterning.**
THOMAS RUSSELL,* *University of Massachusetts at Amherst*

As the size scale of device features becomes increasingly smaller, conventional lithographic processes become increasingly more difficult and expensive, especially at a minimum feature size of less than 50 nm. Consequently, to achieve higher density circuits, storage devices or displays, it is evident that alternative routes need to be developed to circumvent both cost and manufacturing issues. An ideal process would be compatible with existing technological processes/ manufacturing techniques and these strategies, together with novel materials, could allow significant advances to be made in meeting both short-term and long-term demands for higher density and faster devices. The self-assembly of block copolymers (BCP), two polymer chains covalently linked together at one end, provides a robust solution to these challenges. As thin films, immiscible BCP self-assemble into a range of highly-ordered morphologies where with size scale of the features is limited to the size of the polymers chains and are, therefore, nanoscopic in size. While self-assembly alone is sufficient for a number of applications in fabricating advanced microelectronics, directed self-orienting self-assembly processes are also required to produce complex devices with the required density and addressability of elements to meet future demands. By combining tailored self-assembly processes, a bottom-up approach, with microfabrication processes, a top-down approach, the ever-present thirst of the consumer for faster, better and cheaper devices can be met in very simple, yet robust, ways.

**SESSION U8: GRANULAR MATERIALS**
**Thursday Morning, 16 March 2006**
**314, Baltimore Convention Center at 8:00**
**Wolfgang Losert, University of Maryland, presiding**

**8:00**
**U8 1 Statistical and dynamical properties of a vibrated granular polymer** ARSHAD KUDROLLI, MICAH VEILLEUX, *Physics Dept., Clark University* MEHRAN KARDAR, *Physics Dept., MIT* We investigate the structure and dynamics of granular polymers on a vibrated bed to test the applicability of models of self-avoiding random walks. The granular polymer is composed of a chain of hollow 3 mm steel beads connected by flexible links, and moves on a 30 cm diameter flat circular bed which is roughened by gluing a layer of 1 mm steel beads in order to give the chain random kicks in the vertical and horizontal directions. High speed digital imaging is used to track the position of the particles to a fraction of the bead diameter using a centroid technique. Using the identified bead positions, we analyze the motion of the center of mass over a time interval $\Delta t$, and its standard deviation as a function of chain length $L$. The standard deviation is consistent with a scaling of $\sqrt{\Delta t/L}$. The chain end-to-end distance scales as $L^{\nu}$, with $\nu \approx 3/4$ as for self-avoiding walks. The evolution of the scattering functions and the effect of the size of the container on the observed scaling will be also discussed.

**8:12**
**U8 2 Power Spectra of Force Fluctuations in Granular Materials Under Shear** ERIC CORWIN, HEINRICH JAEGER, SIDNEY NAGEL, *The James Franck Institute and Department of Physics, The University of Chicago* We measure the time-varying forces at the bottom surface of a granular system sheared at the top. The shear is applied by rotating a roughened piston while maintaining a constant, uniaxial compressive force. We report on the force autocorrelation and the corresponding power spectrum $S$ of the variation of force on individual grains at the bottom surface. These forces are obtained from video tracking of imprints in a pressure-sensitive birefringent layer across the bottom surface. Averaging over concentric annuli we find power-law behavior $S \sim 1/f^{\alpha}$ over several orders of magnitude in each annulus. The power law exponents $\alpha$ appear to be correlated with the in-plane shear strain rate. In our system friction with the stationary side walls introduces a radial gradient in the shear rate, which is maximum at the outer edge and zero at the center. The corresponding power law exponents suggest strict $1/f$ noise ($\alpha = 1$) at the outer, shearing edge and an increasing index as one approaches the center and the shear rate vanishes.

**8:24**
**U8 3 Self-diffusion of particles in gas-driven granular layers with periodic flow modulation*** CARLOS ORELLANA, *Departamento de Fisica, Universidad de Chile, Santiago, Chile* IGOR ARANSON, WAI KWOK, *Argonne National Laboratory* SERGIO RICA, *Departamento de Fisica, Universidad de Chile, Santiago, Chile* We study particles self-diffusion in gas-driven granular layers by high-speed fluorescent video-microscopy. We show that periodic flow modulation results in an enhancement of the particle's diffusion. The diffusion enhancement, which in turn is an indication of more efficient fluidization of the granular layer, is associated with the onset of disordered sub-harmonic patterns. Our measurements provide a sensitive characterization method of the fluidization properties of particulate/gas systems.

**8:36**
**U8 4 Free cooling of the one-dimensional wet granular gas** VASILY ZABURDAEV, MARTIN BRINKMANN, STEPHAN HERMINGHAUS, *Max Planck Institute for Dynamics and Self-Organization* In the present work we consider a one-dimensional gas of hard balls covered with a thin liquid film. A liquid bridge, formed at each collision, is responsible for the hysteretic and dissipative interaction. Each rupture of a liquid bridge requires a fixed amount of energy, and thus determines a threshold of relative velocities below which the two colliding particles form a bounded state loosing their relative kinetic energy. We aim to study the cluster formation process in the free cooling system. Macroscopic laws of energy dissipation and cluster growth are studied in this model on the basis of numerical simulations supported by a scaling-like system of equations. We show that the sticky gas regime is an attracting asymptotic limit of the wet granular gas and does not dependent on the liquid bridges strength. The next neighbor velocities correlations play the key role in the establishing of this regime.

**8:48**
**U8 5 A Theory of Stochastic Plasticity in Dense Granular Flow** KEN KAMRIN, MARTIN BAZANT, *MIT* There have been many attempts to derive continuum models for dense granular flow, but a general theory is still lacking, which can describe different flow conditions, such as gravity-driven silo drainage and forced shear cells. Here, we start with Mohr-Coulomb plasticity for quasi-2d granular materials to calculate stresses and slip planes, but we propose a simple ''stochastic flow rule'' to replace the principle of co-axiality in classical plasticity. This formulation takes into account two crucial features of granular materials – discreteness and randomness at the scale of a continuum element – via diffusing ''spots'' which cause chain-like cooperative particle displacements, as in recent simulations of silo drainage. We postulate that spots perform random walks along slip lines, biased by body forces (gravity) and local fluidization (switch from static to dynamic friction). Stochastic plasticity allows a natural description of dense granular flows in silos and shear cells within a single theory, rooted in classical mechanics.

**9:00**
**U8 6 The Solitary Wave Collision Problem in Granular Alignments*** EDGAR AVALOS, *SUNY-Buffalo* SURAJIT SEN, *SUNY-Buffalo* JAN PFANNES, *Univ of Wuerzburg* T.R. KRISHNA MOHAN, *SUNY-Buffalo* Any impulse travels as a solitary wave in an alignment of spherical elastic grains where the system grains are barely in contact. These solitary waves are about 7 grain diameters wide. Their speeds depend upon the maximum displacement amplitudes associated with these waves. We focus on the dynamical problem associated with the collision of two identical and opposite propagating solitary waves. Interface and grain center collisions reveal markedly different dynamics. Solitary wave collisions lead to the destruction of the original waves and the subsequent creation of new smaller waves along with ''baby'' or secondary solitary waves. In the absence of dissipation,

these granular systems point towards the existence of a generalized equilibrium phase that involves Maxwellian distribution of velocities with no depedence on initial conditions but one that violates the equipartition theorem.

**U8 7 Toward Zero Surface Tension Limit: Granular Fingering Instability in a Radial Hele-Shaw Cell** XIANG CHENG, LEI XU, AARON PATTERSON, HEINRICH JAEGER, SIDNEY NAGEL, *The James Franck Institute and Department of Physics, The University of Chicago* Because of the absence of cohesive forces between grains, dry granular material can, in many respects, be thought of as a fluid with zero surface tension. In the zero surface-tension limit, viscous fingering is known to possess singular behavior. We have studied the viscous fingering instability in such a granular ''fluid.'' In our experiment, we use a conventional radial Hele-Shaw cell consisting of two parallel glass plates separated by a gap. Gas with controlled pressures is blown through a hole at the center of one glass plate and displaces the surrounding dry granular material. We have systematically studied the fingering pattern as a function of gas pressure, gap thickness, and grain size. Two stages are observed during pattern growth. In the first stage, we find fluid-like fingering. However, as opposed to normal fluids, the pattern is more ramified at low pressure. In the second stage, we find several new behaviors in the system such as merging and pinching off of fingers and the existence of satellite bubbles.

**U8 8 Force fluctuations in collisional and frictional granular flows** EMILY GARDEL, EFROSYNI SEITARIDOU, ELLEN KEENE, NALINI EASWAR, *Smith College, Northampton, MA*. NARAYANAN MENON, *University of Massachusetts, Amherst, MA*. We make measurements of the force delivered to the wall in 2D and 3D flow geometries to explore the difference between collisional and frictional flows, and between flow geometries with and without velocity gradients in the flow direction. The distribution of force fluctuations has an exponential tail at large force in collisional flows, but falls off slower than an exponential in frictional flows. We do not see a clear signature in the force distribution of the approach to jamming and therefore the connection to force distributions in quasistatic flows remains to be understood. However, the temporal characteristics of the force fluctuations do show the approach to jamming. As reported earlier, the distribution of collision times tends to a power law in collisional flows. Similarly, the power spectrum of forces in frictional flows develops power-law behaviour at low frequencies as jamming is approached. Supported by NSF DMR 0305396 and NSF MRSEC DMR 0213695

**U8 9 Thermal collapse of a granular gas under gravity*** LEV S. TSIMRING, *University of California at San Diego* DMITRI VOLFSON, *University of California at San Diego* BARUCH MEERSON, *Hebrew University of Jerusalem* Free cooling of a gas of inelastically colliding hard spheres is a central paradigm of the kinetic theory of granular gases. At zero gravity the temperature of a freely cooling homogeneous granular gas follows a power law in time. How does gravity affect the cooling? We consider a semi-infinite layer of granular gas bounded from below by an elastic wall. An initially isothermal dilute granular gas is prepared in the state of hydrostatic equilibrium with barometric density distribution. We combine molecular dynamics simulations, a numerical solution of granular hydrodynamic equations and an analytic theory to show that the cooling gas undergoes thermal collapse: it condenses on the bottom of the container and cools down to zero temperature in a finite time $t_c$ as $T \sim (t_c - t)^2$. The cooling scenraio is determined by the interplay between the collisional energy loss and heat conduction, while the collapse time $t_c$ is much longer than the typical free fall time of the grains if the inelasticity of the particle collisions is small. The hydrodynamic description is found to be in excellent agreement with molecular dynamics simulations until very close to $t_c$.

**U8 10 Two particle contact lifetime distribution in gravity driven granular flow*** ROBERT BREWSTER, *UCLA* LEONARDO SILBERT, *University of Chicago* GARY GREST, *Sandia National Laboratories* ALEX LEVINE, *UCLA* The distribution of two particle contact life times for gravity driven granular flow down an inclined plane are determined from large-scale, three-dimensional discrete element simulations. Results are presented for both cohesive and non-cohesive particles for Hertzian and Hookean contact forces. The distribution of lifetimes is analyzed as a function of height from the surface for different strength $k_n$ of the normal force, coefficient of restitution $e_n$ and coefficient of friction $\mu$. In addition a generalized form of the Bagnold constitutive relation in which the shear stress depends on a sum of terms that are linear and quadratic in the shear rate is proposed for cohesive granular flows. The linear term represents a new mode of momentum transport made possible through the long lived contacts in the network while the quadratic term represents the usual Bagnold contribution from short time scale collisions. For non-cohesive grains, the strength of the linear term disappears as strength of the normal interaction $k_n$ increased.

**U8 11 Particle collisions in a granular gas*** HONG-QIANG WANG, KLEBERT FEITOSA, NARAYANAN MENON, *University of Massachusetts* We report a study of particle collisions in a 2D granular system vibrated in a vertical plane. We have previously studied this experimental system in a variety of contexts. With improved image analysis algorithms, we are able to locate particles with enough precision to allow detailed tracking of the collision process, when the particles are close to each other. This allows us to better study the role of the vertical walls in the collision process and to place a limit on the dissipation by mechanisms other than inelastic collisions. We report the distribution of collision parameters and comment on violations of molecular chaos resulting from the inelasticity of the system.

*We acknowledge support from NSF-DMR 0305396

**10:12**

**U8 12 Boltzmann's itstosszahlansatz generalized for granular contact forces** PHILIP METZGER, *NASA, John F. Kennedy Space Center* Is there a valid way to generalize Boltzmann's itstosszahlansatz (molecular chaos), the assumption that colliding molecules are not statistically correlated before the collision takes place, to the case of granular contact forces in a static packing? In thermal statistical mechanics the assumption produces a transport equation that obtains the density of single particle states and the Maxwell Boltzmann distribution. The problem in generalizing this to granular contact forces is that we must maintain the spatial symmetries of granular packing ensembles, which is not trivial. The essential trick is to sum the density of states over all particle exchanges, which destroys multi particle state information but maintains the distribution of single particle states. This summation transforms the equations into a generalized form of boson statistics. I will show that, in the summation, the first shell approximation of the fabric is transformed into the properly symmetric version of Boltzmann's itstosszahlansatz. This produces a transport equation that obtains the density of single particle states and hence the distribution of granular contact forces. Granular simulation data will also be presented to validate the theory.

**U8 13 Dynamical Heterogeneity close to the Jamming Transition in a Sheared Granular Material** OLIVIER DAUCHOT, *CEA/SPEC* GUILLAUME MARTY, *City College of New York* GIULIO BIROLI, *CEA/SPhT* The dynamics of a bi-dimensional dense granular packing under cyclic shear is experimentally investigated close to the jamming transition. Measurement of multipoint correlation functions are produced. The self-intermediate scattering function, displaying slower than exponential relaxation, suggests dynamic heterogeneity. Further analysis of four point correlation functions reveal that the grain relaxations are strongly correlated and spatially heterogeneous, especially at the time scale of the collective rearrangements. Finally, a dynamical correlation length is extracted from spatio-temporal pattern of mobility. Our experimental results open the way to a systematic study of dynamic correlation functions in granular materials.

**10:36**

**U8 14 The Decorated Tapered Chain as a Granular Shock Absorber*** ROBERT DONEY, *US Army Research Lab - APG* SURAJIT SEN, *SUNY-Buffalo* DORIAN DICOCCO, *SUNY-Buffalo* A 1*D* alignment of progressively shrinking spherical grains (a tapered chain) turns out to be an excellent impulse absorber with rich nonlinear dynamical behavior. Here we discuss a tapered chain with interstitial grains between every sphere of the original tapered chain and demonstrate analytically (using the hard sphere approximation), numerically and experimentally that the shock absorption ability of the ''decorated'' system is far superior to that of the system without the interstitial grains.

*Supported by ARO

**10:48**

**U8 15 Shock Absorption by Small, Scalable, Tapered Granular Chains*** JAN PFANNES, *University of Wuerzburg* ADAM SOKOLOW, *Duke University* ROBERT DONEY, *US Army Research Lab - APG* MASAMI NAKAGAWA, *Colorado School of Mines* JUAN AGUI, *NASA-Glenn Research Center* SURAJIT SEN, *SUNY-Buffalo* Making shock proof layers is an outstanding challenge. Elastic spheres are known to repel softer than springs when gently squeezed but develop strong repulsion upon compression and the forces between adjacent spheres lead to itballistic-like energy transfer between them. Here we demonstrate for the first time that a itsmall alignment of progressively shrinking spheres of a strong, light-mass material, placed horizontally in an appropriate casing, can absorb$\sim$ 80% ($\sim$ 90%) of the incident force (energy) pulse. The system can be scaled down in size. Effects of varying the size, radius shrinkage and restitutive losses are shown via computed ''dynamical phase diagrams.''

**U9 1 An itin-situ Study of Martensitic Transformation in Shape Memory Alloys using PEEM** GANG XIONG, T. DROUBAY, A. JOLY, W. HESS, *Pacific Northwest National Laboratory, Richland, WA 99352, USA* M. CAI, S. LANGFORD, J. DICKINSON, *Physics Department, Washington State University, Pullman, WA 99164 USA* M. WU, Q. HE, W. HUANG, *School of Mechanical Production Engineering, Nanyang Technological University, 50 Nanyang Ave., Singapore* The thermally-induced martensitic transformation in a polycrystalline CuZnAl and NiTi thin film shape memory alloy (SMA) was probed using photoemission electron microscopy (PEEM). Ultra-violet photoelectron spectroscopy (UPS) measurements indicate that the apparent surface work function changes reversibly during transformation, presumably due to the contrasting electronic structures of the martensitic and austenitic phases. itIn situ PEEM images provide information on the spatial distribution of these phases and the microstructural evolution during transformation. The evolution of the photoemission intensities obtained from PEEM images during transformation can provide quantitative information on fractional percentages of austenite and martensite phases as the transformation proceeds. PEEM offers considerable potential for improving our understanding of martensitic transformations in shape memory alloys in real time.

**8:12**

**U9 2 Investigation of ferroelectric materials with scanning microwave microscope*** JEWOOK PARK, JONGHOON CHO, SANGYUN LEE, KOOKRIN CHAR, *Seoul National University* By using scanning microwave microscope (SMM), we investigated dielectric properties of ferroelectric materials in high frequency regime (1.5GHz). Our SMM had the capability to measure a complex dielectric constant of the samples from the shift of resonant frequency (fr) and Q value of the probing resonator. In order to obtain non-linear dielectric constants of the ferroelectric samples, we applied oscillating electric field perpendicular to the sample and measured the $1^{st}$ order derivative of the resonant frequency of the resonator (dfr/dE) with respect to the applied field. In this way we could image the ferroelectric domain and the do-

main boundary structure of the triglycine sulfate single crystal using the dfr/dE and the fr signal, respectively. Moreover we observed the ferroelectric responses from the tunable dielectric $Ba_{0.6}Sr_{0.4}TiO_3$ thin film under the additional DC voltage bias to the film.

**U9 3 Plasmon-based Enhanced NSOM Spectroscopy.** A.T. CHANG, C.L. NEHL, F. TAM, N.J. HALAS, J.H. HAFNER, K.F. KELLY, *Rice University* Surface enhanced Raman spectroscopy is a well established technique for enhancing the Raman signal of a particular sample, allowing for spectroscopy of far lower quantities of the molecule of interest than other procedures allow. This enhancement is mainly caused by the enhancement of the incident electric field by exciting the plasmon resonance of the surface. By attaching metal nanoparticles on an NSOM probe, we demonstrate that the plasmon-based enhancement can come from the probe itself instead of the surface, resulting in a powerful tool for the chemical analysis at the nanometer scale.

**8:36**

**U9 4 Dielectrophoretic Force Microscopy** AL HILTON, BRIAN LYNCH, GARTH SIMPSON, *Purdue University Dept. of Chemistry* Dielectrophoretic force microscopy, a novel scanning probe microscopy technique in which a tip-sample dielectrophoretic force is incorporated into the feedback mechanism of a standard atomic force microscope, is shown to allow for the facile noncontact imaging of the dieelctric properties of systems in aqueous media. By tuning the ac frequency, dielectric spectroscopy can be performed at solid/liquid interfaces with high spatial resolution. In studies of cells, the frequency-dependent dielectrophoretic force is sensitive to biologically relevant electrical properties, including local membrane capacitance and ion mobility. Additionally, the presence of a dielectrophoretic force reduces the mechanical tip-sample contact forces that frequently hinder microscopy studies of soft, deformable systems. Consequently, dielectrophoretic force microscopy is well suited for itin situ scanning probe microscopy studies of biological systems.

**U9 5 Spectral density of fluctuations for a driven, nonlinear micromechanical oscillator at kinetic phase transition** COREY STAMBAUGH, *University of Florida* HO BUN CHAN, *University of Florida* We measure the spectral densities of fluctuations of an underdamped nonlinear micromechanical torsional oscillator. By applying a sufficiently large periodic driving force, two stable dynamical states occur within a particular range of drive frequency. White noise is injected into the driving force allowing the system to overcome the activation barrier and to switch between the two states. While the system predominately resides in one of the two states for most excitation frequencies, a narrow range of frequencies exist where the population levels are approximately equal and the system is at a 'kinetic phase transition' that bears resemblance to the phase transition of thermal equilibrium systems. By examining the power spectral densities of the measured oscillation amplitude, the fluctuation characteristics of the system can be studied. At the 'kinetic phase transition' a supernarrow peak, centered at the excitation frequency, arises as a result of noise-induced transitions between the two dynamic states. Smaller, secondary peaks associated with fluctuations about the two attractors are also examined. Its dependence on noise and excitation frequency is shown to be distinct from that of the supernarrow peak.

**U9 6 Nonlinear coupling of nano mechanical resonators to Josephson quantum circuits** XINGXIANG ZHOU, ARI MIZEL, *The Pennsylvania State University* We study a technique to couple the position operator of a nano mechanical resonator to a SQUID device by modulating its magnetic flux bias. By tuning the magnetic field properly, either linear or quadratic couplings can be realized, with a discretely adjustable coupling strength. This allowes us to realize nonlinear dynamics on the nano mechanical resonator by coupling it to a Josephson quantum circuits. As an example we show how squeezing of the nano mechanical resonator can be realized with this technique. We also propose a simple method to measure the uncertainty in the position of the nano mechanical resonator without quantum state tomography.

**9:12**

**U9 7 Nanomanipulation with dynamic AFM** IVAN STICH, PETER DIESKA, *Slovak University of Technology* RUBEN PEREZ, *Universidad Autonoma de Madrid* Nanomanipulation [1] is one of the most important current issues in dynamic AFM (DAFM). Following the first vertical manipulation on Si(111)-(7x7) [1] a lateral manipulation was documented by interchange manipulation of Sn and Ge adatoms on the Ge(111)- c(2x8) surface [2]. However, the atomistic details and nature of these processes remain unclear. In order to shed light on these experiments we have performed DFT simulations on two model systems: (1) anionic antisite defect on the InP(110) surface [3], and (2) the Sn-covered Ge(111)-c(2x8) surface. In (1) the P defect atom moves vertically in a double well potential with two minima, which opens the possibility to vertically manipulate the defect atom from one minimum into the other. We will addresses issues such as whether the experiments can be performed in both attractive and repulsive interaction regimes and whether the basic atomistic mechanism is related to lowering of the barriers by the presence of the tip, or by a purely mechanical effect where the atom is pushed over a barrier. In (2) we will show how presence of the tip can affect the charge transfer processes between the different dangling bonds and hence induce atomic manipulation. [1] N. Oyabu et al., Phys. Rev. Lett. 90, 176102 (2003) [2] Y. Sugimoto et al., Nature Mater. 4, 156 (2005); N. Oyabu et al., Nanotechnology 16, S112 (2005). [3] P. Dieska, I. Stich, R. Perez, Phys. Rev. Lett. 95 126103 (2005)

**U9 8 Assembly of Nanoparticle-Attached AFM Tips for Nano-Optical Applications*** TAEKYEONG KIM, SUNG MYUNG, NARAE CHO, SEUNGHUN HONG, *School of Physics, Seoul National University, Seoul, Korea* The well-defined geometry and chemical properties of the end of atomic force microscopy tips are critical components for various tip-enhanced nano-optical applications such as nanoscale Raman and FRET imaging. However, conventional AFM tip fabrication method often results in a large variation of tip shapes and chemical properties. Recent nanotechnology allows us to synthesize 'nanoparticles' (e.g. Au, Ag, CdSe, etc). We developed a method to mass-produce 'AFM tips with well-defined geometry and chemical properties' by assembling a single nanoparticle at the end of the tip via self-assembly strategy.

In this way, only the end part of the tip is functionalized with organic molecules which attract nanoparticles in the solution. When the functionalized tip is placed in the nanoparticle solution, nanoparticles are selectively assembled only onto the end of the tip. We assembled a nanoparticle (e.g. 50nm diameter Au nanoparticle) at the end of the tip and demonstrated AFM imaging using these tips. Our method allows us to assemble nanoparticles at the end of the tip, and it can be scaled up for large scale assembly.

**U9 9 Investigation of Electrical Behaviors of Nanostructures through Scanning-Probe Microscopy** BEVERLY CLARK III, HANS HALLEN, *NC State University NSOM Lab* A scanning-probe microscope with two electrically-isolated electrodes fabricated on one probe is used to locally investigate electrical behavior of nanostructures. The split-tip probe, which we have recently developed, is optimized for light coupling into a particular region of a nanostructure while non-contact measurements are simultaneously made between the two electrodes. The capacitance is influenced by the presence of a conducting region on the surface beneath the electrodes. The capacitance coupled or scanning conductivity mode allows rapid characterization of large numbers of molecules so that molecules of interest can be identified for further study. Finite element models aid in the quantification and understanding of the data.

**9:48**

**U9 10 Scanning Tunneling Potentiometry for Nanoscale Transport Studies** MICHAEL ROZLER, M.R. BEASLEY, *Stanford University* We have developed a scanning tunneling potentiometry (STP) system for study of electrical transport on nanometer length scales. A novel biasing scheme is used to achieve electrochemical potential resolution at the theoretical limits of this measurement - the thermal noise of the tunnel junction. We apply this technique to several materials in order to explore the capabilities of the instrument. These include thin films of Au, the ''bad metal'' $SrRuO_3$ and amorphous indium oxide. Homogeneity of transport in these systems is discussed. Work supported initially by the AFOSR and currently by the NSF.

**U9 11 Alpha Control - A New Concept in SPM Control** P. SPIZIG, D. SANCHEN, G. VOLSWINKLER, W. IBACH, J. KOENEN, *WITec GmbH, www.WITec.de* Controlling modern Scanning Probe Microscopes demands highly sophisticated electronics. While flexibility and powerful computing power is of great importance in facilitating the variety of measurement modes, extremely low noise is also a necessity. Accordingly, modern SPM Controller designs are based on digital electronics to overcome the drawbacks of analog designs. While todays SPM controllers are based on DSPs or Microprocessors and often still incorporate analog parts, we are now introducing a completely new approach: Using a Field Programmable Gate Array (FPGA) to implement the digital control tasks allows unrivalled data processing speed by computing all tasks in parallel within a single chip. Time consuming task switching between data acquisition, digital filtering, scanning and the computing of feedback signals can be completely avoided. Together with a star topology to avoid any bus limitations in accessing the variety of ADCs and DACs, this design guarantees for the first time an entirely deterministic timing capability in the nanosecond regime for all tasks. This becomes especially useful for any external experiments which must be synchronized with the scan or for high speed scans that require not only closed loop control of the scanner, but also dynamic correction of the scan movement. Delicate samples additionally benefit from extremely high sample rates, allowing highly resolved signals and low noise levels.

**U9 12 Theory of Q-Controlled Dynamic Force Microscopy in Liquids** HENDRIK HOLSCHER, UDO D. SCHWARZ, *Dep. Mech. Eng., Yale University* The so-called Q-control method allows the active modification of the effective cantilever damping in dynamic force microscopy (DFM) by increasing or decreasing the Q-value of the cantilever. This feature has been used in recent years in numerous experimental studies to improve the apparent imaging capabilities of DFM in liquids. However, it is striking that an in-depth analytic description that would allow a rigorous theoretical explanation of the various features of Q-controlled dynamic force microscopy (QC-DFM) is still missing. Here, we present an analysis of QC-DFM based on the analytical solution of the equation of motion considering a model tip-sample interaction force. Explicit formulas allowing for the calculation of relevant parameters such as amplitude, surface deformation, and maximum forces during an individual oscillation cycle are given. It is found that higher effective Q-factors assist in reducing the maximum tip-sample forces. This helps suppressing unwanted deformations of the sample surface, leading to the reported enhanced image quality. Finally, the results are discussed in relation to the situation in air.

**U9 13 Simulation of contact and non-contact AFM images of H-terminated Si(100) surface with a CH3 impurity** AKIRA MASAGO, SATOSHI WATANABE, *Department of Materials Engineering, The University of Tokyo* KATSUNORI TAGAMI, MASARU TSUKADA, *Department of Nanoscience and Nanoengineering, Waseda University* Using a density-functional-based tight-binding method, we have investigated whether atomic force microscope (AFM) images with atomic resolution can be obtained for hydrogen-terminated silicon (100) 1x1 surface including a methyl. We have simulated contact mode images of this surface using a silicon tip with and without a hydrogen atom at the apex. For the silicon tip without hydrogen at the apex, we obtained good images with anisotropic spots reflecting the symmetry of a methyl for large tip-sample distance. For the silicon tip with hydrogen at the apex, we found that better images with atomic resolution, showing internal hydrogen and carbon atoms of a methyl, are expected if the forces can be measured precisely. We have also examined non-contact mode images. Although a force line profile of non-contact mode is smoother than one of contact mode, their difference is not so large.

**U10 1 Nanoscale Patterning of Electrochemically Deposited Metallic Features on Si, Ge, InP and GaAs Surfaces.***
JILLIAN BURIAK, *Dept. of Chemistry, University of Alberta and the National Institute for Nanotechnology, National Research Council, Edmonton, Canada*

Nanostructured materials continue to be the focus of intense research due to their promise of innumerable practical applications as well as advancing the fundamental understanding of these intriguing materials. In particular, the need for metallic features of increasingly smaller size regimes has imposed stringent demands upon chemists to produce a variety of highly functional materials with reduced dimensions.While much effort has been expended towards the synthesis of nanoscale structures, one of the most challenging aspects for the nanoscale materials community is the question of how to 'wire in' these functional elements with the real world. In this talk, we will describe recent work towards the synthesis and nanoscale patterning of metallic structures on semiconductor surfaces such as silicon, germanium, gallium arsenide and indium phosphide. Through simple and efficient galvanic displacement reactions on these interfaces, complex metal nanostructures form spontaneously, and can be patterning via self-assembling soft block copolymer materials. The self-assembled materials direct transport of reagents to the semiconductor so that the reaction takes place in a spatially defined manner, with precise control over the quantity of reagent delivered. Even mixtures of reagents can be ''sorted out'' by these interfaces to produce nanoscale ( $\sim$ 10 nm) domains of different chemical functionalities, simultaneously. We will describe these and related approaches towards precise patterning of semiconductor surfaces, entirely via wet-chemical processes that are compatible with existing fabrication strategies.

**U10 2 Scanning Tunneling Microscopy Study of Molecular Structure: Controlled Monolayer Formation on Graphite at the Liquid-solid Interface** C. SU, *Dept of Molecular Science and Engineering, National Taipei Univ. of Tech.* K. KANNAPPAN, V. NORA CHIN, L. AVILA-BRONT, S. JAYARAMAN, N.J. TURRO, *Dept of Chem, Columbia Univ* G.W. FLYNN, *Dept of Chem and Columbia Center for Integrated Science and Engineering, Columbia Univ* The self-assembly of heptadecanoic acid **1** and racemic 2-bromoheptadecanoic acid **2** mixtures on the basal plane of a graphite surface has been studied using scanning tunneling microscopy at the liquid-solid interface. The domain structure varies as a function of the ratio of coadsorbed molecules. At lower concentration of acid **2**, heptadecanoic acid controls the surface structure by forming a template with fixed lamellar axis-molecular axis angle and domains with alternating R- and S-enantiomer molecular rows. Increasing the concentration of acid **2** leads to the segregation of chiral domains. The inter-correlation between heptadecanoic acid and 2-bromoheptadecanoic acid determines the 2D chiral configuration in the mixed monolayer. A model based on energetically favorable molecular conformations is proposed and will be discussed.

**U10 3 Static and Dynamic Aspects of Surfactant Surface Aggregates studied by AFM** HANNES SCHNIEPP, DUDLEY SAVILLE, ILHAN AKSAY, *Department of Chemical Engineering, Princeton University* Using AFM, we show that surfactants form micellar aggregates of varying morphology, depending on the surface structure. While all previous studies were limited to atomically flat substrates, we achieve imaging the micelles on rough gold. By gradually annealing these surfaces, we show the influence of roughness on the aggregate structures. For crystalline gold (111), aligned, hemi-cylindrical micelles that recognize the symmetry axes of the gold lattice are found. With increasing roughness, the degree of organization of the aggregates decreases. We also show that the micellar pattern on HOPG and gold(111) surfaces changes with time and responds to perturbations in a self-healing way. Our results suggest that this organization happens at the molecular scale. Theoretical analysis for HOPG, however, show that the micelle orientation cannot be explained on the molecular level, but the anisotropic van der Waals interaction between micelles and HOPG has to be considered as well [1]. **U10 4 Accelerated Molecular Dynamics Simulation of Alkane Desorption** KELLY McLAUGHLIN, KRISTEN FICHTHORN, *Pennsylvania State University* Thermal desorption has been the focus of much surface science research. Studies of alkanes on graphite[1] and gold[2] have shown prefactors that are constant with alkane chain length but vary by over six orders of magnitude. Other studies on magnesium oxide[3] and gold[4] show a prefactor that increases with increasing chain length. We have developed an all-atom model to study alkane desorption from graphite. Transition state theory is used to obtain rate constants from the simulation. Accelerated MD is used to extend the desorption simulation to experimentally relevant temperatures. Our results show a prefactor that increases with increasing chain length. We predict that it will become constant as internal conformational changes occur significantly. We examine the effect of desorption environment

through varying the alkane surface coverage. 1. K.R. Paserba and A.J. Gellman, J. Chem. Phys.**115**, 6737 (2001). 2. S.M. Wetterer et al., J. Phys. Chem. **102**, 9266 (1998). 3. S.L. **U10 5 Atomic force microscopy and fluorescence correlation spectroscopy studies of interfacial fluids.** S. PATIL, G. MATEI, C. GRABOWSKI, P. HOFFMANN, A. MUKHOPADHYAY, *Department of Physics, Wayne State University* We have studied the dynamic structure of thin ( $\sim$ few nm) liquid films of a nearly spherical, nonpolar molecule tetrakis(2-ethylhexoxy)silane by using a combination of atomic force microscopy (AFM) and fluorescence correlation spectroscopy (FCS). Ultra-sensitive interferometer-based AFM was used to determine the stiffness (force gradient) and the damping coefficient of the liquid film. The experiments show oscillations in the damping coefficient with a period of $\sim$ 1 nm, which is consistent with the molecular dimension as well as previous x-ray reflectivity measurements. However, it fails to detect any stiffness oscillation, indicating that molecules are layered weakly near the solid-liquid interface. Additionally, we performed FCS experiments for direct determination of the molecular dynamics within the liquid film. From the fluctuation autocorrelation curve, we measure the translational diffusion of the probe molecule. The autocorrelation function cannot be fitted with a single diffusion coefficient indicating that the dynamics may vary in different layers.

**U10 6 A Single Molecule View of Bi-stilbene Photoisomerization Using Scanning Tunneling Microscopy.***
JUEN-KAI WANG, *National Taiwan University*

The advent of scanning tunnelling microscopy (STM) has permitted a detailed atomic view of organic molecules adsorbed on solid surfaces. With the use of the STM, we present an unprecedented direct single-molecule perspective on the cis-trans photoisomerization of stilbene molecules within ordered-monolayers physisorbed on the Ag/Ge(111) surface. The STM view of the molecular structure transformation upon irradiation provides a direct evidence for the generally accepted one-bond-flip mechanism proposed for the photoisomerization process. We also find that the surface environment produces a profound effect on the reaction mechanism. The reaction is observed to proceed mainly through pairs of co-isomerizing molecules situated at domain boundaries. To explain these observations, we propose a mechanism whereby excitation migrates to the domain boundary and the reaction occurs through a biexciton reaction pathway.

**U10 7 A combined theoretical and experimental study on the structure of Methylthiolates on the Au(111) surface** RICCARDO MAZZARELLO, R. ROUSSEAU, *SISSA and ICTP, Trieste, Italy* S. SCANDOLO, *ICTP, Trieste, Italy* A. VERDINI, A. COSSARO, *TASC-INFM, Trieste, Italy* L. CASALIS, *Sincrotrone, Trieste, Italy* L. FLOREANO, A. MORGANTE, *TASC-INFM, Trieste, Italy* M. F. DANISMAN, *Princeton University, USA* G. SCOLES, *SISSA, Trieste, Italy and Princeton University, USA* Self-assembled monolayers (SAMs) of sulphur containing organic molecules on gold have received enormous attention due to the central role these interfaces play in molecular electronic devices, biosensors, surface coatings and nanolithography. Despite their interest the atomic structure of Methylthiolates on Au(111) surfaces, the simplest SAM in this class, is not fully understood. Here we address this problem with a combined theoretical and experimental study. We show that an asymmetric bridge (quasi on-top) site fits both the X-Ray and Photoelectron Diffraction data better than either the symmetric bridge site or on-top site. To understand this phenomenon we have performed molecular dynamics simulations employing density functional theory within the generalized gradient approximation. We show that at high temperatures the presence of vacancies and gold adatoms tends to favour the quasi on-top site, in spite of the fact that the symmetric bridge site is the lowest energy site at $T = 0$.

**U10 9 STM study of adsorption and dissociation of trichloroethylene molecules on the Si(111)7x7 surface.*** POUYA MARAGHECHI, *Department of Physics, University of Lethbridge, Lethbridge, Alberta, T1K 3M4, Canada* STEVEN A. HORN, *Department of Physics, University of Lethbridge, Lethbridge, Alberta, T1K 3M4, Canada* WEIMING LIU, *Department of Physics, University of Lethbridge, Lethbridge, Alberta, T1K 3M4, Canada* S.N. PATITSAS, *Department of Physics, University of Lethbridge, Lethbridge, Alberta, T1K 3M4, Canada* We have performed, for the first time, STM studies of the adsorption of trichloroethylene (TCE) on clean silicon. The results were taken with a home-built UHV STM operating at room temperature. Our STM is capable of obtaining both topographic as well spectroscopic images. One of the products of the dissociation has been determined to be single chlorine atoms bound to Si adatoms as evidenced by topographic imaging and tip induced diffusion.[1] The other product of the dissociation is believed to be a vinyl group attached to an adatom as proposed in a study using EELS and TDS.[2] Results on the binding site preference (ex. corner vs. middle adatoms) for the Cl and vinyl group will also be presented as well as conclusions about the diffusion of Cl on Si. 1) Nakamura et al, Surf. Sci. **487**, 127 (2001). 2) He et al, Surf. Sci. **583**, 179 (2005).

*The authors acknowledge the National Sciences and Engineering Research Council of Canada (NSERC) for their support of this work.

**10:36**

**U10 10 Decompositional, incommensurate growth of Ferrocene molecules on a Au(111) surface** KAI-FELIX BRAUN, VIOLETA IANCU, SAW HLA, *Ohio University* OHIO UNIVERSITY TEAM, We have investigated in depth the first layer growth of ferrocene molecules on a Au(111) surface with a low temperature scanning tunneling microscope. Ferrocene molecules adsorb dissociatively and form a two layer structure after being decomposed into fragments. The toplayer unit cell is composed of two tilted cyclopentadienyl rings, while the first layer consists of the remaining fragments. Surprisingly a fourfold symmetry is observed for the top layer while the first layer displays threefold symmetry elements. It is this symmetry mismatch which induces an incommensurability between these layers in all except one surface direction. The top layer is weakly bonded allowing for an antiferromagnetic ordering as shown by density functional theory calculations.

**U11 1 Infrared Spectroscopy of Metal Ion Complexes: Models for Metal Ligand Interactions and Solvation.** MICHAEL DUNCAN, *University of Georgia*

Weakly bound complexes of the form $M^+$-$L_x$ (M=Fe, Ni, Co, etc.; L=$CO_2$, $C_2H_2$, $H_2O$, benzene, $N_2$) are prepared in supersonic molecular beams by laser vaporization in a pulsed-nozzle cluster source. These species are mass analyzed and size-selected in a reflectron time-of-flight mass spectrometer. Clusters are photodissociated at infrared wavelengths with a Nd:YAG pumped infrared optical parametric oscillator/amplifier (OPO/OPA) laser or with a tunable infrared free-electron laser. $M^+$-$(CO_2)_x$ complexes absorb near the free $CO_2$ asymmetric stretch near 2349 $cm^{-1}$ but with an interesting size dependent variation in the resonances. Small clusters have blue-shifted resonances, while larger complexes have additional bands due to surface $CO_2$ molecules not attached to the metal. $M^+(C_2H_2)_n$ complexes absorb near the C-H stretches in acetylene, but resonances in metal complexes are red-shifted with repect to the isolated molecule. $Ni^+$ and $Co^+$ complexes with acetylene undergo intracluster cyclization reactions to form cyclobutadiene. Transition metal water complexes are studied in the O-H stretch region, and partial rotational structure can be measured. $M^+$(benzene) and $M^+(benzene)_2$ ions (M=V, Ti, Al) represent half-sandwich and sandwich species, whose spectra are measured near the free benzene modes. These new IR spectra and their assignments will be discussed as well as other new IR spectra for similar complexes.

**U11 2 Adaptive Tempering Monte Carlo Optimization of Calcium Clusters.*** X. DONG, E. BLAISTEN-BAROJAS, *School of Computational Sciences, George Mason University, Fairfax, VA 22030* The global minimum energy structures of calcium clusters with 15 to 34 atoms were obtained by the Adaptive Tempering Monte Carlo (ATMC) method. The cluster binding energy was obtained within a tight binding approach with parameters reported in previous work[1]. The ATMC optimization process is fast and drives the system across configuration space very effectively reaching the global minimum within a small number of tempering events. The structure of six cluster sizes 15, 16, 18, 21, 23 and 25 corresponding to the global minimum has not been reported in the literature for any other metals. Three clusters $Ca_{15}$, $Ca_{21}$ and $Ca_{23}$ are relatively more stable than the others in this size range. Melting of these clusters are further studied with the weighted histogram analysis method and the free energy profile is predicted. The melting transition is monitored with a novel structural order parameter that reflects the mobility of surface atoms, their bonding order and bonding directionality. [1] X. Dong, G. M. Wang, E. Blaisten-Barojas, Phys. Rev. B 70, 205409 (2004).

**U11 3 Structures and ligand binding energies of size seleceted gold and silver clusters: Approach to the bulk** MICHAEL T. BOWERS, MANUEL MANARD, PAUL KEMPER, *University of California, Santa Barbara* Gold and silver clusters are formed by laser ablation, mass selected, and either reacted with ethene or subjected to ion mobility measurement. Structures are assigned by two methods. In the first sequential ligand binding energies are measured and correlated with possible structures. In the second experimental cross sections are correlated with cross sections from model structures. Both anionic and cationic clusters are measured in the size range 3 to 13. For the anions calculated and experimental detachment energies are also used as structural diagnostics. The various data are compared with bulk values and approach to the bulk assessed.

**U11 5 Signatures of Random Matrix Theory in the Discrete Energy Spectra of Shaped Disordered Metallic Clusters** LAURA ADAMS, BRIAN LANG, ALLEN GOLDMAN, *University of Minnesota* It has been predicted that the distribution of the discrete energy levels of disordered metallic clusters should follow random matrix theory. It has been possible to study distributions of energy levels for different shaped metallic clusters using a low temperature scanning tunneling microscope. Depending on the degree of ''shape'' disorder, the statistics either follow Wigner-Dyson statistics, a mixed state, or Poisson-like statistics for the distribution of energy levels. We will present a summary of results on Pb clusters grown by a buffer layered assisted growth technique and in addition show how it is possible to use scanning tunneling spectroscopy to image a quantity proportional to the square of the amplitude of the eigenfunctions for quantum confined systems. These images resemble images acquired in microwave cavity experiments for classically chaotic and nonchaotic systems. This work was supported by the Department of Energy under grant DE-FG02-02ER46004.

**U11 7 Structure in Binary Nanodroplets** HONG XIA NING, GERALD WILEMSKI, *University of Missouri-Rolla* Recent SANS measurements of core-shell structure in binary nanodroplets ( $\sim$ 9 nm) have stimulated our research on the structure of droplets of this size. [Wyslouzil, et. al., Phys. Chem. Chem. Phys. **8**, xxx (2006)] By structure, we mean the spatial distribution of chemical species within the droplet. Based on recent work by Cordeiro and Pakula [J. Phys. Chem. **109**, 4152 (2005)], we developed an efficient Lattice Monte Carlo (LMC) method to simulate binary droplets containing 5000 to 10000 particles. Simulations of nanodroplets of various compositions were made to study phenomena such as species segregation and phase separation. Depending on the relative strengths of the intermolecular interactions, various interesting structures were found. Droplets may be fairly well-mixed, strongly segregated core-shell structures, or even highly segregated nonspherical shapes resembling partially disassembled Russian dolls. We explored the temperature dependence of the droplet structures and observed that the reversible change between the core-shell and Russian doll structures could be viewed as a wetting—dewetting transition. The transition temperature was determined for a specific system.

**10:12**
**U11 8 Source for a Temperature-Controlled Metal Cluster Beam** WEI JIANG, FORREST PAYNE, LOUIS BLOOMFIELD, *University of Virginia* Metal clusters can be produced easily by laser vaporization of a sample into an inert cooling gas. We have used a pulsed Nd:YAG laser to evaporate cobalt from a rotating rod into a 20cm-long narrow pipe filled with helium gas, injected by a pulsed gas valve. The outgoing part of the pipe (15cm long) is attached to a helium refrigerator and an electrical heater, which allow us to control the pipe's temperature over the range from 60K to room temperature. If the gas-cluster mixture stays in the pipe long enough before supersonic expansion, it reaches thermal equilibrium with the pipe.

**U11 9 Modeling the Melting of Free and Supported Metal Clusters*** KIM BOLTON, *Physics Department, Goteborg University, SE-412 96, Goteborg, Sweden; School of Engineering, University College of Boras, SE-501 90, Boras, Sweden* FENG DING, *MEMS Department, Rice University, MS 321, Houston, TX 77005* HAIMING DUAN, ARNE ROSEN, *Physics Department, Goteborg University, SE-412 96, Goteborg, Sweden* AVETIK R.

HARUTYUNYAN, TOSHIO TOKUNE, *Honda Research Institute USA Inc., 1381 Kinnear Road, Columbus, OH 43212* STEFANO CURTAROLO, *Department of MEMS, Duke University, Durham, NC 27708* The growth rate and mechanism of one-dimensional structures, such as carbon nanotubes and zinc-oxide nanorods, is expected to be significantly affected by the phase of catalytic metal particle. It is therefore important to understand the structure and dynamics of these particles in their solid and liquid phases, and to know how their melting points depend on cluster size and substrate adhesion. Results from molecular dynamics studies on the structural and dynamic changes during melting of free and supported iron clusters, ranging from 150 to 10 000 atoms, will be presented. We will also present a method to determine effective diameters of supported metal clusters, so that the melting point dependence on cluster size can be predicted in a physically meaningful way by the same analytic model used for free clusters.

**U11 10 Geometric and electronic structure of mixed metal-semiconductor clusters from global optimization.** FRANK HAGELBERG, JIANHUA WU, *Jackson State University* In addition to pure metal and semiconductor clusters, hybrid species that contain both types of constituents occur at the metal-semiconductor interface. Thus, clusters of the form Cu(x)Si(y) were detected by mass spectrometry [1]. In this contribution, the geometric and energetic features of Me(m)Si(7-m) (Me=Cu and Li) clusters are discussed. The choice of these systems is motivated by the structural similarity of the pure Si(7), Li(7), and Cu(7) systems which all stabilize in D(5h) symmetry. On the other hand, Li and Cu, representing the alkali group (IA) and the noble metal group (IB) of the periodic system, are expected to display strongly differing behavior when integrated into a Si(n) cluster, resulting in different ground state geometries for the cases Me = Li and Me = Cu. Addressing this problem by means of geometry optimization requires, in view of the large number of possible atomic permutations for Me(m)Si(7-m) with $0 < m < 7$, the use of a global search algorithm. Equilibrium geometries are obtained by simulated annealing within the Nose' thermostat frame. It is observed that Cu(m)Si(7-m) clusters with $m < 6$ tend towards ground state geometries derived from the D(5h) prototype. For Li(m)Si(7-m), the Li(m) subsystem is found to adsorb on the framework of the Si(7-m) dianion. [1] J.J. Scherer, J.B. Pau, C.P. Collier, A. O'Keefe, and R.J. Saykally, J. Chem. Phys. 103, 9187 (1995).

**U11 11 Unbiased search of minimal energy nanocluster structures*** JOSÉ ROGAN, *Universidad de Chile* GRISELDA GARCÍA, *Universidad Católica de Chile* CLAUDIA LOYOLA, WALTER ORELLANA, *Universidad de Chile* RICARDO RAMÍREZ, MIGUEL KIWI, *Universidad Católica de Chile* A new strategy to find global minima is applied to the structure of metallic clusters. It consists in implementing a conformational space annealing (CSA) unbiased search in combination with many body phenomenological potential techniques to create a data bank of putative minima. Next, the clusters in this data bank are examined by first principle methods to obtain the minimum energy cluster. The scheme is successfully applied to magic number 13 atom clusters of rhodium, palladium and silver. Global minimum energy cluster structures not previously reported are found through our procedure.

**U12 1 Physical Origin of Long-Range-Order in Lateral Development of Crystallites: A New Lateral Growth Mode.***
MU WANG, *Department of Physics, Nanjing University, Nanjing 210093, China*

The basic picture of heteroepitaxial growth can be summarized as formation of islands on a foreign substrate first, followed by horizontal expansion of the islands on the substrate. Previously little attention has been paid to how the interfacial tensions affect the horizontal expansion of a crystalline island over the substrate, which has recently been found to affect the physical property of thin film significantly. For example, tilting of crystallographic orientation has frequently been observed in epitaxial layers, and our understanding of such effect is very limited. Recently Wang and his colleagues studied lateral growth of $NH_4Cl$ crystallite on a foreign substrate mediated by successive nucleation. With state-of-the-art structural and morphological characterization methods, they observed that the crystallographic orientation is consecutively rotated, leading to periodic structures on the surface of crystallite aggregate. They demonstrated that this unusual effect is related to the asymmetric surface/interface tensions in the early stage of nucleation, and should be enlightening for a class of thin film growth where nucleation plays a dominate role. **U12 2 Steering induced growth anisotropy as a probe for long range interaction** FRITS RABBERING, TEUN WARNAAR, HERBERT WORMEESTER, BENE POELSEMA, *Solid State Physics, MESA+ Institute for Nanotechnology, University of Twente, Enschede, The Netherlands* Grazing incidence homoepitaxy of 0.5 ML on Cu(001) leads to anisotropic structures as determined with high-resolution LEED. This is the result of attractive forces between the surface and the incoming particle. The trajectory of an incoming particle changes so dramatically that a large deposition flux enhancement on protruding structures results [1]. Trajectory calculations based on an attractive Lennard-Jones potential were combined with a kMC simulation that treats the surface diffusions processes in order to investigate the evolution of the observed anisotropy. Modifications of this potential at short range distances only slightly influence the anisotropy, while modifications at long range has a significant influence on the anisotropy as observed during sub-monolayer growth. This enables to probe the long range interaction. The experimental feasibility of the detailed probing will be discussed. [1] S. van Dijken, L.C. Jorritsma and B. Poelsema, Phys. Rev. Lett. 82 4038 (1999)

**U12 3 Analysis of Chemical Reactions between Radical Growth Precursors Adsorbed on Plasma-Deposited Silicon Thin-Film Surfaces** TAMAS BAKOS, MAYUR VALIPA, DIMITRIOS MAROUDAS, *University of Massachusetts, Amherst* The dominant precursor in the plasma deposition of hydrogenated amorphous silicon (a-Si:H) thin films is the $SiH_3$ radical. In this presentation, we report results of first-principles density functional theory calculations on the crystalline Si(001)-(2× 1):H surface and molecular-dynamics simulations on a-Si:H surfaces for the interactions between $SiH_3$ radicals adsorbed on Si thin-film surfaces. The analysis reveals that two $SiH_3$ radicals may either form disilane ($Si_2H_6$) that desorbs from the surface or undergo a disproportionation reaction producing an $SiH_2$ radical that is incorporated in the film and a silane molecule that is released in the gas phase. The corresponding activation barriers depend on the local atomic coordination of the surface Si atoms; $Si_2H_6$ formation is barrierless if both radicals are bonded to overcoordinated surface Si atoms and exhibits barriers in excess of 1 eV for two chemisorbed $SiH_3$ radicals.

**U12 4 Controlling the periodicity of the Si(112)nx1-Ga surface via tuning of the chemical potential** E.J. MOON, *University of Tennessee, Knoxville, USA* P.C. SNIJDERS, *Kavli Institute of Nanoscience, Delft, The Netherlands* S. ROGGE, *Kavli Institute of Nanoscience, Delft, The Netherlands* H.H. WEITERING, *University of Tennessee, Knoxville, and Oak Ridge National Laboratory* We show that the chemical potential, an important parameter in the initial stages of (hetero-) epitaxial semiconductor growth, can be tuned for the Ga atoms on the Si(112)nx1-Ga surface. As a result the periodicity of the surface can be controlled in the range of n=5 to n=6. STM shows that meandering vacancy lines determine the local size of the unit cell. Large scale statistics of the unit cell size extracted from STM images show that the average periodicity n is not an integer, but lies somewhere in between 5 and 6. These findings are confirmed by a careful analysis of new LEED data, which show a range of periodicities in between 5x1 and 6x1 depending on the surface preparation conditions. The extracted periodicities are consistent with periodicities extracted from Fourier Transform STM images. Thus, changes of the chemical potential of the Ga atoms on the surface can be easily monitored in situe by extracting the average surface periodicity from LEED images.

**U12 5 Nanolithographic Write, Read and Erase via Reversible Nanotemplated Nanostructure Electrodeposition on Alkanethiol Modified Au(111) in an Aqueous Solution*** KYOUNGJA SEO, ERIC BORGUET, *Temple University* A Write, Read and Erase nanolithographic method, combining in-situ electrodeposition of metal nanostructures with atomic force microscopy (AFM) nanoshaving of a 1-hexadecanethiol (HDT) self-assembled monolayer (SAM) on Au(111) in an aqueous solution, is reported. The AFM tip defines the local positioning of nanotemplates via the irreversible removal HDT molecules. Nanotemplates with lateral dimensions as narrow as 25 nm are created. The electroactive nanotemplates determine the size, shape and position of the metal nanostructures. The potential applied to the substrate controls the amount of metal deposited and the kinetics of deposition. Metal nanostructures can be reversibly and repeatedly electrodeposited and stripped out of the nanotemplates by applying appropriate potentials.

**U12 6 Growth of Electrodeposited Ag Nanowires in Anionic Surfactant Nanotemplates on Au(111)*** ERIC BORGUET, *Temple University* KYOUNGJA SEO, *Temple University* TAO YE, *Pennsylvania State University* Ordered molecular systems should provide templates of molecular dimensions as demonstrated by the growth of silver nanostructures in the potential induced nanotemplates of SDS (sodium dodecyl sulfate). Electrochemical STM (Scanning Tunneling Microscopy) results suggest that SDS molecules form hemicylinders on the Au(111) surface in 0.1M $HClO_4$ solution. The hydrophilic sulfate groups self-assemble to face to the aqueous interface while the hydrophobic backbone adopts a tail to tail configuration. The SDS hemicylinders structures are stable over the potential range of -0.1 $V_{SCE}$ to 0.4 $V_{SCE}$. Silver electrodeposition takes place near the hydrophilic sulfate head, and leads to the formation of nanowires that grow in the same direction as the SDS hemicylinders. Ag nanowires are typically less than 2 nm wide.

**U12 7 A New Phase of the Au(111) Surface in Electrolyte Revealed by STM and Asymmetric Potential Pulse Perturbation.*** YUFAN HE, ERIC BORGUET, Asymmetric potential pulse perturbations were combined with STM to separately the $(22\times \sqrt{3}) \leftrightarrow (1\times 1)$ phase transition from the dynamics of the dynamics of nanoscale island growth and dissolution at Au(111)/ 0.1M $HClO_4$ interfaces. In the course of these experiments a new surface phase, characterized by a gas of highly mobile Au adatoms on the surface, the absence of islands and a paucity of reconstruction stripes, was observed. This phase coexists with a low density of reconstructed stripes in ''holes.'' This new phase is an inter-

mediate state and can only be observed over a potential range range from 0.3 $V_{SCE}$ to 0.45$V_{SCE}$, after a potential pulse lifting the reconstruction. In addition, and contrary to previous reports, the (1× 1) ◇ (22× $\sqrt{3}$) reconstruction process can be fast.

**U12 8 Observation of surface layering in a nonmetallic liquid** HAIDING MO, GUENNADI EVMENENKO, SUMIT KEWALRAMANI, KYUNGIL KIM, PULAK DUTTA, *Dept. of Physics & Astronomy, Northwestern University* STEVEN EHRLICH, *Brookhaven National Laboratory* Non-monotonic density profiles (layers) have previously been observed at the free surfaces of many metallic liquids, but not in isotropic dielectric liquids. Whether the presence of an electron gas is necessary for surface layering has been the subject of debate. Until recently, MD simulations have suggested that layering at free liquid interface may be a generic phenomenon and is not limited to the metallic liquids[1]. The theories predict that if normal liquids can be cooled down to temperatures low enough, layering structure should be observed experimentally. However, this is difficult for most molecular liquids because these liquids freeze well above the temperature necessary for observing the layering structure. By studying the surface structure of liquid TEHOS (tetrakis(2-ethylhexoxy)silane), which combines relatively low freezing point and high boiling point compared to that of most molecular liquids, we have observed the evidence of layering at the free interface of liquid TEHOS using x-ray reflectivity. When cooled to $T/T_c \approx 0.25$ (well above the bulk freezing point, Tc is the critical temperature of TEHOS), the surface roughness drops sharply and density oscillations appear near the surface. Lateral ordering of the surface layers is liquid-like, just as at liquid metal surfaces. 1. E. Chacón and P. Tarazona, Phys. Rev. Lett. **91** 166103-1 (2003)

**U12 9 Chemical Electrode Modification for Charge Injection in Organic Thin Film Transistors*** ELBA GOMAR-NADAL, DANIEL HINES, ANDREW TUNNELL, *Department of Physics, University of Maryland, College Park, MD 20742* WINSTON YAN, *T. Jefferson High School* ELLEN WILLIAMS, *Department of Physics, University of Maryland, College Park, MD 20742* The nature of the interface between an organic material and an inorganic electrode (metal or semiconductor) is critical to the performance of organic electronic and optoelectronic devises. To improve the electrical contact between gold electrodes and pentacene thin film transistors prepared by nanotransfer printing [1], the effect of coating the gold electrodes with self-assembled monolayers (SAMs) of organic molecules with electro-withdrawing groups is being explored. The first experiments have been done with commercially-available molecules and oligo(phenylene ethylene) derivatives have been synthesized for further investigation. The transport and noise characteristics of pentacene TFTs fabricated using the different coating groups will be presented. [1] D.R. Hines et al, Appl. Phys. Lett. 86, 163101 (2005).

**U12 10 Effects of Stress and Void-Void Interactions on Current-Driven Void Surface Evolution in Metallic Thin Films** JAESEOL CHO, M. RAUF GUNGOR, DIMITRIOS MAROUDAS, *University of Massachusetts, Amherst* We report results of electromigration- and stress-induced migration and morphological evolution of voids in metallic thin films based on self-consistent numerical simulations. The analysis reveals the complex nature of void-void interactions and their implications for the evolution of metallic thin-film electrical resistance, providing interpretation for experimental measurements in interconnect lines. Interestingly, for two voids migrating in the same direction under certain conditions, we find that a smaller void does not always approach and coalesce with a larger one, while a larger void may approach and coalesce with a smaller one. In addition, we find that under certain electromechanical conditions, biaxially applied mechanical stress can cause substantial retardation of void motion, as measured by the constant speed of electromigration-induced translation of morphologically stable voids. This effect suggests the possibility for complete inhibition of current-driven void motion under stress.

**U12 11 Characterization and Control of Microstructure in Combinatorially Prepared Aluminum-Silicon Thin Film Nanocomposites** DAAD HADDAD, *School of Materials Engineering, Purdue University, West Lafayette, IN 47907* CHARLES OLK, MICHAEL LUKITSCH, *Materials and Processes Laboratory, General Motors Research and Development Center, Warren, MI 48090* In this presentation, we describe the application of thin film combinatorial methods to systematically control the microstructure of $Al_xSi_{(1-x)}$ alloys through variations in composition and growth temperature. Libraries of compositionally graded films have been sputter deposited onto silicon substrates. The microstructure was investigated using x-ray diffraction while atomic force microscopy techniques were employed to obtain surface morphology and phase distribution. We will also report the results of the mechanical properties we have investigated on these films.

**10:36**

**U12 12 Mechanical Properties of Electrophoretically-Deposited CdSe Nanocrystal Films** SHENGGUO JIA, SARBAJIT BANERJEE, DONGYUN LEE, WEI WANG, JOZE BEVK, JEFFREY KYSAR, IRVING HERMAN, MATERIALS RESEARCH SCIENCE AND ENGINEERING CENTER, COLUMBIA UNIVERSITY, NEW YORK, NY TEAM, Approaches to measuring and then minimizing the strain in electrophoretically deposited CdSe nanocrystal films are investigated. The films are seen to fracture above a critical thickness which vaies with nanocrystal size. Cracking and delamination have been studied by SEM and AFM and are attributed to the high strain energy in the film. Raman microprobe scattering and EDX mapping show the strain distribution in the nanocrystal films. The Young's modulus measured by nanoindentation is in good agreement with the parameters obtained from Raman scattering. The deposition conditions have been varied to minimize this strain, which is thought to be due to the evaporation of residual hexane solvent after electrophoretic deposition. In situ observations confirm this assumption about the origin of film strain. Thermogravimetric analysis and differential scanning calorimetry measurements provide the chemical composition of CdSe nanocrystals. The CdSe nanocrystal films become mechanically stronger and more resistant to chemical dissolution after being treated by different cross-linker molecules. This work was supported primarily by the MRSEC Program of the National Science Foundation under Award No. DMR-0213574 and by the NYSTAR.

**10:48**
**U12 13 Characterization of electromigration in semiconductor device interconnects using microscopic techniques** NARAHARA DINGARI, DAVID HESKETT, *University of Rhode Island* Electromigration is an important failure mechanism which affects the functionality and lifetime of integrated circuits. The addition of relatively small amounts of copper has been previously shown to improve device interconnect lifetimes. Through the use of Scanning Electron Microscope (SEM) with Energy Dispersive Spectroscopic (EDS) capabilities we have measured the copper concentration as a function of position along an interconnect after several accelerated stress time periods. We observe a migration of copper atoms from the cathode to the anode side of the interconnect as a function of stressing time. In some cases, a pileup of copper near the middle of the interconnect indicates a blocking of copper diffusion and creates a site for interconnect failure. Metal pileup (hillocks) and depletion (voids) are observed by Atomic Force Microscopy (AFM). We also observe a correlation between relative reflectance using optical microscopy and roughness (observed by AFM) of an interconnect line.

**U16 1 Development of Carbon Nanotube Based Isotropic X-ray Source for Cone-Beam Tomography Imaging** ZEJIAN LIU, YUEH LEE, GUANG YANG, JIAN ZHANG, JIANPING LU, OTTO ZHOU, *University of North Carolina at Chapel Hill* We have developed a carbon nanotube based microfocus X-ray source with an isotropic focal spot. Two focusing electrodes were implemented in the design with one electrode harnessing the divergence of field-emitted electrons from gate and the other focusing electrons onto the anode. Isotropic X-ray focal spot was achieved by utilizing an elliptical cathode that forms elliptical electron probe on the anode after electrostatic focusing. Based on the design method, an x-ray source with an isotropic focal spot of 65 $\mu$m in diameter was experimentally demonstrated in X-ray projection images. This type of X-ray source sees wide applications in cone-beam tomography imaging studies.

**8:12**
**U16 2 Stationary scanning x-ray source based on carbon nanotube field emitters** GUANG YANG, JIAN ZHANG, *Department of Physics and Astronomy, University of North Carolina, Chapel Hill, NC 27599* YUAN CHENG, BO GAO, QI QIU, *Xintek, Inc. P.O. Box 13788, 7020 Kit Creek Rd., Research Triangle Park, NC 27709* YUEH LEE, JIANPING LU, OTTO ZHOU, *Department of Physics and Astronomy, University of North Carolina, Chapel Hill, NC 27599* Carbon nanotube is an ideal field emitter thanks to its large aspect ratio and small diameter. Based on its field emission property, we have developed a stationary scanning x-ray source, which can generate a scanning x-ray beam to image an object from multiple projection angles without mechanical motion. The key component of the device is a gated carbon nanotube field emission cathode with an array of electron emitting pixels that are individually addressable via a metal-oxide-semiconductor field effect transistor-based electronic circuit. The characteristics of this x-ray source are measured and its imaging capability is demonstrated. The device can potentially lead to a fast data acquisition rate for laminography and tomosynthesis.

**8:24**
**U16 3 A New Thermionic Cathode Using Oxide Coated Carbon Nanotubes*** CHRISTOPHER DAY, FENG JIN, YAN LIU, SCOTT LITTLE, *Ball State University* We have demonstrated a new type of thermionic cathode utilizing carbon nanotubes that exhibited superior electron emission properties. A field enhancement factor as high as 2000 was observed and thermionic electron emission current at least an order of magnitude higher than the emission from a conventional oxide cathode was obtained. This cathode combines the low work function of the oxide coating with a high field enhancement factor introduced by carbon nanotubes and we have demonstrated that it can be used as a highly efficient electron source. The cathode was fabricated by sputter deposition of a thin film of oxide materials on aligned carbon nanotubes, which were grown on a tungsten substrate with plasma enhanced chemical vapor deposition.

*This work is supported by the Department of Energy.

**8:36**
**U16 4 Selective Adsorption and Alignment Phenomena of ZnO Nanorods on Molecular-Patterned Substrates for Large-Scale Integrated Device Fabrication*** JUWAN KANG, SUNG MYUNG, SEUNGHUN HONG, *School of Physics Seoul National University* DONGJIN OH, GYUTAE KIM, *Korea University* ZnO nanorods have been utilized for various device applications such as field effect transistor, UV sensor, etc. However, a major stumbling block holding back their practical applications is a lack of mass-production method of such devices. Since ZnO nanorods are first synthesized in solution, one has to pick up and assemble individual nanorods onto substrate for device fabrication, which is not an easy task. We studied the selective assembly and alignment phenomena of ZnO nanorods on molecule-patterned solid substrates. When the molecule-patterned substrate is placed in the solution of ZnO, ZnO nanorods are selectively adsorbed onto negatively charged surface region. Furthermore, we found the adsorbed nanorods slide on the substrate resulting in aligned nanorod structures. This presentation will discuss the systematic study of ZnO nanorod assembly process on patterned substrates and applications of this method for large-scale assembly of ZnO nanorod-based integrated devices.

**8:48**
**U16 5 Atom selective force measurement with STM** APARNA DESHPANDE, *Ohio University* VIOLETA IANCU, *Ohio University* SAW-WAI HLA, *Ohio University* Scanning tunneling microscope (STM) manipulation and spectroscopy is used to determine the strength of interactions necessary to manipulate individual silver and bromine atoms on a Ag(111) surface at 4.6 K. In order to distinguish between the two types of atoms, we use local atom extraction procedures: bromine atoms are extracted from individual molecules of cobalt porphyrin (5,10,15,20-Tetrakis-(4-bromophenyl)-porphyrin-Co(II)), which are deposited prior to this

experiment, by selectively breaking the C-Br bonds with the STM tip. The individual silver atoms are extracted from the native Ag(111) surface by a controlled tip-crash procedure. Then, we laterally manipulate these two atoms using the same STM-tip along the close packed rows of the Ag(111) surface. The tip-height signals during manipulation are recorded as a function of the tip-atom distance, which include the force information necessary to move a halogen atom, bromine, and a metallic atom, silver, on this surface. This work is financially supported by US-DOE grant, DE-FG02-02ER46012.

**U16 6 Nanofabrication Based on Nanoporous Membranes** ZHEN WU, *Northeastern University* L. TIAN, *Texas Tech University* C. RICHTER, *Northeastern University* D NAGESHA, *Northeastern University* S. SRIDHAR, *Northeastern University* L. MENON, *Northeastern University* We describe nanofabrication methods to produce nanopore array templates in aluminum oxide and titanium dixode films. The method is based on anodization of thin films of aluminum and titanium under itdc conditions in an acid. We also describe non-lithographic means of transferring the pore pattern from such nanoporous membranes onto a generic substrate. This is based on reactive ion etching through the nanoporous template grown directly on the substrate. In our demonstration, a thin alumina template consisting of a hexagonal array of pores $\sim$ 50nm in diameter is first deposited on the substrate. The pores reach within 10-20 nm of aluminum, which is protected by an alumina barrier layer. By controlling reactive ion etching conditions, we demonstrate highly anisotropic etching through the aluminum layer, barrier alumina layer and into the substrate. The 50nm pore layer is thus directly transferred to create nanoporous and nanopillar arrays of a variety of materials such as Al, Si, GaN, GaAs, etc. Such nanoporous, nanopillar arrays will be useful in a variety of applications involving biosensors, optoelectronic and spintronic devices.

**9:12**

**U16 7 Resonant Operation of Nanoelectromechanical Systems in a Viscous Fluid** DEVREZ KARABACAK, KAMIL L. EKINCI, *Dept. of Aerospace and Mechanical Eng., Boston University* Up to date, most work on nanoelectromechanical systems (NEMS) has been done in high vacuum. Yet, many applications may require fluidic NEMS operation. Here, we present measurements of the quality ($Q$) factor and resonance frequency in nanomechanical doubly-clamped beam resonators as a function of surrounding gas pressure — from high vacuum to atmospheric conditions. Atmospheric $Q$s obtained are $\sim 10^2$. The experimental results also suggest that viscous effects become less severe in high frequency devices.

**9:24**

**U16 8 Experimental Measurement of Elastic Contact Diameter** CHARLES YING, *NIST* Manipulation of nano-objects, as well as further development of the MEMS technology, needs an understanding and control of surface forces, including friction and adhesion forces, which depend on contact area in the nanoscale. Meaningful measurements of surface forces and correct interpretation of the force data require knowledge of contact area. Due to experimental difficulties of contact area measurements, a common practice today in surface force research using atomic force microscopy (AFM) is to compute the contact area using the contact mechanics theories. In this talk, I will present a method of experimental determination of contact diameter, or contact width, between a diamond tip and a flat silicon surface. The experiments used diamond tips with their surface geometry determined by AFM imaging. The measured elastic contact widths for diamond tips with a spherical shape, under controlled magnitudes of force in the surface normal direction, agree with the Hertzian contact mechanism. The technique has also been used successfully to obtain contact widths for non-spherical tip geometry.

**U16 9 Preparation of different protected bimetallic nanoelectrodes with 30nm gapwidth and access window** STEPHAN KRONHOLZ, SILVIA KARTHÄUSER, RAINER WASER, *Center of Nanoelectronic Systems for Information Technology Research Center Jülich GmbH, 52425 Jülich, Germany* Reproducible fabrication of 30 nm metallic nanogaps on silicon chips and their electrochemical characterization are presented. The fabrication of the chip is a combination of an optical lithography step and two electron-beam (e-beam) steps. An optimized adhesion layer/metal layer combination (Ti/Pt/Au) and an adopted two layer e-beam resist are used. Specifically the chip has been covered with different protection layers, except of an access window located on top of the nanogaps, calibration electrodes and contact pads, respectively (Fig.1). After characterising the gaps and of the protection layer by cyclical voltammetry in 0.1 M $H_2SO_4$ aqueous electrolyte, the deposition of Cu onto the nanogaps will be presented. Fig.1: Different Nanoelectrode Structures with access window on top covered by $SiO_2/Si_3N_4/SiO_2$ used as protection layer.

**9:48**

**U16 10 Nanoscale metal thermometry using a radiofrequency single electron transistor** LOREN SWENSON, *University of California, Santa Barbara* DAVID WOOD, ANDREW CLELAND, We report on the development of single electron transistors for thermometric readout of nanoscale normal metal volumes. Due to the weak electron-phonon interaction at low temperatures, the electron gas in a normal metal can be heated to a temperature significantly greater than that of the surrounding lattice. Below 100 mK, the electron-phonon coupling time is on the order of microseconds to milliseconds, making direct measurements of the electron temperature's time dependence possible. Achieving sensitive and high frequency readout of this system is of critical importance for applications in nanocalorimetry and nanobolometry. We will describe the use of a radiofrequency single electron transistor to time-resolve the temperature of the electron gas in a submicron scale normal metal volume.

**10:00**

**U16 11 Electrothermal Tuning of Nanomechanical Resonators** MICHAEL MANOLIDIS, *Columbia University* SEONG CHAN JUN, X.M. HENRY HUANG, J. HONE, A highly effective electrothermal tuning method has been demonstrated for Al-SiC nanomechanical resonators. Doubly clamped beam devices are actuated and read out using a magnetomotive technique under moderate vacuum. DC current applied to a beam heats the structure and shifts the resonance frequency downward. Frequency shifts of 10 percent are easily achievable, and the thermal time constant of these structures is in the $\mu$s range. The initial frequency and frequency tunability are studied for beams of varying Al thickness, and the device performance can be accurately modeled using simple mechanical and thermal models. Because of the different mechanical properties of SiC and Al, both the initial frequency and the frequency tunability can be modified by varying

the Al layer thickness. This approach has the potential to become an important tool for effective frequency tuning in deployable SiC-based NEMS devices and systems for applications that would benefit from SiC as the structural material.

**10:12**
**U16 12 Resonant absorption in micrometer and nanometer absorbing particles*** ESHEL FARAGGI, BERNARD GERSTMAN, *Physics Department, Florida International University, Miami, Florida 33199* Resonance effects can occur in laser absorption by micrometer and nanometer sized particles when a train of pulses is used. The pressure generated by the train of pulses may be significantly different than the pressure generated by a single pulse with the same total energy. For pulsed lasers with a gap duration between pulses that is an integer multiple of the characteristic oscillation time of the absorber, constructive interference occurs and the pressure generated inside the absorber is approximately the same as that generated by a single laser pulse. For pulsed lasers with a gap duration between pulses that is not an integer multiple of the characteristic oscillation time, destructive interference occurs and the pressure is significantly decreased. We present numerical computations comparing this effect in two model systems: 1 micrometer melanosome and a 100 nm gold absorber. The resonance effects have implications for both damage thresholds and therapeutic applications of laser radiation.

**U16 13 Optical Trapping and Integration of Semiconductor Nanowire Assemblies in Water** ALEKSANDRA RADENOVIC, ELIANE TREPAGNIER, HARI SHROFF, JAN LIPHARDT, *UC Berkeley, Department of Physics* PETER PAUZAUSKIE, PEIDONG YANG, *UC Berkeley, Department of Chemistry* JAN LIPHARDT TEAM, PEIDONG YANG TEAM, The use of nanowires in scientific, biomedical, and microelectronic applications is greatly restricted due to a lack of methods to assemble nanowires into complex heterostructures with high spatial and angular precision. Here we show that an infrared single-beam optical trap can be used to individually trap, transfer, and assemble high-aspect-ratio semiconductor nanowires into arbitrary structures in a fluid environment. Nanowires with diameters as small as 20 nm and aspect ratios of above 100 can be trapped and transported in three dimensions, enabling the construction of nanowire architectures which may function as active photonic devices. Moreover, nanowire structures can now be assembled in physiological environments, offering novel forms of chemical, mechanical, and optical stimulation of living cells.

**10:36**
**U16 14 Low temperature internal friction peak in Boron doped nanocrystalline diamond** THOMAS METCALF, BRIAN HOUSTON, JAMES BUTLER, *Naval Research Laboratory* TATYANA FEYGELSON, *GeoCenters, Inc.* Recent measurements of the low-temperature internal friction ($Q^{-1}$) of nanocrystalline diamond films have revealed that these films have a broad but distinct internal friction peak at approximately 2K. In contrast to the off-peak baseline low-temperature $Q^{-1}$ of these films, which show no measureable variation over a factor of 4 span in amplitude, the $Q^{-1}$ at the peak decreases by as much as 60% when the measurement amplitude is increased by a factor of 4. The similarity of this peak with a low-temperature peak previously observed in boron-doped silicon led to the possibility that the peak is the result of boron contamination of the diamond films. To further investigate this, diamond films with varying degrees boron doping were grown and measured between room temperature and 400 mK. The films are typically 0.5 $\mu$m thick and are grown on silicon double paddle oscillator substrates, which have an extremely low internal friction background and enable highly sensitive measurements of the mechanical properties of thin films. Preliminary results show an upwards shift in temperature of the peak with increasing boron levels.

**U16 15 Microwave Dielectric Resonance and Negative Permittivity Behavior in $Al_2O_3$-CuO-Cu Nanocomposites*** JEFFREY CALAME, JACOB BATTAT, *Naval Research Laboratory, Washington DC 20375* The frequency-dependent microwave (0.1-18 GHz) complex permittivity of nanocomposites based on the $Al_2O_3$/CuO/Cu system is investigated. The composites are formed by solution infusion of copper precursors into a porous $Al_2O_3$ matrix, followed by thermal decomposition to copper oxides and localized formation of $CuAl_2O_4$ spinels, and finally partial reduction by $H_2$ firing. The final material has a complicated microstructure and exhibits strong amplitude, relatively narrowband dielectric resonance in the microwave regime at intermediate concentrations ( $\sim$ 15-18% by volume) of Cu. The resonances are superficially similar in structure to plasmon and Reststrahlen resonances typically seen in conductors at far-infrared to optical frequencies, but occurring at much lower frequencies in the composites. This is in contrast to the usual broadband induced-polarization dielectric relaxations observed in standard composites. Large concentrations of copper cause negative permittivity behavior below 6 GHz. Permittivity data, SEM micrographs, and possible explanations will be presented.

## SESSION U17: PHYSICS AND IMAGING IN MEDICINE
**Thursday Morning, 16 March 2006; 313, Baltimore Convention Center at 8:00**
**Steven Avery, University of Pennsylvania, presiding**

**8:00**
**U17 1 Careers in Medical Physics and the American Association of Physicists in Medicine.**
HOWARD AMOLS, *American Association of Physicists in Medicine*

The American Association of Physicists in Medicine (AAPM), a member society of the AIP is the largest professional society of medical physicists in the world with nearly 5700 members. Members operate in medical centers, university and community hospitals, research laboratories, industry, and private practice. Medical physics specialties include radiation

therapy physics, medical diagnostic and imaging physics, nuclear medicine physics, and medical radiation safety. The majority of AAPM members is based in hospital departments of radiation oncology or radiology and provide technical support for patient diagnosis and treatment in a clinical environment. Job functions include support of clinical care, calibration and quality assurance of medical devices such as linear accelerators for cancer therapy, CT, PET, MRI, and other diagnostic imaging devices, research, and teaching. Pathways into a career in medical physics require an advanced degree in medical physics, physics, engineering, or closely related field, plus clinical training in one or more medical physics specialties (radiation therapy physics, imaging physics, or radiation safety). Most clinically based medical physicists also obtain certification from the American Board of Radiology, and some states require licensure as well.

**U17 2 International Standardization of the Clinical Dosimetry of Beta Radiation Brachytherapy Sources: Progress of an ISO Standard.**
CHRISTOPHER SOARES, *National Institute of Standards and Technology*

In 2004 a new work item proposal (NWIP) was accepted by the International Organization for Standardization (ISO) Technical Committee 85 (TC85 – Nuclear Energy), Subcommittee 2 (Radiation Protection) for the development of a standard for the clinical dosimetry of beta radiation sources used for brachytherapy. To develop this standard, a new Working Group (WG 22 - Ionizing Radiation Dosimetry and Protocols in Medical Applications) was formed. The standard is based on the work of an ad-hoc working group initiated by the Dosimetry task group of the Deutsches Insitiut für Normung (DIN). Initially the work was geared mainly towards the needs of intravascular brachytherapy, but with the decline of this application, more focus has been placed on the challenges of accurate dosimetry for the concave eye plaques used to treat ocular melanoma. Guidance is given for dosimetry formalisms, reference data to be used, calibrations, measurement methods, modeling, uncertainty determinations, treatment planning and reporting, and clinical quality control. The document is currently undergoing review by the ISO member bodies for acceptance as a Committee Draft (CD) with publication of the final standard expected by 2007. There are opportunities for other ISO standards for medical dosimetry within the framework of WG22.

**U17 3 Scientific Programs and Funding Opportunities at the National Institute of Biomedical Imaging and Bioengineering.**
RICHARD BAIRD, *NIBIB, NIH*

The mission of the National Institute of Biomedical Imaging and Bioengineering (NIBIB) is to improve human health by promoting the development and translation of emerging technologies in biomedical imaging and bioengineering. To this end, NIBIB supports a coordinated agenda of research programs in advanced imaging technologies and engineering methods that enable fundamental biomedical discoveries across a broad spectrum of biological processes, disorders, and diseases and have significant potential for direct medical application. These research programs dramatically advance the Nation's healthcare by improving the detection, management and, ultimately, the prevention of disease. The research promoted and supported by NIBIB also is strongly synergistic with other NIH Institutes and Centers as well as across government agencies. This presentation will provide an overview of the scientific programs and funding opportunities supported by NIBIB, highlighting those that are of particular important to the field of medical physics.

**9:48**
**U17 4 Medical Physics Graduate Program At An HBCU.**
PAUL GUEYE, *Hampton University*

The Physics Department at Hampton University houses the first Medical Physics graduate program at a minority institution, and the first in the state of Virginia. Jointly established with the Eastern Virginia Medical School, the program requires students to take standard physics courses in addition to medical physics classes and clinical rotations performed at local hospitals. The associated medical physics research primarily focuses on detectors development for absolute 3D dose distribution measurements (with accuracy better than $\pm$ 100 microns), characterization of the uniformity or non-uniformity of Brachytherapy sources, and extraction of the 2D and 3D in-vivo dose maps for real time dose monitoring. Recent novel fundamental studies on the energy dependence of cancer cells to address, among others, mono-energetic Brachytherapy source treatments, reaction mechanisms associated with cancer cell destruction, and cancer genome identification have been launched. Each of the research conducted is strongly coupled to dedicated Geant4 Monte Carlo simulations. After presenting this unique medical physics program, we will review results obtained from its research group.

**U18 1 Electron Phonon Coupling Effects in Nanotubes.**
ANDREA C. FERRARI,* *University of Cambridge*

Electron-phonon coupling (EPC) is a key physical parameter in nanotubes. Here we discuss its effects on phonon dispersions, Raman spectra and electron transport. The main EPC effect on the phonon dispersions is the presence of Kohn anomalies. These are distinct features of the phonon dispersion in metallic systems, associated to the presence of a Fermi surface [1]. Graphite has two Kohn anomalies for the Gamma-$E_{2g}$ and K-$A'_1$ optical modes [2]. Their strength is proportional to the EPC square [2]. Kohn anomalies are enhanced in metallic nanotubes due to their reduced dimensionality, but absent in semiconducting nanotubes [2,3]. At 0 K all metallic nanotubes are not stable and undergo a Peierls distortion. We show that the Peierls distortion temperature decreases exponentially with the tube diameter [3]. For nanotubes generally used in experiments, with diameters larger than 0.8 nm, we find that this temperature is smaller than $10^{-8}$ K [3]. We then show that EPC is the major source of broadening for the Raman G and $G^-$ peaks in graphite and metallic nanotubes [3]. The EPC explains the difference in the Raman spectra of metallic and semiconducting nanotubes and their dependence on tube diameter [3]. We dismiss the common assignment of the $G^-$ peak in metallic nanotubes to a Fano resonance between phonons and plasmons. We assign the $G^+$ and $G^-$ peaks to TO (circumferential) and LO (axial) modes, the opposite of what often done. We then present five independent approaches to directly measure the optical phonons EPC in graphite and nanotubes from their phonon dispersions and Raman spectra. This allows us to quantify the EPC effects on high field electron transport in nanotubes. High field measurements show that electron scattering by optical phonons breaks the ballistic behavior. From our EPCs we derive a simple formula for the electron mean free path for optical phonon scattering in high-field transport [4]. The comparison with the scattering lengths fitted from experimental I-V curves shows that hot phonons are created during high-bias transport [4]. Their effective temperature is thousands K and sets the ultimate limit of ballistic transport [4].

**U18 2 Self-Heating and Non-Equilibrium Optical Phonons in Suspended Carbon Nanotubes** DAVID MANN, ERIC POP, JIEN CAO, HONGJIE DAI, *Stanford University* Understanding of current-limited transport in single-walled carbon nanotubes (SWNTs) is vital to many potential nanotube applications. In this talk I will discuss the high bias electrical transport characteristics of well-contacted suspended SWNTs in various environments. Negative differential conductance at low bias (below 0.4V) appears as a result of extreme self-heating and the formation of non-equilibrium optical phonons. Various gas and molecular solid environments lead to the reduction or elimination of the non-equilibrium phenomenon. Finally I will discuss the ways in which we can use the data to directly and indirectly measure the nanotube's intrinsic properties and temperature.

**U18 3 Direct measurements of electron-phonon coupling of radial breathing modes in carbon nanotubes and their chirality dependence** Y. YIN, A. WALSH, B.B. GOLDBERG, *Physics Department, Boston University* S.B. CRONIN, *Electrical Engineering Department, University of Southern California* M. TINKHAM, *Department of Physics, Harvard University* A.N. VAMIVAKAS, M.S. ÜNLÜ, A.K. SWAN, *Electrical and Computer Engineering, Boston University* A method for direct measurement of electron-phonon coupling matrix elements, $M_{e-ph}$, is proposed and demonstrated experimentally by correlating resonant Raman excitation profiles of the first and second harmonics of the radial breathing mode. $M_{e-ph}$ values are quantitatively determined for individual carbon nanotubes (CNT) excited in small ropes suspended in air. The results show that the matrix elements satisfy S. V. Goupalov and coworkers empirical tight binding theory calculation[1] with quantitative values that show a smaller electron-phonon coupling than reported from ab initio calculations[2] for isolated carbon nanotubes. We find that resonant excitation profile broadening $\eta$ for CNTs in small ropes show a correlation with chiral angles that appears to be unchanged from isolated carbon nanotubes. 1. S. V. Goupalov, Satishkumar B. C., and S. K. Doorn, Pre- print (2005). 2. M. Machon, S. Reich, H. Telg et al., Phys. Rev. B 71 (3) (2005).

**U18 4 Nonequilibrium phonon occupation in carbon nanotube quantum dots*** LUTFE SIDDIQUI, *School of Electrical and Computer Engineering, Purdue University, West Lafayette, IN 47907* AVIK GHOSH, *Department of Electrical and Computer Engineering, University of Virginia, Charlottesville, VA 22903* SUPRIYO DATTA, *School of Electrical and Computer Engineering, Purdue University, West Lafayette, IN 47907* We present a formalism for electron transport through a coulomb blockaded quantum dot strongly coupled with vibrations and weakly with leads and the thermal environment. By calculating the joint electron-phonon probability distribution, we show that recently observed anomalous conductivity through single-walled carbon nanotube (SWCNT) quantum dots arises from 'hot' phonons that are generated by the current at a faster rate than their extraction rate by the surrounding. We explain semi-quantitative details of the experiment and predict a nontrivial temperature dependence of the phonon population arising from a subtle interplay between phonon emission and absorption rates at specific bias voltage values.

**U18 5 Phonon scattering in Carbon Nanotube Field Effect Transistors – an NEGF Treatment.*** SIYURANGA KOSWATTA, SAYED HASAN, MARK LUNDSTROM, *Electrical and Computer Engineering, Purdue University* M.P. ANANTRAM, *NASA Ames Research Center* DMITRI NIKONOV, *Intel Corp.* We examine the influence of phonon scattering on DC current transport in carbon nanotube field-effect transistors using the non-equilibrium Green's function (NEGF) formalism. Both optical and acoustic phonon modes are considered, and electron-phonon interaction is modeled through a scattering self-energy. Intra-valley scattering due to longitudinal optical (LO) and radial breathing mode (RBM) phonons is examined. Zone-boundary phonon eigenmodes that mediate inter-valley scattering are found to be a mixture of fundamental polarizations such as LO/TA and to couple strongest to the electrons. The effect of phonon scattering on the current vs. voltage characteristic of a filed-effect transistor is found to have distinct gate voltage (Vg) dependence. High-energy optical phonons can significantly degrade the ON-current (large Vg) while their effect is negligible in the OFF-state (low Vg). On the other hand, low-energy phonons (acoustic and RBM) can considerably affect the current transport for all gate biases. Their influence is enhanced at low Vg due to the one-dimensional density of states.

**U18 7 Electrical Switching in Metallic Carbon Nanotubes*** HYOUNG JOON CHOI, *Institute of Physics and Applied Physics, Yonsei University, Seoul, Korea* YOUNG-WOO SON, *Department of Physics, University of California at Berkeley and Materials Sciences Division, LBNL* JISOON IHM, *School of Physics, Seoul National University, Seoul, Korea* MARVIN L. COHEN, STEVEN G. LOUIE, *Department of Physics, University of California at Berkeley and Materials Sciences Division, LBNL* We present first-principles calculations of quantum transport which show that the resistance of metallic carbon nanotubes can be changed dramatically with homogeneous transverse electric fields if the nanotubes have impurities or defects. The change of the resistance is predicted to range over more than two orders of magnitude with experimentally attainable electric fields. This novel property has its origin that backscattering of conduction electrons by impurities or defects in the nanotubes is strongly dependent on the strength and/or direction of the applied electric fields. We expect that this property will open a path to new device applications of metallic carbon nanotubes. Ref.) Young-Woo Son *et al.*, Phys. Rev. Lett. **95**, 216602 (2005).

**U18 8 High Temperature Conductivity and Reactivity of Carbon Nanotube Electronic Circuits*** A. KANE, PHILIP G. COLLINS, *University of California at Irvine* At sufficiently high temperatures, carbon nanotubes (CNTs) begin to react with their immediate environment. For example, adsorbates first desorb, then the carbon may react with connective electrodes, and ultimately Stone-Wales defects become mobile and can be annealed. These reactions are conventionally studied by thermogravimetric analysis (TGA), but they can also profoundly effect the conductance of the nanotubes. We have measured the four probe impedance and transimpedance of individual metallic and semiconducting nanotube devices from room temperature to 1200 K in ultra-high vacuum. When the nanotubes are initially heated from room temperature, the conductance increases as adsorbates are desorbed. On subsequent heating, the device resistance is linearly dependant on temperature over the range 300 to 900 K. Above 900 K the temperature dependence becomes more complex as chemical reactions change the nanotube and as optical phonon modes become thermally populated. This electronic characterization agrees with and complements TGA of bulk, purified CNTs.

**U18 9 On Current Carrying Capacity of Single Wall Semiconducting Carbon Nanotubes** YIJIAN OUYANG, YOUNGKI YOON, JING GUO, *Department of Electrical and Computer Engineering, University of Florida* The current carrying capacity of single wall semiconducting carbon nanotubes (CNTs) in the presence of phonon scattering and band-to-band tunneling is studied by self-consistently solving Poisson and Schrödinger equation using the non-equilibrium Green's function formalism. We show that the current delivery capacity of semiconducting CNTs strongly depends on the bias regime and is drastically different from metallic CNTs. A long metallic single wall CNT carries a saturation current of $\sim 25\mu$A due to optical phonon (OP) scatter-

ing. In contrast, a semiconducting CNT can deliver a current well above 25$\mu$A in ambipolar transport regime even when the channel length is much longer than the OP scattering mean free path (mfp). When the channel length is short (comparable to the OP scattering mfp), a semiconducting CNT biased in unipolar transport regime can deliver a current larger than 25$\mu$A. Biasing the CNT in ambipolar transport regime, however, further doubles the current. The different current carrying capacity in the ambipolar transport regime is due to nearly uncoupled dissipative transport through both the lowest conduction and valence subbands in the channel.

**10:12**

**U18 10 A comparison of measured electron-phonon and electron-photon coupling strengths in isolated and small ropes of single wall carbon nanotubes** B.B. GOLDBERG, Y. YIN, A. WALSH, *Physics Department, Boston University* S.B. CRONIN, *Electrical Engineering Department, University of Southern California* M. TINKHAM, *Department of Physics, Harvard University* A.N. VAMIVAKAS, M.S. ÜNLÜ, A.K. SWAN, *Electrical and Computer Engineering, Boston University* Resonant Raman scattering excitation profiles and photoluminescence (PL) are measured for isolated carbon nanotubes (CNT) and small ropes suspended in air. Most of the measured CNTs do not exhibit PL and are believed to be in small ropes. The radial breathing mode electron-phonon coupling, $M_{e-ph}$, are measured, and values for the isolated CNT are in good quantitative agreement with ab initio calculations. The matrix elements $M_{e-ph}$ and electron-photon coupling, $M_{e-op}$, for a CNT in a small rope are 1.7 times and 1.4-2.7 times weaker than in an isolated CNT. The reduced e-phonon coupling in small ropes is correlated with a smaller RRSE broadening $\eta$, compared to the value (45meV) obtained from an isolated CNT. Despite the reduced values of $M_{e-ph}$ and $\eta$, $M_{e-ph}$ in small ropes still display the same chiral dependence predicted for isolated CNTs.

**10:24**

**U18 11 Anharmonic decay of the Radial Breathing Mode in Suspended Single-walled Nanotubes** RAHUL RAO, *Dept. of Physics and Astronomy, Clemson University* JOSE MENENDEZ, *Dept. of Physics and Astronomy, Arizona State University* APPA-RAO RAO, *Dept. of Physics and Astronomy, Clemson University* The growth of isolated single-walled nanotubes (SWNTs) suspended over trenches in Si substrates makes it possible to study the Raman lineshapes of individual tubes. High-resolution room temperature resonant micro-Raman spectra from a number of suspended SWNTs exhibit very narrow radial breathing modes (RBMs), with full-width at half maximum (FWHM) values ranging from 1.3-2.5 $cm^{-1}$. These values are much smaller than previously reported in the literature. The observed FWHM is itnot a smooth function of the tube's radius. We note that the two-phonon density of states (2DOS) for the anharmonic decay of the RBM phonon shows many singularities whose energies depend both on the tube's radius itand chirality. Therefore, tubes with very similar RBM frequencies, and similar radii, could have different linewidths because of a different 2DOS. The observed linewidths increase with increasing incident laser power, as expected if the origin of the linewidth is anharmonic. We analyze the RBM linewidth in terms of down-conversion and up-conversion third-order anharmonic contributions. A comparison of the temperature dependence of both FWHM and peak frequency suggest that up-conversion processes are important, as found previously for low-frequency optical phonons in semiconductors.

**10:36**

**U18 12 Phonon anomalies in the resonance Raman spectra of graphite and single-wall carbon nanotubes** GEORGII G. SAMSONIDZE, HYUNGBIN SON, *Department of Electrical Engineering and Computer Science, MIT, Cambridge, MA* SHIN GRACE CHOU, *Department of Chemistry, MIT, Cambridge, MA* GENE DRESSELHAUS, *Francis Bitter Magnet Laboratory, MIT, Cambridge, MA* MILDRED S. DRESSELHAUS, *Department of Electrical Engineering and Computer Science and Department of Physics, MIT, Cambridge, MA* RIICHIRO SAITO, JIE JIANG, *Department of Physics, Tohoku University and CREST JST, Japan* EDUARDO B. BARROS, ANTONIO G. SOUZA FILHO, *Departamento de Fisica, Universidade Federal do Ceara, Fortaleza, CE, Brazil* Phonon dispersion relations for a graphene sheet and single-wall carbon nanotubes (SWNTs) are calculated within the extended tight-binding model that has recently been shown to accurately predict the optical transition energies in small-diameter SWNTs. Anomalies in the dispersion relations are found at certain high- symmetry points of the reciprocal lattice and these anomalies are attributed to the strong electron-phonon coupling. These anomalies are very sensitive to changes to electron and lattice temperatures, electron doping, mechanical stress, SWNT diameter, and SWNT metallicity. Resonance Raman measurements of doping and strain induced shifts of the phonon frequencies in SWNTs are in qualitative agreement with the present calculations. The MIT authors acknowledge support under NSF Grant DMR 04-05538.

**10:48**

**U18 13 Phonon stiffening in semiconducting single-walled carbon nanotubes under n-type doping** ELENA R. MARGINE, PAUL LAMMERT, VINCENT H. CRESPI, *The Pennsylvania State University* The doping dependence of the high-frequency Raman-active modes in single-walled semiconducting carbon nanotubes is studied by density functional theory. We find that the $A_{1g}$ longitudinal mode in $(3*n + 1,0)$ zigzag tubes shows a small anomalous upshift, followed by a large downshift under electron doping. This doping-induced stiffening of the $A_{1g}$ mode is related to the large anharmonicity of the mode. Connections are made to recent experiments in the group of P. C. Eklund.

## SESSION U19: FOCUS SESSION: SEMICONDUCTOR SPIN NANOSTRUCTURES FOR QUANTUM COMPUTING

**U19 1 Electron spin decoherence by interacting nuclear spins in quantum dot I: Quantum theory** WANG YAO, *Department of Physics, University of California, San Diego* R.-B. LIU, *Department of Physics, University of California, San Diego and Department of Physics, The Chinese University of Hong Kong* LU J. SHAM, *Department of Physics, University of California, San Diego* We present a quantum theory to the electron spin decoherence by a nuclear pair-correlation method for the electron-nuclear spin dynamics under a strong magnetic field and low temperature. The theory incorporates the electron nuclear hyperfine interaction, the

intrinsic nuclear interactions, and the nuclear coupling mediated by the hyperfine interaction with the electron in question. Results for both single electron spin free-induction decay (FID) and ensemble electron spin echo will be discussed. Single spin FID is affected by both the intrinsic and the hyperfine-mediated nuclear interactions, with the dominance determined by the dot size and external field. The spin echo eliminates the hyperfine-mediated decoherence but only reduces the decoherence by the intrinsic nuclear interactions. Thus, the decoherence times for FID and spin echo are significantly different. Electron spin decoherence is explained in terms of the quantum entanglement with the pair-flip excitations in the nuclear spin environment. This work was supported by NSF DMR- 0403465, NSA/ARO, and DARPA/AFOSR.

**8:12**

**U19 2 Electron spin decoherence by interacting nuclear spins in quantum dot II: Coherent control** REN-BAO LIU, *Department of Physics, University of California, San Diego, California and Department of Physics, The Chinese University of Hong Kong, Hong Kong* WANG YAO, LU J. SHAM, *Department of Physics, University of California, San Diego, California* Due to the hyperfine interaction, the nuclear spins in a quantum dot, driven by nuclear spin pair-wise flip-flops, evolve in different pathways in the Hilbert space for different electron spin states, resulting in the electron-nuclei entanglement and hence the electron spin decoherence. When the electron spin is flipped by a pulse, the nuclear spin states for different electron spin states swap their pathways, and could intersect in the Hilbert space, which disentangles the electron and the nuclei and hence restores the electron spin coherence. The coherence restoration by disentanglement and the conventional spin echo in ensemble dynamics are fundamentally different and generally occur at different time. Pulse sequences can be applied to force the disentanglement to coincide with the spin echo, making the coherence recovery observable in ensemble dynamics. This work was supported by NSF DMR-0403465, NSA/ARO, and DARPA/AFOSR.

**8:24**

**U19 3 Analytical Solution of Electron Spin Decoherence Through Hyperfine Interaction in a Quantum Dot** CHANGXUE DENG, XUEDONG HU, *State University of New York at Buffalo* We analytically solve the *Non-Markovian* single electron spin dynamics due to hyperfine interaction with surrounding nuclei in a quantum dot. We use the equation-of-motion method assisted with a large field expansion, and find that virtual nuclear spin flip-flops mediated by the electron contribute significantly to a complete decoherence of transverse electron spin correlation function. Our results show that a 90% nuclear polarization can enhance the electron spin $T_2$ time by almost two orders of magnitude. In the long time limit, the electron spin correlation function has a non-exponential $1/t^2$ decay in the presence of both polarized and unpolarized nuclei.

**8:36**

**U19 4 Quantum dot dynamical Quantum dot dynamical nuclear spin polarization in the** C.W. LAI, P. MALETINSKY, A. BADOLATO, A. IMAMOGLU, *ETH Zurich* Hyperfine interaction in quantum dots (QD) is qualitatively different than in atoms: coupling of a single electron spin to the otherwise well isolated QD nuclear spins plays a key role in spin-based solid-state quantum information processing. Dynamical nuclear spin polarization (DNSP) is observed by resonant optical pumping of single self-assembled QDs in gated structures that allow deterministic charging with a single excess electron or hole. In the absence of external magnetic fields, the optically polarized electron spin induces an effective inhomogeneous magnetic (Knight) field which determines the direction along which the mesoscopic ensemble of nuclear spins could polarize and enables nuclear spin cooling by surpassing depolarization induced by nuclear dipolar interactions. Due to the effective magnetic (Overhauser) field induced by the polarized nuclei, photoluminescence of these charged trion transitions exhibit spin splitting $\approx 15\mu eV$ which can be determined by high-spectral-resolution ( $< 1\mu eV$) spectroscopy based on a scanning Fabry-Perot interferometer. Our experiments constitute a first step towards a quantum measurement of the Overhauser field, which is in turn predicted to suppress electron spin decoherence in QDs.

**8:48**

**U19 5 Dynamical nuclear spin polarization in a double quantum dot*** GUY RAMON, CHANGXUE DENG, XUEDONG HU, *Department of Physics, University of Buffalo, SUNY* The hyperfine interaction between an electron spin confined in a semiconductor quantum dot and the nuclear spins in the surrounding lattice has been identified as one of the main sources for decoherence in low temperature GaAs quantum dots. Recent experiments in gated double dot systems [1] have attempted to utilize the degeneracy point between the two-electron singlet and polarized triplet states to polarize the nuclear spins, thereby reducing their decoherence effects on the electron spins. Here we analyze the dynamics of the system of two electrons and a nuclear spin bath subject to the hyperfine interaction. We consider the effective spin Hamiltonian for the two-electron system, and represent the nuclear spins in the basis of their collective states. The nuclear polarization rates are evaluated for various initial conditions of the nuclear spin system, and optimal conditions for efficient polarization are discussed. [1] J. R. Petta, A. C. Johnson, J. M. Taylor, E. A. Laird, A. Yacoby, M. D. Lukin, C. M. Marcus, M. P. Hanson, A. C. Gossard, Science 309, 2180 (2005).

**U19 6 Coherent Control of Entangled Spin Pairs in a CdMnTe Quantum Well.** PAUL JACOBS, ROBERTO MERLIN, *University of Michigan* JACEK FURDYNA, *University of Notre Dame* We used ultrafast light pulses to control the spin state of electrons bound to donors in a CdMnTe quantum well. Previously, we reported on the observation of up to three harmonics of the bound electron spin flip transition indicating that at least three bound electron sites were entangled (J.M. Bao, A.V. Bragas, J.K. Furdyna, R. Merlin, Phys. Rev. B 71 045314 (2005)). Using a pulse shaper, we are now able to suppress all coherent oscillations, but the signal of the first spin flip overtone. Therefore, only entangled electron pairs remain oscillating; all non-entangled donor bound electrons have been restored to their ground state. The quantum state of the remaining entangled electron spins is closely related to the Bell state. This technique holds promise for quantum computing applications.

**U19 7 Electron-spin quantum computation: Three- and four-body interactions and other implementation challenges.***
ARI MIZEL, *Pennsylvania State University*

Several leading quantum computer proposals are based upon electron spins. While these designs do potentially satisfy the DiVincenzo criteria, subtle implementation challenges have been uncovered that need to be addressed if these designs are to be realized successfully. In this talk, we start by pointing out that, when several spins are engaged mutually in pairwise interactions, a change can arise in those interactions. In the case of three spins, the quantitative strengths of the interactions can change. For four or more spins, qualitatively new terms can arise in the Hamiltonian, including four-body interactions. Other implementation challenges are also considered, including the difficulty of performing strong projective measurements on solid state qubits (weak measurements are generally more natural to implement but their behavior is more subtle). These issues will need to be handled in quantum computer realizations, either as a source of error to be overcome or as new physics to be exploited.

**U19 8 Transport of Quantum Information Using Spin Wires*** VANITA SRINIVASA, *University of Pittsburgh* JEREMY LEVY, *University of Pittsburgh* C. STEPHEN HELLBERG, *Naval Research Laboratory* COSMQC TEAM, One-dimensional antiferromagnetically coupled spin systems have properties that make them useful as conduits for quantum information (PRL **90**, 047901 (2003)). Here we investigate possible mechanisms for using engineered spin chains as ''spin wires'' that can faithfully transport qubits. An analysis of the spin chains is carried out through numerical diagonalization of the effective spin Hamiltonian. We find that dimerized chains with a defect can support a highly localized qubit. We also demonstrate how it may be possible to propagate these kinks rapidly through a large system, thus providing a mechanism for producing''flying'' spin qubits in the solid state.

**U19 9 GHz Optical Spin Transceiver*** PATRICK IRVIN, PETRU FODOR, JEREMY LEVY, *University of Pittsburgh* COSMQC TEAM, The ability to measure spin coherence in semiconductor nanostructures is important for determining the feasibility of spin-based quantum computing architectures. Quantum dots are often referred to as 'solid-state atoms' because of their sharp absorption and emission lines that resemble those of single atoms. Electron spins localized on these quantum dots may be useful for storing quantum information, but their small optical cross section makes detection challenging. In order to take advantage of resonant enhancement of spin detection using the magneto-optical Kerr effect, we have developed a GHz Optical Spin Transceiver (GHOST) which uses a cw optical probe to measure Kerr signals in the time domain with 5 GHz bandwidth. Initial results will be presented for a test sample consisting of n-doped GaAs.

*This work was supported by DARPA QuIST through ARO contract number DAAD-19-01-1-0650.

**U19 10 Photocurrent spectroscopy of self−assembled quantum dots.*** PETRU FODOR, JEREMY LEVY, *University of Pittsburgh* GILBERTO MEDEIROS-RIBEIRO, *Laboratorio Nacional de Luz Sincrotron* COSMQC TEAM, Quantum dots systems had been envisioned as possible candidates for building the hardware of quantum computers. They provide the necessary localization of electrons on length scales comparable to the electron Fermi wavelength and also exhibit distinct discrete energy spectra due to quantum confinement. Nevertheless, the characterization of optical and coherence properties of single quantum dots, especially at wavelengths larger than 1100 nm, is challenging due to the small SNR in these systems and the lack of high quantum efficiency detectors at these wavelengths. To circumvent these challenges, we use photocurrent measurements as a probe of the absorption spectra of quantum dots systems embedded in Schottky diode structures. The use of spectrally narrow laser sources allows the exciton absorption spectra of single quantum dots to be characterized as a function of temperature and magnetic field.

**U19 11 Spin dynamics in coupled core/shell quantum dots*** J. BEREZOVSKY, M. OUYANG, F. MEIER, D. D. AWSCHALOM, *Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106* D. BATTAGLIA, X. PENG, *Department of Chemistry and Biochemistry, University of Arkansas, Fayetteville, AR 72701* Colloidal nanoparticles provide a flexible system for studying individual quantum-confined electrons and holes. By layering different semiconducting materials in a single nanoparticle, we can create a low bandgap (CdSe) core and surrounding shell, separated by a high bandgap (ZnS) barrier. We have studied spin dynamics in such colloidal heterostructures using two-color time-resolved Faraday rotation (TRFR). By tuning the excitation energy, electron spins can be initialized into different states either in the core or the shell of the nanoparticle. The resulting spin dynamics show a g-factor (spin splitting) that depends on the size of the core or the shell. This g-factor dependence, as well as the spectroscopic dependence of the Faraday

effect, allow electron spins in the core or the shell to be addressed independently.

**U19 12 Spin Manipulation in lateral quantum dots under time-dependent confinement.*** JAMIE WALLS, ERIC HELLER, *Harvard University* Single spin manipulations are a critical component to potential realizations of spintronic devices and quantum computers in lateral quantum dots. In this work, we demonstrate a new method for creating spin excitations in lateral quantum dots which uses the interplay between the spin-orbit interaction and a time-dependent lateral confining potential. For an asymmetric dot in the presence of an in-plane magnetic field, the spin quantization axis can be tilted away from the applied magnetic field due to the Rashba spin-orbit coupling, with the degree of tilting depending parametrically upon the confinement potential. By making small modulations to the confinement potential at a frequency given roughly by the Zeeman splitting, efficient spin excitations can be performed. We have performed theoretical and numerical calculations which demonstrate that Rabi frequencies on the order of tens of megahertz can be achieved for experimentally accessible parameters. Extensions to spin excitations in multi-electron quantum dots will also be presented.

**U19 13 Effect of photon-assisted tunneling through the leads on spin current polarization in ac-driven quantum dot molecules*** ERNESTO COTA, *Universidad Nacional Autonoma de Mexico* RAFAEL SANCHEZ, RAMON AGUADO, GLORIA PLATERO, *Instituto de Ciencia de Materiales de Madrid-CSIC* A new scheme for realizing spin pumping and spin filtering has been recently proposed using an ac-driven double quantum dot in the Coulomb blockade regime. Using a master equation approach for the density matrix, it was shown[1] that the spin polarization of the current through the system can be controlled by tuning the parameters (amplitude and frequency) of the ac-field. In the present work we extend our previous model to include photon-assisted tunneling through the contact barriers. This introduces new features in the current due to absorption and emission processes affecting the spin polarization of the current. We discuss these new features, their dependence on the ac-field parameters and the effects on the robustness of the proposed device as a spin pump and spin filter. In particular, we find that the spin filtering property depends strongly on the intensity of the applied ac field. The effect of photoassisted cotunneling on the spin current polarization will also be discussed. [1]E.Cota, R. Aguado and G. Platero, Phys. Rev. Lett. **94**, 107202 (2005)

**U20 1 'CMR' Manganites: Strongly or Weakly Correlated?*** ANDREW MILLIS, SATOSHI OKAMOTO, A newly developed ''semiclassical impurity solver'' [1] is used to perform dynamical mean field calculations of the kinetic energy, optical conductivity and magnetic transition temperature of the two-orbital double-exchange model for colossal magnetoresistance manganites, including the full Kanamori ($U - U' - J$) interactions for the $e_g$ multiplet as well as the $e_g - t_{2g}$ Hunds coupling $J_H$. The effective correlation strength is shown to be weak in the ferromagnetic ground state, while in the high temperature paramagnetic state the multiplet interactions block many of the possible final states, leading to an effectively strongly correlated situation characterized by a large effective $J_H$. **U20 2 Resistivity peak in the one-band double-exchange model with cooperative phonons** CENGIZ SEN, *National High Magnetic Field Laboratory and Department of Physics, Florida State University, Tallahassee, FL* GONZALO ALVAREZ, HORACIO ALIAGA, *Oak Ridge National Laboratory, Oak Ridge, TN* ELBIO DAGOTTO, *Oak Ridge National Laboratory, Oak Ridge, TN and Department of Physics, University of Tennessee, Knoxville, TN* We present the results of Monte Carlo simulations of a single-band double-exchange model with cooperative phonons, both with and without quenched disorder, at a carrier density $n=0.3$. Both in two and three dimensions, the simulations reveal a peak in the resistivity at $T_{\mathrm{Curie}}$, in agreement with previous studies by other groups. The peak gets destroyed upon the application of an external field, resulting in a large magnetoresistance. The results are in good agreement with experiments involving CMR manganites. Studies at other densities are also presented, and an intuitive picture for the presence of the resistivity peak is discussed.

**U20 3 Exchange Striction and Heat Conduction in $Ca_{1-y}Sr_yMnO_3$ ($0 \leq y \leq 0.5$)*** JOSHUA COHN, *University of Miami* CORNELIU CHIORESCU, *University of Miami* JOHN NEUMEIER, *Montana State University* $CaMnO_3$, a G-type antiferromagnet with orthorhombic structure, exhibits a substantial enhancement of its thermal conductivity[a,b] ($\kappa$) for $T < T_N = 125$ K associated with exchange striction, the spin-phonon interactions for which are not well understood. One possibility[a] is that this enhancement results from a suppression, in the ordered state, of phonon scattering from bond disorder induced by magnetic fluctuations in the paramagnetic state. The homovalent substitution of Sr for Ca in the $Ca_{1-y}Sr_yMnO_3$ compounds increases the Mn-O-Mn bond angle without changing the crystal structure, and $T_N$ rises[c] to $\sim$ 165 K for $y = 0.5$. We present measurements demonstrating that the enhancement of $\kappa$ is gradually suppressed

as $y$ increases, disappearing for $y \simeq 0.5$. The implication of these results for the origin of the enhancement will be discussed. [a] J.-S. Zhou and J. B. Goodenough, Phys. Rev. B **66**, 052401 (2002). [b] J. L. Cohn and J. J. Neumeier, Phys. Rev. B **66**, 100404(R) (2002). [c] O. Chmaissem *et al.*, Phys. Rev. B **64**, 134412 (2001).

**U20 4 Strong current dependence of resistivity in $CaMnO_3$*** CORNELIU CHIORESCU, *University of Miami* JOHN NEUMEIER, *Montana State University* JOSHUA COHN, *University of Miami* The perovskite manganite $CaMnO_3$ (CMO) has a G-type antiferromagnetic ground state with Néel temperature $T_N = 125$K. Prior transport measurements in the magnetic and paramagnetic phases[a] establish that CMO is a $n$-type semiconductor with $n \sim 10^{18} - 10^{19}\text{cm}^{-3}$ (from native defects like oxygen vacancies) and modestly heavy (large- polaron) mass, $m^* \sim 10m_0$. Here we report transport measurements on single crystal and polycrystalline CMO which reveal a strong current dependence of the resistivity ($\rho$) at low temperatures where $\rho > 10^6\Omega$cm and impurity-band conduction predominates. For example, at 30 K, $\rho$ decreases by an order of magnitude for small current densities ($J < 100\mu\text{A/cm}^2$), indicating that the effect is not associated with Joule heating. The possible role of spin-polarized hopping in this phenomenon will be discussed. [a] J. L. Cohn, C. Chiorescu, and J. J. Neumeier, Phys. Rev. B **72**, 024422 (2005).

**U20 5 On the nature of the pressure-induced insulator-to-metal transition in $LaMnO_3$** ATSUSHI YAMASAKI, *Max-Planck-Institut für Festkörperforschung* MARTIN FELDBACHER, *Max-Planck-Institut für Festkörperforschung and Department of Physics and Astronomy, Rutgers University* OLE K. ANDERSEN, KARSTEN HELD, *Max-Planck-Institut für Festkörperforschung* Since the discovery of colossal magnetoresistance, manganites have been intensively studied. We focus on the pressure induced insulator-to-metal (IM) transition which was found experimentally [1] in the undoped parent compound $LaMnO_3$ with configuration $t_{2g}^3 e_g^1$. This transition occurs at room temperature (above $T_N = 140$ K) and at a hydrostatic pressure of 32 GPa where the Jahn-Teller distortion appears to be completely suppressed [1]. The IM transition thus seems to be a bandwidth-driven Mott-Hubbard transition of the $e_g$ electrons. We employ the local density approximation combined with static and dynamical mean-field theories (LDA+$U$ and LDA+DMFT) and conclude that the IM transition observed at 32 GPa in paramagnetic $LaMnO_3$ at room temperature is *not* a Mott transition, but is caused by the overlap of the majority-spin $e_g$ bands, orbitally polarized by the Coulomb repulsion. Crucial are also the bandwidth reduction of $\sim 0.6$ and 2/3 arising from, respectively, the gap generated by the crystal-field splitting and the random, spatially uncorrelated direction of the $t_{2g}$ spin at room temperature. [1] I. Loa *et al.*, Phys. Rev. Lett. **87**, 125501 (2001).

**U20 6 Double-exchange driven metal-insulating transition in Mn-doped CuO** ALESSIO FILIPPETTI, VINCENZO FIORENTINI, *SLACS and Physics Dept., University of Cagliari, Italy* Doping antiferromagnetic CuO with Mn causes a uncommon metal-insulating transition where the low-temperature ($T < T_c = 80$ K) phase is ferromagnetic, with a large but metallic-like resistivity, while the high-temperature phase is paramagnetic and insulating, but with a resistivity typical of Mott insulators in the hopping conducting regime. Applying a first-principles, self-interaction corrected local spin density approach, we are able to understand and rationalize this puzzling behavior: each doping Mn in CuO acts as a single donor, inducing a double-exchange driven metallic regime and a Mn-Mn ferromagnetic allignement. Nicely, here double-exchange can also work at rather low Mn concentrations since carriers can freely flow within the CuO (x,y) planes and only need the Mn assistance to move through the c axis. In the antiferromagnetic phase the system is insulating, but a polaron hopping conductivity through a few meV-wide Coulomb gap is envisaged. This scenario depicts the intriguing possibility of designing double-exchange driven ferromagnetic cuprates.

**U20 7 Computational Studies of Magnetoresistance in Double-Exchange-Based Models for Manganites.*** GONZALO ALVAREZ, *Computer Science and Mathematics Division, Oak Ridge National Laboratory*

Double-exchange-based models for manganites are studied using Monte Carlo techniques, with both exact-diagonalization and polynomial-expansion of the fermionic sector. One and two- orbital models are investigated, with and without phonons. We focus our analysis on the study of the resistance (R) vs. temperature (T) using the Landauer formalism. Highlights of investigations by our group and others are: (1) R vs. T curves, parametric with magnetic fields, that closely resemble experimental data for the case of one orbital and considering cooperative phonons; and (2) an insulator to bad metal transition induced by quenched disorder for the two-orbital model. In spite of these positive results, we remark that this is just the beginning of a frontal attack to the manganite problem using realistic models and efficient algorithms that scale linearly with the lattice volume. Future directions and open problems will also be discussed.

**U20 8 Neutron Scattering Study of Electron- Phonon Coupling in $La_{1/3}Sr_{2/3}FeO_{3-\sigma}$ Perovskite** J. MA, J.-Q. YAN, S. CHANG, R. J. MCQUEENEY, *Ames Lab., Dept. of Phys. and Astro., Iowa State U., Ames, IA 50011* F. TROUW, M. HEHLEN, *Los Alamos National Laboratory, Los Alamos, NM 87545* $La_{1/3}Sr_{2/3}FeO_{3-\delta}$ compounds are reported to have an unusual magneto-structural transition at low temperatures. Below $\sim 210K$, it is proposed that charge disproportionation occurs according to $2Fe^{4+} => Fe^{3+}+Fe^{5+}$, thereby creating different valence on the iron sites. The different iron valences order along the body diagonal $[111]_c$, resulting in a change in crystal structure from rhombohedral to orthorhombic and antiferromagnetic ordering. Inelastic neutron scattering was used to determine the effect of simultaneous charge and magnetic ordering on the phonon and spin wave excitations. We find that the high frequency oxygen phonons ( $\sim$ 80 meV) soften above the transition by several meV. Spin wave excitations appear below the transition with a characteristic energy of 50 meV at the Brillouin zone boundary. The result and relationship between the charge ordering and the electron-phonon interaction are discussed.

**U20 9 Magnetic polarons in a one-dimensional antiferromagnetic chain** I. GONZALEZ, *Oak Ridge National Lab., USA* J. CASTRO, D. BALDOMIR, *Universidade de Santiago de Compostela, Spain* A.O. SBOYCHAKOV, A.L. RAKHMANOV, K.I. KUGEL, *Institute for Theoretical and Applied Electrodynamics, Russia* We present several results concerning magnetic polarons in a double-exchange system. We use a simplified model consisting on an antiferromagnetic (AF) chain doped with donor impurities. First, we study the ''back-effect'' in the AF background of a conduction electron bound to its donor impurity. We show that a region with extended spin distortions appear in the AF structure, similar to a domain wall and stabilizing the magnetic polaron. Second, we discuss the effect of these distortions in a system doped with a finite density of donor impurities. We show that from a critical density a non-trivial energy dependence on conduction electrons density appears, which can be interpreted as an attractive interaction between magnetic polarons. Third, we analyze temperature evolution of such a system of magnetic polarons. We show that they remain stable up to rather high temperatures, larger than the Néel temperature of the undoped chain. Our results may be relevant to understand the physics of low-doped manganites.

**U20 10 Zener Polarons Ordering Variants Induced by A-Site Ordering in Half-Doped Manganites** AZIZ DAOUD-ALADINE, *ISIS Department, Rutherford Appleton Laboratories, Chilton, Didcot, Oxfordshire OX11 0QX, UK* CRISTIAN PERCA TEAM, LOREYNNE PINSARD-GAUDART TEAM, JUAN RODRIGUEZ-CARVAJAL TEAM, Zener Polaron (ZP) ordering [1] provides a still polemic [2] and elusive interpretation of the charge ordering (CO) phenomenon in A site disordered half doped $(A_{1/2}Ca_{1/2})$ $MnO_3$, which is classically pictured by the Good-enough model (GM) of $Mn^{3+}$ and $Mn^{4+}$ CO [3,4]. ZP ordering considers instead the ordering of pre-formed ferromagnetic Mn pairs sharing an charge and keeping Mn in a $Mn^{+3.5}$ valence state. The recently synthesized A site cation ordered $ABaMn_2O_6$ were shown to not present the generic magnetic CE state found of $(A_{1/2}Ca_{1/2})MnO_3$ [5]. We present our magnetic structure determination of $YBaMn_2O_6$: the non- collinear magnetic order obtained unexpectedly reveals ferromagnetic plaquettes of four Mn attributable to larger 4-Mn ZPs, whose presence additionally fits very well the effective paramagnetic moments inferred from susceptibility measurements. The results unambiguously reveal the possible existence of ZP ordering variant in charge ordered manganites. [1] A. Daoud-Aladine et al., Phys. Rev. Lett. 89, 097205 (2002) [2] S. **U20 11 Evolution of the local Jahn-Teller distortion across the phase diagram of $La_{1-x}Ca_xMnO_3$ ($0 \leq x \leq 0.5$)** EMIL BOZIN, GIANLUCA PAGLIA, ADAM DECONINCK, SIMON BILLINGE, *Dept. of Physics and Astronomy, Michigan State University* MAREK SCHMIDT, PAOLO RADAELLI, *ISIS, Rutherford Appleton Laboratory* JOHN MITCHELL, *Material Science Division, Argonne National Laboratory* THOMAS PROFFEN, *LANSCE, Los Alamos National Laboratory* We report on the most comprehensive study to date of the *local* Jahn-Teller (JT) distortion across the phase diagram of the colossal magnetoresistive (CMR) $La_{1-x}Ca_xMnO_3$ ($0 \leq x \leq 0.5$). The local structure has been measured, using the neutron powder diffraction based atomic pair distribution function (PDF) approach, over the wide temperature and Ca-doping range. These results are compared to the conventional crystallographic results obtained by Rietveld analysis. The results will be compared with both homogeneous and inhomogeneous models of the electronic structure. The magnitude of the *local* JT distortion is quantified over the entire phase diagram. In agreement with earlier work, we see the local JT distortion disappear in the metallic phase. However, in contrast with some earlier studies, we show that in the insulating phases the magnitude of the JT distortion decreases with increasing doping, becoming constant at higher doping. This new result should be incorporated in theoretical models of CMR manganites.

**10:36**

**U20 12 Structural and Transport Study of $La_{0.9}MnO_3$ Under Pressure.** ZHIQIANG CHEN, TREVOR TYSON, *Department of Physics, New Jersey Institute of Technology, Newark, New Jersey 07102* ZHONG ZHONG, *National Synchrotron Light Source, Brookhaven National Laboratory* The detailed transport and structural properties of the self-doped system $La_{0.9}MnO_3$ have been studied under hydrostatic pressures extending to 6GPa and 11GPa, respectively. Like the doped manganite systems previously studied by our group, in the La deficiency (x=0.9) system a maximum shift of the peak resistivity is obtained at around 3.4GPa. A crossover from metallic to insulating behavior is observed above this optimum pressure. The x-ray diffraction study results show that the self-doped system is compatible with a single phase of monoclinic space group up to 11 GPa. The detailed changes in the lattice parameters, volume, bond distances and bond angles have been obtained. Comparisons with pressure dependent measurements on the doped manganites will be made. This work was supported by NSF DMR-0209243 and DMR-0512196.

**U20 13 A quantum phase transition in the monoxides of the first transition series** FRANCISCO RIVADULLA, *Dpto. Química-Física, Universidad de Santiago de Compostela* JOAQUÍN FERNÁNDEZ-ROSSIER, *Dpto. Física Aplicada, Universidad de Alicante* MAR GARCÍA-HERNÁNDEZ, *ICMM, CSIC, Madrid, Spain* JOSÉ RIVAS, *Dpto. Física Aplicada, Universidad de Santiago de Compostela* JOHN GOODENOUGH, *TMI, University of Texas at Austin, Austin TX, USA* The monoxides of the 3d metals (MO; M= Ti to Ni) provide an isostructural series (cubic, Fm $\bar{3}$m) in which to study the transition from metallic paramagnetism (TiO) to insulating antiferromagnetism (MnO, FeO, CoO, NiO). But the transition is not smooth, and while CrO has eluded synthesis over the years, the intrinsic properties of VO are under discussion. Here we present strong experimental and computational evidence that VO is a strongly correlated metal with Non-Fermi Liquid low temperature thermodynamics, a pseudogap in the density of states and an unusually strong spin-lattice coupling. All these properties are interpreted as signatures of the proximity to a magnetic quantum phase transition. Interestingly, TiOx displays a superconducting transition with a dome-shape dependence of the superconducting critical temperature with doping in x ($0.8 < x < 1.2$). The analogies with the phase diagram of the High Tc cuprates and their structural and electronic simplicity makes 3d monoxides ideal candidates to make progress in the understanding of correlated electron systems.

**U21 1 Aggregation in Two Dye Systems That Form Chromonic Liquid Crystals*** PETER J. COLLINGS,[†] VIVA R. HOROWITZ,[‡] MICHELLE R. TOMASIK, *Department of Physics & Astronomy, Swarthmore College, Swarthmore, PA 19081* X-ray scattering and various optical techniques are utilized to study the aggregation process and aggregate structure for two water-soluble dyes that form chromonic liquid crystal phases. The x-ray measurements indicate that the molecules stack in columns with a cross-section approximately equal to the area of a single molecule. The optical measurements point to an aggregation process that occurs at all concentrations, with the distribution of aggregate size shifting to larger and larger aggregates as the concentration is increased. A simple theory based on the law of mass action and an isodesmic aggregation process is in excellent agreement with the experimental data, yielding a value for the ''bond energy'' between the molecules in an aggregate.

**U21 2 Orientational order of an ideal rodlike nematic: Rewriting the theory of nematic liquid crystals?** EDWARD SAMULSKI, LOUIS MADSEN, THEO DINGEMANS, *University of North Carolina - Department of Chemistry* Order in rodlike nematic liquid crystals (LCs) represents a rich field described by myriad theories and studied using various analytical methods. We have made deuterium (D) NMR observations on the labeled paraquinquephenyl LC, which closely approximates a rigid rod. To investigate this high-melting nematic (range 390 - 427 deg. C), we have fabricated a high-efficiency oven on an NMR probehead using fumed silica tiles and utilizing only ambient air cooling. Observations on p-quinquephenyl clearly and drastically deviate from the Maier-Saupe theory and all other molecular theories of nematics, thus indicating the necessity for more a complete theory (e.g., including microscopic director fluctuations) to describe nematic order. We measure the complete order tensor for this LC using combinations of quadrupole and dipolar NMR coupling constants and different D label positions. We will discuss progress on refinements to nematic order theory, relations to NMR measurements, and fits using the phenomenological Landau-deGennes theory.

**8:24**

**U21 3 Interlayer interactions in ferroelectric liquid crystals*** MEHDI HAMANEH, PHILIP TAYLOR, *Case Western Reserve University* We have recently drawn attention to a physical mechanism that can lead to an aligning interaction between distant layers in a ferroelectric smectic-C* liquid crystal. This effect arises because the amplitude of thermal fluctuations in layer shape is sensitive to correlations in *c*-director orientation in layers that are not nearest neighbors. This makes the entropy of the system dependent on the relative alignment of the *c*-director in all the smectic layers. In earlier treatments of this problem, a mean-field approximation was made in order to obtain an order-of-magnitude estimate of the strength of the interlayer interaction. While this was sufficient to demonstrate the significance of the mechanism, it led to an overestimate of the overall strength of the interaction because it included a self-energy term related to the anisotropy of a single layer. We have now remedied this shortcoming by evaluating in more detail the interlayer interaction due to layer shape fluctuations. We find that the rate at which the interaction decays as a function of interlayer distance does not follow any simple power-law form, but depends on a number of material parameters.

**U21 4 The B4 phase: layer curvature driven by frustrated intralayer packing** L.E. HOUGH, *LCMRC, Physics Dept., CU Boulder* D. KRUERKE, *Institute of Inorganic and Analytical Chemistry, TU of Berlin* C.D. JONES, *LCMRC, Physics Dept., CU Boulder* H.T. JUNG, J. ZASADZINSKI, *Dept. of Chemical Engineering, UCSB* G. HEPPKE, *Institute of Inorganic and Analytical Chemistry, TU of Berlin* J. RABE, W. STOCKER, *Institute for Physics, Humboldt U. Berlin* E. KORBLOVA, D. WALBA, *LCMRC, Dept of Chemistry and Biochemistry, CU Boulder* N.A. CLARK, *LCMRC, Physics Dept., CU Boulder* We combine freeze fracture transmission electron microscopy, atomic force microscopy, and x-ray diffraction to show that the B4 phase is a smectic phase with highly curved layers (mean radius $\sim$ 4 layer spacings). The layer structure of the phase is a TGB-like phase made up of parallel arrays of multiple burgers vector screw dislocations (grain boundaries) giving 45 degree rotations across the grain bound-

aries. Models of the layer structure are based on periodic arrays of grain boundaries, each described by Scherk's first surface, and yield key features of the observed structures. This layered structure is dominated by saddle splay and we propose that the energy cost of defects required to make such a structure is offset by an energy gain of the layer curvature. We show that analysis of the wide angle x-ray diffraction of this phase indicates that layer curvature relieves the intralayer frustration produced by the packing of bent-core molecules. **U21 5 Polarization-Enhanced Interaction between Islands on Freely-Suspended Smectic C* Liquid Crystal Films*** APICHART PATTANAPORKRATANA, *Department of Physics and Liquid Crystal Materials Research Center, University of Colorado, Boulder, CO 80309, U.S.A* CHEOL S. PARK TEAM, JOSEPH MACLENNAN TEAM, NOEL A. CLARK TEAM, Smectic liquid crystals can be made to form freely suspended films, two-dimensional systems locally quantized in thickness by an integral number of smectic layers, on which islands, circular regions of greater thickness than the surrounding film area, can be generated. In smectic C films, each such island is accompanied by a topological defect pair, an $s = +1$ topological defect inside and an $s = -1$ defect nearby on the background film. The distortions of the in-plane orientational order of the smectic C director field result in elastic interactions between the islands, with a short-range repulsion and a long-range dipolar attraction governing their stability and leading to their organization in chain-like structures with an equilibrium island separation. We have directly measured the repulsive and attractive forces between smectic C* islands using multiple optical traps and have compared the results quantitatively with theory. We find that the interactions between islands are much smaller in the racemic smectic C case than in the chiral smectic C*, an effect we attribute to long- range coulombic forces arising from polarization charges.

**U21 6 Riverbottom texture: Patterns of compressional stress in an SSFLC cell** CHRISTOPHER D. JONES, DAVID A. COLEMAN, NOEL A. CLARK, *Liquid Crystal Materials Research Center and Department of Physics, University of Colorado, Boulder, CO 80309 USA* MICHAEL D. WAND, *Diplaytech, Inc., Longmont, CO 80503 USA* We have been studying the texture of remnant compressional stress in a bookshelf aligned SmA phase of the Displaytech mixture MDW8068. MDW8068 exhibits isotropic - nematic - SmA - SmC phases, and throughout the range of the SmA phase the layers show significant expansion on cooling. This layer expansion causes layer compression, which is relieved by dislocation formation and surface depinning events throughout the cell. The resulting SmA has essentially perfect alignment, but with a pattern of remnant stress that can be visualized near the SmA - SmC transition because of the divergent tilt susceptibility and resulting compression-induced tilt near the SmA - SmC transition. Low dislocation density areas are the areas of greatest layer compression, implying that the edge dislocations relieve the compressive stress. Temperature cycling shows the texture is set near the N - SmA transition, though x-ray diffraction data shows that the layer expansion occurs through the entire range of the SmA. X-ray diffraction from oriented samples has been done which shows that the texture is a result of competition between smectic ordering and surface pinning. Work supported by ED GAAN Fellowships P200A030179 and P200A000839, and NSF MRSEC Grant DMR-0213918.

**U21 7 Random Lasing in Multidomain Cholesteric Liquid Crystals** MICHELE MOREIRA, MINGXIA GU, OLEG LAVRENTOVICH, BAHMAN TAHERI, PETER PALFFY-MUHORAY, *Liquid Crystal Institute, KSU* A conventional laser consists of a pumped amplifying medium and an optical cavity to provide feedback for light amplification. In disordered materials, light can be trapped by multiple scattering processes and, if a gain medium is added, random lasing can occur. This random laser source does not require a regular cavity, but instead depends on multiple scattering in a random medium. Random lasers have attracted considerable attention recently because of their low cost and ease of construction. We present recent results of our random lasing experiments in dye-doped multidomain cholesteric liquid crystals, with submicron pitch, where the highly reflective cholesteric domains are the scattering elements. We discuss the underlying physics, compare the performance of these systems with others, consider the effects of temperature on the emission spectrum, and suggest possible applications.

**9:24**

**U21 8 Wavelength Hopping in Cholesteric Liquid Crystal Lasers** MICHELE MOREIRA, CHRISTOPHER BAILEY, WENYI CAO, BAHMAN TAHERI, PETER PALFFY-MUHORAY, *Liquid Crystal Institute, KSU* Due to their birefringence and periodic structure, cholesteric liquid crystals (CLCs) in the helical cholesteric phase are one-dimensional photonic band gap materials. Gain enhancement and distributed feedback effects give rise to low threshold mirrorless lasing at the band edges. Since the wavelength at the band edge is proportional to the cholesteric pitch, which is a smooth function of temperature, one would expect the lasing wavelength to vary smoothly with temperature. Observations show, however, that the lasing wavelength does not depend smoothly on temperature, but instead exhibits periodic jumps between regions of smooth monotonic behavior. We have determined the reflection band dynamics, observed multiple lasing peaks at the hopping wavelength, and see evidence of hysteresis on measuring the reflection band and lasing peaks at different heating rates. We compare our observations with theoretical models, and propose an explanation for the observed dynamics.

**U21 9 Poisson-bracket formulation of the dynamics of polar liquid crystals*** WILLIAM KUNG, M. CRISTINA MARCHETTI, *Syracuse University* KARL SAUNDERS, *California Polytechnic State University* We develop the dynamical theory of polar liquid crystals with local $C_{\infty v}$-symmetry using the general Poisson-bracket formalism. We obtain dynamical equations for the slow macroscopic fields that govern the dynamics in both the polarized and the isotropic phases. Starting from a microscopic definition of an alignment vector proportional to the polarization, we obtain Poisson bracket relations for the director field. The hydrodynamic equations differ from those of nematic liquid crystals ($D_{\infty h}$) in that they contain terms violating the $\mathbf{n} \rightarrow -\mathbf{n}$ symmetry. We find that the $\mathcal{Z}_2$-odd terms induce a general splay instability of a uniform polarized state in a range of parameters.

**U21 10 Finite Element Elastodynamics Studies of Shape Evolution in Liquid Crystal Elastomers*** ROBIN SELINGER, BADEL MBANGA, JONATHAN SELINGER, *Kent State University* Liquid crystal elastomers change shape under heating/cooling, applied fields, or optical illumination, with induced strains up to 400%. We present a novel finite element elastodynamics technique to model dynamics of shape change in these materials, with explicit coupling between nematic order and elastic strain. Without added dissipation, the elastodynamics algorithm conserves the sum of kinetic and potential energy to one part in $10^6$, even for large strains and rotations. In initial studies, we model shape evolution during a transition from the isotropic phase to nematic and back again, and model the induced curvature of an elastomer strip under local optical illumination. This method allows modeling of complex geometries and dynamic perturbations, and can serve as a bridge between fundamental soft condensed matter theory and engineering design.

**U21 11 Temperature Dependence of Acousto-Optic Effect in a Nematic Liquid Crystal Cell** STEVEN SUNDBECK, ANTHONY MALANOSKI, BRIAN WESLOWSKI, DEVANAND SHENOY, *United States Naval Research Laboratory* JONATHAN SELINGER, *Kent State University* The acousto-optic effect occurs in a nematic liquid crystal cell when an incident ultrasonic wave causes a rotation of the director. This effect is observable as a change in the optical transmission through a cell, and has been exploited as a means of nondestructive imaging. The sensitivity and speed of this rearrangement are dependent on the viscosity of the liquid crystal material. Because of this, the effect is sensitive to the temperature. In this work we investigate quantitatively how the acousto-optic response is affected by the temperature of the liquid crystal cell. We present the results of studies of changes to the acoustic sensitivity of the cells and changes of their dynamic responses to the introduction of the ultrasonic wave.

**10:12**

**U21 12 Elliptic Phases: A Study of the Nonlinear Elasticity of Twist** CHRISTIAN SANTANGELO, RANDALL KAMIEN, *University of Pennsylvania* The twist-grain boundary phase in smectic-A liquid crystals, constructed from rotating walls of parallel screw dislocations, is a prime example of a stable, ordered configuration of defects. In smectics, nonlinearities in the strains strongly affect the energetics and interactions between defects, thus complicating their analysis. By exploiting the properties of Jacobi elliptic functions, we construct a triply-periodic surface locally composed of screw dislocations, called Schnerk's surface, which has the structure of a series of ninety degree twist-grain boundaries. This is a candidate structure for the recently observed large-angle twist-grain boundary phases. Because of the analytic tractability of our construction, we compute that the grain boundaries interact exponentially at long distances through both the compression and bending energies, and that there is a preferred grain boundary spacing.

**U21 13 Calorimetric study of aligned liquid crystal + aerosil*** F. CRUCEANU, G. S. IANNACCHIONE, *Worcester Polytechnic Institute* D. LIANG, R. L. LEHENY, *Johns Hopkins University* A high-resolution ac-calorimetric study was performed on magnetically aligned colloidal dispersions of 8CB and aerosil spanning the weakly first-order itI-itN and second order itN-SmitA phase transitions. Stable aligned samples were prepared by repeated cycling between the isotropic and nematic phase in the presence of a 2 T magnetic field. Zero-field measurements were carried out on six aligned conjugate density samples ranging from 0.03 to 0.15 g $cm^{-3}$ (mass of aerosil per volume of liquid crystal). For comparison, two unaligned samples from the same batch (0.05 and 0.13 g $cm^{-3}$) were also studied. The unaligned samples reproduce very closely previous studies on this system. The magnetically aligned samples, exhibits lower transition temperatures for the same aerosil density sample and a shift to higher aerosil density of the non-monotonic $T_c$ evolution. The clear differences between aligned and unaligned sample indicate the ''memory'' of the magnetic field even after heating deep into the isotropic phase. The origin of this ''memory'' remains unexplained.

**U21 14 Disordering Effects in Smectic − Aerosil Gels*** VISHAL PANDYA, DANIELE FINOTELLO, *Kent State University* We studied quenched disorder effects on the 12CB liquid crystal upon dispersion of silica nano particles (type A-300): hydrophilic silica spheres of diameter 7nm and surface area S = 300 $m^2g^{-1}$, with hydroxyl groups covering the surface. The LC-aerosil dispersions form a gel if aerosil density exceeds the percolation threshold. For low densities of aerosil dispersions and in cooling the sample, the LC director in the void volume is parallel and follows the external NMR field; a well defined and stable LC configuration forms. When a complete silica network forms and the sample orientation in the field is changed, a few silica links are broken by the field, re-aligning only a few Sm layers; the aerosil locks in the LC configuration which follows a $P_2$ ($Cos\Theta$) dependence. In contrast, if the dispersion is cooled from isotropic phase outside the field, the spectra in the Sm phase is a powder pattern. The field anneals the aerosil-induced random disorder up to a certain density beyond which, disordering effects dominate; for aerosil densities greater than $\rho_S \approx$ 0.055 g/$cm^3$ spectral patterns are consistent with an isotropic distribution of smectic domains. The quenching of the 12CB Sm-A phase at $\rho_S \approx$ 0.055 g/$cm^3$, is one order of magnitude less than that in 8CB [1]. The aerosil induced disorder, quantified by the percent of LC molecules in a powder pattern, depends linearly on the density. [1] T. Jin and D. Finotello, Phys. Rev. E 69, 041704 (2004); Phys. Rev Lett. 86, 818 (2001). *Supported by NSF-INT 03-06851, OBR B-7844 and B-7845.

**U21 15 The Effect of Aerosil Network on Smectic A-Reentrant Nematic Liquid Crystal** MEHMET RAMAZANOGLU, SIMON LAROCHELLE, *U. Toronto* ROBERT J. BIRGENEAU, *U. Toronto and U.C. Berkeley* We report on a high resolution x-ray scattering study of aerosil dispersion effects on nematic-smectic A and smectic A-reentrant nematic phase transitions in 6OCB (hexyloxycyanobiphenyl) and 8OCB (octyloxycyanobiphenyl) liquid crystal mixtures. Dispersed aerosil particles introduce quenched randomness to the liquid crystal phases, which destroys the long range smectic order [1]. The experiment was conducted on mix-

tures with different 6OCB:8OCB concentrations and aerosil densities. The parabolic smectic A phase boundary is found to be slightly distorted in the presence of the aerosil network, with shifted transition and median ($T_M$) temperatures. Above $T_M$, the order parameter, susceptibility and parallel correlation lengths for the thermal and random parts of the structure factor show behaviors similar to those observed in non-reentrant nematic-smectic A second order phase transitions [2]. At $T_M$, where the order parameter has its maximum value, the scattering peaks are only defined by the random part of the structure factor. The smectic order parameter decreases with a further decrease in temperature, while the susceptibility and thermal correlation length increasingly show nematic-like behavior. Finally, at the lowest temperature, the mixtures are found in the reentrant nematic phase. [1] P.S. Clegg et. al. PRE 67,021703 (2003) [2] S. Larochelle et. al. in preparation

**U22 1 Tunneling spin polarization in planar tunnel junctions: measurements using NbN superconducting electrodes and evidence for Kondo-assisted tunneling.**
HYUNSOO YANG, *IBM Almaden Research Center*

The fundamental origin of tunneling magnetoresistance in magnetic tunnel junctions (MTJs) is the spin-polarized tunneling current, which can be measured directly using superconducting tunneling spectroscopy (STS). The STS technique was first developed by Meservey and Tedrow using aluminum superconducting electrodes. Al has been widely used because of its low spin orbit scattering. However, measurements must be made at low temperatures ( $<$ 0.4 K) because of the low superconducting transition temperature of Al. Here, we demonstrate that superconducting electrodes formed from NbN can be used to measure tunneling spin polarization (TSP) at higher temperatures up to $\sim$ 1.2K. The tunneling magnetoresistance and polarization of the tunneling current in MTJs is highly sensitive to the detailed structure of the tunneling barrier. Using MgO tunnel barriers we find TSP values as high as 90% at 0.25K. The TMR is, however, depressed by insertion of ultra thin layers of both non-magnetic and magnetic metals in the middle of the MgO barrier. For ultra-thin, discontinuous magnetic layers of CoFe, we find evidence of Kondo assisted tunneling, from increased conductance at low temperatures ( $<$ 50K) and bias voltage ( $<$ 20 mV). Over the same temperature and bias voltage regimes the tunneling magnetoresistance is strongly depressed. We present other evidence of Kondo resonance including the logarithmic temperature dependence of the zero bias conductance peak. We infer the Kondo temperature from both the spectra width of this conductance peak as well as the temperature dependence of the TMR depression. The Kondo temperature is sensitive to the thickness of the inserted CoFe layer and decreases with increased CoFe thickness.

**U22 2 High sensitivity of tunneling spin polarization to chemical bonding of transition metal ferromagnetic alloys at interface with insulating barrier** SEE-HUN YANG, HYUNSOO YANG, CHRISTIAN KAISER, STUART PARKIN, *IBM Almaden Research Center* IBM ALMADEN RESEARCH CENTER TEAM, We report that the tunneling spin polarization (TSP) is found to be strongly influenced by the amount of oxygen used in the deposition of the tunnel barrier itself that chemical bonding at the interface between $Al_2O_3$ and ferromagnetic Co and Co-Pt alloys. For reactive sputter (RS) deposition of alumina using an argon-oxygen gas mixture with a low concentration of oxygen ( $\sim$ 0.1 mTorr), much lower TSP values are found than when the alumina barrier is formed by post-plasma oxidation (PO) with $\sim$ 100mTorr oxygen of Al layers. X-ray absorption spectroscopy (XAS) has been used to characterize the chemical bonding at the Co or Co-Pt/$Al_2O_3$ interface. These studies show that Co-O bonds are much more formed for the barrier fromed by PO of Al than for that formed by RS deposition. We attribute the changes in TSP to changes in the relative tunneling probabilities from Co and Pt which are strongly influenced by oxygen bond formation.[1] [1]C. Kaiser, S. van Dijken, S.-H. Yang, H. Yang, and S. S. P. Parkin, Phys. Rev. Lett. 94, 247203 (2005).

**U22 3 Anomalous magnetic behaviors in $AlO_x/Co_{84}Fe_{16}$ Tunneling Magnetoresistance (TMR) systems induced by the interfacial oxidations** K.-J. RHO, *POSTECH* K.-J. KIM, *PLS* J.-Y. KIM, *PLS* J.-H. PARK, *POSTECH/PLS* J.-S. LEE, *POSTECH* K.-B. LEE, *POSTECH* S. J. JOO, *KIST* K. RHIE, *Korea University* Due to the practical application of the magnetic tunnel junction as magnetic memory cells and sensors, tunneling magnetoresistance (TMR) in the magnetic tunnel junction (MTJ) has been very actively studied, and extensive effort has been exerted in order to improve the physical properties of MTJs. As a result, it is well recognized that the performance of the MTJs strongly depends on the environment at the interface between the magnetic layer and the insulating oxide layer. In spite of such critical importance, the interface environment and its effects on the magnetic behaviors have not been well understood yet. Here we present

anomalous magnetic behaviors observed in $AlO_x/Co_{84}Fe_{16}$ magnetic tunnel junction structures prepared in various oxidation processes. We examined the magnetic behaviors using the magneto-optical Kerr effect (MOKE) measurements in vacuum. The system turns out to exhibit a strong temperature dependence of the magnetic coersive field, and the behavior consistently varies with the oxidation process. The interface environments and the origin of the anomalous behaviors will be also discussed based on x-ray reflectivity and diffraction results.

**U22 4 Tunneling magnetoresistance in MgO-based magnetic tunneling junction with (001) oriented FeCo electrode fabricated by sputtering deposition.*** TAKAHIRO MORIYAMA, WEIGANG WANG, JOHN Q. XIAO, *Department of Physics and Astronomy, University of Delaware* MgO-based Magnetic Tunneling Junction (MTJ) is now one of the most promising structures for spintronics applications due to its very large Tunneling Magnetoresistance (TMR). However, the high TMR is generally achieved only after the annealing at high temperature that promotes the crystallization of MgO. We fabricated FeCo/MgO/FeCo MTJs on both oriented and non-oriented buffer layers by DC and RF sputtering depositions at room temperature. MgO barrier layer was formed by reactive sputtering method following a very thin Mg deposition. Without annealing, 70% TMR ratio was observed for MTJ with oriented buffer layers, whereas 40% TMR ratio was observed with non-oriented buffer layers. This indicates that an oriented buffer layer can enhance the TMR ratio even without high temperature annealing. We also studied the dependence of TMR on the Mg layer thickness, MgO barrier thickness, and annealing conditions.

**U22 5 Effect of interface states on spin-dependent tunneling in Fe/MgO/Fe tunnel junctions** KIRILL BELASHCHENKO, JULIAN VELEV, EVGENY TSYMBAL, *University of Nebraska-Lincoln* The electronic structure and spin-dependent tunneling in epitaxial Fe/MgO/Fe(001) tunnel junctions are studied using first-principles calculations.[1] For small MgO barrier thickness the minority-spin resonant bands at the two interfaces make a significant contribution to the tunneling conductance for the antiparallel magnetization, whereas these bands are, in practice, mismatched by disorder and/or small applied bias for the parallel magnetization. This explains the experimentally observed decrease in tunneling magnetoresistance (TMR) for thin MgO barriers. We predict that a monolayer of Ag epitaxially deposited at the interface between Fe and MgO suppresses tunneling through the interface band and may thus be used to enhance the TMR for thin barriers. [1] K. D. Belashchenko, J. Velev, and E. Y. Tsymbal, Phys. Rev. B **72**, 140404(R) (2005).

**9:24**

**U22 6 The atomic and electronic structure of the FeCoB/MgO interface** J.D. BURTON, S.S. JASWAL, E.Y. TSYMBAL, *University of Nebraska Lincoln* O.N. MRYASOV, O.G. HEINONEN, *Seagate Technology* Magnetic tunnel junctions (MTJs) have recently aroused much interest due to their potential applications as random access memories and magnetic field sensors. MTJs consist of a thin insulating layer separating two ferromagnetic electrodes. Very recently FeCoB/MgO/FeCoB MTJs have shown promising results. Upon annealing, the amorphous FeCoB electrodes crystallize in a bcc structure epitaxial to the MgO(001) surface. Many groups have observed a significant increase in TMR ratios (higher than 300% at room temperature [1]) after annealing. It is clear that the crystallization of the electrodes plays an important role in this increase. It is not clear, however, what happens to B after annealing and what role it plays in enhancing TMR. We present results of first-principles total energy calculations that suggest that it is energetically favorable for B to reside at the crystalline FeCoB/MgO interface rather than remain in the bulk of the FeCoB electrode. We also find that the presence of B at the interface significantly weakens bonding between the FeCoB electrode and the MgO barrier. We are investigating the presence of resonant states[2] at the FeCoB/MgO interface and will discuss the effects of interfacial B on them. [1] J. Hayakawa et al., 2005 MMM Conference. [2] Belashchenko et al., Phys. Rev. B **72**, R140404 (2005).

**U22 7 Structural and magnetic properties of Fe/MgO/Ge(100) heterostructures and Fe/MgO/Fe(100) magnetic tunnel junctions** YUEH-FENG CHIANG, KYLE PI, YAN LI, ROLAND KAWAKAMI, *University of California Riverside* MgO is one of the most attractive materials for spintronic devices due to a novel spin filtering effect that dramatically increases spin polarization. We utilize molecule beam epitaxy (MBE) to synthesize ferromagnet (FM)/MgO/semiconductor heterostructures for efficient spin injection and detection in Si, Ge and GaAs lateral devices and MgO-based magnetic tunnel junctions (MTJs) for MRAM applications. Initial studies have focused on optimizing the growth of Fe/MgO/Ge(100) heterostructures and Fe/MgO/Fe MTJs and investigating their magnetic properties. Results indicate high-quality layer-by-layer growth with roughness at the atomic scale. itIn situ reflection high energy electron diffraction (RHEED) is utilized for investigating surface roughness during growth. We observe streaky RHEED patterns and intensity oscillations for the homoepitaxial growth of Ge on Ge(100) at 370$^o$C, which indicates an atomically flat Ge buffer layer. Epitaxial MgO layers grown on top of the Ge buffer at room temperature also showed streaky RHEED patterns and atomic force microscopy (AFM) images revealed the rms roughness to be 0.2 nm ( $\sim$ 1 atomic layer) for a 3 nm thick MgO film. High remanance and small coercive field have been observed in epitaxial Fe (5nm)/MgO(3nm)/Ge(100) heterostructures via magneto-optic Kerr effect (MOKE) illustrating good magnetic properties.

**9:48**

**U22 8 XPS studies of MgO based magnetic tunnel junction structures** JOHN READ, *Cornell University* PHIL MATHER, *Cornell* EILEEN TAN, *TDSI, Singapore* ROBERT BUHRMAN, *Cornell* The very high tunneling magnetoresistance (TMR) obtained in MgO magnetic tunnel junctions (MTJ)[(1,2)] motivates the investigation of the electronic properties of the MgO barrier layer and the study of the ferromagnetic metal - MgO interface chemistry. Such large TMR values are predicted by theory due to the high degree of order apparent in the barrier and electrode materials. However, as grown ultra-thin MgO films generally contain defects that can influence electron transport properties through the creation of low energy states within the bulk MgO band-gap. We will report the results of x-ray photoelectron spectroscopy (XPS) studies of (001) textured ultra-thin MgO layers that are prepared by RF magnetron sputtering and electron beam evaporation on ordered ferromagnetic electrodes and in ordered MTJ structures with and without post growth vacuum annealing. XPS spectra for both MgO deposition techniques clearly indicate a surface oxygen

species that is likely bound by defects in the oxide[3] in half-formed junctions and improvements in MgO quality after counter electrode deposition. We will discuss our results regarding the chemical properties of the oxide and its interfaces directed towards possibly providing guidance to engineer improved MgO MTJ devices. [1] S.S.P. Parkin et. al., Nature Materials, **3**, 862 (2004). [2] S. Yuasa et. al., Nature Materials, **3**, 868 (2004). [3] E. Tan et. al., Phys. Rev. B., **71**, 161401 (2005).

**U22 9 Interlayer Exchange Coupling in Fe|MgO|Fe Magnetic Tunnel Junctions** T. KATAYAMA, S. YUASA, *National Institute of Advanced Industrial Science and Technology (AIST)* JULIAN VELEV, S. JASWAL, E. TSYMBAL, *University of Nebraska - Lincoln* Fully epitaxial Fe|MgO|Fe(001) films with wedge-shaped MgO layer were prepared on single-crystal MgO(001) substrates using MBE technique [1]. Structure of the films is Fe-free-layer(15, 20, 30 nm)/MgO(0.3-1.8 nm)/Fe-pinned-layer(10 nm)/Ir-Mn. The interlayer exchange coupling (IEC) energy was obtained at room temperature from a unidirectional shift of the Kerr hysteresis loop. The IEC was found to be antiferromagnetic for small MgO thickness but changed sign at 8.5Å. In order to explain this behavior we performed itab-initio calculations of IEC in Fe|MgO|Fe(001) MTJs with and without oxygen vacancies in MgO. Our results show that without O vacancies the IEC is ferromagnetic and decays exponentially with MgO thickness. However, in the presence of O vacancies the IEC is antiferromagnetic for thin barriers and changes sign with increasing barrier thickness. This behavior is consistent with our experimental observations and is explained by the resonance contribution to the IEC due to localized defect states [2]. [1] S. Yuasa itet al., Nature Mater. **3**, 868 (2004). [2] M. Y. Zhuravlev et al., Phys. Rev. Lett. **94**, 026806 (2005).

**U22 10 Inelastic electron tunneling spectroscopy of $MgO_xF_y$ barriers** JUN HYUNG KWON, TESU KIM, JINO LEE, KOOKRIN CHAR, *Center for Strongly Correlated Materials Research, School of Physics, Seoul National University, Seoul, Republic of Korea* Recent development in TMR junction with MgO barrier attracts a great deal of attention. It is reported that the junctions with MgO barrier exhibit higher TMR with lower RA value. Combined with the spin-transfer switching that has been demonstrated, the future MRAM architecture will to incorporate the MgO barrier TMR junctions. The device parameters for MRAM will require the RA value of about 100 $\Omega - \mu m^2$, corresponding to about 1 nm thick MgO barrier layer. In order to understand the electrical properties of MgO barrier, we have fabricated Mg/MgO/Mg tunneling junctions as the function of oxidation time of the Mg metal layer. These Mg/MgO/Mg cross-strip junctions are deposited using stencil masks without a vacuum break, and the size of junction area is about 130 $\mu$m by 160 $\mu$m. When measuring $d^2I/dV^2$-V, namely the inelastic tunneling spectroscopy, we observed the peaks correponding to MgO bonds, indicating that the MgO barrier is a stable and good insulator. Using the IETS measurement technique, we will present the interface properties between the ferromagnetic electrode and the MgO barrier layer. Moreover, we will report on our $MgO_xF_y$ tunnel barrier made by our fluorine-doping method.

**U22 11 Spin torque and spin current in magnetic tunnel junctions*** MAIRBEK CHSHIEV, WILLIAM H. BUTLER, *Center for Materials for Information Technology, The University of Alabama, Tuscaloosa, AL* ALAN KALITSOV, NICK KIOUSSIS, *Department of Physics, California State University, Northridge, CA* In recent years, current-induced spin torque [1] has attracted strong interest both because it may advance our understanding of fundamental physics and because it may have useful applications. We present a study of non-equilibrium spin currents and the corresponding spin torques in magnetic tunnel junctions with non-collinear moments. Calculations are based on the Keldysh formalism in which the non-equilibrium Green functions are calculated within a tight-binding model using the technique of Caroli et al. [2]. The properties of spin torque and spin currents are studied as a function of applied bias, barrier thickness and lattice structure type. In addition, the exchange coupling between ferromagnetic layers in magnetic tunnel junctions is investigated via its relation to the current induced spin torque. [1] J. C. Slonczewski, J. Magn. Magn. Mat. 159, L1 (1996); L. Berger, Phys. Rev. B 54, 9353 (1996); E. Myers, D. Ralph, J. Katine, R. Louie, R. Buhrman, Science, 285, 867 (1999). [2] C. Caroli, R. Combescot, P. Nozieres, D. **U22 12 Shot noise in Cr-doped and undoped $Co/Al_2O_3/Py$ magnetic tunnel junctions*** FARKHAD ALIEV, RUBEN GUERRERO, *Departamento de Física de la Materia Condensada, C-III, Universidad Autónoma de Madrid, Cantoblanco, 28049, Madrid, Spain* PATRICK LE CLAIR,† JAGADEESH MOODERA, *Massachusetts Institute of Technology, Massachusetts 02139, USA* We have found that shot noise in Co(80Å) /$Al_2O_3$(14Å)/Py(100Å) magnetic tunnel junctions (MTJs) is reduced with respect to Poisonian value. The Fano factor, obtained at frequencies ($100 < f < 1000$Hz), temperatures ($T < 10$K) and biases (below 150 meV) where the shot noise dominates, varies between $F \approx 0.8$ and 0.65, indicating correlated electron tunnelling. Doping of the insulating barrier with Cr inclusions suppresses the conductivity and tunnelling magnetoresistance, and restores the Fano factor to a value corresponding to uncorrelated transport ($F \approx 1$). These results indicate an enhanced cross-correlation between electrons due to trapping or spin-flip assisted tunnelling in the undopped MTJs, and a possible Coulomb blockade in the Cr doped MTJs.

**U23 1 Spin Frustration, Magnetic Susceptibility and Excitations in Spatially Anisotropic Triangular-Lattice Antiferromagnets*** RAJIV SINGH, *University of California at Davis* WEIHONG ZHENG, *University of New South Wales, Sydney, Australia* JOHN FJAERESTAD, ROSS McKENZIE, *University of Queensland, Brisbane, Australia* RADU COLDEA, *University of Bristol, UK* We calculate the temperature dependent

magnetic susceptibility and excitation spectra for the spatially anisotropic triangular- lattice Heisenberg model. We show that suitably scaled plots of magnetic susceptibility provide a direct measure of frustration in the system and allow one to infer the exchange parameters from the susceptibility data. We find that the organic material $\kappa - (BEDT - TTF)_2Cu_2(CN)_3$ is very well described by the isotropic triangular lattice model. We also find that the excitation spectra of the model shows various anomalies in the Neel and Spiral phases.

**U23 2 Anomalous renormalization of excitation spectra of the triangular-lattice antiferromagnet*** JOHN FJAERESTAD, *University of Queensland* WEIHONG ZHENG, *University of New South Wales* RAJIV SINGH, *University of California, Davis* ROSS McKENZIE, *University of Queensland* RADU COLDEA, *University of Oxford* We use series expansions to calculate the excitation spectra of the spin-1/2 triangular-lattice Heisenberg antiferromagnet above the 3-sublattice ordered phase. We find that the spectra are renormalized downwards with respect to linear spin-wave theory. This is in sharp contrast to the square-lattice antiferromagnet, where the spectral frequencies are renormalized upwards due to quantum fluctuations. The triangular-lattice spectra show sharp downward renormalization at special wavevectors, which (a) can be interpreted as evidence of high-energy spinons and (b) provides an explanation for rapid loss of antiferromagnetic correlations with temperature, consistent with earlier high-temperature series expansion studies.

**U23 3 Pairing of doped holes in the Shastry-Sutherland lattice** JUN LIU, JOERG SCHMALIAN, *Iowa State University* NANDINI TRIVEDI, *Ohio State University* We investigate the magnetic and pairing correlations in a hole doped Shastry-Sutherland lattice. We use a variational wave function that reproduces the valence bond ground state of the un-doped material, relevant to $SrCu_2(BO_3)_2$. For finite doping we study the disappearance of the valence bond crystal and the emergence of pairing of doped holes.

**8:36**

**U23 4 In Gap Excitations and Triplet Lifetime Broadening in the Dilute Singlet Ground State System $SrCu_{2-x}Mg_x(BO_3)_2$** S. HARAVIFARD, S.R. DUNSIGER, B.D. GAULIN, H.A. DABKOWSKA, *McMaster University* M.T.F. TELLING, *ISIS Pulsed Neutron Facility* S. EL SHAWISH, J. BONCA, *J. Stefan Institute* We have carried out high resolution time-of-flight neutron scattering measurements on a new high quality single crystal of $SrCu_{2-x}Mg_x(BO_3)_2$ with $x = 0.1$. These studies revealed the presence of new excitations within the singlet-triplet gap of this quasi-two dimensional, dilute, singlet ground state system. These new excitations showed little or no shift in energy with increasing applied magnetic field. In addition, we observe substantial broadening of the three triplet excitations in the dilute single crystal, as compared with pure $SrCu_2(BO_3)_2$.[1] The triplet excitations in doped $SrCu_{2-x}Mg_x(BO_3)_2$ therefore possess finite lifetimes at low temperatures in the range that can be measured with cold neutron spectroscopy. We have also calculated the dynamical spin structure factor using the zero temperature Lanczos method, and solving a Shastry-Sutherland model at zero and finite doping for different strengths of external magnetic field. This theory reproduces all the qualitative features observed in the experiments on $SrCu_{2-x}Mg_x(BO_3)_2$.

**U23 5 Infrared studies of a quantum magnet $SrCu_2(BO_3)_2$** T. RÕÕM, D. HÜVONEN, U. NAGEL, *Natl. Inst. of Chem. Phys. & Biophysics, Akadeemia tee 23, EE12618 Tallinn, Estonia* S.V. DORDEVIC, C.C. HOMES, *Brookhaven National Laboratory* A. GOZAR, G. BLUMBERG, *Bell Laboratories* N. DRICHKO, M.M. DRESSEL, *Universitat Stuttgart* H. KAGEYAMA, *Kyoto University* We will report results of our infrared studies of $SrCu_2(BO_3)_2$, a two-dimensional spin system with a disordered ground state even at very low temperatures, and a spin gap of about 24 $cm^{-1}$ (3 meV). This material has recently attracted attention because of a possibility that doping may lead to a superconductivity mediated by antiferromagnetic fluctuations, possibly similar to high-$T_c$ cuprates. Using polarized light we have probed both crystallographic directions over a broad range of frequencies (from about 30 $cm^{-1}$ to 20,000 $cm^{-1}$) and temperatures (from 4.2 K to 300 K). The results reveal significant differences between the ab-plane and c-axis directions. We will discuss these findings in relation with the resonance effects observed in inelastic light scattering experiments from collective magnetic excitations.

**9:00**

**U23 6 Magnetization plateaus for $Cs_2CuBr_4$** SHIN MIYAHARA, KIYOSHI OGINO, MASAHIRO SHIMIZU, NOBUO FURUKAWA, *Aoyama Gakuin University* $Cs_2CuBr_4$ is a new two-dimensional spin-1/2 system, where 1/3- and 2/3-plateaus have been observed in external magnetic fields. The magnetic behaviors of the material are well explained by a two-dimensional antiferromagnetic Heisenberg model on a distorted triangular lattice. In the model, there are two types of interactions $J_1$ and $J_2$, where $J_1$ chains are coupled with inter chain interactions $J_2$. Using an exact diagonalization method, we investigated magnetic properties, especially magnetization curve. In the magnetization, 1/3-plateau appears for $0.7 .3ex < / \sim J_2/J_1 .3ex < / \sim 1.3$. At the plateau, three-fold degenerate ground state, up-up-down structure, is realized. Our results indicate that the material has a more frustrated character $J_2/J_1 \approx 0.7$ than what has been expected from a classical theory $J_2/J_1 = 0.47$. The magnetic properties at 2/3-plateau will also be discussed.

**9:12**

**U23 7 Dynamical properties of the anisotropic triangular quantum antiferromagnet with Dzyaloshinskii-Moriya interaction** RASTKO SKNEPNEK, DENIS DALIDOVICH, JOHN BERLINSKY, JUNHUA ZHANG, CATHERINE KALLIN, *Department of Physics and Astronomy, McMaster University, Hamilton, Ontario, Canada L8S 4M1* We present a detailed study of the anisotropic triangular quantum antiferromagent with Dzyaloshinskii-Moriya (DM) interaction building on earlier work by Veillette, James and Essler [Phys. Rev. B, **72**, 134429 (2005)]. The DM interaction generates an easy-plane anisotropy and opens a gap in the spin-wave spectrum at the incommensurate ordering wave vector $\vec{Q}$. Our calculation utilizes the Holstein-Primakoff representation of spins and goes beyond linear spin wave theory by taking into account magnon-magnon interactions in a $1/S$ ex-

pansion. We calculate renormalized dispersion relations for the magnons to order 1/$S$ for different values of the DM interaction and pay particular attention to the interesting case of zero DM interaction. The dynamical structure factor is calculated to order 1/$S$. It is found that, compared to linear spin wave theory, a significant fraction of the scattering intensity is shifted to higher energies. We compare our findings with the recent neutron scattering data measured on the frustrated quantum antiferromagnet $Cs_2CuCl_4$, [R. Coldea, *et. al.*, Phys. Rev. B, **68**, 134424, (2003)].

**9:24**

**U23 8 Spiral magnetic order on an anisotropic triangular lattice in the presence of Dzyaloshinskii-Moriya interaction** DENIS DALIDOVICH, RASTKO SKNEPNEK, A. JOHN BERLINSKY, JUNHUA ZHANG, CATHERINE KALLIN, *Department of Physics and Astronomy, McMaster University, Hamilton, Ontario, Canada L8S 4M1* We consider the ground state energy, magnetization and the energy spectrum of the two-dimensional antiferromagnets on the triangular lattice in the presence of anisotropy in the exchange couplings, and Dzyaloshinskii-Moriya (DM) interaction $D$. $J$ and $J'$ are meant to be the couplings along the chain direction and zigzag bonds respectively. Assuming that in the wide range of those parameters the system has the spiral Neel ordering, we consider the role of quantum fluctuations within the framework of a standard 1/$S$ expansion. We show that DM interaction considerably suppresses fluctuations and seems to play an important role in stabilizing the spiral Neel ordering in this frustrated system. We discuss our theoretical results within the context of the recent experimental measurements in the frustrated quantum magnet $Cs_2CuCl_4$, [R. Coldea, et. al., Phys. Rev. B, **68**, 134424, (2003)], and the recent theoretical structure factor calculations by M. Y. Veillette, et. al., Phys. Rev. B **72**, 134429 (2005)

**9:36**

**U23 9 A quasi-1d approach to the triangular antiferromagnet $Cs_2CuCl_4$** LEON BALENTS, *Physics Department, UCSB* OLEG STARYKH, *Physics Department, University of Utah* We discuss the low-temperature properties of a spin-1/2 triangular Heisenberg antiferromagnet in a field, including the effects of Dyaloshinskii-Moriya interactions, as believed appropriate to $Cs_2CuCl_4$.[1] Our treatment is based upon a view of the problem as a system of weakly-coupled spin chains. Analytic results are obtained through a combination of renormalization group, chain mean-field, and bosonization methods. Using various exactly-known properties of the individual Heisenberg chains, we calculate numerous physical properties, including various phase boundaries in longitudinal and transverse fields. We compare our results to published experimental data.

[1]R. Coldea et al., Phys. Rev. Lett. 88, 137203 (2002).

**U23 10 Simultaneous breaking of lattice symmetry and spin frustration in triangular lattice antiferromagnet $CuFeO_2$** Y. REN, *XFD/XOR, Argonne National Laboratory* F. YE, *Center for Neutron Scattering, Oak Ridge National Laboratory* Q. HUANG, *NIST Center for Neutron Research, NIST* J.A. FERNANDEZ-BACA, *Center for Neutron Scattering, Oak Ridge National Laboratory & Dept of Physics and Astronomy, Univ. of Tennessee* PENGCHENG DAI, *Dept of Physics and Astronomy, Univ. of Tennessee & Center for Neutron Scattering, Oak Ridge National Laboratory* J.W. LYNN, *NIST Center for Neutron Research, NIST* T. KIMURA, *Los Alamos National Laboratory* We use high resolution synchrotron X-ray and neutron diffraction to study the geometrically frustrated triangular lattice antiferromagnet (TLA) $CuFeO_2$. We show that the occurrence of the two magnetic transitions, at 14 K and 11 K, respectively is accompanied simultaneously by a second-and first- order structural phase transitions from a hexagonal structure to a monoclinic form. This is the first observation of two successive spin-driven structural transitions directly coupled with incommensurate and commensurate magnetic orderings in frustrated TLA systems. This work is supported by the U. S. NSF DMR-0453804 and DOE Nos. DE-FG02-05ER46202 and DE-AC05-00OR22725 with UT/Battelle LLC. Use of the Advanced Photon Source was supported by the U. S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. W-31-109-Eng-38.

**U23 11 Neutron scattering studies on Kagome bilayers − Spin fluctuations in a broad dynamic range** H. MUTKA, *Institut Laue Langevin, Grenoble, France* C. PAYEN, *Institut des Materiaux Jean Rouxel, Nantes, France* G. EHLERS, J.R. STEWART, *Institut Laue Langevin, Grenoble, France* A. MELLERGARD, *Studsvik Neutron Research Laboratory, Nyköping, Sweden* The kagome bilayer compounds Ba2Sn2ZnCr7xGa10-7xO22 and SrCr9xGa12-9xO19 are localized spin (S=3/2) systems with strong antiferromagnetic exchange (J/k $\approx$ 50 K) that show no long-range order down to mK temperatures. This remarkable behaviour originates from the geometrical frustration. We have examined these systems using polarized neutron diffraction, inelastic neutron scattering (INS) and neutron spin-echo (NSE) spectroscopy for characterizing the magnetic correlations in a very broad energy range. INS data reveals the dynamic nature of the broad diffuse scattering that characterises the quasi-elastic magnetic response above the spin freezing. New aspects on the freezing phenomenon and the ground state properties are revealed using NSE.

**10:12**

**U23 12 Hall constant on triangular lattice ladder systems** JAN HAERTER, MICHAEL PETERSON, SRIRAM SHASTRY, *University of California at Santa Cruz* To make the transition from a one-dimensional to a planar system one can connect $n$ 1D-chains to yield $n$-leg ladders. For square lattices, this approach has already led to quite interesting and unexpected results (Dagotto et al, Prelovšek et al). In this work, frustration is introduced through triangular geometry, achieved by adding additional bonds to the square lattice ladders. We study the response of such $t$-$J$ ladders to an applied magnetic field and investigate the Hall constant $R_H$ as function of temperature, interaction strength, doping, and frequency. These systems complement toroidal or spherical systems since these allow the limit $\partial/\partial B$ to be taken more accurately which leaves the geometric frustration fully preserved. We investigate the crossover from a degenerate Fermi system to a high T regime where $R_H$ grows indefinitely ($R_H \propto T$) with temperature.

**10:24**

**U23 13 Position-Space Renormalization-Group Treatment of the Triangular Ising Antiferromagnet with Quenched Disorder** MICHAEL E. MIHALCO, SUSAN R. McKAY, *University of Maine* We apply the Niemeijer-van Leeuwen cluster approximation [1] to frustrated Ising models on a triangular lattice. The homogeneous Ising antiferromagnet is fully frustrated and shows no ordered phase. Frustration can be relieved via the addition of

quenched randomness through either dilution or the introduction of ferromagnetic bonds. The result is a rich phase diagram with different types of ordering depending upon the details of the quenched disorder [2]. Using a binning procedure to retain the full distribution of interactions under rescaling [3], we are able to calculate the phase diagram of this system, with each phase having its own characteristic attractor. This model system provides a two-dimensional example of the impacts of tunable frustration on short- and long-range order. 1. T. Niemeijer and J.M.J. van Leeuwen, Phys. Rev. **U24 1 Patterns and Defects in Nematic Elastomers*** FANGFU YE, *University of Pennsylvania* TOM LUBENSKY, *University of Pennsylvania* Nematic elastomers are materials that combine the orientational properties of nematic liquid crystals with the elastic properties of rubber. Ideal nematic elastomers, formed via a spontaneous symmetry breaking transition from the isotropic rubber state, exhibit soft elasticity in which one of the five elastic moduli of a uniaxial elastic medium vanishes. Monodomain samples crosslinked under imposed strain exhibit semi-soft elasticity in which that elastic modulus is small but nonzero. Applying linear stability analysis to the semi-soft elastic energy, we investigate two phenomena observed in experiments on nematic elastomers: (1) the formation, in experiments by Bob Meyer at Brandeis, of periodic modulations of the nematic director and elastic displacement (stripes) in cells subjected to a normal electric field in which the direction of stripe normals is at an oblique angle to the original nematic director and (2) the formation of +1 disclination defects at the surface of nanotube gel films [Islam, M. F., Nobili, M., Ye, Fangfu, Lubensky, T. C. and Yodh, A. G., Phys. Rev. Lett. **95**, 148301/1-4 (2005)].

**8:12**
**U24 2 In situ synchrotron studies of structure development during injection molding of liquid crystalline polymers** STANLEY RENDON, WESLEY BURGHARDT, *Northwestern University* As in all polymer materials, the effect of polymer processing on the underlying molecular structure has a profound effect on the properties of liquid crystalline polymer products. While in situ scattering techniques have proven powerful for studying complex polymer structure during comparatively simple shearing or channel flows, their application to processing flows has largely been limited to in situ x-ray scattering/diffraction studies of structure development during fiber spinning. Here we report a new experiment in which a lab-scale injection molding machine has been modified to allow real-time, in situ measurements of molecular orientation development and subsequent crystallization during injection molding. The experiment requires high x-ray energy to reduce absorption in the aluminum mold wall, and high flux and a fast area detectors to achieve the necessary resolution to track time-dependent changes in fluid structure during mold filling. Hence it is ideally suited to the capabilites of the Advanced Photon Source. We report measurements injection molding of a commercial liquid crystalline copolyester (Vectra A) as a function of position in the mold and various process variables.

**8:24**
**U24 3 Liquid crystalline pattern formation in drying droplets of biopolymers*** IVAN SMALYUKH, *University of Illinois at Urbana-Champaign and Kent State University* OLENA ZRIBI, *University of Illinois at Urbana-Champaign* JOHN BUTLER, *University of Illinois at Urbana-Champaign* OLEG LAVRENTOVICH, *Kent State University* GERARD WONG, *University of Illinois at Urbana-Champaign* When a droplet of DNA in water dries out, a ring-like deposit is observed along the perimeter, similar to the stains in spilled drops of coffee. However, the dried ring of DNA is a self-similar birefringent pattern composed of extended molecules. We examine dynamics of the pattern formation at the droplet's rim. This gives us an insight into the underlining physics. During the major part of drying process the contact line is pinned so that DNA molecules are brought to the perimeter and extended by the radial capillary flow. Lyotropic nematic phase is formed in which highly concentrated DNA aligns along the triple line to minimize elastic energy. When the contact angle becomes small, the contact line starts to retract and the radial dilative stress causes buckling distortions at the rim which then propagate deep into the elastic liquid-crystalline medium and give rise to the pattern.

*We acknowledge support of the Institute for Complex and Adaptive Matter

**8:36**
**U24 4 Orientational dynamics of dipolar or magnetized rigid nematic liquid crystal polymers and suspensions in imposed flow and external fields** QI WANG, In this talk, I will present a scheme for computing the exact solution of the Smoluchowski equation under imposed flow and electric or magnetic external fields for rigid nematic liquid crystal polymers. This includes a suite of mathematical theorems that reveal the intrinsic relationship among the lower order moments of the pdf and the flow as well as the external field. Then, a simple mathematical transformation links the problem to some target model problems for which the solutions can be readily obtained using the existing numerical tools. The orientational dynamics is then studied from the exact solutions of the Smoluchowski equation.

**8:48**
**U24 5 Spacer length controlled lamello-columnar to oblique-columnar mesophase transition in liquid crystalline DNA - discotic cationic lipid complexes** LEI ZHU, LI CUI, JIANJUN MIAO, *Polymer Program, Institute of Material Science and Department of Chemical Engineering, University of Connecticut, Storrs, Connecticut 06269-3136* A series of asymmetric triphenylene imidazolium salts with different spacer lengths (C5, C8, and C11) were synthesized and their ionic complexes with double-strand DNA were prepared in aqueous solution. The molecular composition of the complexes was determined by FTIR analysis. The liquid crystalline morphology was characterized by polarized

light microscopy, X-ray diffraction (XRD), and transmission electron microscope. 2D XRD results indicated an oblique columnar phase for the complex with a short spacer length of C5, while lamello-columnar phases for those with longer spacer lengths (C8 and C11). Thin film circular dichroism results showed the disappearing of any helical conformation in the DNA in all the complexes. Instead, the complexation between single-strand RNA and discotic cationic lipids did not show columnar morphology; therefore, the columnar liquid crystalline morphology in the DNA-discotic cationic lipid complexes was attributed to the DNA double-strand chain rigidity.

**9:00**

**U24 6 Binary phase diagrams of liquid crystal/polymer systems exhibiting crystal, smectic, and nematic transitions*** P. DAYAL, R. MATKAR, *University of Akron* V. GINZBURG, *Dow Chemicals* T. KYU, *University of Akron* Current theories describing the phase diagrams of nematic-nematic mixtures and polymer-nematic liquid crystal mixtures are based on the combination of classical Flory-Huggins (FH) theory of isotropic mixing and the Maier-Saupe (MS) free energy of nematic ordering. This combined FH-MS theory was extended by Kyu and Chiu to polymer-smectic-A systems by incorporating McMillan free energy of the nematic-smectic-A transition. We have developed a generalized model for an LC system undergoing crystallization, extending the Maier-Saupe-McMillan theory in conjunction with the Landau-Brazowiskii model of weak first order phase transition such as solidification. The generalized FH-extended MSM free energy is then minimized with respect to all order parameters and the phase diagram is constructed by balancing the chemical potentials of corresponding phases. This form of the free energy could be valuable in the time evolution studies of phase transitions in polymer/liquid crystal mixtures.

**U24 7 Interfacial Characteristics of Semi Fluorinated Polymeric and Polymeric Liquid Crystalline Surfaces** GANG CHENG, BRYAN SPRAUL, DENNIS SMITH, DVORA PERAHIA, *Clemson University* The interfacial interactions of semi fluorinated perfluorocyclobutane (PFCB) liquid crystalline, and semi crystalline polymers have been investigated. The interfacial characteristics are critical in any of their applications in which a well define stable interface is required from LCD technology to waveguides and lithography. The inherent segregation between fluorine rich and hydrogen rich segments results in induced liquid crystallinity within the polymers themselves, even though these groups are small. The segregation to the interfaces controls the capability of the surface energy of the system. In addition of interfacial tension measurements, we used their alignment of small LC molecules using of 4, 4'-octylcycanobiphenyl (8CB) as a model system to further explore their interfacial characteristics. The correlation between surface energies, dynamics of the interface and their effects of the orientation of small LC will be discussed.

**9:24**

**U24 8 The Origin of Supra-Molecular Columnar Structures from Symmetrically Tapered Bisamides** KWANG-UN JEONG, HONG SHEN, MATTEW J. GRAHAM, HUABING WANG, MINGMING GUO, FRANK W. HARRIS, STEPHEN Z. D. CHENG, MAURICE MORTON INSTITUTE AND DEPARTMENT OF POLYMER SCIENCE, THE UNIVERSITY OF AKRON TEAM, A series of symmetrically tapered 1,4-bis[3,4,5-tris(alkan-1-yloxy)benzamido] benzene bisamides (CnPhBA) were synthesized to study the effect of alkyl chain length on supramolecular structures. Phase transitions were studied with DSC, PLM, WAXD, IR, SAED, solid-state $^{13}C$ NMR and computer simulations. All of the CnPhBAs formed a highly-ordered oblique columnar ($\Phi_{OK}$) phase and a low-ordered oblique columnar ($\Phi_{OB}$) phase. The two main driving forces to form these supramolecular structures were identified: One is the *H*-bond between N-H and C=O groups, and the other is the micro-phase separation of the bisamide cores and the alkyl chains. With increasing alkyl length, the isotropization temperature decreased, while the alkyl chain disordering temperature increased. The 2D lattice structures perpendicular to the columnar axis also increasingly deviated from the pseudo-hexagonal packing with increasing alkyl length. However, the alkyl length did not have a significant influence on the packing along the columnar axis.

**9:36**

**U24 9 Crystallization, the gel point and DQ NMR in PDMS networks** MOSHE GOTTLIEB, YOAV HAYOUN, INBAL PREKER, RACHEL YERUSHALMI-ROZEN, *Chemical Engineering Department and Stadler Minerva Center for Mesoscopic Macromolecular Engineering, Ben-Gurion University, Beer Sheva, 84105 ISRAEL* KAY SAALWAECHTER, *Institut fur Makromolekulare Chemie, Universitaet Freiburg, 79104 Freiburg, GERMANY* In the framework of classical models, the presence of constraints that reduce the mobility of the chains should lead to a reduction in the crystallization rate of polymer melts and result in a lower degree of crystallinity at a given cooling rate. An increasing number of experimental observations which seem to contradict the basic premises of the classical picture have been reported in the last couple of years. In particular, recent experiments findings suggest that in some cases crystallization from a crosslinked melt is more efficient than that from the non crosslinked analogue. In this work we report on a detailed study carried out in order to examine the relation between crystallization and the crosslinked network parameters. The effect of precursor molecular weight, crosslinker functionality and degree of crosslinking were examined. The thermal characteristics of the system were obtained by DSC. These were complemented by DQ NMR (dynamic order parameter) and rheological measurements. The use of DQ NMR as means to determine the gel point is also discussed.

**9:48**

**U24 10 Phase Separation of Model Segmented Poly(Carbonate Urethanes)** REBECA HERNANDEZ, ELENA HUNG, JAMES RUNT, *Department of Materials Science and Engineering, Penn State University* The present paper focuses on the phase separated morphology and segment demixing of model poly(carbonate urethanes) [PCU] with hard segment contents ranging from 30 – 65% and soft segments composed of 1,6 poly(hexamethylene carbonate) [MW = 1K]. Hard segments were formed from 4,4'-methylenediphenyl diisocyanate and 1,4 butanediol. This family of materials represents a recent approach in the development of polyurethanes with improved long-term biostability, and is under clinical investigation in a number of biomedical devices. Only a single glass transition temperature was observed for each copolymer, increasing in temperature with increasing hard segment content. However, loss spectra from dynamic mechanical analysis showed clear evidence of two mixed phases. The results of small-angle X-ray scattering and tapping mode AFM experiments were

consistent with these observations and will be discussed. Finally, these results will be compared with initial findings on phase separation in another family of polyurethane copolymers of current interest as blood-contact materials in biomedical devices having mixed poly(dimethylsiloxane) – poly(hexamethyleneoxide) soft segments.

**10:00**
**U24 11 How Does Rubber Crystallizes Upon Application of Strain*** MINDAUGAS RACKAITIS, XIAORONG WANG, *Bridgestone CRT* Strain induced crystallization of natural and synthetic rubbers is one of the most interesting phenomena in the field of rubber science and technology. Most of the research in the field was done using X-ray diffraction techniques. However up to this day there are no reports of direct observation of strain induced crystallization of rubber. This presentation reports first atomic force micrographs of high cis polybutadiene rubber surface at various strains. The crystallization of the rubber was confirmed by X-ray diffraction and crystallite orientation is discussed.

*We are thankful to Dr. Jan Genzer and his collegues for NEXAFS and IR experiments

**10:12**
**U24 12 Melt-processable high acrylonitrile copolymers** SHAWN R. HUTCHINSON, *Institute of Textile Technology* JUAN HINESTROZA, *Cornell University* BHUPENDER S. GUPTA, DAVID R. BUCHANAN, ALAN E. TONELLI, *North Carolina State University* High acrylonitrile homo- and copolymers (PAN) are unique because of chemical, ultraviolet, and corrosion resistances. Historically, because of the atypical processing and thermal behavior of solution-processable PAN, consensus regarding the actual microstructure and paracrystalline order was elusive – it has been described as 'two-dimensional liquid crystalline-like structure with many defects.' New, sequence-structured copolymers rendered PAN for the first time melt-processable before degradation and are providing new insight into the solid state conformation. Solution $^{13}C$ nuclear magnetic resonance was used to compare the new and historical comonomer sequence lengths. Optimal processing conditions were obtained using capillary rheometry as a function of dwell time and melt temperature. A filament extrusion investigation was conducted and wide angle x-ray diffraction, differential scanning calorimetry thermograms and mechanical properties of the filaments were used to characterize the nonequilibrium melt transitions and paracrystal morphology as a function of processing parameters.

**U25 1 Preparation and properties of substituted acenes for organic electronics: pentacene through heptacene** JOHN ANTHONY, *Univ. of Kentucky, Dept. of Chemistry* Acenes (such as pentacene and tetracene) and functionalized acenes (such as rubrene) have demonstrated remarkable electronic properties in thin film devices and in single crystals. Our research effort is directed toward the synthesis of new classes of acene-based compounds that are stable, soluble, and that can be used to probe the relationships between solid-state order and electronic properties. Careful consideration of the relationship between molecular substituent and crystal packing has led to the development of new, soluble materials with thin-film properties comparable to their unfunctionalized counterparts. Functionalization of the central ring of pentacene can lead to a change in solid-state order from the classic herringbone arrangement to the less-common face-to-face interactions, while functionalization of the outermost rings of pentacene leads to subtle variations in the herringbone arrangement. Similar approaches can be taken with heteroacenes, again leading to solid-state interactions that favor strong interactions between the aromatic pi-clouds. Furthermore, the added stability gained through functionalization has allowed for the first time the preparation and study of derivatives of higher acenes such as hexacene and heptacene. The detailed study of the optical and electronic properties of a variety of functionalized acenes has led to the development of new materials for use in photovolatics, light-emitting diodes and thin-film transistors. We are grateful to the Office of Naval Research for support of this research.

**8:12**
**U25 2 Conducting AFM and 2D GIXD Studies on Pentacene Thin Films** HOICHANG YANG, CHANG Y. RYU, *Rensselaer Polytechnic Institute* TAE JOO SHIN, *Brookhaven National Laboratory* KILWON CHO, *POSTECH, Korea* MANG-MANG LING, ZHENAN BAO, *Stanford University* 2D GIXD, TM-, and C-AFM analyses of pentacene films support the idea that the morphology of ultrathin layers plays a crucial role in determining mobility in OTFT. While 60-nm-thick pentacene films exhibited similar terrace-like multilayer structure with the long axis of pentacene perpendicularly oriented as determined from TM-AFM and 2D GIXD, its charge mobility in an OTFT was quite different, depending on the types of hydrophobic SAM surface treatment. This difference is related to the morphological difference of the first pentacene layer ''buried'' under the terrace-like multilayers. We found that the faceted islands on HMDS showed larger current flow than the dendritic islands on OTS using C- AFM. This trend in C-AFM current images correlated well with the charge carrier mobility measured in OTFTs. Such faceted morphology represents single crystal-like pentacene islands, which have fewer internal crystal defects and higher current flow than the dendritic islands.

**U25 3 Hall Effect Measurements in Organic Single-Crystal FETs** VITALY PODZOROV, *Rutgers University* ETIENNE MENARD, JOHN ROGERS, MICHAEL GERSHENSON, RUTGERS UNIVERSITY TEAM, UNIVERSITY OF ILLINOIS AT URBANA CHAMPAIGN TEAM, We have observed classical Hall effect in the single-crystal rubrene OFETs [1]. The mobility determined from the Hall measurements (mu_H) represents intrinsic, i.e. trap independent mobility of the charge carriers. At high temperatures, Hall mobility coincides with the longitudinal mobility determined from the standard FET measurements. In the investigated temperature range T = 170-300 K, mu_H monotonically increases with decreasing T, while the longitudinal mobility first increases at high T (intrinsic regime) and then decreases at low T (non-intrinsic regime), consistent with the previous observations [2, 3]. In the intrinsic regime, the density of mobile field-induced charge carriers extracted from the Hall measurements, n_H, coincides with the density n calculated using the gate-

channel capacitance, and becomes smaller than n in the trap-dominated regime. The Hall data strongly support a band-like nature of the charge carrier transport in this system. 1. Podzorov, et al., Phys. Rev. Lett. 95, 226601 (2005); 2. V. C. Sundar, et al., Science 303, 1644 (2004); 3. V. Podzorov, et al., Phys. Rev. Lett. 93, 086602 (2004);

**U25 4 Hall effect in organic single-crystal field-effect transistors** J. TAKEYA, KOICHI YAMADA, *CRIEPI* K. TSUKAGOSHI, Y. AOYAGI, *RIKEN* T. TAKENOBU, Y. IWASA, *IMR, Tohoku University* Hall effect is detected in organic field-effect transistors at room temperature, using appropriately shaped rubrene ($C_{42}H_{28}$) single crystals. It turned out that inverse Hall coefficient, having a positive sign, is close to the amount of electric-field induced charge upon the hole accumulation. The observation of the normal Hall effect means that the accumulated surface charge is well extended in space over molecules, so that the external magnetic field can provide a transverse electromotive force. The result is consistent with band-like transport of the surface carriers rather than consecutive hopping processes occurring in response to the source-drain voltage in the organic transistors.

**8:48**

**U25 5 Control of Channel Conductivity of Rubrene Single Crystal Field Effect Transistors.** CHRISTIAN KLOC, MAGNUS WIKBERG, WOO-YOUNG SO, DAVE V. LANG, THEO SIEGRIST, ARTHUR P. RAMIREZ, *Bell Laboratories, Lucent Technologies* Carrier mobility higher than 1 $cm^2$/Vs has been measured in numerous organic single crystal FETs, making them interesting for microelectronic applications. The understanding why some organic pi-electron systems show high mobility and others, very similar molecules, show much lower mobility is crucial for design of efficient and robust organic semiconductor devices. It seems that transistor properties measured on FETs are extrinsic properties limited by technology used for transistor fabrication. However, to evaluate the applicability of organic semiconductors, intrinsic properties need to be assessed. We have carried out a program to purify and grow low defect density single crystals and fabricate FETs on their surfaces. Using graphite as electrodes and parylene as an insulator we measured maximal mobility in rubrene of 13 $cm^2$/Vs and significant anisotropy of transport properties. To control the transistor properties, we chemically modify the channel area and measured the conductivity of transistor channels before covering it with dielectrics and gate electrode. We found that the channel area of rubrene is very sensitive on reduction and oxidation and that the transistor properties may be modified by performing chemical reactions on the crystal surfaces before finishing transistor structure.

**U25 6 Thermal Expansion and Molecular Motion in Rubrene and Tetracene*** THEO SIEGRIST, CHRISTIAN KLOC, MAGNUS WIKBERG, *Bell Laboratories* SIMON HAAS, *ETH Zuerich* The closely related molecules rubrene (tetra-phenyl-tetracene) and tetracene are model systems for organic semiconductor materials. Very high carrier mobilities have been observed in rubrene crystals. Single crystals of rubrene and tetracene, produced by vapor phase growth at elevated temperatures, show clear differences in their quality. The thermal expansion/contraction coefficients for crystals of the two molecules have been measured using X-ray diffraction. The triclinic symmetry of tetracene crystals is reflected in the strongly anisotropic thermal expansion observed. In the case of rubrene, relatively small thermal expansion coefficients are found. Libration/translation values obtained using the rigid molecule model will be presented for both systems.

**U25 7 A Systematic Study of Metal Contacts on Single Crystalline Rubrene*** WOO-YOUNG SO, *Columbia University* A. MIKE SERGENT, *Bell Labs* CHRISTIAN KLOC, *Bell Labs* ARTHUR RAMIREZ, *Bell Labs, Columbia University* The performance of semiconductor devices is critically dependent on the metal- semiconductor heterojunction. In organics, despite the technological importance of such interfaces, little is known about the fundamental mechanisms that govern their performance in real devices. We have studied a series of metal contacts on rubrene single crystals and find systematic dependence of the transport barrier on the metal workfunction. These data provide insight into surface states that strongly influence the contact resistance. In the process of the study of metal-rubrene heterojunctions, we have realized an efficient single-crystal rubrene diode employing a hole-blocking metal contact.

**U25 8 Negative Thermal Expansion in Pentacene** S. HAAS, *ETH Zurich* T. SIEGRIST, *Bell Labs, Murray Hill, NJ* P. PATTISON, *EPF Lausanne, Switzerland* B. BATLOGG, *ETH Zurich, Switzerland* The molecules in organic semiconductors, such as the oligoacenes, are held together by weak van-der-Waals (v-d-W) forces. As a result, one observes low dissociation temperatures, and large thermal expansion coefficients. Surprisingly, we have found a negative expansion coefficient in particular crystal directions. We have performed a complete X-ray structure analysis of pentacene and tetracene single crystals in a temperature range from 100–380 K. The anisotropic thermal parameters are analyzed in terms of librations and translations of the rigid molecules. Interestingly, we find upon increasing temperature a near-zero thermal expansion along *a* in tetracene, and a distinct contraction in pentacene. Upon close inspection of the full expansivity tensor and the thermal parameters we find a consistent explanation assuming that the v-d-W forces tend to minimize the relative shift along the long axis of adjacent molecules. This is further supported by the observation of an unusually large thermal expansion perpendicular to the layers, and the indications in our data of a distinctly anharmonic potential for the sliding motion along the long axis. These v-d-W forces leading to negative thermal expansion are expected to be larger in longer molecules and also to be the driving force behind the well known polymorphism of pentacene.

**U25 9 Charge transport in single-crystals of pentacene studied with temperature dependent THz time-domain spectroscopy.** H.A. VAN LAARHOVEN, *Eindhoven, University of technology.* M. KOEBERG, E. HENDRY, M. BONN, *AMOLF, Amsterdam* C.F.J. FLIPSE, *Eindhoven, University of Technology* We study the charge dynamics and transport mechanisms in single crystals of pentacene by investigating the frequency dependent complex conductivity using THz time-domain spectroscopy. Such measurements on this material show generation of THz radiation from the

sample as well as ultra-fast charge decay. Our measurements have been corrected for these effects, giving us the ability to see the true frequency dependent behaviour of the conductivity. Two different pump energies were used (266 and 400 nm) in the experiments. In the low temperature regime the mobile charges give a different response when being photo-excited at different wavelength. This disparity in charge transfer will be discussed and compared to theoretical models.

**9:48**

**U25 10 Optical emission and vibrational modes of uniform pentacene monolayers*** RUI HE, *Columbia Univ* NANCY TASSI, GRACIELA BLANCHET, *Dupont, Central Research and Development* ARON PINCZUK, *Columbia Univ, Bell Labs* Pentacene monolayers are probed by photoluminescence and resonant Raman spectroscopies below 10K. Monolayers grown on polymeric substrate of poly-alpha-methyl-styrene (PAMS) exhibit high uniformity within micron size clusters. These films show sharp exciton luminescence bands, and the energy of the exciton optical emission displays a red-shift as the average film thickness increases. The large resonance enhancements of Raman scattering intensities enable the measurements of low-lying (40- 200cm-1) optical lattice vibrations from these monolayers. These experiments demonstrate that luminescence and resonant Raman scattering from single pentacene monolayers are venues for probing 2D properties, studies of interface effects, and thin film characterization. *Supported primarily by the Nanoscale Science and Engineering Initiative of the National Science Foundation under NSF Award No. CHE-0117752 and by the New York State Office of Science, Technology, and Academic Research (NYSTAR), and by a research grant of the W. M. Keck Foundation.

**10:12**

**U25 12 Interface and Contact Formation in Pentacene Monolayer Transistors** BYOUNG-NAM PARK, SOONJOO SEO, FAN ZHENG, FRANZ HIMPSEL, PAUL EVANS, *University of Wisconsin-Madison* Understanding charge transport in the accumulation layer of organic field effect transistors is crucial to improving their performance. Our in-situ electrical measurements during the deposition of pentacene onto a bottom-contact transistor structure with a silicon dioxide gate dielectric allowed us to study the formation of a transistor channel at the single-molecular-layer scale. At pentacene coverages near a percolation threshold the monolayer-high islands come into contact and current begins to flow through the channel. Using pauses in the deposition we have extracted transistor characteristic parameters with well-defined submonolayer island structures. Van der Pauw sheet resistance measurements show that the small field effect mobilities of monolayer transistors are associated with the formation of contacts rather than with the mobility of carriers within the semiconductor layer. Both near edge x-ray absorption fine structure measurements and atomic force microscopy show that the morphology and crystal structure of the pentacene layers changed as the total amount deposited onto the sample increased through the few-monolayer regime.

**10:24**

**U25 13 Growth and structure of pentacene thin films** BOQUAN LI, *Uniersity of Illinois at Urbana-Champaign, Department of Materials Science and Engineering* During the last few years, there has been an explosion of interests in exploring organic thin-films of small conjugated molecules, like pentacene ($C_{22}H_{14}$), as active semiconductor devices. The full potential of organic thin-film semiconductor devices for applications will not be realized until the growth of highly ordered organic thin films can be optimized and well controlled. Thin films of pentacene are known to crystallize in different polymorphs, which have layered structures characterized by their different interlayer spacings, d(001). How to grow highly ordered single phase molecular thin films remains a challenging subject. Motivated by this, we have investigated the growth of pentacene thin films on hydrogen-terminated Si (111) and clean Si (111) surfaces in an effort to gain a comprehensive understanding of the molecule-substrate interactions and explore strategies to suppress the formation of polymorphism and therefore to grow highly ordered pentacene thin films. Electron diffraction is used to investigate the in-plane molecular structure. The crystallographic results are correlated with growth. The detailed structural analysis results will be presented.

**10:36**

**U25 14 Electron and hole transport in organic single crystals*** J. PFLAUM, A.K. TRIPATHI, S. MEYER, *Dept. of Physics, University of Stuttgart, 70550 Stuttgart, Germany* Transport measurements reported in literature often classify the semiconducting behavior in organic thin films and single crystals to be whether p-type or n-type. Moreover, the majority of polyaromatic hydrocarbons such as pentacene in combination with technically relevant contact materials such as Au are found to preferentially show hole conductivity. In this presentation, we will discuss these key aspects of the charge carrier transport in case of highly-ordered organic crystals, the latter grown by diferent methods from previously purified material. By time-of-flight spectroscopy it will be demonstrated for various compounds that the chemical purity rather than the growth conditions determine the resulting semiconducting behavior. E.g. anthracene single crystals grown by sublimation provide as good electron as hole mobilities of about 1 $cm^2$/Vs if the material is purified by zone- refinement. For crystals made of sublimation purified anthracene, no electron transport could be detected. Finally, comparing various structural motifs we will discuss possible concepts of molecular design enabling stability against photo- oxidation and allowing for the formation of highly-ordered thin films.

**10:48**

**U25 15 Oxygen and water defect formation processes in pentacene.** LEONIDAS TSETSERIS, SOKRATES PANTELIDES, *Department of Physics and Astronomy, Vanderbilt University* Organic thin-film devices have emerged as promising candidates for novel electronic applications. Unlike traditional solid-state devices, the weak intermolecular non-covalent bonding of organic thin films leads to flexibility and possible pattern formation. The same mechanism, however, is responsible for the appearance of a variety of defects that may interfere with film growth and are potentially detrimental to the desired transport properties. Here we use first-principles calculations to study defect formation processes in the prototypical system of pentacene. In particular, we report on defect configurations of oxygen and water molecules in bulk pentacene and ultra-thin films on Si-based substrates. The results show that several stable configurations of such defects exist. Their presence has a direct bearing on growth processes and transport properties through strong covalent bonding and induced molecular distortions in their vicinity. This work was supported in part by DOE Grant DEFG0203ER46096.

**U26 1 Isotropic, nematic and polarized states in active motor-filament solutions*** APHRODITE AHMADI, M. CRISTINA MARCHETTI, *Physics Department, Syracuse University, Syracuse, NY 13244* TANNIEMOLA B. LIVERPOOL, *Department of Applied Mathematics, University of Leeds, Leeds LS2 9JT, UK* We characterize the phase diagram of interacting polar biofilaments and motor proteins in terms of experimentally accessible parameters. The active filament solution is described by a set of hydrodynamic equations. These in turn are obtained by coarse-graining the Smoluchowski equation for rods coupled by active crosslinkers that mediate the exchange of forces among the filaments. We find that motor activity and the polarity of motor clusters play a key role in the formation of homogeneous isotropic, nematic and polarized states. We also investigate the stability of such homogeneous states against spatially varying fluctuations in the hydrodynamic fields. Motor-induced bundling can destabilize each homogeneous state at high filament and motor density, albeit via different mechanisms (diffusive versus oscillatory). Our analysis suggests that spatially inhomogeneous oscillatory structures, such as vortices, can be formed in the polarized state.

**U26 2 Rheology of active polymer solutions** M. CRISTINA MARCHETTI, *Syracuse University* TANNIEMOLA B. LIVERPOOL, *Leeds University, UK* In vitro solutions of biopolymers and associated motor proteins have been used to probe cytoskeletal dynamics under controlled conditions. Experiments have shown that motor-induced filament sliding competes with the slow Brownian polymer dynamics, driving the organization of the polymer network into complex patterns and altering its rheological and mechanical properties. Starting from a semi-microscopic model of the motor-mediated interaction among filaments, we have obtained continuum equations for the coarse-grained fields (filament and motor densities, polarization, alignment tensor) describing the response of the active solution to an externally imposed flow. After deriving an expression for the active contribution to the stress tensor, we have evaluated the linear viscoelastic response of a dilute solution to a shear stress. In the isotropic state motor activity strongly enhances the viscoelasticity of the system, especially near the transition to an orientationally ordered state. Activity also increases the high-frequency shear modulus of the solution. – MCM was support by the National Science Foundation, grants DMR-0305407 and DMR-0219292. TBL acknowledges the support of the Royal Society.

**U26 3 Thermally Controlling the Polymeric Cytoskeleton in Living Cells** CHAO-MIN CHENG, PHILIP LEDUC, *Department of Mechanical Engineering, Carnegie Mellon University* Cell structure is controlled to a large degree by the cytoskeleton, which is an intracellular polymer network. This cytoskeleton is critical as it strongly influences many cellular functions such as motility, organelle transport, mechanotransduction and mitosis. In our studies, we controlled the thermal environment of living cells and after applying an increase in temperature of only 5 $^{o}$C, we observed a change in the polymer network as the actin filaments depolymerized. Interestingly, when we then lowered the temperature, the actin repolymerized indicating a reversible phase that is controlled by the thermal environment. We characterized the presence of F-actin and G-actin for these phases through analyzing the intensity from immunofluorescent studies for these proteins. The F-actin concentration decreased when increasing the temperature from the initial state and then increased when decreasing the temperature. Although the cell is known to be affected by heat shock responses, this is not a function of just the polymers as they do not exhibit these polymerization characteristics when we probed them as single filaments in vitro. These studies suggest that the cell has distinct phases or patterns while maintaining a reversible equilibrium due to the thermal environment for these networked polymers.

**8:36**

**U26 4 How to detect single cancer cell?** NADINE PERNODET, *SUNY* JESSICA FIELDS, *Princeton* LENNY SLUTSKY, *Duke* TAYLOR BERNHEIM, KAUSTABH GHOSH, SHOUREN GE, MIRIAM RAFAILOVICH, *SUNY* Cell mechanics is now considered as a critical parameter closely related to cell functions. Moreover, we know that cytoplasm of cancer cells compared to normal cells is disorganized; therefore this should be directly translated to their mechanical properties. Here we show that we are able to distinguish cancer cells from normal cells in a cell mixture through their mechanical properties. Advantage of our method is that we measure single cell mechanical response where any cells, cancer or normal, are attached on a surface in situ. When imaged in the

mixture of cells, through usual microscopic imaging, cancer and normal cells did not show obvious differences and could not be identified with certitude unless using specific biochemical markers. In a mixture of cancer and normal cells, mechanical measurements were done randomly on six different cells. The relative modulus gave a bimodal distribution. These moduli were compared to the known modulus obtained from normal or cancer cell and assigned to each group of cells very precisely. This method, which is directly related to the intrinsic cytoskeleton cell mechanical properties, is a sensitive and reliable tool to detect cancer cells from a culture or a tissue at a single cell level.

**8:48**
**U26 5 The Effects of Chronological Age on the Cellular Mechanics of Human Dermal Fibroblasts** Z. PAN, V. HUNG, S. KAMBHAMPATI, S.R. GE, M. RAFAILOVICH, *Mat Sci & Eng Dept,SUNY Stony Brook* K. GHOSH, R. CLARK, *BME Dept, SUNY Stony Brook* Y.J. LIU, T. NAKAMURA, *Mech Eng Dept, SUNY Stony Brook* X.Z. SHU, G. PRESTWICH, *Med Chem Dept, Univ. Utah* It is often observed that older people display diminished wound healing abilities. Understanding of this phenomenon is important for many in vivo applications of tissue engineering. In this study, the cell mechanics of dermal fibroblasts from 25, 40 and 84 years old female subjects were compared. These cells were cultured on functionalized hyaluronic acid hydrogel substrates which emulated physiological conditions in dermal tissue. The deformation of the substrate caused by cellular traction forces was detected by tracing the displacement of fluorescent beads embedded in the substrate using Digital Image Speckle Correlation. Then cellular traction forces were quantitatively determined by Finite Element Method in a linear elastic model with a high spatial resolution. These results were correlated with auxiliary measurements of substrate modulus, cell modulus and migration. We found that with increasing age, the magnitude of the cellular traction forces diminished. Similarly, the ability of the cells to adapt to changes in the mechanical properties of their environment and migrate was also impaired. The interrelationship between these factors and wound healing will be discussed. This work is supported by NSF-MRSEC program.

**U26 6 Interplay between crosslinkers and dynamic molecular motor-induced instabilities in the moderation of biopolymer organization** DAVID SMITH, *University of Leipzig, Institute for Soft Matter Physics* DAVID HUMPHREY, *Center for Nonlinear Dynamics, University of Texas at Austin* FALKO ZIEBERT, WALTER ZIMMERMANN, *Physikalisches Institut, Universität Bayreuth* JOSEF KÄS, *University of Leipzig, Institute for Soft Matter Physics* Structure and function of biological cells rely on the highly-dynamic self-organization of protein filaments to an intracellular cytoskeleton responsive to mechanical and chemical stimuli. While dissolving these complex cellular structures through Brownian motion is inherently slow (tens of minutes), changes in the activity of the molecular motor myosin II cause rapid order-disorder transitions within 1-2 minutes in reconstituted cytoskeletal actin networks. When motor-induced filament sliding decreases, actin network structure rapidly and reversibly self-organizes into various assemblies triggered by a nonlinear instability. Modulation of static crosslinker concentrations allow for a wide phase space of order ranging from nematics to compact asters & dense packing of motor-filament clusters. The observed isothermal transitions between disorder and self-organization illustrate that molecular motors can substantially contribute to dynamic cellular organization.

**U26 7 The mechanics of cell protrusion.***
GAUDENZ DANUSER, *The Scripps Research Institute*

The protrusion of the cell edge is the first step in a cycle of molecular processes that drive cell movements during development, immune responses, wound healing and many other physiological functions. It is also the earliest pathological event observed during metastasis of cancer. Textbook models associate protrusion with the assembly of an actin polymer network subadjacent to the cell plasma membrane. However, for this process to be transformed into edge advancement, polymerization-induced forces need to be balanced by adhesion complexes that link the actin network to the extracellular domain. Also, the effectiveness of network assembly in mediating forward movement of the cell edge depends on how contraction forces pull the network in the cell front retrogradly towards the cell center. Thus, what is observed in a microscope as cell protrusion reflects the kinematic output of at least three space- and time-modulated mechanisms of force generation. The coordination of these machineries is thought to be regulated by a complex network of mechano-chemical signals. Our goal is to establish the contributions of each those mechanisms and their control by reconstructing the spatiotemporal distribution of intracellular forces via inverse dynamics and molecular intervention with the relevant signalling pathways. To this end, we have developed quantitative Fluorescent Speckle Microscopy (qFSM) which provides high-resolution spatiotemporal measurements of actin network deformation and material properties in migrating cells. In addition, qFSM delivers maps of cytoskeleton assembly and disassembly, so that we can infer the plasticity of the material in situ. Together, this data allows us to deduce intracellular force distributions from the constitutive laws of strain and stress in the actin polymer network. Using this approach we discovered that unperturbed cells protrude in a dynamic steady state where periodic patterns of network assembly, adhesion formation, and cytoskeleton transport are tightly connected to protrusion waves. We exploited the sub-cellular heterogeneity of these patterns to identify the causality and timing between dynamic events in the actin network, leading towards a first integral view of the mechano-chemical process interaction in the protrusion machinery.

**U26 8 Tensile Force Generation by Actin-Myosin Networks** ANDERS CARLSSON, *Washington University in St. Louis* Tensile force generation by the actin-myosin system is a crucial factor in many cellular processes, including the function of the contractile ring in cytokinesis. Calculations of such tensile forces have often been based on specific one-dimensional models of the structure based on parallel overlapping filaments, sometimes in sarcomere-like structures. However, the detailed arrangement of the actin filaments is not known in general, and it is likely to be disordered. For this reason we have developed a general theory of force generation by myosin in actin networks, based on treating the myosin motors as external forces in a viscoelastic medium. The analysis is based on two ingredients: the strain field of a force dipole in a homogeneous medium, and a correction for the inhomogeneity of the actin network. We obtain a simple expression for the tensile stress induced by the myosin motors in terms of the density of motors and the average actin filament length. This formula is used to relate the force that can be generated by a contractile ring to the actin network structure.

**U26 9 Simulation of Actin-Polymerization Near Moving Surface*** KUN-CHUN LEE, *University of Pennsylvania* ANDREA LIU, *University of Pennsylvania* An important component of the cellular cytoskeleton is F-actin, a biopolymer whose self-assembly is key to the process of cell crawling. The polymerization and branching of F-actin near the cell membrane is known to drive cell crawling, but the precise mechanism by which these processes lead to the generation of a mechanical force is still controversial. We have constructed a Brownian dynamics simulation of F-actin polymerizing near a surface, which includes all known important processes, including polymerization, depolymerization, branching, severing and capping. Using this model, we study the dynamics of the moving surface in conjunction with the morphology of the resulting actin network.

**U26 10 The Fysics of Filopodia (or The Physics of Philopodia)** JEN SCHWARZ, *Syracuse University* AJAY GOPINATHAN, *UCSB* KUN-CHUN LEE, *University of Pennsylvania* ANDREA LIU, *University of Pennsylvania* LOUISE YANG, *Cambridge University* Cell motility is driven by the dynamic reorganization of the cellular cytoskeleton which is composed of actin. Monomeric actin assembles into filaments that grow, shrink, branch and bundle. Branching generates new filaments that form a mesh-like structure that protrudes outward allowing the cell to move somewhere. But how does it know where to move? It has been proposed that filopodia serve as scouts for the cell. Filopodia are bundles of actin filaments that extend out ahead of the rest of the cell to probe its upcoming environment. Recent in vitro experiments [Vignjevic *et al.*, J. Cell Bio. **160**, 951 (2003)] determine the minimal ingredients required for such a process. We model these experiments analytically and via Monte Carlo simulations to estimate the typical bundle size and length. We also estimate the size of the mesh-like structure from which the filopodia emerge and explain the observed nonmonotonicity of this size as a function of capping protein concentration, which inhibits filament growth.

**U26 11 Lipid-Protein Nanotubes with Open or Closed Ends, Microtubules Bundles and Inverted Tubulin Nanotubes*** URI RAVIV, DANIEL J. NEEDLEMAN, MIGUEL A. OJEDA-LOPEZ, YOULI LI, HERB P. MILLER, LESLIE WILSON, CYRUS R. SAFINYA, *University of California, Santa Barbara* We describe synchrotron x-ray diffraction, electron microscopy, and optical imaging data of the self-assembly of microtubules (MTs) with various cationic agents. We established the conditions under which cationic liposomes can coat MTs and form lipid-protein nanotubes (LPNs). The LPNs exhibit a rather remarkable architecture with the cylindrical lipid bilayer sandwiched between a MT and outer tubulin oligomers forming rings or spirals. By controlling the cationic lipid/tubulin stoichiometry it is possible to switch between two states of nanotubes with either open ends or closed ends with lipid caps, a process which forms the basis for controlled chemical and drug encapsulation and release (Raviv et al, PNAS, 2005). Multivalent (3+,4+ and 5+) cations can form three dimensional MT bundles that in some cases become tubulin based inverted nanotubules. Divalent cations form two dimensional MT necklaces (Needleman et al, PNAS, 2004).

**U26 13 Micromechanical Properties of Endothelial Cell Cytoskeleton** MERON MENGISTU, LINDA LOWE-KRENTZ, H. DANIEL OU-YANG, *Lehigh University* DEPARTMENT OF BIOLOGICAL SCIENCES, LEHIGH UNIVERSITY COLLABORATION, PHYSICS DEPARTMENT, LEHIGH UNIVERSITY COLLABORATION, Atherosclerotic plaques occur in regions of arterial curvature, where there is blood re-circulation and physiologically low shear stress conditions. This phenotype may be related to flow-induced shear stress on the monolayer of endothelial cells that make up the endothelium. When endothelial cells in static culture are exposed to laminar flow, they respond by rearranging their cytoskeleton, and aligning their actin filaments in the direction of flow. The changes in cytoskeletal structures induced by flow are different from region to region of the same cell. We employ the optical tweezers technique to obtain very local mechanical properties of endothelial cell cytoskeleton. We used endocytosed polystyrene beads, as well as intrinsic granular structures, as probes for our measurements. Endothelial cells were also

treated with Cytochalasin B and Nocadozole, which are drugs that de-polymerize actin filaments and microtubules respectively, to measure the visco-elastic moduli, and obtain the contribution of each cytoskeletal structure in the cells' micro-mechanical properties.

**U27 1 Density-Matrix Based Fixed-Node and Fixed-Phase Approximation for Quantum Monte Carlo*** JOHN SHUMWAY, *Dept. of Physics and Astronomy, Arizona State University* We have generalized the fixed-node and fixed-phase approximations to use density matrices. For a given trial density matrix, we generate a quantum Monte Carlo algrithm that minimizes the free energy, subject to the nodal or phase restriction. This method has enabled us to perform efficient fermion path-integral simulations at all temperatures. In the T=0 limit the algorithm simulates two copies of the system that do not interact, but which are entangled through the nodal constraint. We illustrate the advantages of this density matrix formalism in applications to semiconductor nanostructures and small molecules. We are currently investigating the use of the Kubo formula and other linear response theories within the fixed-node approximation. (For simulation codes, preprints, and other information, see http://phy.asu.edu/shumway.)

**U27 2 Worm algorithm for continuous-space Path Integral Monte Carlo simulations** MASSIMO BONINSEGNI, *University of Alberta* NIKOLAY PROKOF'EV, BORIS SVISTUNOV, *University of Massachusetts* We present a new approach to Path Integral Monte Carlo (PIMC) simulations based on the ''worm'' algorithm, originally developed for lattice models,[1] and recently extended to continuous-space many-body systems.[2] The scheme allows for efficient computation of thermodynamic properties, including winding numbers and off-diagonal correlations, for systems of much greater size than that accessible to conventional PIMC. We present results for the superfluid transition of Helium-four in two and three dimensions. Using systems comprising several thousand particles, a very accurate determination of the superfluid transition temperature is feasible.

**U27 3 Green's function analysis of path integral Monte Carlo molecular simulations*** DAEJIN SHIN, *Arizona State University* JOHN SHUMWAY, *Arizona State University* We demonstrate the direct determination of molecular properties from path integral Monte Carlo simulations. By sampling Matsubura Green's functions, we have calculated several linear response properties of the hydrogen molecule ($H_2$) directly from quantum Monte Carlo. We show that the vibration frequency of $H_2$ as calculated directly from the phonon temperature Green's function is in very good agreement with the calculated Born-Oppenheimer potential energy surface. We have also obtained the polarizability from the polarization correlation function, and we are looking at Raman spectra. For the high-accuracy simulations needed in chemical physics, we have developed new, fast and accurate techniques for the tabulation of Coulomb density matrices. This work motivates future path integral Monte Carlo simulations on larger molecules and could also be immediately useful in simulations of hydrogen storage materials.

**U27 4 Energy Optimization of Many-Body Wave Functions: Application to Silicon Interstitial Defects*** W. D. PARKER, K. P. DRIVER, R. G. HENNIG, J. W. WILKINS, *the Ohio State University* C. J. UMRIGAR, *Cornell University* Energy minimization [1], as opposed to the standard variance minimization [2], of the Jastrow factor results not only in lower variational Monte Carlo (VMC) energies but also in lower diffusion Monte Carlo (DMC) energies for systems that employ a nonlocal pseudopotential. We apply this approach to solids: single-interstitials in silicon. Allowing the Jastrow for the defect atom(s) to differ from that for bulk atoms lowers the VMC energy but not the DMC energy, indicating the pseudopotential locality error is small. DMC energies from 8 and 64 atom cells (plus interstitial) computed with energy-optimized trial wave functions estimate a 0.2 eV finite-size error in the formation energy. Cubic spline and Lagrange polynomial representations of orbitals have comparable efficiency in memory usage, run time and accuracy. [1] C. J. Umrigar and C. Filippi, Phys. Rev. Lett. 94, 150201 (2005). [2] C. J. Umrigar, K. G. Wilson and J. W. Wilkins, Phys. Rev. Lett. 60, 1719 (1988).

**U27 5 Study of Atoms and Molecules with Auxiliary-Field Quantum Monte Carlo*** WIRAWAN PURWANTO, MALLIGA SUEWATTANA,[†] HENRY KRAKAUER, SHIWEI ZHANG, ERIC J. WALTER, *College of William and Mary, VA* We study the ground-state properties of second-row atoms and molecules using the phaseless auxiliary-field quantum Monte Carlo (AF QMC) method.[1] This method projects the many-body ground state from a trial wave function by means of random walks in the Slater-determinant space. We use a single Slater-determinant trial wave function obtained from density-functional theory (DFT) or Hartree-Fock (HF) calculations. The calculations were done with a plane-wave basis and supercells with periodic boundary condition. We investigate the finite-size effects and the accuracy of pseudopotentials within DFT, HF, and AF QMC frameworks. Pseudopotentials generated from both LDA (OPIUM[2]) and HF[3] are em-

ployed. We find that the many-body QMC calculations show a greater sensitivity to the accuracy of the pseudopotentials. With reliable pseudopotentials, the ionization potentials and dissociation energies obtained using AF QMC are in excellent agreement with the experimental results.

**U27 7 Accuracy of the pseudopotential and fixed-node approximations for $C_2$, $Si_2$ and defects in crystalline Si*** RICHARD G. HENNIG, *Department of Physics, Ohio State University* CYRUS J. UMRIGAR, JULIEN TOULOUSE, *Cornell Theory Center, Cornell University* JOHN W. WILKINS, *Department of Physics, Ohio State University* Quantum Monte Carlo calculates binding energies and atomic structures for molecules and defect energies in solids. Accurate QMC calculations require the control of the pseudopotential and the fixed-node approximation. The calculated binding energies and bond lengths for the Si and C dimer and the energies of defects in crystalline Si test the accuracy of a range of pseudopotentials and optimized trial-wave functions. For the Si dimer and defects in crystalline Si different pseudopotentials provide similar results. The results for the Si dimer are comparable with experiments with HF pseudopotentials being most accurate. While a single determinant wave functions is sufficient for the Si dimer, the C dimer requires an optimized multideterminant trial-wave function to achieve experimental accuracy.

**U27 8 Structure of fermion nodes and nodal cells for QMC wave functions*** LUBOS MITAS, *North Carolina State University* We study nodes of fermionic ground state wave functions. For $2D$ and higher we analytically prove that spin-polarized, noninteracting fermions in a harmonic well have two nodal cells for arbitrary system size. The result extends to other noninteracting/mean-field models such as fermions on a sphere, in a periodic box or in Hartree-Fock atomic states. Spin-unpolarized noninteracting states have multiple nodal cells, however, interactions and many-body correlations generally relax the multiple cells to the minimal number of two. This is again analytically proved, with some restrictions, for general interactions in $2D$ and higher-dimensional harmonic fermions of arbitrary size using the Bardeen-Cooper-Schrieffer variational wave function. We discuss implications and limits of the proofs for more complicated systems. The results offer an elegant and unifying framework for several previously conjectured or numerically investigated ideas and open exciting perspectives for studies of many-body effects which are beyond the usual fixed-node quantum Monte Carlo limits.

**U27 9 Multi-pfaffian pairing wave functions for quantum Monte Carlo** MICHAL BAJDICH, LUBOS MITAS, *CHIPS, Department of Physics, North Carolina State University, Raleigh, NC 27695* KEVIN E. SCHMIDT, *Department of Physics, Arizona State University, Tempe, AZ 85287* We investigate the limits of accuracy of trial wave function for quantum Monte Carlo based on pfaffian functional form with singlet and triplet pairing. Using a set of first row atoms and molecules we find that this wave function provides very consistent and systematic behaviour in recovering the correlation energies on the level of 95%. In order to get beyond this limit we have explored the possibilities of multi-pfaffian pairing wave functions. We show that small number of pfaffians recovers another large fraction of the missing correlation energy comparable to the larger-scale configuration iteraction wave functions. The trade-offs between the size of the underlying optimization problem and amounts correlation energy recovered will be discussed.

**9:48**
**U27 10 Backflow transformations in inhomogeneous systems** PABLO LOPEZ RIOS, ANDREA MA, NEIL D. DRUMMOND, RICHARD J. NEEDS, *TCM Group, University of Cambridge* The quality of trial wave-functions, and of their nodal surface in particular, determines the accuracy of the results obtained within the Fixed-Node Diffusion Monte Carlo (DMC) method. Backflow transformations have been proven capable of improving the nodal surface of Slater-Jastrow (SJ) wave-functions in homogeneous systems. In this work we will present the extension of backflow to inhomogeneous systems, along with DMC results for atoms, molecules and solids which show the improved accuracy of this form of trial wave-function. We will also discuss the advantages of using electron-by-electron algorithms to enhance the computational efficiency of QMC with backflow wave-functions.

**U27 11 The equation of state of diamond from quantum Monte Carlo calculations** RYO MAEZONO,* *National Institute for Materials Science, Japan.* ANDREA MA, *TCM, Cavendish Laboratory, University of Cambrigde, U.K.* MIKE D. TOWLER, *TCM, Cavendish Laboratory, University of Cambrigde, U.K.* NEIL D. DRUMMOND, *TCM, Cavendish Laboratory, University of Cambrigde, U.K.* RICHARD J. NEEDS, *TCM, Cavendish Laboratory, University of Cambrigde, U.K.* We describe variational and diffusion quantum Monte Carlo (VMC and DMC) calculations that have been performed to evaluate the elastic properties of diamond up to pressures of about 500 GPa. We have used a smooth, norm-

conserving, Hartree-Fock carbon pseudopotential in our work. Our trial wave functions were of Slater-Jastrow form, containing orbitals generated in plane-wave DFT-GGA calculations, which were re-expanded in a blip-function basis set. We propose a new scheme for determining the cutoff lengths that occur in our Jastrow factor. Using a 512-electron simulation cell, and fitting a Vinet equation of state to our energy-volume data, we have calculated the equilibrium lattice constant (A, in Angstrom), bulk modulus (B, in GPa), and pressure derivative of the bulk modulus (B') to be (A,B,B')=(3.547, 4.83, 3.43) within VMC and (3.563, 4.52, 3.61) within DMC, as compared with the experimental values of (A,B,B')=(3.567, 4.4-4.5, 3.0-4.0).

**U27 12 Improved estimators for quantum Monte Carlo calculation of spherically averaged intracule densities*** JULIEN TOULOUSE, *Cornell University* ROLAND ASSARAF, *Universite Pierre et Marie Curie* CYRUS UMRIGAR, *Cornell University* System-averaged pair densities or ''intracule densities'' are important for qualitative and quantitative descriptions of electron correlation [1] In quantum Monte Carlo (QMC) simulations, spherically averaged intracule densities are usually calculated by means of the traditional histogram technique (i.e., by counting the number of times two electrons are found at a certain distance) that is very noisy at short electron-electron distances. We will show how previously-used improved estimators for the on-top pair density [2,3] can be generalized to the case of non-vanishing electron-electron distances, as an application of the ''zero-variance'' procedure [4]. The obtained estimators lead to noise several orders of magnitude smaller than the histogram technique, allowing unprecedented fast and accurate calculations of intracule densities in QMC. Illustrative calculations on simple atomic systems will be given. [1] J. M. Mercero, E. Valderrama and J. M. Ugalde, in ''NATO-ASI Series in Metal-Ligand Interaction in Molecular-, Nano-, Micro, and Macro-systems in Complex Environments,'' Ed.: N. Russo, D. R. Salahub and M. **U27 13 Accurate energy differences with Quantum Monte Carlo** SIMONE CHIESA, DAVID CEPERLEY, JEONGNIM KIM, RICHARD MARTIN, *UIUC* Computation of accurate energy differences is of primary importance in the study of transformations as those occurring in solid to solid phase transitions or chemical reactions. In stochastic quantum simulations this can be done efficiently, employing correlated sampling techniques whereby fluctuations cancel with each other leading to results with a much smaller statistical error. Although correlated sampling is very effective for variational Monte Carlo such is not the case for diffusion Monte Carlo where branching and different nodal structures force the introduction of uncontrolled approximations. Here we describe the use of reptation Monte Carlo as a method that maintains a single path for both systems and leads to energies which are exact within the fixed node approximation. We show how to combine umbrella sampling with coordinate transformations to give a simple and efficient algorithm to compute small energy differences. Application to dissociation reaction paths and weakly bound systems are presented.

**U28 1 Fluidic control over cell proliferation and chemotaxis.**
ALEX GROISMAN, *University of California San Diego*

Microscopic flows are almost always stable and laminar that allows precise control of chemical environment in microchannels. We describe design and operation of several microfluidic devices, in which various types of environments are created for different experimental assays with live cells. In a microfluidic chemostat, colonies of non-adherent bacterial and yeast cells are trapped in micro-chambers with walls permeable for chemicals. Fast chemical exchange between the chambers and nearby flow-through channels creates essentially chemostatic medium conditions in the chambers and leads to exponential growth of the colonies up to very high cell densities. Another microfluidic device allows creation of linear concentration profiles of a pheromone ($\alpha$-factor) across channels with non-adherent yeast cells, without exposure of the cells to flow or other mechanical perturbation. The concentration profile remains stable for hours enabling studies of chemotropic response of the cells to the pheromone gradient. A third type of the microfluidic devices is used to study chemotaxis of human neutrophils exposed to gradients of a chemoattractant (fMLP). The devices generate concentration profiles of various shapes, with adjustable steepness and mean concentration. The ''gradient'' of the chemoattractant can be imposed and reversed within less than a second, allowing repeated quantitative experiments.

**U28 2 The Conformation of Clathrin Triskelia in Solution**
MATTHEW L. FERGUSON, *Department of Physics, University of Maryland College Park MD* KONDURY PRASAD, *Department of Biochemstry, University of Texas Health Science Center, San Antonio TX* DAN L. SACKETT, HACENE BOUKARI, *Laboratory of Integrative and Medical Biophysics, NICHD, National Institutes of Health, Bethesda MD* EILEEN M. LAFER, *Department of Biochemstry, University of Texas Health Science Center, San Antonio TX* RALPH NOSSAL, *Laboratory of Integrative and Medical Biophysics, NICHD, National Institutes of Health, Bethesda MD* A principal component in the protein coat of certain post-golgi and endocytic vesicles is clathrin, a three-legged heteropolymer (known as a triskelion) that assembles into polyhedral cages principally made up of pentagonal and hexagonal faces. In vitro, this assembly depends on the pH, with cages forming more readily at low pH and less readily at high pH. We have developed procedures, based on static and dynamic light scattering, to determine the radius of gyration, $R_g$, and hydrodynamic radius, $R_H$, of isolated triskelia, under conditions where cage assembly occurs. Calculations based on rigid molecular bead models of a clathrin triskelion show that the measured values can be accounted for by bending of the legs and a puckering at the vertex. We also show that the values of $R_g$ and $R_H$ measured for clathrin triskelia in solution are qualitatively consistent with the conformation of clathrin in a ''$D_6$ barrel'' cage assembly measured by cryoEM tomography.

**U28 3 A macromolecular model for the endothelial surface layer** JAMES HARDEN, *Department of Physics, University of Ottawa* DARINA DANOVA-OKPETU, *Department of Physics, Vrije Universiteit* GARY GREST, *Sandia National Labs* The endothelial surface layer (ESL) is a micron-scale macromolecular lining of the luminal side of blood vessels composed of proteoglycans, glycoproteins, polysaccharides and associated plasma proteins all in dynamic equilibrium. It has numerous physiological roles including the regulation of blood flow and microvascular permeability, and active participation in mechanotransduction and stress regulation, coagulation, cell adhesion, and inflammatory response. The dynamic structure and the mechanical properties of the ESL are crucial for many of its physiological properties. We present a topological model for the ESL composed of three basic macromolecular elements: branched proteoglycans, linear polysaccharide chains, and small plasma proteins. The model was studied using non-equilibrium molecular dynamics simulations and compared with scaling theories for associating tethered polymers. We discuss the observed dynamical and mechanical properties of the ESL captured by this model, and the possible physical insight it provides into the physiological behavior of the ESL.

**U28 4 Simulation of metachronal wave in a model of pulmonary cilia*** SORIN MITRAN, *UNC* A simulation of the formation of metachronal waves in carpets of pulmonary cilia is presented. The cilia move in a two-layer fluid model. The fluid layer adjacent to the cilia base is purely viscous while the tips of the cilia move through a viscoelastic fluid. An overlapping fixed-moving grid formulation is employed to capture the effect of the cilia on the surrounding fluid. The 9+2 internal microtubule structure of an individual cilium is modeled using large-deflection, curved, finite-element beams. Realistic models of the forces exerted by dynein molecules are extracted from measurements of observed cilia shapes. The possibility of formation of metachronal waves under different assumptions of boundary conditions is investigated and shown to be dependent on the surrounding geometry.

**U28 5 On the Evolution of Voltage Gated Ion Channels.**
MICHAEL BRENNER, *Harvard University*

This talk summarizes some ideas, calculations and data analysis/collection surrounding the structure and evolution of ion channels, in particular voltage gated sodium channels. The great advantage of ion channels is that they are individual proteins whose function has long been known and is readily inferred through voltage measurements. Their evolution can be tracked through the growing data base of sequences. Kinetic data is readily available, showing important differences between nearly identical channels. I will discuss our efforts to collate available functional data on voltage gated sodium channels into an ''ion channel property space''. We then use this dataset to infer underlying kinetic models, and to create evolutionary trees based on the function of the channels. Finally, I will discuss our endeavors to how ion channels evolved to be the way they are: Examples of questions we would like to answer include: to what extent do design principles dictate the details of the kinetic schemes of ion channels, such as (a) the symmetry of the sodium and potassium channels (or lack thereof), as reflected in their kinetic schemes; (b) the coupling of sodium channel kinetics to potassium channel kinetics; or (c) activation/inactivation of the channels themselves.

**U28 6 Optimization of Anguilliform Swimming** STEFAN KERN, PETROS KOUMOUTSAKOS, *ETH Zurich* Anguilliform swimming is investigated by 3D computer simulations coupling the dynamics of an undulating eel-like body with the surrounding viscous fluid flow. The body is self-propelled and, in contrast to previous computational studies of swimming, the motion pattern is not prescribed a priori but obtained by an evolutionary optimization procedure. Two different objective functions are used to characterize swimming efficiency and maximum swimming velocity with limited input power. The found optimal motion patterns represent two distinct swimming modes corresponding to migration, and burst swimming, respectively. The results support the hypothesis from observations of real animals that eels can modify their motion pattern generating wakes that reflect their propulsive mode. Unsteady drag and thrust production of the swimming body are thoroughly analyzed by recording the instantaneous fluid forces acting on partitions of the body surface.

**10:00**
**U28 7 Flow measurement in an in-vitro model of a single human alveolus*** SUDHAKER CHHABRA, AJAY PRASAD, *Department of Mechanical Engineering, University of Delaware, Newark, DE 19716* The alveolus is the smallest and most important unit in the acinar region of the human lung. It is responsible for gas exchange between the lungs and the blood. A complete knowledge of the airflow pattern in the acinar region is necessary to predict the transport and deposition of inhaled aerosol particles. Such knowledge will benefit the pharmaceutical community in its effort to deliver therapeutic aerosols for lung-specific as well as system-wide ailments. In addition, it can also help to assess the health effects of the toxic aerosols in the environment. We have constructed an in-vitro model of a single spherical alveolus on a circular tube. The alveolus is capable of expanding and contracting in phase with the oscillatory flow through the tube. Realistic breathing conditions are reproduced by matching Reynolds and Womersley numbers. Experimental methods such as particle imaging velocimetry and laser induced fluorescence are used to study the resulting flow patterns. In particular, recirculating flow within the alveolus, and the fluid exchange between the alveolar duct and the alveolus are important for better understanding the flow in the acinar region.

**U28 8 Transport and collective dynamics in suspensions of swimming particles** MICHAEL GRAHAM, JUAN HERNANDEZ, *Univ. of Wisconsin-Madison* Direct simulations of large populations of hydrodynamically interacting swimming particles at low Reynolds number are performed. Hydrodynamic coupling between the swimmers leads to large-scale coherent vortex motions in the flow that are consistent with experimental observations. At low concentrations, swimmers propelled from behind (like spermatazoa) strongly migrate toward solid surfaces in agreement with simple theoretical considerations; at higher concentrations this localization is disrupted by the large-scale coherent motions. Correspondingly, at large concentrations the swimmers move with velocities several times larger than they could achieve in isolation.

**10:24**
**U28 9 Computational Modeling of Microfluidic Rapid-Mixing Device Used in Infrared Micro-Spectroscopy** MARK DICKINS, *University of Texas at Austin* JARMILA GUIJARRO, AIHUA XIE, *Oklahoma State University* Microfluidic rapid-mixing device is employed to chemically trigger biological functions of proteins for time-resolved Fourier transform Infrared (FTIR) micro-spectroscopic study. There are two criteria for the optimal design of such devices: (i) minimizing the mixing time (thus better time-resolution) and (ii) minimizing the consumption of protein samples. Computational modeling has been performed on the Poiseuille and diffusional flow patterns. Due to the low-Reynolds number of microfluidic flow in study, finite-difference methods for the Navier-Stokes and advection-diffusion equations are employed in our computational modeling. The viscosity of the fluids is related to the pressure gradient required to achieve maximum velocity according to Pouisulle flow. Several mixing channels are modeled in order to determine the optimal dimensions for our microchip according to the design criteria. We will report our computational modeling results and their relevance to the optimal design of rapid-mixing devices used in time-resolved infrared micro-spectroscopy.

**U29 1 DNA's Liaison with RNA Polymerase Physical Consequences of a Twisted Relationship** IGOR KULIC, PHIL NELSON, *University of Pennsylvania* RNA polymerase is the molecular motor that performs the fundamental process of transcription. Besides being the key- protagonist of gene regulation it is one of the most powerful nano-mechanical force generators known inside the cell. The fact that polymerase strictly tracks only one of DNA's strands together with DNA's helical geometry induces a force-to-torque transmission, with several important biological consequences like the ''twin supercoil domain'' effect and remote torsional interaction of genes. In the first part of the talk we theoretically explore the mechanisms of non-equilibrium transport of twist generated by a moving polymerase. We show that these equations are intrinsically non-linear in the crowded cellular environment and lead to peculiar effects like self-confinement of torsional strain by generation of alternative DNA structures like cruciforms. We demonstrate how the asymmetric conformational properties of DNA lead to a ''torsional diode'' effect, i.e. a rectification of polymerase-generated twist currents of different signs. In the second part we explore the possibility of exploiting the polymerase as a powerful workhorse for nanomechanical devices. We propose simple and easy to assemble arrangements of DNA templates interconnected by strand-hybridization that when tran-

scribed by the polymerase linearly contract by tenfold. We show that the typical forces generated by such ''DNA stress fibers'' are in the piconewton range. We discuss their kinetics of contraction and relaxation and draw parallels to natural muscle fiber design.

**8:12**
**U29 2 Enhanced Fano factor in a molecular transistor coupled to phonons and Luttinger-liquid leads** SO TAKEI, YONG BAEK KIM,* *University of Toronto* ADITI MITRA,† *Columbia University* We study how the electron-phonon coupling *and* intralead electron interaction affect the transport properties of a molecular quantum dot coupled to leads. We consider the effects on the steady state current and DC noise for both equilibrated and unequilibrated on-dot phonons. The density matrix formalism is applied in the high temperature approximation and the resulting semi-classical rate equation is numerically solved for various strengths of electron-electron interactions in the leads and electron-phonon coupling. We have found that the Fano factor, which measures the noise to current ratio, is enhanced as the intralead electron interaction is increased, while both the current and its noise are smeared out and suppressed due to the interaction. Interestingly, the Fano factor exhibits super-poissonian behaviour as the electron-phonon coupling becomes greater than order one.

**U29 4 Multi-scale dynamics and relaxation of a tethered membrane in a solvent by Monte Carlo simulations*** RAS PANDEY, *University of Southern Mississippi* KELLY ANDERSON, *The Procter & Gamble Company* BARRY FARMER, *Air Force Research Laboratory* A tethered membrane modeled by a flexible sheet dissipates entropy as it wrinkles and crumples. Nodes of a coarse grained membrane are connected via multiple pathways for dynamical modes to propagate. We consider a sheet with nodes connected by fluctuating bonds on a cubic lattice. The empty lattice sites constitute an effective solvent medium via node-solvent interaction. Each node execute its stochastic motion with the Metropolis algorithm subject to bond fluctuations, excluded volume constraints, and interaction energy. Dynamics and conformation of the sheet are examined at a low and a high temperature with attractive and repulsive node-node interactions for the contrast in an attractive solvent medium. Variations of the mean square displacement of the center node of the sheet and that of its center of mass with the time steps are examined in detail which show different power-law motion from short to long time regimes. Relaxation of the gyration radius and scaling of its asymptotic value with the molecular weight are examined.

**U29 5 Ion distribution inside a nanopore in the presence of a polyelectrolyte** LEI GUO, ERIK LUIJTEN, *University of Illinois at Urbana-Champaign* Experimental studies of the translocation of DNA through nanopores rely on measurements of the ionic current. In order to understand the behavior of this current, we employ molecular dynamics simulations to study the ion distribution within a nanopore in the presence of a polyelectrolyte. We characterize the ion distribution in terms of radial density profiles around the polyelectrolyte. Several factors affecting the ion distribution are studied, including the role of chain flexibility, salt concentration, nanopore size and its polarizability. Our study also provides information on the dynamics of the ions inside the pore. The combination of static and dynamic information is used to explain experimental observations.

**U29 6 Measuring the direction of coupling between biological oscillators*** JORGE BREA, *Department of Physics and Astronomy, University of Missouri Saint Louis* ALEXANDER NEIMAN, *Department of Physics and Astronomy, Ohio University* DAVID RUSSELL, *Department of Biological Sciences, Ohio University* The electroreceptor system of the paddle fish comprises two self-sustained noisy oscillators: one oscillator resides in the sensory epithelium and is coupled through excitatory synapse with another oscillator residing in the afferent neuron terminal. We test recently developed algorithms for estimating the directionality of their coupling from experimental recordings of spontaneous and stimulated activity. These experimental bivariate time series are structurally different: while the signal from the epithelial oscillations is represented by a continuous stochastic process, the neuron oscillations are represented by a stochastic point process. We show that the tested algorithms detect reliably directionality of coupling both in experimental and simulated data and can be used for physiologically relevant short segments of data.

**U29 7 Applications of the ratchet effect at nano- and mesoscopic scales.***
BOLDIZSAR JANKO,† *University of Notre Dame*

I will discuss the application the ratchet effect in superconducting vortex dynamics and interacting colloidal systems. We have shown theoretically how in superconductors patterned on sub-micron or nanometer scale with various pinning potentials a DC vortex transport and vortex manipulation can be achieved with an external AC drive. I will discuss several applications of the vortex ratchet effect as well as a series of experiments aimed at the detection and investigation of the vortex ratchet transport. For colloidal systems, we have recently shown that a rich variety of dynamic phases can be realized for mono- and bidisperse mixtures of interacting colloids under the influence of a symmetric flashing periodic substrate. With the addition of dc or ac drives, phase locking, jamming, and new types of ratchet effects occur. In some regimes we find that the addition of a non-ratcheting species increases the velocity of the ratcheting particles. We show that these effects occur due to the collective interactions of the colloids.

We have developed a technology for submicron integration of functional genes and on-chip protein synthesis using a cell-free transcription/translation system. The interaction between genes is facilitated by diffusion of on-chip gene expression products from 'source' genes towards 'acceptor' genes. Our technology is simple and inexpensive and can serve as an improved platform for a wide variety of protein and DNA biochip applications.

**10:24**
**U29 9 ''Burnt Bridge'' Mechanism of Molecular Motor Motion** TIBOR ANTAL, PAUL KRAPIVSKY, *Boston University* Motivated by a biased diffusion of molecular motors with the bias dependent on the state of the substrate, we investigate a random walk on a one-dimensional lattice that contains weak links (called ''bridges'') which are affected by the walker. Namely, a bridge is destroyed with probability $p$ when the walker crosses it; the walker is not allowed to cross it again and this leads to a directed motion. The velocity of the walker is determined analytically for equidistant bridges. The special case of $p = 1$ is more tractable — both the velocity and the diffusion constant are calculated for uncorrelated locations of bridges, including periodic and random distributions.

**U30 1 Shock Wave Theory for Rupture of Rubber.**
MICHAEL MARDER, *The University of Texas at Austin*

The rupture of rubber differs from conventional fracture. It is supersonic, and the speed is determined by strain levels ahead of the tip rather than total strain energy as for ordinary cracks. Dissipation plays a very important role in allowing the propagation of ruptures, and the back edges of ruptures must toughen as they contract, or the rupture is unstable. In this talk I will review the experimental evidence for these claims. I will present several levels of theoretical description of the phenomenon: first, a numerical procedure called mesoscopic particle modeling, which is capable of incorporating large extensions, dynamics, and bond rupture; second, a simple continuum model that can be solved analytically, and which reproduces several features of elementary shock physics; and third, an analytically solvable discrete model that

accurately reproduces numerical and experimental results, and explains the scaling laws that underly this new failure mode. Rupture speeds compare well with experiments, although opening angles of the rupture are not captured especially well. Some additional interesting topics that may be encountered along the way include the question of how to model sound dissipation in disordered solids, and a numerical instability that is suggestive of the phenomenon of strain crystallization.

**U30 2 Tuning the Adhesion of Soft Elastomers with Topographic Patterns** ALFRED CROSBY, EDWIN CHAN, *University of Massachusetts* Nature (e.g. gecko and jumping spider) utilizes surface patterns to control adhesion. The primary mechanism of adhesion for these systems can be sufficiently described by linear elastic fracture mechanics theory and material-defined length scales. Based upon these natural inspirations, similar mechanisms can be used to control the adhesion of elastic polymers. For viscoelastic polymers, patterns tune adhesion through additional mechanisms that have not been previously observed. Here, we illustrate the effects of topographic patterns in tuning the adhesion for soft, elastic or viscoelastic, elastomers. Contact adhesion tests based on Johnson, Kendall and Roberts (JKR) theory are used to characterize the adhesion of patterned poly(dimethyl siloxane) as well as poly(n-butyl acrylate) elastomers. We demonstrate that patterns can be utilized to control the adhesion of these polymers by: 1) controlling the balance of initiation and propagation for local separation process, 2) controlling the local crack velocity to alter the global viscoelastic response, and 3) altering the local separation mode through modification of a polymer layer's lateral confinement.

**U30 3 Finite Element Calculations Using a New Constitutive Model for the Chemical Aging of Rubber** JOANNE BUDZIEN, DAVID LO, JOHN G. CURRO, *Sandia National Laboratories* DANA ROTTACH, *University of New Mexico* We have developed a constitutive model for rubber networks undergoing simultaneous crosslinking and scission reactions. This model is a modification of the independent network hypothesis that includes the coupling between strain history and chemical reactions. This coupling occurs because formation of networks in the strained state is greatly affected by the networks that were already present. Even when early networks scission, the overall material response shows some memory of the initial networks (i.e., some later stage networks act as earlier stage networks). We account for this effect using stress transfer functions. The model has been tested on microscopic molecular dynamics simulations. We will present results using this constitutive model in finite element calculations showing the large effect that the coupling of strain history and chemical reaction has.

**U30 4 Effect of chain bridging on mechanical properties of lamellae-forming block copolymers** ALHAD PHATAK, LISA LIM, CLETIS REAVES, FRANK BATES, *Department of Chemical Engineering and Materials Science, University of Minnesota* We report studies on solid-state mechanical properties of lamellae-forming block copolymers composed of poly(cyclohexylethylene) (C) and poly(ethylene) (E). Specifically, we have investigated the effect of bridging conformations in the semicrystalline E block. We studied CEC, ECEC, and ECECE architectures and found that tensile properties of C/E block copolymers are extremely sensitive to the fraction of ''soft'' E chains tethered between glassy C domains. While the CEC polymer has a strain-to-failure of $\sim$ 300%, the ECEC and ECECE polymers fail at $\sim$ 1% strain. By employing ECEC/CEC and ECECE/CEC blends, we have come up with a molecular parameter that describes a sharp brittle-to-ductile transition and captures the tensile properties of a broad range of C/E block copolymer architectures having equal sized E blocks. In another set of experiments, increasing the ''middle-to-loose'' E block length ratio was found to toughen the ECECE block copolymers. We propose that these effects are related to a critical concentration of bridged E chains that governs the failure mechanisms in glassy-semicrystalline block copolymers.

**U30 5 Probing the Contact and Sliding of Elastomer/Polymer Interfaces*** BETUL YURDUMAKAN, *The University of Akron* KUMAR NANJUNDIAH, ALI DHINOJWALA, In this study, we have designed a novel approach to couple interface sensitive infrared-visible sum frequency generation (SFG) spectroscopy with adhesion and friction experiments. This provides a direct probe of the interfacial structure in terms of orientation and density of molecules during contact and sliding which is important in understanding the molecular origin of adhesion and friction. Here, we show that the friction forces between poly(dimethyl siloxane) (PDMS) lens and glassy poly(styrene) (PS) are $\approx$ 4 times higher than PDMS sliding on surfaces of crystalline alkyl side chain comb polymers. This cannot be explained by the differences in adhesion energy or hysteresis. The in-situ SFG measurements indicate local interdigitation during contact, which is evident from the decrease in the number of oriented phenyl groups at the interface. The local penetration is unexpected at room temperature ($T_R$) that is much below the $T_g$ of PS. For comparison, we have also studied poly(n-butyl methacrylate) and poly(n-propyl methacrylate) having $T_g$ above and below $T_R$, respectively. Both of these polymers show similar adhesion and friction forces as PS. The SFG results indicate that local changes in interfacial structure affect friction, regardless of the bulk $T_g$. These results also show that the adhesion energy and hysteresis are not sufficient to predict friction, which makes the characterization of the molecular structure during contact and sliding essential.

**U30 6 Mesoscopic Random Lattice Models of Rupture in Rubber*** DAVID REYNOLDS, MICHAEL MARDER, *The University of Texas at Austin* In an earlier work, Marder illustrated how rupture in rubber differs from conventional fracture. Dissipation and toughening of the back edges of ruptures are critical for the propagation of stable ruptures. In this earlier work, mesoscopic models were arrived at by approximating the Mooney-Rivlin theory of rubber by a finite difference scheme on a triangular lattice. From this perspective, qualitatively the lattice sites are considered to be crosslinkers and the bonds are polymers. We extend this work by considering the crosslinkers to be randomly distributed throughout the material rather than being ordered. For both random and ordered lattices, without rupture, there are many

different ways to construct free energy functionals that reproduce the continuum theory. However, not all of the constructions are numerically stable. We explore the physical consequences of the disorder and the physical interpretations of the observed numerical instabilities.

**U30 7 Annealing History Dependence of Young's Modulus in Thin Polymer Films Using an Axi-symmetric Peel Test Apparatus** ADAM N. RAEGEN, KARI DALNOKI-VERESS, *Physics and Astronomy, McMaster University* We present a study of chain relaxation in thin spincast films above the glass transition temperature. We employ a novel axi-symmetric peel test, which uses the deformation of a thin spincast polymer film brought into contact with a flat substrate. The use of a thin membrane minimises uncertainty in the contact radius while the use of spincast films provides very smooth surfaces by means of a very simple method. The experimental profile of the deformed membrane shows good agreement with the expected logarithmic profile. While this agreement allows measurement of the Young's modulus and solid-solid work of adhesion in thin films, this study will focus on the dependence of the Young's modulus on the annealing history in thin films. The thermal history dependence shows that for short annealing times Young's modulus is larger than expected, suggesting that the chains are oriented during spincasting. For longer times, Young's modulus reaches literature values.

**U30 8 Contributions to the Adhesion of Glassy Polymers from Radical Recombination and Segmental Interpenetration at Elevated Temperatures** MURAT GUVENDIREN, MICHELLE LEFEBVRE, CHRISTINE DETTMER, SONBINH NGUYEN, KENNETH SHULL, *Northwestern University* We study two examples of adhesive interactions between glassy polymers that occur when the polymers are heated to elevated temperatures. First set is the adhesion between thin films of poly(phenylene oxide) (PPO). The samples are brought into contact at an elevated temperature and cooled to room temperature prior to measuring the fracture energy by using the contact mechanics approach based on JKR (Johnson, Kendall and Roberts) theory. Very little adhesion is observed at temperatures below about 130°C, which enables us to perform a second set of experiments, where adhesion is due to radical recombination across the interface. Polystyrene (PS) is synthesized by anionic polymerization, and terminated by an end-capped nitroxide radical group. Nitroxide mediated polymerization is used to attach a poly (tert-butyl acrylate) (tBA) block to the PS chains. These block copolymers are added to the PPO films that are brought into contact with one another. Nitroxide radicals become uncapped at elevated temperatures, with subsequent radical recombination providing another potential mechanism for the formation of bonds across the interface.

**U30 9 Adhesion and Spatial Distribution of Water in the Presence of Moisture: Surface Chemistry Affects.** CHRISOPHER WHITE, BRYAN VOGT, EMMETT OBRIEN, WEN-LI WU, *NIST* Many polymer adhesive bonds experience a complete loss of adhesion above a critical threshold relative humidity value. The adhesion loss from water exposure does not generally correlate with moisture solubility of the polymer; instead the surface layer of the polymer appears to be the controlling factor in the adhesion. Here, the adhesion and spatial distribution of water of a series of PMMA-Al adhesive samples in the presence of moisture is measured with neutron reflectivity, while the adhesive strength of the joint is measured using the shaft-loaded blister test. The role of changing surface chemistry was examined to determine their effect on this interfacial moisture content. The loss of adhesive strength upon exposure to moisture correlates directly with the interfacial water content. Surface modification methods that decrease the interfacial water content are used to tune the adhesive strength in moist environments. Minimization of the interfacial water concentration does not however result in the best adhesion in moist environments as interplay between the dry adhesion and water content exists.

**10:12**

**U30 10 Quantifying Ballistic Armor Performance: A Minimally Invasive Approach** GALE HOLMES, JAEHYUN KIM, WILLIAM BLAIR, WALTER McDONOUGH, CHAD SNYDER, *National Institute of Standards and Technology* Theoretical and non-dimensional analyses suggest a critical link between the performance of ballistic resistant armor and the fundamental mechanical properties of the polymeric materials that comprise them. Therefore, a test methodology that quantifies these properties without compromising an armored vest that is exposed to the industry standard V-50 ballistic performance test is needed. Currently, there is considerable speculation about the impact that competing degradation mechanisms (e.g., mechanical, humidity, ultraviolet) may have on ballistic resistant armor. We report on the use of a new test methodology that quantifies the mechanical properties of ballistic fibers and how each proposed degradation mechanism may impact a vest's ballistic performance.

**10:24**

**U30 11 Measurement of the Viscoelastic Bulk Modulus*** YAN MENG, SINDEE SIMON, *Texas Tech University* A new piston-cylinder type pressurizable dilatometer has been developed to measure the time-dependent bulk modulus of viscoelastic materials. The PVT behavior and the glass transition temperature of a polystyrene have been measured as a function of pressure. Preliminary measurements of the time-dependent bulk modulus have also been made. The isothermal bulk modulus is important because its magnitude is directly related to isotropic residual stress development in curing thermoset-reinforced composites; in addition, by comparing the bulk and shear responses, proposed differences in the molecular origins can be explored.

*Funding from NSF DMR 0308762 is gratefully acknowledged.

**U30 12 Influence of Physical Aging on the Mechanical Properties of a Random Polypropylene-Polyethylene Copolymer** SAMUEL AMANUEL, *Materials Science and Engineering* XIAOFENG CHEN, *Chemical and Biological Engineering* RAHMI OZISIK, SANFORD S. STERNSTEIN, *Materials Science and Engineering, Rensselaer Polytechnic Institute* Spontaneous aging of a random polypropylene-polyethylene copolymer was studied at 50 $^{o}$C above its glass transition temperature using differential scanning calorimetry, wide (WAXS) and small (SAXS) angle X-ray scattering, and dynamic mechanical relaxometry. Both the melting temperature and melting enthalpy of the copolymer increased with physical aging time at room temperature suggesting increased crystallinity. WAXS measurements also indicated an increase in crystallinity along with coexistence of $\gamma$ and $\alpha$ forms for highly aged samples. Dynamic mechanical measure-

ments showed that the shear storage modulus increased uniformly at all frequencies of measurement from 0.1 Hz to 20 Hz. Furthermore a direct correlation was observed between the storage modulus and the melting enthalpy of the copolymer. Conversely, the change in shear loss modulus was frequency dependent, with larger changes at 20 Hz than at 0.1 Hz. This suggests that there are changes in the relaxation time spectra with aging. The aging process will be explored in more detail using both the SAXS and stress relaxation data.

**U30 13 Fracture versus cavitation in probe-tack geometry: theory and experiments** PASCALE FABRE, *CRPP-CNRS 115 av. Dr. Schweitzer F-33600 Pessac* JÉRÉMIE TEISSEIRE, FRÉDÉRIC NALLET, CYPRIEN GAY, *CRPP-CNRS* We perform traction experiments on viscous liquids highly confined between parallel plates, a geometry known as the probe-tack test in the adhesion community. Direct observation during the experiment coupled to force measurement shows the existence of several mechanisms for releasing the stress. Bubble nucleation and instantaneous growth had been observed in a previous work. Upon increasing further the traction velocity or the viscosity, the bubble growth is progressively delayed. At even higher velocities, fractures at the interface between the plate and the liquid are observed before the bubbles have grown to their full size. We present a theoretical model that describes these regimes, using a Maxwell fluid as a model for the actual fluid. We present the resulting phase diagram for the different force peak regimes. It remarkably accounts for the data. Our results show that in addition to cavitation, interfacial fractures, commonly thought to be characteristic of soft viscoelastic solids like adhesives are already encountered in *liquid* materials.

**U31 1 Controlled Dielectrophoretic Positioning of Carbon Nanotubes** SARBAJIT BANERJEE, BRIAN WHITE, LIMIN HUANG, STEPHEN O'BRIEN, IRVING HERMAN, *Nanoscale Science and Engineering Center, Columbia University, New York, NY* Single-walled carbon nanotubes have been dielectrophoretically aligned between micropatterned electrodes. Use of a limiting resistor enables control over the number of carbon nanotubes deposited in the electrode gap. Further, the electric field between micropatterned electrodes can be perturbed by arrays of metal nanostructures. Simulating electric fields in the presence of metal objects allows us to design electrodes with arrays of metal dots for the precise positioning of nanotubes. Complex network structures can be fabricated using carefully placed metal nanostructures and also by varying the electrode geometry. Crossed-junction nanotube structures have been controllably fabricated by optimization of the electrode geometry, applied electric field, and load resistor. The dielectrophoretically aligned nanotube structures work as functional field-effect transistors. Several approaches to improving the contact resistances will be discussed. The work is supported by the NSEC program of the National Science Foundation under NSF Award Number CHE-0117752 and by NYSTAR.

**U31 2 Tuning the electrical and mechanical properties of carbon nanotubes interfaced with silicon surfaces using the UHV-STM** PETER ALBRECHT, JOSEPH LYDING, *University of Illinois at Urbana-Champaign* Nanoscale patterning of the Si(100)-2x1:H surface with the UHV-STM [1] is used to selectively modify the Si substrate acting as a semiconducting support for isolated single-walled carbon nanotubes (SWNTs) deposited via dry contact transfer (DCT) [2]. By desorbing H at the SWNT-Si interface, we can mechanically stabilize SWNTs that initially were only weakly coupled to the Si surface and thus highly sensitive to STM tip induced perturbations. Moreover, on the degenerately doped n-type H-Si(100) surface, the presence of negatively charged Si dangling ponds patterned in close proximity to a semiconducting SWNT decreases the magnitude of the substrate voltage required for the onset of filled states conduction through the SWNT. Our results suggest new opportunities for engineering – on the sub-nm scale – both the mechanical and electronic properties of SWNTs integrated with semiconductor platforms. [1] J.W. Lyding et al., APL 64, 2010 (1994). [2] P.M. Albrecht and J.W. Lyding, APL 83, 5029 (2003).

**U31 3 Effect of doping on electro-optical properties of thin carbon nanotube membranes** MATTHEW GARRETT, *University of Tennessee* ILIA IVANOV, BIN ZHAO, ALEX PURETZKY, DAVID GEOHEGAN, *Oak Ridge National Laboratory* Nanotube membranes can prove to be a practical alternative to the current transparent conductors, such as ITO, that are in touch screen displays and photovoltaic devices. ITO with a transmittance of 80% in the visible spectrum has a resistance of 10ohms/square. Similar transmittance could be obtained only with very thin membranes with nanotube loadings below the percolation threshold and would have very high resistance. Doping of membranes changes transmittance at the S11 and S22 transitions of semiconducting nanotubes, but does not change the transmission in the visible spectrum, while decreasing the resistance. Membranes of different thicknesses have been produced and characterized. Post-production doping of the membranes has been achieved and the change in resistance and in transmission spectrum has been examined. We will discuss effect of donor and acceptor dopants on the conductivity and transmittance of the nanotube membranes.

**8:36**

**U31 4 Environmental Manipulation of the Electronic Structure of Suspended Carbon Nanotubes** A.G. WALSH, Y. YIN, *Physics Dept, BU* A.N. VAMIVAKAS, *ECE Dept, BU* S.B. CRONIN, M. TINKHAM, *Physics Dept, Harvard* M.S. UNLU, *ECE Dept, BU* B.B. GOLDBERG, *Physics Dept, BU* A.K. SWAN, *ECE Dept, BU* We use tunable resonant Raman spectroscopy to study the effect of changing the dielectric environment on the electronic structure of single wall carbon nanotubes (CNTs) suspended over trenches. The 1D nature of CNTs is responsible for weak intrinsic screening and large Coulomb interactions are anticipated. Two-photon absorption experiments have determined the presence of excitons with large binding energies [1,2]. Therefore, modulation of the surrounding dielectric constant signifi-

cantly alters the strength of the Coulomb interactions and leads to changes in the exciton binding energy and band-gap renormalization which should be evident in the resulting spectra.[3] Until recently, CNTs were primarily studied in bulk, in suspensions, or coated in surfactants. We measure resonance excitation profiles (REPs) from individual suspended CNTs where the intensity of the Raman peak is plotted vs. excitation energy. We vary the humidity and monitor the shift of the REP peak of the radial breathing mode and the G-Band. We thereby directly measure the relative shift of the renormalized band-edge and exciton binding energy as a function of dielectric constant. [1] Wang, Science, 308, 838 (2005). [2] Maultzsch, arXiv, 0505150 (2005). [3] Perebeinos, PRL, 92, 257402 (2004).

**8:48**

**U31 5 Capacitance measurements of individual carbon nanotubes** LUKE A. K. DONEV, SHAHAL ILANI, PAUL L. McEUEN, *Laboratory of Atomic and Solid-State Physics, Cornell University* We present measurements of the capacitance of individual single walled carbon nanotubes. The nanotubes were grown from ethylene at 700°C using evaporated iron nanoclusters as the catalyst. Electrical contacts and local top gates were patterned using optical lithography and liftoff. The top gate consists of a thin oxide film ( $\sim$ 15 nm, different oxides have been used) covering the nanotube with metal on top. The capacitance was measured between the nanotube and the top gate using a commercially available capacitance bridge. We also measure the transport through the tube and correlate the transport and capacitance measurements. For semiconducting tubes, we measure the difference in capacitance between the conducting state and the state where the charge carriers in the tube are depleted. The measured capacitance per unit length of the nanotube is in reasonable agreement with the geometric capacitance of a metal wire embedded in oxide near a conducting plane.

**U31 6 Electrical Characterization of Y-junction Carbon Nanotubes of Fish-bone Structure*** Y. SUN, J. I. OH, S. CHEN, D. Z. WANG, K. KEMPA, Z. F. REN, *Boston College* W. Z. LI, *Florida International University* M. J. NAUGHTON, *Boston College* Y-junction carbon nanotubes (YCNTs) of fish-bone structure, synthesized by the pyrolysis of methane over cobalt supported on magnesium oxide [1], have been characterized by means of electrical transport measurements. We report both 2- and 4-probe I-V characteristics of YCNTs down to $T = 3$ K and up to $B = 8$ T. At 3 K, we found that change in magnetoresistance was about 0.5 % at 8 T, perhaps due to piezoeffect of YCNTs. Also, we report the piezoresistivity of YCNTs directly obtained by an itin situ STM incorporated into TEM. This piezoresistivity appeared to be substantially bigger than that of straight fish-bone CNTs. In addition, we fabricated some FET-shaped samples with YCNTs whose all 3 branches were contacted by Ti/Au electrodes. We found that there is no rectifying behavior in the fish-bone junctions unlike in similar YCNTs reported in [2]. [1] W. Z. Li, J. G. Wen, Z. F. Ren, Appl. Phys. Lett. **79**, 1879 (2001). [2] P. R. Bandaru, C. Daraio, S. Jin, A. M. Rao, Nature Mats. **4**, 663 (2005).

**U31 7 Resonant Raman spectroscopy analysis of single wall carbon nanotubes treated with high density plasma of different gases.*** DAVID MAST, CHAMINDA JAYASINGHE, ZHANDOS UTEGULOV,† *University of Cincinnati* Single wall carbon nanotubes (SWNTs) have been plasma treated with different gases (Ar, $O_2$ and Ar and $H_2$ gases mixtures) using an inductively coupled RF plasma system (IC-RFP). The gas pressure was varied from 50mtorr to 315mtorr at 50W plasma power. Microscopic plasma parameters including ion density ($n_i$) and electron temperature ($T_e$) (thermal energy of electrons) were been determined using a double Langmiur probe in the plasma. Treated SWNTs was been characterized using resonance Raman spectroscopy at 515nm and 633nm laser excitation. It was observed that there was a considerable increase of the D to G-band ratio of treated SWNTs with increasing gas pressures and also that the Breit-Wigner-Fano band ($G_{BWF}$) to $G^+$-band ratio was been considerably increased. Further, at 515nm laser excitation the frequency up-shift of the G-band for Ar &(5%) $H_2$ (gas mixture) plasma treated SWNTs was higher at all pressures than those of other gases.

*Thanks to Dr. John Maguire, AFRL/MLBP Wright-Patterson AFB for the use of the Raman Spectrometer.

**9:36**

**U31 9 Temperature dependence of mean free length of electrons in single walled carbon nanotubes** MENINDER PUREWAL, *Columbia University, Department of Applied Physics and Applied Mathematics* ANIRUDDH RAVI, BYUNG HEE HONG, JOSHUA SMALL, *Columbia University, Department of Physics* BHUPESH CHANDRA, JAMES HONE, *Columbia University, Department of Mechanical Engineering* PHILIP KIM, *Columbia University, Department of Physics* We have measured how single walled carbon nanotube resistance scales with channel length. Multiple two-terminal devices of varying source-drain separation are fabricated on isolated ultra-long ( $>$ 1 mm) SWNTs grown by chemical vapor deposition. Pd electrodes provide low resistance contacts to the SWNTs. The resistance of SWNT devices are investigated in length scales ranging from 100 nm to 200 $\mu$m, from which the 1-dimensional resistivity is extracted. The temperature dependence of the electron mean free path obtained from the resistivity values indicate that in the majority of metallic SWNT devices the electron transport is ballistic up to $\sim$ 500 nm at room temperature and $\sim$ 10 $\mu$m at 1.6K.

**9:48**

**U31 10 Field Enhanced Thermionic Electron Emission from Oxide Coated Carbon Nanotubes*** CHRISTOPHER DAY, FENG JIN, YAN LIU, SCOTT LITTLE, *Ball State University* We have created a novel nanostructure by coating carbon nanotubes with a thin functional oxide layer. The structure was fabricated by sputter deposition of a thin film of oxide materials on aligned carbon nanotubes, which were grown on a tungsten substrate with plasma enhanced chemical vapor deposition. This structure combines the low work function of the oxide coating with a high field enhancement factor introduced by carbon nanotubes and we have demonstrated that it can be used as a highly efficient electron source. A field enhancement factor as high as 2000 was observed and thermionic electron emission current at least an order of magnitude higher than the emission from a conventional oxide cathode was obtained.

*This work is sponsored by the Department of Energy.

**U31 11 Low-temperature conductive tip scanning measurements of single walled carbon nanotubes.** MATTHEW PRIOR, ALEXANDER MAKAROVSKI, ALEXEI ZHUKOV, GLEB FINKELSTEIN, *Department of Physics, Duke University* We have built a low-temperature atomic force microscope (AFM) that fits inside a 38 mm bore cryostat. The scanning probe is attached to a quartz tuning fork, and a frequency shift is used as the feedback signal. By using a conductive tip we can locally tunnel into single walled carbon nanotubes grown on a non-conducting (SiO2) substrate. The nanotubes are contacted by a metal grid ''electrode'' evaporated on top of the sample. The tip is used as a second, movable contact. We measure the nanotube conduction as a function of the tip position and the gate voltage.

**10:12**

**U31 12 Local Density of States in Nanoscale Systems Measured by Electrostatic Force Microscopy*** CRISTIAN STAII, *Materials Science and Engineering, Drexel University* DOUGLAS R. STRACHAN, *Physics and Astronomy, University of Pennsylvania* DAWN A. BONNELL, *Materials Science and Engineering, University of Pennsylvania* ALAN T. JOHNSON, *Physics and Astronomy, University of Pennsylvania* JONATHAN E. SPANIER, *Materials Science and Engineering, Drexel University* DREXEL TEAM, PENN TEAM, We use Electrostatic Force Microscopy (EFM) to measure the local density of states (LDOS) in carbon nanotubes and semiconducting nanowires. A voltage biased EFM cantilever, driven at its resonant frequency is used to perturb the local charge density in these systems. The recorded change in the oscillation phase is proportional to the LDOS of the sample. We monitor the phase change as a function of both the tip voltage and cantilever oscillation amplitude for a fixed cantilever position above the sample. We also show that this is a general electrostatic method that can be used to measure the band gap and LDOS of both conducting and insulating nanoscale systems with no need for electrical contacts.

**U33 1 Critical behavior and Griffiths effects in the disordered contact process** THOMAS VOJTA, MARK DICKISON, *Department of Physics, University of Missouri-Rolla* We study the nonequilibrium phase transition in the one-dimensional contact process with quenched spatial disorder by means of large-scale Monte-Carlo simulations for times up to $10^9$ and system sizes up to $10^7$ sites. In agreement with recent predictions of an infinite-randomness fixed point, our simulations demonstrate activated (exponential) dynamical scaling at the critical point. The critical behavior turns out to be universal, even for weak disorder. However, the approach to this asymptotic behavior is extremely slow, with crossover times of the order of $10^4$ or larger. In the Griffiths region between the clean and the dirty critical points, we find power-law dynamical behavior with continuously varying exponents. We discuss the generality of our findings and relate them to a broader theory of rare region effects at phase transitions with quenched disorder.

**U33 2 Monte Carlo Studies of Phase Separation in Compressible 2-dim Ising Models** S.J. MITCHELL, D.P. LANDAU, *Center for Simulational Physics, University of Georgia* Using high resolution Monte Carlo simulations, we study time-dependent domain growth in compressible 2-dim ferromagnetic ($s = 1/2$) Ising models with continuous spin positions and spin-exchange moves [1]. Spins interact with slightly modified Lennard-Jones potentials, and we consider a model with no lattice mismatch and one with 4% mismatch. For comparison, we repeat calculations for the rigid Ising model [2]. For all models, large systems ($512^2$) and long times ($10^6$ MCS) are examined over multiple runs, and the growth exponent is measured in the asymptotic scaling regime. For the rigid model and the compressible model with no lattice mismatch, the growth exponent is consistent with the theoretically expected value of 1/3 [1] for Model B type growth. However, we find that

non-zero lattice mismatch has a significant and unexpected effect on the growth behavior. Supported by the NSF. [1] D.P. Landau and K. Binder, *A Guide to Monte Carlo Simulations in Statistical Physics*, second ed. (Cambridge University Press, New York, 2005). [2] J. Amar, F. Sullivan, and R.D. Mountain, Phys. Rev. B 37, 196 (1988).

**U33 3 Rate of Entropy Extraction in Compressible Turbulence.*** MAHESH BANDI, WALTER GOLDBURG, *Department of Physics and Astronomy, University of Pittsburgh* JOHN CRESSMAN, *Krasnow Institute, George Mason University* The rate of change of entropy is measured for a system of particles floating on the surface of a fluid maintained in a turbulent steady state. This rate of entropy $\dot{S}$ equals the time integral of the two point temporal velocity divergence correlation function with a negative prefactor. The measurements satisfactorily agree with the sum of Lyapunov exponents (Kolmogorov-Sinai entropy rate) measured from previous simulations, as expected of dynamical systems that are very chaotic (Sinai-Ruelle-Bowen statistics).

*This work is supported by the NSF (Grant No. DMR-0201805).

**8:36**

**U33 4 Non-constant nucleation rate in a system in apparent metastable equilibrium** HUI WANG, HARVEY GOULD, *Clark University* KIPTON BARROS, AARON SCHWEIGER, BILL KLEIN, *Boston University* The distribution of nucleation times for the two-dimensional Ising model with nearest-neighbor and with long-range interactions is simulated using the Metropolis algorithm. The distribution is exponential at long times as would be expected if the nucleation rate is a constant, but is suppressed at earlier times even after the mean magnetization is apparently in metastable equilibrium. We explain this discrepancy by investigating the relaxation behavior of the clusters whose size is comparable to the nucleating droplet.

**8:48**

**U33 5 4:1 Resonance phenomena in the forced Belousov-Zhabotinsky chemical reaction** BRADLEY MARTS, *Duke University Physics* ANNA LIN, *Duke University Physics and Center for Nonlinear and Complex Systems* The oscillatory Belousov-Zhabotinsky (BZ) reaction has been successfully used to study generic aspects of resonance in spatially extended systems parametrically forced with pulses of light. Experiments have reproduced Arnol'd tongues and pattern forming behavior predicted by reaction diffusion models and amplitude equations. We use the BZ reaction to experimentally demonstrate a transition in the 4:1 resonance regime from patterns of $\pi/2$ fronts to patterns of $\pi$ fronts. The transition matches the theoretical predictions. Above a certain driving strength, traveling $\pi/2$ fronts become unstable and a new stable pattern of stationary $\pi$ fronts emerges.

**9:00**

**U33 6 Mode locking in quasiperiodic structures** THOMAS CREIGHTON, *Syracuse University* A. ALAN MIDDLETON, *Syracuse University* AC driven extended systems, such as charge density waves or arrays of Josephson junctions, exhibit mode locking or giant Shapiro steps. This mode locking is seen experimentally as plateaus in a generalized velocity or current as a function of drive parameter. In conventional mode locking, the frequency of the response is a rational multiple of the frequency of the AC drive. For a model, we use a sandpile automaton model with local nonlinear update rules. When random quenched disorder is present in the automaton, a Devil's staircase with mode locking at all rational numbers has been previously seen. We investigate the use of quasiperiodic structures in place of the disordered structures. We find the novel phenomena of mode locking where the currents are a quasiperiodic multiple of the drive frequency. These quasiperiodic steps turn out to be stable to thermal fluctuations. Application of this model to Josephson junction arrays and structured colloidal systems will be presented.

**9:12**

**U33 7 Periodic time dependent problems in nonequilibrium quantum statistical mechanics** SELMAN HERSHFIELD, *Univ. of Florida* The usual Kadanoff-Baym or Keldysh formulation of nonequilibrium quantum statistical mechanics can be reformulated for steady state problems in terms of a nonequilibrium density matrix of the form $\exp(-(H-Y)/k_BT)$, where $H$ is the hamiltonian and $Y$ contains the information about how the system is driven out of equilibrium.* This approach has now been used to solve exactly solvable models as well as in approximate techniques. Here we show that for a periodic time dependent hamiltonian there is a similar formulation in terms of a nonequilibrium density matrix, where the density matrix acts in one higher dimension than in the original problem. Thus, a time dependent nonequilibrum problem is mapped onto a time independent nonequilibrium problem in one higher dimension. This is true for interacting as well as noninteracting problems. The approach is illustrated by applying it to some exactly solvable time dependent nonequilibrium problems such as tunneling through a resonant level where the level and/or the voltage applied are time dependent. * S. Hershfield, PRL **70**, 2134 (1993).

**9:24**

**U33 8 On Rolling Loaded Dice*** GARY WHITE, When an unfair die is tossed, what are the factors that determine the side upon which it lands? Sir Hermann Bondi (see European Journal of Physics 14, pp. 136-140) asked a related theoretical question in 1993 with the intention of determining the theoretical probability of a coin landing on its edge. He notes that the center of mass, the coefficients of restitution and friction, and the radius of gyration all play a role, perhaps. A simple model assumes that the probability of landing on a particular side is proportional to the solid angle subtended from the center of mass, but this model predicts too few base landings for tall cylinders, and too many rolling landings for squatty cylinders. Here we propose a thermodynamic modification of this model which qualitatively improves the match between experiment and theory by introducing an effective ''temperature'' parameter. We apply the model to several different geometrical shapes where the landing odds are not even, including right circular cylinders, rectangular prisms, hemispheres and semicylinders. We obtain, perhaps unreasonably, somewhat promising results.

**9:36**

**U33 9 Broad spectrum period adding chaos in a transistor circuit.** THOMAS CARROLL, *Naval Research Lab* Period adding chaos, in which a driven system makes transitions such as period 2-chaos-period 3-chaos-period 4, is well known. In most cases, however, the frequency of the chaotic signal is close to the frequencies of the periodic signals. I have done expriments with a

simple circuit in which the chaos has a very broad power spectrum, covering 6 orders of magnitude. I have confirmed this broad band feature in numerical simulations of the circuit. These experiments have technological implications, because they show that a narrow band high frequency signal could produce broad band interference in even simple circuits.

**9:48**

**U33 10 Solving the Problem of Excessive Time Delay in Attractor Reconstruction** LOUIS PECORA, JON NICHOLS, THOMAS CARROLL, *Naval Research Laboratory* LINDA MONIZ, *US Geological Survey* We recently showed that the seemingly separate problems of finding a proper time delay and then finding a proper embedding dimension for attractor reconstruction are really the same problem which can be solved with a mathematical statistic faithful to the Takens reconstruction theorem. This approach also deals well with disparate time scales in data, and optimally choosing time series to use from a multivariate data set. However, the problem of when a time delay is too long for a chaotic time series remains. We introduce a new statistic that resolves this issue. The statistic is based on the mathematical observation that long time delays will result in data points that do not adequately populate the dynamical system's manifold. We present results with models and data that show we can predict when we have used excessively long time delays in attractor reconstruction.

**10:00**

**U33 11 Stochastic Loewner evolution driven by Lévy processes** ILIA RUSHKIN, *University of Chicago* PANAGIOTIS OIKONOMOU, *University of Chicago* LEO KADANOFF, *University of Chicago* ILYA GRUZBERG, *University of Chicago* Standard stochastic Loewner evolution (SLE) is driven by a continuous Brownian motion, which then produces a continuous fractal trace. If jumps are added to the driving function, the trace branches. We consider a generalized SLE driven by a superposition of a Brownian motion and a stable Lévy process. The situation is defined by the usual SLE parameter, $\kappa$, as well as $\alpha$ which defines the shape of the stable Lévy distribution. The resulting behavior is characterized by two descriptors: $p$, the probability that the trace self- intersects, and $\tilde{p}$, the probability that it will approach arbitrarily close to doing so. These descriptors are shown to change qualitatively and singularly at critical values of $\kappa$ and $\alpha$. These transitions occur as $\kappa$ passes through four (a well-known result) and as $\alpha$ passes through one (a new result). Numerical simulations are then used to explore the associated touching and near-touching events.

**10:12**

**U33 12 Positional Order and Diffusion Processes in Particle Systems** HIROSHI WATANABE, *Department of Complex, Systems Science, Graduate School of Information Science, Nagoya University* YUKAWA SATOSHI, NOBUYASU ITO, *Department of Applied Physics, School of Engineering, The University of Tokyo* In particle systems, a relation between the positional order parameter $\Psi$ and the mean square displacement $M$ is derived to be $\Psi \sim \exp(-vK^2M/2d)$ with a reciprocal vector $vK$ and the dimension of the system $d$. On the basis of the equiation, the behavior of $\Psi$ is found to be $\Psi \sim \exp(-vK^2Dt)$ when the system involves normal diffusion with a diffusion constant $D$. While the behavior in two-dimensional solid is predicted to be $M \sim \ln t$, numerical simulations shows a linear diffusion $M \sim t$. This can be explained by a swapping diffusion process which allows particles to diffuse without destroying the positional order.

**10:24**

**U33 13 Brownian dynamics of colloids in tilted periodic potential*** WEIQIANG MU, *Northwestern University* GANG WANG, *Indiana University, Purdue University Fort Wayne* GABRIEL SPALDING, *Illinois Wesleyan University* JOHN KETTERSON, *Northwestern University* We have studied the Brownian movements of micron-sized colloidal spheres in the presence of a periodic potential and the potential associated with gravity (which together form a so-called tilted-washboard potential). The optical potential is generated by the interference of two argon laser beams that are tightly focused through a common objective lens to form an in-plane standing wave in the vicinity of a substrate surface. As the intensity of standing wave is increased, the escape time of a particle trapped in a given potential well to the next lower one increases super-exponentially. More generally we have measured the time dependence of the probability density distribution of a colloidal particle as a function of the amplitude of the standing wave. The experimental data have been compared with a simulation based on the numerical integration of the Smoluchowski equation in the presence of the optical and gravitational potentials.

## SESSION U35: NANOWIRES
**Thursday Morning, 16 March 2006**
**338, Baltimore Convention Center at 8:00**
**Hyun Park, Naval Research Laboratory, presiding**

**8:00**

**U35 1 Dielectrophoretic assembly of reversible and irreversible metal nanowire networks and vertically-aligned arrays** STERGIOS J. PAPADAKIS, *Johns Hopkins University Applied Physics Laboratory* ZHIYONG GU, *Johns Hopkins University Department of Chemical and Biomolecular Engineering* DAVID H. GRACIAS, *Johns Hopkins University Departments of Chemistry and Chemical and Biomolecular Engineering* We demonstrate dielectrophoretic control of metallic nanowires in liquid suspensions. By varying parameters including the magnitude and frequency of the applied electric field, the liquid suspending the nanotubes, the nanowire metal, and the flow conditions, we can generate sparse or dense networks, multiply branching or predominately end-to-end networks, and vertically aligned nanowires standing on top of metal electrodes. The networks can be made reversibly or irreversibly. These results demonstrate the applicability of dielectrophoresis in aligning and positioning nanowires, either in the plane of the substrate or perpendicular to it, thereby suggesting a simple and versatile strategy for fabricating a range of integrated devices composed of nanowires. For example, sparse end-to-end networks are promising for individual electronic devices, dense branching networks take advantage of the large surface-to-volume ratio of nanowires for use as sensors, vertically-aligned arrays of nanowires may be used as vertical interconnects in damascene integration of microelectronic devices or in controlling the flow of fluid or light in microfluidic or nanophotonic devices, etc.

**8:12**

**U35 2 The Dielectrophoretically Guided Growth of Submicron, Near Single Crystal Indium Wires*** BRET FLANDERS, *Oklahoma State University* ISHAN TALUKDAR, *Oklahoma State university* BIROL OZTURK, *Oklahoma State University* TETSUYA MISHIMA, *University of Oklahoma* Dielectrophoresis was used to direct the growth of crystalline indium wires between lithographic electrodes immersed in solutions of indium acetate. Determination of the conditions that suppress side branching on these structures has enabled the fabrication of arbitrarily long needle-shaped wires with diameters between 367nm and 556nm. Electron diffraction studies indicate that these wires are crystalline indium, that the unbranched wire segments are single-crystal domains, and that the predominant growth-direction is near $\langle 110 \rangle$. This outcome constitutes a critical step towards the use of simply prepared aqueous mixtures as a convenient means of controlling the composition of submicron, crystalline wires.

*Supported by the National Science Foundation and Oklahoma EPSCoR.

**8:24**

**U35 3 Growth Characteristics of Dielectrophoretically Fabricated Single Crystal Wires*** ISHAN TALUKDAR, *Department of Physics, Oklahoma State University, Stillwater, Oklahoma, 74078* BIROL OZTURK, *Department of Physics, Oklahoma State University, Stillwater, Oklahoma, 74078* BRET FLANDERS, *Department of Physics, Oklahoma State University, Stillwater, Oklahoma, 74078* We investigate the mechanism underlying the dielectrophoretically guided growth of single-crystal metallic wires in aqueous solutions of metal-salts. The weak dependence of the mass deposition rate on the growth velocity suggests that the growth mechanism is consistent with microscopic solvability theory. We have also observed interesting dependencies of the growth velocities and the radii of these wires on the frequency of the dielectrophoretic voltage, and will report on our progress towards understanding these phenomena. The dependence of the wire's radius on the frequency is of potential technological interest in that it provides a sensitive means of controlling the submicron wire diameter.

*Supported by the National Science Foundation and Oklahoma EPSCoR.

**8:36**

**U35 4 Self-assembly of $Eu_2O_3$ nanoneedles and nanocrystals** JAMES DICKERSON, *Dept. of Physics and Astronomy, Vanderbilt University* SAMEER MAHAJAN, *Interdisciplinary Program in Materials Science, Vanderbilt University* MARCELA REDIGOLO, *Dept. of Physics and Astronomy, Vanderbilt University* DMITRY KOKTYSH, *Department of Chemistry, Vanderbilt University* Growth of anisotropic nanostructures starting from isotropic nanostructures is observed in $Eu_2O_3$ system. Anisotropic structures, like nanoneedles and nanospindles, are grown from the concentrated solution of $Eu_2O_3$ nanocrystals. This process involved the stepwise thermal growth of nanocrystals into ordered, high aspect ratio, one dimensional nanoneedles and the subsequent assembly of said nanoneedles into larger, oriented bundles (nanospindles). The $Eu_2O_3$ nanocrystals were synthesized following a room temperature, colloidal chemistry procedure, adapted from the synthesis of G. Wakefield et al.[1] We present the results of this self-assembly phenomenon using 4-nm $Eu_2O_3$ nanocrystals. High resolution transmission electron microscopy was employed to characterize the approximate shape, size distribution, and crystallinity of the nanostructures. Absorption and photoluminescence measurements were performed to investigate what effect the size and shape of materials has on optical properties. 1. G. Wakefield, H. A. Keron, P. J. Dobson, and J. L. Hutchison, J. of Coll. Interf. Sci. **215**, 179, 1999.

**U35 5 Three-dimensional nanoscale composition mapping of semiconductor nanowires.*** LINCOLN LAUHON, DANIEL PEREA, JONATHAN ALLEN, STEVEN MAY, BRUCE WESSELS, DAVID SEIDMAN, *Northwestern University* The composition of a single InAs nanowire was mapped in three dimensions with single-atom sensitivity and sub-nanometer resolution using local-electrode atom probe (LEAP) tomography. Arrays of epitaxial InAs nanowires were grown by chemical vapor deposition on GaAs substrates. Nanowires with diameters of 10-20 nm were analyzed over lengths of hundreds of nanometers. Three-dimensional reconstructions of the atoms in the nanowire showed hexagonal faceting, indicating that the LEAP analysis accurately reproduces the cross-section and shape of the nanowires. The Au catalyst particle sitting atop a nanowire was also analyzed; tomographic slices across the nanowire diameter, when displayed in 0.5 nm increments along the growth axis, revealed an extremely abrupt catalyst-nanowire interface that is also very flat. Despite the abruptness of the catalyst-nanowire interface, individual gold atoms were detected within the nanowire at a concentration of 100 ppm. These results indicate that LEAP microscopy can be used to (1) image buried nanowire interfaces in three dimensions and (2) analyze the concentration and distribution of dopant and impurity atoms in nanowires.

**U35 6 Ligand Functionality to Control Morphology, Solubility, and Assembly Behavior of CdSe Nanorods** WEI WANG, SHENGGUO JIA, SARBAJIT BANERJEE, MICHAEL STEIGERWALD, IRVING HERMAN, *Columbia University* MATERIALS RESEARCH SCIENCE AND ENGINEERING CENTER, COLUMBIA UNIVERSITY TEAM, By varying the length of the carbon chain of the ligand, while keeping other reaction parameters the same, CdSe nanorods with different diameters and lengths, branched nanorods, and even nano-arrows have been synthesized. Since all the ligands used are phosphonic acids with the same binding group, the length of the carbon chain of the ligand can dramatically change the size and morphology of the nanocrystals. Thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC) have been used to investigate the chemical composition of the nanorods. CdSe nanorod thin films have been made in hexane by electrophoretic deposition. The number and length of the ligands can dramatically change solubility, electrophoretic mobility of the nanorods, and quality of the nanorod film. We shall discuss mechanisms for ligand control of the nanocrystal structure. This work is supported by the MRSEC program of the National Science Foundation under Award No. DMR-0213574 and by the New York State Office of Science, Technology, and Academic Research (NYSTAR).

**9:12**

**U35 7 Twinning Superlattices in Semiconducting Nanowires** QIHUA XIONG, *Department of Physics, The Pennsylvania State University, University Park, PA 16802 USA* J. WANG, *Materials Research Institute, The Pennsylvania State Unviersity* PETER EKLUND, *Department of Physics, The Pennsylvania State University* We report the first observation of quasi-periodic twinning superlattices (TSLs) in semiconducting nanowires. The periodicity of the superlattice appears to be controlled by $\Delta T = T_m - T$, i.e., the degree of undercooling of the liquid phase in contact with the solid phase during VLS growth, where $T_m$ is the melting point of the solid phase. We present results from two III-V systems (GaP, InP) in which the superlattice is generated by the periodic 180[r] flipping of the $< 112 >$ direction relative to the $< 111 >$ growth direction of the nanowire. We suspect that our observations mean that a TSL structure can be grown in many compound semiconducting nanowire systems. Control of the superlattice period should allow significant design possibilities for thermoelectric, electronic and electro-optic applications. This work was supported, in part, by NSF-NIRT DMR-0304178

**9:24**

**U35 8 First Principles Studies of the Structural and Opto-Electronic Properties of Silicon Nanowires*** TRINH VO, *LLNL* ANDREW WILLIAMSON, *LLNL* GIULIA GALLI, *UC Davis and LLNL* We report the results of first principles studies of the structural, electronic, and optical properties of hydrogen-passivated silicon nanowires with [001], [011], and [111] growth directions and diameters ranging from 1 to 3 nm. We show that the growth direction, diameter, and surface structure all have a significant effect on the structural stability, electronic band gap, band structure, and band edge effective masses of the nanowires. The band gap is found to decrease with increasing diameter and to be further reduced by surface reconstruction. The band gap is direct for [001] and [011] NWs with diameters smaller than 3nm and [111] NWs with diameters smaller than 2nm. While the electron and hole effective masses are found to depend on NW size for [001] and [111] NWs, they are almost independent of size for [011] NWs. Finally, we use FEFF calculations to predict the EXAFS spectra produced by the relaxed atomic structure of the NWs and show that these spectra can serve as a tool for detection of surface reconstructions of the NWs.

*This work was performed under the auspices of the U.S. Dept. of Energy at the University of California/Lawrence Livermore National Laboratory under contract no. W-7405-Eng-48.

**9:36**

**U35 9 Ab initio investigation into the stability and electronic properties of GaN-nanowires** D.J. CARTER, *The University of Sydney, Australia* J.D. GALE, *Curtin University of Technology, Australia* B. DELLEY, *Paul Scherrer Institut, Switzerland* C. STAMPFL, *The University of Sydney, Australia* Recent reports of successful fabrication of high quality gallium nanostructures such as quantum dots, nanocrystallites and nanowires, e.g. [1], open the door to their possible role as important nanoscale building blocks for future optoelectronic, high-temperature/power and spintronic device applications. In the present work we perform itab initio calculations, using the DMol$^3$ [2] and SIESTA [3] codes, for wurtzite GaN nanowires. We have examined nanowires in the [0001], $[10\bar{1}0]$, and $[11\bar{2}0]$ directions, and investigated the stability, electronic and atomic structures as a function of nanowire radius. We found that only nanowires in the [0001] direction are stable, and that wires in the other directions can be stabilised by saturating dangling bonds with hydrogen. We have also investigated the properties of key point defects and dopants. [1] J. C. Johnson, et al. Nature Materials **1**, 106 (2002). [2] B. Delley, J. Chem. Phys. **92**, 508 (1990); ibid **113**, 7756 (2000). [3] J.M. Soler, et al. J. Phys.: Condens. Matter. **14**, 2745 (2002).

**9:48**

**U35 10 Au wetting of GaAs(111) studied on the atomic scale** EMELIE HILNER, ANDERS MIKKELSEN, JESSICA ERIKSSON, EDVIN LUNDGREN, *Lund University, Sweden* HONGSUK YI, PETER KRATZER, *FHI-MPG, Berlin, Germany* Because of the potential importance of semiconductor nanowires in future devices, a full understanding of their growth mechanism is desired. Au is commonly used to catalyze III-V nanowire growth, however the exact role of the Au in the growth process of the resulting wire is not known. This makes atomic scale studies of the Au/GaAs interface system well motivated. Here we report on the interaction of thin Au films and Au aerosol nanoparticles with the GaAs(111)B surface on the atomic scale using STM, LEED,LEEM, PEEM and ab-initio DFT calculations. We show that after deposition of Au either as a thin film or as aerosol nanoparticles and subsequent annealing to 450-600°C, a well ordered ($\sqrt{3}$x $\sqrt{3}$)R30° structure is formed. A structural model with a Au atom on every third threefold hollow hcp site of the Ga lattice is proposed based on theoretical calculations and experimental data.

## SESSION U36: FOCUS SESSION: OPTICAL PROPERTIES OF NANO-DOTS, HOLES, AND WIRES

**U36 1 Geometrical scale invariance of the enhanced transmission spectra of subwavelength hole arrays*** SINAN SELCUK, KWANGJE WOO, DAVID B. TANNER, ARTHUR F. HEBARD, *Department of Physics, University of Florida* There is at present a lack of consensus on the relative strength of contributions from surface plasmon polaritons (SPPs) and composite diffracted evanescent waves (CDEWs) to the mechanism responsible for enhanced transmission through subwavelength hole arrays. For regular square hole arrays with small open area fraction $d^2/a^2$ ($a$ = lattice constant and $d^2$ = square hole area), both theories predict that the wavelength $\lambda = \lambda_m$ at which maximum transmission occurs scales linearly with $a$. The two interpretations diverge however when the open area fraction increases and the distance between two adjacent hole edges decreases. We test these ideas by comparing transmission spectra of sets of arrays where each set has a fixed open area fraction but is scaled to different sizes by changing $a$. We find in our preliminary data that for a factor of 10 change in $a$, from 1 $\mu$m to 10 $\mu$m, the transmission peaks, when plotted as a function of $\lambda/a$, collapse onto the same scaling curve. This collapse is independent of hole size $d$ and is in good agreement with SPP theory when the wavelength-dependent refractive indices of the substrates (quartz and ZnSe) are taken into account.

*Supported by Raytheon

**8:12**

**U36 2 Polarization and hole-shape dependence of the transmission of sub-wavelength hole arrays*** KWANGJE WOO, SINAN SELCUK, ARTHUR F. HEBARD, DAVID B. TANNER, *Department of Physics, University of Florida* We have measured the infrared and visible transmission of arrays of holes in silver films, to study the effects of hole shape and hole spacing as a function of the polarization of the light. The anomalous transmission enhancement of sub-wavelength hole arrays in metal films has been attributed to surface plasmon polaritons (SPPs) but this picture is not enough to explain the dependence of hole shape on the transmission due to the long wavelength approximation. We have measured the transmission of arrays of square holes, rectangular holes, and slits in a silver film. We studied the effect of different hole shapes on the enhanced transmission as a function of the polarization angle of the light and found a strong dependence on the hole shape and the polarization angle. In addition, transmission spectra of an array of square holes on a rectangular grid will be presented.

*This work was supported by Raytheon.

**U36 3 Tunneling, dipole interactions and coherent Rabi oscillations in quantum dot molecules.*** JUAN E. ROLON, JOSE M. VILLAS-BOAS, SERGIO E. ULLOA, *Ohio University* Quantum dot molecules (QDMs) - coupled quantum dot systems - have proved to be a promising optoelectronic circuit element for future implementation of quantum computation at the nanoscale. Here we investigate theoretically the coherent manipulation between exciton states in a single QDM. In particular, we study Rabi oscillations induced via strong laser pumping and their dependence on the interdot quantum coupling strength, including particle interdot tunneling and Coulomb interactions. The dynamics of the system is extracted by solving a quantum master equation using a multilevel density matrix that considers direct and indirect excitons in a rotating wave approximation. Possible decoherence mechanisms, such as coupling to wetting layer states and nonradiative recombination, are incorporated into the master equation using a Lindblad formulation. Careful control of the interdot coupling strength, laser detuning, and intensity, results in different population level dynamics. These are found to be critical for the entanglement between exciton states and the ultimate realization of Bell states for potential quantum information processing.

*Supported by Indiana 21st Century Fund

**8:36**

**U36 4 Microscopic Models of Hybrid Nanocrystal Superstructures: photonic properties** ALEXANDER O. GOVOROV, *Department of Physics and Astronomy, Ohio University* GARNETT W. BRYANT, *NIST, Atomic Physics Division* WEI ZHANG, TIMUR SKEINI, *Department of Physics and Astronomy, Ohio University* JAEBEOM LEE, NICHOLAS A. KOTOV, *University of Michigan* We investigate the optical properties of hybrid superstructures composed of metal and semiconductor nanoparticles (NPs), and bio-linkers/polymers. Our study is inspired by recent experiments on bio-conjugated semiconductor-metal NP complexes and their potential applications as sensors. Metal NPs can quench semiconductor NP photoluminescence (PL). However, a plasmon enhancement can be achieved by organizing many Au NPs into a spherical or cylindrical shell around a CdTe NP. We compute electromagnetic fields induced in NP superstructures using a multipole expansion approach to describe the optical response of these complexes. Enhancement of CdTe emission can result from plasmon mediated enhancement of the excitation (Ag structures) or enhancement of the emission process (Au structures). The resultant optical response comes from a complex interplay of this enhancement and quenching and determines the potential applications of these superstructures.

**8:48**

**U36 5 Spectroscopy of Charged Quantum Dot Molecules** E.A. STINAFF, M. SCHEIBNER, A.S. BRACKER, I.V. PONOMAREV, M.E. WARE, M.F. DOTY, T.L. REINECKE, D. GAMMON, *Naval Research Laboratory* V.L. KORENEV, *A.F. Ioffe Physical Technical Institute* Spins of single charges in quantum dots are attractive for many quantum information and spintronic proposals. Scalable quantum information applications require the ability to entangle and operate on multiple spins in coupled quantum dots (CQDs). To further the understanding of these systems, we present detailed spectroscopic studies of InAs CQDs with control of the discrete electron or hole charging of the system. The optical spectrum reveals a pattern of energy anticrossings and crossings in the photoluminescence as a function of applied electric field. These features can be understood as a superposition of charge and spin configurations of the two dots and represent clear signatures of quantum mechanical coupling. The molecular resonance leading to these anticrossings is achieved at different electric fields for the optically excited (trion) states and the ground (hole) states allowing for the possibility of using the excited states for optically induced coupling of the qubits.

**9:00**

**U36 6 Multi-Excitonic Quantum Dot Molecules** M. SCHEIBNER, E.A. STINAFF, M.F. DOTY, M.E. WARE, A.S. BRACKER, D. GAMMON, I.V. PONOMAREV, T.L. REINECKE, *Naval Research Laboratory, Washington DC 20375 USA* V.L. KORENEV, *A.F. Ioffe Physical Technical Institute, St. Petersburg 194021 Russia* With the ability to create coupled pairs of quantum dots, the next step towards the realization of semiconductor based quantum information processing devices can be taken. However, so far little knowledge has been gained on these artificial molecules. Our photoluminescence experiments on single InAs/GaAs quantum dot molecules provide the systematics of coupled quantum dots by delineating the spectroscopic features of several key charge configurations in such quantum systems, including X, $X^+$,$X^{2+}$, XX, $XX^+$(with X being the neutral exciton). We extract general rules which determine the formation of molecular states of coupled quantum dots. These include the fact that quantum dot molecules provide the possibility to realize various spin configurations and to switch the electron hole exchange interaction on and off by shifting charges inside the molecule. This knowledge will be valuable in developing implementations for quantum information processing.

**9:12**

**U36 7 Spin interactions in InAs quantum dots** M.F. DOTY, M.E. WARE, E.A. STINAFF, M. SCHEIBNER, A.S. BRACKER, D. GAMMON, I.V. PONOMAREV, T.L. REINECKE, *Naval Research Laboratory* V.L. KORENEV, *A.F. Ioffe Physical Technical Institute* Fine structure splittings in optical spectra of self-assembled InAs quantum dots (QDs) generally arise from spin interactions between particles confined in the dots. We present experimental studies of the fine structure that arises from multiple charges confined in a single dot [1] or in molecular orbitals of coupled pairs of dots. To probe the underlying spin interactions we

inject particles with a known spin orientation (by using polarized light to perform photoluminescence excitation spectroscopy experiments) or use a magnetic field to orient and/or mix the spin states. We develop a model of the spin interactions that aids in the development of quantum information processing applications based on controllable interactions between spins confined to QDs. **U36 8 Theory of Charged Quantum Dot Molecules** I.V. PONOMAREV, M. SCHEIBNER, E.A. STINAFF, A.S. BRACKER, M.F. DOTY, M.E. WARE, D. GAMMON, T.L. REINECKE, *Naval Research Laboratory, Washington DC* V.L. KORENEV, *A.F. Ioffe Physical Technical Institute, St. Petersburg, Russia* Recent optical spectroscopy of excitonic molecules in coupled quantum dots (CQDs) tuned by electric field reveal a richer diversity in spectral line patterns than in their single quantum dot counterparts. We developed a theoretical model that allows us to classify energies and intensities of various PL transitions. In this approach the electric field induced resonance tunneling of the electron and hole states occurs at different biases due to the inherent asymmetry of CQDs. The truncated many-body basis configurations for each molecule are constructed from antisymmetrized products of single-particle states, where the electron occupies only one ground state level in single QD and the hole can occupy two lowest levels of CQD system. The Coulomb interaction between particles is treated with perturbation theory. As a result the observed PL spectral lines can be described with a small number of parameters. The theoretical predictions account well for recent experiments.

**U36 9 Ultrafast dynamics of surface plasmon polaritons in subwavelength nanohole array on metallic film*** A.S. KIRAKOSYAN, T.V. SHAHBAZYAN, *Jackson State University* M. TONG, Z.V. VARDENY, *University of Utah* The ultrafast dynamics of surface plasmon polaritons (SPP) photogenerated on the surfaces of an Al film perforated with 2D subwavelength hole array ( $\sim$ 300 nm lattice constant) was studied by the pump-probe correlation spectroscopy. Following an instantaneous rise at the onset of the impinging pulse, the transient differential transmission exhibits a fast rise with characteristic time constant of $\sim$ 300 fs reaching a plateau at $\sim$ 2 ps, followed by a slower decay with characteristic time of $\sim$ 40 ps. The observed dynamics can be explained by a fast energy transfer in the Al film from the electron gas to the lattice, with subsequent cooling of the Al film by heat transfer to the glass substrate. The fast dynamics is accompanied by a blue shift of the SPP band due to the increase in the Al lattice temperature. The obtained fast lattice temperature rise is caused by the strong electron-phonon interaction in Al, which makes the electron-lattice energy transfer rate comparable to the rate of nonequilibrium electrons thermalization via electron-electron interactions. A theoretical model based on the Boltzmann equation for nonequilibrium electron gas interacting with quasi-equilibrium phonons was developed, and is in good agreement with the data.

**U36 10 Internal and external polarization memory loss in single quantum dots** Q.Q. WANG, A. MULLER, *University of Texas at Austin* M.T. CHENG, H.J. ZHOU, *Wuhan University, P.R. China* P. BIANUCCI, C.K. SHIH, *The University of Texas at Austin* Exciton spin relaxation counts among the most basic features of quantum dot (QD) ground-state dynamics and is intimately connected to the ubiquitous fine-structure doublet anisotropy. Numerous resonant measurements on QD ensembles support a spin relaxation frozen on the exciton lifetime, in agreement with theoretical expectations. Recent investigations, however, question this breakdown based on strictly non-resonant experiments on single QDs, pointing to possible variations among QDs. By using non-linear resonant control of single QDs we examine spin relaxation under different environments and excitation conditions. Data from dots with different dipole moments reveals two distinctive channels for polarization memory loss: (i) an external pathway due to carrier escape and capture to and from the wetting layer that is responsible for memory loss increasing with intensity; and (ii) an internal loss channel, independent of external excitation, due to intrinsic spin relaxation. The values obtained for the latter rule out a universal freezing of exciton spin relaxation in self-assembled QDs.

**U36 11 Polarized Mid-Infrared Surface Emission from InAs Quantum Dots** D. WASSERMAN, S.A. LYON, C. GMACHL, *Princeton University* E.A. SHANER, *Sandia National Laboratories* Polarized mid-infrared surface electroluminescence from self-assembled InAs quantum dots has been observed at 77K. A graded AlGaAs injector is used to inject electrons into excited states in the quantum dot layer. A superlattice electron filter prevents direct electron tunneling out of the quantum dot excited states, increasing the probability of optical transitions to lower energy dot states. Two mid-infrared peaks are seen in the electrically pumped surface emission spectra of the device, one at 100meV, the other at 170meV. The emission peaks are orthogonally polarized within the growth plane, indicating photon emission from intersublevel electron transitions within anisotropically shaped quantums dots. This work suggests the feasibility of using quantum dot mid-infrared emission to study both the morphology of, and intersublevel transitions within, self-assembled quantum dots.

**U36 12 Optical properties of semiconductor-metal nanocrystal molecules: Exciton-plasmon interactions** WEI ZHANG, ALEXANDER O. GOVOROV, *Department of Physics and Astronomy, Ohio University* GARNETT W. BRYANT, *NIST, Atomic Physics Division* Motivated by recent experiments on bio-conjugated semiconductor-metal hybrid nanocrystal superstructures, we develop a theory to describe a system composed of a semiconductor quantum dot (QD) and a metal nanoparticle (NP) in the presence of external electric fields. The interaction between exciton (in QD) and plasmon (in NP) leads to interesting optical properties. We explore both the linear regime (for weak external field) and the non-linear regime (for strong external field). The interference between the external field and the induced internal field results in strong enhancement of energy absorption (compared with the energy absorption of QD in the absence of a metal NP) and also leads to an asymmetric peak and valley in the total energy absorp-

tion (Fano-like shape). We also consider Rayleigh scattering which also reveals this type of behavior. Our theory is useful for understanding present experimental results and can give guidance for future experiments, which may have important applications.

**U36 14 First-Principles Optical Cross-Sections of Ultrathin ZnO Nanowires** SHELLY ELIZONDO, JOHN MINTMIRE, *Oklahoma State University, Department of Physics* One-dimensional nanostructures such as inorganic nanowires and nanotubes represent potential materials for key components of future electronic, optoelectronic, and nanoelectromechanical systems. They will also serve as important model systems to demonstrate quantum-size effects in nanostructured materials. We examine the electronic and optical properties of ZnO nanowires with different geometrical configurations within a first-principles, all-electron self-consistent local density functional (LDF) approach. Orientations along different growth directions are taken into account, with the preferred $\pm$ [0001] direction as the primary focus. The ultrathin nanowires considered here range in diameter from approximately 0.50 nm to 3 nm. We discuss trends in electronic properties and resulting optical properties as a function of nanowire axis orientation and diameter. This work was supported by the US Office of Naval Research, the DoD HPCMO CHSSI program through the Naval Research Laboratory, and the NSF IGERT program.

**U37 1 Quantum Coherence and Time Dependent Conductance Fluctuations in Dilute Magnetic Semiconductors** SUNGBAE LEE, AARON TRIONFI, *Dept. of Physics and Astronomy, Rice University* TIMO SCHALLENBERG, HIRO MUNEKATA, *Imaging Science and Engineering Lab., Tokyo Institute of Technology* DOUG NATELSON, *Dept. of Physics and Astronomy, Rice University* Low temperature electrical properties of ferromagnetic nanowires are influenced by the interplay between disorder, quantum coherence, and magnetic correlations. Quantum coherence corrections to the conductance are of particular interest, and can be difficult to characterize experimentally. Time dependent universal conductance fluctuation (TD-UCF) at low temperatures provides a means of assessing these effects. Samples were fabricated by standard electron beam lithography and ion etching technique using $In_{1-x}Mn_xAs$ quantum well samples grown by off-equilibrium molecular beam epitaxy. Initial measurements of temperature and field-dependent TD-UCF in these devices are presented and compared with permalloy nanowire data.

**U37 2 Microwave-enhanced decoherance in one-dimensional metal wires** JIAN WEI, SERGEI PEREVERZEV, MICHAEL GERSHENSON, *Rutgers University* We report the effect of monochromatic microwave (MW) radiation on the weak localization corrections to the conductivity of quasi-one-dimensional silver wires. Due to the improved electron cooling in the wires, the MW-induced dephasing was observed without a concomitant overheating of electrons over wide ranges of the MW power $P_{MW}$ and frequency $f$. The observed dependences of the conductivity and MW-induced dephasing rate on $P_{MW}$ and $f$ are in agreement with the theory by Altshuler, Aronov, and Khmelnitsky.[1] Our results suggest that the saturation of dephasing time, often observed at $T \leqslant 0.1$ K, may be caused by an insufficient screening of the sample from the external microwave noise.

**U37 3 Toward Single-Walled Nanotube Aharonov-Bohm interferometers** JINSEONG HEO, *Caltech* MARC BOCKRATH, *Caltech* Single-walled carbon nanotubes (SWNTs), which have micron-scale phase coherent lengths at low temperatures, are grown so that they cross themselves, producing a loop that may act as an Aharonov-Bohm interferometer. In order to determine electron pathways at the junction, we performed scanned gate microscopy (SGM) using an Atomic Force Microscopy(AFM) tip as a local gate. If a SGM signal is observed when the tip is over any particular segment it indicates current flow in that segment. Surprisingly, one semiconducting tube showed that most electrons tunnel into the other segment at the junction without flowing through the loop. For other samples, however, current flow was observed in the loop. Taken together, this suggests the possibility of controlling tunneling probabilities at the junction. Moreover, for metallic or small bandgap nanotubes, we reproducibly observe an unusual conductance peak near zero gate voltage, obtaining nearly identical behavior from devices made from the same 100 micron long nanotube. The results and interpretations of our ongoing experiments will be discussed.

**U37 4 Quantum Transport of Semiconductor Nanowires Coupled to Superconductors.***
YONG-JOO DOH, *Harvard University*

We report the electronic transport properties of the first superconducting transistors based on semiconductor nanowires [Y.-J. Doh et al., Science 309, 272 (2005)]. These nanoscale superconductor-semiconductor devices enable the fabrication of new nanoscale superconducting electronic circuits and at the same time provide new opportunities for the study of fundamental quantum transport phenomena. Indium arsenide (InAs) semiconductor nanowires individually contacted by two aluminum-based superconductor electrodes yield surprisingly low contact resistances. Below 1 kelvin, the high transparency of the contact gives rise to proximity-induced supercondcutivity and a resistance-free current (supercurrent) can flow through the nanowire from one superconducting contact to another. The supercurrent can be switched on and off by a gate voltage acting on the electron density in the nanowire. A variation in gate voltage induces universal fluctuations in the normal-state conductance, which are clearly correlated to critical current fluctuations. The alternating-current Josephson effect gives rise to Shapiro steps in the voltage- current characteristic under microwave irradiation. For indium phosphide (InP) nanowire devices, however, Coulomb blockade effect dominates the electrical transport, which can be modeled as a quantum dot weakly coupled to superconductors. As a result of BCS (Bardeen-Cooper-Schriffer) singularity of density of states, a negative differential conductance is observed in the superconducting state. By applying high magnetic field, Zeeman splitting is observed and g-factor of InP nanowire is estimated to be 1.5.

**U37 5 Four-probe measurements of individual metallic and superconducting nanowires** SHENG-YONG XU,* *DMP* MINGLIANG TIAN, *DMP* NITESH KUMAR, *DMP* MOSES H. W. CHAN, *DMP* CHAN GROUP TEAM, We have performed 4-probe measurements for a number of individual Au, Ag, Sn and Zn nanowires. The resistivity of these nanowires is always larger than their bulk values, and varies with the crystallinity of the nanowires. Single crystalline Sn nanowires have a resistivity similar to that of bulk Sn, while polycrystalline Au nanowires shows a resistivity twenty to thirty times higher than that of bulk Au. For Sn nanowires with diameter from 280 nm to 70 nm, the superconducting transition temperature $T_c$ remains the same as, or slightly lower than the $T_c$ of bulk Sn, 3.7 K. The critical current density of these Sn nanowires is measured to be in the order of 105 A/cm2 at low temperature. The critical fields of the nanowires, as expected, are much higher than that of Sn films. A finite resistance, which increases with increasing excitation current, is observed in all the samples. The origins of this finite resistance will be discussed. We have also obtained evidence that the four metallic leads assembled on each single nanowire may have remarkable effects on the transport properties of the nanowire.

**U37 6 Modifying Mesoscopic 1/f Noise Via Surface Chemistry.** A. TRIONFI, *Rice University Dept. of Physics and Astronomy* J.W. CISZEK, J.M. TOUR, *Rice University Dept. of Chemistry* D. NATELSON, *Rice University Dept. of Physics and Astronomy* Attempts to extrinsically control the 1/f noise related to Universal Conductance Fluctuation Theory in quasi-one dimensional Au wires were made using self-assembled monolayer (SAM) molecules. Measurements before and after the deposition of the SAM molecule comparing the noise power amplitude and the phase coherence of the devices via the weak localization magnetoresistance and noise power amplitude versus magnetic field were performed. The resulting data were used to determine if the 1/f noise is approaching the so-called saturated limit as the system is lowered from 14 to 2 K. The results may also shed light on the microscopic details of the two level systems responsible for time-dependent conductance fluctuations in normal metals. Preliminary results will be reported.

**U37 7 Coulomb Blockade Imaging of Few-Electron Quantum Dots in a Magnetic Field*** P. FALLAHI, R. WESTERVELT, M. STOPA, *Harvard University* M. HANSON, A.C. GOSSARD, *U.C. Santa Barbara* One-electron quantum dots are important candidates for quantum information processing. We have developed a technique to image electrons inside a quantum dot in the Coulomb blockade regime, using a scanning probe microscope (SPM) at liquid He temperatures (1). We have used this technique to image the last electron in the dot in a strong perpendicular magnetic field.dots are formed in a two-dimensional electron gas in a GaAs/AlGaAs heterostructure by surface gates. Images are obtained by recording the dot conductance while scanning the SPM tip above the dot. SPM Images show a ring of increased conductance about the center of the dot, corresponding to a Coulomb blockade peak in the dot conductance.observe changes in the shape and the size of the conductance rings with magnetic field. This is due to a combination of energy shifts and orbital changes of the electrons in the quantum dot. (1) P. Fallahi et al, Nano Letters 5, 223 (2005)

**U37 8 Kondo and Superconducting Proximity Effect in Semiconductor Nanostructures** ANDY VIDAN, MICHAEL STOPA, ROBERT WESTERVELT, *Harvard University* MICAH HANSON, A.C. GOSSARD, *UC Santa Barbara* JIE XIANG, CHARLES M. LIEBER, *Harvard University* We have fabricated a unique device containing three quantum dots in a GaAs/AlGaAs heterostructure containing a two-dimensional electron gas using

lithographically patterned gates and an etched trench in the center of the ring. By only energizing certain gates, this device allows us to study electron transport through a single dot, a double dot, or a triple dot ring. We can determine the absolute number of electrons in a quantum dot using a nearby charge sensor and find that we are able to tune a single dot to the one and two electron regime. We find several sharp peaks in the differential conductance, occurring at both zero and finite source-drain bias, for the one and two electron quantum dot. At zero source-drain bias, the temperature and magnetic field dependence of the conductance is consistent with a standard Kondo resonance. We attribute the peaks at finite-bias to a Kondo effect through excited states of the quantum dot. We also present recent observations of supercurrents in Gels: 1D nanowire heterostructures.

**U37 9 Transition to Scarred States Probed by a Single Electron Spectrometer** ROBERT E. PARROTT, *Harvard University* DOMINIK M. ZUMBUHL, *Massachusetts Institute Of Technology* ERIC J. HELLER, CHARLES M. MARCUS, *Harvard University* MICAH P. HANSON, ARTHUR C. GOSSARD, *University of California, Santa Barbara* We examine the use of a novel mesoscopic spectrometer to image electron dynamics in a large, open lateral quantum dot in a perpendicular magnetic field $B_z$. The spectrometer is comprised of a small single-electron quantum dot weakly coupled to the large dot via a tunnel junction; the current through the dots is measured at finite bias. By varying the energy level of the small dot, the local density of states, $g(r_o,E)$ is measured at the tunnel junction. An unexpected interference effect persists at energies 1 meV below $E_F$. Using semiclassical and quantum approaches, we show these interference bands in $(E,B_z)$ are due to a dominant, diamond-shaped periodic orbit in the large dot. As $B_z$ is varied, the orbit changes to unstable: the dominant state becomes a scar. This transition is marked by an abrupt change in the area of the orbit, and hence in the spacing $\Delta B_z$ of the bands. In a billiard model of the system, this coincides with a pitchfork bifurcation of the orbit. The existence of the bands depends strongly on whether the orbit has appreciable magnitude at the tunnel junction, belying the local nature of the measurement. In this way the tunnel junction, coupled to the small dot, acts like a fixed STM tip embedded in the 2DEG.

**U37 10 Magneto-transport studies in mesoscopic InAs 2DEG devices*** ERNESTO MARINERO, THOMAS BOONE, LIESL FOLKS, BRUCE GURNEY, JORDAN KATINE, SERGIO NICOLETTI, *Hitachi San Jose Research Center* We report on magneto-transport studies in lithographically patterned InAs 2DEG devices. Electron transport between adjacent current injection and extraction channels was studied as a function of temperature and magnetic field. The mean free path in the quantum well at RT and 5 K in our devices is approximately 280 nm and 980 nm respectively. The spacing between the current tabs in our devices range from 1000 nm to 300 nm and typical tab widths range from 300 nm to 100 nm. Low temperature measurements reveal contributions of ballistic transport in our devices; fluctuations in magneto-resistance are observed at distinct values of the perpendicularly applied magnetic field. Said fluctuations will be discussed in the context of ballistic electron focusing trajectories and possible contributions from the quantum Hall effect.

*We gratefully acknowledge collaborative efforts with Mark Field, Gerry Sullivan, and Robert Brar from Rockwell Scientific Co, who grew the InAs 2DEG structures.

**U37 11 Asymmetry of Nonlinear Transport and Electron Interactions in Quantum Dots** D. M. ZUMBÜHL, *MIT and Harvard University* C. M. MARCUS, *Harvard University* M. P. HANSON, *UCSB* A. C. GOSSARD, *UCSB* The magnetic field symmetry of conductance beyond the linear source-drain bias regime in open chaotic GaAs quantum dots is experimentally investigated using gate-controlled shape distortion to gather ensemble statistics. We measure a conductance component $g_{B-}$ antisymmetric in perpendicular magnetic field $B$ which is of the form $\tilde{g} = \alpha VB$ for source-drain bias voltages $V$ smaller than the quantum dot level spacing $\Delta$ and for $B$ smaller than a flux quantum through the device area. Interestingly, according to recent theories, $\tilde{g}$ of this form vanishes in absence of electron interactions and $\alpha$ is proportional to the electron interaction strength. $g_{B-}$ shows mesoscopic fluctuations with shape gate and with $B$ and $V$ on a scale of the flux quantum through the dot area and quantum dot level spacing $\Delta$, respectively. As anticipated by theories, the average coefficient $\alpha$ measured over an ensemble of dot shapes vanishes. The standard deviation of $\alpha$ is used to characterize the strength of electron interactions. We discuss the dependence of the typical $\alpha$ on the number of modes in the quantum-point-contact leads, compare our experiment with theories and discuss related issues of electron equilibration, decoherence and thermal smearing in the quantum dot. This work was partially supported by DARPA QuIST, ARO/ARDA and by the NSEC program of the NSF.

**U37 12 Two Electron Singlet Triplet Spectroscopy** IULIANA RADU, D.M. ZUMBÜHL, C.R. DILLARD, G. GRANGER, M.A. KASTNER, *MIT* M.P. HANSON, A.C. GOSSARD, *UCSB* We present measurements of few electron quantum dots formed by lateral depletion of a GaAs/AlGaAs 2D electron gas by surface gates. The two electron regime, on which we focus here, is characterized by singlet and triplet states which are relevant for quantum computation proposals. These two states are revealed in electronic transport through the dot in various ways: sequential tunneling, inelastic cotunneling as well as by an additional mode of transport we ascribe to sequential tunneling activated by inelastic cotunneling. These various signatures provide independent ways to measure the singlet-triplet energy splitting J over large ranges of gate voltages. We present the temperature, magnetic field and tunnel-coupling dependence of these transport features, which are in good agreement with recent theory. Further, we observe signatures of spin-blockade that becomes visible for source-drain voltages exceeding the triplet energy. This work was partially supported by the ARO (W911NF-05-1-0062), by the NSEC program of the NSF (PHY-0117795) and by NSF (DMR-0353209).

**U37 13 Superpoissonian noise with positive current correlations** YUANZHEN CHEN, RICHARD WEBB, *USC Nanocenter, University of South Carolina* We report shot noise cross correlation measurements in a beam splitter configuration. We fabricated our devices in a two dimensional electron gas in a GaAs/AlGaAs heterostructure using a splitting gate technology. Electrons tunneling across tunnel barriers are incident on a beam splitter and are scattered into two different channels. Shot noise cross correlation between the two electrical currents is measured as a function of both the transmission coefficient of the beam splitter and the Fano factor of the tunnel barriers. Due to the Fermi statistics of electrons, such a measurement usually yields a negative correlation.

However, in some barriers under certain circumstances, a positive correlation has also been observed. A correspondence between the Fano factor of the tunnel barriers and the cross correlation has been established. For example, positive cross correlation is always associated with barriers exhibiting superpoissonian shot noise (with a Fano factor greater than one). Studies on the frequency dependence of shot noise suggest that the observed positive cross correlation can be related to the dynamics of localized states in the tunnel barriers.

**U38 1 High-Tc superconductivity in entirely end-bonded carbon nanotubes** JUNJI HARUYAMA, IZUMI TAKESUE, NAOKI KOBAYASHI, *Aoyama Gakuin University* SHOHEI CHIASHI, SHIGEO MARUYAMA, *Tokyo University* TOSHIKI SUGAI, HISANORI SHINOHARA, *Nagoya University* One-dimensional (1D) systems face some obstructions that may prevent the emergence of superconductivity(SC), e.g., a Tomonaga-Luttinger liquid (TLL) and Peierls transition. A carbon nanotube (CN) is one of the best candidates for investigating a possibility of 1D SC and its interplay with such obstructions. Only two groups have experimentally reported SC in ropes of single-walled CNs (SWNTs) and very thin SWNTs [1] to date. In addition, those interplay with 1D phenomena have never been clarified. Some theoretical papers also predicted strong correlation between TLL states and SC for SWNT ropes and importance of electron-phonon interaction for thin SWNTs [2]. Here, we report that entirely end-bonded multi-walled CNs (MWNTs) can show SC with the $T_c$ as high as 12K [3] (about 50-times larger than $T_c$ in former of [1]). We find that emergence of this SC and its interplay with TLL states are highly sensitive to junction structures of Au electrode/MWNTs. Only MWNTs with optimal numbers of electrically activated shells realized by the entire end-bonding can allow the SC due to intershell effects. Refs. 1. M. Kociak, et al., PRL 86, 2416 (2001); Z. K. Tang, et al., Science 292, 2462 (2001). 2. J. Gonzalez, PRL 88, 076403 (2002); R. Barnett, et al., PRB 71, 035429 (2005). 3. J. Haruyama et al., PRL Accepted

**U38 2 Superconductivity of granular Bi nanowires fabricated by electrochemical deposition at ambient condition** MINGLIANG TIAN, JINGUO WANG, TIANHENG HAN, YOJI KOBAYASHI, NITESH KUMAR, SHENGYONG XU, YING LIU, THOMAS MALLOUK, MOSES CHAN, *Penn State University, University Park, PA 16802* Rhombohedral bulk Bi is a semimetal which is not superconducting down to low temperatures under ambient pressure. Amorphous Bi films and bulk Bi subjected to high pressure can be superconducting. We report here the observation of superconductivity of Bi nanowires (the diameter ranges from 40 to 100 nm) fabricated by electrochemical deposition at room temperature under atmospheric pressure. The superconducting transition temperature Tc, depending on the sample morphology, can be either of 3.7 K, 7.2 K or 8.3 K, which correspond exactly to the Tc's reported for the three high pressure Bi phases (II, III and V). However, structural studies showed that these superconducting Bi nanowires showed granular morphology consisting of rhombohedral Bi particles oriented along the [001] direction. Because the superconducting Bi wires did not show any detectable diamagnetic signature, the observed superconductivity might be related to the interfacial structures of the granular wires. Further studies are in progress. This work is supported by it the Center for Nanoscale Science (Penn State MRSEC) funded by NSF under grant DMR-0213623.

**U38 3 Enhancing superconductivity: Magnetic impurities and their quenching by magnetic fields** TZU-CHIEH WEI, DAVID PEKKER, ANDREY ROGACHEV, ALEXEY BEZRYADIN, PAUL M. GOLDBART, *University of Illinois at Urbana-Champaign* Magnetic fields and magnetic impurities are each known to suppress superconductivity. However, it has recently been found theoretically that in superconducting films with magnetic impurities the critical temperature can be raised by applying a magnetic field ($H$) [1]. Here, we extend the Eilenberger-Usadel formalism and use it to investigate this interplay of magnetic fields and magnetic impurities. Hence, we are able to compute the critical current ($J_c$) of a thin superconducting wire, in addition to its critical temperature ($T_c$). We find three regimes of wire parameters. In one, both $T_c$ and $J_c$ simply decrease with $H$; in a second, both $T_c$ and $J_c$ first rise and then fall with $H$; and in a third, $T_c$ simply decreases with $H$ but, at sufficiently low temperatures, $J_c$ first rises and then falls [2]. Our results are consistent with recent experiments on thin superconducting wires [3]. [1] M. Kharitonov and M. Feigel'man JETP Lett. **82**, 473 (2005). [2] T.-C. Wei et al. cond-mat/0510476. [3] A. Rogachev et al. (manuscript in preparation).

**U38 4 Anomalous behavior of the critical current in superconducting MoGe nanowires exposed to high magnetic fields.** A. ROGACHEV, T.-C. WEI, D. PEKKER, A.T. BOLLINGER, P.M. GOLDBART, A. BEZRYADIN, *University of Illinois at Urbana-Champaign* At low temperatures the critical current of superconducting MoGe nanowires with diameters 6-10 nm shows an unusual initial growth with increasing magnetic field, and reaches a maximum at the field 3-5 T. The non-monotonic behavior is present both in parallel and perpendicular field orientations and disappears at high temperatures. We suggest that the effect is caused by magnetic impurities, which suppress superfluid density in the nanowire at low fields but, due to partial polarization in the applied magnetic field, become less efficient pair-breakers in high fields. We compare our data with the microscopic theory that considers this competition of the reduced depairing by localized spins and the increasing depairing by the orbital effects [1]. The theory reproduces all experiential observations and suggests that magnetic impurities reside on a surface of a wire. [1] T.-C. Wei, D. Pekker, A. Rogachev, A. Bezryadin, and P.M. Goldbart, cond-mat/0510476.

**U38 5 Confined Vortices in $NbSe_2$ Nanowires** ABRAM FALK, *Department of Physics, Harvard University* MANDAR DESHMUKH, AMY PRIETO,* ANDREA JONES, *Department of Chemistry, Harvard University* HONGKUN PARK, *Department of Chemistry, Department of Physics, Harvard University* Superconducting $NbSe_2$ nanowires have been studied with electrical transport. The cross-sectional dimensions are smaller than the London penetration depth, and signatures of confined magnetic vortices have been observed. The critical current shows non-monotonic behavior as the external magnetic field is increased, including periodic features corresponding to matching fields. In the vicinity of the critical current, we observe several peaks in the differential resistance as a function of bias current, consistent with the plastic flow of vortices. These observations are discussed in the context of theoretical London model studies and experiments in thin-film superconductors and bulk $NbSe_2$.

**U38 6 Growth Mechanism of $EuBa_2Cu_3O_{7-\delta}$ Whiskers and Their superconducting properties for Intrinsic Josephson Junction Applications*** A.T.M. NAZMUL ISLAM, T. KAWAE, Y. TACHIKI, S. WATAUCHI, Y. TAKANO, T. HATANO, T. YAMASHITA, I. TANAKA, We have grown Eu-123 single-crystal whiskers by annealing of precursor pellets containing Ca and Te. Microstructural and compositional analysis was performed on the longitudinal cross-section and the area of origin of a whisker to elucidated some aspects of the growth mechanism from bulk precursor. Sub-micron sized junctions fabricated by focus ion-beam etching on Eu-123 whiskers showed clear multi-branch with hysteresis structure in the I-V curve, which suggest excellent crystalline quality both of as-grown and high pressure annealed whiskers. We have also doped Er and Tm having a smaller ionic radius in single crystalline whiskers of (Eu,R)-123 (R= Er, Tm) and observed that Eu-rich whiskers, which require higher temperature to be grown, are more susceptible to oxygen deficiencies and structural instabilities. Our results shows that the carrier doping can be systematically controlled from highly underdoped to slightly overdoped range by suitable choice of average ionic radius of rare-earth elements in as-grown whiskers. The critical current density $J_c$ of a Eu-123 whisker ($T_c$=45K) was estimated to be $1.43 \times 10^5$ A/cm$^2$ at 4.2K, twice as much as observed for Y-123 having a similar $T_c$ .

**U38 7 Evidence for Current-Driven Phase Slip Lines in Submicron High-$T_c$ Superconducting Wires*** P. MORALES, J.Y.T. WEI, *Department of Physics, University of Toronto* We present superconducting current-voltage characteristics of submicron $YBa_2Cu_3O_{7-\delta}$ wires. The submicron-wide wires were fabricated using a chemical-free technique based on selective epitaxial growth. Pulsed current-biased and voltage-biased measurements were made between 4.2 K and $T_c$ and as a function of an applied magnetic field. The current-voltage characteristics exhibit distinctive behaviour suggesting that the current-driven or voltage-driven transition of our submicron high-$T_c$ wires into the resistive state is through the formation of phase slip lines.

**U38 8 Quantum phase slips in the presence of finite-range disorder** LEONID P. PRYADKO, *University of California, Riverside* SERGEI KHLEBNIKOV, *Purdue University* To study the effect of disorder on quantum phase slips (QPS) in superconducting nanowires, we consider the plasmon-only model where disorder can be incorporated into a first-principles instanton calculation. We consider weak but general finite-range disorder and compute the formfactor in the QPS rate associated with momentum transfer. We find that the system maps onto dissipative quantum mechanics, with the dissipative coefficient controlled by the wave (plasmon) impedance $Z$ of the wire and with a superconductor-insulator transition at $Z_c = 6.5$ kOhm. The usual Ohmic resistivity of the wire at the transition point is non-universal. Its value depends on both the strength and the correlation length of disorder, and in the considered regime is much smaller than the normal-state resistivity. We argue that the system will remain in the same universality class after resistive effects at the QPS core are taken into account.

**U38 9 Magnetization controlled superconductivity in a Pb film on a perpendicular array of ferromagnetic Co nanowires*** ZUXIN YE, DAYA RATHNAYAKA, WENHAO WU, HAIDONG LIU, HONG ZHANG, DONALD NAUGLE, IGOR LYUKSYUTOV, JOSEPH ROSS JR., *Texas A&M University* We report the studies of superconductivity in a Pb film on a perpendicular array of ferromagnetic Co nanowires. We first evaporate a Pb film of 300nm in thickness on a 60$\mu$m-thick porous $Al_2O_3$ membrane as the cathode for electroplating. Cobalt nanowires 100nm in diameter were electrochemically deposited in the pores starting from the Pb film. Scanning electron microscopy images showed uniform distribution of cobalt nanowires. The magnetization of the individual Co nanowires should be oriented perpendicular to the Pb film due to the high aspect ratio of the Co nanowires. We have observed significant difference in the superconducting behavior of the Pb film between zero-field cooled experiments and field-cooled experiments. In field-cooled experiments, the samples are cooled from room temperature to 20 K in fields of 1-5 T applied along the direction of the Co nanowires. This field aligns the magnetization of the Co nanowires, and as a result, enhances the superconducting transition temperature by 1.5-2.0 K in comparison to zero-field cooled experiments in which case the magnetization of the nanowires is not aligned. These experimental data support recent theory by I. F. Lyuksyutov et al. [PRL **81**, 2344(1998)].

**U38 10 Current carrying edges in unconventional superconductors** RAHUL ROY, *University of Illinois at Urbana Champaign* While the bulk of a p or d wave superconductor does not carry any current, a current can run along the edges of a sample even in the absence of a magnetic field, unlike the case of a s wave superconductor. Such a current is often quantized and is independent of the magnitude of the gap. However, the existence of such a current violates Bloch's theorem. Here, we examine, by computation and analytic calculation, the question of the edge current in p and d wave superconductors in various geometries and the connection with the Bloch argument. The computation of the edge current also allows us to shed some light on the angular momentum paradox in the A phase of Helium 3.

**U38 11 The coherence conundrum in BEDT-TTF superconductors; how does interlayer transport die as temperature rises?*** JOHN SINGLETON, *Natl. High Magnetic Field Lab* PAUL GODDARD, ARZHANG ARDAVAN, *Oxford University Physics* STAN TOZER, ROSS MCDONALD, *Natl. High Magnetic Field Lab* JOHN SCHLUETER, *ANL* Recent attention has focused on ''bad metals,'' systems which appear to be Fermi liquids at low temperatures ($T$), but whose conductivity falls below the minimum metallic limit as $T$ rises. A key question concerns the coherence of the electron orbitals, and whether, as suggested by Anderson and others, it is destroyed by thermal fluctuations as $T$ rises. To address this, we have studied magnetic-field-orientation-dependent transport in the organic superconductor $(BEDT\text{-}TTF)_2Cu(NCS)_2$ at temperatures of up to 45 K in magnetic fields of up to 45 T. This material was chosen because its Fermi surface (FS) is well characterized by experiment. We find that the angle-dependent magnetoresistance oscillations (AMROs) due to orbits on the quasi-one-dimensional (Q1D) and Q2D FS sections are suppressed by rising $T$, with a $T$ dependence suggesting phonon scattering. The coherence peak in the resistivity seen in exactly in-plane fields, and other signatures of a 3D FS, remain to values of $T$ that exceed the proposed Anderson criterion for incoherent transport by a factor of order 80! The implications of these data for currently-held ideas about bandstructure will be discussed.

**U38 12 Interplane penetration depth in $\kappa$-$(ET)_2Cu[N(CN)_2]Br$*** RUSSELL GIANNETTA, *University of Illinois at Urbana-Champaign, Urbana, IL 61801* Z. SHI, T.A. OLHEISER, A. MCCORMICK, D.D. LAWRIE, *Loomis Laboratory of Physics, U. of Illinois at Urbana-Champaign, Urbana, IL 61801* R. PROZOROV, *Ames Laboratory and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011* J.A. SCHLUETER, A.M. KINI, U. GEISER, *Material Sciences Division, Argonne National Laboratory, Argonne, IL 60439* We report measurements of the interplane penetration depth $\lambda_\perp(T)$ in the organic superconductor $\kappa - (ET)2Cu[N(CN)2]Br$ ($TC = 11.9$ K). At low temperatures, the superfluid density $\rho\perp = [\lambda\perp(0)/\lambda\perp(T)]2 \propto 1-ATN$ with $N = 1.3 -- 1.5$, close to the exponent measured for the in−plane superfluid density. This result adds support to a d−wave picture, but with transport between planes more coherent than is observed in similarly anisotropic copper oxide superconductors.

**U38 14 Pauli limiting in the superconductor $\kappa$-$(ET)_2Cu(NCS)_2$ under pressure** KYUIL CHO, BRAUNEN SMITH, CHRIS REA, MIKE VIOTTI, CHARLES AGOSTA, *Clark University* JOHN SCHLUETER, *Argonne National Laboratory* We have strong evidence that the organic superconductor $\kappa$-$(ET)_2Cu(NCS)_2$ is Pauli limited when it is compressed with a small ($< 2$ kbar) amount of pressure. A superconductor is considered Pauli limited when the magnetic energy, $\mu_b H$, overcomes the binding energy of the Cooper pairs to destroy superconductivity. In most situations superconductivity is destroyed by the formation of vortices. At ambient pressure, $\kappa$-$(ET)_2Cu(NCS)_2$ shows some behavior that is reminiscent of a Fulde Ferrell Larkin Ovchinnikov state, although no direct evidence of a transition into this state has been measured. Through a series of penetration depth measurements using a tunnel diode oscillator under pressure, we can show the evolution of the ambient pressure state to the clearly Pauli limited state at 1.75 kbar. We will also discuss the design of our new plastic, gas charged pressure cell that has allowed us to make these measurements in dc and pulsed magnetic fields. We acknowledge support from the DOE #ER46214 and the NSF #DMR- SGER-0331272.

## SESSION U39: SUPERCONDUCTING PROXIMITY EFFECT-S/N AND S/F

**U39 1 Proximity effect and Josephson current in clean strong/weak/strong superconducting tri-layers** FRANK MARSIGLIO, LUCIAN COVACI, *University of Alberta* Recent measurements of the Josephson critical current through LSCO/under-doped LSCO/LSCO thin films showed an unusually large proximity effect. Using the Bogoliubov-de Gennes (BdG) equations for a tight binding Hamiltonian we describe the proximity effect in weak links between a superconductor with critical temperature $T_c$ and one with critical temperature $T_c'$, where $T_c > T_c'$. The weak link (N') is considered to be a superconductor above it's critical temperature and the superconducting regions can have either s-wave or d-wave symmetry. We observe that the proximity effect is enhanced due to the presence of superconducting correlations in the weak link. The dc Josephson current is also calculated, and we

observe a non-zero value for temperatures greater than $T_c'$ for sizes of the weak links that are greater than the conventional coherence length. This effect alone is unable to explain the experimental results, instead, we also consider pockets of superconductivity in the weak link.

**8:12**
**U39 2 Superconducting Proximity Effect in Semiconductor Films - Experiment** SOREN FLEXNER, MICHAEL VISSERS, PAUL WELANDER, KEVIN INDERHEES, JIM ECKSTEIN, *University of Illinois at Urbana-Champaign* Interface transparency and device topology together determine the information regarding the superconducting proximity effect that can be obtained from transport measurements. We have introduced a new three terminal device design and use junctions formed entirely in-situ between niobium(S) and a thin heavily doped InGaAs epitaxial layer(N). The junction design allows us to separately extract the junction conductance and the sheet resistance of the InGaAs from the two terminal and three terminal voltage readings at low bias currents. We see evidence for both fluctuating and phase-stiff superconductivity (SC) in the normal material. At temperatures below, but close to Tc of the niobium, SC fluctuations cause the spreading resistance, Rs, on the normal side of the junction to drop. At lower temperatures, phase-stiff SC emerges in the InGaAs, effectively stealing volume from the normal region. This makes Rs appear to increase as the SC order sets in. The specific junction conductance, Gc, rises to values much greater than the normal value. We propose this is caused by the N-S boundary moving into the semiconductor.

**8:24**
**U39 3 Superconducting Proximity Effect in Semiconductor Films - Device Theory** MICHAEL VISSERS, SOREN FLEXNER, PAUL WELANDER, KEVIN INDERHEES, JIM ECKSTEIN, *University of Illinois at Urbana-Champaign* A new three terminal device architecture is introduced and analyzed for studying the superconducting proximity effect. It consists of a narrow superconducting injector line that injects current into a thin normal film. The current is extracted from one side of the injector line by a superconducting drain electrode that is many normal state coherence lengths ''downstream'' of the injector. A third voltage tap is provided on the other or ''upstream'' side of the injector. We present a theory showing how measurements made in various voltage sensing configurations can be combined to provide enough information to extract the two dimensional sheet resistance of the normal metal under the superconductor, as well as the specific contact conductance between the superconducting and normal parts of the device. This theory has been used to characterize the proximity effect in thin heavily doped InGaAs layers. A transition from fluctuating to phase stiff pair correlations in the normal layer has been observed at temperatures below Tc of the superconductor.

**U39 4 Coexistence of, and Competition between, Magnetism and Superconductivity.***
MATTHIAS ESCHRIG, *Institut fuer Theoretische Festkoerperphysik, University of Kalrsruhe, 76128 Karlsruhe, Germany*

Magnetism and superconductivity are competitive types of order in correlated electron systems. However, when a magnetic material is brought in contact with a superconducting material to build a junction, a coexistence region exists near the boundary that can modify the properties of the heterostructure in a qualitative way. In the case of a ferromagnet in contact with a singlet superconductor, the importance of triplet pairing correlations in the interface region recently became the focus of research. Such triplet correlations have unusual properties. They are typically odd in frequency for the case of a diffusive material. For clean materials in addition a triplet component even in frequency but odd in momentum is present. We have predicted that such triplet correlations can lead to an unusual indirect Josephson effect in a superconductor/half-metal/superconductor structure. In the case of a long half-metal such a Josephson effect is solely due to equal-pair triplet superconducting correlations. The triplet supercurrent is converted into a singlet current in the interface regions of the structure. Although theoretically predicted, a direct experimental verification of the presence of triplet correlations in ferromagnet/superconductor hybrid structures is difficult. In addition to the above effect we propose to use the torque on a ferromagnet/superconductor/ferromagnet trilayer in an external magnetic field as a probe of the presence of triplet correlations in the superconducting phase.

**U39 5 Magnetization-dependent $T_c$ shift in F/S/F trilayers with strong ferromagnets** ION C. MORARU, WILLIAM P. PRATT, NORMAN O. BIRGE, *Michigan State University* Hybrid systems combining ferromagnetic (F) and superconducting (S) metals in contact exhibit a wide range of fascinating behaviors. Several experimental groups have used weak ferromagnetic alloys in F/S experiments to enhance the penetration of Cooper pairs into the ferromagnet. In an F/S/F trilayer structure, a difference in the critical temperature $T_c$, based on the mutual orientation of the outer ferromagnets, has been reported [1] in CuNi/Nb/CuNi. Systems with strong ferromagnets, on the other hand, present new challenges, due to the very different density of states and Fermi velocity for the two different spin bands. Using the strong ferromagnets Ni and NiFe (Permalloy) in F/S/F exchange-biased spin valves [2], we observe that the $T_c$ for the parallel (P) orientation is lower than that of the anti-parallel (AP) case, i.e. $T_c$ (P) $<$ $T_c$ (AP). These results are consistent with theoretical expectations, but opposite to recent experimental work from another group

where an inverse spin switch has been reported in a NiFe/Nb/NiFe structure [3]. [1] J. Y. Gu et al, Phys. Rev. Lett. 89, 267001 (2002). [2] I. C. Moraru et al., submitted for publication (2005). [3] A. Yu. Rusanov et al., cond-mat/0509156 (2005).

**U39 6 Tunneling Studies of Superconductor/Strong Ferromagnet Bilayers** PAUL SANGIORGIO, *Stanford University* SERGE REYMOND, *Université de Lausanne* MALCOLM BEASLEY, *Stanford University* TESU KIM, JUNHYUNG KWON, KOOKRIN CHAR, *Seoul National University* Thin-film heterostructures composed of superconductors and ferromagnets have recently received much interest, as they provide a unique opportunity to study the proximity effect between superconductivity and magnetism. We report systematic tunneling density of states (DOS) measurements on superconductor (Nb) /strong ferromagnet (CoFe, Ni) bilayers made with high quality aluminum-oxide planar tunnel junctions as a function of ferromagnetic thickness, $d_F$. In CoFe, we find that as $d_F$ increases, the superconducting DOS exhibits a scaling behavior in which the deviations from the normal-state conductance have a universal shape, which decreases exponentially in amplitude. The decay length, $d_1$, is approximately 0.4 nm. We do not see oscillations in the DOS as a function of $d_F$, as one would expect from predictions based on the Usadel equations using reasonable parameters, although an oscillation in $T_c(d_F)$ has been seen in the same materials. Measurements on Nb/Ni bilayers will also be presented. This work is supported by AFOSR, DOE, and KOSEF through CSCMR.

**U39 9 Andreev reflection spectroscopy of the heavy-fermion superconductor $CeCoIn_5$ along different crystallographic orientations** WAN KYU PARK, LAURA GREENE, *University of Illinois at Urbana-Champaign* JOHN SARRAO, JOE THOMPSON, *Los Alamos National Laboratory* We have performed Andreev reflection spectroscopy on single crystals of the heavy-fermion superconductor $CeCoIn_5$. Conductance spectra obtained along both (001) and (110) crystallographic orientations exhibit similar features including asymmetry in the background conductance, the magnitude of zero-bias conductance enhancement (12 - 13%) and the energy scale for the conductance enhancement ( $\sim$ 1 meV). Analysis of the (001) junction data taken at the lowest temperature (400 mK) using an extended Blonder-Tinkham-Klapwijk model gives $2\Delta/k_BT_c = 4.64$ [1,2]. The failure to account for the full temperature dependence of the data sets requires further theoretical investigations to account for the magnitude of the Andreev signal, including the possibility of two-fluid behavior. Features in the (110) data may provide the first spectroscopic evidence for $d_{x2-y2}$ superconducting order parameter symmetry [2,3]. [1] W. K. Park et al., Phys. Rev. B **72**, 052509 (2005). [2] W. K. Park et al., cond-mat/0507353. [3] W. K. Park and L. H. Greene, cond-mat/0507489. **U39 10 Elastic Cotunnelling and Crossed Andreev Reflection in Normal-Superconductor Nanostructures*** PAUL CADDEN-ZIMANSKY, ZHIGANG JIANG, VENKAT CHANDRASEKHAR, *Department of Physics and Astronomy, Northwestern University* Transport experiments were made on normal-superconductor-normal systems where the separation of the normal elements is less than a superconducting coherence length. For this geometry two coherent, nonlocal effects have been predicted. In elastic cotunnelling electrons from one normal element can tunnel to the other through a virtual state in the superconducting gap. In crossed Andreev reflection one electron from each spatially separated normal element join to enter the superconductor as a Cooper pair. We present evidence of these nonlocal effects and show that their spatial dependence agrees with theory.

**U39 11 Anomalous Proximity Effect in Nb/Al/CoFe Trilayers** KOOKRIN CHAR, JUN HYUNG KWON, JINHO KIM, KYUNGMOON KIM, *Center for Strongly Correlated Materials Research, School of Physics, Seoul National University, Seoul, Republic of Korea* HYEONJIN DOH, HAN-YONG CHOI, *Department of Physics, Sung Kyun Kwan University, Suwon, Republic of Korea* We have fabricated Nb/Al/CoFe(Ni, $Cu_{40}Ni_{60}$) trilayers to study the interaction between superconductivity and ferromagnetism. Increasing the thickness of Al in S/N/F trilayer, we observed that Tc values of S/N/F trilayers increase sharply close to the Tc of S/N bilayer until the Al thickness reaches 3 nm. As Al thickness increases from 3 nm to 180 nm, Tc value of S/N/F

decreases again, following those of the S/N data. In order to fit the Tc data of Nb/Al/CoFe trilayers as a function of Al thickness in a conventional Usadel formalism, we had to use a large $\gamma_b^F (= R_b A/\rho_f \xi_f)$ value of about 4, which seems unphysically large. In order to examine the role of Al/CoFe interface, we fabricated Nb/Cu(2 nm)/Al(2 nm)/CoFe and Nb/Au(2 nm)/Al(2 nm)/CoFe and compared them with Nb/Al(4 nm)/CoFe. The Tc of the double N layer system showed lower value than the Tc of the single Al layer system, although the three systems shared the same Al/CoFe interfaces. Our data suggests the large $\gamma_b^F$ value in a conventional Usadel picture is not sufficient and rather indicates towards the unique role of Al instead of the Al/CoFe interface. We will discuss other possibilities such as the triplet superconductivity in order to explain our experimental findings.

**10:36**
**U39 12 The Role of Inelastic Scattering in Intermediate Spin Polarized Normal Metal/Superconductor Point Contacts** CHARLES W. SMITH, *University of Maine, Orono, ME* PAUL J. DOLAN, JR., *Northeastern Illinois University, Chicago, IL* Charge transport in ferromagnetic normal metal/superconductor point contacts is constrained by both the limited minority spin population, which reduces the probability of the Andreev reflection process, and by quasiparticle finite-lifetime effects, i.e., inelastic scattering, which influences the probability of ordinary electron transport. For the case of intermediate polarization $0.30 \leqslant P \leqslant 0.60$, where $0 \leqslant P \leqslant 1.0$, these processes can play equally important roles. We present results for normalized conductance at zero bias, as a function of temperature, and for conductance as a function of voltage, at $P = 0.40$, parametrically, for the entire range of inelastic scattering. Experimental results for point contacts will be presented.

**10:48**
**U39 13 Magnetically Induced Superconductor-Metal-Insulator Transition in Thin Tantalum Films** CARLOS VICENTE, YONGGUANG QIN, JONGSOO YOON, *University of Virginia* Homogeneously disordered superconducting thin tantalum films are found to exhibit a metallic behavior in the limit of zero temperature when the superconductivity is suppressed by weak magnetic fields. The metallic behavior is characterized by an apparent saturation of sample resistance to a finite value, which can be order of magnitude smaller than the normal state resistance. This implies that the metallic state exists as a separate phase rather than a point in phase diagram. Such a metallic behavior is in strong contrast to the traditional belief that the electronic state of a 2D superconducting film can either be superconducting or insulating. We present details of transport characteristics in the magnetically induced metallic and insulating phase. We also discuss the influence of disorder, represented by normal conducting sheet resistance, on the metallic behavior and the superconductor-metal-insulator phase transition.

**11:00**
**U39 14 Magnetic Field-Induced Metallic Behavior in Superconducting Tantalum Films** YONGGUANG QIN, CARLOS VICENTE, JONGSOO YOON, *University of Virginia* We present the results of electronic transport measurements on superconducting thin tantalum films. The films are grown by dc sputtering on Si substrates. No sign of crystalline ordering is found from X- ray diffraction studies, particularly for films with thickness less than $\sim$ 5nm, indicating that the structure of the films is amorphous. The superconducting transition temperatures are found to continuously decrease with decreasing film thickness, which is characteristic of homogeneously disordered superconducting films. At zero magnetic field, a direct superconductor-insulator transition is observed at a critical thickness $\sim$ 3 nm. At this thickness the normal conducting sheet resistance is close to the quantum resistance, $h/4e^2$. When the superconductivity is suppressed by applying magnetic fields, however, the system exhibits an unexpected metallic behavior in the limit of zero temperature. The metallic behavior is characterized by a drop in resistance followed by an apparent saturation to a finite value as the temperature is reduced. We observe qualitatively different nonlinear voltage-current characteristics across the ''superconductor- metal'' boundary, and also the ''metal-insulator'' boundary.

**U40 1 Ion traps and cold atoms for quantum computers.**
IGNACIO CIRAC,* *Max-Planck Institute for Quantum Optics*

Atoms can be used to store and manipulate quantum information. In particular, their internal state can be considered to form a register, and they can also be manipulated using laser light. In the case of trapped ions, the Coulomb force gives the required interaction to perform two-qubit gates. For neutral atoms, cold collisions can be used for that purpose. During the last years there has been an extraordinary experimental progress with those systems, and it is now possible to perform simple quantum information tasks with them. In this talk I will review several proposals for implementing quantum computers and quantum simulators using trapped ions and neutral atoms in optical lattices, and I will report on the latest experimental advances. Then, I will consider two particular aspects of those systems: (i) the possibility of simulating spin and bosonic systems with trapped ions; (ii) the possibility of performing quantum computations with neutral atoms without addressing them and in the presence of defects.

*Other authors (with same affiliation): Diego Porras, Karl Vollbrecht, and Enrique Solano.

**U40 3 Robust quantum memory using magnetic-field-independent atomic qubits*** C. LANGER, R. OZERI, J. D. JOST, B. DEMARCO,† A. BEN-KISH,‡ B. BLAKESTAD, J. BRITTON, J. CHIAVERINI, D. B. HUME, W. M. ITANO, D. LEIBFRIED, R. REICHLE, T. ROSENBAND, P. SCHMIDT, D. J. WINELAND, Scalable quantum information processing requires physical systems capable of reliably storing coherent superpositions for times over which quantum error correction can be implemented. We experimentally demonstrate a robust quantum memory using a magnetic-field-independent hyperfine transition in $^9Be^+$ atomic ion qubits at a field B = 0.01194 T. Qubit superpositions are created and analyzed with two-photon stimulated-Raman transitions. We observe the single physical qubit memory coherence time to be greater than 10 seconds, an improvement of approximately five orders of magnitude from previous experiments. The probability of memory error for this qubit during the measurement period (the longest timescale in our system) is approximately $1.4 \times 10^{-5}$ which is below fault-tolerance threshold for common quantum error correcting codes.

**U40 4 Quantum logic in Group-II neutral atoms via nuclear-exchange interactions** DAVID HAYES, *University of New Mexico* IVAN DEUTSCH, PAUL JULIENNE, *NIST* The spin exchange-interaction generates an entangling quantum-logic gate, the square-root of SWAP, at the heart protocols employing single electron quantum dots. This is typically accompanied by strong Coulomb interactions and commensurate decoherence due to strong coupling of charge degrees of freedom to the noisy environment. We propose a protocol utilizing a itnuclear-exchange interaction that occurs through ultracold collisions of identical spin $.5ex1kern - .1em/kern - .15em.25ex2$ Group-II neutral atoms. A natural advantage is gained by storing the quantum information in nuclear spin states with long coherence times. Unlike NMR protocols based on weak magnetic dipole-dipole interaction, the nuclear exchange interaction stems from strong s-wave scattering of electrons. Nuclear exchange is ensured by the Fermi symmetry of the overall wave function. We have studied this protocol in the context of $^{171}Yb$ atoms trapped in far-off resonance optical dipole traps. Using quantum control analysis, high-fidelity operation is possible through controlled collisions in dynamically varied double-well trapping potentials.

**9:12**
**U40 5 Quantum state reconstruction via continuous measurement** ANDREW SILBERFARB, IVAN DEUTSCH, *University of New Mexico* GREG SMITH, POUL JESSEN, *University of Arizona, Tucson* We present a new protocol for quantum state reconstruction based on weak continuous measurement of an ensemble average. This procedure applies the techniques of quantum control theory and quantum measurement theory to achieve a more efficient reconstruction than those performed using standard projective measurement techniques. This efficiency allows reconstruction of a quantum state using an single emsemble with minimal quantum backaction, setting the stage for state-based feedback control. An experimental demonstration of the technique will be presented in the context of reconstruction of the spin state of the F=3 hyperfine ground-state manifold of Cs-133 using continuous polarization spectroscopy.

**9:24**
**U40 6 Quantum state control of atoms in microscopic optical traps*** MARK SAFFMAN, DENIZ YAVUZ, MARIE DELANEY, *University of Wisconsin* PASAD KULATUNGA, *Hobart and William Smith Colleges* TODD JOHNSON, ERICH URBAN, THOMAS HENAGE, NICHOLAS PROITE, THAD WALKER, *University of Wisconsin* We present recent progress in loading and manipulation of neutral atoms in microscopic optical traps. Single Rb atoms are loaded into far off resonant optical traps from a background vapor of cold atoms. Tightly focused optical beams are used to perform two-photon stimulated Raman rotations between hyperfine qubit states. We demonstrate qubit rotations at a rate of 1.4 MHz, 1 ms coherence time, and individual site addressing with crosstalk at the level of $10^{-3}$. These results are a significant step towards quantum computing using optically trapped neutral atoms. We discuss work in progress aimed at observing strong, angle independent dipole-dipole interactions for fast two-qubit gates using microwave dressing of Rydberg states. We demonstrate two-photon coherent excitation of Rydberg levels by a $5s_{1/2} - 5p_{3/2} - nd_{5/2}$ sequence. The possibility of dipole-dipole interactions without angular zeroes will be important for gates, as well as for coupling to mesoscopic qubits to enable transmission of quantum states.

**U40 7 Stochastic One-Way Quantum Computing with Ultracold Atoms in Optical Lattices** MICHAEL C. GARRETT, *University of Calgary* DAVID L. FEDER, *University of Calgary* The one-way model of quantum computation has the advantage over conventional approaches of allowing all entanglement to be prepared in a single initial step prior to any logical operations, generating the so-called cluster state. One of the most promising experimental approaches to the formation of such a highly entangled resource employs a gas of ultracold atoms confined in an optical lattice. Starting with a Mott insulator state of pseudospin-1/2 bosons at unit filling, an Ising-type interaction can be induced by allowing weak nearest-neighbor tunneling, resulting in the formation of a cluster state. An alternate approach is to prepare each spin state in its own sublattice, and induce collisional phase shifts by varying the laser polarizations. In either case, however, there is a systematic phase error which is likely to arise, resulting in the formation of imperfect cluster states. We will present various approaches to one-way quantum computation using imperfect cluster states, and show that the algorithms are necessarily stochastic if the error syndrome is not known.

**9:48**

**U40 8 Generalized Coherent States via Markovian Decoherence** SERGIO BOIXO, *University of New Mexico, Albuquerque* LORENZA VIOLA, *Dartmouth College* GERARDO ORTIZ, HOWARD BARNUM, *Los Alamos National Laboratory* Coherent states were introduced in the early days of quantum physics as 'quasiclassical' quantum states of an isolated quantum system. The decoherence program defines 'quasiclassical' (or 'pointer') states as states which are most stable in the presence of a coupling with the environment. Pointer states may be identified through the extremization of a 'predictability' functional on the Hilbert space. It has been known for some time that for the harmonic oscillator both concepts coincide under very generic conditions. Coherent states have been extended in the 70s to generalized coherent states. Recently, this approach has served as the basis to define generalized entanglement and conditions for quantum complexity. Here, we investigate the stability of generalized coherent states under Markovian open-system dynamics. In particular, we identify conditions under which generalized coherent states emerge as pointer states for systems described by algebras more general that the standard oscillator algebra. We present a streamlined method to find pointer states in the weak-coupling approximation, and discuss conditions for this approximation to be valid. We find that generalized coherent states and pointer states coincide under more restrictive conditions than the canonical, harmonic-oscillator coherent states. Finally, we address the connection of generalized coherent states to noiseless subspaces and subsystems.

**U40 9 Generation of Werner states via collective decay of coherently driven atoms** KISHOR KAPALE, *Jet Propulsion Laboratory, California Institute of Technology* GIRISH AGARWAL, *Department of Physics, Oklahoma State University* We demonstrate deterministic generation of Werner states as a steady state of the collective decay dynamics of a pair of neutral atom coupled to a leaky cavity and strong coherent drive. We also show how the scheme can be extended to generate $2N$-particle analogue of the bipartite Werner states.

**10:12**

**U40 10 Two-Qubit Quantum Computing using Pulsed ESR of $N@C_{60}$** GAVIN MORLEY, *NHMFL* JOHAN VAN TOL, *NHMFL* JINYING ZHANG, *Materials Department, Oxford University* KYRIAKOS PORFYRAKIS, *Materials Department, Oxford University* ARZHANG ARDAVAN, *Clarendon Lab, Oxford University* ANDREW BRIGGS, *Materials Department, Oxford University* $N@C_{60}$ is a fullerene molecule containing an atom of nitrogen. The low-temperature decoherence time, $T_2$, can be increased to 215 $\mu$s, which is attractive for quantum information processing applications. The electronic and nuclear spins of the nitrogen atom are good quantum numbers in a strong magnetic field, coupled by the hyperfine interaction. Pulsed ENDOR (electron nuclear double resonance) can be used to initialize, manipulate and measure this two-qubit system. We used dynamic nuclear polarization (DNP) to prepare an initial state in which the nuclear and electronic spins were aligned with the applied field.

**10:24**

**U40 11 Optimal control of logical operations in the presence of decoherence: A two-spin model** MATTHEW GRACE, CONSTANTIN BRIF, HERSCHEL RABITZ, *Department of Chemistry, Princeton University, Princeton, NJ 08544* IAN WALMSLEY, *Department of Physics, University of Oxford, Oxford OX1 3PU, UK* ROBERT KOSUT, *SC Solutions, Inc., 1261 Oakmead Parkway, Sunnyvale, CA 94085* DANIEL LIDAR, *Chemistry and Electrical Engineering Departments, University of Southern California, Los Angeles, CA 90089* We study the feasibility of optimal control of logical operations in a simple model system composed of two interacting spins. In our model, one spin serves as a qubit and its evolution is controlled by a time-dependent external field. The other (uncontrolled) spin serves as an effective environment, coupling to which is a source of decoherence. The aim of control is to generate a target unitary operation for the qubit in the presence of the environmentally-induced decoherence. Given a target unitary operation $G$ for the system, the fidelity of the actual transformation achieved is maximized with respect to the electric field $\epsilon(t)$ using two techniques, optimal control theory (OCT) and ''pre-design'' methods, which are well-developed in the field of nuclear magnetic resonance. The primary goal of this work is to illustrate the importance of OCT in designing logical operations, especially in the presence of environmental coupling, and the inadequacy of pre-designed gates in such situations.

**U40 12 Rapid State-Reduction of Quantum Systems Using Feedback Control*** JOSHUA COMBES, *Griffith University* KURT JACOBS, *Louisiana State University* Many potential applications of quantum devices, particularly in information processing, require quantum systems to be prepared in pure states. Due to environmental noise quantum systems often exist naturally in mixed states, and as a result a process of cooling or measurement must be used to purify them. In this work we consider the use of measurement for this purpose. The speed with which a measurement can purify, or reduce, the state of a quantum system is determined by the interaction between the system and measuring device, and places a limit on the speed of state-preparation. Here we consider using feedback control during the measurement to increase the rate of state-reduction. It was shown in [1] that for a single qubit this rate could be increased by a factor of 2. Here we show that for higher dimensional systems feedback control can provide a much larger speed-up. In particular, we show that for a measurement of an observable with $N$ equally spaced eigenvalues, there exists a feedback algorithm which will increase the rate of state-reduction by a factor proportional to $N$. **U40 13 Quantum Zeno stabilization in weak continuous measurement of two qubits** RUSKO RUSKOV, *Penn State University* ALEXANDER N. KOROTKOV, *University of California, Riverside* ARI MIZEL, *Penn State University* We have studied quantum coherent oscillations of two qubits under continuous measurement by a symmetrically coupled mesoscopic detector. The analysis is based on a Bayesian formalism that is applicable to individual quantum systems. Measurement continuously collapses the two-qubit system to one of the sub-spaces of the Bell basis. For a detector with linear response this corresponds to measurement of

the total spin of the qubits. In the other extreme of purely quadratic response the operator $\sigma_y^1\sigma_y^2 + \sigma_z^1\sigma_z^2$ is measured. In both cases, collapse naturally leads to spontaneous entanglement which can be identified by measurement of the power spectrum and/or the average current of the detector. Asymmetry between the two qubits results in evolution between the different measurement subspaces. However, when the qubits are even weakly coupled to the detector, a kind of quantum Zeno effect cancels the gradual evolution and replaces it with rare, abrupt switching events. We obtain the asymptotic switching rates for these events and confirm them with numerical simulations. We show how such switching affects the observable power spectrum on different time scales.

**U41 2 Low temperature specific heat and Brillioun scattering in nano-oscillator arrays** DOUGLAS PHOTIADIS, JOSEPH BUCARO, XIAO LIU, *US Naval Research Laboratory* We consider a large, free-standing array of coupled, planar oscillators each several hundred nanometers on a side fabricated from a single layer of dielectric. In particular, we predict the low temperature heat capacity and Brillouin scattered cross section based upon a numerical calculation of the density of states (DOS) for this nano-structured array. The DOS, which is interesting in its own right, is found to have an average value nearly independent of frequency and a number of gaps of varying depths. The predictions suggest that it should be possible to use low temperature measurements of Brillouin cross section and/or the specific heat to observe the quantum statistics obeyed by various rigid body modes of the array, some of which involve the center of mass motion of a large number of atoms. As such, these measurements would result in a considerable extension of the domain in which quantum mechanics has been tested.

**8:24**
**U41 3 Determining the quantum phase coherence time of a NEMS resonator** EMILY PRITCHETT, *University of Georgia* MICHAEL GELLER COLLABORATION, Recently steps have been made toward characterizing macroscopic quantum behavior in nanoelectromechanical devices (NEMS), particularly resonators with large frequencies and high Q factors. While the quantum phase coherence time as well as energy relaxation time of NEMS resonators are believed to be long, this cannot be tested directly using standard techniques. Using formalism typically found in quantum computation, we propose a procedure for directly measuring both phase coherence and energy relaxation times of NEMs resonators by coupling them to anharmonic Josephson junction devices. We hope that using this proposed method experiments will verify current models of decoherence in harmonic oscillator systems.

**8:36**
**U41 4 Tunable Electronic Energy Transfer in Layered Inorganic Solids Codoped with $Tb^{3+}$ and $Eu^{3+}$** CHRISTIE LAROCHELLE, *Franklin & Marshall College* $Ln[M(CN)_2]_3$ systems (Ln=trivalent rare earth, M=Au,Ag) have a layered structure consisting of alternating layers of the $M(CN)_2^-$ ions and $Ln^{3+}$ ions. Our past studies of tunable energy transfer have focused on transfer from $Au(CN)_2^-$ or $Ag(CN)_2^-$ donor ions to a variety of rare earth ions, including $Tb^{3+}$ and $Eu^{3+}$. Most recently, we have characterized systems with mixed metal donors, such as $La[Ag_{.5}Au_{.5}(CN)_2]_3$, $La[Ag_{.75}Au_{.25}(CN)_2]_3$, and $La[Ag_{.9}Au_{.1}(CN)_2]_3$. We have found that these systems exhibit ''tunability'' of emission energy due to the variation of the donor emission associated with varying the Ag/Au ratio. Tunability also occurs with changing temperature and excitation wavelength. Also, the steady-state luminescence spectra of these compounds reveals that they are strongly luminescent at room temperature, in contrast to the corresponding $La[Ag(CN)_2]_3$ and $La[Au(CN)_2]_3$ pure metal systems. Results will be presented from a new series of samples incorporating both $Tb^{3+}$ and $Eu^{3+}$ as acceptors. The tunability of the donor's emission wavelength allows for changes in the spectral overlap with each of the two donors. Preliminary results show variation in the rare earth (acceptor) emission with changing temperature and excitation wavelength, indicating the possibility of tuning the energy transfer off of one acceptor and onto the other.

**U41 5 EPR and ENDOR of two axial $Fe^{3+}$ centers in stoichiometric lithium tantalate** VALENTIN GRACHEV, GALINA MALOVICHKO, ROBERT PETERSEN, *Physics Department, Montana State University* CHRISTOFF BAEUMAN, *Department of Physics, University of Osnabrück, D-49069, Osnabrück, Germany* The determination of structures of centers in oxide crystals created by impurity ions, including those of transition metals and rare- earth elements, is one of the most important tasks in defect study. The iron ions play a key-role in the photovoltaic and photorefractive effects, holographic records and many other physical properties of lithium tantalate. The axial $Fe^{3+}$ center, Fe1 with the crystal field parameter $b_2^0 \approx 0.313$ 1/cm is well studied in congruent lithium tantalate crystals. Using the EPR we have discovered and investigated a new axial $Fe^{3+}$ center, Fe2 in stoichiometric samples prepared by vapor transport equilibrium treatment. The crystal field parameter of the Fe2 center $b_2^0 \approx 0.205$ 1/cm is significantly smaller than for Fe1. The ENDOR measurements have shown that hyperfine interactions of the $Fe^{3+}$ electrons with

the surrounding Li nuclei for Fe2 are stronger than for Fe1. Therefore, the conclusion was made that in the case of Fe2 center the iron ion substitutes for Ta and has Li nuclei in the nearest neighborhood, whereas in the case of Fe1 it substitutes for Li, has Ta nuclei as nearest neighbors and Li nuclei in the second shell only.

**U41 6 Near infrared emission properties of Nd doped Potassium Lead Halides** JESSICA FREEMAN, EI NYEIN, UWE HOMMERICH, *Hampton University* SUDHIR TRIVEDI, *Brimrose Corporation of America* JOHN ZAVADA, *US Army Research Office* The incorporation of rare earth (RE) ions into host materials with low maximum phonon energies provides opportunities for improved RE infrared emission properties. In this work, we evaluated the IR emission from Nd doped potassium lead halides, namely Nd: $KPb_2Cl_5$ and Nd: $KPb_2Br_5$, for possible applications in IR lasers and optical communications. Both halides are nearly non-hygroscopic and have low maximum phonon energies, which reduces non-radiative decay rates through multi-phonon relaxations. Following optical excitation at 800nm, near IR emission bands were observed from the $^4F_{5/2}$ and $^4F_{3/2}$ excited states of $Nd^{3+}$. The $^4F_{5/2}$ level was strongly quenched through non-radiative processes in Nd: $KPb_2Cl_5$. On the contrary, for Nd: $KPb_2Br_5$ the $^4F_{5/2}$ was highly radiative with an emission efficiency of $\sim$ 50%. More detailed results of the material synthesis, purification, steady-state and time-resolved emission spectroscopy will be presented at the conference.

**U41 7 Non-resonant Inelastic X-Ray Scattering and Energy-Resolved Wannier Function Investigation of Local Excitations in Transition Metal Monoxides NiO and CoO** B.C. LARSON, J.Z. TISCHLER, *ORNL* WEI KU, *BNL and SUNY, Stoney Brook* CHII-CHENG LEE, *Tamkang Univ. Taiwan* OSCAR RESTREPO, *Univ. TN, Knoxville* A.G. EGUILUZ, *Univ. TN, Knoxville and ORNL* P. ZSCHACK, *FS-MRL UIUC* K.D. FINKELSTEIN, *CHESS, Cornell Univ.* Non-resonant inelastic x-ray scattering (NIXS) and energy- resolved Wannier function analysis have been used to probe the strongly correlated electronic structure of NiO and CoO. NIXS measurements of the dynamical structure factor s(q,w) as a function of momentum transfer q and frequency w have shown that dipole-forbidden, d-d excitations appear within the optical gap for large wavevectors ($q > 2/A$), become the dominant structure in the loss spectra for $q > 3/A$, and reach a maximum at $q \sim 7/A$. In contrast to the loss-spectra observed in resonant-probe studies of NiO and CoO, non-resonant spectra show only two excitations that are highly anisotropic - strongest in the [111] direction and weakest (or missing) in the [001] direction. Energy-resolved Wannier function analyses of vertex matrix elements within LDA+U demonstrate that the anisotropy provides a sensitive measure of electronic symmetry-breaking in these atomic-like d-d excitations as a result of point-group symmetry selection rules.

**U41 9 Determining the Critical Dose Threshold of Electron-Induced Electron Yield for Minimally Charged Highly Insulating Materials** RYAN HOFFMANN, J.R. DENNISON, JONATHAN ABBOTT, *Utah State University* When incident energetic electrons interact with a material, they excite electrons within the material to escape energies. The electron emission is quantified as the ratio of emitted electrons to incident particle flux, termed electron yield. Measuring the electron yield of insulators is difficult due to dynamic surface charge accumulation which directly affects landing energies and the potential barrier that emitted electrons must overcome. Our recent measurements of highly insulating materials have demonstrated significant changes in total yield curves and yield decay curves for very small electron doses equivalent to a trapped charge density of $< 10^{10}$ electrons /$cm^3$. The Chung-Everhart theory provides a basic model for the behavior of the electron emission spectra which we relate to yield decay curves as charge is allowed to accumulate. Yield measurements as a function of dose for polyimide (Kapton$^{TM}$) and microcrystalline $SiO_2$ will be presented. We use our data and model to address the question of whether there is a minimal dose threshold at which the accumulated charge no longer affects the yield.

**9:48**

**U41 10 Comparison of Methods for Determining Crossover Energies in Insulators** JONATHAN ABBOTT, RYAN HOFFMANN, J.R. DENNISON,* SARAH BARTON, *Brigham Young University* When a material is irradiated with energetic particles electrons can be emitted from the material. For electron-induced emission, the number of electrons that leave a particular material depends on the incident energy of the electrons, among other things. There are two critical energies where the ratio of emitted electrons to incident electrons crosses unity, called crossover energies. Measurements of the absolute total yield, secondary electron emission spectra, and sample and detector currents are used for a variety of methods to determine first and second crossover energies of both conductors and insulators. Precision is discussed for the following methods: i) Total Yield Curve, ii) Backscattered-to-Secondary Yield Ratio, iii) Mirror Potential, iv) Emission Spectral Shift, and v) Sample Null Current. Also, theoretical models for the Emission Spectral shift and Sample Null Current methods will be discussed. This work was funded by the NASA Space Environments and Effects Program, a Willard L. Eccles Undergraduate Research Fellowship, and a USU Undergraduate Research and Creative Opportunities award.

**U41 11 Piezoelectric Coupling in Non-piezoelectric Materials due to Nonlocal Size Effects at the Nanoscale: Fundamental Solutions, Embedded Inclusions and Piezoelectric Composites without Electromechanical Constituents** PRADEEP SHARMA, *University of Houston* In a piezoelectric material an applied ituniform strain can induce an electric polarization (or vice-versa). Crystallographic considerations restrict this technologically im-

portant property to non-centrosymmetric systems. It has been shown both mathematically and physically, that a itnon-uniform strain can potentially break the inversion symmetry and induce polarization in non-piezoelectric materials. The coupling between strain gradients and polarization; and strain and polarization gradients, is investigated in this work. Based on a field theoretic framework accounting for this phenomena, we (i) develop the fundamental solutions (Green's functions) for the governing equations (ii) solve the general embedded inclusion problem with explicit results for the spherical and cylindrical inclusion shape and, (iii) Illustrate using the simple example of a bilaminate how an apparently piezoelectric composite may be created without using constituent piezoelectric materials.

**U41 12 Ionic-Mode Contributions to the Refractive Index of Glasses*** CARRIE E. BLACK, E. SHILES, *University of Vermont* D. Y. SMITH, *University of Vermont and Argonne National Laboratory* The refractive index of materials transparent in the visible is commonly much smaller in the infrared than at shorter wavelengths because low-frequency ionic polarization lags the **E** field of higher-frequency light. This is often described by an IR Sellmeier term in empirical index fits. However, this separation of ionic and electronic contributions is not unique. A unique separation is given by Taylor expansion of the K-K relations in the region of transparency that yields a Laurent series in photon energy squared as the IR contribution. The coefficients are odd moments of the IR extinction coefficient. We studied this for vitreous silica and Corning ULE glass (92.5 % $SiO_2$ + 7.5% $TiO_2$). While the oscillator strength of the IR modes is four orders of magnitude less than that of the electronic transitions, the IR contribution to the index is comparable to the electronic contribution in the IR. In our examples, IR terms are sufficiently negative to bring the total index well below unity (but greater than zero) between 7 to 9 $\mu$m.

**U41 13 Enhanced fluorescence in rare earth doped sol-gel glasses containing $Al^{3+}$*** GREGORY ARMSTRONG, ANN SILVERSMITH, *Hamilton College* DANIEL BOYE, *Davidson College* Sol-gel synthesis is a low temperature method for preparing rare earth (RE) doped glass. Aluminum is often used as a co-dopant because it increases fluorescence yield from RE's. There is a tendency for RE ions to form clusters in the sol-gel preparation, facilitating inter-ion interactions and fluorescence quenching from cross relaxation. It is generally believed that Al prevents clustering of RE ions, but recent work questions this long-established role of Al. We report on spectroscopic investigations of energy transfer in Tb- and Eu- doped glasses that probe the effect of Al co-doping. Pulsed laser excitation of $^5D_3$ fluorescence is used to measure Tb-Tb cross-relaxation rates. In materials containing Al, cross-relaxation occurs in concentrations much lower than 0.1%Tb, indicating that RE clustering persists in glasses with Al. Line narrowing experiments in dilute Eu glasses confirm that ions remain clustered in co-doped samples. Our results point toward a model of aluminum rich regions in the glass that attract and confine RE ions. Reduced association with $OH^-$ in the confined regions causes RE fluorescence enhancement.

**U41 14 Site-specific modification of oxide nanoclusters: Towards atomic-scale surface structuring*** KENNETH M. BECK, MATTHIAS HENYK, CHONGMIN WANG, WAYNE P. HESS, *Pacific Northwest National Laboratory* PAOLO E. TREVISANUTTO, PETER V. SUSHKO, ALEXANDER L. SHLUGER, *University College London* Atomic emission from MgO and CaO nanostructures is induced using laser light tuned to excite specific surface sites at energies well below the excitation threshold of the bulk material. Using selective 4.66 eV laser excitation of nanocrystalline thin films and nanocube metal oxide samples we have recorded a unique pattern of hyperthermal atomic desorption. Not only neutral O-atoms, but neutral Mg-atoms, with hyper-thermal kinetic energies in the range of 0.1–0.4 eV are readily observed. Our itab initio calculations suggest that metal atom emission is induced predominantly by electron trapping at surface 3-coordinated metal sites followed by electronic excitation at these sites- an 'electron plus an exciton' mechanism. The proposed elementary mechanism involves both sequential excitation and localization of excitons as well as electrons and holes at 3-coodinated surface sites. This mechanism differs from all previously suggested mechanisms for desorption induced by electronic transitions. This desorption process serves as an example of atomic scale modification of a nanostructured metal oxide using laser light tuned to excite specific surface sites at energies well below the excitation threshold of the bulk material.

**U41 15 Optical Spectroscopy of Low-k Dielectric Films*** JOANNA ATKIN, DAOHUA SONG, SRIKANTH IYER, *Columbia University* NILS HOIVIK, ROBERT R. ROSENBERG, THOMAS M. SHAW, *IBM T. J. Watson Research Center, Yorktown Heights, NY 10598* ROBERT B. LAIBOWITZ, TONY F. HEINZ, *Columbia University, New York, NY 10027* Low-k dielectric materials based on porous carbon-doped oxides are widely used in the microelectronics industry. Despite their importance, relatively little is known about their spectroscopic properties. In this paper we report results of two classes of optical spectroscopy measurements, absorption spectroscopy and photocurrent spectroscopy. Optical absorption spectroscopy has been performed on various thin-film low-k materials. These measurements show the presence of strong optical absorption in the ultraviolet and yield the effective band gap of the medium. Photocurrent spectroscopy has been performed on films of low-k material deposited on both Si and metallic substrates using a transparent counter-electrode. A well-defined spectral dependence of the photocurrent efficiency is observed. The data provide information on the band offsets of the low-k materials, parameters that play a crucial role in models of electrical conduction.

**U42 1 Condensed Matter and its Orderings: The Pressure Variable.***
NEIL ASHCROFT, *Cornell University*

Advances in experimental high pressure condensed matter physics have led to near order-of-magnitude static isothermal compressions (high densities are also realizable in dynamic compressions). In sufficiently light systems the new realms of density have associated zero-point effects, which are substantial. Also generally anticipated are significant changes in electronic structure (band widths not always increasing with density, however) and effective state dependent interparticle potentials. Propitious use of the pressure variable can elucidate the many-body problem in incisive ways through new orderings including structural, magnetic and especially superconducting. Significant challenges to theory include the appearance at higher densities of exceedingly complex structures in systems hitherto regarded as ''simple''. Invasion of the valence electron domain by core space appears to impel an interesting clash of length scales. Not unrelated to the rise of quantum effects is the possibility (and even observation) of depression of melting points in low mass systems. Hydrogen, a tenacious insulator (but now a decreasingly reluctant alkali) remains a candidate for significant superconductivity in a metallic state, one which may also be manifested as a quantum liquid. In combination with other light elements further orderings are also predicted, but at pressures less than anticipated for pure hydrogen itself. For the future, this area of experimental investigation appears to be ideally matched to advanced electronic structure and simulation techniques.

**U42 2 The Nature of the Hydrogen Plasma Phase Transition** KRIS DELANEY, DAVID CEPERLEY, *University of Illinois at Urbana-Champaign* CARLO PIERLEONI, *Università del L'Aquila, Italy* We present details of a study of pure hydrogen fluid at high pressure. Using the Coupled Electron-Ion Monte Carlo (CEIMC) method [1,2], a quantum Monte Carlo scheme capable of accurately simulating systems at low temperature, we study the nature of the plasma phase transition (PPT): the mechanism by which a molecular to non-molecular transformation occurs under increasing pressure. We find no evidence for a first-order PPT. The CEIMC method centers on exploring the nuclear configuration space (classically or with quantum path integrals) using a modified Metropolis algorithm. Configurational energy differences are computed within the Born-Oppenheimer (BO) approximation using accurate ground-state quantum Monte Carlo techniques. 1. D. Ceperley, M. Dewing and C. Pierleoni, in Bridging Time Scales: Molecular Simulations for the Next Decade, eds. P. Nielaba *et al*, Springer-Verlag, pgs. 473-500 (2002). 2. C. Pierleoni, D. M. Ceperley and M. Holzmann, Phys. **U42 3 Developments in the path integral Monte Carlo method for simulating fluids under extreme conditions** KENNETH ESLER, *University of Illinois at Urbana-Champaign* DAVID CEPERLEY, *University of Illinois at Urbana-Champaign* We summarize a number of improvements we have developed for the quantum simulation of fluids under extreme conditions with path integral Monte Carlo (PIMC). PIMC provides way to combine fully-correlated quantum effects with thermal fluctuations in a natural formalism by sampling the many-body thermal density matrix. These developments include the construction of accurate pseudohamiltonians and their incorporation into PIMC, computation of high-accuracy pair density matrices, improved optimization of the long/short-range breakup, a fast embedded band-structure calculation for the fermion nodal restriction, Brillouin-zone integration through twist-averaged boundary conditions, and coupled PIMC/Langevin dynamics. We present preliminary results for the simulation of sodium near its liquid/vapor critical point.

**U42 4 Vibron Dynamics of Hydrogen at High Pressures and Temperatures** KARL JOHNSON, *University of Pittsburgh* JOSEPH FELDMAN, *Center for Computational Materials Science, Naval Research Laboratory, and School of Computational Sciences, George Mason University* RUSSELL HEMLEY, *Geophysical Laboratory, Carnegie Institution of Washington* There is currently great interest in the behavior of molecular hydrogen at high pressures and temperatures. The van Kranendonk theory of vibrons in solid hydrogen has been used previously to provide a description of the Raman response as a function of pressure and para-ortho concentrations at low temperature. Here we apply the same model to very different environments, namely to the solid at high P-T conditions, and, with less justification, to the dense fluid. The effect of temperature is presumed to be to renormalize the hopping parameter. Within our model of the vibrons and approximate harmonic lattice dynamics, a $1/R^6$ dependence of the hopping parameter on intermolecular distance, $R$, gets averaged over fluctuations in the interatomic distance, and the average increases with temperature. Preliminary results using configurations obtained from hybrid path integral molecular dynamics calculations with empirical potentials suggest that there is very little change in the Raman peak upon melting at high pressure, in agreement with previous high P-T measurements.

**U42 5 A systematic search method for finding new high-pressure phases of polymeric nitrogen** SERGEY DUDIY, FEDERICO ZAHARIEV, JAMES HOOPER, *Department of Chemistry, University of Ottawa, Ottawa, Ontario, K1N 6N5, Canada* FAN ZHANG, *Defense Research and Development Canada - Suffield, PO Box 4000, Medicine Hat, Alberta, T1A 8K6, Canada* TOM WOO, *Department of Chemistry, University of Ottawa* A recent discovery of single-bonded polymeric form of nitrogen in diamond anvil cell high pressure experiments [Nature Mat. **3**, 558 (2004)] opens a new promising direction in the development of high energy density materials. Besides the cubic gauche phase of polynitrogen stabilized in experiment, other yet unidentified metastable phases could emerge under certain experimental conditions. We present a systematic search method for finding metastable phases of single bonded nitrogen based on a set of Peierls distortions of a given reference structure. Using the most basic reference structure, a simple cubic unit cell, our approach not only reproduces all the single-bonded nitrogen phases reported so far, but also reveals many new metastable structures with promising properties. The equations of state of the structures calculated at the first-principles level are studied over a broad range of pressures up to 300 GPa. The stability of the structures is analyzed using directly calculated phonon spectra. This approach can be extended using more complex reference structures and relaxing the constraint of a pure single bonded phase.

**U42 6 Complexity and Pressure Induced Fermi Surface Deformation in Lithium** AITOR BERGARA, ALVARO RODRIGUEZ-PRIETO, *University of the Basque Country (UPV/EHU) and Donostia International Physics Center (DIPC)* V.M. SILKIN, *Donostia International Physics Center (DIPC)* UPV/EHU AND DIPC TEAM, Recently reported structural complexity and high temperature superconducting transition in lithium under pressure has increased the interest in light alkalis, otherwise considered as simple and well known systems under normal conditions. In this work we present an analysis of the pressure induced Fermi surface deformation in lithium and its relation to the observed complexity. According to our calculations, the Fermi surface becomes increasingly anisotropic with pressure and at around 8 GPa it contacts the Brillouin zone boundary, which preludes the bcc to fcc phase transition. Furthermore, at around 30 GPa, besides the increasing necks in the Fermi surface along the fcc ΓL direction, it develops an extended and well defined nesting in the ΓW direction, which enhances the electronic response for the nesting momentum and induces an strong phonon softening along the ΓK. The increasing electron-phonon coupling associated to this softening, besides preluding the transition to complex structures, also provides a better understanding of the observed superconducting transition in lithium at around the same pressure range.

**U42 7 Prediction of a superionic phase of hydrogen fluoride (HF) at high temperature and pressure*** LAURENCE FRIED, NIR GOLDMAN, *Lawrence Livermore National Laboratory* We report first principles simulations of hydrogen fluoride. Ab initio molecular dynamics simulations of HF were conducted at densities of 1.8 – 4.0 g/cc along the 900 K isotherm. At experimentally observable conditions, we find a transition to a superionic phase, in which the fluorine ions exhibit a stable lattice and the hydrogen ions exhibit rapid diffusion. This phase is similar to the recently reported superionic phase in water, in that there is a symmetrization of the hydrogen bond, and we observe a transient partially covalent network at pressures greater than 66 GPa. In addition, we describe a mechanism for hydrogen diffusion through the fluorine sub- lattice. Our results provide evidence that superionic solids are prevalent in solids that manifest low temperature symmetric hydrogen bonding. The pressures needed to induce superionic diffusion in HF are significantly lower than what is required for other known superionic hydrides, and thus will permit much more extensive experimental studies of this exotic phase.

**U42 8 High-pressure and high-temperature phases of nitrous oxide*** BRENDAN OSBERG, STANIMIR A. BONEV, *Department of Physics, Dalhousie University, Canada* The phase diagram of nitrous oxide ($N_2O$) is investigated up to 50 GPa and 1000 K using first principles theory. The calculated stability and properties of numerous crystalline structures are compared with experimental results. We identify the structure of phase II of $N_2O$. On the basis of its stability with respect to orthorhombic deformations, an explanation for measured Raman spectra is provided. Similarly to $CO_2$ [1], crystalline structures with bent molecules are found to be extremely unfavorable energetically. [1] Bonev et al., Phys. Rev. Lett. 91, 065501 (2003).

**U42 9 Mechanical strength and coordination defects in compressed silica glass** YUNFENG LIANG, *International School for Advanced Studies (SISSA) and INFM-CNR Democritos National Simulation Center, Trieste (Italy)* CAETANO R. MIRANDA, SANDRO SCANDOLO, *The Abdus Salam International Centre for Theoretical Physics (ICTP) and INFM-CNR Democritos National Simulation Center, Trieste (Italy)* Contrary to ordinary solids, which are normally known to harden by compression, the mechanical strength of compressed $SiO_2$ glass shows a minimum around 10 GPa. Around this pressure, the compression of silica glass undergoes a change from purely elastic to plastic, leading to the recovery of a densified amorphous polymorph. The compressibility of silica glass is also anomalous, with a maximum at about 2-4 GPa. Despite the large pressure difference between the onset of the two anomalies, microscopic theories have traditionally attempted to explain both anomalies with the pressure induced appearance of coordination defects. Such models are seriously questioned however by the lack of evidence for coordination defects below 10 GPa, in Raman and NMR experiments. Here we show, using an improved interatomic potential for $SiO_2$, that a correct description of the pressure-induced appearance of five-fold coordination defects in silica glass is crucial to address the above phenomenology and to obtain a theoretical model consistent with experiments.

**U42 10 USPEX - Predicting crystal structures of new phases** COLIN W. GLASS, ARTEM R. OGANOV, *Lab. of Crystallography, ETH Zuerich* We have developed an very efficient and reliable method for crystal structure prediction [1], merging an evolutionary algorithm, based on local optimization and spatial heredity, with itab initio total-energy calculations. This method allows one to predict the most stable crystal structure and a large

number of robust metastable structures for a given compound at any $P - T$ condition, without requiring experimental input. The success rate is extremely high – USPEX succeeded in all of the 25 tests performed so far, including ionic, covalent, metallic, and molecular structures with up to 20 atoms per unit cell. Using this methodology we have succeeded in predicting hitherto unknown structures [2]. Implementation of the algorithm, several applications and physical reasons for its success will be discussed. [1] Glass C.W, Oganov A.R., Hansen N. (2005). USPEX: a universal structure prediction algorithm. In prep. [2] Oganov A.R., Glass C.W., Ono S. (2005). High-pressure phases of $CaCO_3$: crystal structure prediction and experiment. Earth Planet. Sci. Lett, in press.

**U43 1 Low-Dimensional Fermi Gases** HENNING MORITZ, *ETH Zurich* KENNETH GÜENTER, THILO STÖFERLE, MICHAEL KÖHL, TILMAN ESSLINGER, Optical lattices are a powerful tool to create novel many-body quantum systems with ultracold atoms. They allow to study the role of interactions in the system in reduced dimensions. We have observed two-particle bound states of atoms confined in a one-dimensional matter waveguide. These bound states exist irrespective of the sign of the scattering length, contrary to the situation in free space. The strongly interacting one- dimensional Fermi gas which we create in an optical lattice represents a realization of a tunable Luttinger liquid. In a spin-polarized Fermi gas interacting via a p-wave Feshbach resonance the strong confinement allows us to restrict the asymptotic scattering states. When aligning the spins along (or perpendicular to) the axis of motion in a 1D gas, scattering into channels with the angular momentum projection of $|m| = 1$ (or $m = 0$) can be completely suppressed.

**U43 2 Empirical manifestations of integrability in cold quantum gases** MAXIM OLSHANII, VANJA DUNJKO, *USC* VLADIMIR YUROVSKY, *U Tel-Aviv* MARCOS RIGOL, *UC Davis* Integrable quantum many-body systems traditionally belong to the domain of mathematical physics, with little or no connection to experiments. However, the experiments on confined quantum-degenerate gases has recently yielded faithful realizations of a number of integrable systems, thus making them phenomenologicalily relevant. We show that the presence of few-body conserved quantities in a quantum system leads to dramatic, initial-state-dependent discrepancy between the state of the system after relaxation and the predictions of thermodynamics. Using the newly introduced concept of constrained thermal equilibrium we study quantitatively the effects of the memory of the initial conditions. As objects of study we choose bosons in one-dimensional optical lattices in the deep Mott regime and spin-0 Bose gases confined to waveguides, both of which have been experimentally realized already. We suggest momentum distribution and chemical composition as the simplest experimental observables sensitive to the effects of integrability. Overall, we argue that the kinetic and thermodynamic properties of integrable quantum gases are so different from the usual, that they well-qualify for a new state of quantum matter.

**8:24**
**U43 3 Noise and counting statistics in one-dimensional insulators** AUSTEN LAMACRAFT, *All Souls College, Oxford* We discuss the correlation properties of current carrying states of one-dimensional insulators, which could be realized by applying an impulse to atoms loaded onto an optical lattice. While the equilibrium noise has a gapped spectrum, the quantum uncertainty encoded in the amplitudes for the Zener process gives a zero frequency contribution out of equilibrium. We derive a general expression for the generating function of the full counting statistics and find that the particle transport obeys binomial statistics. Finally, we discuss the extent to which the technique employed in a recent experiment (Phys. Rev. Lett. 95, 090404 (2005)) can be considered an ideal measurement of counting statistics.

**U43 4 Dynamics of reduced dimension Bose gases in optical lattices.**
J. V. PORTO, *National Institute of Standards and Technology*

We use deep optical lattices to tightly confine cold atoms in reduced dimensions. By applying shallower optical lattices in the weakly confined direction, we realize well-characterized one- and two- dimensional Bose-atom lattice gases. Transport dynamics is studied by observing motion of the atom cloud through the lattice. For a 1D quantum degenerate Bose gas, we report the observation of strongly damped dipole oscillations in a combined harmonic and optical lattice potential. Damping is significant for very shallow axial lattices (0.25 photon recoil energies), and increases dramatically with increasing lattice depth, such that the gas becomes nearly immobile for times an order of magnitude longer than the single-particle tunneling time. Surprisingly, we see no broadening of the atomic quasimomentum distribution after damped motion.

**U43 5 The superfluid-Mott insulator transition in 2D** I. B. SPIELMAN, J. HUCKANS, J. STRABLEY, M. ANDERLINI, J. KRUSE, J. V. PORTO, W. D. PHILLIPS, *NIST* Ultra-cold atoms in optical lattices have been exploited to study the Mott-insulator transition in 1, 2, and 3 dimensions; here focus on the 2D Mott-insulator transition. Initially Bose-condensed rubidium atoms are loaded into a 3D optical lattice with an average occupancy of one atom per-site. By making one lattice much deeper in one direction than the remaining two, we construct an ensemble of 2D lattice systems. These 2D systems exhibit a superfluid-insulator transition as the lattice depth is increased. In this talk I present new measurements that show that even when the conventional signature of long-range order (namely diffraction) disappears, the system is not a perfect insulator – partially responding to an impulsive force.

**U43 6 Crystalline phases of bosons in rotating traps: Tonks-Girardeau gas on a ring.*** IGOR ROMANOVSKY, *Georgia Inst. of Technology* CONSTANTINE YANNOULEAS, *Georgia Inst. of Technology* UZI LANDMAN, *Georgia Inst. of Technology* We analyze the systems of strongly repelling bosons in two-dimensional harmonic and ring-shaped traps as a function of the rotational frequency of the trap for neutral atoms (and of an applied magnetic field for charged bosons). Our two-step approach consists of breaking the rotational symmetry at the Hartree-Fock level and of subsequent symmetry restoration via projection techniques,[1] thus taking into account correlations beyond the Gross-Pitaevskii (GP) solution. The bosons localize and form crystalline patterns both for a repulsive contact potential and a Coulomb interaction, as revealed via conditional probability distribution (CPD) analysis. This behavior of the bosons in the ring-shaped traps in the strong repulsion limit is similar to the behavior of fermions and is a manifestation of the fermionization phenomenon. We present calculations for the ground state energies as a function of the rotational frequency (or the strength of the magnetic field) and as a function of the repulsion strength.

**U43 7 Ordering and Entropy Production Across Qauntum Phase Transitions** ROBERT CHERNG, *Harvard University* LEONID LEVITOV, *MIT* We consider the transverse field Ising spin chain swept through a quantum critical point from the disordered to the ordered phase (and vice versa) and present exact results on the ordering and entropy production. Prepared in the ground state of the initial Hamiltonian, the system evolves to a state characterized by a non-equilibrium distribution of excitations of the final Hamiltonian. We show that the evolved system, while described by a pure many-body state, possesses finite entropy if considered ''locally.'' The notion of local entropy is defined by coarse-graining in momentum space, and is linked to the properties of the system of Kibble-Zureck domain walls. Exact results obtained for the spin correlation functions are presented and used to elucidate the relationship with the Kibble-Zureck theory of critical dynamics. Possible manifestations in ultracold atoms trapped in optical lattices will be discussed.

**U43 8 Spin 1/2 fermions on spin-dependent optical lattices.***
ANDREW HO, *School of Physics and Astronomy, Birmingham University*

We study the phase diagram of one-dimensional two-component (i.e. pseudo-''spin''-1/2) ultracold atomic Fermi gas. The two atom species can have different hopping or mass. A very rich phase diagram for equal densities of the species is found, containing Mott insulators with various quasi-long-range-order, superfluids and perhaps phase separation. We also discuss coupling such 1D systems together and the experimental signatures of the phases. In particular, we compute the ''spin''-structure factor at small momentum, which should reveal a ''spin'' gap.

**U43 9 Quartetting and pairing instabilities in one dimensional spin 3/2 fermionic systems** CONGJUN WU, *Kavli Institute for Theoretical Physics, UCSB* Novel competing orders are found in spin 3/2 cold atomic systems in one-dimensional optical traps and lattices. In particular, the quartetting phase, a four-fermion counterpart of Cooper pairing, exists in a large portion of the phase diagram. The transition between the quartetting and singlet Cooper pairing phases is controlled by an Ising symmetry breaking in one of the spin channels. The singlet Cooper pairing phase also survives in the purely repulsive interaction regime. In addition, various charge and bond ordered phases are identified at commensurate fillings in lattice systems.

**U44 1 First-principles calculations of magnetic transition temperatures** XIANGANG WAN, *University of California, Davis* SERGEY SAVRASOV, *University of California, Davis* We introduce a method to evaluate magnetic transition temperatures of strongly correlated systems. It is based on a combination of dynamical mean field theory, the local density functional theory, and employs ''magnetic force theorem'' for evaluating exchange constants. The method automatically predicts at a given temperature whether the system is ordered or disordered magnetically. We illustrate the approach on several systems, and discuss its accuracy in comparison with the experiment. The effect of electron-electron correlations on these predictions will be discussed.

**8:12**
**U44 2 Electron-phonon-coupling-driven pairing symmetry transition in a ladder** KA-MING TAM, ANTONIO H. CASTRO NETO, *Boston University* SHAN-WEN TSAI, *University of California, Riverside* DAVID K. CAMPBELL, *Boston University* We address the effects of electron-phonon coupling in the electron-electron interacting ladder using the recently developed functional renormalization group method, in which the full retardation effects can be taken into account impartially[1]. We study the doped Holstein-Hubbard ladder as a typical example and show that there is a transition between s-wave and d-wave pairing as a function of electron-phonon coupling and doping level. This contrasts with recent results from a two-step renormalization group, which suggest that the electron-phonon coupling only contributes in a subdominant fashion and that the spin-gapped pairing phase always has d-wave symmetry, unchanged from the doped Hubbard ladder without electron-phonon interaction[2].

**U44 3 Dynamical Mean Field Study of the Extended Hubbard Model** ANDREW BALDWIN, *University of California, in Davis* ALEXANDRU MACRIDIN, MARK JARRELL, *University of Cincinnati* RICHARD SCALETTAR, *University of California, in Davis* The competition between on-site $U$ and intersite $V$ repulsion in the extended Hubbard model drives ground state phase transitions between spin density wave (sdw) and charge density wave (cdw) phases. While it was originally thought that in one dimension the sdw-cdw transition was first order at strong coupling and second order at weak coupling, it is now known that for small $U$ and $V$ a bond ordered wave phase intervenes. Here we present studies of the extended Hubbard model using the dynamical cluster approximation. We study the influence of $V$ on the CDW and SDW transition temperatures, $T_c$ and $T_N$. We find $T_N$ is almost unmodified in the sdw region, even if $J = 4t^2/(U - V)$ is strongly modified. We also study the effect of V on the pairing interaction and the pseudogap.

**8:36**
**U44 4 Exact transformation for spin-charge separation of spin half fermions** STELLAN ÖSTLUND, *Göteborgs Universitet* MATS GRANATH, We demonstrate an exact local transformation which maps a purely Fermionic manybody system to a system of spinfull Bosons and spinless Fermions, demonstrating a possible path to a non-Fermi liquid state. We apply this to the half-filled Hubbard model and show how the transformation maps the ordinary spin half Fermionic degrees of freedom exactly and without introducing Hilbert space constraints to a charge-like ''quasicharge'' fermion and a spin-like ''quasispin'' Boson while preserving all the symmetries of the model. We present approximate solutions with localized charge which emerge naturally from the Hubbard model in this form. Our results strongly suggest that charge tends to remain localized for large values of the Hubbard U. The results suggest that checkerboard patterns are natural patterns that result for the strongly interacting Hubbard model away from half filling.

**8:48**
**U44 5 Dynamical Cluster Approximation Study of Ferromagnetism in the Periodic Anderson Model** MUHAMMAD AZIZ MAJIDI, *University of Cincinnati* MARK JARRELL, *University of Cincinnati* JUANA MORENO, *University of North Dakota* SUMITH DOLUWEERA, *University of Cincinnati* The ferromagnetic phase in the strong coupling limit of the Periodic Anderson Model (PAM) is not fully understood. Previous studies using the Dynamical Mean Field Approximation (DMFA) (Tahvildar-Zadeh *et al.* (PRB **55**, R3332 (1997)) pointed to the importance of a ferromagnetic mechanism other than RKKY at conduction-band fillings near a quarter. This mechanism is related to the formation of a charge-density wave of the conduction electrons. However, it is questionable whether or not this effect persists when non-local correlations are incorporated into the theory. We try to answer this question by performing parametric studies on the phase diagram, the RKKY coupling, and the charge and spin susceptibilities for a three-dimensional system using the Dynamical Cluster Approximation (DCA).

**9:00**
**U44 6 Phase Diagrams of Hubbard Models with Small Unit Cells** WEI-FENG TSAI, *Department of Physics and Astronomy, UCLA* STEVEN A. KIVELSON, *Department of Physics and Astronomy, UCLA, and Department of Physics, Stanford University* We present a controlled approach to the low temperature phase diagram of highly inhomogeneous Hubbard models in the limit of small coupling, $t'$, between clusters. We apply this to the dimerized and checkerboard models with any strength of $U$. The dimerized model is found to behave like a doped semiconductor, with a Fermi-liquid groundstate with parameters (*e.g.* the effective mass) which are smooth, and unspectacular functions of $U$. By contrast, the checkerboard model has a Fermi liquid phase at large $U > U_c = 4.67$, a d-wave superconducting state with a full gap for $U_c > U > 0$, and a narrow strip of an intermediate d-wave superconducting phase with gapless ''nodal'' quasiparticles for $|U - U_c| < \mathcal{O}(t')$.

**9:12**

**U44 7 Effects of interplay between electron-electron and electron-phonon interactions in two-dimensional systems** FILIPPOS KLIRONOMOS, SHAN-WEN TSAI, *Physics Department, University of California, Riverside* We study the two-dimensional Hubbard model in the presence of electron-phonon interaction which is integrated into an effective electron-electron coupling producing a retardation effect [S.-W. Tsai *et al* Phys. Rev. B **72**, 054531 (2005)]. We work in the context of the functional renormalization group method [R. Shankar, Rev. Mod. Phys. **66**, 129 (1994)] to one loop accuracy, where self-energy corrections are included, and investigate the effect that isotropic and anisotropic phonons have near van Hove band fillings. This approach conveniently takes into consideration the effect of phonons at every step of the renormalization group method. We focus on the two-patch and many-patch schemes, where the Fermi surface is subdivided into two or multiple patches that label the electrons involved in each interaction process and produce a phase diagram for the different instabilities associated with the Hubbard model. We also depart from half-filling and investigate various specific cases of momentum transfer as well.

**9:24**

**U44 8 Nearest-Neighbor Repulsion and Competing Charge and Spin Order in the Extended Hubbard Model.** DAVOUDI BAHMAN, A.-M.S. TREMBLAY,* *Universite de Sherbrooke* We generalize the Two-Particle Self-Consistent (TPSC) approach to study the extended Hubbard model where the nearest-neighbor interaction $V$ is present in addition to the local interaction $U$. Our results are in good agreement with available Quantum Monte-Carlo results over the whole range of density $n$ up to intermediate coupling. As a function of $U, V$ and $n$ we observe different kinds of charge and spin orders, like commensurate/incommensurate charge and spin density wave, phase separation, and ferromagnetic order. For attractive $V$ superconductivity could exist in the regions where the other types of charge and spin orders do not dominate. B. Davoudi and A.-M.S. Tremblay, cond-mat/0509707

**U44 9 Quantum Monte Carlo Study of the Triangular Hubbard Model** CHRISTOPHER VARNEY, RICHARD SCALETTAR, *University of California, Davis* MARK JARRELL, ALEXANDRU MACRIDIN, *University of Cincinnati* We study the Hubbard model on a triangular lattice using Determinant Quantum Monte Carlo and the Dynamic Cluster Approximation. We compare the spin, charge and pairing response functions obtained with the two methods as a function of spatial lattice and cluster size, and also compute the one particle spectrum. We examine the possibility of charge ordering at one third filling driven by the avoidance of magnetic frustration.

**9:48**

**U44 10 Theory of Cu K-edge Resonant Inelastic X-ray Scattering in Cuprates.** KENJI TSUTSUI, TAKAMI TOHYAMA, SADAMICHI MAEKAWA, *IMR, Tohoku Univ., Sendai 980-8577, Japan* Resonant inelastic x-ray scattering (RIXS) has received much attention as a powerful technique to investigate elementary excitations in strongly correlated electron systems. In particular, the momentum-dependent spectra of Cu K-edge RIXS in high-Tc cuprates have been obtained by several experimental groups. The knowledge of these excitations across the gap as well as single-particle excitations is of importance for understanding the electronic properties in cuprates. We demonstrate theoretically momentum dependences of the RIXS in insulating and doped cuprates. The RIXS spectra are calculated by using the exact diagonalization techniques on small clusters in two-dimensional Hubbard models with 1s-core bands. In the insulating case, we find the anisotropic momentum dependence in the RIXS spectrum. The dependence is explained by the particle-hole excitations in which the antiferromagnetic correlation of the ground state plays a crucial role. Upon hole-doping, the spectrum from the lower Hubbard band to the upper Hubbard band becomes broad and less momentum dependent. This is in contrast to the case of electron-doping, where the momentum dependence of the spectrum in the undoped system remains, except that along the $< 1,0 >$ direction. The difference in the spectra between hole- and electron-doped systems follows the carrier-dependence of short-range AF spin correlations.

**U44 11 Fermi Surface of the Half Heusler Compounds $Ce_{1-x}La_xBiPt$** A. D. BIANCHI, J. WOSNITZA, *HLD, FZR, P.O. Box 51 01 19, D-01314 Dresden, Germany* N. KOZLOVA, D. ECKERT, L. SCHULTZ, I. OPHALE, S. ELGAZZAR, M. RICHTER, *IFW Dresden, D-01171 Dresden, Germany* J. HAGEL, M. DOERR, *IFP, TU Dresden, D-01062 Dresden,Germany* G. GOLL, H. V. LÖHNEYSEN, *Physikalisches Institut, Universität Karlsruhe, D-76128 Karlsruhe, Germany* G. ZWICKNAGL, *Institut für Mathematische Physik, Technische Universität Braunschweig, D-38106 Braunschweig, Germany* T. YOSHINO, T. TAKABATAKE, *Department of Quantum Matter, ADSM, Hiroshima University, Higashi-Hiroshima 739-8530, Japan* We report on the Fermi surface in the correlated half-Heusler compound $Ce_{1-x}La_xBiPt$. In CeBiPt we find a field-induced change of the electronic band structure as discovered by electrical-transport measurements in pulsed magnetic fields. For magnetic fields above $\sim$ 25 T, the charge-carrier concentration determined from Hall-effect measurements increases nearly 30%, whereas the Shubnikov–de Haas (SdH) signal disappears at the same field. In the non-4$f$ compound LaBiPt the Fermi surface remains unaffected, suggesting that these features are intimately related to the Ce 4$f$ electrons. Electronic band-structure calculations point to a 4$f$-polarization-induced change of the Fermi-surface topology. In order to test this hypothesis, we have measured the (SdH) signal in a $Ce_{0.95}La_{0.05}BiPt$ sample with a low La concentration.

**U44 12 Charge Physics of the Falicov-Kimball Model** PHILIP BRYDON, MIKLOS GULACSI, *Australian National University, Canberra, Australia* The charge-ordered phases of the one-dimensional Falicov-Kimball model are examined using a non-perturbative representation of the itinerant electrons. An effective model allows us to understand the competition between phase separation and long-range order. We construct a ground-state phase diagram for partial band-filling. The addition of an on-site hybridization potential is found to significantly alter the form of the phase diagram, with the appearance of mixed-valence phenomena.

**10:24**

**U44 13 Application of LDA+DMFT to systems near volume collapse transition** KRISTJAN HAULE, The physical origin of the volume collapse transition in Cerium and related materials will be addressed. Using recently developed self-consistent LDA +DMFT method, we will show that the Kondo Volume collapse model, involving both the f and spd electrons, describes the optical data better than a Mott transition picture. We predict the full temperature dependence of the optical spectra and find the development of a hybridization pseudogap in the vicinity of the collapse transition.

**10:36**

**U44 14 Functional renormalization group analysis of the one-dimensional half-filled Holstein-Hubbard model** SHAN-WEN TSAI, *University of California, Riverside* KA-MING TAM, DAVID K. CAMPBELL, ANTONIO H. CASTRO NETO, *Boston University* The one-dimensional half-filled Holstein-Hubbard model (HHM) is studied by the newly developed electron-phonon coupled functional renormalization group (ep-FRG) [1]. The ep-FRG enables us to study the electron-phonon coupled system in an unbiased manner by taking account of the scatterings at different energy scales and momenta systematically. Previous studies of the half-filled HHM showed that there is a direct transition between the charge-gapped spin-density wave (SDW) phase and the spin-charge-gapped charge-density wave (CDW) phase. Recently, it has been proposed that there is an intermediate spin-gapped metallic phase with dominant superconducting (SC) pairing correlation between SDW phase and CDW phase [2]. Our ep-FRG results show that the dominant correlation in this intermediate phase is not SC pairing. [1] S.-W. Tsai, A. H. Castro Neto, R. Shankar, and D. K. Campbell, Phys. Rev. B 72, 054531 (2005). **U44 15 Antiferromagnetism and hot spots in CeIn3*** PAVEL GRIGORIEV, LEV GOR'KOV, *NHMFL, FSU* Enormous mass enhancement at ''hot spots'' on the Fermi surface (FS) of the antiferromagnetic $CeIn_3$ has been reported at strong magnetic field near its antiferromagnetic quantum critical point [T. Ebihara et al., Phys. Rev. Lett. 93, 246401 (2004)]. The effect was ascribed to anomalous spin fluctuations at these spots owing to peculiar strong many-body interactions. The ''hot spots'' lie at the positions on FS same as in non-magnetic $LaIn_3$ where the narrow necks are protruded, thus, hinting on their possible relation. Assuming that in paramagnetic phase $CeIn_3$ has similar spectrum, we study the influence of the antiferromagnetic ordering (AFM) on the energy spectrum of $CeIn_3$ and show that its FS undergoes a topological change at the onset of AFM. The necks at the ''hot spots'' are truncated by the AFM, thus restoring the almost spherical d-part of the FS of $CeIn_3$. Applied field suppresses the AFM and restores the necks on the FS (so-called 2.5-order phase transition) leading to logarithmic divergence of the dHvA effective mass when the electron trajectory passes near or through the restored necks. This effect fully explains the observed dHvA mass enhancement in the ''hot spots'' in the frameworks of one-particle approximation and leads to the predictions concerning the spin-dependence of the effective electron mass.

**U45 1 Effect of external strain on the order-disorder phase transition of the Si(001) surface** MASANORI YATA, *National Research Institute for Materials Science* The Si(001) surface exhibits the phase transition from c(4× 2) to the (2× 1) structure at about 200 K[1, 2]. This is an order-disorder phase transition with respect to the buckling of the dimmer: the c(4× 2) structure results from an antiferromagnetic ordering of the buckled-dimmer and the (2× 1) structure is attributed to the time average of the flip-flop motion of the buckled-dimers. Externally applied tensile strain along the $< 110>$ direction on the Si(001) surface is found to induce the flip-flop motion of the buckled dimmer below the critical temperature. This motion occurs cooperatively to form the disordered domain of the (2× 1) structure. Then the shape of the ordered domain as well as the size change with the strain. These results can be interpreted by the spontaneous shape instability originated from the strain relaxation energy. References [1] J. Ihm, D.H. Lee, J.D. Joannopoulos and J.J. Xiong, Phys. Rev. Lett. **51**, 1872(1983). [2] T. Tabata, T. Aruga and Y. Murata, Surf. Sci. **179**, L63(1987).

**U45 2 Faceting and defaceting phase transitions of Pd/W(111)** YU-WEN LIAO, *Natl. Taiwan Univ., Taiwan and Inst. of Atomic and Molecular Sciences, Taiwan* L.H. CHEN, K.C. KAO, *Natl. Central Univ., Taiwan* MINN-TSONG LIN, *Natl. Taiwan Univ., Taiwan and Inst. of Atomic and Molecular Sciences, Taiwan* CHENG-HSUN NIEN, *Natl. Central Univ., Taiwan* KER-JAR SONG, *Inst. of Atomic and Molecular Sciences, Taiwan* We have studied the faceting and the defaceting phase transitions of the Pd/W(111) surface. Our studies show that for creating the largest facets, the best annealing temperature is right below the defaceting transition temperature, confirming the prediction by Oleksy (Surf. Sci. 549 (2004) 246). As we vary the programmed heating/cooling rate from 1/8 to 8 K/s, the paths of faceting transitions show normal retardation effect and shift to lower temperatures as the cooling rate increased. Surprisingly, the paths of defaceting transitions show negligible dependence on the heating rate. Detailed studies of this peculiarity lead us to propose that the defaceting transition is initiated at places subject to loss of too much Pd due to thermal desorption. As such loss can more readily be replenished at places near any one of the Pd 3-d islands, we propose that the rate independent path of defaceting transition is the consequence of a temperature dependent balance between the loss and the supply of Pd. Such balance should depend on the density of the Pd islands. Indeed, we find the paths of defaceting transition can be shifted to lower temperature by reducing the density of the Pd 3-d islands.

**U45 3 Ultrafast lattice dynamics of FeRh*** D.A. WALKO, E.C. LANDAHL, JIN WANG, *Argonne National Laboratory* J.-U. THIELE, E.E. FULLERTON, *Hitachi Global Storage Technologies* FeRh undergoes magnetic and structural phase transitions at $\sim$ 100° C where a transition from antiferromagnetic to ferromagnetic orders occurs upon heating. Commensurate with this magnetic transition is a $\sim$ 1% expansion in the lattice parameter. Recent optical measurements have shown that the magnetic transition can be quite fast, i.e., on the picosecond or sub-picosecond time scales [1,2]. We have used ultrafast x-ray diffraction techniques at the Advanced Photon Source to probe the speed of the corresponding structural transition. An epitaxial FeRh thin film on a MgO(001) substrate was driven through the phase transition by ultrafast laser excitation, and the response of the lattice was directly observed via picosecond-time-resolved x-ray diffraction. The temporal evolution of the FeRh lattice is reported as a function of laser fluence. [1] J.-U. Thiele et al., Appl. Phys. Lett. 85, 2857 (2004). [2] G. Ju et al., Phys. Rev. Lett. 93, 192301 (2004).

**U45 4 Phase stability and Jahn-Teller distortion in doped lithiated manganese oxides: A LSDA+U study** RAJENDRA PRASAD, NITYA NATH SHUKLA, *Indian Institute of Technology, Kanpur* ROY BENEDEK, *Argonne National Laboratory* We discuss how the rhombohedral phase of lithiated manganese oxide can be stabilized by doping with various impurities. Our study is based on LSDA+U calculations as implemented in the VASP code. We have considered rhombohedral and monoclinic phases using a supercell of 16 atoms. Our results are based on total energy calculations for 25% dopant concentration and pure lithiated manganese oxide. Several dopants such as Co, Fe, Ni, Mg and Zn are considered. We find that oxidation state of the dopant plays an important role in suppressing the Jahn-Teller distortion. Divalent impurities are found to be most effective. The effect of including U in the calculation is discussed.

**8:48**

**U45 5 Crystal Fields and the $\gamma \rightarrow \alpha$ transition in Ce** SUKALPA BASU, PETER RISEBOROUGH, *Temple University* In the $\gamma \rightarrow \alpha$ transition of Cerium, the material undergoes an isostructural change at which the volume changes by 15% and the magnetic character changes. Recently, the transition has been described in terms of a balance between the free energy of the magnetic moments and the characteristic energy scale of the $\alpha$ phase. The field-temperature dependence of the phase diagram has been predicted, and was confirmed by experiment. Inelastic neutron scattering experiments on the $\gamma$-phase of Ce have shown indications of crystal field splittings, and similar experiments have determined the energy scale of the $\alpha$ phase. We shall examine the effects of the crystalline field splittings within the framework of NCA calculations on the single-impurity Anderson model, and examine their consequence for the phase diagram.

**9:00**

**U45 6 Bifurcation Techniques for Structural Phase Transitions** RYAN S. ELLIOTT, *University of Minnesota* JOHN A. SHAW, NICOLAS TRIANTAFYLLIDIS, *University of Michigan* A new technique for studying structural phase transitions in crystals has been developed which uses bifurcation theory to investigate a material's free energy landscape. In this method a material's behavior is numerically interrogated by beginning with its high temperature structure and mapping out the equilibrium branch corresponding to the distortions of the crystal structure that occur due to changes in parameters such as temperature or stress. The investigation of this equilibrium branch is continued into unstable regions of the material's free energy landscape, i.e., regions which are physically unobservable. In these unstable regions the equilibrium branch bifurcates, or splits, and leads to other stable regions corresponding to different crystal structure branches (phases), thus revealing the links and interactions between the various phases of the material. Often, unexpected stable phases are identified in this way. It is common to encounter non-generic bifurcation points, where a single equilibrium branch splits into many (instead of two) new equilibrium branches. In these complex situations, the current bifurcation method is guaranteed to systematically identify all of the new branches. To illustrate the method, an atomistic model for shape memory alloys is investigated and a commonly observed hysteretic transformation is identified between a cubic $B2$ (austenite) structure and an orthorhombic $B19$ (martensite) structure.

**U45 7 Imaging the evolution of a glassy magnetic transition in a disordered ferromagnetic manganite*** WEIDA WU, CASEY ISRAEL, ALEX DE LOZANNE, *Dept. of Physics, UT Austin* NAMJUNG HUR, *Los Alamos National Lab, Cond. Matt. and Thermal Physics* SOONYONG PARK, S.-W. CHEONG, *Dept. of Physics & Astronomy, Rutgers* An intriguing glass-like transition in (La,Pr,Ca)$MnO_3$ is, for the first time, imaged using a variable-temperature magnetic force microscope. Images showing the temperature and magnetic- field evolution of the local magnetic structure illustrate the microscopic origin of the bifurcation of magnetic susceptibility, which is a ubiquitous phenomenon in heavily-disordered ferromagnets, and traditionally considered as a signature of a ''cluster glass transition.'' The observed avalanche-type behavior reveals the collective nature of the glassy transition in the manganites, where ferromagnetic and antiferromagnetic phases are intricately mixed.

**U45 8 Quantum Relaxation in a Proton Glass** C. ANCONA-TORRES, Y. FENG, T. F. ROSENBAUM, S. R. NAGEL, *University of Chicago* E. COURTENS, *Universit Montpellier II* D. PRICE, *University of Orleans* G. REITER, *University of Houston* $Rb_{1-x}(NH_4)_xH_2PO_4$ is a dipolar structural glass with spatial frustration from the mixture of ferroelectric RDP and antiferroelectric ADP. We measure the ac dielectric susceptibility of RADP:72 and RADP:35 over 7 decades of frequency for $0.3 < T < 300$ K. The relaxation is quantitatively similar for both concentrations at low temperatures, pointing to a local mechanism. We correlate the dielectric susceptibility with the potential energy landscape derived from neutron Compton scattering experiments and solve for

the tunneling parameters of the protons, finding correlated rearrangements of the hydrogen network. By analogy with vortex tunneling in high-Tc superconductors, we relate the logarithmic decay of the polarization to the quantum mechanical action.

**U45 9 Switching between one and two dimensions: Pb induced chain structures on Si(557)** CHRISTOPH TEGENKAMP, ZIAD KALLASY, HERBERT PFNÜR, *Institute for Solid State Physics, Universität Hannover, Germmany* The conductivity of epitaxially grown Pb-structures on Si(557) has been measured. Different characteristic transport mechanisms have been found: For coverages above the percolation limit(0.6ML) up to 3ML the electronic transport in the annealed Pb-films is activated. Furthermore, the uniaxial symmetry of the Si(557) surface is reflected directly in a higher conductance in the parallel direction compared to the direction perpendicular to the steps. For coverages higher than 3ML a metallic behavior is found for both directions, i.e. the conductance decreases with increasing temperature. In contrast, already one ML, but annealed to 640K, leads to the formation of atomic wires, as seen by STM, with an extremely high and quasi one-dimensional surface state conductance along the wire direction. At a critical temperature of $T_c = 78$K, the system switches from low to high conductance anisotropy, with a metal-insulator transition in the direction perpendicular to the chain structure, while in the direction along the chains conductance with a (1/T + const.) temperature dependence was found. STM has shown further, that the 1D/2D transition is associated with an order-disorder phase transition of a 10-fold superperiodicity along the Pb chains.

**U45 10 Spontaneous polarization in one-dimensional Pb(Zr-Ti)$O_3$ nanowires*** IVAN NAUMOV, HUAXIANG FU, *Department of Physics, University of Arkansas* Formation of spontaneous polarization in one-dimensional structures is the key phenomenon that reveals collective behaviors in systems of reduced dimension, but has remained unsolved for decades. Here we report *ab initio* studies on finite-temperature structural properties of infinite-length nanowires of $Pb(Zr_{0.5}Ti_{0.5})O_3$ solid solution. Whereas existing studies have ruled out the possibility of phase transition in 1D chains, our atomistic simulations demonstrate an unambiguous otherwise. We show that phase transitions in 1D wires occur on a remarkable macroscopic length scale, but not necessarily on an infinite length scale as assumed in the general theories of 1D phase transition. Such phase transitions are characterized by large longitudinal $d_{33}$, $\chi_{33}$ responses and a large $c/a$ strain. The long rang ordering in PZT nanowires is explained by use of depolarizing effects associated with finite thickness of wires. Our results suggest no fundamental constraint that limits the use of ferroelectric nanowires and nanotubes arising from the absence of spontaneous ordering.

**U45 11 Computational investigation of wetting and prewetting phase behavior*** JEFFREY ERRINGTON, *Dept. of Chemical and Biological Engineering, University at Buffalo* Fluids in the presence of one or more surfaces exhibit a rich variety of phase transitions that are absent in bulk fluids. Even the simplest of systems display a broad range of phase behavior. In this presentation, we describe our recent efforts aimed towards obtaining a better understanding of surface phase behavior through the use of molecular simulation. The first part of the presentation will be used to provide an overview of transition-matrix based Monte Carlo algorithms that enable one to efficiently locate and characterize phase transitions. Results will then be presented that describe how the wetting behavior of a model substrate-fluid system evolves with temperature and the relative strength of the substrate-fluid interaction. Simulation results will be compared with density functional theory calculations. Finally, we will describe a series of calculations that enable us to estimate the boundary tension along the prewetting saturation line. This quantity is related to the line tension associated with the formation of liquid droplets on a solid substrate. The magnitude of this tension has been the subject of debate recently, with experimental values spanning several orders of magnitude.

**10:24**

**U45 13 Scaling Behavior of Classical Wave Transport in Mesoscopic Media at the Localization Transition** SAI-KIT CHEUNG, ZHAO-QING ZHANG, The propagation of classical wave in disordered media at the Anderson localization transition is studied. Our results show that the scaling behavior of wave transport depends on the sample's geometry. It is found that the averaged static diffusion constant $D(L)$ scales like $\ln L/L$ in cubes or slabs, and the corresponding transmission follows $\langle T(L)\rangle \propto \ln L/L^2$. This is in contrast to the scaling behavior of $D(L) \propto 1/L$ and $\langle T(L)\rangle \propto 1/L^2$ obtained previously for electrons or spherical samples. For wave dynamics, we solve the Bethe-Salpeter equation in a disordered slab with the recurrent scattering incorporated in a self-consistent manner. All of the static and dynamic transport quantities studied are found to follow the new scaling behavior of $D(L)$.

**10:36**

**U45 14 Optical Near-Field Based Nanoscale Rapid Melting and Crystallization of Amorphous Silicon Thin Films** DAVID HWANG, ANANT CHIMMALGI, COSTAS GRIGOROPOULOS, *Univ. of California Berkeley* Nanostructuring of thin films is gaining widespread importance owing to ever-increasing applications in a variety of fields. The current study details nanosecond laser-based rapid melting and crystallization of thin amorphous silicon (a-Si) films at the nanoscale. Two different near-field processing schemes were employed. In the first scheme, local field enhancement in the near-field of a SPM probe tip irradiated with nanosecond laser pulses was utilized. As a second approach, the laser beam was spatially confined by a cantilevered near field scanning microscope tip (NSOM) fiber tip. Details of various modification regimes produced as a result of the rapid a-Si melting

and crystallization transformations that critically depend on the input laser fluence are presented. At one extreme corresponding to relatively high laser fluence, ablated area surrounded by a narrow melt region was observed. At the other extreme, where the incident laser energy density is much lower, single nanostructures with a lateral dimension of $\sim$ 90 nm were defined. The ability to induce nucleation and produce single semiconductor nanostructures in a controlled fashion may be crucial in the field of nano-opto-electronics.

**10:48**

**U45 15 Explosive Crystallization of Amorphous Semiconductor Films in the Presence of Melting** ALEXANDER GOLOVIN, *Northwestern University* COSTAS GRIGOROPOULOS, MATTHEW ROGERS, SEUNG HWAN KO, *University of California Berkeley* BERNARD MATKOWSKY, *Northwestern University* Explosive crystallization (EC) of thin amorphous solid films of germanium is investigated theoretically and experimentally. EC regime characterized by a propagating melting layer between the amorphous and the crystalline phases is considered. Laser-induced, linear EC fronts, uniformly propagating over large distances are achieved in films with various thicknesses deposited on quartz substrate. Depending on the front speed, the film thickness and the substrate temperature, different types of morphology of the resulting crystal phase are observed: columnar, scalloped and mixed. A theory of EC in the presence of melting is developed. The EC front propagation speed is calculated as a function of the substrate temperature and the film thickness; it is found to be in a good agreement with experiments. Linear stability analysis of a uniformly propagating planar EC front is performed. It is shown that for the parameter values where the columnar crystalline structure was observed the front is unstable with respect to a fingering instability similar to the Mullins-Sekerka instability of a solidification front in an undercooled melt. Nonlinear evolution of this instability is simulated numerically and is shown to exhibit a structure similar to the columnar one.

## SESSION U46: OPTICAL PROPERTIES OF SEMICONDUCTORS: EXCITONS AND PHONONS

**Thursday Morning, 16 March 2006**
**349, Baltimore Convention Center at 8:00**
**David Reitze, University of Florida, presiding**

**8:00**

**U46 1 Laser induced trapping of excitons in coupled quantum wells** A.T. HAMMACK, M. GRISWOLD, L.V. BUTOV, *University of California, San Diego* A.L. IVANOV, L.E. SMALLWOOD, *Cardiff University* A.C. GOSSARD, *University of California, Santa Barbara* Optical trapping and manipulation of neutral particles plays a major role in single particle studies in physics, chemistry, and biology [1]. An exciting recent outgrowth of the technique has been the experimental implementation of atom Bose- Einstein Condensation [2,3]. In this contribution, we report proposal and demonstration of laser induced trapping for a new system - a cold gas of excitons in coupled quantum wells. We report trapping a cold gas of excitons in laser induced traps and on the formation of a highly degenerate Bose gas of excitons in the trap. [1] A. Ashkin, *IEEE Journal on Selected Items in Quantum Electronics* **6**, 841 (2000). [2] E. A. Cornell, C. E. Wieman, *Rev. Mod. Phys.* **74**, 875 (2002). [3] W. Ketterle, *Rev. Mod. Phys.* **74**, 1131 (2002).

**8:12**

**U46 2 Spontaneous First-order Optical Coherence in Cold Exciton Gases in Coupled Quantum Wells** SEN YANG, A.T. HAMMACK, L.V. BUTOV, *Department of Physics, University of California, San Diego* A.C. GOSSARD, *Materials Department, University of California, Santa Barbara* A Mach-Zehnder interferometer with spatial and spectral resolution was used to probe spontaneous coherence in cold exciton gases, which are implemented experimentally in the ring of indirect excitons in coupled quantum wells[1]. A strong enhancement of spontaneous first-order optical coherence was observed at low temperatures below a few Kelvin where the thermal de Broglie wavelength becomes comparable to the interparticle separation and the exciton gas becomes nonclassical. The onset of spontaneous first-order optical coherence was found to be correlated with macroscopic spatial ordering in the exciton system. [1] L.V. Butov, A.C. Gossard, D.S. Chemla, *Nature* **418**, 751 (2002).

**8:24**

**U46 3 Theory of coherent population trapping and electromagnetically induced transparency in quantum wells and dots** ZACHARY DUTTON, *Naval Research Lab* Recently, there has been important experimental progress in quantum coherent phenomena in quantum-wells and dots, opening up possibilities for observations of quantum optical effects previously observed in atomic systems. In particular, coherent population trapping (CPT), electromagnetically-induced transparency (EIT), and slow light can occur in systems with sufficiently long ground state coherence, optically connected to an excited level, forming a Lambda-like system. We find that a quantum well or ensemble of dots, in Voigt geometry and illuminated by a bi-chromatic circularly polarized laser, can exhibit CPT and EIT. In this scheme, the electron spin provides the long lived ground states and a trion excitation acts as the excited level. By including optical and g-factor inhomogenous broadening, dephasing due to nuclear hyperfine interaction, and coupling to the both trion excitations, we derive a compact set of criteria for observations of these effects. We compare with experiments to date and discuss future prospects.

**8:36**

**U46 4 Stimulated Emission of Terahertz Radiation from Internal ExcitonTransitions in $Cu_2O$*** B.A. SCHMID, R. HUBER, Y.R. SHEN, R.A. KAINDL, D.S. CHEMLA, *Department of Physics, UC Berkeley, and Materials Sciences Division, Lawrence Berkeley National Laboratory* Excitons are among the most fundamental optical excitation modes in semiconductors. Resonant infrared pulses have been used to sensitively probe absorptive transitions between hydrogen-like bound pair states [1,2]. We report the first observation of the reverse quantum process: stimulated emission of electromagnetic radiation from intra-excitonic transitions [3]. Broadband terahertz pulses monitor the far-infrared electromagnetic response of $Cu_2O$ after ultrafast resonant photogeneration of 3*p* excitons. Stimulated emission from the 3*p* to the energetically lower 2*s* bound level occurs at a photon energy of 6.6 meV, with a cross section of $\sim 10^{-14}$ cm$^2$. Simultaneous excitation of both exciton levels, in turn, drives quantum beats which lead to efficient terahertz emission sharply peaked at the difference

frequency. Our results demonstrate a new fundamental process of THz quantum optics and highlight analogies and differences between excitonic and atomic systems. [1] R. A. Kaindl et al., Nature **423**, 734 (2003). [2] M. Kubouchi et al., Phys. Rev. Lett. **94**, 016403 (2005). [3] R. Huber et al., Phys. Rev. Lett., to appear.

*Supported by the U.S. Department of Energy under Contract No. DE-AC02-05CH11231.

**8:48**

**U46 5 Ultrafast Raman Studies of Electron Transient Transport in InN Thick Film Grown on GaN** KONG-THON TSEN, D.K. FERRY, *Arizona State University* HAI LU, WILLIAM J. SCHAFF, *Cornell University* GaN, AlN, InN and their alloys have long been considered as very promising materials for device applications. Semiconductor alloys such as $In_xGa_{1-x}N$ have been successfully used in the fabrication of blue-green light emitting diodes and laser diodes. Recently, growth of high quality InN as well as $In_xGa_{1-x}N$ have been demonstrated. In Particular, progress in the manufacturing of very high quality, single-crystal InN thin films has opened up a new challenging research avenue in the III-nitride semiconductors. InN together with its alloys of GaN and AlN enable the operation of light emitting diodes and diode lasers ranging in spectral wavelength from infrared all the way down to deep ultraviolet. It has also been predicted that InN has the lowest electron effective mass among all the III-nitride semiconductors. As a result, very high electron mobility and very large saturation velocity are expected. In this paper, we report experimental results of electron transient transport on InN thick film grown on GaN. Electron drift velocity as large as $7.5x10^7 cm/\text{sec}$ has been found when the sample is excited by an ultrafast laser pulse with pulse width about 600 femtoseconds. Our findings demonstrate that InN has great potential for use in the ultrafast electronic devices.

**9:00**

**U46 6 Exciton-mediated one phonon resonant Raman scattering from 1-dimensional systems** A. N. VAMIVAKAS, *Department of ECE, Boston University* A. G. WALSH, *Department of Physics, Boston University* Y. YIN, *Department of Physics, Boston University* M. S. UNLU, *Department of ECE, Boston University* B. B. GOLDBERG, *Department of Physics, Boston University* A. K. SWAN, *Department of ECE, Boston University* The Kramer's-Heisenberg approach is well developed for the theory of one phonon resonant Raman scattering (OPRRS) based on both intermediate states of free electrons and correlated electron-hole pairs in 3, 2 and 0-dimensional (D) systems. But to our knowledge, a theory of OPRRS incorporating excitonic effects has not yet been developed for quantum confined 1D system. In this talk we present a generic expression for the resonant Raman scattering cross section from a 1D system explicitly accounting for excitonic effects. We show how the theory is useful for analyzing the Raman resonance excitation profile lineshapes for of a variety of 1D systems. We apply this formalism to simple model systems to the similarities and differences between the free electron and correlated electron-hole 1D theory and also compare with the 3D excitonic theory.

**9:12**

**U46 7 Wurtzite Effects on Spin Splitting of GaN*** WAN-TSANG WANG, M.H. GAU, IKAI LO, S.F. TSAY, J.K. TSAI, K.L. HSIEH, J.C. CHIANG, *Department of Physisc, Center for Nanoscience and Nanotechnology, National Sun Yat-Sen University, Kaohsiung, Taiwan, Republic of China* We report the theoretical study of the wurtzite effects on spin-splitting of GaN within a third-neighbor Linear Combination of Atomic Orbitals (LCAO) model. For wurtzite structure, there are two intrinsic wurtzite effects which are band-folding effect and structure inversion asymmetry. The band-folding effect generates two conduction bands ($\Delta_{C1}$and $\Delta_{C3}$), in which the *p*-wave probability and, consequently, the spin-splitting energy have abrupt changes when $k_z$ increases toward the anti-crossing zone. The wurtzite effects, in addition to Rashba and Dresselhaus effect, give significant contributions to the large spin-splitting in GaN/AlN quantum wells.

*Research supported by National Science Council, Core Facilities Laboratory in Kaohsiung-Pintung area, Taiwan (ROC).

**9:24**

**U46 8 Ab initio calculations of excitons in wurtzite-type semiconductors.** NIELS E. CHRISTENSEN, *University of Aarhus. DK-8000 Aarhus.* ROBERT LASKOWSKI, *Technical University of Vienna, A-1060 Vienna* The optical absorption spectra are calculated with inclusion of electron-hole correlations for GaN, ZnO, and AlN, all in the wurtzite structure. Quasi-particle states are approximated by local-density-functional calculations with gaps corrected by a scissors operator, and the final spectra are obtained by solving the Bethe-Salpeter Equation. The results for ZnO depend sensitively on the energetic positions of the Zn-3d states. These are corrected by means of LDA+U. The excitons originating from the valence-band maximum are labeled A, B, and C, but their symmetry type, and thus dependence on the polarization of the light, are related to the specific values of the spin-orbit and crystal field splittings, SOC and CFS. The SOC is positive in GaN and AlN, negative in ZnO. The CFS is positive in GaN and ZnO, but negative in AlN. The sensitivity of the excitonic states to structural parameters is discussed, and in one case, AlN, we examine the validity of Elliott's model, the effective hydrogen-atom model.

**9:36**

**U46 9 Pump-Probe studies of Carrier Dynamics in bulk ZnO and ZnO epilayers and Nanorods*** X. WANG, Y.D. JHO, D.H. REITZE, C. COOK, G.D. SANDERS, C.J. STANTON, *Department of Physics, University of Florida* X. WEI, *National High Magnetic Field Laboratory* J.K YOO, G.-C. YI, *Department of Materials Science and Engineering, Pohang University of Science and Technology* ZnO-based devices are potentially useful as short wavelength emitters and in spintronics applications, yet little is known about the ultrafast relaxation properties of ZnO. We have performed time-resolved differential reflectivity (TRDR) measurements of bulk ZnO, ZnO epilayers and nanorods as a function of temperature and excitation wavelength. Bi-exponential decays of the A and B exciton states are observed with fast ( $\sim$ ps scale) and slower ( $\sim$ 50-100 ps scale) components, which depend strongly on excitation wavelength. We find that decay times can be correlated with relaxation channels in the band structure. In addition to their bi-exponential nature, the relaxation times we observe on ZnO epilayers and nanorods are shorter than high quality bulk ZnO, indicating a higher density of defects and impurity states in these samples.

*Supported by the NSF through grant DMR-0325499 and by the NHMFL through an IHRP grant.

**U46 10 Rate Equation Model for Carrier and Exciton Dynamics in ZnO*** C. J. COOK, G. D. SANDERS, C. J. STANTON, X. WANG, Y. D. JHO, D. H. REITZE, *University of Florida* There has been a renewed interest in ZnO materials for possible applications to short wavelength optical devices including blue lasers owing to its wide band-gap (3.37) and large exciton binding energy (approx. 60 meV). Recently, there have been several experimentalstudies of the dynamics of photoexcited carriers in bulk ZnO as well as epitaxial films and nanorods. In this talk, we report on theoretical calculations of the exciton and photoexcited carrier dynamics based on a multi-state, coupled rate equation model. We compare our theoretical results with recent tunable time resolved reflectivity measurements performed at the National High Magnetic Field Laboratory that study the relaxation dynamics when pumping and probing near the A and B excitons. In addition to solving the coupled rate equations, we also discuss the role of diffusion as well as phase space filling (non-linear rate equations) on the experimental results.

**U46 11 Direct Observation of the Strength of Plasmon-Longitudinal Optical Phonon Interaction in n-type GaAs** HAKAN ALTAN, XUYING XIN, DAVID MATTEN, ROBERT ALFANO, *City College of New York* The screening of longitudinal optical phonons by plasmons is investigated by time-resolved visible pump-mid infrared probe transmission measurements in a series of light to highly doped n-type GaAs wafers. The reduced relaxation of photogenerated carriers is strongly correlated to the coupling between longitudinal optical phonons and background plasmons as suggested by the variation of the phonon strength over the doping range. Our results show that at low photogeneration ( $< 10^{16}cm^{-3}$) the critical doping density at which the strength of the coupling between LO phonons and plasmons decreases significantly is on the order of $N_c \sim 1x10^{18}cm^{-3}$. The lack of LO phonons that participate in relaxation of carriers due to the hybridization of the longitudinal modes above this doping level, can either result in adverse effects in the spectrum of diode lasers and semiconductor electronic devices or enhance photonic device performance due to longer minority carrier recombination times.

**U46 12 THz radiation from coherent acoustic phonon waves in strained GaN-based heterostructures** YOUNG-DAHL JHO,* *Univ. of Florida* JIN-YOUNG SOHN, *Seoul Nat'l Univ.* GARY D. SANDERS, CHRISTOPHER J. STANTON, *Univ. of Florida* EUNSOON OH, *Chungnam Nat'l Univ.* DAI-SIK KIM, *Seoul Nat'l Univ.* We present experimental results and discuss the generation mechanism of newly found THz radiation in GaN/InGaN based light emitting diode (LED) structures. These structures show strong coherent acoustic phonon oscillations under ultra-short optical excitation and we discuss the role these coherent phonons play in the generation of the THz signal. To better understand the role of piezoelectricity on the generation of the acoustic phonons and THz radiation, an external field was applied to compensate the built-in piezoelectric field. The coherent oscillatory behavior of the differential reflectivity spectra was reduced and finally become independent of the increasing applied voltage. However, with reverse bias, the THz emission from these structures was found to increase with increasing reverse voltage and excitation energy, slightly distinct from the trend of the photocurrent. The frequency of the THz emission is related to the transit time of the acoustic phonons between the AlGaN layers. The bias and wavelength dependence of the THz generation suggests that wavefunctions of confined carriers at the AlGaN/GaN and AlGaN/InGaN interfaces, are modulated by a temporally-changing potential shape associated with the piezoelectric field of the lattice and are responsible for the THz radiation.

**U46 13 Theory of carrier dynamics and coherent phonons in piezoelectric semiconductor heterostructures*** GARY SANDERS, CHRIS STANTON, *University of Florida* We model generation and propagation of coherent acoustic phonons in time resolved reflectivity experiments on InGaN/GaN multi quantum wells embedded in a pin diode structure. Carriers are created in the InGaN wells by ultrafast pumping below the GaN band gap. The electronic states in the multiquantum well structure are obtained in an effective mass model and the generation and subsequent relaxation of photogenerated carriers in the well are treated in a Boltzmann equation formalism. Coherent acoustic phonons are generated in the quantum well via a strong piezoelectric electron-phonon interaction with photogenerated carriers. These propagate into the structure at the LA sound speed modifying the optical properties and giving rise to an oscillatory differential reflectivity signal. We also study the THz radiation emitted by the photoexcited carriers and phonons. In addition to studying the multiquantum well structure, we also study chirped superlattices were the well widths increase with distance and investigate the possibility of selectively exciting carriers in a given well to coherently control the response.

**U46 14 Studies of Coherent Acoustic Phonons in CdMnTe Single Crystals** D. WANG, S. WU, R. SOBOLEWSKI, *University of Rochester, Rochester, NY 14627* A. MYCIELSKI, *Polish Academy of Sciences, PL-02668 Warszawa, Poland* We have demonstrated generation and detection of coherent acoustic phonons (CAPs) in $Cd_{0.91}Mn_{0.09}Te$ (CdMnTe) single crystals using a femtosecond pump-probe spectroscopy technique. The Thomsen model based on propagation of a strain pulse in a crystalline lattice accounted very well the observed dependences of the frequency and the dephasing time of our CAP oscillations on the optical probe beam wave-vector. The CAP oscillation frequency was found to be dispersionless with the speed of sound equal to 3579 m/s. The comparison studies, performed using the pump beam with the photon energy well above the CdMnTe energy gap and the sub-gap probe beam demonstrated that in our crystals the measured dephasing time of CAP oscillations was limited by the absorption depth of the probe light rather than the intrinsic decay time of the coherent phonons. The latter value was estimated to be at least in the nanosecond range. Optically-induced electronic stress was determined to be the main generation mechanism of CAPs in CdMnTe.

**U46 15 Dynamical interfacial-electric-field-induced electro-optics in multilayer semiconductors** Y.D. GLINKA, J.K. MILLER, N.H. TOLK, *Vanderbilt University* X. LIU, Y. SASAKI, J.K. FURDYNA, *University of Notre Dame* Multilayer semiconductors with the thickness of layers of a few tens of nanometers are common materials for designing novel multifunctional electronic and opto-electronic devices. Once the materials are subjected to ultrafast laser light, the dynamical interfacial electric fields between adjacent layers is created as a result of charge separation at the interfaces within the carrier thermalization process. This dynamical electric field affects the ultrafast optical properties of the materials additionally to that of the bleaching effect (phase space filling-Pauli blocking). We report the first application of pump−probe technique allowing the interfacial-field-induced both electro-optical refractive-index change and the second harmonic generation to be monitored simultaneously. The pump-probe spectroscopy of GaAs/GaSb/InAs multilayers reveals predominantly the electro-optical nature. The interfacial fields contribute to the variety of electro-optical effects allowing the temporal and spatial resolution in carrier dynamics to be reached by monitoring responses resulted from different order nonlinear polarizations. The absorption bleaching is a secondary effect appearing with much smaller magnitude.

**V1 1 Bending the quantum Hall effect: Novel metallic and insulating states in one dimension.***
MATTHEW GRAYSON, *Walter Schottky Institut, Tech. Univ. Muenchen*

One-dimensional conductors are the wires that will connect the circuits of tomorrow's nanoworld, so it is important to characterize their possible conducting phases. We study a novel one-dimensional wire state which arises at the corner of two quantum Hall systems joined at a 90 degree angle, and observe one-dimensional metallic and insulating states. Such non-planar confinement structures are unconventional for the quantum Hall effect and reveal the striking observation of a macroscopic one- dimensional state whose conductance increases with decreasing temperature. This single system can map out generic properties of disordered one-dimensional conductors since the metallic, critical, or insulating character is tunable with an external parameter, the magnetic field.

**V1 2 Coupled Luttinger Liquid State in Quantum Hall Line Junction.***
INSEOK YANG, *University of Chicago, and Korea Research Institute of Standards and Science*

We report on tunneling spectroscopy of quantum Hall tunnel junctions that juxtaposes two counterpropagating edge states across a high quality tunnel barrier. As the only current-carrying excitation of quantum Hall effect, edge states possess a unique ability to form robust one-dimensional electronic state along the perimeter of two-dimensional electron system. In our tunnel junctions, produced by cleaved edge overgrowth, the two edge states are laterally separated by an in-plane semiconductor barrier on the order of magnetic length and interact strongly over a junction that is $\sim 100\mu m$ long. Due to the quality of the tunnel barrier and the ballistic property of the edge states, inter-edge electron-electron interaction effects become predominant and disorder plays a negligible role to the leading order. Tunneling strongly mix the single particle states from two chiral one-dimensional systems, and the inter- edge correlation transforms the two counterpropagating edge states into a system of coupled, non- chiral Luttinger liquid whose Luttinger liquid properties are continuously tuned by magnetic field through the filling factor $\nu$ of the bulk quantum Hall state. The tunneling density of states of this many-body state possesses a power- law dependence on energy with an exponent $\alpha$, that is inversely proportional to the bulk filling factor, $\alpha \sim 1/\nu$. Inter-edge correlation also manifests in a series of quantum critical points between successive strong and weak tunneling regimes that are reminiscent of the plateau-transitions in quantum Hall effect. Tunneling spectroscopy consequently provides a direct probe of the quantum order underlying within these highly correlated one-dimensional states.

**V1 3 Universality of the Edge-Tunneling Exponent of Fractional Quantum Hall Liquids.***
EDWARD REZAYI, *Physics Department CSU-Los Angeles*

Fractional quantum Hall states are characterized by their topological order. For example, the edge physics is uniquely determined by the bulk and gives a non-Ohmic relation $I \propto V^{\alpha}$ for tunneling into the edge, where the exponent $\alpha$ is a universal constant. In the simplest case of filling factors $\nu = n/(np + 1)$, ($n$ and $p$ are integers $> 0$, $p$ even) the

exponent is $p + 1$. However, experiments show substantial deviations. In a microscopic model of fractional quantum Hall liquids, we calculate the edge Greens function by exact diagonalization and obtain the exponent $\alpha$. We consider the 1/3 and 2/3 states with the Coulomb interaction and a variety of edge confining potentials. We find that the form of the confinement, such as sharpness of the edge and/or the strength of the confining potential which could lead to edge reconstruction, may cause deviations from universality in the edge-tunneling I-V exponent. We study two types of edge potentials: a sharp edge induced by a cut-off of angular momentum beyond $m_{max}$) and one induced by a uniform neutralizing background charge (a distance $d$ from the 2-d layer). Without the background charge, the exponent retains its universal value for soft edges (large $m_{max}$) but is non-universal for hard edges. In the presence of background charge and strong confinement (small $d$), the exponent is universal even for hard edges; for weak confinement and hard edges there is a deviation from the universal value while for soft edges there are finite-size corrections to $\alpha$, consistent with the edge reconstruction scenario. The relation of these results to experiments will be discussed.

**V1 4 Particle-hole symmetry and Luttinger liquids in a quantum Hall circuit.***
STEFANO RODDARO, *NEST-INFM CNR and Scuola Normale Superiore*

I shall present recent experimental results on edge-state transport through quantum point contacts in the quantum Hall (QH) regime. Finite-bias backscattering measurements between edge channels at filling factor $\nu = 1$ will be presented at different temperatures. Transport through the constriction displays a non-linear Luttinger-like behavior even in the integer QH regime in contrast with the linear tunneling predicted for integer edge states [1,2]. Both zero-bias enhancement and suppression of the inter-edge tunneling will be shown in a controllable way as a function of gate bias [2,3,4]. The observed evolution is connected to the local charge depletion in the constriction region and offers new insight into the link between QH charge-conjugation and Luttinger liquid description of edge channels [2]. I shall discuss the relevance of these experimental results in the context of the dynamics of the highly-correlated edge channels in the fractional QH regime [5]. Finally I shall demonstrate how charge-conjugation can be exploited in the design of new QH circuits where the transport properties of the hole component of a partially filled Landau level can be directly addressed. **V1 5 Edge State Tunneling in Split Hall Bar Models.**
EMILIANO PAPA

Edge states of Quantum Hall systems offer a rich ground for testing theoretical predictions on the properties of 1D strongly interacting fermionic systems. More importantly they are considered clean realizations the Luttinger Liquid description. In the past two years we [1,2,3,4] have examined a number of models that attempt to describe coupled edge density waves in the quantum Hall regime in various different geometries and to confront the large number of experimental observations that are at odds with the models that have been thought to apply in the past. Work that is currently in progress attempts to explain experimental results of the Pisa experimental group in which tunneling through a constriction between incompressible quantum Hall edge states is tuned from relevance to irrelevance by adjusting a gate voltage. This property is explained in terms of an interplay of the change in the connectivity of multi-mode edge magnetosplasmon and the role played by the metallic gates on the structure of the edge state, as well as the interactions between the edges. I will talk also for unresolved questions that have appeared in recent experiments in quantum Hall systems divided by thin cleaved-edge-overgrowth barriers. An important difficulty that arises in interpreting transport properties of QH line junction systems is the uncertainty about the strength and sometimes even the sign of these interactions, which can be difficult to estimate because of subtleties in understanding their relationship to underlying Coulombic interactions, because of edge reconstruction or because of the role played by the nearby metallic gates. We propose theoretical ideas and experimental measurements to obtain the required information. [1] E. Papa and A. H. MacDonald, Phys. Rev. Lett. 93, 126801 (2004). [2] E. Papa and A. H. **V2 1 Photoexcitation dynamics in SWCNT from sub-10 fs to ms.**
GUGLIELMO LANZANI, *Politecnico di Milano*

Photophisics in Single Walled Carbon Nanotubes, SWCNT-PEG, prepared by HiPco embedded PMMA is investigated with cw and pulse photo-excitation. Using ultra-short pulses in the visible and near infrared, with time duration of 7 fs and 20 fs respectively, pump-probe spectroscopy is carried out in SWCNT-PEG films in air at room temperature. Photo-bleaching recovery and photoinduced absorption build-up, upon excitation into the second absorption band, are time resolved providing a time constant of 40 plus/minus 5 fs. This is associated to exciton relaxation within semiconducting NTs, due to Fano-type resonances between localized excitonic levels and the underlying continuum density. Pumping in different regions of the absorption spectrum and probing a broad range of wavelengths, gives a complete description of the phenomenon. After relaxation, the decay of the equilibrated exciton occurs with a broad distribution of time constants, which is consistent with the inhomogeneous broadening of the sample. When using the shortest pulses (sub-10 fs) coherent phonons are clearly detected in the transmission difference traces. A radial breathing mode (RBM) at 250 wavenumber is observed, with dephasing of 1.2 ps. Anharmonic coupling between the RBM mode and the G-mode is detected for the first time in the time domain. Using cw excitation at 2.3 and 1.3 eV we observed photorefractivity in SWCNT-PEG samples, kept in vacuum at low temperature, in close analogy with conjugated polymers. Charges, which are photogenerated in the films, can separate giving rise to local electric fields which in turn induce Stark shift of the excitonic resonance.

**V2 2 Ultrafast and CW Optical Probes of Photoexcitations in Semiconducting Carbon Nanotubes.***
CHUAN-XIANG SHENG, *Department of Physics, University of Utah, Salt Lake City, Utah 84112*

Ultrafast dynamics of photoexcitations in semiconducting single walled carbon nanotubes (S-NT) in the form of films and $D_2O$ solutions, have been investigated using low intensity high repetition rate femtosecond laser system based on Ti-sapphire optical parametric oscillator in the spectral range from 0.13 to 1.05 eV. Various transient photoinduced bleaching (PB) and photoinduced absorption (PA) bands were observed, which also show pronounced polarization memory. The PA spectrum does not show Drude free carrier absorption, but instead is composed of two PA bands below the PB of the lowest S-NT absorption band. Also the PB spectrum exactly follows the cw photoluminescence (PL) emission spectrum. We therefore conclude that the primary photoexcitations in S-NT are itexcitons polarized along the NTs. We thus conjecture that the S-NT absorption bands are excitonic in origin; this conclusion is also supported by electroabsorption measurements that show quadratic Stark shift of the absorption bands. In addition, we found that the PL emission is also polarized; from the average PL polarization degree and ps transient polarization memory decay we estimate the PL lifetime in isolated S-NTs in solution to be of the order of 500 ps. Non-radiative decay processes dominate this relatively long PL lifetime. From the PL lifetime and the minute PL quantum efficiency we estimate the radiative PL lifetime in S-NTs to be $\sim$ $\mu$sec. This shows that the lowest lying exciton in S-NTs has small oscillator strength, and is in fact dark. The similarity of the PA spectrum in S-NTs and $\pi$-conjugated polymers indicates that quasi-1D excitons dominate the photophysics in both organic semiconducting materials. From this and the photon energy of the PA band we estimate the binding energy of the lowest exciton in S-NTs with diameters $\geqslant$ 1 nm to be $\sim$ 0.4 eV; in good agreement with two-photon absorption spectroscopy. Supported in part by the DOE.

**12:27**
**V2 3 Photophysics of single-walled carbon nanotubes: similarity with $\pi$-conjugated polymer.***
HONGBO ZHAO, *University of Arizona*

Coulomb electron-electron (e-e) interactions among the $\pi$-electrons have a strong effect on the energy spectra of semiconducting single-walled carbon nanotubes (S-SWCNTs), because of their quasi-one-dimensionality. The primary photoexcitations in S-SWCNTs as a consequence of e-e interactions are excitons, as opposed to free electrons and holes. There already exists a vast literature on excitons in $\pi$-conjugated polymers, the other class of carbon-based quasi-one-dimensional semiconductors. In order to seek guidance from this knowledge base, we have performed theoretical calculations of the excited state electronic structures, linear absorptions and excited state absorptions for ten different S-SWCNTs with a wide range in diameters,[1] within the same correlated $\pi$-electron model that has previously been applied to $\pi$-conjugated polymers. We found remarkable similarities in the excitonic energy spectra and nonlinear optical properties of S-SWCNTs on the one hand, and $\pi$-conjugated polymers on the other. The ''essential states'' model[2] of third-order optical nonlinearity, previously developed for $\pi$-conjugated polymers, applies also to S-SWCNTs (with minor

modifications for chiral S-SWCNTs which lack center of inversion). Our theory is able to explain semiquantitatively the results of nonlinear spectroscopic measurements on both S-SWCNTs and $\pi$-conjugated polymers. For wide S-SWCNTs with diameters ranging from 0.8–1.0 nm, we calculate exciton binding energies of 0.3–0.4 eV, in strong agreement with the values predicted from the experiments. We also remark on the occurrence of dark excitons below the optical excitons in the S-SWCNTs,[3] and the consequence thereof on the photoluminescence of these materials.

**V2 4 Dephasing and weak localization in an interacting 1D system.***
ALEXANDER MIRLIN, *Forschungszentrum Karlsruhe*

We study the transport properties of interacting electrons in a disordered quantum wire (e.g. carbon nanotube) within the framework of the Luttinger liquid model. The conductivity at finite temperature is nonzero only because of inelastic electron-electron (e-e) scattering. We demonstrate that the notion of weak localization (WL) is applicable to the strongly correlated one-dimensional electron system and calculate the WL correction to the conductivity at not too low temperatures. The relevant dephasing rate is governed, for spinless electrons, by the interplay of e-e interaction and disorder. This WL dephasing rate is parametrically different from the dephasing rate of Aharonov-Bohm oscillations in a ring. Our approach, combining bosonization with fermionic treatment of the problem, provides a framework for systematically studying the mesoscopic phenomena in strongly correlated 1D electron systems. In the end, the fate of dephasing at lower temperatures (in the strong-localization regime) is briefly discussed.

**V2 5 Tuning photo-carrier lifetimes by the atomic structure and environment of single-walled carbon nanotubes.**
STEPHANIE REICH, *Department of Materials Science and Engineering, Massachusetts Institute of Technology*

Carrier relaxation in single-walled carbon nanotubes depends on their chirality, the tube's atomic structure. Excitons decay by interacting with phonons in most tubes, but a fast electron-electron channel becomes available in a subset of tubes. Carrier relaxation at the band gap depends on the tube's environment, with an order of magnitude difference between isolated (10-100 ps) and bundled tubes (1 ps). In this talk we discuss carrier relaxation in carbon nanotubes after photoexcitation. Our results explain the varying luminescence intensity in nanotubes and why nanotube bundles do not emit light. We estimate nanotube abundances from luminescence and discuss our concepts in view of non-linear optical devices made from single-walled carbon nanotubes.

**V3 1 Noise in nonlinear nanomechanical resonators.**
ANDREW CLELAND, *UC Santa Barbara*

Noise limits the sensitivity of linear sensors, in a manner that is well understood, but also limits nonlinear systems in a less trivial way. Nonlinear nanomechanical resonators present interesting possibilities for the sensitive detection of forces and masses, but the noise limitations have not been explored much to date. Here we report on noise effects on nonlinear resonators operated in regimes where they have either one or two stable attractors. We have made quantitative measurements of the nonlinear response of a radiofrequency mechanical resonator with very high quality factor, measuring the noise-free transitions between the two attractors, and find good agreement with theory. We measure the transition rate response to controlled levels of white noise, and extract the basin activation energy. This allows us to obtain precise values for the relevant frequencies and the cubic nonlinearity in the Duffing oscillator, with applications to parametric sensing, in particular mass sensing.

**V3 2 Noise activated switching in a driven, nonlinear micromechanical torsional oscillator.**
HO BUN CHAN, *University of Florida*

We study noise induced switching in an underdamped micromechanical torsional oscillator driven into the nonlinear regime, a system that is far from equilibrium. Within a certain range of driving frequencies, the oscillator possesses two stable dynamical states with different oscillation amplitudes. We induce the oscillator to escape from one dynamical state into the other by introducing noise in the excitation. Close to the birfucation point, the activation energy for switching is expected to display system-independent scaling. By measuring the rate of random transitions at different noise intensities, we deduce the activation energy as a function of frequency detuning and measure a critical exponent that is in good agreement with theoretical predictions. While the oscillator predominately resides in one of the two states for most excitation frequencies, a narrow range of frequencies exist where the occupations of the two states are approximately equal. At these frequencies, the oscillator undergoes 'kinetic phase transition' that resembles phase transition of thermal equilibrium systems. We observe a supernarrow peak in the power spectral densities of fluctuations in the measured oscillation amplitude. This peak is centered at the driving frequency and arises as a result of noise-induced transitions between the two dynamic states.

**12:27**
**V3 3 Multiphoton antiresonance and quantum activation in driven oscillators.***
MARK DYKMAN, *Michigan State University*

Resonantly modulated oscillators are predicted to display quantum effects, which have no analog in two-level systems. One of them is antiresonance of the coherent nonlinear response: the amplitude of forced vibrations of the oscillator displays a sharp minimum or maximum when the modulation frequency passes adiabatically through multiphoton resonance. The other is escape from metastable states of forced vibrations via quantum diffusion over quasienergy levels. The escape is studied for the cases of resonant and parametric modulation of the oscillator. In both cases, even for zero temperature, the rate of diffusion over quasienergy states is faster than the rate of interstate dynamical tunneling given that the latter is smaller than the relaxation rate. The effective activation energy of escape is a sharp function of temperature in the quantum regime. It displays a power-law dependence on the distance to the bifurcation value of the modulation amplitude or frequency. We show the fragility of the distribution over quasienergy for $T = 0$, when the system has detailed balance: it strongly differs from the distribution for $T \to 0$ and from the distribution in the presence of dephasing even where the dephasing rate is small.

**V3 4 Metastable states in an RF-driven Josephson oscillator.**
RAJAMANI VIJAYARAGHAVAN, *Yale University*

A superconducting tunnel (Josephson) junction can be viewed as a non-linear, non-dissipative inductor and can be used to construct an oscillator by shunting it with a capacitor. Under certain driving conditions, the non-linear oscillator can adopt one of two possible modes of oscillation with different amplitude and phase. I will present experimental results which characterize these metastable states, and the transitions between them in the thermal and quantum regime. The dynamical switching between the metastable states can be used to make sensitive detectors. I will present data demonstrating the successful implementation of such a detector (Josephson Bifurcation Amplifier) to measure superconducting quantum bits. Other implementations of such non-linear oscillators using superconducting transmission line resonators will also be discussed.

**13:39**
**V3 5 Quantum nano-electromechanics: non-equilibrium cooling and strong feedback effects.**
AASHISH CLERK, *Dept. of Physics, McGill University*

A nano-electromechanical system consists of a micron-scale mechanical resonator coupled to a mesoscopic electronic conductor (e.g. a single-electron transistor, an atomic quantum point contact, etc.). The dissipative quantum mechanics of these systems are particularly interesting. How do the tunneling excitations in the conductor heat and damp the oscillator? To what extent do they act as an effective thermal bath? I will review recent theoretical work which demonstrates how a generic out-of-equilibrium mesoscopic conductor can act as an effective thermal bath. I will also

discuss the interesting case where this bath is formed by out-of-equilibrium, incoherently-tunneling Cooper pairs. This is system is remarkable in that significant cooling of the oscillator is possible, as well as a negative-damping instability which leads to a regime of strong-feedback between the oscillator and the Cooper pairs. Both these effects are analogous to ponderomotive effects occurring in a driven optical Fabry-Perot cavity having a moveable mirror; in our case, tunneling Cooper pairs play the role of the cavity photons.

**V4 1 Phase coherence, visibility, and the signatures of superfluid-Mott and metal-Mott insulator transitions on optical lattices.**
GEORGE BATROUNI, *Institut Non-Linéaire de Nice, University of Nice*

Experiments are revealing, with increasing precision, details of the Mott insulating (MI) and superfluid (SF) phases of atomic condensates confined on optical lattices. Recently, details of the transition between the MI and the SF phases, as the lattice potential is changed, were examined by studying the visibility and phase coherence of the condensate. Reproducible kinks were observed in the visibility as the lattice potential was made deeper and the system moved into the MI phase. These kinks were interpreted as being due to the formation of the Mott region. We shall first review briefly the properties of the various phases of this system and how it makes the transition from SF to MI. Then we present a detailed Quantum Monte Carlo study of the visibility and other physical quantities as Mott domains begin to form. We show that as the lattice potential gets deeper and Mott domains become well established, the evolution of the system stalls: the density profile stops evolving for a substantial range of values of the lattice potential. As a consequence, the evolution of several other quantities also stalls and the visibility kink is produced. We offer an explanation of this behavior. We then extend our study to the formation of Mott domains in fermionic atoms on confined one-dimensional optical lattices. We find a new property of the metal–Mott insulator transition in a trap. The sum of kinetic and interaction energies exhibits minima when Mott domains appear in the system. In addition, we examine the derivatives of the kinetic and interaction energies, and of their sum, which display clear signatures of the Mott transition. We discuss the relevance of these findings to time of flight experiments that could allow the detection of the metal–Mott-insulator transition in confined fermions on optical lattices.

**V4 2 Superfluid-Insulator Transition in a Moving System of Interacting Bosons.**
ANATOLI POLKOVNIKOV, *Boston University*

Cold atomic systems with their high tunability and nearly perfect isolation from environment give an exciting possibility to address non-equilibrium problems, where both quantumand dynamic effects are important. In this talk I describe a moving system of interacting bosons in a periodic optical lattice potential and generalize the conventional superfluid-Mott insulator transition to this highly non-equilibrium situation. I will discuss implications of our results to recent and future experiments.

**12:27**
**V4 3 Non-equilibrium one-dimensional Bose gases.***
DAVID WEISS, *Penn State*

I will describe the preparation and time evolution of arrays of trapped one-dimensional Bose gases with highly non-equilibrium momentum distributions. We observe negligible thermalization, in both the strong and intermediate coupling regimes, even after each atom has undergone thousands of collisions. These experiments can be understood as quantum mechanical versions of Newton's cradle, with hundreds of particles simply exchanging specific momentum values. The absence of thermalization demonstrates nearly integrable dynamics, which is a theoretical rarity and an experimental first for many-body systems with many degrees of freedom. By allowing tunnelling among the tubes, we can continuously change the collisions from one-dimensional to three-dimensional. We have thus been able to study the onset of thermalization in a many-body system.

**13:03**
**V4 4 Equilibrium and nonequilibrium properties of Tonks-Girardeau gases confined on optical lattices.***
MARCOS RIGOL, *University of California, Davis*

In this talk we discuss recent exact results for the in and out of equilibrium properties of Tonks-Girardeau (TG) bosons confined on one-dimensional lattices. The TG gas, introduced theoretically more than 40 years ago, has been recently realized in experiments with ultracold quantum gases loaded on optical lattices. We show that universal quasi-long range correlations are present in the ground state of trapped TG gases. These correlations account for the existence of quasi-condensates whose occupation scales proportionally to the square root of the number of particles in the trap. We find that when such systems are allowed to expand, by turning off the confining potential, their momentum distribution function rapidly approaches the one of noninteracting fermions. Remarkably, no loss in coherence is observed in the system as reflected by a large occupation of the quasi-condensates. We also study the expansion of TG gases starting their evolution from a pure Mott insulating state with one particle per lattice site. In this case quasi-long range correlations develop dynamically, and lead to the formation of traveling quasicondensates with a momentum determined by the underlying lattice. This effect could be used to create atom lasers with full control of the wavelength. Finally, we analyze the dipolar oscillations of TG gases in the combination harmonic trap - optical lattice. We show that damping is always present, and produces dramatic effects in the momentum distribution of the bosons. These effects are similar to the ones that would create a finite temperature in the system. In the presence of Mott insulating domains, the dipolar oscillations of the TG gas are overdamped and the center of mass barely moves from its initial displaced position.

**13:39**
**V4 5 One-dimensional spin-polarized fermions.**
ANNA MINGUZZI, *Laboratoire de Physique et Modelisation des Mileux Condenses, C.N.R.S., B.P. 166, 38042 Grenoble, France*

The fermionic Tonks-Girardeau (FTG)gas is a spin-aligned one-dimensional Fermi gas with infinitely strong attractive zero-range odd-wave interactions. This model describes experiments on ultracold atomic gases subjected to tight quasi-1D waveguides and close to a Feshbach resonance. I will report on the recent investigations of the FTG gas under different trapping conditions (harmonic and ring traps) and in the presence of disorder. In particular I will discuss the pairing properties of this gas, the possibility of metastable current flows and the response to rotation. Finally, for a gas initially under harmonic confinement I will show that during an expansion the momentum distribution undergoes a ''dynamical bosonization,'' i.e., approaches the one of an ideal Bose gas, without violating the Pauli exclusion principle.

## SESSION V5: SURFACES AND INTERFACES OF CORRELATED OXIDES
**Thursday Morning, 16 March 2006; 309, Baltimore Convention Center at 11:15**
**James Eckstein, University of Illinois, presiding**

**11:15**
**V5 1 Magnetic Oxide Superlattices.***
MASASHI KAWASAKI, *IMR Tohoku University and CERC-AIST*

Atomically regulated interfaces and superlattices composed of oxides are very interesting research arena for physics and possible applications. By selecting magnetic oxides as one of the components, one can study basic phenomena of spin polarized electrons at the interfaces [1]. Also, one can realized ?multiferroics? at the interface because magnetization and electric dipole due to interface charge imbalance can coexist. We demonstrated that non-linear Kerr effect [2] can be a tool of detecting interface magnetism in ?tricolor superlattices? composed of asymmetric A-B-C-A-B-C- sequence with A, B, and C being component oxides [3]. This technique was successfully applied to detect, design and enhance interface magnetism in a single heterointerface [4]. We now extend the artificially built-in multiferroic superlattices to other sequences, which include DNA superlattices (D: donor, N: neutral, and A: acceptor) and Ratchet superlattices (asymmetric doping profile). We also demonstrate realization of interface ferromagnetism at pn junctions made of two Mott insulators and tuning the magnitude through the channels of orbital and charge degrees of freedom. [1] M. Izumi et al., J. Phys. Soc. Jpn., 71, 2621 (2002); Phys. Rev. B 64, 064429 (2001). [2] Y. Ogawa et al., Phys. Rev. Lett. 90, 217403 (2003). [3] H. Yamada et al., Appl. Phys. Lett., 80, 622 (2002). **V5 2 Electrostatic Modulation of the Charge Density of Correlated Oxides.***
CHARLES AHN, *Yale University*

A commonly occurring feature of correlated complex oxides is the sensitivity of their physical properties to changes in the carrier concentration. Modification of the carrier concentration is typically accomplished through chemical doping, which can introduce chemical and structural disorder into the system. Here, we discuss electric field effect experiments on colossal magnetoresistive manganites, showing the possibility of inducing large, reversible changes in the magnetic properties through electrostatic modulation of the carrier concentration. We compare electrostatic doping with chemical doping, showing that differences in transport properties arise because of structural distortions that occur during chemical substitution.

**12:27**
**V5 3 Ferromagnet / superconductor oxide superlattices.**
JACOBO SANTAMARIA, *GFMC, Departamento de Fisica Aplicada, Universidad Complutense de Madrid, 28040 Madrid*

The growth of heterostructures combining oxide materials is a new strategy to design novel artificial multifunctional materials with interesting behaviors ruled by the interface. With the (re)discovery of colossal magnetoresistance (CMR) materials, there has been renewed interest in heterostructures involving oxide superconductors and CMR ferromagnets where ferromagnetism (F) and superconductivity (S) compete within nanometric distances from the interface. In F/S/F structures involving oxides, interfaces are especially complex and various factors like interface disorder and roughness, epitaxial strain, polarity mismatch etc., are responsible for depressed magnetic and superconducting properties at the interface over nanometer length scales. In this talk I will focus in F/S/F structures made of $YBa_2Cu_3O_7$ (YBCO) and $La_{0.7}Ca_{0.3}MnO_3$ (LCMO). The high degree of spin polarization of the LCMO conduction band, together with the d-wave superconductivity of the YBCO make this F/S system an adequate candidate for the search of novel spin dependent effects in transport. We show that superconductivity at the interface is depressed by various factors like charge transfer, spin injection or ferromagnetic superconducting proximity effect. I will present experiments to examine the characteristic distances of the various mechanisms of superconductivity depression. In particular, I will discuss that the critical temperature of the superconductor depends on the relative orientation of the magnetization of the F layers, giving rise to a new giant magnetoresistance effect which might be of interest for spintronic applications. **13:03**
**V5 4 (Giant) Proximity Effects in high-$T_c$ superlattices.**
IVAN BOZOVIC, *Brookhaven National Laboratory*

Molecular beam epitaxy enables one to synthesize HTS thin films with rms surface roughness in the range 0.2-0.5 nm, much less than the unit cell height (1-2 nm).[1] One can also make atomically smooth multilayers and superlattices in which HTS or spacer layers can be just one unit cell thick if so desired. A detailed study of transport properties of such heterostructures has already revealed some unexpected findings.[2] In junctions where the barrier is made out of underdoped cuprate with a reduced critical temperature $T_c$, we observe the Giant Proximity Effect: supercurrent runs through very thick barrier layers even at temperature well above $T_c$ (contrary to what is expected from the standard theory). Atomic smoothness of films and multilayers, excellent device uniformity, and reversible modulation of barrier properties by oxygen intake provided solid evidence against experimental artifacts such as pinholes and micro-shorts. Hence, the effect is real and intrinsic, and it defies the conventional explanation. Interpretation and significance of our experimental results will be discussed in the context of theoretical concepts such as the pseudogap, midgap states, electronic inhomogeneity, preformed pairs, and possibly resonant pair tunneling. The work at BNL is done in collaboration with G. Logvenov, V. Butko, A. Gozar, and A. Bollinger. [1] I. Bozovic et al., Phys. Rev. Lett. **89**, 107001 (2002); P. Abbamonte et al., Science **297**, 581 (2002). [2] I. Bozovic et al., Nature **421**, 873 (2003); Phys. Rev. Lett. **93**, 157002 (2004).

**13:39**
**V5 5 Surprising Properties of Interfaces in the Cuprate Superconductors.***
JOCHEN MANNHART, *Augsburg University*

Interfaces in the cuprate superconductors, in particular the grain boundaries, play a decisive role for the realization of large scale applications of these materials, such as superconducting power cables. The approach followed worldwide to optimize the boundaries for superconducting cables consists in aligning all grains in the cables to less than 10[r], which presents an enormous effort. From the viewpoint of a solid state physicist, the grain boundaries in the cuprates are interfaces at which two oxides with highly correlated electron systems meet. If described as linear defects in the $CuO_2$-planes, can the properties of the boundaries be understood and new approaches for their optimization be identified? To address these questions, we have performed experiments to study the properties of these interfaces below and above the superconducting transition temperature. We find for the superconducting as well as for the normal state startling phenomena which challenge our understanding of the underlying physics.

## SESSION V7: NOISE IN BIOLOGICAL SYSTEMS
**Thursday Morning, 16 March 2006; 307, Baltimore Convention Center at 11:15**
**Alex van Oudenaarden, Massachusetts Institute of Technology, presiding**

**11:15**
**V7 1 Fluctuation-adaptation relation in bacterial chemotaxis.**
PHILIPPE CLUZEL, *University of Chicago*

I will present experiments and computer simulations demonstrating, at the single cell level, that the expression of key chemotaxis proteins is fine-tuned to values that maximize fluctuations and the chemotactic response.

**11:51**
**V7 2 Noise effects in bacterial motor switch.**
YUHAI TU

The clockwise (CW) or counter clockwise (CCW) spinning of bacterial flagellar motors is controlled by the concentration of a phosphorylated protein CheY-P. In this talk, we represent the stochastic switching behavior of a bacterial flagellar motor by a dynamical two-state (CW and CCW) model, with the energy levels of the two states fluctuating in time according to the variation of the CheY-P concentration in the cell. We show that with a generic normal distribution and a modest amplitude for CheY-P concentration fluctuations, the dynamical two-state model is capable of generating a power-law distribution (as opposed to an exponential Poisson-like distribution) for the durations of the CCW states, in agreement with recent experimental observations of Korobkova et al. [Nature 428, 574 (2004)]. In addition, we show that the power spectrum for the flagellar motor switching time series is not determined solely by the power-law duration distribution, but also by the temporal correlation between the duration times of different CCW intervals. We point out the intrinsic connection between anomalously large fluctuations of the motor output and the overall high gain of the bacterial chemotaxis system. Suggestions for experimental verification of the dynamical two-state model will also be discussed.

**12:27**
**V7 3 Noise limitations on E. Coli cell division accuracy.**
HERBERT LEVINE, *University of California, San Diego*

Accurate cell division in E. Coli requires the Min family of proteins. Remarkable, MinD and MinE exhibit spatial oscillations, resulting in a minimum of MinD near the center of the cell. This minimum is thought to be the signal for assembly of the cell division machinery. Although deterministic models reproduce many observed features, a stochastic treatment is needed to test the extent to which finite particle number noise limits the accuracy of this determination. This talk describes a stochastic dynamics based simulation of this system; our results are then compared to the measured cell division accuracy.

**13:03**
**V7 4 Physical Limits to Biochemical Signaling.***
SIMA SETAYESHGAR, *Department of Physics, Indiana University*

Many crucial biological processes operate with surprisingly small numbers of molecules, where the impact of noise associated with these small numbers is potentially significant. Over twenty–five years ago, Berg and Purcell [1] showed that bacterial chemotaxis, where a single celled organism must respond to small changes in concentration of chemicals outside the cell, is limited directly by molecule counting noise, and that aspects of the bacteria's behavioral and computational strategies must be chosen to minimize the effects of this noise. We revisit and generalize their arguments to estimate the physical limits to biochemical signaling, where a ligand interacts with its receptor or cluster of receptors within the cell, and argue that recent experiments are consistent with performance approaching these limits [2]. [1] H. C. Berg and E. M. Purcell, *Biophysical Journal* **20**, 193 (1977). [2] W. Bialek and S. Setayeshgar, *Proc. Natl. Acad. Sci.* **102**, 10040 (2005).

*This work is in collaboration with Prof. William Bialek at Princeton University.

**13:39**
**V7 5 Gene expression noise and robustness of signaling in bacterial chemotaxis.***
VICTOR SOURJIK, *ZMBH, University of Heidelberg*

Stochastic variations in protein levels are one of the major sources of noise affecting biological networks. Since networks involved in gene regulation and signal transduction must have a defined input-output relation, they can be expected to have undergone evolution for inherent robustness against such perturbations. Chemotaxis of a model bacterium itEscherichia coli – a mechanism that allows motile cells to follow chemical gradients in the environment – has one of the most thoroughly studied signaling networks in biology. Combining theoretical and experimental analysis, we investigated robustness of this network to intercellular variations in expression levels of chemotaxis proteins, or gene expression noise. The single-cell levels of different chemotaxis proteins showed strong co-variation, which implies that stochastic variations in transcriptional control are the main source of the noise. We demonstrated that the pathway is indeed robust to such kind of perturbations by testing the effect of concerted overexpression of all chemotaxis proteins on the pathway output. Using computer simulations and theoretical analysis, we determined the network design features responsible for robustness and showed that the experimentally established network in itEscherichia coli has the smallest topology that is sufficiently robust to allow a majority of the individuals in a population to maintain a correct pathway output.

## SESSION V8: FOCUS SESSION: SIMULATIONS USING PARTICLES
**Thursday Morning, 16 March 2006; 314, Baltimore Convention Center at 11:15**
**Lorena Barba, University of Bristol, presiding**

***Invited Papers***

**11:15**
**V8 1 Nanoscale flows on open chemical channels.**
JOEL KOPLIK, *City College of New York*

We investigate the nano-scale flows of low-volatility liquids along ''chemical channels'': patterns of completely-wetting solid embedded in a planar substrate, and sandwiched between less wetting solid regions. In the case of a long, straight wetting stripe, we use molecular dynamics simulations as basic computational tool, comparing the results to a simple long-wavelength approximation and a full stability analysis based on the Stokes equations. The different approaches are qualitatively consistent, and we find that while thin liquid ridges are stable both statically and during flow, a (linear) pearling instability develops if the thickness of the ridge exceeds half of the width of the channel. In the flowing case periodic bulges propagate along the channel and subsequently merge due to nonlinear effects. However, the ridge does not break up even in the unstable case, and the qualitative behavior is unchanged when the fluid can spill over onto a partially wetting exterior solid region. For more complicated patterns involving the splitting or merger of wetting stripes, we again find that liquid flows continuously along the wetting region despite the pearling instability. In this case, intriguing switching dynamics is found for moving pearls at junctions.

**11:51**
**V8 2 Immersed boundaries and particles.**
GEORGES-HENRI COTTET, *Universite Joseph Fourier*

This talk will present ongoing works in our group dealing with particle simulation of complex flows. We will show some non conventional particle methods to simulate incompressible elasticity and fluid-structure interactions. We will also show how particle methods in these fields, as well as for more conventional advection dominated physics, can lead to new ideas for Eulerian schemes.

***Contributed Papers***

**12:27**
**V8 3 Particle Methods in Numerical Cosmology** HUGH COUCHMAN, *McMaster University* Particle methods play a central role in numerical simulations of cosmic structure. These methods are particularly important for simulations of two-component universes that include both baryonic and ''dark matter.'' Particles are used to model both the collisionless dark matter—using a classical inverse square law gravitational attraction—and, with Smoothed Particle Hydrodynamics (SPH), the baryonic component. Although Eulerian methods are also now widely used to model cosmological hydrodynamics, SPH exhibits many useful and important properties for cosmology: it is robust and simple to code, meshes well with the necessary particle representation of the collisionless dark matter and is able to model large density contrasts and irregular geometries easily and reliably. These methods have been used to model purely collisionless cosmic fluids with up to $10^{10}$ particles and to model both baryonic and dark matter universes with approximately $10^{8.5}$ particles.

**12:39**
**V8 4 Fast Parallel Particle Methods: Angstroms to Gigaparsecs** MICHAEL WARREN, *Los Alamos National Laboratory* Fast multipole methods have become an ubiquitous tool for the simulation of physical systems with long-range interactions. Since their introduction they have been applied to a vast range of problems. Our own parallel hashed oct-tree code (HOT) has been applied to a number of physical systems with long-range interactions, including gravitational and smoothed particle hydrodynamic interactions in astrophysical systems, fluid flows with vortex-particle methods, electromagnetic scattering and aerodynamics. Several these simulations were recognized with Gordon Bell prizes for significant achievement in parallel processing. We will discuss some recent work which used a series of 1-billion particle dark matter simulations to accurately determine the mass function of galaxy halos. These simulations required over $4 \times 10^{18}$ floating point operations (4 exaflops). Another focus of our current research is extending the HOT framework to biological systems, with the goal of simulating systems using over ten times as many atoms as the current state-of-the-art. This requires addressing several issues with current multipole algorithms, such as spatially-correlated errors and the ability to handle disparate time scales efficiently.

**12:51**
**V8 5 Efficient particle simulations based on combining the Vortex-In-Cell and the Parallel Fast Multipole methods** GREGOIRE WINCKELMANS, ROGER COCLE, GOERIC DAENINCK, *Universite catholique de Louvain (UCL)* FRANCOIS THIRIFAY, *CENAERO and UCL* Particle methods are quality methods for simulating unsteady, convection dominated, flows, as they have negligible dissipation and dispersion. The vortex particle method is used for incompressible flows; also for buoyancy-driven flows by adding the temperature. The method can also be used for combustion, by using variable volume particles with vorticity, velocity divergence, temperature and species mass fractions. Quality particle methods also require interpolation/redistribution schemes. We here consider the Vortex-In-Cell (VIC) approach, where all operations, except convection, are done using a grid: Poisson solver, stretching, diffusion, etc. The vorticity field is also maintained divergence free by projection when required (which also requires solving a Poisson equation). In our implementation, we use the Fast Multipole method to obtain the boundary condition for solving the Poisson equation: this allows for a grid that tightly contains the particles. The method is also parallelized: the Parallel Fast Multipole (PFM) code provides the proper boundary condition on each subdomain, without iteration. Illustrative results will be presented in DNS and LES (also using multiscale models): vortex rings, wake vortices (also with ground effects), combustion.

**13:03**
**V8 6 A Particle/Panel Method for Vortex Sheet Roll-Up** ROBERT KRASNY, *University of Michigan* Vortex sheets are commonly used in fluid dynamics to model thin shear layers in slightly viscous flow. Some of the first Lagrangian particle simulations in fluid dynamics used the point vortex approximation to study vortex sheet roll-up. We will review the early fundamental contributions on this topic by Rosenhead, Birkhoff, and Moore, and then discuss more recent developments. In particular, a method is described for computing vortex sheet roll-up in 3D flow in which the sheet surface is represented by a set of quadrilateral panels with Lagrangian particles at the vertices. The particles are advected by a regularized Biot-Savart integral and the induced velocity is evaluated by a particle-cluster treecode. The panels are adaptively subdivided to maintain resolution as the sheet deforms. The method is applied to simulate the collision of two vortex rings. The results shed light on the dynamics of vortex filaments in fully 3D flow.

**13:15**
**V8 7 Particle dynamics-based hybrid simulation of vibrated gas-fluidized beds of cohesive fine powders** SUNG JOON MOON, YANNIS KEVREKIDIS, SANKARAN SUNDARESAN, *Princeton University* We use three-dimensional molecular dynamics simulations of macroscopic particles, coupled with volume-averaged gas phase hydrodynamics, to study vertically vibrated gas-fluidized beds of fine, cohesive powders. The interstitial gas flow is restricted to be effectively one-dimensional (1D) in the beds of narrow cross-sectional areas we consider. This model captures the spontaneous development of 1D traveling voidage waves, which corresponds to bubble formation in real fluidized beds. We use this model to probe the manner in which vibration and gas flow combine to influence the dynamics of cohesive particles. We find that as the gas flow rate increases, cyclic pressure pulsation produced by vibration becomes more and more significant than direct impact, and in a fully fluidized bed this pulsation is virtually the only relevant mechanism. We demon-

strate that vibration assists fluidization by creating large tensile stresses during transient periods, which helps break up the cohesive assembly into agglomerates. We also study spontaneous demixing in beds of a mixture of particles of different densities, so-called the ''phase separation,'' using an equation-free multiscale approach.

**13:27**

**V8 8 Dissipative Particle Dynamics Simulations of Two-Phase Flows** ANUPAM TIWARI, JOHN ABRAHAM, *School of Mechanical Engineering, Purdue University* Dissipative particle dynamics (DPD) is a coarse-grained particle method that includes thermal fluctuations. A mean-field theory based model is developed for two-phase flows. Surface tension arises in the model due to terms that account for long-range attractive forces. The model is validated through static simulations carried out to reproduce the Laplace law relationship, and dynamic simulations of liquid cylinder and drop oscillations. It is shown that in both cases analytical and computed results agree within 8%. We will also present results from simulations of capillary waves and Rayleigh-Taylor instability. In the case of capillary waves, comparisons will be shown with analytical results, and in the case of Rayleigh-Taylor instability, comparisons will be shown with analytical and other computed results. As an application of the model, results from simulations of thermally induced jet breakup will also be presented.

**13:39**

**V8 9 Polymer chain simulations in microchannels with Dissipative Particle Dynamics** VASILEIOS SYMEONIDIS, *MIT / Brown University* GEORGE KARNIADAKIS, *Brown University* BRUCE CASWELL, *Brown University* In this work we employ Dissipative Particle Dynamics (scdpd) for simulations of dilute polymer solutions using bead-spring representations. We present comparison of two time-marching schemes: the popular velocity-Verlet and Lowe's scheme. Schmidt number effects are investigated for a series of cases, including $\lambda$-scdna molecules under shear (using the Marko-Siggia wormlike chain spring law) and Poiseuille flow in microchannels. Effects on the polymer depletion layer, power-law profiles and apparent viscosities are presented as a function of the number of beads per polymer chain.

**13:51**

**V8 10 High order viscous vortex methods with deforming elliptical Gaussians** LOUIS ROSSI, *University of Delaware* RODRIGO PLATTE, *Arizona State University* Vortex methods are numerical schemes for approximating solutions to the Navier-Stokes equations using a linear combination of moving basis functions to approximate the vorticity field of a fluid. Typically, the basis function velocity is determined through a Biot-Savart integral applied at the basis function centroid. Since vortex methods are naturally adaptive, they are advantageous in flows dominated by localized regions of vorticity such as jets, wakes and boundary layers. A semi-discrete convergence formulation leads to a new viscous vortex method based on deforming elliptical Gaussian basis functions that achieves fourth order spatial convergence. One odd thing about the new method is that basis functions do not move with the physical flow velocity at the basis function centroid as is usually specified in vortex methods. Rather, high order accuracy is obtained when one adds a consistently small flow field curvature correction. We will present two distinct approaches to the evaluation of the Biot-Savart integral for elliptical Gaussian basis functions. Non-trivial flow field calculations will demonstrate the efficacy of the method for both convection-diffusion problems and Navier-Stokes flows in 2D.

**14:03**

**V8 11 Accelerating Atomistic Molecular Dynamics Simulation in Entropic Systems** XIN ZHOU, *Los Alamos National Laboratory* The time scale of the traditional atomistic molecular dynamics simulations is too short to study wide slow dynamics of complex systems. Hyperdynamics method developed by A. F. Voter in studying of solids can not use directly in entropic systems such as fluids, biopolymers etc. By applying suitable order parameters with the symmetry of the studied systems and the characteristics of short trajectory, we build the condition of extending the hyperdynamics into fluids and algorithms. We test our results in a few modeling systems and expect the methods is used generally in simulating atomistically slow dynamics of complex fluids and biopolymers.

**SESSION V9: MAGNETIC FORCE MICROSCOPIES**
**Thursday Morning, 16 March 2006**
**301, Baltimore Convention Center at 11:15**
**Albert Macrander, Argonne National Laboratory, presiding**

**11:15**

**V9 1 Localized Spectroscopy using a Magnetic Resonance Force Microscope.** GIORGIO MORESI, QIONG LIN, *ETHZ* SCHAHRAZEDE MOUAZIZ, *EPFL* ANDREAS HUNKELER, CHRISTIAN DEGEN, URBAN MEIER, *ETHZ* JUERGER BRUGGER, *EPFL* BEAT MEIER, *ETHZ* LABORATORY OF PHYSICAL CHEMISTRY, ETHZ, CH-8093 ZUERICH TEAM, LABORATORY OF MICROSYSTEMS, EPFL, CH-1015 LAUSANNE TEAM, The Magnetic Resonance Force Microscope (MRFM) constitutes a promising next-generation magnetic resonance detection device at room temperature. A MRFM observes nuclear (or electron) spin magnetization as a force, which occurs when a paramagnetic sample is polarized in inhomogeneous static magnetic field (10E5 T/m) and a high frequency drives the cantilever on-resonance by a cyclic adiabatic modulation, which make able to measure T1 rho. In this contribution, we combine the MRFM with spin-echo spectroscopy to add spectral resolution to NMR signals of micro-scale objects at room temperature. First experimental spectra recorded with the amplitude detection technique from a sample of barium chlorate monohydrate and ammonium sulfate single crystals mounted on a non commercial cantilever show resolution of $2\mu$m and a sensitivity of 10E13 spins. The new microscope, which uses the frequency detection down to m-Hz resolution and the annealed non-commercials cantilevers, which have Q factor up to 250000 at room temperature, improve the sensitivity to 10E9 spins. This new setup and a new measurement technique should make able to measure T1.

**11:27**

**V9 2 High Sensitivity Magnetic Resonance Force Microscopy** P. BANERJEE, Y. CHE, K.C. FONG, T. MEWES,* V. BHALLAMUDI, YU OBUKHOV, D.V. PELEKHOV, P.C. HAMMEL, *Ohio State University* We report high sensitivity detection of electron spin resonance from E′ centers in fused silica using the Magnetic Resonance Force Microscope. Operating at low temperatures and with high magnetic field gradients in the 2–3 G/nm range, we easily observe magnetic resonance signals from less than 1000 $\mu_B$, and signal averaging enables detection of less than 100 $\mu_B$ with a spin sensitivity of 10 $\mu_B$. While $T_1$ at low temperatures is approximately 5 sec, the lifetime of the magnetization under conditions of periodic adiabatic reversal is considerably shorter and is observed to be of order 100 ms. We will discuss design features necessary to operate the microscope at millikelvin temperatures.

*now at University of Alabama

**11:39**

**V9 3 Using High Coercivity Magnet Particle for High Sensitivity Magnetic Resonance Force Microscopy** K.C. FONG, I.H. LEE, P. BANERJEE, Y. CHE, YU. OBUKHOV, D.V. PELEKHOV, P.C. HAMMEL, *Physics Department, Ohio State University* We report on the application of a 40 micron diameter, high coercivity NdFeB magnetic particle for high sensitivity electron spin resonance detection using Magnetic Resonance Force Microscopy. The relatively large NdFeB magnetic particle allows us to obtain large field gradients at relatively large tip-sample separations which can reduce surface induced noise. Force signals due to two different spin manipulation protocols in high field gradient will be presented. Model of the forces generated by these excitation schemes provide insight, into the various spin manipulation techniques and the impact of magnetic particle size on high sensitivity spin detection.

**V9 4 Experiments in Nuclear Magnetic Resonance Microscopy** YONG LEE, WEI LU, J.-H. CHOI, *Korea Research Institute of Standard and Science* H.J. CHIA, U.M. MIRSAIDOV, S. GUCHHAIT, A.D. CAMBOU, R. CARDENAS, K. PARK, J.T. MARKERT, *University of Texas at Austin* We report our group's effort in the construction of an 8-T, $^3$He cryostat based nuclear magnetic resonance force microscope (NMRFM). The probe has two independent 3-D of piezoelectric x-y-z positioners for precise positioning of a fiber optic interferometer and a sample/gradient-producing magnet with respect to a micro-cantilever. The piezoelectric positioners have a very uniform controllable step size with virtually no backlash. A novel RF tuning circuit board design is implemented which allows us to simply swap out one RF component board with another for experiments involving different nuclear species. We successfully fabricated and are characterizing $50\mu m \times 50\mu m \times 0.2\mu m$ double torsional oscillators. We have also been characterizing ultrasoft cantilevers whose spring constant is on the order of $10^{-4}$ N/m. We also report NMRFM data for ammonium dihydrogen phosphate(ADP) at room temperature using our 1.2-T system. Observed features include the correct shift of the NMR peak with carrier frequency, increases in signal amplitude with both RF field strength and frequency modulation amplitude, and signal oscillation (spin nutation) as a function of tipping RF pulse length. Experiments in progress on $NH_4MgF_3$ (at 1.2 T) and $MgB_2$ (at 8.1 T) will also be briefly reviewed. Robert A. Welch Foundation grant No.F-1191 and the National Science Foundation grant No. DMR-0210383.

**V9 5 Three-dimensional Imaging using Magnetic Resonance Force Microscopy** I. H. LEE, *The Ohio State University* K.C. FONG, *The Ohio State University* YU. OBUKHOV, *The Ohio State University* D.V. PELEKHOV, *The Ohio State University* P.C. HAMMEL, *The Ohio State University* We describe techniques for obtaining 3D spin density images using Magnetic Resonance Force Microscopy. The apparatus, specifically designed to test imaging techniques, operates in vacuum at room temperature. We record the spatial dependence of the force generated by the Electron Spin Resonance signal from a DPPH particle mounted on the cantilever as it is scanned over a spherical NdFeB particle used as a high gradient probe magnet. Details of apparatus design, experimental data, challenges and approaches to 3D MRFM image deconvolution will be presented.

**V9 6 Development of a Room Temperature High Sensitivity Magnetoelectric Scanning Microscope*** JASON HATTRICK-SIMPERS, LIYANG DAI, ICHIRO TAKEUCHI, MANFRED WUTTIG, *Department of Materials Science and Engineering, University of Maryland* In recent years the interest in magnetoelectric (ME) materials has increased dramatically, since they promise to have a number of unique functionalities and capabilities including ultrahigh magnetic field sensitivity. To date there has been little work done to actually use them in applications. We have constructed a high sensitivity room temperature scanning magnetic field microscope using a ME composite device made of a metglass/xyz(PVDF)/metglass sandwitch structured laminate. The smallest ME composite device used was 1 mm x 2 mm x 200 microns. The ME coefficient and the peak voltage of a typical device are 50 mV/Gcm and 3 mV at an AC modulation field of 10 Gauss. Scans of a conducting ring carrying an AC current, with the sensor DC biased at 100 Gauss, will be shown for various ring dimensions and AC currents. Through the variation of AC current we have shown that the sensitivity of the microscope to the z-axis component of AC field is better than $10^{-9}$ T. We will discuss the relationship between the ME device dimensions and the spatial resolution of the microscope.

**12:27**

**V9 7 Feature doubling in MFM imaging** ZHIFENG DENG, *Department of Physics, Stanford University, Stanford CA 94305, USA* ERHAN YENILMEZ, HONGJIE DAI, KATHRYN MOLER, Recently, magnetic material coated nanotube tips have been used for high resolution magnetic force microscopy. It is convenient to control the total thickness of a metal-coated nanotube by change the nominal deposition thickness. The thinner the coating is, the less magnetic material attaches to the nanotube. With cobalt coated nanotube tip eleven nanometers in diameter, we measure twenty-five nanometer features clearly. We also observe feature doubling with cobalt coated carbon nanotube tips in an experimental hard drive sample, indicating paramagnetic behavior for the smallest tips.

**12:39**

**V9 8 Progress of Magnetic Force Microscope for detecting spin-polarized electrons in non-magnetic materials** V.P. BHALLAMUDI, *The Ohio State University* Y. JUNG, *The Ohio State University* D.V. PELEKHOV, *The Ohio State University* YU OBUKHOV, *The Ohio State University* P.C. HAMMEL, *The Ohio State University* T. MEWES, *University of Alabama* While optical methods for detection of spin-polarized currents and spin accumulation in non-magnetic materials have proved quite successful, their applicability is limited to certain class of materials. Magnetic force microscopy (MFM) offers a more widely applicable alternative. We report here on the progress towards building such a high sensitivity low temperature-MFM spin detector. It employs optical interferometry for displacement detection. Issues related to techniques for detection and various challenges are discussed. Sample images demonstrating the high force sensitivity of the microscope are also presented.

**12:51**

**V9 9 Focused ion beam deposition of $Co_{71}Cr_{17}Pt_{12}$ and $Ni_{80}Fe_{20}$ on tips for magnetic force microscopy*** ALFRED LEE, CHANGBAE HYUN, ALEX DE LOZANNE, *Department of Physics, University of Texas at Austin, Austin, TX 78712* We demonstrate that a focused ion beam can deposit magnetic coatings on cantilevers used for atomic force microscopy, thereby producing a sensor for magnetic force microscopy. This technique is highly versatile, allowing the convenient deposition of complex or expensive materials, such as $Co_{71}Cr_{17}Pt_{12}$. A second material chosen for this demonstration was permalloy ($Ni_{80}Fe_{20}$). We show magnetic images acquired with these cantilevers to illustrate their excellent properties and the differences between coatings. In principle, multilayer coatings could be easily made with this technique.

*This work is supported by NSF DMR-0308575.

**13:15**

**V9 11 Scanning Hall Probe Microscopy (SHPM) using Quartz Crystal AFM Feedback** MUNIR DEDE, KORAY URKMEN, AHMET ORAL, *Bilkent* IAN FARRER, DAVID RITCHIE, *Cambridge* Scanning Hall Probe Microscopy (SHPM) [1] is a quantitative and non-invasive technique for imaging localized surface magnetic field fluctuations such as ferromagnetic domains with high spatial and magnetic field resolution of $\sim$ 50nm & $7mG/Hz^{-1/2}$ at room temperature. In the SHPM technique, Scanning Tunneling Microscope (STM) [1] or Atomic Force Microscope (AFM) [2] feedback is usually used for bringing the Hall sensor into close proximity of the sample. In the latter, the Hall probe has to be integrated with an AFM cantilever in a complicated microfabrication process. In this work, we have eliminated the difficult cantilever-Hall probe integration process; a Hall sensor is simply glued at the end of 32,768Hz Quartz tuning fork, as force sensor. The sensor assembly is set to oscillate with a PLL. SHPM electronics is modified to detect AFM topography and the frequency shift, along with the magnetic field image. The resonant frequency of the sensor drops to $\sim$ 5 kHz due to mass of the Hall sensor. Hard Disk, NdFeB Magnet, Garnet samples are imaged with the Quartz Crystal AFM feedback and the performance is found to be comparable with the SHPM using STM feedback. Quartz Crystal AFM feedback offers a very simple sensor fabrication and operation in SHPM. This method eliminates the necessity of conducting samples for SHPM. [1] A. Oral et al. Appl. Phys. Lett., 69, 1324 (1996) [2] A.J. Brook et al. Appl. Phys. Lett. 82, 3538 (2003)

**13:27**

**V9 12 Approach to Dipolar Field Microscopy** CARLOS MERILES, WEI DONG, PHILLIP STALLWORTH, *CUNY - City College of New York* Nuclear Magnetic Resonance (NMR) is arguably one of the most powerful techniques available today to characterize diverse systems. However, the low sensitivity of the standard detection method constrains the applicability of this technique to samples having effective dimensions not less than a few microns. Here, we propose a novel scheme and device for the indirect detection of the nuclear spin signal at a submicroscopic scale. This approach – for which the name Dipolar Field Microscopy (DFM) is suggested – is based on the manipulation of the long-range nuclear dipolar interaction created between the sample and a semiconductor tip located close to its surface. After a preparation interval, the local magnetization of the sample is used to modulate the nuclear magnetization in the semiconductor tip, which, in turn is determined by an optical inspection. Based on results previously reported, it is shown that, in principle, images and/or localized high-resolution spectra of the sample can be retrieved with spatial resolution proportional to the size of the tip. These calculations are accompanied by recent proof-of-principle experimental results in a model system.

**13:39**

**V9 13 Force-gradient detection of electron spin resonance** NEIL JENKINS, JOHN MAROHN, *Cornell University* Electron spin resonance of single unpaired electron spins in fused silica has recently been demonstrated [Rugar, *et al*, *Nature* **430** 329 (2004)]. The techniques employed rely on being able to coherently modulate electron spin magnetization for many hundreds of milliseconds, and are thus not well suited for observing unpaired electrons in spin-labeled biomolecules, for example, where the relevant spin relaxation times will be orders of magnitude shorter. In this presentation, we will discuss force gradient methods for detecting and imaging electron spin resonance that are more generally applicable. In our methods, applied rf is used to cyclically saturate electron spin magnetization at twice the cantilever frequency. A theory for the effect will be presented and data from sample-on-cantilever experiments performed at cryogenic temperatures will compare conventional force-detected MRFM to the signal from the force gradient experiment.

**V10 1 Formation Processes and (Photo-)electrochemical Properties of Organic Monolayers on Hydrogen Terminated Si(111).**
KOHEI UOSAKI, *Hokkaido University*

Construction of molecular layers on solid surfaces is one of the most important subjects not only for fundamental science but also for a wide range of applications. The most studied mono-molecular layer system is self-assembled monolayers (SAMs) of alkanethiols on various metals especially on gold and SAMs with a wide variety of functionalities have been constructed. It may be more important, however, to construct ordered molecular layers with various functionalities on a semiconductor surface, Si in particular, as far as technological applications are concerned because of possible applications for molecular and biomolecular devices in conjunction with the advanced silicon technology. Here we followed the thermal and photochemical organic monolayer formation process of by ATR-IR, ellipsometry, and sum frequency generation spectroscopy, and constructed and investigated electrochemical and photoelectrochemical properties of the organic monolayers with electron transfer function, i.e., viologen moiety, on hydrogen-terminated Si(111) surface. Furthermore, effect of platinum nanoparticles deposited on the surface on hydrogen evolution reaction was also investigated [1]. Photo-switching property was also introduced by incorporating a diarylethene moiety. [1] T. Masuda, K. Uosaki, Chem. Lett. **33**, 788 (2004).

**V10 2 New SiOH complexes and proton release mechanism in silica as a source of Si/$SiO_2$ interface-trap build up** I.G. BATYREV, S.T. PANTELIDES, *Department of Physics and Astronomy, Vanderbilt University* M.P. RODGERS, D.M. FLEETWOOD, R.D. SCHRIMPF, *Electrical Engineering and Computer Science Department, Vanderbilt University* Water molecules in $SiO_2$ have been studied extensively in the context of reliability of electronic devices. Here we report results of new density-functional first-principles calculations and experimental data that demonstrate a key role of $H_2O$ molecules in the long-term degradation of MOSFETs by increases in interface-trap densities. A new low energy complex formed by $H_2O$ has been identified. The complex consists of two SiOH groups located on neighboring rings. The energy of the complex is 0.3 eV lower than that for the free interstitial water molecule in the ring of $\sim$ 0.7 nm. The two silanol groups have different local topology, which results in different ability of the SiOH elements to capture holes and release protons under X-irradiation. The release of $H^+$ has a barrier of the reaction $\sim$ 0.45 eV and is accompanied by creation of a peroxy-type structure inside network ring. The released protons can diffuse or drift (driven by electric fields) to the interface, where they depassivate dangling bonds by forming $H_2$ molecules. We will present experimental data on the radiation response of devices that have been in storage for 20 years. The results are consistent with the theoretical picture, when water molecules are responsible for a substantial increase of interface-trap densities over time.

**V10 4 X-ray Photoelectron Spectroscopy of Buried Electronic Layers and Interfaces** JASON J. BLACKSTOCK, CARRIE L. DONLEY, *Quantum Science Research, HP Labs* WILLIAM F. STICKLE, *HP Labs Corvallis* DUNCAN R. STEWART, DOUGLAS OHLBERG, R. STANLEY WILLIAMS, *Quantum Science Research, HP Labs* Miniaturization of integrated circuits requires ever more detailed nanoscale physical and chemical characterization to engineer successful devices, as critical device layers are now only nanometers thick and frequently buried within complex material stacks. Nonetheless, correlating electronic device behavior with internal chemical structure remains essential for producing reliable devices. We present a new method for accessing the internal chemical structure of critical nanoscale layers in electronic device stacks via x-ray photoelectron spectroscopy (XPS). The method is based on engineering a weakened interface between two critical layers, then cleaving the stacks at this interface in a UHV environment and using XPS to characterize the layers and interfaces adjacent the cleave-plane. We present data from Pt/Pt-oxide/organic-monolayer/metal device stacks which show useful electrical switching behavior. This method reveals unexpected changes to the metastable Pt-oxide occur during stack fabrication. These changes to the buried nanoscale Pt-oxide layer are also shown to be inaccessible with conventional ion-milling or sputtering techniques that destroy the evidence of these subtle changes.

**V10 5 Quantum Size Effects in Nanostructures.**
CHING-MING WEI, *Institute of Atomic and Molecular Sciences, Academia Sinica, Taipei, TAIWAN 106*

Quantum size effects in metal thin films and metallic clusters are studied using first-principles density functional theory. For metal thin films, Pb(111), Pb(100), Al(110), and Al(111) films up to 30 monolayers are calculated. Significant oscillatory quantum size effects are found on surface energy, work function, and surface relaxations. These oscillations are correlated with the thickness dependence of the energies of confined electrons, which can be properly modelled by an energy-dependent phase shift of the electronic wave function upon reflection at the interface. It is found that a quantitative description of these quantum size effects requires full consideration of the crystal band structure. For metallic clusters, the highly symmetric particles of sizes up 4 nm ($Al_{923}$, $Pb_{923}$, and $Au_{309}$) in the icosahedral (ico), decahedral, and cubotohedral (fcc) structures are calculated. We propose a simple scheme to compare their relative stability and to identify the quantum size effect. In addition, the famous Mackay (fcc-to-ico) transition for metallic clusters is investigated by itab-initio elastic-band method. The transition path can in general be described by an angular variable **its**. The barriers of the Mackay transition for large Al, Pb, and Au clusters are found to be smaller than the thermal energy at room temperature. Finally CO oxidation on metallic clusters will be presented. A catalytic reaction path for CO oxidation on $Au_{55}$, $Ag_{55}$, and $Au_{25}Ag_{30}$ ico clusters is found with activation energies of less than 0.5 eV. The reaction consists of a peroxolike transition intermediate involving the OOCO configuration. A crucial factor to determine the reaction rate on these clusters is identified as the co-adsorption energy of CO and $O_2$ on these clusters.

**V10 7 Surface-enhanced Raman scattering of wurtzite-type GaN(0001) and ZnO(0001):** CHIH-YI LIU, MYKHAYLO M. DVOYNENKO, TSU-SHIN CHAN, JUEN-KAI WANG, YUH-LIN WANG, INSTITUTE OF ATOMIC AND MOLECULAR SCIENCES, ACADEMIA SINICA, TAIPEI, TAIWAN, REPUBLIC OF CHINA COLLABORATION, CENTER FOR CONDENSED MATTER SCIENCES, NATIONAL TAIWAN UNIVERSITY, TAIPEI, TAIWAN, REPUBLIC OF CHINA COLLABORATION, DEPARTMENT OF PHYSICS, NATIONAL TAIWAN UNIVERSITY, TAIPEI, TAIWAN, REPUBLIC OF CHINA COLLABORATION, We first-time report surface-enhanced Raman scattering (SERS) of Ag-deposited wurtzite-type GaN(0001) epitaxial film and ZnO(0001) substrate. On non-deposited region, two Raman-active modes, $A_1$(LO) and $E_2$(high), were observed in backscattering geometry, which is consistent with the Raman selection rule on wurtzite structure. In contrast, on the Ag-deposited region of both samples, only $A_1$(LO) mode (734 $cm^{-1}$ for GaN and 572 $cm^{-1}$ for ZnO) exhibits clear Raman enhancement. We propose that the macroscopic polarization field accompanied by LO-phonons is responsible for this anomalous Raman enhancement. The study of SERS effect on ionic crystals thus provides a simple test to investigate the mechanism beside electromagnetic effect in enhanced Raman scattering.

**V10 8 Organic Field Effect Transistor Interfaces Probed In-situ during operation by Sum Frequency Generation**
HONGKE YE, ASHRAF ABU-AKEEL, *Department of Chemical and Biomolecular Engineering* JIA HUANG, HOWARD KATZ, *Department of Materials Science and Engineering* DAVID H. GRACIAS, *Department of Chemical and Biomolecular Engineering, Johns Hopkins University, Baltimore, Maryland 21218* In order to gain a molecular level understanding of the electrical conduction in thin film organic semiconductors, we have integrated an electrical probe station with an SFG spectroscopy system. Thin film transistors consisting of organic semiconductors 5,5'-bis(4-hexylphenyl)-2,2'-bithiophene (6PTTP6) and pentacene, were fabricated on silicon substrates with top contacts. SFG spectra show strong correlations with the electrical characteristics measured. In particular, the SFG spectra of the interfaces changed with increasing gate voltage (Vg). For both 6pttp6 and pentacene the nonresonant SFG background correlated with the increase in conductivity (slope of the IV curve after turn on) measured of the semiconductor layer with increasing Vg. For 6pttp6 we observed that the dependency of the methylene peak intensity on gate voltage correlated well with the dependence of the saturation current on gate voltage. These results point to the fact that charging of molecules and the field effects in OFETs can be probed in-situ using SFG and electrical testing, and we can gain a molecular level understanding of OFET interfaces from the results.

**V11 1 Structure Determination of Noble Metal Clusters by Trapped Ion Electron Diffraction.**
DETLEF SCHOOSS, *Institute for Nanotechnology, Forschungszentrum Karlsruhe*

The structures of noble metal cluster ions have been studied by the recently developed technique of trapped ion electron diffraction (TIED)[1]. In brief, cluster ions are generated by a magnetron sputter source and injected into a cooled (95 K) quadrupole ion trap. After mass selection and thermalization, the trapped ions are irradiated with a 40 keV electron beam. The resulting diffraction pattern is integrated with a CCD detector. The assignment of the structural motif is done via a comparison of the experimental and simulated scattering function, calculated from density functional theory structure calculations. The structures of mass selected silver cluster cations $Ag_{19}^+$, $Ag_{38}^+$, $Ag_{55}^+$, $Ag_{59}^+$, $Ag_{75}^+$ and $Ag_{79}^+$ have been investigated.[2] The resulting experimental data are best described by structures based on the icosahedral motif, while closed packed structures could be ruled out. Additionally, we present a comparison of the structures of $Cu_{20}^{+/-}$, $Ag_{20}^{+/-}$ and $Au_{20}^{+/-}$. Our findings show unambiguously that the structure of $Au_{20}^-$ is predominantly given by a tetrahedron in agreement with the results of L.S. Wang et al.[3] In contrast, structures of $Ag_{20}^-$ and $Cu_{20}^-$ based on the icosahedral motif agree best with the experimental data. Small structural differences between the charge states are observed. The possibilities and limitations of the TIED method are discussed. [1] M. Maier-Borst, D. B. Cameron, M. Rokni, and J. H. **11:51**
**V11 2 Electric deflection studies of rhodium clusters*** MARK KNICKELBEIN, *Argonne National Laboratory* MARTIN BEYER, *Technische Universität Berlin* The electric susceptibilities of rhodium clusters ($Rh_n$, n=5-32) have been studied via a DC molecular beam deflection technique. It is observed that all clusters are high-field seekers, indicating that the induced dipole moments are larger than any small permanent dipole moments that may be present. The per atom polarizabilities determined from the beam deflections exceed the classical value. $Rh_7$ and $Rh_{10}$ exhibit per- atom polarizabilities that are both anomalously large and temperature dependent. Peak broadening is most pronounced for $Rh_7$, indicating the presence of a small permanent dipole moment. It is proposed that the anomalous polarizabilities exhibited by $Rh_7$ and $Rh_{10}$ are a consequence of their being dynamic Jahn-Teller molecules.

**V11 3 On the Possibility of Multiple Valence Superatoms** SHIV KHANNA, J. ULISES REVELES, *Department of Physics, Virginia Commonwealth University, Richmond Va. 23284* A. WELFORD CASTLEMAN JR., DENNIS BERGERON, PATRICK ROACH, *Department of Chemistry and Physics, The Penn State University, University Park, PA 16802* It was recently demonstrated that an $Al_{13}$ cluster behaves like a halogen atom while an $Al_{14}$ cluster has properties analogous to an alkaline earth atom in gas phase clusters containing aluminum and iodine atoms. These observations, together with findings that $Al_{13}^-$ is inert like a rare gas atom, have reinforced the idea that chosen clusters can exhibit chemical behaviors reminiscent of atoms in the periodic table, offering the exciting prospect of a new dimension of the periodic table formed by cluster elements, called the superatoms. As the properties of the clusters can be controlled by size and composition, the superatoms offer the potential to create unique compounds with tailored properties. In this paper, we provide evidence of a new class of superatoms that exhibit multiple valences, like some of the atoms in the periodic table, and hence have the potential to form stable compounds when combined with diverse atoms.

**12:15**
**V11 4 Geometrical and electronic properties of sodium, copper, and silver clusters: A comparative study*** MINGLI YANG, KOBLAR A. JACKSON, *Department of Physics, Central Michigan University, Mt. Pleasant, MI 48859* JULIUS JELLINEK, *Chemistry Division, Argonne National Laboratory, Argonne, IL 60439* The structures of sodium, copper, and silver clusters with up to 20 atoms are investigated using density functional theory computations. Utilizing an extensive unbiased search procedure, we first find a large number of low-energy isomers of Cu clusters. The structures of these isomers are then reoptimized for Na and Ag clusters. We find a strong propensity to form similar conformations for clusters of these three elements. In most cases their energetically preferred forms have the same packing. As the cluster size increases, it changes from planar (less than 7 atoms) to layered (7 to 16 atoms) and eventually to compact (17 to 20 atoms). The similarities and differences between the clusters of the three elements will also be characterized in terms of their

electronic properties such as ionization potential, HOMO-LUMO gap, dipole moment, and polarizability.

**V11 5 Self-Similar Size Distribution of Atom Clusters in Cooling Vapors** YONG W. KIM, HEDOK LEE, PAUL BELONY, JR., *Lehigh University* Aluminum atom clusters of nanometer dimensions grow out of dense vapors. We have both measured and modeled their formation process by first creating dense atomic vapors as remnants of a 3-D laser-produced plasma plume from a solid aluminum target. By real-time diagnosis, we have fully characterized the plume into more than 140,000 vapor cells. [Kim, Lee, Rev. Sci. Instr. **75**, 3953 (2004)] Clustering of atoms in each cell has been followed during the cooling of the vapors by numerical simulation of atom-atom and atom-cluster collisions. The distribution of clusters by size evolves as the vapor cools, and is sensitively dependent on the initial atom density in each plasma cell. When the population and cluster size are rescaled as fractions of their respective maximal values, the distribution functions all collapse into a single functional form regardless of the time in the evolution or the initial value of the vapor density. The maximal population decreases while the maximal size grows over time. The cluster size distribution for the plasma plume is found by summing the distributions from all plasma cells. Independently, the clusters are captured onto electron microscope grids and size analyzed by means of transmission electron microscopy. The computed result is in excellent agreement with the measured histogram of clusters by size. The agreement is absolute, indicating the Brownian motion nature of cluster-cluster interaction.

**V11 6 On Metal to Insulator Transitions in Bivalent Metal Clusters.***

ORI CHESHNOVSKY, *School of Chemistry, Tel Aviv University, 69978 Tel Aviv Israel*

We discuss the issue of metal to insulator transitions in bivalent metal clusters, in view of our new photoelectron spectroscopy (PES) studies on $Zn_n^-$ clusters in the size range of n=3-117. We show that zinc clusters exhibit a distinct transition in their electronic structure characteristics as a function of their size. At small sizes up to $n=18$ the clusters follow the Bloch-Wilson picture of the development of a metal from closed-shell atoms, exhibiting a gradual decrease of the gap between the fully occupied *s* band and the empty *p* band. For large sizes ($n \geq 32$) the band overlap allows the valence electrons to fully delocalize. This leads to an almost perfect free-electron density of states, as is demonstrated by discussing the spectra in the light of standard free-electron models and by comparison to the results obtained on sodium clusters. These results will be compared with the PES of $Hg_n^-$ and $Mg_n^-$ clusters.

**V11 7 Quantized Ferromagnetic Moments of Free Cobalt Clusters** XIAOSHAN XU, SHUANGYE YIN, ANTHONY LIANG, WALTER DE HEER, The magnetic moments $\mu$(N) of free $Co_N$($20 <= N <= 200$) clusters has been measured in a cryogenic molecular beam. Besides the ground states with $\mu(N)/N \sim 2\ \mu B$, an electronic state has been found in all clusters studied. The magnetic moments $\mu^*(N)/N$ of this state is approximately 1/2 $\mu$(N)/N. Ionization potential of Co clusters at each of the two states are determined from photo-ionization efficiency measurements. The ionization potentials for the excited states are systematically lower than that for ground states by about 100meV for small clusters, and merge for larger clusters ($N > 100$). This suggests that molecular magnetism of small clusters evolves to itinerant (band) ferromagnetism in the bulk ($\mu(N)/N \sim 1.7\ \mu B$) when the energy gap between these two states vanishes.

**V11 8 Magnetism in Gold Nano-clusters*** R.J. MAGYAR, V. MUJICA, *INEST Group, Philip Morris USA Postgraduate Research Program and NIST* C. GONZALEZ, *NIST* M. MARQUEZ, *Philip Morris USA Research Center* Intrinsic magnetism in thiolated and unthiolated gold nano-clusters is explored from a first-principles perspective. The computed electronic structures elucidate the relevant mechanism whereby these nano-clusters develop a permanent magnetic moment. Polarized ground states are favorable due to surface paramagnetism, and bare clusters are expected to be magnetic for $Au_{38}$ and larger. How the thiolates effect the magnetic moment is also considered.

*This research has been conducted by the INEST (Interdisciplinary Network of Emerging Science) group, Philip Morris USA Postgraduate Research Program

**V11 9 Anomalous magnetic enhancement by doping Mn in Co clusters** SHUANGYE YIN, *Georgia Institute of Technology* RAMIRO MORO, XIAOSHAN XU, WALTER DE HEER, Magnetic moments of $Co_NMn_M$ and $Co_NV_M$ clusters (with Mn and V concentration less than 30%) are measured using Stern-Gerlach deflection method in molecular beams. Their average moments per atom as a function of impurity concentrations are studied and compared with bulk. Both $Co_NMn_M$ and $Co_NV_M$ clusters have higher average moments than their bulk counterpart due to reduced sizes. The average moments for $Co_NMn_M$ clusters are found to increase with Mn concentration, opposite to that of CoMn bulk. The enhancement effect is found to be independent of cluster size and composition. Meanwhile, $Co_NV_M$ clusters show reduction of average moments with V doping, consistent with what are expected in CoV bulk. The results are discussed within the virtual bound states model.

**V11 10 Analysis of the response of atomic clusters to static electric fields in terms of position-dependent polarizabilities*** KOBLAR A. JACKSON, MINGLI YANG, *Department of Physics, Central Michigan University, Mt. Pleasant, MI 48859* JULIUS JELLINEK, *Chemistry Division, Argonne National Laboratory, Argonne, IL 60439* To explore in detail the response of atomic clusters to external electric fields, we have developed a method to compute position-dependent polarizabilities (PDP's). The essence of the method is to partition the overall cluster dipole into local, atom-centered contributions. The local moments are naturally decomposed further into charge-transfer and dipole components. This decomposition furnishes added insight into the response behavior of the clusters. By tracking the changes in the local moments with an external field, we arrive at the PDP's. In this talk we will present the details of the method and will compare and contrast different approaches to computing the local moments. We will also discuss results for $Na_n$, $Si_n$ and $Ar_n$ as a function of cluster size. These results show strong qualitative similarities in the response of $Na_n$ and $Si_n$ clusters, including clear evidence for metallic screening of the cluster interiors.

**V12 1 Water Enhanced Catalysis of CO Oxidation on Free and Supported Gold Nanoclusters** ANGELO BONGIORNO, UZI LANDMAN, *Georgia Institute of Technology* The enhancement by water molecules of the catalytic activity of gas-phase and supported gold nanoclusters toward CO oxidation is investigated with first-principles calculations. Coadsorption of water and oxygen molecules leads to formation of a complex well-bound to the gold cluster, even on a defect-free MgO(100) support. Formation of the complex involves partial proton-sharing between the adsorbates, that in certain configurations results in proton transfer leading to the appearance of a hydroperoxyl-like complex. The O-O bond is activated, leading to a weakened peroxo or superoxo-like state, and consequently the reaction with carbon oxide to form carbon dioxide occurs with a small activation barrier of about 0.5 eV. A complete catalytic cycle of the water-enhanced CO oxidation is discussed.

**11:27**

**V12 2 Tuning the diamond surface from hydrophobic to superhydrophilic by submonolayer surface modification*** SHENG MENG, *Physics, University of Texas at Austin and Physics, Harvard University* ZHENYU ZHANG, *Condensed Matter Sciences Division, Oak Ridge National Lab* EFTHIMIOS KAXIRAS, *Physics, Harvard University* The extreme limits of wettability, superhydrophilic and superhydrophobic behavior, are useful in industrial applications such as anti-fogging and self-cleaning. Superhydrophilic behavior is highly desirable in biomedical applications, protecting biomolecules from damage in their interaction with biomaterials. While substantial progress has been made in designing superhydrophobic materials, relatively little effort has been devoted to the development of superhydrophilic materials, particularly biocompatible ones. Here we show, using first-principles calculations, that the water affinity of an initially highly hydrophobic H-passivated diamond (111) surface can be drastically altered with introducing a fraction of a monolayer of alkali metals. In particular, terminating the diamond surface with F and replacing 1/3ML F by Na, or introducing one third monolayer of Li and methylating half of the remaining surface sites, produces stable surfaces with superhydrophilic behavior which are perfect candidates for biomedical applications.

**V12 3 Infrared Studies of Water Adsorption on Acetic Acid thin films** MICHEL MALICK THIAM, MARYAM EBRAHIMI, KAM TONG LEUNG, *WATLABs, Department of Chemistry, University of Waterloo, 200 University Ave. W., Waterloo, Ontario, N2L 3G1, Canada* WATLABS TEAM, Infrared reflection-absorption spectroscopy is used to investigate $H_2O$ ice deposited onto non-crystalline (dimers [1]) and polycrystalline (infinite chains [1]) acetic acid films. The condensed water film grown at $\sim$ 135 K on these different substrates can be characterized as amorphous dense ice. The $H_2O$ molecules are shown to interact mainly with the carbonyl and the carboxyl oxygens, forming hydrogen bonds. Upon water adsorption on the non-crystalline acetic acid film, saturation of the change induced in the intensity of the C=O and C-O peaks occurs at an average $H_2O$ exposure of $\sim$ 2.52 L. The amount of H-bonding involving C=O or C-O (of acetic acid) and OH (of water) on the polycrystalline film has been reduced considerably compared to the situation on the non-annealed one, but saturation of the carbonyl oxygen even for a water exposure of 9 L has not been observed while the carboxyl oxygen saturates at $\sim$ 2.76 L. Thermal evolution studies for the ice film on non-crystalline and polycrystalline acetic acid films show that water co-evaporates with acetic acid likely as a water-acetic acid complex in the temperature range of 140-155 K, which continues until the entire ice film has been exhausted at 160 K. **V12 4 Ab-initio simulations of H2O interaction with b-SiC surfaces.**
GIANCARLO CICERO, *Politecnico of Turin*

We report on the interaction of gas phase water molecules with polar and non polar stoichiometric surfaces of cubic silicon carbide, a leading candidate semiconductor for bio-compatible devices. Finite temperature ab-initio molecular dynamics shows that the specific geometric arrangement of atoms on the outermost surface layer is responsible for water orientation and coordination and thus plays a major role in determining the surface reactivity. In particular, irrespective of coverage, water spontaneously dissociates on both polar [1] Si-terminated (001) and non-polar [2] (110) surfaces, while the C-terminated1 (001) surface is non-reactive and hydrophobic. Based on our results, we propose that STM images and photoemission experiments may detect specific changes induced by water on both the structural and electronic properties of SiC surfaces. We completed our investigation by studying a realistic solid/liquid interface [3] for the case of Si-SiC(001), after full hydroxylation takes place. We observed the formation of a thin (3/AA) interfacial layer, which presents a higher density than bulk water. The liquid does not uniformly wet the surface, rather molecules preferably bind along directions parallel to the Si dimer rows. Our calculations also predict that at 1 nm, the structural and electronic properties of liquid water are weakly affected by one-dimensional confinement between hydrophilic, solid substrates. [1] G. Cicero, A. Catellani and G. Galli Phys Rev. Lett. 93 (2004), 0161102; G. Cicero, A. Catellani and G. Galli J. Phys. Chem. B 108 (2004), 16518. [2] A. Catellani, G. Cicero and G. Galli J. Chem. **V12 5 Physics of solid and liquid alkali halide surfaces near the melting point** TATYANA ZYKOVA-TIMAN, DAVIDE CERESOLI, UGO TARTAGLINO, *SISSA, INFM, Democritos, via Beirut 2-4* ERIO TOSATTI, *SISSA, Democritos, ICTP, P.O. Box 586, I-34014 Trieste, Italy* NaCl (and other alkali halide) crystal surfaces have the peculiar property of repelling their own melt. As a result they let themselves be wetted only partially by their own liquid at the melting point $T_M$. We recently investigated the physical reasons for this unusual behavior. We found them through theory and molecular dynamics simulation to stem from the conspiracy of three factors. First, the solid NaCl(100) surface is exceptionally anharmonic,but also exceptionally stable. It can in fact survive even well above the melting point, for unlike most other surfaces it does not spontaneously melt. Second, the solid-liquid interface is very costly, due to a 27% density difference between solid and liquid. Third, the surface tension of liquid NaCl is relatively high. This last feature is due to an unexpected entropy deficit, that can in turn be traced to incipient molecular charge order in the outermost regions of the molten salt surface[1,2]. [1] T. Zykova-Timan, D. Ceresoli, U. Tartaglino, E. Tosatti, Phys. Rev. Lett. 94, 176105 (2005) [2] T. Zykova-Timan, D. Ceresoli, U. Tartaglino, E. Tosatti, J. Chem. Phys. 123, 164701 (2005)

**V12 6 Nanoscale Observation of Alkane Dewetting*** MENGJUN BAI, KLAUS KNORR, MATTHEW SIMPSON, SVEN TROGISCH, HASKELL TAUB, *U. Mo.-Columbia* ULRICH VOLKMANN, *P. U. Católica Chile* FLEMMING HANSEN, *Tech. U. Denmark* To investigate the structure, morphology, and wetting of both solid and liquid films of an intermediate-length alkane, we have conducted Atomic Force Microscopy measurements in the noncontact mode on dotriacontane ($n$-$C_{32}H_{66}$ or C32) films deposited from a heptane solution onto $SiO_2$-coated Si(100) wafers. At low coverages after annealing, the C32 film consists at room temperature of isolated bulk particles situated above one to two layers of molecules oriented with their long axis parallel to the surface. For such samples, we find a narrow temperature range close to the bulk C32 melting point $T_b$ in which a monolayer with C32 molecules oriented perpendicular to surface is stable. This perpendicular monolayer phase undergoes a dewetting transition to a three-dimensional (3D) fluid phase on heating to just above $T_b$ and to a 3D crystalline phase on cooling to a few degrees below $T_b$. We summarize our results in terms of an equilibrium phase diagram that provides a useful framework for interpreting the unusual spreading and receding behavior that we observe for the perpendicular monolayer phase.

**V12 7 Energetics of benzene and phenol adsorption on a $TiO_2$(110) surface** S. DAG, J. ZHOU, S. KALININ, S. OVERBURY, D. MULLINS, A. BADDORF, V. MEUNIER, *Oak Ridge National Laboratory* Using large-scale density functional theory calculations, we have studied the structural and electronic properties of benzene and phenol adsorbed on a $TiO_2$ (110) surface. We found that at low coverage, a benzene molecule impinging to the $TiO_2$ surface is most likely to be adsorbed flat on the surface 3.3 Å above the Ti row, such that the $C_{2[]'}$ symmetry axis of the molecule is oriented along the top Ti row, between consecutive bridging oxygen rows. Because of the high repulsive energy between benzene and bridging oxygens, benzene molecules diffuse in quasi one-dimensional channels along a Ti row. At high coverage, benzene molecules organize in a chain-like fashion with two of their C-C bonds being oriented alternatively parallel and perpendicular to a Ti row. The interaction of phenol molecules on the same surface has also been studied. In this case, the adsorption is much stronger and involves interaction between multiple phenol molecules and bridging oxygen rows. Results of our calculations are in excellent agreement with experimental STM data.

**V12 8 Adsorption and reaction of benzene and phenol with Pd nanoparticles supported on $TiO_2$(110)*** J. ZHOU, S. V. KALININ, S. DAG, V. MEUNIER, S. H. OVERBURY, D. R. MULLINS, A. P. BADDORF, *Oak Ridge National Laboratory* Adsorption and reaction of benzene and phenol molecules on a $TiO_2$(110)(1× 1) surface and with titania-supported Pd particles were

studied under ultrahigh vacuum conditions using scanning tunneling microscopy (STM) and temperature programmed desorption (TPD). At 300 K, benzene could not be imaged with STM due to its high mobility. At 20 K, images show benzene in ordered rows on top of substrate Ti. Adsorption of phenol differs due to the presence of the OH functional group. At 300 K, adsorption of phenoxy adjacent to surface defects is indicated in STM images. Low temperature studies indicate that phenol adsorbs on the titania surface with a different configuration than benzene, with tunneling spanning two Ti rows. No obvious modifications to benzene or phenol adsorption were observed adjacent to Pd particles by STM, however catalytic effects were explored by TPD. Our results are in excellent agreement with calculations obtained using first-principles density functional theory.

**V12 9 LEEM study of the growth of 6,13-pentacenequinone thin films** JERZY SADOWSKI, ABDULLAH AL-MAHBOOB, TSUGUKI NISHIHARA, YASUNORI FUJIKAWA, TOSHIO SAKURAI, *Institute for Materials Research, Tohoku University, Sendai, Japan* The morphology and dynamics of the growth of 6,13-pentacenequinone (PnQ – $C_{22}H_{12}O_2$) films on Si(111)-7x7 surface have been investigated itin-situ by the low-energy electron microscopy (LEEM), in order to evaluate the possibility of using PnQ molecules as an organic dopant in pentacene (Pn) films. The results of the experiments show that the nucleation and growth mechanisms dramatically differ between Pn and PnQ films, respectively. At the initial stage of the PnQ growth, after the saturation of the Si dangling bonds by the formation of a disordered wetting layer, the amorphous islands (type-I) having compact shapes were formed. After they have reached a critical size (few hundreds to several thousands nanometers, depending on the molecular flux), a second stage nucleation of the crystalline, highly anisotropic, needle-shaped islands (type-II) occurred. A gradual rotation of the in-plane (**ab**) unit cell along the type-II islands have been observed, with the direction of the 2D 'chirality' dependent on the direction of the **c** axis of the PnQ crystal lattice and associated with selective mass incorporation at the side of the island having edge parallel to long diagonal (direction of minimum strain and a favorable direction of a kink formation) of the **ab** unit cell.

**V12 10 Growth of divalent metal carbonates at soft organic templates.** SUMIT KEWALRAMANI, GEOFFREY DOMMETT, KYUNGIL KIM, GUENNADI EVMENENKO, HAIDING MO, PULAK DUTTA, *Northwestern University* PULAK DUTTA, DEPARTMENT OF PHYSICS AND ASTRONOMY, NORTHWESTERN UNIVERSITY TEAM, Soft template mediated inorganic mineral nucleation and growth proceeds via specific interactions between the ordered organic lattice headgroups and inorganic constituents at the organic-inorganic interface. We are studying the growth of divalent metal carbonates of R-3 (167) space group from supersaturated solutions under fatty acid, alcohol and glutamic acid rich poypeptide monolayers via in-situ grazing incidence X-ray diffraction and scanning electron microscopy. Previous studies[1] show that the presence of $Cd^{2+}$, $Mn^{2+}$, $Mg^{2+}$, even in small quantities produce highly ordered fatty acid monolayer phases and result in the formation of ionic inorganic superlattices under them. For $Ba^{2+}$, $Ca^{2+}$ and $Co^{2+}$ the extent of organic monolayer order is lower and no ionic lattice is observed. We now find that the orientation and morphology of bulk crystals grown from supersaturated solutions is strongly correlated to the order induced in organic monolayers by dilute subphases. Headgroup- ion interactions in the dilute phase can thus serve as a better guideline for choosing the monolayer for face specific nucleation as opposed to the proposed[2] geometric and stereochemical match mechanism. 1.Kmetko et al. J. Phys. Chem. B 105, 10818 (2001). 2. Mann et al. Science, 261, 1286 (1993).

**V12 11 Structural characterization and molecular dynamics within low-coverage films of *p*-terphenyl adsorbed onto graphite** EDWARD KINTZEL, KENNETH HERWIG, *Oak Ridge National Laboratory* Neutron scattering experiments have been carried out on low-coverage films of *p*-terphenyl molecules physisorbed onto the surface of graphite. The molecular arrangement within these films has been determined as a function of temperature and coverage. Analysis of the diffraction data reveals two-dimensional film structures where the molecules prefer a parallel orientation relative to the underlying substrate. Further examination provides evidence for an order-disorder phase transition within a monolayer film, temperature-dependent structural evolution within bilayer films, and structural variations based on film coverage. Initial dynamics results indicate a structural phase change in the temperature range 275-325 K. Below this temperature range, the scattering is consistent with phenyl ring reorientations around the long molecular axis. At elevated temperatures, the quasielastic signal is stronger and consistent with translational motion in combination with the phenyl ring reorientations.

**V12 12 Comparative STM study of azobenzene derivatives on bare and insulator coated metal surfaces** NIV LEVY, MATTHEW J. COMSTOCK, JONGWEON CHO, ARMEN KIRAKOSIAN, CARINE EDDER, JEAN M. J. FRECHET, FRANK LAUTERWASSER, JESSICA HARVEY, DIRK TRAUNER, M. F. CROMMIE, *Dept. of Physics, Dept. of Chemistry, UC Berkeley; Mat. Sci. Div, Lawrence Berkeley Natl. Lab* Photoactive molecules, such as azobenzene and its derivatives, have great potential for nanoscale opto-mechanical applications. However, one of the main difficulties in optical actuation of singe molecules at a surface is decoupling them from the electronic states of the substrate. One technique to accomplish this is to coat the substrate with a thin insulating layer, while another is to functionalize the molecule with ''spacer legs'' to lift it off the surface. We have conducted a comparative study of adsorption and self-assembly behavior of bare azobenzene, functionalized bis-tert-butyl-azobenzene, and functionalized tetra-tert-butyl-azobenzene molecules on bare and insulator coated metal surfaces using a variable temperature UHV STM. We observe a variety of temperature dependent molecular configurations, from which we infer the degree of molecule/surface decoupling due to surface modification and molecular functionalization.

**14:03**

**V12 13 Unoccupied electronic states at the interface of alkanethiol SAMs on Au(111)** MATTHIAS MUNTWILER, CHAD LINDSTROM, XIAOYANG ZHU, *University of Minnesota, Minneapolis* Alkanethiol self-assembled monolayers (SAMs) on Au(111) are model systems for metal-molecule contacts in molecular electronics. Using time-resolved two-photon photoemission (TR- 2PPE) we probe the unoccupied electronic structure of the alkanethiolate/Au interface. Two distinct peaks appear in

the spectra: The first, non-dispersive peak is attributed to the antibonding $\sigma^\star$ orbital of the Au-S chemisorption bond, and the second, dispersive peak to a laterally delocalized interfacial resonance induced by the image potential at the metal surface. Both peaks show lifetimes shorter than 30 fs. For the $\sigma^\star$ resonance such a short lifetime is expected due to the wavefunction overlap with the metal, whereas for the second resonance it is an effect of scattering at S atoms inside the molecular layer. In fact, the insensitivity of the energy level, dispersion, and lifetime to layer thickness suggests that the electron wavefunction is concentrated inside the dielectric layer close to the metal-molecule interface – in contrast to physisorbed alkanes where it is pushed out of the layer.

**SESSION V16: NANOTECHNOLOGY: BIOLOGICAL AND POLYMER**

**V16 1 Microfluidic device for bacterial genome extraction and analysis** PETER GALAJDA, ROBERT RIEHN, YAN-MEI WANG, JUAN KEYMER, *Department of Physics, Princeton University* IDO GOLDING, EDWARD C. COX, *Department of Molecular Biology, Princeton University* ROBERT H. AUSTIN, *Department of Physics, Princeton University* Although single molecule DNA manipulation and analysis techniques are emerging, methods for whole genome extraction from single cells, genomic length DNA handling and analytics is still to be developed. Here we present a microfabricated device to address some of these needs. This microfluidic chip is suitable for culturing bacteria and subsequently retrieve their genetic content. As a next step, the extracted DNA can be introduced in a nanostructured segment of the chip for precise handling, stretching and analysis. We hope that similar microdevices can be useful in studying genetic aspects of the cell lifecycle in a variety of organisms.

**11:27**
**V16 2 Virus-Mimetic DNA Encapsulation Using Novel ABC Triblock Copolymers** RAHUL SHARMA, YOU-YEON WON, *School of Chemical Engineering, Purdue University, West Lafayette, IN-47907* To address the challenge of developing a safe and effective delivery system currently faced in gene therapy technologies, our research explores a novel approach for improving DNA encapsulation and delivery using a novel three-component block copolymer which by design has the self-assembling properties tailored for virus-like encapsulation of DNA. Our approach utilizes an ABC triblock copolymer composed of (A) ithydrophilic poly(ethylene oxide) (PEO), (B) ithydrophobic poly(n-butyl acrylate) (PnBA) and (C) itcationic poly(ethyleneimine) (PEI). With such an ABC sequence of blocks, the C block primarily interacts with the negatively charged phosphates on DNA, and the viral capsid-like morphology of the nanometers-thick membrane can be derived from the A and B blocks at the outer surface of collapsed DNA. In this presentation, we will discuss our recent experiments that establish a proof of concept and processing strategies for achieving the desired virus-mimetic DNA-encapsulating morphology composed of a compact DNA core covered with a layer of protective coating created by the ABC triblock copolymer.

**11:39**
**V16 3 Electron Binding Energies in DNA Modified Surfaces: Theory and Experiment** JAMES SULLIVAN, *Virginia Commonwealth University* DMITRI PETROVYKH, *University of Maryland-College Park, Naval Research Lab* GEORGE SCHATZ, *Northwestern University* LLOYD WHITMAN, *Naval Research Lab* X-ray photoelectron spectroscopy is emerging as a powerful method for characterizing DNA on surfaces [1]. The relative positions of core electron binding energies (CBEs) suggest likely binding geometries and strength of chemical bonds, and the peak areas provide a quantitative measure of the coverage. Although CBEs for simple molecules can often be readily assigned to specific adsorption sites and bonding configurations based on historical data, such interpretation for CBEs of DNA is not generally possible. We are using density functional theory to determine the geometric and electronic configuration of DNA nucleobases, nucleosides, and nucleotides. We find the theoretical XPS spectra for isolated nucleic components are surprisingly similar to experimental spectra measured on DNA films, suggesting that—although the films are adsorbed on the surface—the underlying electronic structure of the nucleobases is ''free-like.'' 1. D. Y. Petrovykh, et al., J. Am. Chem. Soc. 125, 5219 (2003); D. Y. Petrovykh, et al., Langmuir 20, 429 (2004).

**11:51**
**V16 4 Sequencing by Hybridization with Noisy Inputs** RICHARD YEH, Sequencing by hybridization (SBH) is a proposed method for obtaining the base-by-base sequence of an unknown nucleic acid molecule in two steps: hybridization of fragments of the unknown DNA molecule to known subsequences, and reconstruction of the entire unknown sequence from the hybridization spectrum. Work in computer science has produced algorithms for the reconstruction process approaching information-theoretic bounds, but most treatments have ignored the effect of physical hybridization noise. I have been working on this problem by modeling the effect of noisy inputs on SBH algorithms and by calculating bounds on their reconstruction fidelity. This talk will give the progress of this effort.

**12:03**
**V16 5 Surface Electrophoresis of DNA on Microporous Materials** ELI HOORY, *Stony Brook University* ANDREW DUBITSKY, JOHN FRENNA, *Pall Corporation* MICHAEL DING, *Glen Cove High School* JONATHAN SOKOLOV, MIRIAM RAFAILOVICH, *Stony Brook University* PALL CORPORATION COLLABORATION, STONY BROOK UNIVERSITY TEAM, Separation of single strand DNA molecules on solid surfaces can potentially be used for genomic research and diagnostic applications. Feasibility of DNA electrophoresis on solid surfaces has been demonstrated using insulating and semi-conducting substrates. Microporous membranes can offer advantages in separation because of the variety of surface-DNA interactions and surface morphologies. Droplets of Lambda Hind III DNA were applied to surfaces containing 0.2 to 2ng DNA. Results showed that variations in the electric field and Tris Borate EDTA buffer concentration both affected efficiency of separation. Significant differences in separation were found between different membrane types, including polyethersulfone and polyvinylidene fluoride.

Better separation was obtained on low binding, small pore size membranes which could retain the DNA molecules on the surface. Further work includes sputter coating and other surface modifications of best candidate membranes to optimize efficiency of separation.

**12:15**

**V16 6 Design of Mao Tensegrity Triangles – Successful Prediction of Stable DNA Nanostructures.*** WILLIAM B. SHERMAN,† *Department of Chemistry, New York University* JENS KOPATSCH, *Department of Chemistry, New York University* PAMELA E. CONSTANTINOU, *Department of Chemistry, New York University* NADRIAN C. SEEMAN, *Department of Chemistry, New York University* One of the most promising motifs for crystal formation is the tensegrity triangle first developed by Mao and co-workers. This structure consists of three duplex domains ''woven'' across each other. Because the three edges of the triangle are not coplanar, it can serve as a fundamentally three-dimensional motif. This nonplanarity, however, makes the design of tensegrity triangles more complicated than most of the other DNA motifs built to date. We present a geometry-based method for estimating the strain associated with various tensegrity triangle edge lengths. Experiments confirm that the predicted low-strain structures form stably, while structures with strain larger than about 5% tend to form multimers easily.

**V16 7 Co-electrospinning of bacteria and viruses** WAEL SALALHA, *Faculty of Mechanical Enginnering* JONATHAN KUHN, *Faculty of Biology* SHMUEL CHERVINSKY, EYAL ZUSSMAN, *Faculty of Mechanical Enginnering, Technion* Co-electrospinning provides a novel and highly versatile approach towards composite fibers with diameters ranging from a few hundred nm down to 30 nm with embedded elements. In the present work, co-electrospinning of poly(vinyl alcohol) (PVA) and viruses (T7, T4, λ) or bacteria (Escherichia coli, Staphylococcus albus) was carried out. These preparations should have applications for tissue engineering, gene therapy, phage therapy and biosensing. The average diameter of the co-spun nanofibers was about 300 nm. We found that the encapsulated viruses and bacteria manage to survive the electrospinning process, its pressure buildup in the core of the fiber and the electrostatic field in the co-electrospinning process. Approximately 10% of the Escherichia coli and 20% of Staphylococcus italbus cells are viable after spinning. Approximately 5% of the bacterial viruses were also viable after the electrospinning. It should be noted that the encapsulated cells and viruses remain stable for two months without a further decrease in number. These results demonstrate the potential of the co-electrospinning process for the encapsulation and immobilization of bio-objects and the possibility of adapting them to technical applications (e.g., bio-chips).

**12:39**

**V16 8 The Design of Potent Liposome-Based Inhibitors of Anthrax Toxin** PRAKASH RAI, CHAKRADHAR PADALA, VINCENT POON, ARUNDHATI SARAPH, SALEEM BASHA, SANDESH KATE, KEVIN TAO, JEREMY MOGRIDGE, RAVI KANE, Several biological processes involve the recognition of a specific pattern of binding sites on a target surface. Theoreticians have predicted that endowing synthetic biomimetic structures with statistical pattern matching capabilities may impact the development of sensors and separation processes. We demonstrated for the first time that statistical pattern matching significantly enhances the potency of a polyvalent therapeutic – an anthrax toxin inhibitor. We functionalized liposomes with an inhibitory peptide at different densities and observed a transition in potency at an inter-peptide separation that matches the distance between ligand-binding sites on the heptameric subunit of anthrax toxin. Pattern-matched polyvalent liposomes neutralized anthrax toxin itin vitro at concentrations four orders of magnitude lower than the corresponding monovalent peptide. We also showed that polyvalent liposome-based inhibitors can neutralize a microbial toxin itin vivo. Statistical pattern matching represents a facile strategy to enhance the potency of therapeutics targeting toxins or pathogens. Our results also illuminate other fundamental aspects of polyvalent recognition –specifically we found that the efficiency of polyvalent inhibition is influenced by the competition between the rates of ligand dissociation and diffusion.

**12:51**

**V16 9 Submicrometer Hall sensors for detection of magnetic nanoparticles in biomolecular sensing*** GORAN MIHAJLOVIC, P. XIONG, S. VON MOLNAR, *MARTECH and Dept. of Physics, Florida State Univ.* K. OHTANI, H. OHNO, *Research Inst. of Electrical Communication, Tohoku Univ.* M. FIELD, G.J. SULLIVAN, *Rockwell Scientific Company LLC* Significant progress has been made in the recent years in synthesis and biomolecular functionalization of magnetic nanoparticles. These magnetic bio-nanolabels can be utilized as protein or gene markers in biomolecular sensing assays, in contrast to the much larger micron sized magnetic beads that are usually limited to cell labeling. However, the low magnetic moments of individual nanoparticles ($10^4$-$10^5$it$\mu_B$) render their sensitive detection still a challenging task. In order to address this issue we are developing miniaturized Hall sensors from InAs/AlSb quantum well semiconductor heterostructures with active Hall cross areas down to 300 nm $\times$ 300 nm. Our preliminary characterization measurements performed at room temperature show functional devices with magnetic field resolution $< 100\ \mu\mathrm{T}/\sqrt{\mathrm{Hz}}$ at frequencies above 100 Hz, yielding a moment sensitivity $\sim\ 10^5\ \mu_B$. In addition to the progress in improving the moment sensitivity of the submicrometer Hall detectors, we will also present efforts in device integration with on-chip microcoils for the generation of local magnetic excitation fields. Results on nanoparticle detection will also be presented.

**V16 10 Novel glucose biosensor based on organic thin-film transistors.** MARIA NIKOLOU, SEIICHI TAKAMATSU, DANIEL MACAYA, GEORGE MALLIARAS, *Department of Materials Science and Engineering Cornell University, Ithaca, NY*

GRACIELA BLANCHET, *Dupont, Central Research, Wilmington, DE* We report on a novel design of an organic thin-film transistor which utilizes a double channel transistor configuration. This electrochemical sensor-transistor is based on conducting polymers and operates at low voltages. The sensor response is measured as the drain-source current of one channel while a potential is applied on the other channel. The behavior of the transistor can be understood in terms of an electrochemical mechanism which is proven to depend on the ionic concentration of the electrolyte. The possible applications of these devices in biological sensing are explored as the advantages of their use are many, e.g. high sensitivity and selectivity, and low manufacturing cost. We present results from devices exploiting different conducting polymers, e.g. PEDOT:PSS, PANI, on a variety of substrates, e.g. glass, plastic, and demonstrate the capability of this type of device to sense glucose in a neutral pH buffer solution by a mechanism involving sensing of hydrogen peroxide. These devices can also be used effectively in the detection of other biological analytes.

**13:15**

**V16 11 Application of hydroxyapatite thin film as a biosensor*** HIROAKI NISHIKAWA, *B.O.S.T., Kinki Univ., CREST-JST, Wakayama PRef. C.R.E.A.T.E. of the JST* DAICHI OKUMURA, *B.O.S.T., Kinki Univ., CREST-JST* MASANOBU KUSUNOKI, SHIGEKI HONTSU, *B.O.S.T., Kinki Univ., CREST-JST, Wakayama PRef. C.R.E.A.T.E. of the JST* Hydroxyapatite (HAp) surface has an excellent ability of adsorption for functional biomolecules such as protein, DNA and so on. The surface electronic state of the HAp is affected by the adsorption of biomolecules. Thus, the electric properties of the surface such as resistivity and capacitance will vary. Because the property is effective for a receptor and transducer of biomolecule, we have investigated the application of the HAp as a suitable material for a biosensor. In this study, thin film of the sodium-doped HAp (Na-HAp) is prepared. The sodium doping is to decrease the resistivity of the HAp because the stoichiometric HAp is a good insulator. When bovine serum albumin of 1 ml was dropped to a Na-HAp thin film in a 100 ml pure water, the sample shows the drastic change of the AC resistance (at 120 kHz). This result shows that the Na-HAp will be one of the most effective materials for the biosensor applications.

*This study was supported by a grant from the Wakayama Prefecture Collaboration of Regional Entities for the Advancement of Technological Excellence of the JST.

**V16 12 Directed Diblock Copolymer Self-Assembly Using Engineered Topologies To Drive Defect Motion.** RICARDO RUIZ, CHARLES BLACK, ROBERT SANDSTROM, *IBM T.J. Watson Research Ctr.* Self-organizing materials hold great promise for delineating the critical nanometer-scale elements of future integrated circuits. While self assembly provides a pathway to defining sub-lithographic dimensions, its Achilles heel lies in minimizing defects. Unlike lithographic processes, self assembly involves optimization of thermodynamic free energy, which can require prohibitively long equilibration times and may never reach pattern perfection. We have begun to address this intrinsic limitation by engineering surfaces to influence the assembly process. In this way we eliminate defects in the critical device areas, while driving unavoidable imperfections to predefined, non-crucial regions. We discuss this approach within the context of lamellar-phase poly(styrene-b-methylmethacrylate) diblock copolymer films, which possess excellent material characteristics for use as lithographic templates. Understanding the dynamics of pattern formation in these materials is crucial to optimizing their performance. We use correlation length measurements of lamellar diblock copolymer domains to extract information about mechanisms of defect annihilation. We also quantify the quality of these self-assembled materials within a framework of resist performance metrics, including resist profile, line-edge roughness, and etch characteristics.

**V16 13 Conformational molecular architecture in alkylthiolate monolayer using atomic force microscopy electrostatic nanolithography** OLGA MAYEVSKA, SERGEI LYUKSYUTOV, *The University of Akron, OH* PAVEL PARAMONOV, *Georgia Tech University, GA* KAZUO UMEMURA, *Musashi Intitute of Technology, Tokyo, Japan* SHANE JUHL, RICHARD VAIA, *AF Research Laboratory, WPAFB OH* We propose a simple approach to form 50-nm raised structures based on conformational changes of organomercaptan molecules assembled in monolayer on surface of gold. Manipulation of amphifunctional molecules may be performed using a strong electric field ($10^8$-$10^{10}$ $Vm^{-1}$) induced by an atomic force microscope (AFM) tip. Such a field leads to rearrangement of alkylthiolates assembled on Au (111) resulting in nano-patterning of raised nanostructure (1.5-9 nm high, 20-50 nm wide) arrays on a second-time scale by manipulating the tip above the monolayer. It is suspected, that as a result of the oxidative cleavage initiated by a weak bias of the tip, the S-end of the chain carrying a sulfenium cation is attracted to the tip forming a bilayer, and the higher-layer structures in monolayer. Stabilization of the multiple-layered structures is accomplished via mutual attraction and entanglement of the hydrocarbon chains.

**13:51**

**V16 14 Neutron Reflectometry Measurements of the Depth Profile of Water in a Fuel Cell Membrane.** JOSEPH DURA, CHARLES MAJKRZAK, SUSHIL SATIJA, NORMAN BERK, *Center for Neutron Research, NIST, Gaithersburg, MD 20899* JON OWEJAN, THOMAS TRABOLD, *General Motors Corporation, Fuel Cell Activities, Honeoye Falls, NY 14472* Specular neutron reflectometry (NR) measurements have been performed on a prototypical polymer electrolyte membrane (PEM) for fuel cell application, e.g., Nafion. The samples were formed by spin coating onto a variety of substrates, and annealing in vacuum. The measurements are designed to reveal the water distribution across the thickness of the membrane material, as a function of relative humidity and for the case in which the film is in contact with a liquid water reservoir. Data from several samples indicates how the water profile for a given humidity changes with annealing temperature of the polymer film. Finally, we consider the application of phase-sensitive methods to eliminate potential ambiguity in the scattering length density profile of the membrane obtained from NR.

**SESSION V17: MEDICAL PHYSICS PANEL DISCUSSION**

**V18 1 2D Carbon Nanotube Network: A New Material for Electronics.**
GEORGE GRUNER, *University of California Los Angeles*

This talk will focus on the electronic properties of two dimensional carbon nanotube networks, and on their application potential. Percolation issues, together with the frequency, and temperature dependent activity will be discussed. The network can be tuned from having semiconducting to metallic like behavior, and doping with electron withdrawing and donating species leads to networks with tailor-made electronic properties. The network is also highly transparent in the visible spectral range, this attribute – together with simple room temperature fab processes – opens up application opportunities in the area of electronics, opto-electronics, photovoltaics and sensors. Recent results on solar cells, OLEDs and smart windows will be reviewed. Field effect transistors that incorporate nanotube network conducting channels, together with complex functional devices that incorporate networks and functional molecules will also be discussed. Finally a comparison will be made with conventional and emerging materials that compete area of disposable, flexible and printable electronics.

**V18 2 Understanding 1/f noise in carbon nanotube devices** YU-MING LIN, JOERG APPENZELLER, *IBM T. J. Watson Research Center* JOACHIM KNOCH, *Forschungszentrum Juelich* ZHIHONG CHEN, PHAEDON AVOURIS, *IBM T. J. Watson Research Center* Nanotubes and nanowires provide an ideal platform to study the electronic behavior of low-dimensional systems. Although a great deal has been learned about the electronic properties of nanotubes and nanowires, little is known about their noise characteristics. We have characterized the 1/f noise behavior of nano-devices consisting of individual single-walled semiconducting carbon nanotubes. Two types of carbon nanotube field-effect transistors (CNFETs) are fabricated and investigated in order to distinguish between the impacts of the contact and bulk channel on the noise. The first type of CNFET is a back-gated device where the conductance is entirely modulated by the Schottky barriers (SBs) at the nanotube/metal interfaces, while the second type of CNFET incorporates an additional gate electrode so that the device switching can be achieved through the bulk channel of the nanotube. We have also fabricated SB-CNFETs with very different channel lengths using a itsingle nanotube in order to elucidate the impact of scattering on 1/*f* noise. The results indicate that that 1/*f* noise in a 1D system with quasi-ballistic transport behavior provides a measure of the total number of transport carriers in the channel. Morover, the intrinsic 1/*f* noise amplitude of individual single-walled carbon nanotube is, in fact, not larger than that of most bulk materials.

**12:03**
**V18 3 Time-Dependent Transport in Carbon Nanotube Transistors*** YUPENG CHEN, *University of Central Florida* JING GUO, *University of Florida* THOMAS WU, *University of Central Florida* Recently, very high frequency properties of carbon nanotube field-effect transistors (FETs) are attracting extensive research interests due to their high mobility and near ballistic transport [1 – 4]. To explore the performance limit of CNTFETs for very high frequency applications, it is important to understand time-dependent transport in CNTFETs. Self-consistent, quasi-static quantum simulations have been applied to assess the high-frequency performance [4]. However, the validity of quasi-static approximation needs to be examined. In addition, a full-time dependent simulation is necessary to examine some very important characteristics, such as frequency-dependent conductance. Our

study on AC characteristics of CNTFETs is based on solving a full time-dependent quantum transport equation for CNTFETs using the finite difference time domain (FDTD) method for the first time. The dependence of small signal transconductance and gate capacitance on the frequency of the applied bias is examined. The intrinsic cut-off frequency, a device metric important for radio-frequency (RF) applications, and the intrinsic switching time, a metric important for digital switch applications, are computed using the full time-dependent simulations. The validity of the widely used quasi-static approximation is examined.

**V18 4 Carbon Nanotube Low Power Integrated Circuit.** ZHIHONG CHEN, JOERG APPENZELLER, YU-MING LIN, *IBM T.J. Watson Research Center* JENNIFER SIPPEL-OAKLEY, ANDREW G. RINZLER, *University of Florida, Physics Department* JINYAO TANG, *Columbia University, Department of Chemistry* SHALOM J. WIND, *Columbia University, Department of Applied Physics and Applied Mathematics* PAUL M. SOLOMON, PHAEDON AVOURIS, *IBM T.J. Watson Research Center* Identifying a material that can outperform silicon in terms of device density, power consumption and performance is one of the main goals of today's nano-electronics effort. Carbon nanotubes are considered to offer the greatest potential in this context. So far, the emphasis has been on fabricating and characterizing individual nanotube devices. A critical next step is the construction of integrated circuits. Complementary metal-oxide semiconductor (CMOS) technology is the dominant approach for microprocessors, memories, and many other applications, in particular due to its small power consumption. Here, we demonstrate the first CMOS-type, high performance, multiple components logic circuit based on a single carbon nanotube molecule.

**12:27**

**V18 5 Electron Transport in Carbon Nanotube Devices with Several Narrow Top-Gates** JOSEPH SULPIZIO, CHARIS QUAY, *Department of Physics, Stanford University* ZVONIMIR BANDIC, *Hitachi San Jose Research Center, Hitachi Global Storage Technologies* DAVID GOLDHABER-GORDON, *Department of Physics, Stanford University* Carbon nanotubes provide an excellent system for studying one-dimensional (1D) electron systems, known as Luttinger liquids. We report on the nanofabrication of carbon nanotube devices with several narrow top-gates, and provide initial electron transport measurements. Using the top-gates to induce tunable tunnel barriers within the nanotubes, we aim to probe electron-electron interactions by measuring transport across the devices. Fine control over the properties of such devices should enable the further study of other interesting quantum properties of 1D systems (e.g. spin-charge separation).

**12:39**

**V18 6 Probing Chemical Potentials in Solution with Carbon Nanotube Transistors** LISA LARRIMORE, *Laboratory of Atomic and Solid State Physics, Cornell University* SUDDHASATTWA NAD, *Department of Chemistry and Chemical Biology, Cornell University* XINJIAN ZHOU, *Laboratory of Atomic and Solid State Physics, Cornell University* HÉCTOR ABRUÑA, *Department of Chemistry and Chemical Biology, Cornell University* PAUL McEUEN, *Laboratory of Atomic and Solid State Physics, Cornell University* We have used single-walled carbon nanotube transistors to sense redox-active transition metal complexes in a conducting liquid environment. The molecules shift the gate voltage dependence of the nanotube conductance. This shift depends logarithmically on the ratio of oxidized to reduced molecules, which is changed and measured using traditional electrochemical methods. We attribute this signal primarily to the changing electrostatic potential of the solution as set by the water-gate wire, and not to a local interaction between the molecules and the nanotube.

**12:51**

**V18 7 Conductance switching in carbon nanotube transistors induced by electrochemical reactions** JAAN MANNIK, BRETT R. GOLDSMITH, ALEXANDER A. KANE, PHILIP G. COLLINS, *Department of Physics and Astronomy, University of California Irvine, Irvine, CA 92697-4576* Carbon nanotube transistors provide a promising architecture for studying biomolecular dynamics at the single molecule level. To achieve this goal, single bioactive molecules must be integrated into the circuits in a controllable and reliable way. While techniques can be borrowed from bulk chemical functionalization, we focus on the controlled production of a single, chemically-functional site on the sidewall of an operational nanotube transistor circuit. Our approach allows real-time, in situ monitoring of electrical signals from the transistor in order to discern reaction events. Using an electrochemical cell biased under oxidizing or reducing conditions, we have observed sharp, reversible conductance switching events consistent with single-site reactions. The reactions have well-defined electrochemical thresholds, which provides an electronic means to control their production. The dynamics of the switching events, including the rates and degree of reversibility, changes in different electrolyte solutions. This work is partly supported by NSF grant EF-0404057.

**13:03**

**V18 8 Integration of Carbon Nanotubes with III-V(110) Surfaces** LAURA RUPPALT, JOSEPH LYDING, *University of Illinois at Urbana-Champaign* We have used scanning tunneling microscopy (STM) to investigate the unique electronic and physical properties of individual isolated carbon nanotubes dispersed onto semiconducting III-V substrates in an ultrahigh vacuum (UHV) environment. Pristine III-V(110) surfaces were obtained through in situ cleavage, with single-walled carbon nanotubes (SWNTs) subsequently deposited via an UHV-compatible Dry Contact Transfer process[1]. Room temperature STM imagery confirms the intact transfer of individual tubes to the surface, while STM-enabled nanomanipulation suggests a substrate-induced stabilization of isolated SWNTs aligned along the (1bar 1 0) crystallographic direction, in registration with the substrate sublattice rows. Additionally, current image tunneling spectroscopy (CITS) maps of these SWNT/III-V(110) systems yield correlated topographic and electronic information with subnanometer resolution that provide evidence of the sensitivity of local nanotube electronic character to both inherent features of the nanotube as well as to proximal features of the underlying support substrate. **V18 9 Graphene Nanostructures, Fabrication, Physics and Devices.** LI LU, *Beijing National Laboratory for Condensed Matter Physics, and the Institute of Physics, Chinese Academy of Sci-*

*ences, Beijing 100080, China.* S. P. LIU, L. W. LIU, F. ZHOU, H. F. YANG, H. LI, Z. JIN, A. Z. JIN, J. MIAO, W. J. KONG, J. H. FANG, C. Z. GU, Y. X. WENG, Q. K. XUE, *Beijing National Laboratory for Condensed Matter Physics, and the Institute of Physics, Chinese Academy of Sciences, Beijing 100080, China.* S. WANG, L.-M. PENG, *Department of Electronics, Peking University, Beijing 100871, China.* B. JIANG, Q. S. ZHENG, *Department of Engineering Mechanics, Tsinghua University, Beijing 100084, China.* We propose to construct nanoelectronic circuits by directly tailoring graphite, and demonstrate the feasibility of this idea by fabricating specially designed multi-terminal graphene patterns down to a minimum strip width of 50 nm. Electron tunneling measurement confirms the formation of quasi-one-dimensional subbands due to the effect of quantum size confinement. This new approach would in the future provide an efficient way of producing numerous layers of identical graphene nanoelectronic circuits.

**13:27**

**V18 10 Electrical Transport in Carbon Nanotubes with Chirality Changes** B. CHANDRA, Y. WU, H. HAN, M. HUANG, L. HUANG, S. O'BRIEN, T.F. HEINZ, J. HONE, *Columbia University* We present electrical transport measurements of individual single-wall carbon nanotubes in which the chiral indices (n,m) are not fixed along the nanotube length. The nanotube structures are first probed by Rayleigh scattering spectroscopy, after which the tube is transferred to a substrate by a mechanical transfer process. Electrical leads are then fabricated by e-beam lithography. The transport behavior is measured in various sections of the tube to probe the behavior of the molecular junctions.

**V18 11 Miniature Organic Transistors with Carbon Nanotubes as Quasi-One-Dimensional Electrodes.** PENGFEI QI, ALI JAVEY, MARCO ROLANDI, QIAN WANG, ERHAN YENILMEZ, HONGJIE DAI, *Stanford University* As the dimensions of electronic devices approach those of molecules, the size, geometry and chemical composition of the contact electrodes play increasingly dominant roles in device functions. It is shown here that single-walled carbon nanotubes (SWNT) can be used as quasi one-dimensional (1D) electrodes to construct organic field effect transistors (FET) with molecular scale width (about 2 nm) and channel length (1 to 3 nm). An important feature owing to the quasi 1D electrode geometry is the favorable gate electrostatics that allows for efficient switching of ultra-short organic channels. This affords room temperature conductance modulation by orders of magnitude for organic transistors that are only several-molecules in length, with switching characteristics superior to similar devices with lithographically patterned metal electrodes. With nanotubes, covalent carbon-carbon bonds could be utilized to form contacts to molecular materials. The unique geometrical, physical and chemical properties of carbon nanotube electrodes may lead to various interesting molecular devices.

**V18 12 Microwave Conductivity of Single Wall Carbon Nanotube Arrays** C. HIGHSTRETE, MARK LEE, E.A. SHANER, F.E. JONES, A.A. TALIN, D.B. ROBINSON, P.M. DENTINGER, *Sandia National Laboratories* We have developed a coplanar waveguide (CPW) platform compatible with both broadband (0.01 to 50 GHz) microwave scattering parameter measurements and directed assembly of carbon nanotubes (CNTs) and semiconductor nanowires. Utilizing AC dielectrophoresis and lithographic masking techniques, single-wall CNTs prepared with single-stranded DNA as a surfactant were assembled in localized parallel arrays between CPW signal and ground electrodes. This places the CNTs parallel to the electric field in the propagating region where coupling to the CNT conductivity alters the impedance of the CPW. The conductivity of the CNT arrays is deduced from scattering parameter measurements before and after assembly of the CNTs. Preliminary measurements show that at least some types of CNT material have a small but definite high-frequency loss that increases with frequency. Sandia is a multi-program laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**V18 13 Computer Simulations for a Novel Topological Defect on Carbon Nanotube** TAKAZUMI KAWAI, *Fundamental and Environmental Research Lab., NEC Corp.* SUSUMU OKADA, *Inst. of Physics and Center for Computational Sciences, Univ. of Tsukuba* KEI KUWABARA, KOTA DAIGOKU, KYOKO NAKADA, *Dept. of Chemistry and Biological Science, Aoyama Gakuin Univ.* YOSHIYUKI MIYAMOTO, *Fundamental and Environmental Research Lab., NEC Corp.* Topological defects in carbon nanotubes do not just causes a nuisance to the nanotube devices, but they sometimes provide new and interesting properties to them. Since the defect physics of nanotube is just in the early stage of research, it is very important to verify the stability and electronic properties of such defects theoretically prior to experiments. Here, we performed TBMD simulations for defect formations by $C_2$ molecule irradiation. Although $C_2$ molecule often bounce back even with a high kinetic energy of $\sim$ 20 eV, it irradiates several famous defects such as mono-vacancy, di- vacancy, and also Stone-Wales defect. In similar simulations, we also found a novel defect structure, where $C_2$ molecule is incorporated into $sp^2$ network of nanotube. Thermal stability of the nanotubes with the defects is similar to that of intact ones. Interestingly, DFT-LSDA calculations showed that nanotubes with a line of the novel topological defects are found to cause a magnetic ordering, where the polarized electron spins are localized around the defect and ferromagnetically aligned along the tube axis. This work was in part performed under the management of Nano Carbon Technology project supported by NEDO.

**SESSION V19: THE CHANGING DYNAMICS OF INDUSTRIAL RESEARCH AS A CONSEQUENCE OF GLOBAL TRENDS (CO-SPONSORED BY APS AND AIP CORPORATE ASSOCIATES)**

**V19 1 General Motors' R&D: Managing Innovation Globally.**
ALAN TAUB, *Executive Director of R&D, General Motors Corporation*

The rapid pace of technology development and the globalization of the automobile industry are major forces driving General Motors to devise new ways to innovate faster and more efficiently. In response, GM has developed a global R&D network that has transformed GM's research and development organization from a U.S.-based enterprise to one that is over 30 percent leveraged with collaboration in 16 countries. This talk will focus on the challenges faced as well as the lessons learned and best practices developed in building this network.

**11:51**
**V19 2 Not only Texas is flat.**
HANS STORK, *Chief Technology Officer, Texas Instruments*

The internet communication infrastructure has been one of the main factors creating a ''flat'' world, a level playing field for innovation and the value of intellectual contributions. Furthermore, it has enabled a 24×7 frame of mind for development as well as manufacturing. Today it is therefore no longer optional but in fact a necessity to leverage skills and resources around the world, from research through production.

**12:27**
**V19 3 Micron R&D: Global Scope and Nano-Scale in N-Dimensions.**
MARK DURCAN, *CTO & VP Research and Development, Micron Technology*

The Globalization of world markets and the globally dispersed manufacturing that supports them, drives complexity in managing today's leading edge R&D organizations beyond that historically experienced. The dimensions involve not only location, but time, economics, government relations, complex supply and customer chains, and Intellectual Property strategy. Each must be contemplated and optimized in light of the nature of worldwide 24 hour a day competition.

**13:03**
**V19 4 Leap Ahead: Global R&D at Intel.**
ABEL WEINRIB, *VP and Director Corporate Technology Group, Intel Corporation*

Intel does research, development, and manufacturing for our products across the globe for a worldwide market. Get a glimpse into Intel's latest global R&D efforts driving future processor and platform architecture innovations; how these innovations could address existing user needs and enable new possibilities for emerging markets; and the challenges to managing an international research organization.

**13:39**
**V19 5 Sustaining Breakthrough Research in a Changing Global Environment.**
THOMAS FEIST, *Manager, Thin Films Lab, GE Global Research*

As companies face ever-increasing economic and competitive pressures, the imperative to deliver real, sustained growth through innovation is clear. Corporations need to develop and maintain a research and development portfolio that recognizes this reality. This talk examines how General Electric's Global Research Center is implementing a technology portfolio that balances long- and shorter-term RD across four global facilities. Examples from medical imaging and energy business segments will be used to illustrate strategies for delivering growth through sustained investment in technology.

**V20 1 Unusual Nuclear Spin Alignment in GaAs** JAMES McGUIRE, *NIST* TOM SILVA, *NIST* Time-resolved Faraday rotation experiments are used to measure nuclear spin polarization in GaAs due to hyperfine coupling with pumped electron spins. Both bulk and epilayer samples are examined. We find unusual dependence of the induced nuclear field on the cw pump power, the cw pump helicity, and the external magnetic field. Our results are compared with existing theories and experiments of the coupling of the electron and nuclear spin systems.

**11:27**
**V20 2 $^{69}$Ga Knight shift in semi-insulating GaAs observed by optically polarized NMR** KANNAN RAMASWAMY, *Washington University in St.Louis* STACY MUI, *Washington University in St.Louis* SOPHIA HAYES, *Washington University in St.Louis* Optical orientation in semiconductors continues to capture the attention of many researchers all over the world[1,2]. This is especially due to the emergence of a new area called ''spintronics'' where it is proposed that the spin of the electrons instead of its charge will be manipulated to create various devices. We report $^{69}$Ga optically polarized NMR investigations in semi-insulating GaAs at 6K. In our investigations, we have observed $^{69}$Ga Knight shifts for photon energies above and below the band gap. This observation is important in understanding the mechanism of NMR signal enhancement in semiconductors by polarized light. Our investigations also indicate that nuclear spin-diffusion plays a role in the NMR signal intensity for illumination times of the order of 100s and above. Furthermore, an estimate of $\sim$ 0.067 has been obtained for the average electron spin polarization which is 26% of the maximum achievable polarization in bulk GaAs. The cause for the reduction is under investigation. 1. Meier and B. P. Zakharchenya, Modern Problems in Condensed Matter Sciences, Vol 8, F. (1984) 2. **11:39**
**V20 3 Electrically induced changes to optical nuclear polarizations in bulk GaAs*** PATRICK COLES, ANANT PARAVASTU, JEFFREY REIMER, *University of California, Berkeley* The semiconductor crystal contains a spin refrigeration system, which turns on in the presence of near-band-gap laser light. Simultaneous application of a DC electric field to bulk, semi-insulating GaAs was observed to significantly alter the nuclear polarization process. At certain photon energies, the nuclear polarization inverted. Changes to nuclear polarization occurred upon the onset of nonlinear photoconductivity. Polarization in this regime could originate from electron spins that are perturbed first by the light and subsequently by relaxation with their (hot) momentum reservoir, while rapid spin-exchange equilibrates the electron spin reservoirs. The results suggest that a pathway towards localized optical and electric field control of nuclear spin may exist within bulk semiconductors.

**V20 4 Bias-dependent spin lifetimes in quantum wells.**
KIMBERLEY HALL, *Dalhousie University*

The prospect of novel high-performance spin-based semiconductor technologies has lead to new research in spintronics, in which the fields of electronics, photonics, and magnetics merge with the promise of applications in ultra-low-power logic architectures, non-volatile reprogrammable gate arrays, and optoelectronic technologies. Innovation in these areas requires the development of efficient methods for spin manipulation in semiconductor materials. Spintronic device architectures that do not require external magnetic fields or magnetic contacts are especially attractive as they would provide seamless integration with the materials and processing techniques of existing semiconductor devices, while avoiding undesirable stray magnetic fields that may hinder device performance. InAs is an excellent candidate for non-magnetic spintronic device applications due to its strong spin-orbit effects, which lead to gate-controllable pseudomagnetic fields in excess of 1 Tesla [1]. We report the demonstration of room temperature gate control over the electron spin dynamics using the Rashba effect in a (110) InAs/AlSb two-dimensional electron gas. Using the large pseudomagnetic fields in this system, we demonstrate spin manipulation on a picosecond time scale with a low threshold voltage.[1] Our findings are promising for the prospect of nonmagnetic low-power, high-speed spintronics.[2] This research is supported by DARPA MDA972-01-C-0002, DARPA/ARO DAAD19-01-1-0490, NSF ECS 03-22021, and NSERC. [1] K.C. Hall et al., Appl. Phys. Lett. 86, 202114 (2005). [2] K.C. Hall et al., Appl. Phys. Lett. 83, 2937 (2003).

**V20 5 Electron dephasing and decoherence of neutral donor bound electrons in GaAs** KAI-MEI FU, *Stanford University* SUSAN CLARK, *Stanford University* CHARLES SANTORI, *Hewlett-Packard Laboratories* BINGYANG ZHANG, *Stanford University* COLIN STANLEY, *University of Glasgow* M.C. HOLLAND, *University of Glasgow* YOSHIHISA YAMAMOTO, *Stanford University* Strong oscillator strengths, small inhomogeneous broadenings of the optical transitions, and semiconductor device integration possibilities make the GaAs donor-bound exciton (D0X) system an attractive candidate for electromagnetically induced transparency based applications. However, the recent observation of coherent population trapping in the GaAs D0X system indicates a fast (1-2 ns) dephasing rate of the bound- electron spin states which severely limits the achievable transparency. Theoretical and experimental research in other groups indicate the fast dephasing is due to the random nuclear spin environment in the GaAs lattice. We perform measurements of the electron Zeeman Raman transition linewidth which confirm the 1-2 ns dephasing rate. Using this technique, we study the effect of doping density and magnetic field on the Raman linewidth. Both variables can theoretically affect the inhomogeneous broadening due to the nuclear spin environment. If the inhomogeneous broadening can be decreased, spin-echo techniques should be possible to further increase the spin dephasing time to the homogeneous microsecond regime.

**12:39**

**V20 6 Temperature and doping dependence of spin-flip times in n-GaAs** JOHN COLTON, LEE WIENKES, MICHAEL HEEB, *University of Wisconsin-La Crosse* Previously-reported time resolved photoluminescence experiments [1] in lightly-doped n-GaAs have been extended to provide additional measurements of $T_1$ spin-flip times as a function of temperature and of doping density. The samples studied were MBE-grown 1 micron thick layers of doping densities from 3E14 $cm^{-3}$ to 3E15 $cm^{-3}$. The technique was to use a pump pulse to inject spin polarized electrons and a probe pulse to read out the polarization at some later time; spin flips caused the polarization to decrease exponentially with pump-probe delay. Some measured $T_1$ spin-flip times (at low temperature, at low doping densities) were even longer than the previously-reported 1 microsecond value. Work supported by NSF, ACS/PRF, and Research Corporation. [1] J.S. Colton et al., Phys Rev B 69, 121307(R) (2004).

**12:51**

**V20 7 Long-lived precession of spin gratings in *n*-doped GaAs** SAM CARTER, ZHIGANG CHEN, STEVEN CUNDIFF, *JILA and National Institute of Standards and Technology* Transient grating experiments have been performed in lightly *n*-doped GaAs to measure population and spin dynamics. In the presence of a magnetic field perpendicular to the optical axis (Voigt geometry), the spin grating precesses, leading to a diffracted probe signal that oscillates at twice the precession frequency. In contrast to previous experiments in undoped [1] and heavily doped [2] samples, the spin gratings last up to $\sim$ 1 ns at low temperatures, much longer than the lifetime of the photo-excited carriers. These results indicate that a spin grating is formed in the itinerant electrons, which decays due to spin relaxation and diffusion. By measuring changes in the grating decay rate with the grating period, the spin and population diffusion rates have been determined. Attempts to generate a spin grating without generating photo-excited carriers using Raman excitation will also be discussed. [1] A. R. Cameron, P. Riblet, and A. Miller, Phys. Rev. Lett. **76**, 4793 (1996). [2] C. P. Weber, N. Gedik, J. E. Moore, J. Orenstein, J. Stephens, and D. D. Awschalom, Nature **437**, 1330 (2005).

**V20 8 Spin dynamics in a GaAs quantum well with optically controlled charge density: localization vs. delocalization** ZHIGANG CHEN, SAM CARTER, RUDOLF BRATSCHITSCH, STEVEN CUNDIFF, *JILA, University of Colorado and National Institute of Standards and Technology, Boulder, CO 80309-0440, USA* PHIL DAWSON, *School of Physics and Astronomy, Sackville St Building, University of Manchester, Manchester, M60 1QD, England* We have studied electron spin dynamics in a mixed type I/type II quantum well (QW) structure, which consists of narrow and wide GaAs QWs separated by AlAs barriers. The electron (hole) densities in the wide (narrow) QW can be varied continuously over a wide range by low power photoexcitation at an energy above the narrow QW bandgap. We have performed time-resolved Kerr rotation measurements in the Voigt geometry to probe the electron spin dynamics in the wide QW. We measure two *g*-factors for electron spin precession, which we ascribe to the localized and delocalized electrons in the wide QW. Photoexcited holes, localized by the well-width fluctuations in the narrow QW, bind and localize the electrons in the wide QW. A study of the spectral dependence shows strong inhomogeneity of the localized electron *g*-factor, while the delocalized electrons have a constant *g*-factor. With increasing carrier density, the precession amplitude of the delocalized (localized) electrons increases (decreases) until only the delocalized electron precession can be observed at high density.

**13:15**

**V20 9 Coupling single bright spins with channels of intermediate dark spins in diamond*** FELIX M. MENDOZA, RONALD HANSON, RYAN J. EPSTEIN, DAVID D. AWSCHALOM, *Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106* The nitrogen-vacancy (N-V) center in diamond has garnered interest as a room-temperature solid-state system not only for exploring electronic and nuclear spin phenomena but also as a candidate for spin-based quantum information processing. Recent experiments reveal the coupling of a single bright electron spin of an N-V center to small numbers of dark electron spins of nitrogen defects in its immediate vicinity, not otherwise detected in luminescence[1]. We explore the possibility of utilizing this magnetic dipole coupling between bright and dark spins to couple two spatially separated single N-V center spins by means of intermediate dark nitrogen spins. The angle-resolved magneto-photoluminescence microscopy technique is extended to simultaneously detect a pair of single N-V centers a few microns apart.

*This work was supported by AFOSR, DARPA/MARCO, DARPA/CNID and ARO.

**V20 10 Anisotropic Interactions of a Single Spin and Dark-Spin Spectroscopy in Diamond*** R.J. EPSTEIN, F.M. MENDOZA, Y.K. KATO, D.D. AWSCHALOM, *Center for Spintronics and Quantum Computation, University of California, Santa*

*Barbara, CA 93106* Anisotropic spin interactions of single nitrogen-vacancy color centers in diamond are investigated at room temperature using angle-resolved magneto-photoluminescence microscopy.[1] Negative peaks in the photoluminescence intensity are observed as a function of both magnetic field magnitude and angle, and are modeled by coherent spin precession and anisotropic relaxation at spin-level anti-crossings. In addition, precise field alignment reveals the resonant magnetic dipolar coupling to nearby dark nitrogen spins, otherwise undetected by photoluminescence. The results present an avenue for transferring spin information between bright spins through the intermediate dark spins.

**V20 11 External strain engineering of the optical response of (Al,Ga)As/GaAs microdisk lasers** X. LI, M. H. MIKKELSEN, S. GHOSH, D. D. AWSCHALOM, N. SAMARTH, *Materials Research Institute, Penn State University and Center for Spintronics and Quantum Computation, University of California-Santa Barbara* Recent studies show that semiconductor microcavities provide unexpected ways of controlling electron spin coherence via light-matter interactions in confined geometries [S. Ghosh et al., cond-mat/ 0509500], suggesting new routes towards spin-based quantum information processing. Here, we use optical spectroscopy to study the effects of external strain on lattice-matched (Al,Ga)As/GaAs microdisk lasers. We demonstrate that the encapsulation of such lasers with $SiN_x$ allows systematic strain engineering of steady state optical characteristics, where measurements of spontaneous emission show that GaAs quantum wells in the active region of the microdisks experience strain from both the $SiN_x$ and the free standing disk shape, and measurements of stimulated emission show that the laser threshold decreases with the magnitude of net compressive strain. Further, we also explore related modifications in the electron spin coherence time. Work supported by DARPA/QUIST and NSF.

**13:51**

**V20 12 Polarized luminescence in silicon** FREDERIC ROUX, GEORGES LAMPEL, YVES LASSAILLY, JACQUES PERETTI,* Although silicon is a widely used semiconductor in the microelectronic industry, few studies habe been performed so far about its spin-transport properties. Creating and manipulating both spin and charge of electrons in silicon could be very promising in the research of convenient spintronic devices. One way to create and detect spin orientation of the conduction electrons is to perform a photoluminescence experiment under optical pumping conditions. We will present here a stationary photoluminescence experiment. Silicon samples of various doping concentrations, at nitrogen or room temperature, are optically pumped by a Ti:saphir laser. In silicon, the spin relaxation time is much shorter than the carrier life-time, thus yielding to a weak polarization of the recombination radiation. Polarization spectra under either modulated excitation or modulated reception have shown spectral regions where the degree of polarization of the luminescence can be as high as 5 percents. The possibility of a depolarization effect by a transverse magnetic field will be discussed (Hanle effect).

**14:03**

**V20 13 An Interferometric Approach to Time Resolved Faraday Rotation Measurements** J.M. LAFORGE, *University of Victoria* G.M. STEEVES, *University of Victoria* Time Resolved Faraday Rotation (TRFR) is an optical pump-probe technique used to detect electron spin precession about an external magnetic field in semiconductors. In TRFR a net electron magnetic moment can induce small rotations in the polarization of the probe beam, which are detected through a polarizing cube beam splitter and two balanced photodiodes. We present a new approach that divides the probe beam into two orthogonally polarized arms of a free-space Mach-Zender interferometer where one arm contains the sample being studied. Recombination of the probe beams optically amplifies the Faraday Rotation (FR) signal. There are two benefits to this approach; traditional samples can be probed at lower intensities while maintaining signal quality, and weak FR signals, such as those found in the spintronic studies of quantum dot materials, can be optically amplified before detection. Vibrational isolation and thermal stability are important operational factors since the optical gain can be affected by optical path length difference between the two arms of the interferometer.

## SESSION V21: LIQUID CRYSTALS II: NANO & BIO

**V21 1 A Phenomenological Model of the Effect of Magnetic Nanoparticles and Their Surface Coating on Smectic - A Liquid Crystal Order** LUZ J. MARTINEZ-MIRANDA, *University of Maryland, College Park, MD* LYNN K. KURIHARA, *Naval Research Laboratory, Washington, DC* KEVIN McCARTHEY, *University of Maryland, College Park, MD* JASON HARRY, *Xavier University, New Orleans, LA* ALEXIS NOEL, *Morgan State University, Baltimore, MD* We studied the interaction of a smectic-A liquid crystal with magnetic nanoparticles. The behavior of smectic-A liquid crystals with magnetic particles has not been very well characterized., especially where it concerns the effect of the particles' surface coating. The effect of this termination compound on the effect the nanoparticles have on liquid crystals, smectic or nematic, has not been systematically or consistently characterized. The surface coating is needed to ensure that the particles and the smectic liquid crystals do not phase separate. The surface coating in a nanoparticle is used in biological applications to identify a particular cell. We have found out that depending on the surface coating the interaction of the nanoparticles with the liquid crystal varies. This variation is related with how the surface coating aligns the liquid crystal and how it contributes to the concentration of the nanoparticles in the liquid crystal-nanoparticle mixture. This work was partially supported by NSF grant No. NSF-DMR-0080008.

**11:27**

**V21 2 Carbon nanotube liquid crystal composites*** REZA DODGE, SHIN-WOONG KANG, SATYENDRA KUMAR, *Department of Physics, Kent State University, Kent, Ohio 44242* CHEOL PARK, MIA SIOCHI, *National Institute of Aerospace, Hampton, VA 23666, Advanced Materials and Processing Branch, NASA Langley Research Center, Hampton, VA 23681* The miscibility of carbon nanotubes (CNTs) in thermotropic liquid crystals is extremely low, yet they can have marked influence on the properties of their host medium. We mixed very small amounts of multi-walled CNTs in a number of cyanobiphenyl mesogens and measured the dielectric and electro-optical properties, and studied the optical textures of the composites. The homeotropic samples show a unique texture, under polarizing microscope, which indicates that the nanotubes behave as line singularities with the strength of +1. The distorted alignment around these singularities covers a limited range, which is comparable with the sample thickness. The results of experiments on composites with various concentrations of CNT will be presented.

**V21 3 Organization of Magnetic Nanowires via Elastic Forces in a Periodic Multi-Domain Nematic Liquid Crystal*** CLAYTON LAPOINTE, DANIEL REICH, ROBERT LEHENY, *Johns Hopkins University* An anisotropic particle suspended in a thermotropic nematic liquid crystal imposes an elastic energy cost on the nematic that depends on the orientation of the particle relative to the nematic director. In a nematic with a spatially varying director field, such a particle can hence experience translational forces that depend on its orientation. We report experiments in which we exploit these forces to organize ferromagnetic Ni nanowires suspended in the nematic 4-pentyl-4-cyanobiphenyl (5CB). Using lithographic techniques to pattern the nematic anchoring conditions on substrates, we generate periodic multi-domain nematic environments for the wires. With their orientation controlled by a small external magnetic field, the wires sediment to preferred domains to minimize elastic energy.

**11:51**

**V21 4 Liquid Crystal Alignment Induced by a Magnetic Field and the Associated Surface Memory Effect*** RUI GUO, QINGBING WANG, SATYENDRA KUMAR, *Department of Physics, Kent State University, Kent, Ohio 44242* YURI REZNIKOV, *Institute of Physics of National Academy of Science, Prospect Nauki 46, Kyiv 252022, Ukraine* Nematic liquid crystals, 4, 4'-n-pentylcyanobiphenyl (5CB) and a commercial mixture, *E*7, have been found to align in thin cells prepared by cooling from the isotropic phase in the presence of a strong magnetic field parallel to the ITO coated glass substrates. The field induced alignment is very stable and possesses surface memory effect [1]. Surprisingly, the azimuthal anchoring energy is as high as $10^{-3}$erg/cm$^2$ and comparable to that obtained for rubbed polymer alignment layers. The surface memory effect is thermally stable and cannot be erased even after holding the cell more than 40K above the clearing point for up to two hours.We believe that the magnetic field directed rearrangement of the LC molecules adsorbed [2] at the substrate is responsible for the observed behavior. **V21 5 The Study of the Fluorescent Spectrum of Cd-Se Quantum Dots in Liquid Crystal Cell*** YU-SUNG LIN, *Department of Physics, National Sun Yat-sen University, Kaohsiung, 804, Taiwan* WEN-CHI HUNG, WOOD-HI CHENG, *Institute of Electro-Optical Engineering, National Sun Yat- sen University, Kaohsiung, 804, Taiwan* I-MIN JIANG, *Department of Physics, National Sun Yat-sen University, Kaohsiung, 804, Taiwan* MING-SHAN TSAI, *Department of Applied Physics, National Chiayi University, Chiayi, 600, Taiwan* We report the analysis of the fluorescent spectrum of Cd-Se quantum dots in liquid crystal matrices. The cell is filled with the commercial liquid crystal (E7) in homogeneous alignment. We can vary the director field orientation of liquid crystals by applying electrical fields. With a light source of a xenon lamp to excite the Cd-Se quantum dots, the effect on the fluorescent spectrum due to liquid crystal environment is then explored. The shift of fluorescent spectrum affected by the concentration of Cd-Se quantum dots is also discussed in the report. Then the Cd-Se quantum dots are excited by use of a monochromatic Nd-YAG laser, which is a polarized light source. We explore the effects of polarization on fluorescent spectrum of Cd-Se quantum dots also.

**12:15**

**V21 6 Transmissive Fabry-Perot Spectrum of Liquid Crystal Device for measuring the Surface Plasmon Effect of Silver nano-Particle*** WEN-CHI HUNG, *Inst. of Electro-Optical Engr., Natl. Sun Yat-sen Univ.,Taiwan* YU-SUNG LIN, *Dept. of Physics, Natl. Sun Yat-sen Univ., Taiwan* MING-SHAN TSAI, *Dept. of Applied Physics, Natl. Chiayi Univ., Taiwan* I-MIN JIANG, *Dept. of Physics, Natl. Sun Yat-sen Univ., Taiwan* WOOD-HI CHENG, *Inst. of Electro-Optical Engr., Natl. Sun Yat-sen Univ.,Taiwan* A Fabry-Perot scheme for measuring the surface plasmon effect of Ag nano-particles has been presented. As an optical spectrum ananlyzer, the resolution of the Fabry-Perot etalon.is determined by the morphology of reflectors and resonated cavity of the etalon. Ag nano-particles of size 50 nm are deposited on the surfaces of two reflectors. The cavity is filled with liquid crystals which are homogeneous alignment. Because the surface plasmon effect (SPE) of metal nano particles is sensitive to the polarization of incident light (P-wave or S-wave), we apply various polarization lights to explore the spectra of Fabry-Perot etalon filled with liquid crystal to study the SPE of metal nano-particles. In the transmissive spectra, we find the wavelength shift at the peak (603 nm) is about 8 nm when the probed light is changed from P-wave to S-wave. Comparing the measurements of the etalon without filled with the liquid crystal; we discuss the correlation of the wavelength shift and SPE of Ag nano-particles in the liquid crystal etalon device.

**V21 7 Investigating mixtures of rotor molecules and liquid crystals by dielectric spectroscopy and optical microscopy** DEBRA KRAUSE, CHARLES T. ROGERS, *Dept. of Physics, University of Colorado, Boulder* JOSE E. NUNEZ, MIGUEL GARCIA-GARIBAY, *Dept. of Chemistry and Biochemistry, University of California, Los Angeles* Rotor molecules are fundamental in nanotechnology. These molecules are synthesized with one part of the molecule designed to freely rotate while other parts are attached to a surface or within a crystalline super-structure. One class of rotor molecules have fluorobenzene rotors surrounded by bulky triphenyl groups. Studies of these electric dipole rotors in a crystalline state have shown that steric interactions between neighboring molecules can result in large energy barriers (up to 21 kcal/mol) that inhibit motion of the rotor. In an effort to free the rotor but maintain degrees of order in position and orientation, we mix these molecules with liquid crystals, particularly those based on benzylidene-(4-phenylazo-phenyl)-amine. The rotor molecules can dissolve in these liquid crystals into solutions of up to 20 percent by mass. To characterize the environment of the rotor, we study the mixtures using dielectric spectroscopy and optical microscopy.

**12:39**

**V21 8 Flexible plastic cells fabricated using phase separation of liquid crystal from its mixture in a prepolymer*** QINGBING WANG, RUI GUO, SATYENDRA KUMAR, *Department of Physics, Kent State University, OH 44240* During phase separation of liquid crystal (LC) from its mixture in a prepolymer, in a cell, the prepolymer accumulates near the spacers. After the phase separation is complete, UV irradiation is used to crosslink the polymer thereby fixing the position of the spacers and bonding them to the substrates. We employ this method to create polymer-embedded spacers to improve cell gap uniformity for LC displays using plastic substrates. Spacers remain adhered to their initial positions thus preventing them from movement or aggregation during temporary cell deformation. Scanning electron microscopy was employed to evaluate the internal polymer morphologies formed under different polymerization conditions. Electro-optical performances and the flexibility of plastic LC cells were determined and the details will be presented.

*Supported by a grant from Samsung Electronics Corporation

**V21 9 Adding Mono- and Multivalent Ions to Lyotropic Chromonic Liquid Crystals** LUANA TORTORA, HEUNG-SHIK PARK, KELLY ANTION, CHRIS WOOLWERTON, DANIELE FINOTELLO, OLEG LAVRENTOVICH, *Kent State University* Lyotropic Chromonic Liquid Crystals (LCLCs) are a distinct class of liquid crystals formed in aqueous solutions by molecules with rigid polyaromatic cores and ionic groups at the periphery [1-4]. The phase diagrams of these materials should depend on entropic factors (as in the Onsager model) and electrostatic interactions. Using optical polarizing microscopy, we studied the effects of mono- and multivalent ions on the phase diagrams of Blue 27 [3] and Sunset Yellow [2]. The monovalent ions change the temperatures of phase transitions, as described in [4], while the effect of multivalent ions is more dramatic and, in addition to the changed temperatures of phase transitions by tens of degrees, it often involves condensation of LCLC aggregates into domains with birefringence much higher than that in a normal nematic phase. Work supported by OBR B-7844. [1] J. Lydon, Current Opin. Colloid & Interface Sci. **3**, 458 (1998);**8**, 480-489 (2004); [2] V. R. Horowitz, L. A. Janowitz, A. L. Modic, P. J. Heiney, and P. J. **13:03**

**V21 10 Building Shape Surfactants: Creating rod-coil complexes using genetically engineered viruses** PHIL HUANG, SETH FRADEN, *Brandeis University* Complex self-assembled structures (micelles, lamellar phases) are often found in dispersions of amphiphilic molecules like surfactants. We genetically engineered M13 bacteriophage, a long filamentous particle that forms liquid crystalline phases, and coupled a 15 base pair oligonucleotide to one end of the virus. A plasmid DNA fragment was then ligated to the oligonucleotide to form a rod-coil particle. Based on the above complex conjugate, we are attempting to create supramolecular liquid crystalline structures.

**V21 11 Stretching the limits of membrane charge density using Dendrimer Lipids - New Highly Transfecting Hexagonal Phases for Gene Delivery** KAI EWERT, ALEXANDRA ZIDOVSKA, HEATHER M. EVANS, CYRUS R. SAFINYA, *Materials, Physics, and Molecular, Cellular and Developmental Biology Departments, UCSB, Santa Barbara, CA 93106* Newly designed multivalent lipids ranging in head group charge from 4+ to 16+ have been synthesized and investigated as DNA delivery vectors. These dendritic lipids (DLs) allow a controlled study of the relationship between membrane charge density ($\sigma$) and transfection efficiency (TE). An earlier report from our group described that TE of different cationic lipids of charge 1+ to 5+ follows a common, bell shaped curve as a function of membrane charge density [1]. To further probe this universal behavior, the dendritic lipids with higher valence were designed in order to reach higher values of $\sigma$. Structural studies using x-ray diffraction reveal new phases, where cylindrical micelles of DLs form a hexagonal lattice which holds together a continuous DNA network, described as $H_I^C$ [2]. The new hexagonal phase is highly transfecting in the regime where the TE of lamellar complexes follows a decrease in the bell curve. Small angle x-ray scattering studies have revealed a rich phase diagram of micelles made from DL/DOPC mixtures. Funding provided by NIH GM-59288 and NSF DMR-0503347. [1] A. Ahmad et al., itJ. Gene Med., 2005, V7:739-748. [2] K. Ewert et al., itJ. Am. Chem. Soc., (submitted).

**V21 12 Hollow Rectangular Columnar Structure in Dendritic Supramolecular Assemblies*** MIHAI PETERCA, PAUL HEINEY, *Dept. of Physics, Univ. of Pennsylvania* MARC ILIES, ANDRES DULCEY, SAMI NUMMELIN, VIRGIL PERCEC, *Dept. of Chemistry, Univ. of Pennsylvania* Hollow columnar phases have recently attracted interest for their potential applications as channel mimics in membrane transport, as photonic band gap materials, and for selective encapsulation. The first dendritic structures that self-assemble into hollow rectangular phases have been synthesized and a method for their structural analysis by x- ray diffraction experiments has been developed. The structural analysis method developed allows the calculation of the pore separation,

shape and size, creating new opportunities for separation processes of symmetric or asymmetric compounds.

**13:39**

**V21 13 X-Ray Determination of the Structure and Phases of Liquid Crystals of Nanoscale Duplex DNA** MICHI NAKATA, *U. of Colorado* GIULIANO ZANCHETTA, *U. of Milano (IT)* CHRISTOPHER JONES, *U. of Colorado* BRANDON CHAPMAN, *Brookhaven National Lab.* RONALD PINDAK, *Brookhaven National Lab.* TOMMASO BELLINI, *U. of Milano* NOEL CLARK, *U. of Colorado* Polymeric DNA chains are known to exhibit chiral nematic and hexagonal columnar LC phases. Recently we found that even very short duplex B-DNA oligomers 6-basepairs (bp) to 16-bp in length also form nematic and columnar phases depending on the concentration of DNA. To investigate the structure of those phases, we used micro-beam x-ray diffraction (10 micron spot size), enabling the study of single LC domains. In the columnar phases of 8bp, 12bp and 16bp all shows reflection spots corresponding to 20/*AA* which almost the same length scale of the width of DNA double helix. By selecting a proper orientation of the domains the diffraction pattern shows a hexagonal packing of columns of spacing which does not depend on the length of the basepair. On the other hand, there is no clear diffraction in the chiral nematic phase, which indicates that there is no significant highly ordered molecular aggregation. Those data indicate that short oligomers stack end- to end to form flexible rod-shaped DNA aggregates can then form LC phases. Work supported by NSF MRSEC Grant DMR 0213918 and NSF Grant 0072989.

**13:51**

**V21 14 Probing the mechanical unzipping of DNA** NIKOS K. VOULGARAKIS, ALAN R. BISHOP, KIM O. RASMUSSEN, *Theoretical Division and Center for Nonlinear Studies, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA* Recent advances in single-molecule force spectroscopy have made a systematic study of local melting in DNA possible. This provide new insight into important biological processes as replication and transcription. In this work, we present an extensive study of the micromechanical unzipping of DNA in the framework of the Peyrard-Bishop-Dauxois (PBD) model. The force required to separate the doubled strand is derived through analysis of the force-extension curve, while an estimation of the nucleation bubble size of the unzipping process is obtained by the distribution of the rapture force. Our findings are in very good agreement with existing experimental results; for example the force-temperature phase diagram obtained by the PBD model agrees excellently with recent constant-force experimental measurements of the lambda-phage DNA. Fundamental differences between the in vivo and vitro DNA unzipping, as predicted by the PBD model, are also discussed.

**V21 15 Asymmetrical binding of cationic peptides onto an oppositely-charged lipid-bilayer membrane: area expansion and membrane rupture*** SATTAR TAHERI-ARAGHI, BAE-YEUN HA, *Department of Physics, University of Waterloo, Ontario N2L 3G1, Canada* We study asymmetrical binding of cationic peptides onto a negatively charged lipid-bilayer membrane. The peptide not only interacts electrostatically with anionic lipids, rearranging their spatial distributions, but it can also insert hydrophobically into the membrane, expanding the area of its binding layer (i.e., the outer layer). We examine how peptide charges and peptide insertion (thus area expansion) are intertwined. Our results illustrate why high valences are required for selective toxicity of antimicrobial peptides, (i.e., they selectively rupture bacterial membranes while leaving host cells intact).

**V22 1 From ballistic transport to tunneling in electromigrated ferromagnetic breakjunctions** KIRILL BOLOTIN, F. KUEMMETH, A.N. PASUPATHY, D.C. RALPH, *Cornell University* We fabricate ferromagnetic constrictions whose cross section can be reduced gradually from $100 \times 30$ nm$^2$ to the atomic scale and eventually to the tunneling regime by means of electromigration. The contacts are attached to non-magnetic substrates and are measured at 4.2 K, so they are much more mechanically stable than previous room-temperature studies. We measure magnetoresistances (MR) $< 3\%$ for contacts $< 400\ \Omega$, consistent with previous experiments. As the contact diameter is reduced in the range $400\ \Omega$ - $25\ k\Omega$, we observe reproducible non-monotonic changes in the MR. We find first a minimum in the MR and sometimes a change in sign to small negative values, and then a strongly increasing positive MR as the contact approaches the atomic scale ($\sim 25\ k\Omega$). For near-atomic-sized constrictions the maximum MR is 80%. Measurements as a function of the direction of applied magnetic field allow us to separate the contribution of anisotropic magnetoresistance from the MR due to a domain wall. In the tunneling regime the MR fluctuates over a wide range, $-10\%$ to 85%, even for small changes in the atomic structure in a single device.

**11:27**

**V22 2 Magnetoresistance in oxidized Ni nanocontacts** D. JACOB, *Universidad de Alicante* J. FERNANDEZ-ROSSIER, J. J. PALACIOS, Whether or not ferromagnetic nanocontacts display large magnetoresistance (MR) is still a matter of debate [1,2]. From the theory side it has been shown[3] that MR in pure Ni nanocontacts is certainly not large in good agreement with recent experiments [2]. Here we explore the effect of oxygen atoms in the electronic structure and transport of nickel nanocontacts. Since bulk nickel oxide is an insulating antiferromagnets, nano-oxidized nickel is an interesting system on its own. Here we present ab-initio quantum transport calculations of Ni nanocontacts in the presence of oxygen adsorbates in the contact region. We show that the presence of a single oxygen atom leads to strongly spin-polarized transport for parallel alignment of electrodes magnetizations while for antiparallel alignment the conduction is strongly

suppressed resulting in large MR. (1) H. D. Chopra, Nature Materials 4, 832 (2005) (2) K. I. Bolotin et al., cond-mat/0510410; W. F. Egelhoff et al., J. Appl. Phys. 95, 7554 (2004) (3) D. Jacob et al., Phys. Rev. B 71, 220403(R) (2005)

**V22 3 Bias dependent oscillations in spin polarized tunneling*** CASEY MILLER,† *Physics Dept., Univ. Calif. San Diego* JOHAN AKERMAN, *Dept. of Materials Physics, Royal Institute of Technology, Electrum 229, 164 40 Kista, Sweden* ZHI-PAN LI, *Physics Dept., Univ. Calif. San Diego* IVAN K. SCHULLER, *Physics Dept., Univ. Calif. San Diego, 9500 Gilman Dr., La Jolla CA 92093* We investigated the bias dependence of spin polarized tunnelling in (pinned)CoFeB/ MgO/(free)CoFeB and (pinned)CoFeB/ MgO/(free)NiFe tunnel junctions as a function of temperature and applied field angle. The differential magnetoresistance (MR) exhibits oscillations about zero MR when the free layer of the asymmetric devices is above +0.7 V; no oscillations were observed for negative bias. Oscillations were not observed for any bias in the symmetric devices. The zero-crossing voltages were independent of temperature and relative magnetization angle between the two ferromagnetic layers. A model using spin-split free electron energy bands in the ferromagnets and a trapezoidal tunnel barrier demonstrates qualitative agreement with the experimental data.

**V22 4 Negative spin polarization in Co|$SrTiO_3$|Co magnetic tunnel junctions**[1] J. VELEV, K. BELASHCHENKO, *University of Nebraska - Lincoln* D. STEWART, *Cornell University* M. VAN SCHILFGAARDE, *Arizona State University* S. JASWAL, E. TSYMBAL, *University of Nebraska - Lincoln* We perform an itab-initio study of spin-polarized tunneling in epitaxial Coit |$SrTiO_3$|Co magnetic tunnel junctions with bcc Co(001) electrodes. We predict a large tunneling magnetoresistance in these junctions, originating from a mismatch in the majority- and minority-spin bands both in bulk bcc Co and at the Co|$SrTiO_3$ interface. The intricate complex band structure of $SrTiO_3$ enables effcient tunneling of the minority *d*-electrons which causes the spin polarization of the Co|$SrTiO_3$ interface to be negative in agreement with experimental data[2]. Our results indicate that epitaxial Co|$SrTiO_3$|Co MTJs with bcc Co(001) electrodes is a viable alternative for device applications. [1] J. Velev et al., Phys. Rev. Lett. **95**, 216601(2005). **V22 5 Probing spin-dependent tunneling and transmission below the Fermi level with a p-type magnetic tunnel transistor.** B.G. PARK, T. BANERJEE, B.C. MIN, J.C. LODDER, R. JANSEN, *MESA + Institute for Nanotechnology, University of Twente, The Netherlands* A magnetic tunnel transistor (MTT) can be used to probe spin-polarized tunneling involving states away from the Fermi level, as well as spin-dependent transmission of nonequilibrium carriers in a ferromagnet. Here we have used a p-type MTT, in which the magnetocurrent (MC) is determined by the tunnel spin polarization of the states below the Fermi level, and the spin-dependent scattering of hot holes in the magnetic base. For p-type MTT's with the structure p-Si/Au/Co/$Al_2O_3$/NiFe and large Co base thickness (8nm) and/or large emitter bias, the MC has the usual positive sign. Thus, the transmission of holes in the majority spin band of Co is larger than that of minority spin holes. Surprisingly, for smaller Co thickness and bias near the collection threshold (0.3 eV), the MC reverses sign and becomes negative. This unusual result shows that the Co interfaces preferentially transmit carriers of minority spin. With help of specifically designed MTT's and ab-initio calculations we discuss possible contributions of spin-dependent transmission across Au/Co interfaces in the base, and of a negative tunneling spin-polarization of the Co/$Al_2O_3$ interface for states below the Fermi level.

**12:15**

**V22 6 Spin-polarized tunneling time for non-centrosymmetric photonic barriers with out-of-plane magnetization.*** ION BITA, EDWIN THOMAS, *Dept. of Materials Sci & Eng, Massachusetts Institute of Technology* Tunneling barriers that lack space-inversion and time-reversal symmetries along the tunneling axis are found to display fundamentally different tunneling dynamics properties than normally expected. In a model 1D photonic crystal barrier, we show that the two symmetry constraints lead to indirect photonic band gaps which contain eigenmodes that are complex, with nonzero and frequency dispersive real components of their wavevectors. These nonpropagating modes are circularly polarized, and appear as complex conjugate pairs for opposite decay directions. We show that the Hartman effect does not apply, and that the tunneling phase time becomes dependent on barrier length, with, remarkably, the sign of the group delay changing with spin. The tunneling phase time for finite barriers of varying widths is found to agree with the group-like velocity, $1/v_g$ = dRe $\{k_{gap}\}/d\omega$, of the gap eigenmodes of the photonic crystal. The implications of these results for the case of spin-polarized electronic tunneling in noncentrosymmetric barriers (e.g. GaAs-like semiconductors, or chiral carbon nanotubes) with magnetization along the tunneling axis will be discussed.

**V22 7 Spin-Polarized Electron Transport through Nanometer-Scale Al Grains** LIYUAN ZHANG, *School of Physics, Georgia Tech* We had investigated the spin-polarized electron tunnelling through ensembles of nanometer scale Al grains embedded between two Co-reservoirs at 4.2K, and observed tunnelling-magnetoresistance (TMR) and the Hanle effect. The Spin-coherence time ($T2$), measured from the Hanle effect, is around nanoseconds. Fast dephasing is attributed to electron spin-precession in the local fringing fields. Dephasing does not destroy TMR, in contrast to spin-relaxation. itTMR is strongly asymmetric with bias voltage, which we explain by spin-relaxation.

**12:39**

**V22 8 Electron-magnon coupling and non-linear tunneling transport in magnetic nanoparticles** LUKASZ MICHALAK, *Kalmar/Lund University, Sweden* CARLO M. CANALI, *Kalmar University, Sweden* VINCENZO G. BENZA, *Universita' dell'Insubria, Como, Italy* We present a theory of single-electron tunneling transport through a ferromagnetic nanoparticle in which particle-hole excitations are coupled to spin collective modes. The model employed to describe the interaction between quasiparticles and collective excitations captures the salient features of a recent microscopic study. Our analysis of nonlinear quantum transport in the regime of weak coupling to the external electrodes is based on a rate-equation formalism for the nonequilibrium occupation prob-

ability of the nanoparticle many- body states. For strong electron-boson coupling, we find that the tunneling conductance as a function of bias voltage is characterized by a large and dense set of resonances. Their magnetic field dependence in the large-field regime is linear, with slopes of the same sign. Both features are in agreement with recent tunneling experiments.

**12:51**

**V22 9 Point Contact Spin Spectroscopy of Ferromagnetic Fe3Si epitaxial Films** Y.H. CHIU, *Dept. of Phys., National Tsing Hua Univ.* T.W. CHIANG, *Dept. of Phys., National Taiwan Univ.* S.Y. HUANG, S.F. LEE, *Inst. of Phys., Academia Sinica* J. KWO, *Dept. of Phys., National Tsing Hua Univ.* We report transport study of ferromagnetic $Fe_3Si$ epitaxial films using point contact Andreev reflection technique. $Fe_3Si$ is a ferromagnetic metal with a high Curie temperature of 840K and nearly lattice-matched to GaAs. The Heusler-like structure makes it a good candidate of half metals for spintronics. The observed spectra of Nb and NbTi/$Fe_3Si$ point contacts using a Nb or NbTi etched tip are often broad, along with the presence of sharp dips at the superconducting Fermi energy possibly attributed to the proximity effect occurring at the interface of the contact. Using a modified Blonder-Tinkham-Klapwijk theory, the data analysis gave a spin polarization ranging from 27% to 47% under various contact conditions. The best-fit gave P= 41%, Z= 0.05, =1.49 meV at 2K. Since the thickness of our $Fe_3Si$ samples are often small, current distribution effects in the probed layer are specially considered by varying the sample thickness.

**V22 10 Magneto−Optical Ellipsometry on $Ni_2MnIn$ and NiMnIn Heusler Alloys** GERD NEUBER, JAN SCHOLTYSSEK, MARTA BASTJAN, *University of Hamburg* RALF RAUER, *Chalmers University of Technology* ULRICH MERKT, MICHAEL RÜBHAUSEN, GUIDO MEIER, *University of Hamburg* We use generalized magneto-optical ellipsometry [1,2] for measurements of the complete dielectric tensor of $Ni_2MnIn$ [3] and NiMnIn Heusler alloys in the energy range from 1.6 eV to 5.5 eV and in the temperature range from 50 K to 450 K. Generalized magneto-optical ellipsometry allows the investigation of spin-polarized states and to understand the coupling between spin and charge degrees of freedom. We show differences in the metallic behavior of the semi-Heusler alloy NiMnIn and the full-Heusler alloy $Ni_2MnIn$ related to the half-metallic ferromagnetism of the latter one. The polycrystalline $Ni_2MnIn$ and NiMnIn films were co-evaporated from two independent sources of Ni and MnIn on a Si(100) substrate under UHV conditions. The $Ni_2MnIn$ alloy exhibits the ordered $L2_1$ crystalline structure and the NiMnIn alloy has a $C1_b$ structure. [1] A. Berger and M. Pufall, Appl. Phys. Lett. **71**, 965 (1997). [2] R. Rauer, G. Neuber, J. Kunze, J. Bäckström, and M. Rübhausen, Rev. Sci. Instr. **76**, 023910 (2005). [3] S. von Oehsen, J.M. Scholtyssek, C. Pels, G. Neuber, R. Rauer, M. Rübhausen, and G. Meier et al., JMMM **290**, 1371 (2005).

**V22 11 Electronic and structural properties of TBrPP-Fe-Cl molecular self-assembly** GAYANI PERERA, VIOLETA IANCU, SAW-WAI HLA, *Nanoscale & Quantum Phenomena Institute, and Department of Physics and Astronomy, Ohio University, Athens, Ohio, 45701, USA* Self-assembled molecular (SAM) layers of TBrPP-Fe-Cl [5, 10, 15, 20 –Tetrakis -(4-bromophenyl)-Porphyrin-iron-chloride] are formed on a Cu(111) surface. The electronic and structural properties of these SAM layers are investigated by using scanning tunneling microscopy (STM) imaging and tunneling spectroscopy at 4.6 K. The STM images reveal three distinct molecular conformations inside the SAM layers. Local tunneling spectroscopy data are acquired on individual molecules with different conformations. These spectroscopic investigations provide the conformation dependent HOMO-LUMO orbital alignments of the molecules. Further more, the conductance tunneling spectroscopy measured in a small voltage range near the surface. Fermi level show a Kondo resonance originated by interactions between the spin of iron atom inside the molecule, and the surface state free electrons of Cu(111). This work is supported by a US-DOE grant, DE-FG02-02ER46012, and a NSF-NIRT grant, DMR-0304314.

**13:27**

**V22 12 Single molecule Kondo switch** VIOLETA IANCU, APARNA DESHPANDE, SAW-WAI HLA, *Nanoscale & Quantum Phenomena Institute, and Department of Physics and Astronomy, Ohio University, Athens, Ohio, 45701, USA* We present manipulation of Kondo resonance originated from the interaction between the spin of a Co atom inside a TBrPP-Co molecule and free electrons from a copper surface by switching the conformation of isolated single molecules with a scanning tunneling microscope (STM) tip. The STM studies of isolated TBrPP-Co molecules [5, 10, 15, 20 –Tetrakis -(4-bromophenyl)-porphyrin-Co] deposited on a Cu(111) are performed at 4.6K in an ultra-high-vacuum environment. The molecules anchor on Cu(111) with two molecular conformations, planar and saddle. In the saddle conformation, the metal atom is lifted away from the surface as compared to the planar. We are able to switch from a saddle conformation of TBrPP-Co to a planar conformation by applying +2.2V voltage pulses from the STM-tip, thereby varying the vertical distance of Co atom from the Cu(111) surface. This conformational switching increases molecule-substrate interaction resulting in an enhanced spin-electron coupling and changes the associated Kondo temperature from 130K to 170K. This work is supported by a US-DOE grant, DE-FG02-02ER46012, and a NSF-NIRT grant, DMR-0304314.

**V23 1 Spin-wave interactions in quantum antiferromagnets** NILS HASSELMANN, PETER KOPIETZ, *Institut für Theoretische Physik, Universität Frankfurt, Germany* We study spin-wave interactions in quantum antiferromagnets in terms of Hermitian field operators representing staggered and ferromagnetic transverse spin fluctuations. In this parameterization, the two-body interaction vertex between staggered spin fluctuations vanishes at long wavelengths. We derive a new effective action for the staggered fluctuations and show that the quantum critical point separating the renormalized classical from the quantum disordered regime in $D > 1$ dimensions is characterized by an anomalous dimension of the field operator $\eta = D - 1$. We further use this

technique to derive the effective long-wavelength Euclidean action for the antiferromagnetic spin-waves of ordered antiferromagnets subject to a magnetic field. We point out, that the magnetic field dependence of the spin-wave dispersion predicted by the usual $O(3)$ nonlinear sigma model disagrees with spin-wave theory. We argue that the nonlinear sigma-model does not take into account all relevant spin-wave interactions and derive a modified effective action for the spin-waves which contains an additional quartic interaction. At zero temperature the corresponding vertex is relevant in the renormalization group sense below three dimensions.

**V23 2 Spin dynamics of a Half-Metallic Ferromagnet*** RAUL CHURA, KEVIN BEDELL, *Boston College* We determine the dispersion relations, and therefore, the collective modes of a model for a half-metallic ferromagnet by using two approaches: the particle-hole propagator method and the kinetic equation method. We formulate the latter by using the theory of spin polarized Fermi liquids. In both cases we express the results in terms of Landau interaction parameters and make the corresponding comparisons. We also calculate the velocities of propagation of the modes and study the spin stiffness. We discuss the results in the context of the currently available experimental data.

**V23 3 Evolution of Spin-Wave Excitations in Ferromagnetic Metallic Manganites** J. ZHANG, H. SHA, *Florida Intl. Univ.* F. YE, J. FERNANDEZ-BACA, *ORNL* P. DAI, *Univ. of Tenn. and ORNL* J. LYNN, *NIST* H. KAWANO-FURUKAWA, *Ochanomizu Univ., Japan* Y. TOMIOKA, *CERC, Japan* Y. TOKURA, *Univ. of Tokyo and CERC, Japan* The deviation of spin dynamics from the Double-Exchange mechanism in the ferromagnetic metallic manganites is an important yet unsettled issue in the understanding of the close coupling behavior between charge, lattice, orbital, and spin degrees of freedom in these doped ''colossal'' magnetoresistive materials. We have used neutron scattering to systematically study the spin-wave excitations of three ferromagnetic metallic $A_{1-x}A'_xMnO_3$ manganites (where $A$ and $A'$ are rare- and alkaline-earth ions respectively). By combining with previous work, we elucidate the systematics of the spin-spin interaction and interactions between spin and other degrees of freedom as a function of carrier concentration $x$, on-site disorder, and strength of the lattice distortion. The long wavelength spin dynamics show only a very weak dependence across the series, while the Curie temperatures vary substantially. The ratio of the fourth to the first neighbor exchange ($J_4 = J_1$) that controls the zone boundary magnon softening changes systematically with $x$, but does not depend on the other parameters. None of the prevailing models can account for these behaviors. The work was supported by NSF-DMR0453804, NSF-DMR0346826, DE-FG02-05ER46202 and DOE DE-FG02-04ER46125. ORNL is managed by UT-Battelle, LLC, for the U.S. DOE under contract DE-AC05-00OR22725.

**11:51**

**V23 4 Coherent spin waves in epitaxial Fe films on GaAs (001)** HAIBIN ZHAO, DIYAR TALBAYEV, GUNTER LUEPKE, *College of William and Mary* AUBREY HANBICKI, CONNIE LI, BEREND JONKER, *Naval Research Laboratory* Recently, coherent spin waves have been investigated in ferromagnetic thin film using optical pump-probe technique by exploiting the temperature dependence of the magnetic anisotropy. Here, we report on low-order spin wave modes in the dipole-exchange regime in Fe films epitaxially grown on GaAs (001). Three precession modes with zero in-plane wave-vector are observed by applying an external magnetic field along the in-plane hard axis. The lowest frequency mode can be well described by the uniform magnetization precession. The cubic magnetocrystalline anisotropy constant $K_1/M_s$ and effective demagnetization field $4\pi M_s$ are determined to be 270 Oe and 17.5 KOe, respectively. The modes with higher frequencies correspond to the first- and second-order spin waves. An effective exchange stiffness constant of $0.8\times10^{-6}$ erg/cm is obtained from the calculation assuming the single sine- or cosine- type standing spin waves with free spins at both interfaces. The exchange constant is smaller than the values obtained from high order spin wave modes in ferromagnetic resonance experiments and neutron scattering. The difference may result from pinning effects, which modifies the location of the surface antinodes of the standing spin waves thereby changing their effective wavelength.

**12:03**

**V23 5 Evolution of Cr's charge and spin density waves under GPa pressures** YEJUN FENG, R. JARAMILLO, T.F. ROSENBAUM, *JFI, U. Chicago* O.G. SHPYRKO, E.D. ISAACS, *CNM, Argonne* G. SRAJER, J. LANG, Z. ISLAM, *APS, Argonne* M.S. SOMAYAZULU, H.-K. MAO, *Geophys. Lab, CIW* V.B. PRAKAPENKA, *GSECARS, Argonne* We trace the development of Cr's charge density wave (intensity $10^{-4}\times$ Bragg peak) and spin density wave (intensity $10^{-8}\times$ Bragg peak) at GPa pressures at the Advanced Photon Source. Using a diamond anvil cell combined with a newly developed chemical filtering technique, we find a previously unknown incommensurate to commensurate transition at 2 GPa. We analyze the incommensurate Q-vector and intensity changes at the approach to the transition. At much higher pressures ( $>$ 7 GPa), Cr's antiferromagnetism is completely suppressed and the evolution of the line shape at the approach to the quantum critical point directly reveals the role played by quantum fluctuations.

**12:15**

**V23 6 Spin wave in quasi-equilibrium spin systems*** HARI DAHAL, KEVIN BEDELL, *Boston College* Using the Landau Fermi liquid theory we can study a quasi- equilibrium spin system at T=0K to determine the dispersion relations of possible collective modes. By quasi-equilibrium spin system we refer to a spin system which has finite magnetization in the absence of an external magnetic field. Such a system has been realized in liquid helium and in spintronic materials using different methods; one of those is the optical pumping. We have predicted the existence of gapless spin wave modes in such a system. We compare the dispersion relations of different modes of the quasi- equilibrium system with those of a paramagnetic system, in the presence of a magnetic field, and a ferromagnetic system. Using the relaxation time approximation for the collision integral we study the effect of temperature on the dispersion relation of the modes. We will also present the behavior of the dynamical structure function as a function of frequency and discuss the contribution of different modes to the sum rules.

**V23 7 Valence values of the cations in selenospinel $Cu(Cr,Ti)_2Se_4$*** HAN-JIN NOH, S.-W. HAN, S.-J. OH, *Center for Strongly Correlated Materials Research, Seoul National University, Seoul, Korea* J.-S. KANG, S. S. LEE, G. KIM, *Dep. of Phys. The Catholic University of Korea, Puchon, Korea* J.-Y. KIM, H.-G. LEE, *Pohang Accelerator Laboratory, Pohang, Korea* S. YEO, S.-W. CHEONG, *Dep. of Phys. & Astro. Rutgers University, NJ* A long-standing issue about the Cu valency in selenospinel $CuCr_2Se_4$ was investigated by soft x-ray absorption spectroscopy (XAS) and magnetic circular dichroism (XMCD). Using the sensitivity of XAS and XMCD to the valence value of transition metal ion and its local symmetry, we checked the valence value of each cation in selenospinel $CuCr_xTi_{2-x}Se_4$ ($x$ = 1.0, 1.1, 1.5, and 2.0) and obtained spectroscopic evidence that a small amount of the Cu cation changes the valency from Cu(I) to Cu(II) as the Cr concentration increases from 1.0 to 2.0. Dependence of the Cu(II) concentration and the mean field magnetic exchange energy on the Cr concentration suggests the Cu *d*-hole plays a crucial role in the intriguing magnetic/electrical properties of $CuCr_2Se_4$.

**V23 8 The optical and acoustic magnetic excitations in optimum-doped superconductor $YBa_2Cu_3O_{6.95}$ ($T_c$ = 93$K$)*** HYUNGJE WOO, *The University of Tennessee* PENGCHENG DAI, *The University of Tennessee / ORNL* STEPHEN HAYDEN, *University of Bristol UK* HERB MOOK, *ORNL* TOBY PERRING, *ISIS Facility,Rutherford Appleton Laboratory UK* THOMAS DAHM, *Institut fur Theoretische Physik Germany* DOUGLAS SCALAPINO, *UCSB* FATIH DOGAN, *University of Missouri-Rolla* We use high-resolution inelastic neutron scattering to map out the full spin excitations spectra in $YBa_2Cu_3O_{6.95}$ ($T_c$ = 93$K$), probably the most studied high-transition temperature superconductor. In the bi-layer materials where there are two magnetic ions per unit cell, magnetic excitations have two distinct symmetries: odd (or acoustic) and even (or optical) channels. We show that magnetic excitations in the acoustic channel of $YBa_2Cu_3O_{6.95}$ are remarkably similar to that of $YBa_2Cu_3O_{6.6}$ [1] and $La_{1.88}Ba_{0.12}CuO_4$ [2]. That is, they have the universal hourglass shape with incommensurate spin fluctuations below the commensurate resonance. In the optical channel, we discovered incommensurate magnetic excitations in superconducting state. We establish the both the acoustic and optical magnetic excitations spectra of $YBa_2Cu_3O_{6.95}$ in absolute units and compare the results with underdoped $YBa_2Cu_3O_{6.6}$ and single layer families of cuprate superconductors. [1] S. M. Hayden et al. Nature 429, 531 (2004);[2] J. M. Tranquada et al. Nature 429, 534 (2004).

**V23 9 Spin excitations and phonons in $La_{1.5}Sr_{0.5}CoO_4$** ANDREI SAVICI, IGOR ZALIZNYAK, *Brookhaven National Laboratory* Inelastic neutron scattering measurements were performed in $La_{1.5}Sr_{0.5}CoO_4$. At room temperature, the excitation spectrum is dominated by phonons. At low temperatures we see a mix of lattice vibrations and spin modes. By subtracting phonon contributions we are able to identify purely magnetic modes. A resonance mode was found at energies around 25-27meV, the nature of which is under investigation.

**13:03**

**V23 10 Ferromagnetic Relaxation by Magnon Induced Currents** ARKAJYOTI MISRA, RANDALL VICTORA, *University of Minnesota* A theory for calculating spin wave relaxation times based on the magnon-electron interaction is developed. In a conducting ferromagnet the interaction between the conduction electrons and the magnons is important. The magnetic field generated by the spin wave is time dependent and therefore it creates an electric field in the system. In a metallic system, the fields drive the conduction electrons. These magnon induced currents help dissipate the energy of the system by Joule heating. Our study incorporates a thin film geometry and explores relaxation time for a wide range of magnon wave vectors spanning both the magnetostatic and exchange regimes. The relaxation time is calculated directly from the ratio of the energy density of the system and the power loss by magnon induced currents. We propose a wave vector dependent damping constant which approaches values as high as 0.2 for high conductivity metals such as permalloy, showing the large magnitude of the effect. The theory compares reasonably well with spin wave resonance experiments for lower modes. We propose the following picture of ferromagnetic relaxation in switching experiments. The initial rapid approach of magnetization direction to equilibrium is enabled by magnon-magnon scattering that converts the energy into the higher spin wave modes. These modes then decay at a slower pace via the magnon-electron interaction investigated in this work or by the trditionally invoked mechanisms in less pure, lower conductivity films.

**13:15**

**V23 11 On the possibility of electrical detection of spin echoes in a ferromagnetic thin film** MARK FILIPKOWSKI, EDWIN HACH, *Booz Allen Hamilton* We show, via a straightforward calculation, that it is feasible to detect nuclear spin echoes in a ferromagnetic thin film by electrical means. The detection scheme is based on the deflection of the electronic magnetization when the nuclear magnetization reforms during an echo. This deflection is observed as a time-dependent magnetoresistive signal.

**13:27**

**V23 12 Quantum vs. Thermal Annealing of Magnetic Domain Walls in Elemental Chromium** OLEG G. SHPYRKO, ERIC D. ISAACS, *Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL* JONATHAN M. LOGAN, YEJUN FENG, RAFAEL JARAMILLO, THOMAS F. ROSENBAUM, *James Franck Institute and Department of Physics, University of Chicago, Chicago, IL* PAUL ZSCHACK, *Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, Urbana-Champaign, IL* GABRIEL AEPPLI, *London Centre for Nanotechnology and Dpt of Physics and Astronomy, University College London, London, UK* MICHAEL SPRUNG, ALEC R. SANDY, *Advanced Photon Source, Argonne National Laboratory, Argonne, IL* Dynamics of magnetic domain walls separating regions with different orientations of the spin (charge) density wave has been studied with x-ray photon correlated spectroscopy (XPCS) in bulk Cr samples. Measurements were carried out at temperatures ranging from 298K to 4K. Upon cooling down to 4K thermal exploration of energetic landscape is replaced by quantum tunneling between discrete low-energy configurations of domain walls. Direct comparison of coherent speckle pattern fluctuations for Bragg reflection and charge density wave satellite peak provides information about magnetic superlattice dynamics, deconvolved from the motion of underlying atomic lattice or beam components.

**SESSION V24: CHARGED AND ION-CONTAINING POLYMERS: PROPERTIES**

**11:15**
**V24 1 Morphology Diagrams for Polyelectrolytic Diblock Copolymers** RAJEEV KUMAR, MURUGAPPAN MUTHUKUMAR, *University of Massachusetts Amherst* We have calculated morphology diagrams for polyelectrolytic diblock copolymers in melts and highly concentrated solutions. Using the random phase approximation and self-consistent field theory, stability limits of the standard morphologies (lamellae, cylinders and spheres) have been considered both in weak and strong segregation limits. Effects of Coulomb interaction strength, degree of ionization, Debye screening length, block length, chain length, and the chi parameter on the periods of these morphologies will be discussed. Also, the crossover behavior in the whole range of segregation will be presented. Charging a polymer block with electrical charges leads to many unexpected behaviors, which will be discussed in the context of previous theories and experiments.

**11:27**
**V24 2 Synthesis, Solution Phase Behavior, and Properties of Ionic/Nonionic Block Copolymers** MEHUL VORA, FRANK BATES, *Department of Chemical Engineering and Materials Science, University of Minnesota* The study of amphiphilic block copolymers in aqueous solutions has shown rich phase behavior and interesting solution properties. The aim of the current work is to develop an amphiphilic diblock copolymer system containing an ionic block in order to better understand how ionicity affects the phase behavior and solution properties. Relatively monodisperse PEP-*b*-PMAA (poly(ethylene propylene)-*b*-methacrylic acid) copolymer was prepared from anionically synthesized poly(isoprene-*b*-ittert-butyl methacrylate). The rheological behavior of aqueous solutions of PEP-*b*-PMAA in the presence of different counterions was studied. The choice of counterion has a strong influence on the final solution properties. Cryo-TEM and SAXS experiments are used to determine the morphology of the copolymers in these solutions, while rheological experiments revealed the role of diblock composition, counterion type and concentration, and overall polymer loading on the viscometric properties.

**11:39**
**V24 3 Morphological Origin of Thermomechanical Behavior in Semicrystalline Ethylene/Methacrylic Acid Ionomers** KATSUYUKI WAKABAYASHI, RICHARD A. REGISTER, *Department of Chemical Engineering, Princeton University* Two peculiar and intriguing phenomena in ethylene/methacrylic acid (E/MAA) ionomers are an initial sharp increase in stiffness with neutralization and an inverse dependence of Youngs modulus on crystallinity. We have identified how the polyethylene crystallites, amorphous polymer segments, and ionic aggregates combine to produce these unusual effects. At temperatures just below the melting point of the primary crystallites, the ionomers can be satisfactorily described as two-phase composites of crystallites and ionically-crosslinked rubber, but at room temperature, the modulus is much greater. We trace this effect to a synergy between the ionic aggregates and secondary crystallites, which together form percolated rigid pathways through the amorphous phase at room temperature, generating a far higher modulus than one would anticipate from the modest crystallinity and ion content. When the secondary crystallites melt and/or the segments in the regions of restricted mobility surrounding the aggregates devitrify, these paths break down and the simple two-phase composite description is recovered.

**11:51**
**V24 4 Influence of Chain Flexibility on the Self-Assembly of Nanoscale Ionic Aggregates in Ionomers.** NICHOLAS BENETATOS, KAREN WINEY, *Department of Materials Science and Engineering, University of Pennsylvania, Philadelphia, PA 19104* Rigorously establishing the fundamental physics that govern the morphology of ionomers is essential to continuing the development of this versatile class of materials. To explore how chain flexibility impacts the nanoscale self assembly of ionic aggregates, we have investigated the morphology of Cu neutralized poly(styrene-itran-methacrylic acid) (SMAA) and poly(3-methylstyrene-itran-methacrylic acid) (3Me-SMAA) ionomers with small angle X-ray scattering (SAXS) and real space imaging via scanning transmission electron microscopy (STEM). The copolymer 3Me-SMAA is slightly less flexible on local length scales as evidenced by a shift in the position of the ''polymerization'' SAXS peak ($q \sim 6\ nm^{-1}$) to lower q compared to that of SMAA ($q \sim 7\ nm^{-1}$). A commensurate shift toward lower q in the position of the ionomer SAXS peak was observed for Cu-3Me-SMAA. Interpreting these SAXS data with a multi-functional model, including that of Yarusso and Cooper, suggests a homogeneous collection of spherical ionic aggregates with diameters of 1.0 nm and 1.2 nm in Cu-SMAA and Cu-3Me-SMAA, respectively. From STEM imaging, the ionic aggregates in both Cu-SMAA and Cu-3Me-SMAA are indeed spherical with a uniform, dense spatial distribution and average diameters of 1.2 + 0.3 nm and 1.4 + 0.3 nm, respectively, showing slightly larger size as local chain flexibility decreases.

**V24 5 The Effect of Counterions on the Blend Miscibility of Polystyrene with Sulfonated Polystyrene Ionomers** NANCY C. ZHOU, *Department of Chemical and Biomolecular Engineering, University of Pennsylvania* WESLEY R. BURGHARDT, *Department of Chemical and Biological Engineering, Northwestern University* RUSSELL J. COMPOSTO, KAREN I. WINEY, *Department of Materials Science and Engineering, University of Pennsylvania* Our previous study probed the miscibility of polystyrene (PS) and sulfonated polystyrene (P(S-SS$x$)) of differing sulfonation levels ($x$) and found a narrow window of miscibility. Specifically, the PS:P(S-SS$x$) blend system becomes completely immiscible at unexpectedly low sulfonation level, x = 2.7 mol%. Here we extend the study of blend miscibility of PS with P(S-$SS_{0.007}$) to include materials neutralized with sodium, barium and zinc cations. These ionomer blends exhibit an upper critical solution temperature (UCST) behavior with an increase in critical temperature as compared to the blend with unneutralized P(S-$SS_{0.007}$). Forward recoil spectrometry (FRES) results indicate that $Zn^{++}$ and $Ba^{++}$ neutralized ionomers are less miscible than $Na^{+}$ when fully neutralized, while the blend miscibility for $Na^{+}$ and $Zn^{++}$ neutralized ionomers behave similarly when partially neutralized. Rheological studies are underway to compliment the blend miscibility studies. These miscibility information gained from PS/P(S-SS$x$) ionomers blends will serve as a foundation for future ionomer morphology studies.

**12:15**

**V24 6 Viscosity of Aqueous Polyelectrolyte Solutions with Oppositely Charged Surfactant** MATTHEW EGGERT, RALPH COLBY, *Penn State University* The viscosity of polyelectrolyte solutions with oppositely charged surfactants is measured for a series of anionic polyelectrolytes of variable hydrophobicity (alternating copolymers of sodium maleate with hydrocarbon comonomers) in the presence of cationic trimethyl ammonium bromides with various alkyl tail lengths. These results are compared with a simple model that modifies the scaling theory for unentangled semidilute polyelectrolyte solutions to account for the addition of oppositely charged surfactant. The surfactant lowers the viscosity of these solutions through two means. The polyelectrolyte binds to the surface of the surfactant micelle, reducing the effective chain length of the polymer. The binding also causes counterions of the polyelectrolyte and the surfactant to be released into solution, acting as a salt that screens the repulsion between charges of the polyelectrolyte, causing the chains to have smaller size. The fraction of effectively charged monomers (*i.e.*, free counterions) on the polyelectrolyte is measured via an ion-selective electrode, meaning the simple model has no adjustable parameters. Additional electrodes are used to measure the amount of free surfactant in solution in order to estimate the amount of surfactant associated with each polyelectrolyte chain.

**12:27**

**V24 7 Simulations of Volume Phase Transitions in Polyelectrolyte Networks Upon Counterion Exchange** DE-WEI YIN, *Dept of Chemical and Biological Engineering, Univ of Wisconsin-Madison* JUAN J. DE PABLO, *Dept of Chemical and Biological Engineering, Univ of Wisconsin-Madison* Polyelectrolyte networks are known to undergo discontinuous volume phase transitions, the onset of which may be caused by a number of factors. We have shown through molecular dynamics simulations that the interplay between the counterion excluded-volume entropy and the electrostatic energy—factors not explicitly considered in the classical Flory–Tanaka model—appears to have an important role in driving the phase transitions [Yin, Yan, and de Pablo, J. Chem. Phys. 123(17):174909, (2005)]. In our current work, we examine how the exchange of monovalent and divalent counterions induces discontinuous phase transitions in polyelectrolyte networks. It is revealed that divalent counterions condense preferentially over monovalent counterions onto the polyelectrolyte network backbone, thereby screening the charges on the backbone, and thus the different counterion species contribute differently to the osmotic pressure and hence to the free energy of the system. We present our findings as they relate to experiments performed near physiological conditions.

**12:39**

**V24 8 Electrophoretically Assessing Polyelectrolyte Effective Charge** ALEXEY POPOV, DAVID HOAGLAND, *Polymer Science & Engineering, University of Massachusetts, Amherst, MA* Capillary electrophoresis revealed how polyelectrolyte effective charge density varies with backbone charge spacing and solvent dielectric constant. The study focused on ionenes, polyelectrolytes that possess regularly spaced quaternary ammonium groups in the backbone. Complete ionization of functional units and good solvency in water and mixtures of water with methanol or acetonitrile enabled measurements of ionene effective charge density as solvent dielectric constant continuously varied. Ionenes with aliphatic and oxyethylene spacers in the backbone were examined. As expected, effective charge density rose linearly with fixed charge density to a critical value, above which effective charge was nearly constant. Deviating from expectation, the onset of condensation did not occur at a critical fixed charge density predicted by Manning theory. Instead, condensation initiated at the constant critical Bjerrum length. The same onset condition was found for quaternized poly(vinyl pyridine). These results suggest a new type of condensation, one driven by ion-pairing. In support of the ion-pairing hypothesis, the onset of condensation correlates with counterion size.

**12:51**

**V24 9 SAXS Determination of the Correlation Length of Semidilute Polyelectrolyte Solutions** SHICHEN DOU, RALPH H. COLBY, *Materials Science and Engineering, Pennsylvania State University* In semidilute solutions, polyelectrolyte chains have a random walk conformation of correlation blobs. The size of those space filling correlation blobs can be measured using Small Angle X-ray Scattering from the wavevector at which there is a peak. In this study we randomly quaternized monodisperse poly(2-vinyl pyridine) (P2VP) and neutralized to make polyelectrolytes with either chloride or iodide counterions. We study a random copolymer for which 60% of the charges are neutralized, at 25 $^{o}$C in three solvents: (1) Ethylene glycol (EG) is a good solvent for P2VP, with dielectric constant $\varepsilon = 37$ making the Bjerrum length 15 Å and dielectric spectroscopy measures the fraction of monomers bearing an effective charge $f = 0.17$ for $Cl^-$ and $f = 0.07$ for $I^-$ counterions. (2) Water is a poor solvent for P2VP, with $\varepsilon = 78$ making the Bjerrum length 7.1 Å and $f = 0.25$ for $I^-$ counterions. (3) N-methyl formamide (NMF) is a good solvent for P2VP, with $\varepsilon = 182$ making the Bjerrum length 3.1 Å and $f = 0.60$ for $I^-$ counterions (meaning that all counterions are free in NMF). We find that the correlation length of these polyelectrolyte solutions obeys the power law concentration dependence expected by scaling theory, and the correlation length decreases at a given concentration as the solvent is made more polar, because the polyelectrolyte chain has a larger effective charge.

**13:03**

**V24 10 Phase behavior of semidilute polyelectrolyte mixtures of F-actin and DNA** JOHN BUTLER, *Department of Materials Science, Univeristy of Illinois at Urbana Champaign* OLENA V. ZRIBI, *Department of Physics, University of Illinois at Urbana Champaign* GERARD C. L. WONG, *Department of Materials Science and Engineering, Department of Physics, Department of Bioengineering, University of Illinois at Urbana Champaign* RAMIN GOLASTANIAN, *Isaac Newton Institute for Mathematical Sciences, Cambridge, UK, Institute for Advanced Studies in Basic Sciences, Zanjan, Iran* We investigate the phase behavior of semidilute mixtures of polyelectrolyte DNA coils and F-actin rods. F-actin has a persistence length of $\sim$ 10 microns and a linear charge density of $-$1e/0.25nm. DNA has a persistence length of $\sim$ 50nm and a linear charge density of –1e/0.17nm. Confocal and polarized microscopy data show that actin-DNA phase separates into ribbon-like birefringent domains of nematic F-actin and a disordered mesh of DNA coils. Synchrotron Small Angle X-ray Scattering (SAXS) show that DNA compresses F-actin into an ultradense dense nematic phase. The spacing between nematic F-actin domains shows a power-law dependence on DNA concentration which is independent of the contour lenth of either DNA or F-actin.

**13:15**
**V24 11 Counterion correlations in charged macromolecular systems** ARBEN JUSUFI, YU MEI, MATTHIAS BALLAUFF, *Physical Chemistry I, University of Bayreuth, 95440 Bayreuth, Germany* We perfomed Molecular Dynamics simulations of a charged macroion surrounded by counterions. Various scattering contributions result from correlations between counterions, macroion, and between both of them. Experimentally, these scattering contributions can be measured by anomalous small-angle X-ray scattering (ASAXS) experiments. As a result the cross-correlation between the rigid macroion and counterions yields always a meanfield expression for the counterion density distribution even if the counterions exhibit correlated fluctuations. In contrast, in star-like polyelectrolytes, representing a fluctuating macroion, meanfield approximations are valid only if the functionality is sufficiently high. A systematic investigation of the strength of correlated fluctuations and their effect in scattering intensities is demonstrated for these systems. Furthermore, we demonstrate a collapse transition for spherical polyelectroylte brushes (SPB) by adding trivalent counterions. The collapse of the SPB is observed by simulations and experiments.

**13:27**
**V24 12 Chiral Symmetry Breaking and Elastic Response of Frustrated Polyelectrolyte Bundles** GREGORY GRASON, *Department of Physics and Astronomy, University of California, Los Angeles* ROBIJN BRUINSMA, *Department of Physics and Astronomy, University of California, Los Angeles* We present a model for hexagonal aggregates of charged, cylindrical macromolecules (DNA, microtubules, F-actin, *etc.*) in the presence of multivalent counterions at low temperature. Using the Wigner crystal picture of the neutralizing charge condensed onto the rod-like macromolecules, we establish a one-to-one mapping between the statistical mechanics of the charged bundle system and those governing the $T = 0$ properties of a two-dimensional, frustrated Josephson junction array. We find that the superconducting phase of the *quantum* system corresponds to the low-temperature phase of our *classical* bundle system, where the condensed counterions are ordered in three dimensions, while the insulating phase corresponds to the phase where one-dimensional phonon fluctuations destroy long-range order of the condensed charge. Remarkably, the mapping makes the prediction that the transition to the charge-ordered state should be accompanied by a spontaneous breaking of chiral symmetry (even in the absence of any molecular chirality). Finally, we exploit the well-studied critical properties of the electromagnetic response of the two-dimensional *quantum* system to deduce the elastic response of the *classical* charged-rod bundle system.

**13:39**
**V24 13 Studies of Glassy Dynamics in Ionomer melts** MONOJOY GOSWAMI, SANAT KUMAR, *Rensselaer Polytechnic Institute* ANIKET BHATTACHARYA, *University of Central Florida* In this work we investigate one of the challenging problems, the dynamics of ionomer aggregates using Molecular Dynamics simulations. Experimental results show that the glass transition temperature ($T_g$), diffusion and relaxation mechanisms can be influenced dramatically by ion-incorporation or by changing temperature of the system e.g., increase in ion content raises the $T_g$. In this work we show the dynamical behavior of ionomer melts as it goes from liquid to glass/gel state. In the context of ionomers, we investigated the analogy between reversible gelation and the glass transition, and show that many of the beneficial properties of ionomers and difficulties in understanding them can be understood in this framework.

## SESSION V25: POLYMER COMPOSITES - NANOTUBES AND NANOCLAYS

**V25 1 Synthetic Gecko Foot-hairs from Multiwalled Carbon Nanotubes.***
ALI DHINOJWALA, *The University of Akron*

The mechanism that allows a gecko lizard to climb any vertical surface and hang from a ceiling with one toe has attracted considerable interest and awe for over two millennia. Recent studies have discovered that the gecko's ability to defy gravity comes from its remarkable feet and toes. Each five-toed foot is covered with microscopic elastic hairs called setae. The ends of these hairs split into spatulas which come in contact with the surface and induce enough intermolecular [van der Waals (VdW)] forces to hold them in place. Similarly, the same VdW forces act between our two hands when they are held together, but in this case, they do not stick to each other. The reason is that the roughness of our hands prevents them from coming close to each other at separations relevant for VdW forces. On the other hand, based on the gecko's foot anatomy, if our hands were made up of tiny elastic structures that were able to deform or bend at different length scales in accordance with the contact surface and correct for the roughness, then perhaps our hands could also adhere to the surfaces we touch. In my talk, I will present the recent advances we have made in fabricating polymer surfaces with multiwalled carbon nanotube hairs with strong nanometer-level adhesion forces that are 200 times higher than those observed for Gecko foot-hairs. This fabrication process allows the flexibility to create structures that are found in nature on the Gecko's foot and offer excellent potential for applications as dry adhesives for space, microelectronics and MEMS devices. This work was done in collaboration with Betul Yurdumakan, Nachiket Raravikar and Pulickel Ajayan.

**V25 2 Flow Kills Conductivity of Single Wall Carbon Nanotubes (SWNT) Composites** SANJIV BHATT, *Entegris Inc., Chaska, MN* CHRISTOPHER MACOSKO, *Department of Chemical Engineering and Materials Science, University of Minnesota* Most composites of polymer and single wall carbon nanotubes (SWNT) reported in the literature are made by solvent casting or simple compression molding. Commercial utility of these composites requires use of precision injection molding. We have observed a unique behavior wherein the SWNT composites made by injection molding or by extrusion are insulators but upon heating become electrically conductive. This behavior appears to be the result of a relaxation phenomenon in the SWNT composite. During flow into an injection mold or through an extrusion die the well-dispersed SWNT in the polymer matrix tend to align such that they are not in contact with each other and are farther than the minimum required distance, 5 nm (1), to achieve electrical percolation through electron hopping. Upon heating the SWNT relax and either touch each other or are at a distance less than or equal to 5 nm from each other to create a percolating. [1] Du, F., Scogna, R, C., Zhou, W., Brand, Stijn, Fischer, J. E., and Winey, K. I., Macromolecules 2004, 37, 9048-9055.

**12:03**

**V25 3 Fabrication and Characterization of Polyamide Nanocomposites Using Functionalized Nanotubes.** KAREN I. WINEY, M. MONIRUZZAMAN, *University of Pennsylvania* J. CHATTOPADHYAY, W.E. BILLUPS, *Rice University* We have prepared nylon 6,10 nanocomposites with functionalized single wall nanotubes (fSWNT) using an interfacial polycondensation method previously developed in our lab. The specific functional groups (CH2)nCOCl on the sidewall of the nanotubes were designed to permit covalent bonding to the nylon matrix while fabricating the nanocomposite. Using a binary mixture of dichlorobenzene/water solvent system, we have been able to prepare nylon 6,10 and nylon 6,10 / fSWNT nanocomposites with a yield of 80%. The composites were characterized using FTIR and Raman spectroscopies, optical and scanning electron microscopies, differential scanning calorimetry, and thermogravimetric analysis. The composites show good dispersion of nanotubes at the micron and submicron levels. Improved protocols have been developed to reduce the degradation of the composites at elevated temperatures. The nylon 6,10 / fSWNT nanocomposites were spun into fibers using melt fiber spinning at 240C and the mechanical properties of the fibers were studied as a function of nanotube loading.

**12:15**

**V25 4 Electrical, Mechanical, and Morphological Characterization of Carbon Nanotube filled Polymeric Nanofibers** RUSSELL GORGA[1], LAURA CLARKE[2], SETH McCULLEN[1], SATYAJEET OJHA[1], WESLEY ROBERTS[2], *N.C. State University* This work focuses on the inclusion of conductive nanotubes into polymeric matrices with the end goal of creating conductive nanocomposites. This investigation has been carried out by uniform dispersion of multi-walled carbon nanotubes in aqueous solutions of polyvinyl alcohol (PVA) and polyethylene oxide (PEO), which are inherently nonconductive polymers. To fabricate these structures we are using the electrospinning process encompassing an array of collection methods including parallel bars and a static plate. Carbon nanotubes are known to have excellent electrical conductivity and mechanical properties. This investigation shows that the inclusion of carbon nanotubes increases the electronic conduction in these polymers and enhances the mechanical properties of the composites. Dispersion of these nanotubes is the key factor in this process; gum Arabic and surfactants have been utilized for the dispersion of these nanotubes. Conductivity measurements have been carried out by two point probe method and by performing sensitive current and conductance measurements with a femtoammeter. Further morphological characterization has been performed using scanning electron microscopy (SEM) and transmission electron microscopy (TEM). **12:27**

**V25 5 Thermomechanical Properties of Polystyrene-MWNT Nanocomposites.*** ANUPA GEORGE, SUDEEPTO SEN, YUPING XIE, SCHADLER LINDA, SANAT KUMAR, *Rensselaer Polytechnic Institute* In this work we have studied the thermomechanical properties of polystyrene nanocomposites-MWNTs (Multi-walled carbon nanotubes) concentration. A number of different combinations of the matrix and the filler concentrations are being analyzed to study the effect on glass transition temperature using differential scanning calorimetry and a dynamic mechanical analyzer. FE-SEM (Field Emission Scanning Electron Microscope) is being used to study the dispersion and interaction of nanotubes in the matrix. We show that the thermomechanical properties of these materials are very similar to composites with SWNT, thus suggesting that the tube stiffness may not play an important role in this context.

*NSF-NSEC

**12:39**

**V25 6 Carbon Nanotube Composites from Modified Plant Oils** IAN McANINCH, RICHARD WOOL, *Dept Chemical Engineering, University of Delaware* Carbon nanotubes (CNTs) with their impressive mechanical properties are ideal reinforcement material. Acrylated epoxidized soy oil (AESO) has been previously shown to have favorable interactions with carbon nanotubes. CNTs mixed into AESO, both with and without styrene as a co-monomer, using mechanical shear mixing showed dispersion only on the micron level, resulting in modest mechanical property improvements. Greater improvements were seen, especially in the rubbery modulus, when the resin's viscosity was kept high, either through a reduction of the styrene content, or by curing at a lower temperature. CNTs were also dispersed via sonication in methyl methacrylate. The resulting dispersion was then mixed with AESO. The resulting composites showed better CNT dispersion, with no micron-sized aggregates, as verified using SEM and optical microscopy. The mechanical properties also showed greater improvement.

**12:51**

**V25 7 Carbon Fibers from Chicken Feather Keratin** MELISSA E. MILLER, RICHARD WOOL, *Dept Chemical Engineering, University of Delaware* As the availability of synthetic and fossil-fuel based resources is becoming limited, bio-based materials offer an environmentally friendly alternative. Chicken feathers remain a huge agricultural waste. The feathers are comprised of approximately 97% keratin, but are currently used only to enrich animal feed. However, this usage is becoming a problem with the spread of diseases such as Bovine Spongiform Encephalopathy, commonly called ''Mad Cow Disease.'' The hollow, microcrystalline, oriented keratin feather fibers offer a novel, low cost ap-

proach to producing carbon fibers through controlled pyrolysis. Carbonized feather fibers (CFF) were prepared by first heating to 225 $^{o}$C (below the melting point)in $N_2$ for 26 hours to crosslink and stabilize the fiber structure; then carbonization occurred by increasing the temperature to 450 $^{o}$C for two more hours. The resulting CFF were hollow, stiff and strong and had an affine 80% weight loss, which is near the theoretical value for the C-content of keratin. Initial studies showed that a composite with the CFF and an epoxidized soybean oil (AESO) gave an improved fiber modulus $E_{CFF}$ of order 13.5–66.1 GPa. With continued research, the goals are to increase the stiffness of the feathers to 100 GPa, while increasing the strength in the range of 5-10 GPa.

**13:03**

**V25 8 Enhanced Dispersion in Polymer Nanocomposites by Optimized Hydrogen Bonding** MARK DADMUN, ASIF RASHEED, *University of Tennessee* PHILLIP BRITT, DAVID GEOHEGAN, ILIA IVANOV, *Oak Ridge National Laboratory* HAN GI CHAE, SATISH KUMAR, *Georgia Tech* The dispersion of the minor phase in a multi-component polymer system can readily lead to nonlinear enhancement of material properties. In any multi-component polymer system, including polymer nanocomposites, understanding and control of the dispersion of the nanofiller in the polymer matrix is critical to rationally design and create a ituseful new material. This presentation will discuss the work in our group to optimize the specific interactions between components of polymer nanocomposites. We will discuss results that indicate that the optimization of intermolecular interaction between components provides a controllable mechanism to improve the dispersion of nanoscale fillers in a polymer matrix and that the improved dispersion correlates directly to improved thermal, mechanical, and electrical properties.

**13:15**

**V25 9 Supercritical $CO_2$ Processing: A Novel Method for Producing Highly Dispersed Clay-Polymer Nanocomposites** STEVEN HORSCH, ESIN GULARI, RANGARAMANUJAM KANNAN, *Wayne State University* The key challenges in producing high performance nanocomposites are separation of the layered filler into individual platelets, preservation of large aspect ratios and promotion of polymer-filler interactions. By exploiting the ability of $scCO_2$ to diffuse into the layered filler and solvate/swell polymers we have been able to disperse the nanoclay and facilitate polymer-clay interactions even with $Na^+$ montmorillonite. Nanocomposites are prepared by processing the pristine nanoclay and compounding it with an appropriate polymer or processing clay/polymer simultaneously. SEM and WAXD results show significant clay layer separation and preservation of platelet aspect ratios. A high degree of dispersion is also observed in TEM images of these nanocomposites. The facilitation of polymer-clay interactions during the $scCO_2$ process results in higher glass transition temperatures and improved dynamic moduli for these systems. For example, a 5wt% 93A/PS nanocomposite has a 10 degree increase in $T_g$ and G' becomes nearly independent of frequency at low shear rates where it demonstrates an order of magnitude increase.

**13:27**

**V25 10 Evidence of re-entrant behavior in polymer-nanoclay systems** HOSEEIN BAGHDADI, SURITA BHATIA, *University of Massachusetts Amherst* Polymer-clay systems are of interest in a variety of applications, including nanocomposites, personal care products, and oil field products. Rheology and dynamic light scattering capture re-entrant behavior of laponite-polymer systems. Neat laponite at basic pH and concentrations of 2 weight percent or greater forms a viscoelastic isotropic solid due to electrostatic repulsions. This phase appears to be a colloidal glass of laponite particles. We show that that addition of low molecular weight poly(ethylene oxide) (PEO) melts the glass due to a depletion force. The depletion force speeds up dynamics in the system resulting in a low viscosity solution. A re-entrant viscoelastic solid is formed with the addition of high molecular weight PEO due to the polymer chains bridging between laponite particles. In addition we present non-linear rheological behavior below and above the transition. As expected the transition from a low to high viscosity solution scales with size of the polymer mean square end-to-end distance and gap between laponite particles.

**13:39**

**V25 11 Organoclay Networking in Polypropylene-Clay Nanocomposites** JAMES OBERHAUSER, MARK TREECE, *University of Virginia* We report on networking of organoclays and its influence on the rheology of polypropylene-clay nanocomposites. Samples are blended using either a twin screw extruder (TSE) or a single screw extruder with itin situ addition of supercritical $CO_2$ ($SCCO_2$). Blends contain proportional amounts (3:1) of maleic anhydride functionalized PP and organically modified montmorillonite (Cloisite® 15A, Southern Clay Products) at several clay loadings in a base PP resin (MFI 12 g/10 min at 230°C). Small-amplitude oscillatory shear (SAOS) and steady shear flow were utilized to probe clay morphology with varying annealing time. In SAOS experiments repeated over several hours, the terminal behavior of the TSE samples became increasingly solid-like; in steady shear, the magnitude of the viscosity overshoot increased with annealing time. The single-screw/$SCCO_2$ materials at the same clay loadings differed little rheologically from the neat resin. Finally, network formation kinetics accelerated with increasing temperature, and sufficiently large deformations irreversibly weakened the network structure.

**13:51**

**V25 12 Morphology and Gas Barrier of Polystyrene-Clay Nanocomposites** SERGEI NAZARENKO, *School of Polymers and High Performance Materials, University of Southern Mississippi* SYED QUTUBUDDIN, *Department of Chemical Engineering, Case Western Reserve University* Gas barrier of polymer clay nano-composites are often found to be substantially smaller than expected, especially in the case of exfoliated polymer clay nanocomposites where the improvement of gas barrier should be especially noticeable. This fact remains a subject of great controversy and calls for fundamental understanding. Model intercalated and exfoliated polystyrene/montmorillonite (MMT) systems were prepared by in-situ polymerization method, and their oxygen barrier was examined as a function of NaMMT content and related to nano-composite morphology studied by TEM. It was shown that apparent exfoliation of mineral layers, as confirmed by WAXS, not necessary was associated with their homogeneous dispersion. Agglomerates containing 3-6 practically parallel exfoliated layers were observed instead, and this morphology was responsible for poor gas barrier. In contrast, intercalated polymer clay nanocomposites exhibited an interesting phenomenon of layer staircase sliding leading to gas barrier properties better than expected. Gas barrier in both cases was successfully modeled by applying the Nielsen model which was modified to take into account layer agglomeration.

**14:03**

**V25 13 Rheology of Supercritical $CO_2$ dispersed Polymer/Clay Nanocomposites** RANGARAMANUJAM KANNAN, STEVEN HORSCH, GANAPATHY SUBRAMANIUM, ESIN GULARI, *Wayne State University* Effective dispersion of the fillers in a polymer matrix has been a key challenge in the field of nanocomposites. Supercritical carbon dioxide ($scCO_2$) appears, PS/clay, The nanocomposites are characterized using WAXD, SEM, TEM, Rheology and DSC. The high degree of dispersion achieved through sc-$CO_2$ appears to result in an order of magnitude increase in the rheological properties of PS, associated with an increase in the $T_g$ of around 13°C, at 10% clay loading. These moduli improvements are significant better than those obtained with conventional, chemically-modified intercalated clay nanocomposites. The degree of enhancement in the properties appears to be strongly dependant on the polymer-clay interactions, and how it is promoted by the supercritical fluid. In the case of PDMS nanocomposites, where the clay-polymer interactions were weak, the modulus increase at low frequencies (for sc-$CO_2$ processed system) was only a factor of 2. In the case of PVME- I30P clay nanocomposites, the modulus increase was substantial even at moderate loadings and dispersions, perhaps to be hydrogen-bonding interactions. The clay and the polymer orientation and interactions in these nanocomposites are also being probed using rheo-optical FTIR spectroscopy.

**SESSION V26: CELLULAR BIOMECHANICS**

**11:15**

**V26 1 Difference in cellular mechanics of cancer and normal cervical cells as seen with the AFM** IGOR SOKOLOV, SWAMINATHAN IYER, VENKATESH SUBBA-RAO, CRAIG WOODWORTH, *Clarkson University* Oncogenically transformed cells differ from their normal counter parts in many aspects, including organization and the amount of cytoskeleton. Consequently it is natural to expect to see the difference in cellular mechanics. Here we will present the study of such differences by using atomic force microscopy (AFM) in-vitro. So far the present research is the first study of mechanics of cervical cells, and the third comparative study of differences between mechanics of cancer and normal cells down with the help of AFM. Using a micron size silica ball as the AFM probe, we presumably do not overstress the cell surface as it can be in the case of the sharp AFM tip, and consequently, we may use the classical Hertz model. In contrast to the reported previously studies (bladder and fibroblast cells), we found that oncogenically transformed cervical cells are more rigid than the normal cells. The reason for such difference will be discussed. To demonstrate the complexity of the problem, we study cell mechanics in detail. The Young's modulus of rigidity clearly shows two separate regions of rigidity depending on the depth of the probe penetration. There may be two alternative explanations of the difference in rigidity of this top layer: it is either the cell membrane layer or detected long-range (presumably steric) forces due to the molecular ''brush'' of glycocalyx molecules. Experiments and modal calculations will be presented to choose between these two possibilities.

**11:27**

**V26 2 The Penetration of Titanium Dioxide Nanoparticles: From Dermal Fibroblasts to Skin Tissue** LAUREN SIPZNER, JAIMIE STETTIN, *Yeshivah University High School* ZHI PAN, XIAOHUA FANG, WILSON LEE, *Materials Sci. & Engr. Dept, SUNY at Stony Brook* NADINE PERNODET, MIRIAM RAFAILOVICH, *Program in Chemical and Molecular Engineering, SUNY at Stony Brook* $TiO_2$ particles are widely used in industry; however concerns are arising about their penetration into cells and tissue. In this study, we cultured dermal fibroblasts together with different commercial formulations of $TiO_2$ nanoparticles and observed the morphology,traction forces, proliferation, and migration of the cells as a function of nanoparticles dispersion and concentration. The location of the particles within the cell was studied with TEM. We found significant penetration after 30 minutes. In all cases damage to cell structure and function was observed. Actin fibril formation was disturbed, proliferation was severely hindered, and cell motility was impaired. The effects were more pronounced in fibroblasts from older subjects. These effects were attributed to both dimensionality, as well as UV photocatalysis of the particles. The implications for tissues will be discussed. This work is supported by NSF-MRSEC program.

**11:39**

**V26 3 Curvature-induced microphase separation and lipid polar localization in cell membranes - II*** KERWYN HUANG, *Princeton University* RANJAN MUKHOPADHYAY, *Clark University* NED WINGREEN, *Princeton University* In part II of this talk, we discuss how domain sizes in microphase-separated membranes are determined by the physical properties of lipids such as intrinsic curvature in our minimal model for membrane energetics. We then make contact between our model and experiments on the localization of the bacterial phospholipid cardiolipin. We demonstrate that the slight difference in curvature between the poles and midcell region of a micron-sized bacterium is enough to stably localize cardiolipin clusters to the poles, suggesting that cardiolipin clusters could be a target for polarly-localized proteins. We also show that the cardiolipin domain sizes are not sensitive to changes in the membrane composition. Finally, we propose experiments to test our model using inducible expression of cardiolipin in the bacterium *Bacillus subtilis*.

*This work is supported in part by NIH grant number 1K25 GM075000.

**11:51**

**V26 4 Curvature-induced microphase separation and lipid polar localization in cell membranes - I** RANJAN MUKHOPADHYAY, *Clark University* KERWYN HUANG, NED WINGREEN, *Princeton University* Recent research has revealed the prevalence of lipid domains and heterogeneities in biological cell membranes: examples include lipid rafts found in the outer leaflet of eukaryotic plasma membranes and polar localization of the phospholipid, cardiolipin, in bacteria. One of the mysteries has been why domains obsereved in biological cell membranes, such as lipid rafts which are believed to be 10-100 nanometers in size, appear to be much smaller than micron-sized domains observed in model multicomponent lipid vesicles. In this talk we will develop

a minimal model for membrane energetics that accounts for the coupling of the bilayer to an elastic substrate such as the actin cortex or cell wall, and will demonstrate how this coupling can lead to microphase separation and formation of stable lipid domains.

**12:03**

**V26 5 Using Optical Tweezers to Study Cell Mechanics during Airway Reopening*** HUSEYIN YALCIN, *Mechanical Eng., Lehigh University* JING WANG, *Physics Dept., Lehigh University* SAMIR GHADIALI, *Mechanical Eng., Lehigh University* H. DANIEL OU-YANG, *Physics Dept., Lehigh University* Patients suffering from the acute respiratory distress syndrome (ARDS) must be mechanically ventilated in order to survive. However, these ventilation protocols may generate injurious hydrodynamic stresses especially during low tidal volume (VT) ventilation when the flow of micron-sized air bubbles displace the surrounding liquid. In-vitro studies in our lab revealed that microbubble flows can severally damage lung epithelial cells (EC). The degree of injury was elevated for sub-confluent monolayers in small channel heights. Under these conditions, the micromechanics of individual EC may influence the degree of cellular injury. To investigate the role of cell mechanics, we used an oscillating Optical Tweezers (OT) technique to measure the intrinsic mechanical properties of EC before and after the flow of microbubbles. Knowledge of how the EC's micromechanical properties influence cell viability may lead to the development of novel treatment therapies that enhance the EC's ability to withstand injurious hydrodynamic stresses during ventilation treatment.

**V26 6 Probing subcellular force transduction with magnetic soft actuator arrays*** ALEXANDRE ANGUELOUCH, STUART KIRSCHNER, DANIEL REICH, *Johns Hopkins University* NATHAN SNIADECKI, CHRISTOPHER CHEN, *University of Pennsylvania* Microfabricated poly(dimethylsulfoxide) PDMS post arrays provide a method for mapping the distribution of contractile forces produced by adherent cells grown on the tips of the posts through optical tracking of the posts deflections (1). We describe a new technique whereby large local mechanical stimuli can be applied to such cells via magnetic torques applied to anisotropic magnetic nanowires embedded in selected posts. These magnetic post arrays thus serve both as actuators and detectors of cellular contractile response. Experiments characterizing the performance of these post arrays will be presented along with results on global changes in cell contractility induced by magnetic forces applied to a single post under a cell. **12:27**

**V26 7 Establishing threshold toxicity for introducing magnetic nanoparticles into HeLa and HEK 293 cells*** KEZHENG CHEN, WEILI LUO, *Department of Physics, University of Central Florida* PAPPACHAN KOLATTUKUTY, *Bernard College of Biomedical Sciences, University of Central Florida* UNIVERSITY OF CENTRAL FLORIDA TEAM, Although iron oxide nanoparticles have been suggested as candidate in diverse applications such as drug delivery agents, contrast agents of magnetic resonance imaging, cancer treatment through hyperthermia, etc., the upper limit for safe dosage beyond which the toxicity sets in has never been studied. In this work we report quantitative studies on the percentage change in the number of cell as a function of concentration of magnetic nanoparticles. The incubation is at 37°C and lasted for 24 hours. We found that there is a critical value of particle volume fraction, above which appreciable number of cell death occurs. This critical value was found to differ in two different cell lines indicating that HEK cells are more robust against the magnetic nanoparticles.

**V26 8 Modeling cell – extracellular matrix mechanical interactions during in vitro network formation** DAPHNE MANOUSSAKI, *Vanderbilt University* During the formation of vascular networks in vitro, endothelial cells exert traction forces onto the extracellular matrix (ECM), changing both the density and the orientation distribution of ECM fibers. ECM strain, in turn, affects cell migration. We study the effect of mechanical cell-ECM interactions on cell migration and cell distribution assuming a continuum description for the cells and the ECM. The theory assumes that the ECM is a viscoelastic material which deforms under cellular traction, and that resulting ECM strain influences cell movement. Numerical simulations predict that under certain mechanical conditions, cell traction can reorganize the cells and associated ECM into a network that compares well with the vascular networks that arise in vitro. I discuss the potential role of cell mechanical forces and ECM mechanical behavior on cell migration, and compare results with in vitro studies.

**12:51**

**V26 9 Axon growth and dynamics in 3D collagen gels*** RYAN MCALLISTER, WILL ROSOFF, JEFFREY URBACH, *Georgetown University* Living cells exhibit importantly different morphology and behavior in 3D hydrogels than on 2D substrates, but there have been very few studies of the dynamics of axons growing in 3D environments. To compare shape and outgrowth behavior of neuronal cells in 2- and 3D, we have developed a live-cell imaging apparatus using a spinning-disk confocal microscope. We compare growth cone cytoskeletal dynamics in fluorescently transfected neuronal cell-lines growing on a coated glass coverslip with those growing in a collagen matrix. We will describe some of the experimental challenges and our results (movies) to date.

*Work done in collaboration with Herb Geller's lab at NIH and Josef Kas' lab at U. Leipzig.

**V26 10 Investigating the glycocalyx using atomic force microscopy** REBECCA BOREN, ADAM RAFI, JESSICA FARRELL, ANTONIO PERAMO, W. GARRETT MATTHEWS, *Dept. of Physics, University of South Florida* The extracellular surfaces of the peripheral vascular system are coated with an outer filamentous layer of proteoglycan (PG) molecules, forming a brush-like structure known as the glycocalyx. The mechanical properties of PGs have become of increased interest due to their roles in a variety of interactions, including the adhesion of metastatic cells and their use as flow sensors. The goal of this project is to investigate the mechanical properties of the glycocalyx as a function of differing environmental conditions (i.e. pH, various ion concentrations, etc). We use as an experimental model of the glycocalyx an end-tethered brush of PGs oriented so that the protein backbone is upright, emulating their itin vivo formation. We have developed

a technique for patterning PG onto substrates allowing the exposure of the PG layer to different biologically relevant solvents. Resulting brush height changes will be measured using atomic force microscopy. The compression and extension of these PG molecules also will be measured and used to explain the imaged structures and the behaviors relevant to their biological function.

**V26 11 Local structure in diatom biosilica probed by synchrotron x-ray diffraction** MICHAEL DIBICCARI, *Hauppauge High School* SEO-YOUNG KWAK, *Brookhaven National Laboratory* GEOFFREY HIND, *Brookhaven National Laboratory* ELAINE DIMASI, *Brookhaven National Laboratory* Diatoms are single-celled algae that form intricate outer shells, or frustrules, composed of biosilica. They have attracted attention in the context of nanotechnology, since the submicron architectures are genetically determined and thus potentially could be reproduced synthetically, by using organic additives that mimic the proteins responsible for controlling biological silicification. We have compared the local atomic structure of diatom biosilica to that of inorganic silica with synchrotron x-ray diffraction, analyzed as the Pair Distribution Function (PDF). Specimens of Thalassiosira weissflogii (Tw) were cleaned of organic matter using either hydrogen peroxide, commercial bleach, or sodium dodecyl sulfate treatments. Low resolution PDF measurements ($q_{\max} \approx 13.6$ Å$^{-1}$) were made of wet and dry Tw, pure silica microspheres, and diatomaceous earth containing 15% mineral impurities. All samples have similar PDFs, demonstrating that local structure in diatoms and synthetic silica are equivalent, and that the PDF method is insensitive to biological impurites.

**13:27**
**V26 12 Bundle Buckling and Nesting Model of Striated Pattern Formation in Microtubule Solutions*** YONGXING GUO, YIFENG LIU, JAMES VALLES, JAY TANG, *Department of Physics, Brown University* Microtubules that are aligned by magnetic field or flow during the initial stages of polymerization form bundles in high concentration tubulin solutions. These bundles thicken and elongate with time and buckle in coordination with their neighbors into a wave shape. These nested and buckled bundles produce a macroscopically striped pattern of birefringence. We propose a mechanism for the buckling and present a normal mode stability analysis of a simplified model of it. The results show that the characteristic wavelength and critical buckling force are determined by the properties of the bundles and their neighboring elastic network, which is formed by unaligned and relatively short Microtubules.

**V27 1 Parallel kinetic Monte Carlo simulations of island-coarsening in two dimensions*** F. SHI, Y. SHIM, J. G. AMAR, *University of Toledo* The evaporation-driven coarsening of 2D islands is studied using a simple bond-counting model along with a recently developed semi-rigorous parallel algorithm for kinetic Monte Carlo (KMC) simulation. Using our parallel algorithm we have been able to simulate both larger system sizes and longer time scales than could be studied using serial KMC simulations. After deposition of less than a half monolayer on a substrate, the flux is stopped and the subsequent time evolution of the average island size and island size distributions were studied for different initial coverages. As expected, the average island size grows as $t^{1/2}$ at intermediate time and approaches the asymptotic $t^{2/3}$ behavior at very late time. Scaled island-size distributions in both regimes are obtained and compared with the predictions of mean-field theory. The efficiency of our parallel KMC simulations is also discussed.

**V27 2 Energy optimization of quantum Monte Carlo wave functions*** C.J. UMRIGAR, J. TOULOUSE, *Cornell University* In recent years many methods have been proposed for energy optimizing quantum Monte Carlo wave functions. Of these, the three highly efficient methods are: 1) The generalized eigenvalue method of Nightingale and Melik-Alaverdian, which was proposed by them for linear parameters only but extended by us to nonlinear parameters. 2) The effective fluctuation potential (EFP) method of Fahy, Filippi and coworkers, and the recent perturbative EFP of Schautz, Scemama and Filippi. We show that the latter can be more simply derived as first-order perturbation theory in a nonorthogonal basis. 3) The modified Newton method of Umrigar and Filippi and of Sorella. We show that the three methods are related to each other and point out that a control parameter can be employed in each of them to make them totally stable. We use these methods to optimize all the parameters in the Jastrow and the determinantal parts of the wave function and point out that different issues arise in optimizing the Jastrow and the determinantal parameters. By systematically increasing the number of determinants we find that seemingly similar systems, such as $C_2$ and $Si_2$ have vastly different fixed-node errors for single-determinant wave functions.

*We thank Claudia Filippi, John Lawson, Peter Nightingale and Andreas Savin for valuable discussions. Supported by NSF.

**V27 3 Monte Carlo Modeling of Luminescent Solar Concentrators** ALEX MOONEY, PAUL FONTECCHIO, BRUCE WITTMERSHAUS, *School of Science, Pennsylvania State University: Erie, The Behrend College* Luminescent Solar Concentrators (LSCs) offer an inexpensive alternative for solar power generation. A LSC is a flat, translucent plate that absorbs sunlight through embedded, highly fluorescent molecules. The emitted light is concentrated via total internal reflection at the edges of the LSC, where photovoltaic cells covert it into electricity. We've developed a Monte Carlo model that predicts the properties of LSCs by tracing individual light rays. The user controls the plate's geometry and spectral properties, along with the spectral profile of the excitation source. The user can include a specular or diffuse reflective background under the LSC. We've demonstrated the ability to predict the output of a LSC as a function of its optical density. Reabsorption distorts the profile of fluorescence as light propagates through a LSC, and the program can accurately reproduce the effect. The goal is to use the model as a predictive tool for improving the design of LSCs.

**11:51**

**V27 4 Efficiency of rejection free Monte Carlo methods** HIROSHI WATANABE, *Department of Complex, Systems Science, Graduate School of Information Science, Nagoya University* YUKAWA SATOSHI, *Department of Applied Physics, School of Engineering, The University of Tokyo* MARK A. NOVOTNY, *Department of Physics & Astronomy, ERC Center for Computational Sciences, Mississippi State University* NOBUYASU ITO, *Department of Applied Physics, School of Engineering, The University of Tokyo* We construct asymptotic arguments for the waiting time, the number of trials to achieve one update in Monte Carlo (MC) methods. We find that the waiting time is proportional to $e^{\beta}$ in the Ising, $\sqrt{\beta}$ in the classical XY, and $\beta$ in the classical Heisenberg spin systems with inverse temperature $\beta$, regardless of the dimension. The behavior in hard particle systems is also obtained, and found to be proportional to $(\rho c - \rho)^{-d}$ with the closest packing density $\rho c$, density $\rho$, and dimension $d$ of the systems. The waiting time determines the efficiency of rejection-free Monte Carlo (RFMC) methods, as well as the inefficiency of the standard MC. Our arguments are general, and applicable to any RFMC implementation of any model studied using kinetic Monte Carlo.

**12:03**

**V27 5 Improved sampling of computationally expensive potentials** MARK DEWING, We wish to evaluate statistical properties of systems using potentials that are accurate but computationally expensive, such as those obtained from Density Functional Theory or Quantum Monte Carlo. Using a cheap, approximate potential that is sufficiently close to the potential of interest, sample points can be generated that allow efficient evaluation of properties of the accurate potential.

**12:15**

**V27 6 Optimally efficient coarse-grained Monte Carlo simulation of rare transition events** BABAK SADIGH, TOMAS OPPELSTRUP, *Lawrence Livermore National Laboratory* WEI CAI, *Dept of Mechanical Engineering, Stanford University* MAURICE DE KONING, MALVIN KALOS, VASILY BUOLATOV, *Lawrence Livermore National Laboratory* We use the idea of coarse graining the multidimensional free energy landscape and present a new Monte Carlo scheme that allows for the exact calculation of the rate of rare transition events within the coarse-grained space defined by a few collective coordinates. This approach is based on a variational algorithm for determining an optimal importance function by which the absolute probability of sampling successful transition events is significantly enhanced, while the relative probabilities of any pair of successful events are preserved.

**12:27**

**V27 7 Optimized parallel tempering simulations of proteins** SIMON TREBST, *Microsoft, Project Q, and Kavli Institute for Theoretical Physics, Santa Barbara, CA 93106* MATTHIAS TROYER, *Theoretische Physik, ETH Zurich, CH-8093 Zurich, Switzerland* ULRICH HANSMANN, *John-von-Neumann Institute for Computing, Forschungszentrum Julich, D-52425 Julich, Germany* We introduce an adaptive algorithm that systematically improves the efficiency of parallel tempering or replica exchange methods in the numerical simulation of small proteins. Feedback iterations allow us to identify an optimal set of temperatures/replicas which are found to concentrate at the bottlenecks of the simulations. A measure of convergence for the equilibration of the parallel tempering algorithm is discussed. We test our algorithm by simulating the 36-residue villin headpiece sub-domain HP-36 where we find a lowest-energy configuration with a root-mean-square-deviation of less than 4 Å to the experimentally determined structure.

**12:39**

**V27 8 Hybrid DFT/Thomas-Fermi simulations and applications to biological systems** MIROSLAV HODAK, *North Carolina State University, Raleigh* WENCHANG LU, JERRY BERNHOLC, We have developped a hybrid simulation method suitable for performing calculations on biological systems. Within this method, Density Functional Theory (DFT) is used for the chemically active region and some solvent molecules, while the rest of the solvent molecules are treated with a variant of Thomas-Fermi (TF) theory, which uses the generalized gradient approximation (GGA) kinetic energy functional. These TF solvent molecules are assumed to be rigid and have frozen electron densities, which allows for their efficient treatment. Both Kleinman-Bylander and ultrasoft types of pseudopotentials are implemented within our method. We find it efficient to first equilibriate bio-molecules in solvent environment using classical molecular dynamics. After the initial equilibriation we use the hybrid method to study chemical reactions involving the bio-molecule. Initial applications to transition metal ions-protein complexes in solution will be discussed.

**12:51**

**V27 9 Environment Dependent Dynamic Charge Interatomic Potential for Silica** LEX KEMPER, KRISHNA MURALIDHARAN, YINGXIA WAN, HAI-PING CHENG, *University of Florida* We present a new interatomic potential to model the various silica polymorphs. Our formulation is loosely based on the embedded atom method (EAM), and accounts for explicit charge variations of atoms as a function of the local chemical environment of atoms. The parameters for the potential are derived from density functional (DFT) calculations. Some preliminary results will be discussed. Work supported by NSF ITR award DMR-0325553.

**13:03**

**V27 10 Universal Dynamic Exponent at the Liquid-Gas Transition from Molecular Dynamics** SUBHRANIL DE, AN CHEN, ELDRED CHIMOWITZ, YONATHAN SHAPIR, The liquid-gas system is expected to exhibit distinct dynamic behavior in the fluid's critical region (Model H). In this work we present molecular dynamics simulations of a Lennard-Jones fluid model starting from specially designed, near-equilibrium, initial conditions. By following the fluid's relaxation towards equilibrium, we calculate the requisite transport coefficients in the fluid's critical region. The results yield the scaling behavior of the thermal diffusion coefficient $D_T \sim \xi^{-1.023 \pm 0.018}$ ($\xi$ is the correlation length) and a non-conventional divergent heat conductivity, all of which are in accord with mode-coupling and renormalization group predictions, as well as some experimental data.

**13:15**

**V27 11 Global and local properties used as analyses tools for molecular-dynamics simulations*** MARTINA E. BACHLECHNER, *West Virginia University, Physics Department* JONAS T. ANDERSON,[†] DENG CAO, ROBERT H. LEONARD, ELI T. OWENS, JARROD E. SCHIFFBAUER, *West Virginia University, Physics Department* MELISSA R. BURKY,[‡] *Chemistry Department, Davis & Elkins College, Elkins, West Virginia 26241* SAMUEL C. DUCATMAN, ERIC J. GUFFEY,[§] *University High School, Morgantown, West Virginia 26505* FERNANDO SERRANO RAMOS, *Department of Computer Science, Metropolitan University, San Juan, Puerto Rico 00928* Molecular dynamics simulations have been used to study mechanical failure in realistic interface materials. Averaging over the individual atoms' contributions yields local and global information including displacements, bond angles, strains, stress tensor components, and pair distribution functions. A combined analysis of global and local properties facilitates detailed insight in the mechanisms of failure, which will eventually guide on how to prevent failure of interfaces.

**V27 12 Molecular Dynamics Simulations of Nanoscratching of 3C-SiC*** ALICE NOREYAN, J.G. AMAR, *University of Toledo* We have carried out molecular dynamics simulations of nanoindentation followed by nanoscratching on the Si terminated (001) surface of 3C-SiC. In particular, we have investigated the dependence of the friction coefficient, scratch hardness and wear on indentation-scratching depth, scratching velocity, scratching direction, indenter size and indenter shape. In general, the scratch hardness decreases with increasing scratching speed, while it increases with increasing indentation depth. In addition, the scratch hardness and the nanoscale chip formation mechanisms depend on the scratching direction. We also find that scratching leads to amorphization of the material along the scratching trajectory. The size of the amorphization region increases with an increase in scratching velocity, which causes the decrease in scratch hardness and friction coefficient for higher scratching velocities.

*Supported by NSF DMR-0219328 and CCF-0428826

**13:39**

**V27 13 Charge density wave and phonon softening in the Holstein model: A Quantum Monte Carlo study** PRABUDDHA CHAKRABORTY, *University of California, Davis* ALEXANDRU MACRIDIN, *University of Cincinnati* RICHARD SCALETTAR, *University of California, Davis* WARREN PICKETT, *University of California, Davis* RAJIV SINGH, *University of California, Davis* We present a Quantum Monte Carlo study of electron-phonon dynamics in the two dimensional Holstein model on a square lattice. We concentrate here on the softening of the phonon modes as the coupling between the electrons and the phonons is varied. Information about the instability of the electronic system toward the formation of a charge-density wave is also extracted from the phonon correlation functions. We also extract information about the phonon spectral densities using the Maximum Entropy method. Results are presented for various values of the wave-vectors in the two dimensional lattice. An intriguing softening of the phonon frequency at vanishing wave-vector is presented. We also present the effect of anharmonicity on the dynamics of the Holstein model.

## SESSION V28: RHEOLOGY OF BIOPOLYMER SOLUTIONS

**Thursday Morning, 16 March 2006**
**325, Baltimore Convention Center at 11:15**
**Daniel Savin, University of Vermont, presiding**

**11:15**

**V28 1 Massively-parallel fluorescence correlation spectroscopy using a spinning disk confocal microscope** DANIEL R. SISAN, RICH AREVALO, CAT GRAVES, RYAN McALLISTER, JEFFREY S. URBACH, *Dept. of Physics, Georgetown University* We describe an extension of fluorescence correlation spectroscopy (FCS) using a spinning disk confocal microscope. This approach can spatially map diffusion coefficients or flow velocities at up to $\sim 10^5$ independent locations simultaneously. Complex media—e.g., a tumor, cell nucleus, or extracellular matrix—are spatially-heterogeneous, making this spatially-resolved technique an ideal tool to understand hindered diffusion. There have been a number of recent extensions to FCS based on laser scanning microscopy. Spinning disk confocal microscopy, however, can be much faster at high resolution—potentially up to 1000 Hz at full resolution for the fastest available cameras—and without temporal delays between pixels. We show how to correct for a pixel size effect not encountered with standard or scanning FCS, and we introduce a method to correct for photobleaching. Finally, we apply this technique to microspheres diffusing in Type I collagen, which show non-trivial spatially varying diffusion caused by hydrodynamic and steric interactions with the collagen matrix.

**11:27**

**V28 2 Diffractive Imaging of Single Biomolecules** NATHAN SCHMIDT, ROBERT CORIDAN, *University of Illinois, Dept. of Physics* JOHN BUTLER, THOMAS ANGELINI, JIAN-MIN ZUO, GERARD WONG, *University of Illinois, Dept. of Physics, Dept. of Materials Science and Engineering* The resolution of Electron Microscopy (EM) images is limited by instrumentation lens aberration. Moreover, many biomolecules and supramolecular complexes are too soft and too large to be crystallized, and crystalline diffraction provides only aggregate structural properties. Coherent nanobeam electron diffraction in principle allows for diffraction-limited resolution analysis of single biomolecules. Image recovery can be achieved using oversampling and iterative phase retrieval to solve the phase problem. We will discuss the use of coherent electron diffraction and its potential to improve TEM image resolution of biomolecular systems. Preliminary diffraction data obtained from cryogenically prepared biomolecules will be presented.

**11:39**

**V28 3 Mechanical Properties of Actin Networks near the Polymerization Transition*** ANDREW POMERANCE, *University of Maryland* ERIN RERICHA, *University of Maryland* WOLFGANG LOSERT, *University of Maryland* Here we present studies of the mechanical properties of actin networks close to the polymerization transition. In the presence of divalent ions, the critical concentration (CC) for polymerization of actin decreases by two orders of magnitude. By studying concentrated actin samples (3 mg/mL) with and without added ions, we compare the behavior near and far above the CC for a sample with very similar concentrations of filamentous actin. To study the response to large forces we use holographic laser tweezers to pull microspheres through an actin network. We found that in samples far above the CC the microspheres strongly resist pulling, and have a well-defined relaxation time. Near the CC, the microspheres are easily pulled through the actin networks, and the relaxation is far more variable, which indicates that the actin filaments may be more dynamic and breakable.

**11:51**

**V28 4 Rheological Investigation of Protein Interactions in Synovial Fluid** REBECCA KLOSSNER, *North Carolina State University* WENDY KRAUSE, *North Carolina State University* RALPH COLBY, *Pennsylvania State University* Hyaluronic acid and the plasma proteins, albumin and $\gamma$-globulins, are the most abundant macromolecules in synovial fluid, the fluid that lubricates our freely moving (synovial) joints. In previous studies, bovine synovial fluid, a synovial fluid model and albumin in phosphate buffered saline (PBS) were observed to be rheopectic—viscosity increases over time under constant shear. Rheopexy is indicative of structure building in solution. To further investigate the contribution of albumin to the observed rheopexy, rheological experiments were conducted on bovine serum albumin (BSA) in PBS at concentrations comparable to those found in the synovial joints. Our data suggests that the plasma proteins aggregate together under these low shear conditions further entangling the hyaluronic acid chains, which results in an increase in the apparent viscosity of the synovial fluid over time. The nature of the proposed aggregation was probed by varying the salt concentration and pH in order to partially denature the protein and interrupt any hydrogen bonding. Additionally, similar rheological experiments were carried out using methylated albumin in order to observe the role of the disulfide bridges in the protein aggregation.

**12:03**

**V28 5 Influence of Anti-inflammatory Drugs on the Rheological Properties of Synovial Fluid and Its Components** WENDY E. KRAUSE, *North Carolina State University* REBECCA R. KLOSSNER, *North Carolina State University* JING LIANG, *North Carolina State University* RALPH H. COLBY, *The Pennsylvania State University* The polyelectrolyte hyaluronic acid (HA, hyaluronan), its interactions with anti-inflammatory drugs and other biopolymers, and its role in synovial fluid are being studied. We are investigating the rheological properties of sodium hyaluronate (NaHA) solutions and an experimental model of synovial fluid (comprised of NaHA, and the plasma proteins albumin and $\gamma$-globulins). Steady shear measurements on bovine synovial fluid, the synovial fluid model, and plasma protein solutions indicate that the fluids are rheopectic (stress increases with time under steady shear). In addition, the influence of anti-inflammatory agents on these solutions is being explored. Initial results indicate that D-penicillamine and hydroxychloroquine (HCQ) affect the rheology of the synovial fluid model and its components. While HCQ has no effect on the viscosity of NaHA solutions, it inhibits/suppresses the observed rheopexy of the synovial fluid model and plasma protein solutions. In contrast, D-penicillamine has a complex, time dependent effect on the viscosity of NaHA solutions,—reducing the zero shear rate viscosity of a 3 mg/mL NaHA (in phosphate buffered saline) by ca. 40% after 44 days. The potential implications of these results will be discussed.

**12:15**

**V28 6 Micromechanics of the pericellular matrix** J. E. CURTIS, H. BOEHM, C. H. J. SCHMITZ, J. P. SPATZ, *University of Heidelberg, Institute of Physical Chemistry and Max Planck Institute for Metals Research, Dept. of New Materials and Biosystems* In recent years, much attention has been directed towards the properties and activities of the cell surface. In particular, the coupling of the membrane to the underlying protein polymer network called the actin cortex plays an important role in many events. The other side of the cell surface is less studied, although it too has a bound polymer network comprised of gigantic cross-linked polysaccharides (sugars). Called the pericellular matrix (PCM), it is associated with many cells including fibroblasts, chondrocytes, endothelial and smooth muscle cells. Its thickness can vary from 10's of nanometers to 10 microns and it is associated with adhesion dependent events like migration and mitosis. Biologists often hypothesize that its viscoelastic properties are responsible for the modulation of cell adhesion activities. To investigate this proposal, we measure the PCM's viscoelasticity using microrheology and probe the sharpness of its edge and its mesh size. The elastic modulus of the PCM under different condition is determined, and we characterize the long, elastic cables that can be pulled from the PCM. These results are compared with an externally reconstituted model PCM on the cell surface.

**12:27**

**V28 7 Microrheology of active actin networks** TRAVIS H. LARSEN, *University of Delaware* ERIC M. FURST, *University of Delaware* To provide insight into the viscoelastic response of non-equilibrium, entangled semi-flexible polymeric networks, we study the model system of F-actin networks in the presence of active fragments of skeletal myosin. To characterize the microrheological response of this system, polystyrene microspheres of $1\mu$m in diameter are suspended into the three-dimensional, entangled F-actin network and diffusing wave spectroscopy is used to measure the mean-squared displacement of the particles on timescales from 100ns to 10ms. Particle motion is a result of both random thermal forces and the dissipation of actin filament fluctuations caused by the interactions of the suspended motor proteins with the network. Upon addition of myosin, we observe an increase in the MSD of the tracer particles and a shift in the scaling–dependence with respect to lag time from $t^{3/4}$ to $t^x$, where $3/4 < x < 1$. This shift indicates that the random, parallel ''tugs'' on the filaments by the motor proteins cause the filaments to develop an apparent decreased persistence length at length scales longer than the crossover length. Finally, we demonstrate that the addition of the cross-linking protein, $\alpha$-actinin, suppresses this ''active'' scaling behavior, while maintaining elevated probe particle diffusivity relative to the control.

**12:39**

**V28 8 Filamin cross-linkers as rheology regulators in biopolymer networks** BRIAN DIDONNA, *University of Minnesota* ALEX LEVINE, *University of California, Los Angeles* We report on the nonlinear mechanical properties of a statistically homogeneous, isotropic semiflexible network cross-linked by polymers containing numerous small unfolding domains. This model captures the main mechanical features of F-actin networks cross-linked by filamin proteins, which contain twenty-four such Ig-domains that may unfold under applied strain. We show that under sufficiently high strain the network spontaneously organizes itself so that an appreciable fraction of the filamin cross-linkers are at the threshold of domain unfolding. We discuss via a simple model the cause of this network organization. We also discuss how observation of this critical state validates a mechanism proposed by Crocker *et al.* to explain the weak power law dependence of the measured strain modulus as observed in intracellular microrheology experiments.

**12:51**

**V28 9 Microrheology of Microtubules ''Networks''** NAAMA GAL, CRAIG MANDATO, MARIA KILFOIL, Microtubules are the largest of the three protein biopolymers comprising the cytoskeleton, the other two being intermediate filaments and filamentous actin. While the mechanical properties of actin networks have been studied extensively, less is known about the mechanical properties of microtubules at high concentrations in the cytosol. Microtubules are involved in many of the cell functions, such as cell division and cargo transport within the cell. We use passive microrheology, extracting a viscoelastic modulus of the network based on the thermal motion of micron sized beads, to measure the elasticity of microtubules under various conditions in vitro. Our results show that the bead motion varies from highly confined to free, indicating the heterogeneous, structure of the network. We study the mechanical properties and the spatial heterogeneity and structure of these microtubule ''networks'' as a function of tubulin monomer concentration, ratio of microtubule associated protein to tubulin monomer concentration, and DMSO or nucleating factor concentration.

**13:03**

**V28 10 Anisotropic dynamic response of stiff biopolymers** OSKAR HALLATSCHEK, *Department of Physics, Harvard* BENEDIKT OBERMAYER, *Institut of Theoretical Physics, University of Leipzig* ERWIN FREY, *Department of Physics und CeNS, Ludwig-Maximilians-University Munich* KLAUS KROY, *Institute of Theoretical Physics, University of Leipzig* We have analyzed the dynamic response of stiff polymers under different force protocols, such as the sudden onset/release of a longitudinal or transverse point forces. In these non-equilibrium situations, an ordinary small gradient expansion fails to describe the Brownian motion of stiff polymers in the limit of short times due to the neglect of tension dynamics. We present an improved (multiple scale) perturbation theory unravelling the underlying nonlinear phenomenon that renders the short time dynamics quite complex. The polymers response exhibits asymptotic power law behaviour with distinct dynamic exponents that depend on the experimental scenario and the time regime.

**13:15**

**V28 11 Biopolymers in Aqueous Medium: Solvent Forces Explored through Atomistic Dynamics Simulations and Continuum Modeling of Solvent Effects** SERGIO A. HASSAN, *CMM/DCB/CIT/NIH/U.S.DHHS* Molecular interactions in solution are modulated by the bulk liquid and by the solvent-induced forces (SIF) originating in the structure of the liquid surrounding the solutes. Because of the difficulty in representing these effects, purely empirical solvation models are commonly used in simulations. Here, a semi-empirical continuum model is presented based on the theory of polar/polarizable liquids, which allows for a derivation of the electrostatic component of the potential. The effects of SIF are still introduced empirically to reproduce interaction energies in amino acids dimers (AAD). The limitations of the model are discussed based on its performance to reproduce structural, dynamic, and thermodynamic properties of peptides and proteins. To reduce the level of empiricism, the molecular origins of the SIF are investigated through dynamics simulations in explicit solvent. The solvent forces on AAD in pure water and NaCl solutions are studied. The reorganization of water and ions due to dimer dissociation is analyzed based on spatial density profiles. The solvent forms a network of high-density peaks consistent with extensive H-bonded water clusters. Long-range structural order develops in the space separating the monomers and contributes to the intermolecular SIF. The ions disrupt this network leading to either a stabilization or destabilization of the dimers. The relevance of these results to quantify SIF in complex solutes en route to a parameter-free continuum model is discussed.

**13:27**

**V28 12 Random energy model for heteropolymer sequence design: the role of solvation** LONGHUA HU, ALEXANDER GROSBERG, *Department of Physics, University of Minnesota* We study the role of surface of the globule and the role of interactions with the solvent for the process of sequence design for heteropolymers. We follow the method developed in recent work (P.Geissler et al, Phys. Rev. E, **70**, 021802, 2004) in which solvation of random sequence heteropolymer was addressed using properly generalized random energy model (REM). By comparing the freezing transition in random and designed sequence heteropolymers, we discuss the effects of design. We discuss phase diagram of the system in the traditional variables of actual temperature versus design temperature. Based on our results we are able to show under which conditions solvation effects improve the quality of sequence design. Finally we discuss sequence space entropy and study how many sequences are available for design at a certain design condition.

**13:39**

**V28 13 Recovery and Stiffening -Transition of Hydrogels Formed Via Peptide Self-Assembly** BULENT OZBAS, KARTHIKAN RAJAGOPAL, JOEL P. SCHNEIDER, DARRIN J. POCHAN, *Materials Sci Eng and Chemistry and Biochemistry, Univ. of Delaware* In this work we present the local nano- and overall network structure, and resultant viscoelastic properties, of hydrogels that are formed via $\beta$-hairpin peptide self-assembly that is triggered either by increasing the solution pH, temperature or ionic strength. These physiological stimuli induce the random-coil to $\beta$ -sheet intramolecular folding event that, in turn, causes intermoleculer self-assembly. The peptide molecules are locally amphiphilic with two linear strands flanking a central tetrapeptide turn sequence. SANS and TEM studies reveal that the peptide molecules self-assemble into semiflexible, fibrillar structures with monodisperse width that is dictated by the strand length of the molecule. Rheological measurements demonstrate that the hydrogels behave as soft-solid materials with tunable rigidity. Hydrogels

recover their initial viscoelastic properties after cessation of high magnitude of strain due to the physically crosslinked network structure and strong inter-fibrillar interactions. These interactions can be turned off by either condensing anions or covalently attaching PEG chains on the lysine-decorated fibrillar surfaces. In addition, stiffening transitions are observed when the hydrogels are cooled due to the hydrogen bonding capability of boric acid/borate ion with lysine residues.

**13:51**

**V28 14 Nanoscale structure and dynamics of colloid-semiflexible polymer solutions** JI YEON HUH, ERIC M. FURST, *University of Delaware* Interactions and structure in colloid-polymer solutions control the phase behavior, viscoelasticity, stability, and vitrification, which play significant roles in many industrial applications. Filled semiflexible networks demonstrate distinctive rheological properties due to their large persistence length. They are important in many biological and surfactant systems, and display additional complexity because of the alignment and isotropic-nematic transition. In this work, we report diffusing wave spectroscopy studies of the dynamics of colloidal particles suspended in F-actin solutions in time scales $10^{-6} < t < 10^{-2}$s, and in the concentration of 14.7$\mu$M. Monodisperse polystyrene spheres are coated using bovin serum albumin to reduce filament adsorption. By adjusting the actin filament length with the capping protein gelsolin, we observe the entanglement transition from dilute to semi-dilute regimes. Our data shows quantitative agreement with the theory of semiflexible polymer solutions in the dilute limit[1]. However, we find discrepancies in the entangled limit which may indicate the difference between local and bulk properties. Using a shell model for the local viscoelastic response[2], we find that the response is consistent with a depletion-like structure surrounding the embedded colloidal particles[3]. **14:03**

**V28 15 Relaxation Behavior of Acrylic Triblock Copolymer Gels** MICHELLE SEITZ, KENNETH SHULL, WESLEY BURGHARDT, *Northwestern University* When dissolved in alcohol, poly(methyl methacrylate)-poly(n-butyl actylate)-poly(methyl methacrylate) triblock copolymers form physical gels by the aggregation of the PMMA blocks into sperhical domains. Shear rheometry was used to study the relaxation behavior of gels formed in 2-ethylhexanol with different block lengths and polymer concentrations. Master curves were used to determine relaxation times at different temperatures. The relaxation time given by zero shear viscosity divided by the plateau modulus were in good agreement with the low frequency limit for a system with a single relaxation time. By increasing the PMMA block length from 9k to 25k or increasing polymer concentration from 5 to 30 vol. percent, the relaxation time increases by five orders of magnitude at a given temperature. The effect of block length and concentration on the aggregation number of the PMMA domains was determined by small angle X-ray scattering. Relaxation behavior is of practical importance because these gels are used for thermoreversible gelcasting of ceramics.

## SESSION V29: NONLINEAR PHENOMENA & PATTERN FORMATION IN BIOLOGY

**Thursday Morning, 16 March 2006**
**326, Baltimore Convention Center at 11:15**
**Igor Aronson, Argonne National Laboratory, presiding**

**11:15**

**V29 1 Thermally activated escape rate for a Brownian particle in a double-well potential for all values of the dissipation** WILLIAM COFFEY, *Department of Electronic and Electrical Engineering, Trinity College, Dublin 2, Ireland* YURI KALMYKOV, *MEPS, Université de Perpignan, 52 Avenue Paul Alduy, 66860 Perpignan Cedex, France* SERGEY TITOV, *Institute of Radio Engineering and Electronics of the Russian Academy of Sciences, Fryazino, Moscow Region, 141190, Russian Federation* The translational Brownian motion in a (2-4) double-well potential is considered. The escape rate, the position correlation function and correlation time, and the generalized susceptibility are evaluated from the solution of the underlying Langevin equation by using the matrix continued fraction method. The escape rate and the correlation time are compared with the Kramers theory of the escape rate of a Brownian particle from a potential well as extended by Mel'nikov and Meshkov [J. Chem. Phys. **85**, 1018 (1986)]. It is shown that in the low temperature limit, the universal Mel'nikov and Meshkov expression for the escape rate provides a good estimate of both escape rate and inverse position correlation time for all values of the dissipation including the very low damping (VLD), very high damping (VHD), and turnover regimes. Moreover, for low barriers, where the Mel'nikov and Meshkov method is not applicable, analytic equations for the correlation time in the VLD and VHD limits are derived.

**11:27**

**V29 2 The spectra of spiral wave breakup** DWIGHT BARKLEY, *University of Warwick* PAUL WHEELER, *University of Warwick* It has been known for many years that spiral waves in excitable reaction-diffusion systems can break up into a state of spatio-temporal chaos. The breakup may occur near the spiral tip (core breakup) or far from the tip (far-field breakup). Past analyses of these phenomena have been almost exclusively based on the study of 1D wave trains. This talk focuses on the computation of linear stability spectra and nonlinear simulations of spiral waves on large 2D disks. Through such computations we determine point eigenvalues associated with both types of breakup and show that these are near to, but not in, the absolute spectra. Hence spiral breakup occurs before the crossing of the absolute spectrum, contrary to prediction. Both types of breakup appear to be simply due to subcritical Hopf bifurcations.

**11:39**

**V29 3 Pattern Formation without Patterning Proteins in Cyanobacteria** JUN ALLARD, ANDREW RUTENBERG, *Department of Physics and Atmospheric Science, Dalhousie University, Halifax, Canada* Filaments of cyanobacteria respond to nitrogen starvation by differentiating one cell in ten into a heterocyst, which is devoted to fixing atmospheric nitrogen. This is an example of self-organized pattern formation. We present a dynamical model explaining the initial selection of heterocysts in mutated cyanobacteria that are effectively without normal patterning pro-

teins. Our simulations of this model produce distributions of heterocyst spacings that are consistent with experimental data, and lead to new qualitative predictions on the mechanisms of pattern formation in filamentous cyanobacteria. We discuss possible experimental tests of our results.

**11:51**

**V29 4 Experimental studies of large-scale collective swimming in dense suspensions of bacteria*** ANDREY SOKOLOV, *Illinois Institute of Technology/Argonne National Laboratory* IGOR ARANSON, *Argonne National Laboratory* RAYMOND GOLDSTEIN, JOHN KESSLER, *University of Arizona* We conducted experimental investigation of large-scale collective swimming in dense suspensions of itBacillus subtilis. This microorganism is flagellated, rod-shaped objects, 5-10 microns long and capable of swimming up to 20 microns/second. The hydrodynamic and chemical interactions between individual cells results in remarkably rich collective behavior; self-concentration due to gradients of dissolved oxygen or pH level; phase transitions and self-organization in confined geometries. The self-organization often takes the form of coherent structures with typical sizes that are many times larger than those of the individual bacteria. The studies were performed in thin liquid film with controlled thickness. We explored experimentally the dependence of the scales of large-scale flow structures on the concentration of cells. The experimental results are compared with the predictions of continuum mathematical model of this phenomenon.

**12:03**

**V29 5 Fiber optical measurements of electrical activity in canine ventricular preparations** AMGAD SQUIRES, GISA E. LUTHER, MICHAEL ENYEART, ROBERT F. GILMOUR, EBERHARD BODENSCHATZ, STEFAN LUTHER, *Department of Biomedical Sciences, Cornell University, NY, and Max Planck Institute for Dynamics and Self-Organization, Goettingen, Germany* Ventricular fibrillation (VF) is a cardiac arrhythmia that kills over 300,000 people every year in the US alone, yet efforts at finding a cure have been stymied by our incomplete information about patterns of electrical activity in the whole heart. As an excitable medium, the heart is a pattern forming system; but only a very limited subset of patterns is compatible with life. In particular, spiral waves have been associated with both tachycardia and VF, but their origin and spatial and temporal dynamics is not fully understood. We propose a novel measurement technique that combines optical mapping of the epicardial surface with data from intramural fiber optical probe arrays. The data obtained from the fiber optical probes is sparse in space but dense in time. The data processing is based on sequential data assimilation using an ensemble Kalman filter. The ensemble Kalman filter provides a numerically efficient (sub-) optimum state space estimate based on the available spatial and temporal observations. The feasibility of the method is demonstrated with numerical data and arterially perfused canine heart preparations.

**12:15**

**V29 6 Motion artifact removal in the optical mapping of cardiac tissue** GISA E. LUTHER, AMGAD SQUIRES, MICHAEL W. ENYEART, ROBERT F. GILMOUR, EBERHARD BODENSCHATZ, STEFAN LUTHER, *Department of Biomedical Sciences, Cornell University, NY, and Max Planck Institute for Dynamics and Self-Organization, Goettingen, Germany* Optical mapping provides measurements of the transmembrane potential in cardiac tissue with high spatial and temporal resolution using voltage senitive dye. However, the contractile motion of cardiac tissue causes substantial artifacts in optical recordings. On the other hand, mechanical or pharmacological inhibition of motion is known to promote ischemia or alter the electrophysiological properties of the tissue and therefore limits the application of the optical mapping technique. Motion artifacts arise due to two dominant mechanisms: (a) Relative motion of the tissue with respect to the optical imaging system or the fiber optical probe. (b) Change of the optical properties of the tissue and of the dye associated with the variation of the tissues mean density. We present a novel model based algorithm, which accounts for both mechanisms. It combines a Lukas-Kanade feature tracking with two-wavelength ratiometric imaging. The robustness and accuracy of this approach is validated using numerical and experimental data. Our approach allows to rephrase the contamination of the signal with motion artifacts as a nonlinear mixing process. De-mixing the signal opens the perspective of retrieving information on both the transmembrane potential and contractile force.

**12:27**

**V29 7 Compact Dynamical Equations for Brain Activity** JONG WON KIM, PETER A. ROBINSON, *School of Physics, University of Sydney, Australia. Brain Dynamics Center, Westmead Hospital and University of Sydney, Australia* A continuum model of brain dynamics has recently been developed to reproduce and unify many features of electroencephalographic (EEG) signals. We further investigate the model and propose a new, more compact, model based on a single delay differential equation which captures the essential features, such as rapid corticocortical feedbacks and delayed feedbacks from extra cortical pathways. Experimentally observed frequency spectra of EEGs, including resonances, are reproduced in relevant regions of parameter space. In the nonlinear regime, onsets of seizures, which often show limit cycles, are explained by the instabilities of resonances at the boundary of a stability zone in the parameter space. This compact model also shows several other points of agreement with previous models and experiments, and thus provides a theoretical basis for analyzing complex brain activities, especially when they exhibit low-dimensional dynamics.

**12:39**

**V29 8 Pattern recognition through collective behaviour in neural networks** JAN R. ENGELBRECHT, *Boston College* We investigate how collective order in networks of integrate-and-fire neurons can lead to computation. Specifically we show that patterns in static and dynamic sensory stimuli can be recognized through the development of synchrony in a simple neural network with a hierarchy of layers. The recognition events ultimately trigger activity in 'grandmother' neurons in the last layer.

**12:51**

**V29 9 Modeling of Protein Subcellular Localization in Bacteria** XIAOHUA XU, RAHUL KULKARNI, Specific subcellular localization of proteins is a vital component of important bacterial processes: e.g. the Min proteins which regulate cell division in *E. coli* and Spo0J-Soj system which is critical for sporulation in *B. subtilis*. We examine how the processes of diffusion and membrane attachment contribute to protein subcellular localization for the above systems. We use previous experimental results to suggest minimal models for these processes. For the minimal models,

we derive analytic expressions which provide insight into the processes that determine protein subcellular localization. Finally, we present the results of numerical simulations for the systems studied and make connections to the observed experiemental phenomenology.

**13:03**

**V29 10 Quantitative measures for mitotic spindle pattern formation structures** STUART SCHAFFNER, *Northeastern U.* JORGE JOSE, *SUNY at Buffalo, Northeastern U.* Recently introduced biophysical models successfully reproduce the basic spindle patterns found in in-vitro meiotic experiments. Numerical simulations of the model show the detailed behavior of microtubules and positive and negative walking molecular motors as they interact to form spindle patterns. Previous results were mostly qualitative in nature, but we are now developing quantitative measures to characterize the formation of spindle structures. In particular, minus-directed crosslinking motors bind microtubules together in pairs. This pairwise binding can be represented by a graph where the vertices are microtubules and the edges are crosslinking motors. Highly interconnected components of this graph correspond to bundles of motion-correlated microtubules. Numerical simulations show that these bundles are a prominent feature of spindle pole assembly. Using general ideas of random graph theory, we can measure deviations from random connectivity. We also calculate an approximation of the strain energy induced by contact forces between the microtubules and make estimates that could be tested experimentally.

**13:15**

**V29 11 Stability and Perturbation Analysis on a Model of Cell Chemotaxis** COLIN McCANN, *University of Maryland* RON SKUPSKY, *National Institutes of Health* WOLFGANG LOSERT, *University of Maryland* RALPH NOSSAL, *National Institutes of Health* Many eukaryotic cells respond with directional movement to spatial and/or temporal gradients of small molecules that bind to cell surface receptors. The computational model of a chemotaxing cell developed in [1], which models cells such as neutrophils or Dictyostelium discoideum, is investigated with regard to stability and response to perturbations. A formal stability analysis finds that, when placed in an initial linear gradient, the model is most sensitive to perturbations at a 60-90 degree offset from the direction of the initial gradient. The model also responds most quickly and strongly to external point sources placed in that direction. These responses hold for all four of the model variants developed in [1]. This suggests that the observed 'zigzag' behavior of real cell movement in a gradient may be influenced by the nature of the biochemical reactions that control a cell's chemotactic response. This research was funded in by the National Institutes of Health (NIH) and the National Institute of Standards and Technology (NIST). [1] Skupsky, R., W. Losert, and R.J. Nossal. 2005. ''Distinguishing modes of eukaryotic gradient sensing.'' Biophys. J. 89:2806–2823

**13:27**

**V29 12 Raman Correlation Spectroscopy*** EDWARD VAN KEUREN, *Georgetown University, Department of Physics* MAKI NISHIDA, *Georgetown University, Department of Physics* We have developed a simple method for measurement of diffusion coefficients of specific components in complex mixtures of suspended particles in a liquid. The method, a variation of photon correlation spectroscopy (PCS), uses temporal fluctuations of Raman scattered light to characterize the particle Brownian motion. This is possible due to the key fact that Raman scattering is a coherent process, which is necessary for meaningful photon autocorrelation functions to be obtained. The time autocorrelation functions of Raman emission lines will yield information similar to that obtained by PCS. However, since the scattering at a particular wavelength is usually specific to only one type of molecule, only the diffusion coefficient of the particles containing that chemical species will be measured. We demonstrate this method with several multicomponent nanoparticle dispersions.

**13:39**

**V29 13 A New Paradigm for Nanoparticle Biosensing: Magnetically Driven Critical Phase Slipping** BRANDON H McNAUGHTON, RAOUL KOPELMAN, *University of Michigan, Applied Physics Program; University of Michigan, Chemistry* Could a single opto-magnetic micro or nanoparticle be used as a noninvasive nanobiosensor? In this work, we imitated microorganism or bacteria sensing by binding a micron sized sphere to a larger rotating magnetic particle. The magnetic particle exhibits a nonlinear rotational behavior that marks a crossover from phase-locking to phase slipping with a remote rotating magnetic field. This critical transition is very sensitive to volume and shape changes, allowing for the detection of an attaching particle or biomolecule. Further miniaturization, combined with the remote sensing ability of this probe, could allow for measurements of viruses or biomolecules like DNA or proteins in a variety of environments, including closed biological systems.

**13:51**

**V29 14 Sum frequency generation microscopy for imaging chirality*** NA JI, *Department of Physics, University of California, Berkeley* KAI ZHANG, HAW YANG, *Department of Chemistry, University of California, Berkeley* YUEN-RON SHEN, *Department of Physics, University of California, Berkeley* Optically active sum frequency generation microscopy was demonstrated for the first time. Using films of solution of chiral 1,1'-bi-naphthol molecules with microstructures, we showed that sum frequency generation microscopy can image molecular chirality with three-dimensional sectioning capability and sub-micron spatial resolution. Because the image contrast originates from the intrinsic chirality of the system, no staining is required. Our microscopy scheme also allows the simultaneous detection of two-photon fluorescence. As a result, optically active sum frequency generation microscopy can be potentially very useful for live cell imaging. Preliminary results of applying this technique to DNA conformation study will also be described.

*This work was supported by DOE and NSF.

**14:03**

**V29 15 Upconversion-Detected Ultrafast Two-Dimensional Infrared Spectroscopy*** KEVIN KUBARYCH, *University of Michigan* MANUEL JOFFRE, *Laboratoire d'Optique et Biosciences Ecole Polytechnique* Two-dimensional infrared (2DIR) spectroscopy provides direct access to ultrafast molecular dynamics by measuring time- and structure-dependent couplings between vibrational transitions. Biological molecules, such as proteins, have rich vibrational spectra that relate to key structural elements including secondary structure ($\alpha$-helix, $\beta$-sheet), hydrogen bonding and protonation state. The ability to reliably measure 2DIR spectra in biological molecules represents a major step towards an

atomic-level picture of biochemical dynamics. A key limitation of ultrafast IR spectroscopy has been the measurement of the spectrum in a grating-based spectrometer due to HgCdTe detectors limited to linear arrays of 128 or fewer pixels. We have circumvented this problem by converting the coherently generated four-wave mixing 2DIR signal into the visible spectrum, and recording it using a 1340x100 pixel silicon CCD camera. The IR signal is mixed in a MgO:$LiNbO_3$ crystal with a chirped, $< 10\ \mu$J, 0.5 ns, 800 nm pulse. Signal detection is sufficient to measure single-shot dispersed vibrational echo spectra, as well as heterodyne detected 2DIR in $Mn_2(CO)_{10}$. The IR emission temporally overlaps only a narrow frequency range of the chirped near-IR pulse resulting in negligible spectral broadening.

**11:51**
**V30 2 Adhesion at Entangled Polymer Interfaces: A Unified Approach.** RICHARD WOOL, *Univeristy of Delaware* A unified theory of fracture of polymer interfaces was developed which was based on the Rigidity Percolation model of fracture [R.P. Wool, J.Polym.Sci. Part A: Polym Phys., 43,168(2005)]. The polymer fractured critically when the normalized entanglement density p, approached the percolation threshold $p_c$. The fracture energy was found to be $G_{1c} \sim [p\text{-}p_c]$. When applied to interfaces of width X, containing an areal density $\Sigma$ of chains, each contributing L chain entanglements, the percolation term $p \sim \Sigma L/X$ and the percolation threshold was related to $\Sigma_c$, $L_c$, or $X_c$. For welding of A/A symmetric interfaces, $p = \Sigma L/X$, and $p_c \approx L_c/M \approx 0$, such that when $\Sigma/X \sim 1/M$ for randomly distributed chain ends, $p \sim L \sim (t/M)^{1/2}$, $G/G^* = (t/\tau^*)^{1/2}$, where the weld time $\tau^* \sim M$. When the chain ends are segregated to the surface, $\Sigma$ is constant with time and $G/G^* = [t/\tau^*]^{1/4}$. For sub-$T_g$ welding, there exists a surface mobile layer (due to the critical Lindemann Atom fraction) of depth $X \sim 1/\Delta T^{\nu}$ such that $G \sim \Delta T^{-2\nu}$, where the critical exponent $\nu = 0.8$. For incompatible A/B interfaces of Helfand width d, normalized width $w = d/R_{ge}$, and entanglement density $N_{ent} \sim d/L_e$, $p \sim d$ such that, $G_{1c} \sim [d\text{-}d_c]$, $G_{1c} \sim [w\text{-}1]$, and $G \sim [N_{ent}\text{-}N_c]$. For incompatible A/B interfaces reinforced by an areal density $\Sigma$ of compatibilizer chains, L and X are constant, $p \sim \Sigma$, $p_c \sim \Sigma_c$, such that $G_{1c} \sim [\Sigma - \Sigma_c]$, which is in excellent agreement with experimental data.

**V30 3 Effect of entanglement density on mechanical properties of glassy polymers*** ROBERT HOY, *Johns Hopkins University* MARK ROBBINS, *Johns Hopkins University* The mechanical properties of model glassy polymers are studied using computer simulations. Using primitive path analysis, we relate the macroscopic stress-strain behavior of polymer glasses to the microscopic evolution of the underlying entanglement network. The network plays little role in phenomena such as the initial yield and strain softening, but dominates the mechanical response at larger strains. Comparison of results for systems with a wide range of entanglement densities allows study of the onset of network- dominated behavior. The density of entanglements is varied by changing the bending stiffness and diluting with shorter chains.

**12:15**
**V30 4 Entanglement Effects in Plastic Deformation of Filled Linear Polymer Glasses*** CAMERON ABRAMS, *Dept. Chemical and Biological Engineering, Drexel University* DAVID RICHARDSON, *Dept. Computer Science, Drexel University* We have performed coarse-grained molecular dynamics simulations of linear polymer glasses with low weight fractions of stiff rodlike particles. This is relevant to understanding the molecular-scale origins of toughness in nanotube-filled polymer composites. Linear polymer glasses are tougher than classical brittle glasses because chains are force to slide along each other under tensile load to undo entanglements. We focus here on the role of (a) the concentration and (b) orientational distibution of the rod-like inclusion particles on the entanglement network. We observed a substantial (10%) increase in the amount of work required to deform a particular glass plastically to a given strain (2.0) when equal weight fractions of rods were oriented randomly vs. parallel to the pulling axis. Using the method of primitive path analysis [Everaers, et al., Science 303:823 (2004)], we identify entanglements and particle-particle bridging interactions which are operative for a given pulling direction in a simulated tensile test in order to predict this enhancement from chain conformations in the initial unstrained sample. We apply this method to many samples with different weight fractions of rods, rod orientations, and rod-polymer interaction strengths.

**12:27**

**V30 5 Nanoparticles alignment, exclusion and entrapment during failure of Glassy Polymer Nanocomposite** JONG-YOUNG LEE, QINGLING ZHANG, TODD EMRICK, ALFRED CROSBY, *University of Massachusetts* Crazing is a polymer deformation process during which dense arrays of nanoscale fibrils grow prior to the propagation of a crack. In the presence of nanoscale inorganic fillers, the mechanisms of craze formation and propagation are altered significantly. We use a model material of polystyrene blended with surface modified CdSe nanoparticles to investigate the interaction between polymer molecules and nanoparticles during the process of crazing. We demonstrate that nanoparticles in the presence of a craze undergo three stages of rearrangement: 1) Alignment along the precraze (fluid-like region), 2) Expulsion from nanoscale craze fibrils, and 3) Assembly into clusters trapped between craze fibrils. These results not only provide direct evidence for the physical mechanisms that control the mechanical properties of polymer nanocomposites, but they give fundamental insight into the behavior of polymers and nanoparticles in the presence of a directed field, which will impact a wide array of advanced material applications.

**12:39**

**V30 6 Crazing in Glassy Polymer Nanocomposites** JONG-YOUNG LEE, QINGLING ZHANG, TODD EMRICK, ALFRED CROSBY, *University of Massachusetts* Crazing is a polymer deformation process in which dense arrays of nanoscale fibrils grow prior to the propagation of a crack. Here, we discuss experimental results on the impact of two nanostructured materials on the crazing process: 1) ordered glassy block copolymers and 2) homopolymer/nanoparticle composites. We not only find that an ordered lamellar microstructure leads a lower craze growth rate compared with polystyrene homopolymer, but also nanoscale, surface terraces significantly decrease the failure strain of these advanced materials. For homopolymer/nanoparticle composites, we discover significant alterations in the crazing process. Specifically, nanoparticles in the presence of a craze undergo three stages of rearrangement: 1) Alignment along the precraze (fluid-like region), 2) Expulsion from nanoscale craze fibrils, and 3) Assembly into clusters trapped between craze fibrils. Although nanoparticles have no effect on the initiation strain, fibril breakdown strain, and craze growth rate, the composite failure strain can be increased significantly by nearly 100% compared to neat homopolymer films. These results provide direct evidence for the physical mechanisms that control the mechanical properties of polymer nanocomposites.

**12:51**

**V30 7 Tensile Modulus Measurements of Carbon Nanotube Incorporated Electrospun Polymer Fibers** YAVUZ OZTURK, JAEMIN KIM, KWANWOO SHIN, *Dep.of Mat.Sci.and Eng., Gwangju Ins.of Sci.and Tech., Gwangju 500-712, Korea.* Electrospinning has become a popular method for producing continuous polymer fibers with diameters in sub-micron scale. By this technique uniaxially aligned fibers can also be obtained, by using two separate parallel strips as conductive collectors. Uniaxial alignment of polymer fibers gives us the chance to well-characterize their structural properties via tensile modulus measurements. Here we report a simple and new technique for tensile testing of polymer fibers which employs a computerized spring-balance/step-motor setup. The key point in our technique is the production of fibers directly on the tensile tester by using two vertical strips as collectors. By this way, even fibers of very brittle nature can be tested without handling them. Calculation of total cross-sectional areas - which is crucial for determining stress values - was done by using scanning electron and optical microscope images for each sample. In this study we have investigated mechanical properties of Polystyrene (PS), Polymethylmethacrylate (PMMA) and PS/PMMA blend fibers; as well as Carbon Nanotube (CNT) incorporated PS, PMMA and PS/PMMA blend fibers. It is expected that the extraordinary mechanical properties of CNTs can be transferred into polymer matrix, by their incorporation into confined space within electrospun fibers. Here we analyzed the influence of CNT on polymer fibers as function of CNT amounts.

**13:03**

**V30 8 Rate-dependent Mechanical Deformation Behavior of POSS-filled and Plasticized Poly(vinyl chloride).** SHARON SOONG, ROBERT COHEN, MARY BOYCE, *Massachusetts Institute of Technology* In different temperatures or strain-rate regimes, the rate sensitivities of polymers change as various primary and secondary molecular mobility mechanisms are accessed. Incorporating nanoparticles into the polymer matrix can potentially alter the molecular level structure and offers an opportunity to tailor the rate-dependent mechanical deformation behavior of the polymer. In this study, methacryl-POSS (C56H88O28Si8) and dioctyl phthalate (DOP) were incorporated into poly(vinyl chloride) (PVC) through melt blending. Dynamic Mechanical Analysis revealed that the incorporation of POSS in PVC plasticizes PVC and reduces both the alpha and beta transition temperatures. As for the PVC/DOP blends, while the alpha-transition temperatures were reduced, beta-motions vanishes with high DOP contents. The rate dependent yield behavior is characterized in compression testing. Zwick Mechine is used for low to moderate strain rate (0.0001 to 0.1/s) and Split Hopkinson Bar is used for high strain rate (500 to 2000/s). It was found that PVC with POSS shows a delay in yield strength rate-sensitivity transition. For PVC with higher DOP contents which show restricted beta-motions, the rate-sensitivity transition in yield stress faded away. Constitutive model used was able to predict the rate-sensitivity transitions in the compression yield behavior of PVC compounds.

**V30 9 Tensile Properties and Hysteresis Behavior of Graft Copolymers with Complex Molecular Architecture** R. WEIDISCH, *Institute of Materials Science and Technology, Friedrich-Schiller-University Jena, Loebdergraben 32, D-07743 Jena, Germany* U. STAUDINGER, *Leibniz-Institute of Polymer Research Dresden, Germany* Y. ZHU, S.P. GIDO, *Polymer Science and Engineering Dept., University of Massachusetts, Amherst, USA* D. UHRIG, J.W. MAYS, *Chemical Sciences Division and Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge,TN 37831, USA* N. HADJICHRISTIDIS, H. IATROU, *Department of Chemistry, University of Athens, Greece* PS-PI multigraft copolymers with tri- tetra- and hexafunctional polystyrene branch points have been studied to investigate the influence of molecular architecture on tensile properties and hysteresis behaviour. It was found that mechanical properties are mainly controlled by functionality of the graft copolymers and the number of branch points per molecule. Tetrafunctional multigraft copolymers show surprising high strain at break values up to 1550%. With increasing number of branch points strain at break and tensile strength increase, where a linear dependence of mechanical properties on the number of branch points is obvious. Hysteresis ex-

periments have proved excellent elasticity of tetra and hexafunctional multigrafts far exceeding that of commercial elastomers like Styroflex. A tetrafunctional multigraft copolymer can be deformed till 1400% showing a residual strain of only 40% demonstrating super elastic property profile.

**V30 10 Structure and Tensile mechanical properties of poly-(ester urethane) materials.** MARILYN HAWLEY, ROBERT HOULTON, PHILIP RAE, E. BRUCE ORLER, DEBRA WROBLESKI, *Los Alamos National Laboratory* Scanning probe microscopy (SPM) techniques, primarily phase imaging, and Stress/Strain Tensile Measurements were used to study the properties of model poly (ester urethane) and 23% Estanetrademark compression molded samples. SPM was used to characterize the surface microstructure and the corresponding distribution of hard and soft segments within these samples. The model samples contained a range of nitroplasticizer (NP) content from 0 to 15%. SPM phase imaging yielded maps of variations in local mechanical properties at the nanometer scale. Tensile stress/strain measurements were carried out at 0.1 mm/min. Sequential tensile stress/strain measurements to increasing strains, sequential tensile stress/strain measurements to the sample strain, and at different temperatures allow us to understand the deformation mechanism in this complex material. Significant elastic behavior was seen below the glass transition.

**13:39**

**V30 11 Identification of key deformation mechanisms of polyethylene materials via in-situ x-ray scattering** THERESA HERMEL-DAVIDOCK, WILLEM DEGROOT, MEHMET DEMIRORS, BRIAN LANDES, RAJEN PATEL, TRACY PELTIER, *Dow Chemical Company* Changes in the microstructure of ethylene based copolymers can be used to modify and enhance their mechanical performance. In this study, the effects of comonomer content, molecular weight, and molecular weight distribution on the mechanical performance of select polyethylene polymers were examined. Two key performance parameters for commercial polymer materials, especially in the area of blown film applications, are tear resistance and puncture resistance. However, polyethylene films exhibiting very different Dart and Elmendorf tear values cannot be differentiated by standard tensile test methods even though they exhibit very similar morphology. Alternative methods to link morphology and mechanical response need to be found. Wide-angle and small-angle x-ray scattering was collected during in-situ tensile testing to understand how compositional and structural differences affect the mechanical response of semicrystalline polyethylene polymers. Microstructural changes observed during the in-situ deformation process are correlated to Elmendorf tear and Dart impact performance for both intrinsic and blown film samples.

**V30 12 Microindentation Studies in Polymers at Very Low Crystallinities** FRANCISCO BALTA-CALLEJA, ARACELI FLORES, *IEM, CSIC, Madrid, Spain* MACROMOL. PHYS. TEAM, Indentation with a sharp indenter, involving a deformation on a micron and submicron scale is known to be a convenient method to measure the mechanical properties of polymers [1-2]. The aim of the present talk is to offer an overview on recent advances concerning the microindentation hardness, H, of a series of very low crystallinity (below 7 percent) polyethylene materials relating to nanostructure. The H values for the ethylene-octene copolymers are found to be notably smaller than those of linear and commercial short-chain branched polyethylene. The microhardness of an ethylene based material having a nearly zero crystallinity value has been measured for the first time. Results are discussed on the basis of the surface free energy, dimensions of the nanocrystals and the energy required for plastic deformation. In these low crystallinity materials the deformation modes involve bond rotation of the molecules within the amorphous phase, and elastic compression, bending and slippage of the nanocrystals. According to these deformation mechanisms, which are mainly modulated by the viscosity of the amorphous phase, the average dimensions of the nanocrystals after deformation remain practically unaffected. **V30 13 Effect of crystalline organization on toughness.*** LAURENT CORTE, *Matiere Molle et Chimie, ESPCI-CNRS* LUDWIK LEIBLER, *Matiere Molle et Chimie, ESPCI-CNRS* Impact resistance of semi-crystalline polymers can be greatly improved by the incorporation of rubber or inorganic particles. We report that the crystalline organization of the polymer matrix is a key-parameter for toughening. Cutting test bars into injected plates of toughened polyamide allows to study the impact behaviour of a same sample volume under various impact directions. When impact is applied perpendicularly to the injection direction, these systems exhibit a ductile behaviour while they become dramatically brittle when impact is parallel to it. More generally, the impact properties of these toughened systems depend strongly on thermo-mechanical history and processing conditions. We show by X-ray and TEM observations that this behaviour is to be correlated to the crystalline organization and propose a theoretical model that links toughness and crystalline organization.

**Laxmidhar Senapati, Naval Research Laboratory, presiding**

**11:15**

**V31 1 Ab initio charge transport through N-doped carbon nanotubes: microscopic understanding of carbon nanotube sensors** FREDERICO D. NOVAES, MARIANA ROSSI, ANTÔNIO J. R. DA SILVA, A. FAZZIO, *Instituto de Física, Universidade de Säo Paulo* We calculate, using an ab initio non-equilibrium Green's function formalism, the conductance of metallic carbon nanotubes with pyridine-like defects. We show that there is a decrease of the conductance at the Fermi energy due to these defects, which is caused by nitrogen related levels within an energy window of 1.5 eV below the Fermi energy. We then investigate how exposure to NH3 can affect the conductance. At the pyridine- like structure the NH3 dissociated into NH2 and H, with both molecules binding to nitrogen atoms. This configuration leads to an increase of the conductance, and cannot, therefore,

explain the increase of resistance that has been experimentally observed. We then investigate other configurations, and suggest that a possible cause of the resistance increase is adsorption of atomic or molecular species at the wall of pristine nanotubes.

**11:27**

**V31 2 A Semi-Empirical Approach to Bandstructure, Chemistry and Transport: Extended Hückel Theory applied to Carbon Nantotubes and Silicon*** DIEGO KIENLE, *Purdue University* JORGE CERDA, *Instituto de Ciencia de Materiales de Madrid* KIRK BEVAN, *Purdue University* GENGCHIAU LIANG, *Purdue University* LUTFE SIDDIQUI, *Purdue University* AVIK GHOSH, *University of Virginia* M.P. ANANTRAM, *NASA Ames Research Center* We apply semi-empirical Extended Hückel Theory (EHT) to calculate electronic structure and zero bias density-of states and transmission for two technologially important materials: carbon nantotubes and silicon. We demonstrate that the EHT-parameters optimized for bulk-silicon and 2D-graphene are transferable to describe qualitatively and quantitatively the electronic structure of structural deformed systems such as small diameter CNTs and relaxed silicon surfaces for different orientations. Finally, we show that the non-orthogonal EHT-approach can handle electronic structure and bonding chemistry simultaneously considering a carbon-monoxide-CNT heterostructure as example for a molecule sensor. To study transport through large nanoscale devices along with attached molecules a semi-empirical approach such as EHT might offer a good compromise between computational expensive DFT-methods and effective mass models which do not capture molecular features.

**V31 3 Ab initio Bandbending and Schottky Barriers of a Carbon Nanotube and Boron Nitride Device** KHORGOLKHUU ODBADRAKH, PAWEL POMORSKI, CHRISTOPHER ROLAND, *North Carolina State University* The quantum transport characteristics of two semiconducting nanotubes (i.e., single-wall (8,0) carbon and boron nitride nanotubes) coupled to metallic leads (i.e., Al (100)) was investigated with a combined nonequilibrium Greens function/density functional theory formalism. The resulting transmission depends very muchon the size of the nanotubes: very short tubes are characterized by metallic current-voltage behavior because of transmission via evanescent modes, while longer tubes are dominated by bandbending and Schottky barrier phenomena. An analysis of the latter phenomena as a function of nanotube characteristics, charge transfer, and gate voltage will be presented.

**11:51**

**V31 4 Effect of Strain and Defects on Transport Properties of Carbon Nanotubes** YAO HE, *University of Florida* CHUN ZHANG, *Georgia Technology Institute* CHAO CAO, HAI-PING CHENG, *University of Florida* Strain dependence of electronic transport properties of carbon nanotubes has been studied using first-principles calculations. We have found that the quantum conductance decreases monotonically with increasing strain, due to the strain-dependent contribution of molecular orbitals. Transport properties are also affected by the presence of defects. Our results have demonstrated that the electronic transport properties of a nano-scale device are closely related to the nature of the band structure of the metallic lead and the details of chemical bonding in the scattering region. DOE/BES under grant FG02-02ER45995 is acknowledged.

**12:03**

**V31 5 Dependence of transport through carbon nanotubes on local Coulomb potential.** ALEXEY ZHUKOV, *Duke University, Physics Department* ALEXANDER MAKAROVSKI, MATTHEW PRIOR, GLEB FINKELSTEIN, ELECTRONIC NANOSTRUCTURES GROUP TEAM, With home made atomic force microscope we perform scanned probed imaging of single-walled carbon nanotube devices at 4.2 K. We also observe changing of the heights and positions of the conductivity peaks in Coulomb Blockade regime with displacement of the AFM conductive tip. Influence of the Coulomb potential of the AFM tip on single-electron charge states in carbon nanotube is discussed.

**12:15**

**V31 6 Origin of hysteresis in gate-modulated transport in single-wall carbon nanotubes** SWASTIK KAR, ARAVIND VIJAYARAGHAVAN, *Department of Materials Science and Engineering, Rensselaer Polytechnic Institute, Troy New York* SAIKAT TALAPATRA, *Rensselaer Nanotechnology Center, Rensselaer Polytechnic Institute, Troy New York* CATERINA SOLDANO, SAROJ K. NAYAK, *Department of Physics, Applied Physics and Astronomy, Rensselaer Polytechnic Institute, Troy New York* OMKARAM NALAMASU, PULICKEL M. AJAYAN, *Department of Materials Science and Engineering, Rensselaer Polytechnic Institute, Troy New York* Transfer characteristics of gate-modulated transport in single-wall carbon nanotubes show significant hysteresis. This hysteresis is usually attributed to a screening of the gate voltage due to mobile charges/ions in the presence of a trapping/de-trapping mechanism within the gate architecture. From a temperature dependence of the hysteresis behavior, we suggest an alternate mechanism, where the screening charges are injected from the nanotube itself into the surrounding dielectric. Any trapping/de-trapping mechanism does not appear to play a significant role, and the experimental results can be understood in terms of a capacitive charging of the surrounding dielectric.

**12:27**

**V31 7 Electrical transport properties of selective area CVD grown single wall carbon nanotube devices*** ZHIXIAN ZHOU, RONGYING JIN, GYULA ERES, DAVID MANDRUS, *Oak Ridge National Laboratory* Individual single wall carbon nanotube (SWNT) devices were constructed by the direct assembly of an individual SWNT on two opposing Au electrons using an acetylene based low temperature selective area Chemical Vapor Deposition (CVD) method. Standard electron beam lithography and subsequent electron-gun assisted metal deposition were used to fabricate both the electrodes and catalyst islands. Electrical transport properties of the SWNT circuits were measured by applying a gate voltage to the Si substrate at various temperatures down to 0.3 K. Both semiconducting and metallic individual SWNTs were found bridging the Au electrodes with relatively small contact resistances. The semiconducting SWNTs exhibit a significant electrical field effect at room temperature with the conductance modulation approaching 5 orders of magnitude. High bias measurements on both suspended and substrate-supported metallic SWNTs reveal strikingly different phenomena. The details of the electrical transport results will be discussed.

*Oak Ridge National Laboratory is managed by UT-Battelle, LLC, for the U.S. Department of Energy under contract DE-AC05-00OR22725.

**12:39**

**V31 8 Electron transport in as-grown suspended semiconducting carbon nanotubes** VIKRAM DESHPANDE, MARC BOCKRATH, *Applied Physics, CalTech* Recently it was reported [1] that as-grown suspended single-walled carbon nanotubes (SWNTs) contacted with Pt or Mo leads afford devices that are devoid of perturbations due to substrate interaction and relatively defect-free. Previously, low-resistance contacts to semiconducting SWNTs have been obtained with Au [2], since the work-function of Au aligns with the valence band of the SWNTs creating ohmic contacts in the p-type region. We present fabrication of as-grown SWNTs with Au contacts, to fully exploit this behavior. We discuss electron transport in semiconducting devices obtained as above, with the aim of understanding the role of electron interactions in transport. Metallic SWNTs are known to exhibit Luttinger liquid behavior as is evident in the power-law dependence of conductance and density of states in a tunneling experiment [3]. We explore Luttinger liquid behavior in devices obtained using our fabrication technique. We will present latest experiments and inferences. **12:51**

**V31 9 The effect of purification on electron transport properties of single-wall carbon nanotubes** HISASHI KAJIURA, MASASHI SHIRAISHI, MASAFUMI ATA, *Sony* ANIL NANDYALA, ULAS COSKUN, ALEXEY BEZRYADIN, *University of Illinois* The effect of purification on room temperature electronic transport properties of laser-produced single-wall carbon nanotubes (SWNTs) was studied by submerging the nanotubes into liquid mercury. As-produced SWNTs were purified using H2O2, HCl, and NaOH solutions and heated at 923K at 0.01Pa for 1 h. Purified SWNTs having clean surface wall showed weak dependence of the electrical resistance on the length of the nanotube segment connecting electrodes. This provides evidence of quasi-ballistic electron transport in SWNTs. The estimated electronic mean free path of the purified SWNTs reached a few microns, which is longer than that of as-produced tubes. The electronic mean free path in purified SWNTs is consistent with the calculation based on the electron scattering by acoustic phonons. [H. Kajiura et al. Appl Phys Lett 86, 2005, 122106.]

**13:03**

**V31 10 Probing the transport property of each individual wall within a multiwall carbon nanotube** X. YAN, J.Y. HUANG, S. CHEN, Z. WANG, *Department of Physics, Boston College, Chestnut Hill, MA 02467* G. CHEN, *Department of Mechanical Engineering, MIT, Cambridge, MA 02139* M.S. DRESSELHAUS, *Department of Physics, Electrical Engineering and Computer Science, MIT, Cambridge, MA 02139* Z.F. REN, *Department of Physics, Boston College, Chestnut Hill, MA 02467* We report the atomic-scale imaging with concurrent transport measurements of the breakdownof individual multiwall carbon nanotubes inside a transmission electron microscope equipped with a piezo manipulator [1]. We found unexpectedly three distinct breakdown sequences; namely, from the outermost wall inward, from the innermost wall outward, and alternatively between the innermost and the outermost walls. Remarkably, a significant amount of current drop was observed when an innermost wall is broken, proving unambiguously that every wall is conducting. Moreover, the breakdown of each wall in any sequence initiates in the middle of the nanotube, not at the contact, proving that the transport is not ballistic. [1] J.Y. Huangetal, Phys. Rev. Lett. 94, 236802 (2005).

**13:15**

**V31 11 Electronic transport in single-walled nanotubes of known chiral indices** R. CALDWELL, *Columbia University* F. WANG, Y. WU, M. HUANG, L. HUANG, S. O'BRIEN, T.F. HEINZ, J. HONE, By measuring the Rayleigh scattering spectra of individual single-walled carbon nanotubes, we are able to measure the optical transition energies and therefore deduce the chiral indices (n,m). Using a simple mechanical transfer process, we can transfer the optically characterized tubes to a substrate. Following fabrication of metallic leads using e-beam lithography, the electrical transport properties of these tubes can be probed. We will present data on semiconducting, chiral metal and armchair metal SWNTs.

**13:27**

**V31 12 Hopping Conduction in Individual Template-Produced Multiwalled Carbon Nanotubes** D. P. WANG, B. R. PERKINS, A. J. YIN, D. E. FELDMAN, A. ZASLVASKY, J. M. XU, *Department of Physics and Division of Engineering, Brown University* We report electrical transport measurements of individual multiwalled carbon nanotubes grown catalytically in a nonporous anodic aluminum oxide template by thermal chemical vapor deposition of acetylene. The conductance shows an $\exp[-(T_0/T)^{1/2}]$ dependence on temperature $T$ and $\exp[-\xi_0/\xi]$ dependence on the applied electric field $\xi$ in the high field regime, suggesting that hopping conduction between the grains is the dominant transportation mechanism. As the nanotubes are granular and highly defective, annealing has been used to change the granularity. Similar $T$- and $\xi$- dependence of conductance is observed for annealed nanotubes with different granularity-related coefficients $T_0$and $\xi_0$. Small magnetoresistance is observed for both types of nanotubes. Comparison with theory is presented and the $T_0$and $\xi_0$ coefficients are used to extract the characteristic conducting grain size.

**13:39**

**V31 13 Thermal effects in non-linear electronic transport in metallic carbon nanotubes*** MARCELO KURODA, *Beckman Institute and Dept. of Physics, University of Illinois at Urbana-Champaign* JEAN-PIERRE LEBURTON, *Beckman Institute and Dept. of Electrical and Computer Engineering, University of Illinois at Urbana-Champaign* Recent experiments have shown that metallic carbon nanotubes exhibit different *IV* characteristics depending on whether or not they lie on a substrate. These interesting features range from current saturation to negative differential resistance at high bias. In this talk, we present a model based on the solution of the Boltzmann transport equation that accounts for the interplay between thermal and electronic transport in the metallic system. Our results reproduce the experimental observations and emphasize the role of heat dissipation in the nanotube nonlinear characteristics.

**13:51**

**V31 14 Thermal Transport in MWNT sheet.** ALI ALIEV, MEI ZHANG, SHAOLI FANG, SERGEY LEE, ANVAR ZAKHIDOV, RAY BAUGHMAN, *Nanotech Institute, University of Texas at Dallas, Richardson, TX 75083* We present the comparative study of the anisotropic thermal conductivity and the thermal diffusivity of aligned multiwalled carbon nanotube sheet using two methods: laser flash and 3 omega methods. The highly aligned transparent nanotube sheets are drawn from a sidewall of a mul-

tiwalled carbon nanotube (MWNT) forest that was synthesized by chemical vapor deposition. The sectional analysis by AFM tip shows that suspended sheet consists on average one layer of 10 nm MWNT. Increase of the sheet density by stacking the layer to layer decreases the thermal conductivity and thermal diffusivity due to phonon-phonon interaction. High thermal conductivity and thermal diffusivity of studied specimens combined with extremely high surface area suggests a variety of application of MWNT sheets.

**14:03**
**V31 15 Nanotube-Metal Junctions: 2- and 3- Terminal Electrical Transport*** SAN-HUANG KE, WEITAO YANG, HAROLD U. BARANGER, *Duke University* We address the quality of electrical contact between carbon nanotubes and metallic electrodes by performing first-principles calculations for the electron transmission through ideal 2- and 3-terminal junctions, thus revealing the physical limit of tube-metal conduction. The structural model constructed involves surrounding the tube by the metal atoms of the electrode as in most experiments; we consider metallic (5,5) and n-doped semiconducting (10,0) tubes surrounded by Au or Pd. In the case of metallic tubes, the contact conductance is shown to approach the ideal $4e^2/h$ in the limit of large contact area. For three-terminals, the division of flux among the different transmission channels depends strongly on the metal material. A Pd electrode has nearly perfect tube-electrode transmission and therefore turns off the straight transport along the tube. The carrier injection is found to occur only at the edge of the contact region. Our results are in good agreement with some recent experimental reports and clarify a fundamental discrepancy between theory and experiment.

**V33 1 Social Balance on Networks: The Dynamics of Friendship and Hatred.***
SIDNEY REDNER, *Boston University*

We study the evolution of social networks that contain both friendly and unfriendly pairwise links between individual nodes. The network is endowed with dynamics in which the sense of a link in an imbalanced triad—a triangular loop with 1 or 3 unfriendly links—is reversed to make the triad balanced. Thus an imbalanced triad is analogous to a frustrated plaquette in a random magnet, while a balanced triad fulfills the adage: ''a friend of my friend is my friend; an enemy of my friend is my enemy; a friend of my enemy is my enemy; an enemy of my enemy is my friend.'' With this frustration-reducing dynamics, an infinite network undergoes a dynamic phase transition from a steady state to ''paradise''—all links are friendly—as the propensity for friendly links to be created in an update event passes through 1/2. On the other hand, a finite network always falls into a socially-balanced absorbing state where no imbalanced triads remain. A prominent example of the achievement of social balance is the evolution of pacts and treaties between various European countries during the late 1800's and early 1900's. Here social balance gave rise to the two major alliances that comprised the protagonists of World War I.

**V33 2 Lamb-lion Problem on Networks and Its Applications** SUNGMIN LEE, SOON-HYUNG YOOK, YUP KIM, *Department of Physics, Kyung Hee University* We numerically study the dynamic properties of diffusing lamb captured by diffusing lion on the complex networks. We find that the survival probability $S(t)$ of a lamb decays exponentially on the complex networks including scale-free networks whose degree distribution follows $P(k) \sim k^{-\gamma}$. We also find that the average life time $< T >$ depends on the size of the underlying networks, $N$, and it satisfies the relation $< T > \sim N^{\alpha}$ for $\gamma > 3$. However, for small values of $\gamma$ ($< 3$) we find that $< T >$ does not follow the power-law. Finally, we investigate the topological property of the node at which the lion captures the lamb by measuring the degree of the node. We also discuss some possible applications of our findings.

**V33 3 Preferential attachment in the growth of social networks: the case of Wikipedia** GUIDO CALDARELLI, *CNR-INFM Istituto dei Sistemi Complessi, and Dipartimento Fisica, Università di Roma ''La Sapienza,'' Piazzale Aldo Moro 2, Rome Italy* ANDREA CAPOCCI, *Centro Studi e Ricerche Enrico Fermi, Rome Italy* VITO SERVEDIO, *Dipartimento di Fisica, Università ''La Sapienza'' Piazzale Aldo Moro 5 00185 Rome, Italy* LUCIANA BURIOL, DEBORA DONATO, *Dipartimento di Informatica e Sistemistica, Università ''La Sapienza''* STEFANO LEONARDI, *Dipartimento di Informatica e Sistemistica, Universita' ''La Sapienza'' via Salaria 113 00198 Rome Italy* CNR-INFM TEAM, CENTRO FERMI TEAM, DIP. DI INF. E SIST. TEAM, Here we present experimental data and a model in order to describe the evolution of a socio-technological system. The case of study presented is that of the online free encyclopedia Wikipedia, for which we have the complete series of pages addition during time. The varioius entries and the hyperlinks between them can be described as a graph. We find scale-invariant behaviour in the

distribution of the degree and a topology similar to that of the World Wide Web. By using the information on dynamics we are able to model and reproduce the features of this system. We also find that regardless the fact that any user has the possibility of global reshape, still Wikipedia has a growth described by local rules as that of the preferential attachment.

**12:15**

**V33 4 Social inertia in collaboration networks** JOSE J. RAMASCO, *Emory University* STEVEN A. MORRIS, *Oklahoma State University* This work is a study of the properties of collaboration networks employing the formalism of weighted graphs to represent their one-mode projection. The weight of the edges is directly the number of times that a partnership has been repeated. This representation allows us to define the concept of *social inertia* that measures thetendency of authors to keep on collaborating with previouspartners. We use a collection of empirical datasets to analyze several aspects of the social inertia: 1) its probability distribution, 2) its correlation with other properties, and 3) the correlations of the inertia between neighbors in the network. We also contrast these empirical results with the predictions of a recently proposed theoretical model for the growth of collaboration networks.

**12:27**

**V33 5 Efficiently achieving consensus in scientific collaboration networks** R. DEAN MALMGREN, SAM SEAVER, ROGER GUIMERA, DANIEL DIERMEIER, JULIO OTTINO, LUIS AMARAL, *Northwestern University* Recent work by Guimerá et al. [1] indicates that successful collaborative networks are developed from a balance of new and old blood. To first approximation, the efficiency of these collaborative networks to reach consensus on a problem depends on (i) the difficulty of the problem and (ii) the fraction of time each individual spends working on his own versus interacting with his peers. We mimic problem difficulty by the likelihood that an individual obtains the correct answer, and we model social interactions by the majority rule, which is efficient even in the presence of noise [2]. We then study the asynchronous dynamics of small-world [3] and collaborative networks [1] to quantify the efficiency of empirical collaborative networks to achieve consensus. Finally, we examine how altering the balance of new and old blood affects the efficiency of collaborative networks to reach consensus. [1] R. Guimerá, B. Uzzi, J. Spiro, and L. A. N. Amaral. *Science* **308**, 697–702 (2005). [2] A. A. Moreira, A. Mathur, D. Diermeier, and L. A. N. Amaral. *PNAS* **101**(33), 12085–12090 (2004). [3] D. J. Watts and S. H. **12:39**

**V33 6 A Network Analysis of Committees in the United States House of Representatives** MASON PORTER, *Caltech* Network theory provides a powerful tool for the representation and analysis of complex systems of interacting agents. Here we investigate the networks of committee and subcommittee assignments in the United States House of Representatives from the 101st–108th Congresses, with committees connected according to ''interlocks'' or common membership. We examine the House's community structure using several algorithms and reveal strong links between different committees as well as the intrinsic hierarchical structure within the House as a whole. We show additionally that structural changes, including a tighter community structure, resulted from the 1994 elections, in which the Republican party earned majority status in the House for the first time in more than forty years. In this work, we combine our network theory approach with analysis of roll call votes using singular value decomposition and successfully uncover political and organizational correlations between committees in the House without the need to incorporate other political information. This is joint work with A.J. Friend, Peter Mucha, Mark Newman, and Casey Warmbrand.

**12:51**

**V33 7 DIMES – New Results from Wide-area Internet Topology Mapping** SHLOMO HAVLIN, SHAI CARMI, *The Physics Department, Bar-Ilan University, Israel* ERAN SHIR, YUVAL SHAVITT, *Department of Electrical Engineering, Tel Aviv University, Israel* SCOTT KIRKPARTRICK, *School of Computer Science and Engineering, The Hebrew University of Jerusalem, Israel* DIMES is a distributed agent-based Internet mapping effort which at present has attracted thousands of volunteers running clients world-wide. Despite the ''law of diminishing returns'' seen when when adding agents in past mapping attempts, we find that significant amounts of new information can be found in the long tails of our measurement process. We use the k-pruning method to decompose the network into nodes with distinct roles. The analysis suggests a new picture of the AS-level Internet structure, which distinguishes a relatively large, redundantly connected core of nearly 100 ASes and two components that flow data in and out from this core. One component is fractally interconnected through peer links; the second makes direct connections to the core only. We plan to use this picture as a framework for measuring and extrapolating changes in the Internet's physical structure. Our analysis may also be relevant for estimating the function of nodes in the ''scale free'' graphs extracted from other naturally-occurring processes.

**13:03**

**V33 8 Modeling search-dominated Web growth** SANTO FORTUNATO, ALESSANDRO FLAMMINI, FILIPPO MENCZER, ALESSANDRO VESPIGNANI, *School of Informatics, Indiana University* Our present understanding of the Web growth, beyond the large number of existing models, is very much based on the paradigm of preferential attachment, that reflects a surf-dominated Web. In fact nowadays most of the traffic on the Web goes through and is driven by search engines. This profoundly affects the dynamics behind Web growth, potentially leading to a monopolistic scenario where few nodes attract a large share of traffic and links. We propose a minimalistic model to describe the evolution of the Web based on the interaction between users and search engines. The model reproduces several characterizing properties of the topology and traffic on the Web, and explains apparently counterintuitive empirical evidences. S. Fortunato, A. Flammini, F. Menczer and A. Vespignani, School of Informatics, Indiana University ''The egalitarian effect of search engines,'' http://arxiv.org/abs/cs.CY/0511005

**V33 9 Evidence of accelerated growth by edge copying and unfairness in the evolution of the AS level of the Internet*** BRUNO GONÇALVES, *Emory University* JOSE MENDES, *Universidade de Aveiro* It is well known that the Internet on the Autonomous System level is in constant evolution and growth. In this paper we show that for the freely available data for the period between Nov, 97 to March, 01 is compatible with a edge-copying model with a probability $p = 0.58$. We also demonstrate that the

Internet is intrinsically unfair since the nodes with higher connectivities remain the same throughout its history.

**V33 10 Vulnerability of complex networks: Effect of traffic and geography** MARC BARTHELEMY, *Indiana University and CEA* LUCA DALL'ASTA, ALAIN BARRAT, *LPT-Universite Paris-Sud* ALESSANDRO VESPIGNANI, *Indiana University* Real-world networks present different levels of complexity: the topology, the weights and the spatial properties are often nontrivial and very different from simple random assumptions. In order to understand the vulnerability to malicious attacks of such networks one has therefore to consider not only topological quantities but also weights and space. We will present results on the paradigmatic example of the airport network which is a weighted heterogeneous network with complex traffic and spatial structures. We define different measures of damage and show that different attack strategies lead to different conclusions about the vulnerability of the network. In particular, we show that strategies need to be adapted depending on the type of damage and on the geographical region considered.

**V33 11 Network theory model of the United States Patent citation network*** JAN TOBOCHNIK, PETER ERDI, *Kalamazoo College* KATHERINE STRANDBURG, *DePaul University College of Law* GABOR CSARDI, LASZLO ZALANYI, *Department of Biophysics, KFKI Research Institute* We report results of a network theory approach to the study of the United States patent system. We model the patent citation network as a discrete time, discrete space stochastic dynamic system. From data on more than two million patents and their citations, we extract an attractiveness function, $A(k,l)$, which determines the likelihood that a patent will be cited. A(k,l) is approximately separable into a product of a function $A_k(k)$ and a function $A_l(l)$, where $k$ is the number of citations already received (in-degree) and $l$ is the age measured in patent number units. $A_l(l)$ displays a peak at low $l$ and a long power law tail, suggesting that some patented technologies have very long-term effects. $A_k(k)$ exhibits super-linear preferential attachment. The preferential attachment exponent has been increasing since 1991, suggesting that patent citations are increasingly concentrated on a relatively small number of patents. The overall average probability that a new patent will be cited by a given patent has increased slightly during the same period.

**13:51**

**V33 12 The social cost of partisanship** SAM SEAVER, ROBERT MALMGREN, ANDRE MOREIRA, DANIEL DIERMEIER, LUIS AMARAL, *Northwestern University* Implementing policies that bring an overall social benefit can be quite difficult due to the myriad of ways in which different individuals and groups may be impacted, and the variety of targets, beliefs and agendas the policy-makers themselves may have. Examples include the implementation of measures with the objective of reducing carbon dioxide emissions and the implementation of guidelines for conducting stem cell research. Here, we use an agent-based modeling approach to investigate the effects of conservatism and partisanship on the efficiency with which large populations reach consensus on the ''correct'' decision. Remarkably, we find that conservative agents do not destroy the groups' ability to reach consensus. In fact, conservatives enable the system to maintain high efficiency, even in the presence of large levels of noise. In contrast, we find that even a small number of partisans results in low efficiency, especially for large levels of noise. We conclude that while conservatism improves social outcomes, partisanship can have significant social costs.

## SESSION V35: PHOTONIC CRYSTALS

**Thursday Morning, 16 March 2006**
**338, Baltimore Convention Center at 11:15**

**11:15**

**V35 1 A Dynamical Effective Medium Theory for Metamaterials** YING WU, JENSEN LI, ZHAO-QING ZHANG, C.T. CHAN, *Department of Physics,The Hong Kong University of Science and Technology* We present a new dynamical effective medium theory in the framework of two-parameter coherent potential approximation. While conventional homogenization theories will fail near resonances, our theory gives simultaneously accurate effective permittivity and permeability near resonant frequencies. The theory can also describe the absorption. Our assertions are supported by the band structure and transmission calculations of periodic composites in both two and three dimensions.

**11:27**

**V35 2 The gap structures and wave functions of two-dimensional quasicrystals for classical waves.** YUN LAI, ZHAO-QING ZHANG, *Department of Physics, The Hong Kong University of Science and Technology, Hong Kong* CHI-HOU CHAN, *Department of Electronic Engineering, City University of Hong Kong, Hong Kong* LEUNG TSANG, *Department of Electrical Engineering, University of Washington, US* By using the sparse-matrix canonical-grid (SMCG) method, we have performed large-scale multiple scattering calculations to study the gap structures and wave functions of two-dimensional quasicrystals for classical waves. As sample size is increased, we find self-similar-like evolution in the gap structures. We also find the self-similar state and large-size localized states. All these findings arise from the quasiperiodic long-range order. A self-similar state at band edge is identified in a large sample containing 33919 scatterers. A coherent picture is presented to describe the relationship between the self-similar-like evolution of gap structures and the formation of self-similar states.

**11:39**

**V35 3 Electromagnetic wave propagation in media whose permittivity varies periodically in time*** JUAN CARLOS CERVANTES, PETER HALEVI, We have developed a general theory for propagation of plane electromagnetic waves in a medium with permittivity that is varying periodically in time. The Bloch-Floquet theorem dictates that these are a superposition of harmonic modes whose frequencies differ by $2\pi/T$, where $T$ is the period of $\varepsilon(t)$. For arbitrary periodicity, the dispersion relation $\omega(t)$ for the ''Bloch frequency'' is given in terms of the roots of an infinite determinant whose elements depend on the Fourier coefficients of $\varepsilon(t)$. For small variation of $\varepsilon(t)$ around an average

$\varepsilon_0$, $\omega(t)$ is characterized by regions of the wave vector $k$ that are forbidden for propagation. These are centered at it$\omega$ and $k$ values that are, respectively, integer multiples of $\pi/T$ and of $\pi\varepsilon_0^{1/2}/cT$. The widths of the gaps are proportional to the corresponding Fourier coefficients of $\varepsilon(t)$. In the special case of square-periodic variation of $\varepsilon(t)$, there is no need to recur to a perturbational calculation, because the dispersion relation can be derived analytically, with no approximations. Again, we find wave vectors gaps whose edges are located at the frequencies $\omega$=0,$\pi$/T,2$\pi$/T.

**V35 4 Achieving a Photonic Band-Edge Near Visible Wavelengths by Copper Coating on 3D Tungsten Photonic-lattices.** DEXIAN YE, SHAWN-YU LIN, JAMES BUR, TOH-MING LU, *Rensselaer Polytechnic Institute* The fabrication of all-metal three-dimensional (3D) photonic lattices (PLs) is a subject that has raised great interest due to their potential in energy applications [1]. However, there are very few metals are suitable for the architecture of 3D PLs with a photonic band-edge near visible wavelengths. 3D tungsten (W) photonic lattice in ''wood-pile'' architecture has been successfully fabricated [1]. But the intrinsic limitation of W prevents the photonic band-edge to go beyond 2 $\mu$m. We show that by material engineering this limitation can be overcome. We coated a very thin layer of copper (Cu) conformally onto the W PLs and modified their optical properties. The Cu thin films were coated on the PLs by electroless deposition. This thin Cu film ( $\sim$ 70 nm) has dramatic effects on the photonic band-gap behavior of the W PLs. After the coating of Cu, the photonic lattice has a much larger photonic band-gap. The band-edge of the photonic lattice is shifted from $\lambda \sim 2\mu$m to $\lambda \sim$ 750nm. Our experimental data agree with the predictions by finite difference time domain calculations. This method provides a new route for tailoring photonic properties and it should work for 3D PLs constructed from other materials. [1] J. G. Fleming, S.Y. Lin, I. El-Kady, R. Biswas and K. M. Ho, Nature **417**, 52-55 (2002).

**12:03**

**V35 5 From Photonic Crystals to Photonic Metamaterials. I*** PETER HALEVI, FELIPE PEREZ-RODRIGUEZ, *INAOE* We present a very general mean-field theory for a photonic crystal (dielectric or metallo-dielectric) with arbitrary (3D) Bravais lattice and arbitrary inclusions within the unit cell. The material properties are characterized by a generalized conductivity at every point in the unit cell. Averaging over many unit cells for very small Bloch wave vectors, we derive the macroscopic response for the metamaterial. This, in general, turns out to be the bianisotropic response, specified in terms of permittivity and permeability tensors and, also, ''crossed'' D/H and B/E tensors. These four tensors are derived in terms of the content of the unit cell. However, in case of inversion symmetry these ''crossed'' tensors vanish. Moreover, for cubic symmetry the system becomes isotropic, described by scalar, frequency-dependent, permittivity and permeability.The response is essentially local, although, spatial dispersion can also be accounted for. Our mean-field theory is valid for optical photonic bands, as well as acoustic bands.

*The authors acknoledge their CONACYT projects 41195-F and 46425-F.

**12:15**

**V35 6 From Photonic Crystals to Photonic Metamaterials. II*** FELIPE PEREZ-RODRIGUEZ, PETER HALEVI, *INAOE* We have applied the mean-field theory (I) described in the preceding abstract to metallo-dielectric photonic crystals with cubic symmetry and for different forms of the metallic inclusions. In particular, we have calculated analytically the effective permittivity and permeability for periodic composites with ''cages'' of thin metallic wires or ''3D crosses'' and for arrays of small metallic or dielectric spheres in vacuum. We compare our results for the permittivity of such systems with former theories and find agreement as far as the real part is concerned. Our results for the imaginary part of the permittivity differ from other works and those for the permeability are new. In fact, the extinction coefficient that we derive for small metallic spheres is three orders of magnitude greater than the prediction of the Maxwell-Garnett theory. We are in the process of applying our theory to other interesting metallo-dielectric systems.

*The authors acknowledge their CONACYT projects 41195-F and 46425-F.

**12:27**

**V35 7 Quantum Hall effect analogs in photonic crystals: semiclassical treatment of ''chiral'' (unidirectional) edge modes*** SRINIVAS RAGHU, F.D.M. HALDANE, *Princeton University* Previously, we have shown that ''photonic crystals'' (periodic metamaterials that transmit electromagnetic waves) made of nonreciprocal media (Faraday effect) can theoretically possess channels that allow light to propagate in one direction only. These channels are the direct photonic analog of the ''chiral edge states'' of electronic systems exhibiting a quantum Hall effect. Here, we construct exactly soluble models of photonic systems having these properties. The models considered here correspond to photonic systems with smoothly varying domain walls across which the Faraday coupling changes. The spectrum of bound states of this model contains bi-directionally propagating modes localized to the interface, and ''zero modes,'' in which light remains localized to the interface and propagates only in a forward direction perpendicular to it. In the semiclassical treatment of this model, we show that the quantization condition for the bound states has an additional contribution from a Z2 Berry phase factor picked up by the modes as they encircle points of degeneracy.

**12:39**

**V35 8 Influence of disorder on the band structure of a photonic crystal** ILYA PONOMAREV, T.L. REINECKE, *Naval Research Laboratory, Washington DC* M. BAYER, *Experimentelle Physik 2, Universitaet Dortmund, Germany* A. FORCHEL, *Technische Physik, Universitaet Wuerzburg, Germany* We investigate both theoretically and experimentally the influence of disorder on the optical mode spectra of chains of coupled micropillar cavities (photonic dot resonators - PDR). These quasi one-dimensional structures were fabricated by lateral patterning of planar Bragg microcavities. Maxwell equations were solved by finite elements methods. The disorder is introduced by systematic variation of the cavity sizes. For periodic chains without disorder (equal PDRs) angle-resolved photoluminescence shows well-pronounced photonic band gaps. We show that even small disorder drastically modi-

fies the properties of the optical modes and their spectra. Instead of set of propagating energy bands with Bloch states, impurity bands with Anderson-like localized states appear. The dependences of the energy bands and their intensities on cavities sizes are investigated and explained.

**12:51**

**V35 9 Photonic band-gaps in two dimensional semiconductor-dielctric composite structures** GERARDO MARTINEZ, MANVIR KUSHWAHA, *Institute of Physics, University of Puebla, Mexico* This paper reports the multiple band-gaps in the two-dimensional semiconductor-dielectric photonic crystals of several compositions: semiconductor (dielectric) cylinders in the dielectric (semiconductor) background. We consider both square lattice and triangular lattice arrangements and compute extensive band structures using a plane-wave method within the framework of an efficient standard eigenvalue problem for both E- and H-polarizations. The whole range of filling fractions has been explored to claim the existence of the lowest (the so-called acoustic band gap) and multiple higher-frequency band gaps within the first thirty to forty bands for various compositions. The completeness of the existing band gaps is substantiated by computing the band structures via detailed scanning of the principal symmetry directions covering periphery as well as the interior of the irreducible part of the first Brillouin zone and through the computation of the density of states. In general, the composition made up of doped semiconducting cylinders in the insulating background is found to be the optimum case for both geometries. Such semiconductor-dielectric photonic crystals which are shown to possess huge lowest band gaps below a threshold frequency (the plasma frequency) have an advantage over the dielectric photonic crystals in the emerging technology based on the photonic crystals.

**13:03**

**V35 10 Fabrication of Highly Reflecting $Si/SiO_2$ Bragg Mirrors Using Transferred Nanomembranes*** WEINA PENG, FRANK S. FLACK, MICHELLE M. ROBERTS, PAULA E. COLAVITA, DONALD E. SAVAGE, ROBERT J. HAMERS, MAX G. LAGALLY, MARK A. ERIKSSON, *University of Wisconsin Madison* A long term goal of electronics and photonics is the integration of both on the same materials platform and substrate. Silicon and silicon- dioxide are an excellent photonic materials pair, due to the superior properties of the oxide-silicon interface, and due to the large index-of- refraction contrast in this materials pair. We present a novel method to fabricate $Si/SiO_2$ mirrors based on transfer of freely released silicon nanomembranes and subsequent thermal oxidation. The surface roughness of the transferred membranes is examined using atomic force microscopy. RMS roughnesses as small as 0.25nm are achieved. The reflectivity is also measured for our transferred membranes, and an increase in reflection is easily observed as the number of stacked membranes is increased. The experimental reflectivity data match theoretical calculations within 10%. We discuss the possibility of aligning many membranes to make complicated photonic structures.

**13:15**

**V35 11 Tuning of the Optical Response of a $Si/SiO_2$ Superlattice at the Wavelength of 1.54$\mu$m** E. GALINDO, P. HALEVI, *INAOE, Apdo. Post. 51, Puebla, Pue.72000, México* ADAN S. SANCHEZ, *INAOE and INTEL, Guadalajara, Mexico* We have studied a one-dimensional photonic crystal of alternating layers of silicon and silicon oxide (and, also, air), fixing the wavelength at 1.54$\mu$m, of great importance for communications in the near infrared. We assume strong doping of the Si layers, the density of free electrons reaching values up to $3\times10^{20}cm^3$. Using a realistic plasma model that takes into account electrons, holes, and the corresponding attenuation, our calculations lead to the conclusion that the reflectance and transmittance can depend very strongly on the carrier density. With a careful choice of parameters, a change in the reflectance from 0 to 90% can be attained in the vicinity of a photonic band edge, with only a moderate change in the impurity concentration.

**13:27**

**V35 12 Improved Photonic Bandgap Structures via Symmetry Breaking** DAVID MACKIE, *Army Research Laboratory* We have previously reported on our efforts to develop a semiconductor based photonic bandgap nano-membrane device with 3D MEMS features which is designed to reconfigure the photonic crystal structure into different types of waveguide devices such as switches, modulators, delay lines, etc.[1] As design and fabrication interact there is tension between what one would like to make and what one can actually make. We have found that in many cases, by breaking some of the symmetry, it is possible to shift gaps around and to introduce new gaps. We discuss various examples of this. As an example with especially good performance, we discuss the case of rotated square holes in a square lattice. 1. ''Design and Fabrication of a Reconfigurable Photonic Bandgap Waveguide Device with MEMS Features,'' Weimin Zhou, Monica Taysing-Lara, Gerard Dang, Lorna Harrison, David Mackie, Matthew Ervin, and Peter Newman, presented at CLEO 2004.

**V35 13 Wannier Function Expansion of Localized States in Photonic Crystals** J. D. ALBRECHT, *Air Force Research Laboratory* P. SOTIRELIS, *High Performance Technologies, Inc., The Advanced Computational Analysis Directorate, Wright-Patterson Air Force Base, OH* We present a theoretical treatment of localized electromagnetic modes in infinite photonic crystals. Our basis states are local vector Wannier functions calculated from the unperturbed crystal eigenstates. Analogous to the calculation of localized electronic states by expansion in terms of electronic orbitals, this Wannier basis is used to expand photonic crystal defect states. The localized nature of the basis states is critical so that the basis can be truncated after a small number of neighbor lattice sites in the vicinity of the defect. We present results that verify the eigenmodes of the crystal and examine defect modes. An analysis is done to determine the convergence of the mode as a function of the number of basis states included in the computation. This formalism equally treats localized states that are bound in a photonic band gap and states resonant with the propagating photon states of the infinite crystal. The present method has certain advantages with regard to computational complexity, spatial resolution, and the efficient accommodation of non-spherical geometric features.

**13:51**

**V35 14 Tangent formulation for the band structure of one-dimensional N-period layered photonic crystals** FRANK SZMULOWICZ,* *Air Force Research Laboratory* At symmetry points of the Brillouin zone, the two-layer Kronig-Penney (KP) problem has even and odd parity solutions that are expressible with tangents and cotangents. Similar solutions are derived here

for an arbitrary number of layers. Namely, the eigenvalue-eigenvector problem for the energy spectra and wave functions of arbitrary, one-dimensional, N-period layered systems is formulated in terms of tangents only. The resulting equations are compact, algorithmically simple, numerically stable, and physically appealing. The derived secular equation is Hermitian and only of order N× N, i.e., half the size of the KP secular equation. The eigenfrequency condition has physically attractive geometric representation in terms of N-sided figures such as triangles and tetrahedrons for N=3. The analytic power of the formalism is demonstrated by diagonalizing the secular equation for N=3, finding a factored form of the KP equation, and deriving analytic eigenfrequency conditions and analytic wave functions for the three layer problem. The analyticity of the formalism should aid the band gap engineering of the band structure and wave functions of multilayer structures. The numerical ease of implementation is demonstrated by calculating the eigenfrequencies and wave functions for a three-layer photonic crystal.

**V35 15 Temperature tuning of two-dimensional photonic crystals in the presence of phonons and a plasma of electrons and holes** JESUS MANZANARES-MARTINEZ, FELIPE RAMOS-MENDIETA, *Universidad de Sonora* PETER HALEVI, *Instituto Nacional de Astrofisica, Opticay Electronica* We have theoretically studied the electromagnetic transmittance in finite samples of InSb-based two-dimensional photonic crystals. Due to the temperature dependence of the intrinsic carrier concentration in the semiconductor, our square arrays of parallel InSb cylinders in air give rise to tunable transmission spectra. As the temperature increases from 200 to 290 K, we find that the midgap frequencies move up in frequency while the widths of the gaps diminish, in agreement with the bulk band structure. We find that absorption affects considerably the transmittance intensity. In order to achieve significant tuning of the transmission, appropriate structural parameters and spectral regions are proposed. We have also studied transmission of light through two-dimensional photonic crystals of finite width, with the radii of the cylinders in the middle row altered in comparison to the host cylinders.

## SESSION V36: FOCUS SESSION: OPTICAL PROPERTIES OF CARBON NANOTUBES AND C60

**V36 1 Spectroscopy of Optical Excitations in Carbon Nanotubes.**
YINGZHONG MA, *University of California, Berkeley and Physical Biosciences Division, Lawrence Berkeley National Laboratory*

Understanding the optical spectra and electronic excited state dynamics of carbon naotubes is important both for fundamental research and a wide variety of potential applications. In this presentation, we will report the results of a systematic study on semiconducting single-walled carbon nanotubes (SWNTs) obtained by utilizing complementary femtosecond spectroscopic techniques, including fluorescence up-conversion, frequency-resolved transient absorption, and three-pulse photon echo peakshift (3PEPS) spectroscopy. Our efforts have focused on optically selective detection of the spectra and dynamics associated with structurally distinct semiconducting SWNT species. Using individual nanotube enriched micelle-dispersed SWNT preparations, in combination with resonant excitation and detection, has enabled us to independently access selected species, such as the (8,3), (6,5), (7,5), (11,0), (7,6) and (9,5) nanotubes. We will discuss the following topics: (1) the excitonic nature of the elementary excitation and its unambiguous identification from direct determination of the exciton binding energy for a selected semiconducting nanotube, the (8,3) tube; (2) the spectroscopic and dynamical signatures of exciton-exciton annihilation and its predominant role in governing ultrafast excited state relaxation; (3) the annihilation-concomitant exciton dissociation and the spectroscopic and dynamic features of the resulting electron-hole continuum; (4) timescales characterizing the ultrafast thermalization processes. In addition, we will demonstrate the power of 3PEPS spectroscopy to elucidate the spectral properties and dynamics of SWNTs. This work was supported by the NSF.

**V36 2 Real time approach for non-linear optical response of nano-scale systems*** Y. TAKIMOTO, F. VILA, J.J. REHR, *U. of Washington* We present a real-time, time-dependent density-functional approach for the calculation of the frequency-dependent linear and non-linear optical response, which is based on the approach of Tsolakidis et al.[1] Tensor components of linear polarizabilities and first order hyper-polarizabilities are extracted by fitting net time dependent polarizations with different electric field strengths. The method is computationally efficient and can be applied to large, molecular and nano-scale systems. Results are presented for $C_{60}$ and for a number of ''push-pull'' molecules. Our results for the static limit are in good agreement with other density-functional calculations.

*Supported by NSF Grant DMR-0120967 (Y.T. and F.V) and DOE Grant DE-FG02-97ER45623 (JJR) and facilitated by the DOE CMSN

**V36 3 First-Principles study of the optical properties of BN nanotubes and h-BN** CHEOL HWAN PARK, CATALIN SPATARU, STEVEN LOUIE, *UC Berkeley and Lawrence Berkeley National Laboratory* We present first-principles calculations of the effects of quasiparticle self-energy and electron-hole interaction on the optical properties of single-walled BN nanotubes (both zigzag and armchair tubes) and bulk h-BN. Excitonic effects are shown to be even more important in BN nanotubes than in carbon nanotubes, giving rise to excitons with binding energy larger than 2 eV for the zigzag (8,0) BN nanotubes. Moreover, unlike the carbon nanotubes, theory predicts that these exciton states are comprised of coherent supposition of transitions from several different subband pairs, giving rise to novel behaviors. Our calculatioins are in quantitative agreement with available experimental data. We also compare the optical properties of single-walled BN nanotubes with those of bulk h-BN. This work was supported by the NSF under Grant No. DMR04-39768, and the U.S. DOE under Contract No. DE-AC03-76SF00098. Computer time was provided by NERSC and NPACI.

**12:15**

**V36 4 *Ab initio* Studies of Potassium Adsorption on Graphite and Carbon Nanotubes*** ALEJANDRO LUGO-SOLIS, IGOR VASILIEV, *New Mexico State University* We present an *ab initio* study of a single potassium atom adsorption on the surface of graphite and single walled carbon nanotubes using density functional theory within the pseudopotential approximation. Our study is, in part, inspired by inconsistent results reported for this system in the existing literature. The potassium adsorption energy on graphite obtained in different calculations ranges from approximately 0.4 eV to 1.75 eV. Our calculations demonstrate that the reported disagreements can be explained by electrostatic interactions rather than complex quantum factors. We illustrate this with a simple model based on a classical electrostatic interaction between the potassium atom and the graphite surface. Adsorption energies predicted by the electrostatic model are in good agreement with our *ab initio* calculations. In contrast, we find that the adsorption energies of potassium on carbon nanotubes are directly related to the nanotube geometry and chirality and cannot be described in terms of a simple classical model.

*Supported by the National Science Foundation under Grant No. DMR-0505270, Petroleum Research Fund under Grant No. PRF-43409-G10 and the Air Force Office of Scientific Research under Award No. FA-9550-05-1-0234.

**V36 5 Bound excitons and optical absorption spectra of (10,10) metallic single-walled carbon nanotubes*** JACK DESLIPPE, *University of California at Berkeley* CATALIN SPATARU, STEVEN LOUIE, *University of California at Berkeley and Lawrence Berkeley National Laboratory* Motivated by recent theoretical prediction of bound excitons [1] in small diameter metallic single-walled carbon nanotubes, we study the optical spectra of the larger diameter (10,10) metallic tube. We use an interacting-particle Greens function approach which includes calculations of the quasiparticle excitation spectrum (within the GW approximation for the electron self energy) and the electron-hole excitation spectrum (within the Bethe-Salpeter formalism). We show that the (10,10) tube has important excitonic effects despite being a metal, due to the quasi-one dimensional nature of the carbon nanotubes. A bound exciton with binding energy of 60 meV is found, and the location of the excitonic peak in the optical spectrum is at 1.8 eV. [1] C. D. Spataru, S. Ismail-Beigi, L. X. Benedict, and S. G. Louie, Phys. Rev. Lett. 92, 077402 (2004).

**12:39**

**V36 6 Photocurrent Generation in Bent Nanostructures*** YURIY PERSHIN, CARLO PIERMAROCCHI, *Michigan State University* We study theoretically the effect of circularly-polarized electro-magnetic radiation on electrons confined in quantum rings and in bent ballistic quantum wires. The radiation couples to clockwise- or counterclockwise-propagating charge excitations in regions of the system with non-zero curvature, depending on the light polarization. This provides a transfer of the angular momentum from the radiation to the electrons. Response of the electron system to the external radiation displays a resonant behavior and can be measured through a current-induced magnetic field in quantum rings or using a standard current measurement technique in quantum wires.

*Supported in part by NSF DMR-0312491.

**12:51**

**V36 7 Ultrafast Carrier Relaxation Measurements of SWCNT-Doped Polymer Thin Films*** ELAINE LALANNE, BRENITRA MOSLEY, ANTHONY JOHNSON, *Center for Advanced Studies in Photonics Research (CASPR), University of Maryland Baltimore County* The primary application of interest of single-walled carbon nanotube (SWCNT) -doped polymer thin films is to serve as a replacement of gold active regions on integrated optic surface enhanced biosensors and as potential transparent conducting polymers. In addition, the ultrafast nonlinear optical switching properties are of particular interest. We report femtosecond time-resolved measurements on SWCNT -doped polymer thin films. These films were made by spin-coating the monomer-SWCNTs suspension onto glass substrates and UV curing to initiate polymerization. The SWCNTs are predominately semiconducting. The thin film contains $\sim$ 0.4 wt % of SWCNTs, with an average thickness of 7 $\mu$m. Non-degenerate pump-probe transmission experiments were performed using $\lambda_{pump}$ at 400 nm and white light continuum as the probe beam generated by a mode-locked Ti:Sapphire laser ($\tau_p$=160 fs, rep. rate 250 kHz). Preliminary results indicated two lifetimes: the fast decay of 1.4 ps and a longer relaxation time of 18 ps. Experiments are underway to study the carrier dynamics and determine the magnitude of the nonlinearity.

*The samples were prepared using facilities at LLNL. This work was partially supported by grant from NSF (DMR-0120967)

**V36 8 Carbon nanotube field effect transistors under high magnetic fields** GEORGY FEDOROV, DMITRY SMIRNOV, *Natl. High Magnetic Field Lab, Florida State Univ.* ALEXANDER TSELEV, YANFEI YANG, *Dept. of Physics, Georgetown Univ.* NIKOLAY KALUGIN, *Dept. of Physics, Texas A&M Univ.* Magnetic field, when applied parallel to the CNT axis, alters the energy gap in the CNT electron spectrum with a period corresponding to one quantum of magnetic flux through the cross-

section of the CNT. With available magnetic fields ($10^1$T by the order of magnitude), gap oscillations can be observed only in multi-wall CNTs with diameters larger than approx 5 nm, where effects of band structure variation are smeared out by defects and by quantum interference effects. As follows from [1], it is possible to separate effects of disorder from those of the band structure modification by studying magnetotransport in small diameter CNTs while controllably changing the position of the Fermi level of the CNT by electrostatic doping, i.e. by applying a gate voltage in the field effect transistor configuration. We have studied several samples of individual CTNs contacted by palladium electrodes placed on an oxidized heavily doped silicon substrate that served as a back-gate. We find that magnetoresistance of a CNT strongly depends on the Fermi level position with respect to the nanotube's charge neutrality point (CNP). Details and the analysis of our experimental data will be presented. [1] S. Roche, R. Saito, Phys. Rev. Lett. 87, 246803 (2001)

**V38 1 Specific heat studies of heavy ion irradiated YBCO*** RUOBING XIE, A. RYDH,† U. WELP, W. K. KWOK, M. ESKILDSEN, *Department of Physics, University of Notre Dame, Notre Dame, IN 46556* L. PAULIUS, *Department of Physics, Western Michigan University, Kalamazoo, MI 49008* We present a systematic study of the effect of heavy ion irradiation induced columnar defects on the vortex phase diagram in single-crystal $YB_2Cu_3O_7$using ac-specific heat measurements. In pristine, naturally untwinned crystals the transition between the vortex liquid and vortex lattice states in intermediate fields is of first order as evidenced by a sharp peak in the specific heat. On our sample we observed the first order transition between the lower critical point near 0.35T and the upper critical point near 6T. The pristine sample was cleaved into several pieces of typical size $70\times100\times9$ $\mu$m, which were irradiated along the c axis with 1.1 GeV Pb ions at different dose matching fields ranging from 0.1 T to 0.35 T. Specific heat measurements pertaining to the transformation of the first order transition to higher order with increasing disorder as exemplified by the shift in the lower critical point will be addressed.

**V38 2 Low temperature specific heat study on $Pr_{0.88}LaCe_{0.12}CuO_{4-\delta}$** SHILIANG LI, SONGXUE CHI, PENGCHENG DAI,* *Department of Physics and Astronomy, The University of Tennessee, Knoxville, Tennessee 37996-1200, USA* HAIHU WEN, *National Laboratory for Superconductivity, Institute of Physics & Center for Condensed Matter Physics, Beijing 100080, China* By annealing the electron-doped $Pr_{0.88}LaCe_{0.12}CuO_{4-\delta}$ (PLCCO) in vacuum at different temperatures, we have successfully obtained several superconducting PLCCO samples with different $T_c$. The specific heat of all the samples show a $1/T^2$ behavior below 1K. Above 1K, the low field specific heat can be fitted by $\gamma(H)T + \beta T^3$, where the $\gamma(H)$ is the Sommerfeld coefficient. We present magnetic field dependent data of $\gamma(H)$ for several samples of PLCCO and discuss the evolution of $\gamma(H)$ as PLCCO is tuned from an antiferromagnetically ordered insulator to a Tc=25 K superconductor.

**V38 3 Anisotropic properties of unconventional superconductors in a magnetic field: testing the nodal stucture** ANTON VORONTSOV, ILYA VEKHTER, *Lousiana State University* We present a calculation of electronic specific heat and heat conductivity in a vortex state of quasi-two dimensional d-wave superconductors. We employ quasiclassical theory and use the Brand-Pesch-Tewordt approximation to model the superconducting state at moderate to high magnetic fields. Within this framework we investigate the dependence of heat capacity and heat conductivity on the angle of rotation of magnetic field with respect to the nodal directions. We find that the fourfold anisotropy due to nodal structure in both quantities changes sign in the temperature-field plane. This result helps resolve the apparent disagreement about the gap symmetry reached from the specific heat and the thermal conductivity measurements in $CeCoIn_5$. We comment on the physics behind the difference between our results and those obtained in the Doppler shift approximation.

**V38 4 Comparative analysis of specific heat of $YNi_2B_2C$ using nodal and two-gap models** HUNG DUEN YANG, CHIEN LUNG HUANG, *Department of Physics, National Sun Yat-Sen University, Kaohsiung 804, Taiwan* JIUNN YUAN LIN, *Institutre of Physics, National Chiao-Tung University, Hsinchu 300, Taiwan* CHIA PIN SUN, *Department of Physics, National Sun Yat-Sen University, Kaohsiung 804, Taiwan* TING KUO LEE, *Institute of Physics, Academia Sinica, Nankang 11592, Taiwan* SUNG IK LEE, *National Creative Research Initiative Center for Superconductivity and Department of Physics, Pohang University of Science and Technology, Pohang, 794* The magnetic field dependence of low temperature specific heat in$YNi_2B_2C$ was measured and analyzed using various pairing order parameters. At zero magnetic field, the two-gap model which has been successfully applied to $MgB_2$and the point-node model, appear to describe the superconducting gap function of YNi2B2C better than other models based on the isotropic s−wave, the d−wave line nodes, or the s+g wave. The two energy gaps, $\Delta$ L=2.67 meV and $\Delta$ S=1.19 meV are obtained. The observed nonlinear field dependence of electronic specific heat coefficient, $\gamma$ (H)∼ H0.47, is quantitatively close to $\gamma$ (H)∼ H0.5expected for nodal superconductivity or can be qualitatively explained using two−gap scenario. Furthermore, the positive curvature in Hc2(T) near Tc is qualitatively similar to that in the other two−gap superconductor MgB2.

**V38 5 Probing the anisotropic phonon attenuation in superconducting lead.*** T.L. HEAD, J.P. WOLFE, *University of Illinois Urbana-Champaign* Phonon imaging of single crystals of superconducting Pb have uncovered a strong attenuation of phonons in (111) planes. Early data by Wolfe and Short[1] raised the possibility of a spin-density-wave ground state as proposed by Overhauser and Daemen.[2] This interpretation depends on the frequencies of the ballistic phonons, which previously were determined by a Planckian heater source and isotope scattering. We have designed and fabricated a low-pass filter in an attempt to select phonon energies below a characteristic activation energy, in order to clarify the source of the attenuation lines. We present new phonon-imaging data under various conditions and discuss the possible interpretations. [1]Physica B 316-317 (2002) 107-109 [2] Phys. Rev. B 39, 6431 (1989)

**V38 6 Hard X-ray Structural Studies of $HgBa_2CuO_{4+\delta}$** GUILLAUME CHABOT-COUTURE, *Applied Physics Department, Stanford University* JASON N. HANCOCK, *Stanford Synchroton Radiation Laboratory, Stanford University* LI LU, *Applied Physics Department, Stanford University* ZAHIRUL ISLAM, *Advanced Photon Source, Argonne National Lab* MARTIN GREVEN, *Stanford University* Recent high-energy x-ray diffuse scattering work on the compounds YBCO and BSCCO shows that these high-$T_c$ superconductors are typically intrinsically inhomogeneous [1-3]. These inhomogeneities are short-range-ordered lattice modulations driven by oxygen dopants, and they appear to have an important role in the electronic, transport, and spectroscopic properties of these systems. $HgBa_2CuO_{4+\delta}$ (Hg1201) has a simple structure and the highest $T_c$ (at optimal doping) among all single-layer compounds. It is thus a perfect candidate system to address the issue of charge modulations. Here we present evidence for short-range incommensurate displacement modulations and discus our results in the context of similar findings in other compounds.

**V38 7 Structure at low temperature of oxygen isotope exchanged $La_{1.8875}Sr_{0.1125}CuO_4$*** A. R. MOODENBAUGH, D. E. COX, T. VOGT, B. NOHEDA, *Brookhaven National Lab.* M. K. CRAWFORD, E. M. McCARRON, W. E. FARNETH, *Dupont* The crystal structures at low temperatures of oxygen isotope-exchanged pairs of $La_{1.8875}Sr_{0.1125}CuO_4$ were examined using high resolution synchrotron powder x-ray diffraction at NSLS X7A. This study was designed to examine the possibility that small structural differences might contribute to the observed superconducting isotope effects. The x-ray diffraction regions about the orthorhombic (200),(020) peaks of $^{16}O$ and $^{18}O$ isotope-exchanged pairs were studied in detail. There is no significant difference in orthorhombic lattice parameters at any temperature. A minority ( $\sim$ 10%) tetragonal (LTT) phase is also necessary to adequately account for the observed intensities at low temperatures. The fraction of LTT phase does not differ perceptibly with oxygen isotope exchange. We conclude, based on direct measurement of crystal structure at low temperatures, that the observed differences in superconductivity of oxygen isotope exchanged pairs are likely intrinsic effects.

**V38 8 Preliminary Inelastic Neutron Scattering Results for the Magnetic Excitations in the Model Superconductor $HgBa_2CuO_{4+\delta}$*** G. YU, X. ZHAO, Y. C. CHO, G. CHABOT-COUTURE, E. M. MOTOYAMA, *Department of Applied Physics, Physics, and Stanford Synchrotron Radiation Laboratory, Stanford University, Stanford, CA 94305, USA* P. BOURGES, *Laboratoire Leon Brillouin, CEA-Saclay, 91191 Gif-sur-Yvette, Cedex, France* M. GREVEN, *Department of Applied Physics and Stanford Synchrotron Radiation Laboratory, Stanford University, Stanford, CA 94305, USA* $HgBa_2CuO_{4+\delta}$ has a simple crystal structure and possess the highest $T_c$ (97 K at optimal doping) among all the single-layer cuprates. In a significant breakthrough, we were able to grow large $HgBa_2CuO_{4+\delta}$ single crystals, enabling us to perform the first inelastic magnetic neutron scattering experiments on this model superconductor. We performed energy scans at $(\pi, \pi)$ and momentum scans at fixed energy at 10 K and above Tc. Our preliminary results include the observation of a 52 meV feature at $(\pi, \pi)$ that resembles the ''resonance'' found in other cuprates.

**V38 9 Stability Constraints and Local Criteria for the Bounds on $T_c$ of Conventional Superconductors*** JONATHAN E. MOUSSA, MARVIN L. COHEN, *University of California at Berkeley and Lawrence Berkeley National Laboratory* In the regime of weak electron-phonon coupling, the scale of and bounds on $T_c$ are set by the real phonon frequencies of a material. In the strong coupling limit of Eliashberg theory, the phonon frequencies no longer limit the transition temperature because $T_c$ can grow without bound as $\sim \sqrt{\lambda}\,\omega_{ph}$, where $\lambda$ is the electron-phonon coupling parameter. However, structural stability of the system puts bounds on $T_c$ even in the strongly coupled regime due to the softening of phonons. In this case, $T_c$ is also bounded by an averaged unrenormalized phonon frequency defined for a non-metallic precursor material. Additional features of this model will also be discussed.

**V38 10 Anisotropic Superconducting Phase Diagram of $C_6Ca$*** ULRICH WELP, R. XIE, D. ROSENMANN, A. RYDH,† H. CLAUS, G. KARAPETROV, W. K. KWOK, *Materials Science Division, Argonne National Laboratory, Argonne, IL 60439* We present a study of the anisotropic superconducting phase diagram of the new carbon intercalation superconductor $C_6Ca$ employing magnetization and specific heat measurements. The intercalation of Ca into flakes of natural graphite takes place through vapor transport at temperatures near 500°C. The resulting crystals dis-

play an onset of superconductivity at 11.3 K and a transition width of about 1 K as seen in heat capacity and low-field magnetization measurements. A clear step in the heat capacity confirms the bulk nature of the superconducting state. Roughly 1/3 to 1/2 of the sample volume is superconducting as evidenced by the reduced step height of the heat capacity. From measurements of the upper critical field, $H_{c2}$, we determined an in-plane coherence length of $\xi_{ab} \approx$ 36 nm. The angular dependence of $H_{c2}$ is well described within the model of effective mass anisotropy yielding an anisotropy parameter of $\Gamma \approx$ 3.5 to 4.

**V38 11 Upper critical field $H_{c2}$ in $PrOs_4Sb_{12}$*** DAVID PARKER, *USC Dept. of Physics* KAZUMI MAKI, *USC Dept. of Physics* HYEKYUNG WON, *Hallym Univ. Dept. of Physics* We study the upper critical field of the A and B phases in the triplet superconductor $PrOs_4Sb_{12}$ within the p+h-wave superconductivity proposed recently for this material. The present result is compared with $H_{c2}$(t) and H*(t), the boundary between the A and B phase in $PrOs_4Sb_{12}$, reported earlier and with more recent data of $H_{c2}(t)$ for the single phase crystal. We find $H_{c2}$(t)'s for both the two phase crystal and the single phase crystal are described by the model for the A phase. From this fitting one can deduce the Fermi velocity as $v = 2.5 \times 10^6$ cm/s. On the other hand $H_{c2}$(t) for the B phase is found to be somewhat smaller than H*(t), which is rather puzzling.

**V38 12 Superconductivity and magnetism in small attractive and repulsive Hubbard clusters** ARMEN KOCHARIAN, *California State University* GAYANATH FERNANDO, KALUM PALANDAGE, *University of Connecticut* JAMES DAVENPORT, *Brookhaven National Laboratory* The existing mapping between the ground state properties of $U > 0$ and $U < 0$ Hubbard models are extended to finite temperatures, arbitrary magnetic field and electron doping or chemical potential for small two and four sites clusters. The microscopic origin of charge-spin separation effect and pseudogap formation are studied in response thermodynamics for spin and charge susceptibilities, using exact analytical diagonalization technique and grand canonical ensemble method. In the limiting case of non-interacting particles there are no temperature or magnetically driven driven spin-charge separation. The obtained knowledge we use to compare the thermodynamic phase diagrams of $U > 0$ and $U < 0$ clusters in a multidimensional parameter space of temperature, magnetic field and chemical potential. Magnetism and superconductivity are often thought to be incomparable with one another, however, we found many identical features for $U > 0$ and $U < 0$ at various range of doping level in the specific heat, spin and charge pseudogaps, Mott-Hubbard and antiferromagnetic crossovers, when these physical characteristics are monitored as a function of chemical potential or doping level. The developed bottom up approach for small clusters displays important intrinsic characteristics of high $T_c$ superconductors.

**V38 13 Spin-triplet pairing in noncentrosymmetric superconductors: $Li_2Pd_3B$ and $Li_2Pt_3B$** H.Q. YUAN, M.B. SALAMON, D. VANDERVELDE, *Department of Physics, University of Illinois at Urbana and Champaign* D.F. AGTERBERG, *Department of Physics, U. Wisconsin-Milwaukee* N. HAYASHI, M. SIGRIST, *Theoretische Phyik, ETHZ* P. BADICA, *Institute for Materials Research, Tohoku University* K. TOGANO, *NIMS, Japan* Superconductors lacking inversion symmetry exhibit qualitatively distinct properties from those with an inversion center. In this presentation, we report strong evidence for triplet superconductivity caused solely by the absence of parity symmetry in two closely related cubic compounds $Li_2Pd_3B$ and $Li_2Pt_3B$. Broken inversion symmetry admits antisymmetric spin-orbit coupling, admixing spin-singlet and spin-triplet pairing even with s-wave orbital symmetry. The triplet contribution is weak in $Li_2Pd_3B$, a BCS-like superconductor with an anisotropic gap. With increased spin- orbit coupling the spin-triplet component dominates in $Li_2Pt_3B$, producing line nodes in the energy gap. Results are supported by the quantitative agreement between experimental penetration depth data and theory. Our findings demonstrate that unconventional superconducting properties can originate from a conventional phonon pairing mechanism rather than requiring purely electronic coupling mechanisms as usually considered.

**V38 14 Low Temperature Normal State Specific Heat properties of $La_{2-x}Sr_xCuO_4$ using High Magnetic Fields** SCOTT RIGGS, GREG BOEBINGER, JON BETTS, FEDOR BALAKIREV, ALBERT MIGLORI, MARCELO JAIME, *Florida State University* A number of models for high Tc cuprates suggest that the anomalous electronic properties of HTS are governed by the existence of a quantum critical point (QCP). According to this scenario, the superconductivity arises from the competition between two states and the resulting fluctuation-mediated pairing. In heavy fermions, non-Fermi liquid behavior has often been observed near a QCP: eg near-linear power-law resistivity and a divergence in the Sommerfeld coefficient in the zero temperature limit. By using extremely high magnetic fields we suppress superconductivity and reveal the normal state in the zero temperature limit. The specific heat is measured using the relaxation technique on several different dopings of LSCO. The electronic specific heat is isolated by subtracting the phonon specific heat measured on LCO, the parent insulating compound. One overdoped single crystal studied (LSCO with a nominal Srx=0.22) was cut from the same crystal that displays a linear electrical resistivity between room temperature and $\sim$ 5K, when the superconductivity is suppressed with a 45T magnetic field applied along the *c*-axis.

**V39 1 Non-Fermi liquid and pairing in electron-doped cuprates*** ANDREY CHUBUKOV, *University of Wisconsin* PAVEL KROTKOV, *University of Maryland* In electron-doped cuprates near optimal doping we show that in the normal state the fermionic self-energy has a non-Fermi liquid form leading to pe-

culiar frequency dependencies of the conductivity and the Raman response. We solve the pairing problem and demonstrate that $T_c$ is determined by the curvature of the Fermi surface, and the pairing gap $\Delta(\mathbf{k},\omega)$ is strongly non-monotonic along the Fermi surface. The normal state frequency dependencies, the value of $T_c \sim 10K$ and the **k**-dependence of the gap agree with the experiment.

*Supported by NSF DMR 0240238.

**11:27**
**V39 2 Antiferromagnetic superconducting state in the electron-doped cuprates?** TANMOY DAS, ROBERT S. MARKIEWICZ, ARUN BANSIL, *Northeastern University* Recent angle-resolved photoemission (ARPES) studies of the electron-doped cuprate $Nd_{2-x}Ce_xCuO_4$ (NCCO)[1] have been interpreted in terms of a uniform antiferromagnetic (AF) metal, with doping into the upper magnetic band and gap collapse close to optimal doping[2]. An open question is whether the system remains uniform in the simultaneous presence of AF and (d-wave) superconducting (SC) order. Here, we explore the properties of a *uniform* AF-SC model for NCCO, to ascertain to what extent we can explain anomalous features, such as the nonmonotonic angle dependence of the superconducting gap[3]. Work supported by the USDOE. [1] N.P. Armitage, *et al.,* PRL **87**, 147003 (2002). [2] C. Kusko, *et al.,* PRB**66**, 140513 (2002); A.-M.S. Tremblay, *et al.,* cond-mat/0511334. [3] H. **11:39**
**V39 3 Spin response in high-$T_c$ superconductors at higher energies** BABAK SERADJEH, IGOR HERBUT, *Simon Fraser University* We discuss our recent results on the spin sector of the theory of underdoped cuprates as fluctating d-wave superconductors (I. Herbut, PRL 94, 237001 (2005)). We improve on an earlier computation of spin response (I. Herbut and D. Lee, PRB 68, 104518 (2003)) by including the effects of non-relativistic terms in the dispersion of nodal quasipartciles and thus by going beyond the low-energy approximation employed in the earlier work. We find that non-relativistic effects tend to reduce the spin gap at $(\pi,\pi)$. This could be relevant for recent neutron scattering measurements.

**11:51**
**V39 4 Screening in anisotropic superfluids and the superfluid density in underdoped cuprates** MATTHEW CASE, IGOR HERBUT, *Simon Fraser University* The effects of quantum and classical phase fluctuations on the superfluid density of underdoped cuprates can be modeled by an anisotropic system of Coulomb interacting bosons. In such a system, the collective excitations screen the Coulomb interaction whose effective strength, together with the strength of the anisotropy, determines the temperature dependence of the superfluid density. We will argue that the underdoped cuprates are in the short-ranged, weakly interacting regime characterized by an approximately linear superfluid density.

**12:03**
**V39 5 Impurity effects in metals and superconductors** KURT SCHARNBERG, SIMON SCHEFFLER, CARSTEN RIECK, In the theoretical analyses of impurity effects in superconductors the assumption is usually made that all quantities are slowly varying functions of energy except for the Green functions, whose energy dependence is integrated out. The energy-integrated normals state Green function for the NFE model is $-i$ and the divergent real part is omitted. The argument of any other momentum dependent quantity is replaced by the Fermi momentum. When defects modelled by scattering potentials of finite range, which lead to scattering in infinitely many angular momentum channels, are treated within this so-called Fermi Surface Restricted Approximation, unacceptable results for the selfenergies, the pair breaking parameters and others follow in the strong scattering limit. It has been found necessary to consider the principal value integral involving the real part of the Green function in the *T*-matrix equation. In this way, the range of the potential is re-introduced as an essential parameter and resonant scattering in different $\ell$-channels can occur for moderately large potentials, while $\delta$-function potentials, even when there strength is infinite, do not scatter at all. This generalized theory of impurity effects will be applied to calculations of the local density of states near an impurity and, using the selfconsistent *T*-matrix approximation for an ensemble of impurities, to calculations of spectral functions.

**12:15**
**V39 6 Type-IV Superconductivity Phenomenon: Cooper Pairs with Broken Parity and Spin-Rotational Symmetries in D- and S-wave Singlet Superconductors** ANDREI LEBED, *Dept. of Physics, University of Arizona* Paramagnetic effects are shown to result in the appearance of a triplet component of order parameter in vortex phases of d- and s-wave singlet superconductors in the absence of impurities. This component, which breaks both parity and spin-rotational symmetries of Cooper pairs, is expected to be of the order of unity in a number of modern superconductors such as high-Tc, organic, $MgB_2$, and some others. A generic phase diagram of such type-IV superconductors [1], which are singlet ones at H=0 and in the Meissner phase and characterized by singlet-triplet mixed Copper pairs, $\Delta_s + i\Delta_t$, in a vortex phase, is suggested. [1] A.G. Lebed, Physical Review Letters, accepted (2006).

**12:27**
**V39 7 Superfluid density and competing orders in *d*-wave superconductors** SERGEI SHARAPOV, *Department of Physics and Astronomy, McMaster University* JULES CARBOTTE, We derive expressions for the superfluid density $\rho_s$ in the low-temperature limit $T \to 0$ in *d*-wave superconductors, taking into account the presence of competing orders such as spin-density waves, *is*-pairing, etc. Recent experimental data for the thermal conductivity and for elastic neutron scattering in $La_{2-x}Sr_xCuO_4$ suggest there are magnetic field induced anomalies that can be interpreted in terms of competing orders. We consider the implications of these results for the superfluid density and show in the case of competing spin-density wave order the usual Volovik-like $\sqrt{H}$ depletion of $\rho_s(H)$ is replaced by a slower dependence of $\rho_s$ on the applied magnetic field *H*. We show that it is crucial to include the competing order parameter in the self-consistent equation for the impurity scattering rate.

**12:39**
**V39 8 Index theorem and quantum order of d-wave superconductors in the vortex state*** OSKAR VAFEK, *Stanford University* ASHOT MELIKYAN, *University of Florida* It is argued that the ground state of the lattice d-wave superconductor in the lattice of singly quantized $hc/2e$ vortices can posses quantum order. This is due to simultaneous crystallization of both the superflow and the fluxes of the $Z_2$ gauge field, the second of which has no classical analog. In the presence of particle hole symmetry we prove an

index theorem which puts a lower bound on the number of zero energy modes. This bound is equal to 4 times the number of lattice sites coinciding with the centers of inversion within the magnetic unit cell. Generic cases are constructed in which this bound exceeds the number of zero modes of an equivalent lattice of doubly quantized vortices (as well as singly quantized vortices without Z2), despite identical classical symmetries. The spectrum around the zero modes is doubly degenerate and Dirac-like, with velocities that become universal functions of $\Delta/t$ in the limit of low magnetic field. For small, but finite strength of particle-hole symmetry breaking, the gapped state can be characterized by a topological quantum number, related to spin Hall conductivity, which differs in the case of $hc/2e$ and $hc/e$ vortex lattice.

**V39 9 Electronic Density of States of a Superconductor with a Spatially Varying Gap and Phase Fluctuations: A Monte Carlo Simulation*** DANIEL VALDEZ-BALDERAS, DAVID STROUD, *Department of Physics, The Ohio State University* Recent experiments have shown that the superconducting energy gap in some high-$T_c$ superconductors is spatially inhomogeneous. Motivated by these experiments, and using exact diagonalization of a model d-wave Hamiltonian (T. Eckl et al. PRB 66 140510), combined with Monte Carlo simulations of a Ginzburg-Landau free energy functional, we have calculated the electronic density of states $n(E)$ of a model high-$T_c$ superconductor with an inhomogeneous gap. The free energy functional incorporates both phase and amplitude fluctuations together with quenched disorder. It leads to a superconducting transition temperature $T_c$ well below the pseudogap temperature $T_{c0}$, and has a spatially varying gap at very low $T$, both consistent with experiments in underdoped Bi2212. Our calculated $n(E)$ shows coherence peaks for $T < T_c$, which disappear for $T > T_c$. We will also present calculated results for both the global and local $n(E)$ as a function of temperature and disorder.

**13:03**

**V39 10 Raising Bi-O bands above the Fermi energy level of hole-doped $Bi_2Sr_2CaCu_2O_{8+\delta}$ and other cuprate superconductors** HSIN LIN, S. SAHRAKORPI, R.S. MARKIEWICZ, A. BANSIL, *Northeastern University* The Fermi surface (FS) of $Bi_2Sr_2CaCu_2O_8$ (Bi2212) predicted by band theory displays Bi-related pockets around the $(\pi,0)$ point, which have never been observed experimentally. We show that when the effects of hole doping by substituting Pb for Bi or by adding excess O in Bi2212 are included, the Bi-O bands are lifted above the Fermi energy ($E_F$) and the resulting first-principles FS is in remarkable accord with measurements. With decreasing hole-doping the Bi-O bands drop below the $E_F$ and the system self-dopes below a critical hole concentration. Computations on other Bi- as well as Tl- and Hg-based compounds indicate that lifting of the cation-derived band with hole doping is a general property of the electronic structures of the cuprates. Work supported by the USDOE.

**13:15**

**V39 11 Evolution of Mid-gap States and Residual 3-Dimensionality in Cuprates*** S. SAHRAKORPI, *Northeastern University* M. LINDROOS, *Tampere University of Technology* R. MARKIEWICZ, *Northeastern University* A. BANSIL, *Northeastern University* We have carried out extensive first principles doping-dependent computations of angle-resolved photoemission (ARPES) intensities in $Bi_2Sr_2CaCu_2O_8$ (Bi2212) and $La_{2-x}Sr_xCuO_4$ (LSCO) over a wide range of binding energies.[1,2,3] Intercell hopping and the associated 3-dimensionality, which is usually neglected in discussing cuprate physics, is shown to play a key role in shaping the ARPES spectra. Despite the obvious importance of strong coupling effects (e.g. the presence of a lower Hubbard band coexisting with mid-gap states in the doped insulator), a number of salient features of the experimental ARPES spectra of LSCO are captured to a surprising extent when $k_z$-dispersion is properly included in the analysis. 1. **V39 12 Dirac-Bogoliubov-de Gennes quasiparticles in the mixed state of lattice d-wave superconductors*** ASHOT MELIKYAN, *University of Florida* ZLATKO TESANOVIC, *Johns Hopkins University* In the mixed state of cuprate superconductors the low energy quasiparticles can be effectively described as Dirac fermions moving in the field of singular scalar and vector potentials. Although the effective linearized Hamiltonian operator formally does not depend on the structure of vortex cores, singular nature of the perturbation requires imposing additional boundary conditions at vortex locations. Each vortex is described by a parameter $\theta$ that effectively represents all effects beyond linearization. We identify the parameters $\theta$ of the solutions found earlier, analyze the relation between fully self-consistent formulation of the problem and the linearized model, and construct the low-field scaling form of the quasiparticle spectra incorporating the parameters $\theta$ explicitly and generalizing the conventional Simon-Lee scaling. We present a detailed numerical study of the lattice $d$-wave superconductor model and examine its low energy, low magnetic field behavior. The low energy limit is faithfully represented by Dirac-like fermions which are either truly massless, massless at the linearized level or massive, depending on the commensuration of magnetic length and lattice spacing.

**V39 13 Phase Fluctuations in Strongly Coupled d-Wave Superconductors** MATTHIAS MAYR, *UT/Knoxville and Oak Ridge National Laboratory* GONZALO ALVAREZ, *Oak Ridge National Laboratory* CENGIZ SEN, *FSU/NHMFL* ELBIO DAGOTTO, *UT/Knoxville and Oak Ridge National Laboratory* We present a numerically exact solution for the BCS Hamiltonian at any temperature, including the degrees of freedom associated with classical phase, as well as amplitude fluctuations via a Monte Carlo integration. This allows for an investigation over the whole range of couplings: from weak attraction, as in the well-known BCS limit, to the mainly unexplored strong-coupling regime of

pronounced phase fluctuations. In the latter, two characteristic temperatures T* and $T_c$, associated with short- and long-range ordering, respectively, can be identified in a mean-field-motivated Hamiltonian. T* at the same time corresponds to the opening of a gap in the excitation spectrum. In addition to introducing a novel procedure to study strongly coupled *d*-wave superconductors, our results indicate that classical phase fluctuations are not sufficient to explain the pseudogap features of high-temperature superconductors.

**13:51**

**V39 14 Excitonic pairing between nodal fermions** WILLIAM SHIVELY, DMITRI KHVESHCHENKO, *Dept. Physics & Astronomy, University of North Carolina at Chapel Hill* We discuss excitonic pairing in nodal fermion systems, characterized by a vanishing quasiparticle density of states at the point-like Fermi surface and a concomitant lack of screening for long-range interactions. We solve the gap equation and obtain the free energy and critical values of the interaction strength for a variety of algebraically interactions and power-law densities of states. On the basis of this insight, we analyze possible phase transitions in this interesting class of non-fermi-liquid systems.

**V39 15 Nodal Quasiparticles at a Nematic Quantum Critical Point** PAUL ORETO, EUN-AH KIM, STEVEN KIVELSON, *Department of Physics, Stanford University* EDUARDO FRADKIN, *Department of Physics, University of Illinois at Urbana-Champaign* The nodal quasiparticles in the high-Tc superconductors are robust consequences of the d-wave symmetry. Under most circumstances, the properties of these Dirac-like particles are generally simple, since most interactions involving them are ''irrelevant.'' However, they are strongly scattered by the symmetry breaking fluctuations near an electronic nematic quantum critical point. In the quantum critical regime, an anomalous damping and enhancement of the dispersion anisotropy of the quasi-particles results. Possible relevance of this to the so-called ''Fermi arc'' seen in the underdoped cuprates is discussed.

**V40 1 High-fidelity linear optical quantum computing with polarization encoding** FEDERICO SPEDALIERI, *Jet Propulsion Laboratory* HWANG LEE, *Lousiana State University* JONATHAN DOWLING, *Louisiana State University* We show that the KLM scheme [Knill, Laflamme and Milburn, Nature **409**, 46] can be implemented using polarization encoding, thus reducing the number of path modes required by half. One of the main advantages of this new implementation is that it naturally incorporates a loss detection mechanism that makes the probability of a gate introducing a non-detected error, when non-ideal detectors are considered, dependent only on the detector dark-count rate and independent of its efficiency. Since very low dark-count rate detectors are currently available, a high-fidelity gate (probability of error of order $10^{-6}$ conditional on the gate being successful) can be implemented using polarization encoding. The detector efficiency determines the overall success probability of the gate but does not affect its fidelity. This can be applied to the efficient construction of optical cluster states with very high fidelity for quantum computing.

**11:27**

**V40 2 Single Photon Source Using Chiral Nematic Liquid Crystal** GANESH SELVARAJ, *Louisiana State University* ANAND JHA, *University of Rochester* PAVEL LOUGOVSKI, MARIAN FLORESCU, *Louisiana State University* ROBERT BOYD, *University of Rochester* JONATHAN DOWLING, *Louisiana State University* With the development of Linear Optics Quantum Computing, a demand for a good single photon source has increased. Here we describe how a cholesteric liquid crystal can be used as a photonic band-gap material to design a single-photon source. We have a dipole embedded in a liquid crystal for which we find the spontaneous emission rate. We calculate the band structureof the cholesteric liquid crystal using the eigenfuncton expansion method and ultimately compute the density of modes. We also determine the field of the dipole embedded inside the cholesteric liquid crystal using the Green's function method from which we determine the spontaneous emmission rate.

**11:39**

**V40 3 How to construct a Universal Linear Optical State Generator?** PAVEL LOUGOVSKI, HWANG LEE, JONATHAN DOWLING, *Louisiana State University* We consider all optical realization of a universal quantum state generator utilizing projective photon measurements to create an effective non-linearity. Specifically we are interested in finding a set of unitary optical devices required in order to generate a given quantum state for a given input and a projective measurement. We illustrate the formalism for a case of multi-photon path entangled states (N00N states). We conjecture an existence of necessary criteria connecting a size of a N00N state to a number of input modes of a generator.

**V40 4 Towards one-way quantum computation with realistic devices.**
TERRY RUDOLPH, *Imperial College London*

The one-way model seems particularly suited to certain proposed architectures for quantum computation, particularly those involving non-deterministic quantum gates. This talk will focus on strategies for dealing with faulty devices in the one-way model, particularly within the framework of linear optical quantum computation, although the results have more general significance. Special mention will made of strategies for dealing with faulty single photon sources and detectors, which are the primary experimental challenge for many proposed implementations of optical quantum computation.

**V40 5 Single-photon sources for linear optics quantum computation** TODD PITTMAN, BRYAN JACOBS, JAMES FRANSON, *Johns Hopkins Univ. Applied Physics Laboratory* JOHNS HOPKINS UNIV. APPLIED PHYSICS LABORATORY TEAM, Although single-photon sources have recently been realized in a number of physical systems, only of few of them have experimentally demonstrated the types of properties required for linear optics quantum computing. In this talk, we review these requirements, and discuss the technical and fundamental challenges in meeting them. We will focus on a periodic source in which single-photons heralded from parametric down-conversion pairs are trapped and released from a storage loop.

**12:39**
**V40 6 Optical Switches for Quantum Information Processing** BRYAN JACOBS, *Johns Hopkins University* TODD PITTMAN, JAMES FRANSON, *Johns Hopkins University* Many of the basic components required for optical quantum computing and quantum communications have recently been demonstrated, including: single photon sources, quantum memories, logic operations, and photon number resolving detectors. Although the results of these proof-of-concept demonstrations are encouraging, errors in the current devices limit the range of applications to relatively small quantum circuits. The majority of the errors in the current devices originates from photon loss and decoherence in the switching elements. The single-photon nature of the signal, when coupled with quantum coherence requirements, limits the feasibility of using standard telecom switches in these applications. Here we discuss our recent work toward the development of optical switches specifically designed to accommodate the characteristics of photonic qubits.

**12:51**
**V40 7 Entangled Photon Holes*** JAMES FRANSON, *Johns Hopkins University* The probabilistic failure events of linear optics logic gates can be suppressed using the quantum Zeno effect enforced by strong two-photon absorption [1]. This would allow deterministic logic operations as a possible alternative to the use of cluster states. We have recently shown, however, that the rate of two-photon absorption can be substantially reduced by the generation of entangled photon holes that are analogous to the holes of semiconductor theory [2]. This reduction in the two-photon absorption rate is inconsistent with classical or semiclassical theory, and the entangled photon holes can violate Bell's inequality as well. As a practical matter, these difficulties can be avoided if the photons travel in opposite directions, in which case the entangled photon holes propagate away from each. The theory of entangled photon holes and their implications for the design of Zeno gates will be discussed.

**V40 8 Creating single time-bin entangled photon pairs** CHRISTOPH SIMON, *University of Grenoble (France)* JEAN-PHILIPPE POIZAT, *University of Grenoble* When a single emitter is excited by two phase-coherent pulses with a time delay, each of the pulses can lead to the emission of a photon pair, thus creating a ''time-bin entangled'' state. Double pair emission can be avoided by initially preparing the emitter in a metastable state. We show how photons from separate emissions can be made indistinguishable, permitting their use for multi-photon interference. Possible realizations with single atoms or ions and with quantum dots are discussed. The method might also allow the direct creation of $n$-photon entangled states (n$>$ 2).

**13:15**
**V40 9 Towards a Quantum Memory for Photons in Erbium Doped Materials** SARA HASTINGS-SIMON, *University of Geneva* MATTHIAS STAUDT, BARBARA KRAUS, WOLFGANG TITTEL, MIKAEL AFZELIUS, NICOLAS GISIN, *University of Geneva* IGNACIO CIRAC, *Max Planck Institute for Quantum Optics* MATTIAS NILSSON, STEFAN KROLL, *Lund Institute of Technology* Quantum memories for single photons could play an important role in quantum communication and optical quantum computing. We present a proposal for the efficient storage and recall of photonic time-bin qubits, based on reversible absorption in a controllably broadened homogeneous absorption line. We report on the first experimental steps towards the realization of this quantum memory protocol. In particular, we have measured the homogenous lifetime of the relevant optical transition in erbium doped optical fibers and erbium doped lithium niobate waveguides by spectral hole burning and photon echo. We have also observed the controlled reversible broadening of spectral holes and spectral hole line shifts due to the Stark effect.

**13:27**
**V40 10 Design of an on demand single photon source using a metal-insulator-semiconductor capacitor structure** B.H. HU, C.H. YANG, *Department of Electrical and Computer Engineering, University of Maryland at College Park* M.J. YANG, *Naval Research Laboratory* We propose an on-demand single photon source for unconditionally secure quantum cryptography. Similar to a typical metal-insulator-semicondoctor capacitor structure, the

main component in the semiconductor is a p-doped quantum well, and the cylindrical gate under consideration is only nanometers in diameter. This MIS system can be biased to inversion, and, due to the small gate area, there are only a few electrons residing in a quantum dot at the onset of inversion. Considering the strong size quantization and large Coulomb energy, the number of electrons can be precisely controlled by the gate voltage. After holding just one electron in the inversion layer, the capacitor is quickly biased back to the flat band condition and the subsequent radiative recombination across the bandgap results in single photon emission. Using GaAs/AlAs as the model system, we present a numerical simulation of three-dimensional band bending and merits of this single photon source.

**13:39**

**V40 11 Superconducting Bolometric Photon Detectors Using Epitaxial Niobium Thin Films** KEVIN M. INDERHEES, PAUL B. WELANDER, SEONGSHIK OH,* JAMES N. ECKSTEIN, *Department of Physics, Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, Urbana, Illinois 61801* Efficient single photon detection is a key part of optical qubit systems. We have made and tested superconducting bolometric photon detectors constructed from high quality epitaxial single crystal niobium films that are very flat. The devices operate at 4.2K and consist of narrow links which are current biased close to their critical current value. Absorption of a photon drives a portion of the device into the normal state, generating an observable voltage signal. The sensitivity is maximized when the link is biased near the critical current. The time averaged output voltage is linearly dependent on the optical power that illuminates the link. In order to optimize detector characteristics, we have studied the effects of changing the film thickness, the device geometry, and adding a protective cap.

**V40 12 Quantum dots as a source of entangled photon pairs.** MARK STEVENSON, ROBERT YOUNG, *Toshiba Research Europe Limited* PAOLA ATKINSON, KEN COOPER, DAVID RITCHIE, *Cavendish Laboratory, University of Cambridge* ANDREW SHIELDS, *Toshiba Research Europe Limited* Quantum dots are considered an attractive system for applications in quantum communication and quantum logic, confirmed by experimental demonstrations of quantum dot based single photon emission devices. Another key quantum optics resource is the on-demand generation of entangled photon pairs, for which the radiative decay of the biexciton state in a quantum dot has been proposed. The realization of such a device has been prevented due to polarization splitting of the exciton fine structure, caused by anisotropies of various structural parameters of the dot. We present the results of recent experiments that manage the splitting in quantum dots, in order to allow entangled photon emission. We demonstrate that dots with splitting within the homogeneous linewidth can be realized by carefully controlling the thickness of the dot layer. Furthermore, we show that the splitting can be reduced to zero by the application of an in-plane magnetic field. Polarization dependent correlation measurements on these dots will be presented that show characteristic features of entanglement, such as polarization correlation for all linear detection bases, and circular polarization anti-correlation. Our results indicate that for the first time, we have observed triggered entangled photon pair emission from a quantum dot.

**V41 1 First principles theory of metal-oxide interfaces: the Schottky-Mott theory revisited** MATIAS NUNEZ, MARCO BUONGIORNO NARDELLI, *North Carolina State University* Using calculations from first principles, we discuss the interplay between structure and functionality at metal-insulator interfaces using the paradigmatic example of the junctions between various metals (Ag, Pd,Pt,Ni,Cu,Al) and binary crystalline oxides (BaO-,CaO and SrO). Our results demonstrate that it is possible to tune the Schottky barrier height in a very broad range of values just manipulating the metal at the interface and elucidate the role of the relative overlap in the density of states of the different components in determining the band alignment. We will also show how we can apply this concepts to interfaces between metals and ferroelectric oxides where the interface structure and charge transfer affect the spontaneous polarization of the ferroelectric.

**11:27**

**V41 2 Strains observed in 180° domain walls in $LiNbO_3$ with Laue topography** TERRENCE JACH, *NIST* SUNGWON KIM, *Penn State University* STEPHEN DURBIN, *Purdue University* VENKATRAMAN GOPALAN, *Penn State University* A comparison of the strains associated with domains in congruent $LiNbO_3$,previously observed with Bragg x-ray topography and currently with Laue x-ray topography, reveals some surprising differences. The Laue geometry allows imaging through the entire crystal. Using monochromatic collimated synchrotron radiation and a magnifying x-ray camera, we are able to image domains and the strains created by electric field poling, as well the additional strain created by the application of electric fields in real time. The unusual strain patterns can be taken into account with higher order terms in the ferroelectric Ginzberg-Landau theory. Electric fields below the coercive field applied along the c-axis produce Pendellösung stripes due to complex strains that are precursors to 180° domain wall switching. The strains observed with field off and field on in the Laue topographs differ significantly from the surface strains observed previously with Bragg topography.

**11:39**

**V41 3 Predicting polarization enhancement in multicomponent ferroelectric superlattices** SERGE NAKHMANSON, *Rutgers University* KARIN RABE, DAVID VANDERBILT, We use ab initio calculations as an input to develop a one-dimensional chain model of the local polarization in epitaxial short-period $CaTiO_3/SrTiO_3/BaTiO_3$ superlattices grown on a $SrTiO_3$ substrate. The model is then combined with a genetic algorithm optimization technique to predict the arrangement of individual $CaTiO_3$, $SrTiO_3$ and $BaTiO_3$ layers in a superlattice that would simultaneously have the highest possible polarization and a low in-plane lattice constant mismatch with the substrate. This modelling procedure can be applied to a wide range of layered perovskite-oxide nanostructures providing guidance for experimental development of nanoelectromechanical devices with substantially improved polar properties.

**11:51**
**V41 4 Self-Poling in Strained Asymmetric Superlattices.***
MAITRI WARUSAWITHANA,† *Department of Physics, University of Illinois at Urbana-Champaign*

We have constructed strained dielectric superlattices consisting of three different perovskite titanate phases - $BaTiO_3$, $SrTiO_3$ and $CaTiO_3$ using ozone assisted atomic layer by layer molecular beam epitaxy, where the stacking architecture of the different phases controls the symmetry of the superlattice. To investigate the effect of structural symmetry (or the lack of symmetry) on the dielectric properties of such superlattices, avoiding effects due to asymmetric electrode interfaces, capacitor devices were constructed with symmetric, lattice-matched, conducting oxide electrodes. I will show that the stacking architecture modifies the dielectric and ferroelectric properties of the constituents leading to new electronic properties uncharacteristic of naturally occurring phases. Superlattices with broken inversion symmetry are self poled and generate a second order susceptibility, $\chi^{(2)}$, as a result of the built-in asymmetric strain fields. The resulting polarization direction and the sign of $\chi^{(2)}$ are fixed by the symmetry of the superlattice. Sensitive pyrocurrent measurements indicate an increasing polarization as the temperature is lowered while below a temperature, $T_x$, an onset of a hysteretic response is observed. I will discuss an unusual ferro-like phase with two unequal polarization states which emerges below $T_x$ where the P-E loops are displaced not only along the E-field-axis by an effective polarizing field, but also along the P-axis by an offset polarization.

**12:27**
**V41 5 X-ray catastrophe focusing with ferroelectrics** STEPHEN DURBIN, *Purdue University* TERRENCE JACH, *NIST* SUNGWON KIM, *Penn State University* VENKATRAMAN GOPALAN, *Penn State University* Familiar ripple patterns reflected from water waves and the characteristic cusp of light seen in the bottom of a coffee cup are examples of catastrophe optics, where focusing occurs without need for highly engineered optical elements; catastrophe theory provides the mathematical tools needed to describe the stability and topology of the caustics that produce these effects. We have discovered catastrophe focusing in the diffraction of hard x-rays from crystalline wafers of ferroelectric lithium niobate, by diffracting monochromated synchrotron undulator radiation from surface planes while applying a voltage across the thin crystal. The presence of anti-phase ferroelectric domains causes a rippling of the surface that produces focusing at an x-ray CCD camera a half meter away. The catastrophe focusing pattern can be uniquely controlled by the applied voltage. These results suggest possible applications of catastrophe optics to x-ray microfocusing, and to the use of voltage-controlled patterned ferroelectrics as a new concept in x-ray optical devices.

**12:39**
**V41 6 The Effect of Grain Boundary Charge on Ferroelectric Transitions in Nanograin $BaTiO_3$** I-WEI CHEN, XIAOHUI WANG, YUDI WANG, *Department of Materials Science and Engineering, University of Pennsylvania, Philadelphia, PA19104-6272, USA* We have recently reported dense polycrystalline $BaTiO_3$ that has sub-100 nm grains. As grain size decreases, the electrical field due to grain boundary charge extends to an increasingly larger fraction of the grain giving rise to a size effect that is fundamentally different from those previously considered in the literature. Using Ginsberg Landau theory we have modeled this effect on ferroelectric transition, polarization/phase distribution and dielectric/piezoelectric responses, and compared it with the experimental results of $BaTiO_3$ (XRD, TEM, and $\varepsilon(T)$). Such nanograin ferroelectric ceramics, currently available at sub-10 nm grain size, are of considerable interest for the next-generation microelectronic component applications. A related grain boundary effect on phase transition has also been reported in coarse grain and bicrystal $SrTiO_3$.

**12:51**
**V41 7 Epitaxial Growth of $BaTiO_3/SrTiO_3$ and $BaO/SrTiO_3$ Superlattices for Phonon Confinement*** A. SOUKIASSIAN, *Materials Research Institute, The Pennsylvania State University* N.D. LANZILLOTTI KIMURA, A. BRUCHHAUSEN, A. FAINSTEIN, *Centro Atómico Bariloche & Instituto Balseiro, C.N.E.A., Argentina* A. CROSS, A. CANTARERO, *Materials Science Inst., University of Valencia, Spain* H.P. SUN, X.P. PAN, *Dept. of Materials Science and Engineering, University of Michigan* W. TIAN, D.A. TENNE, X.X. XI, D.G. SCHLOM, *Materials Research Inst., The Pennsylvania State University* We discuss the design and material parameters of $BaTiO_3/SrTiO_3$ and $BaO/SrTiO_3$ heterostructures relevant for novel phonon devices, including mirrors, filters, and cavities for coherent phonon generation and control. The advantages of using these ferroelectric superlattices include that they have an enormous stop band compared to the GaAs/AlAs superlattices previously reported for this application and that there can be greatly amplified light-sound interaction in these ferroelectric materials. We have grown $BaTiO_3/SrTiO_3$ and $BaO/SrTiO_3$ superlattices on $TiO_2$-terminated $SrTiO_3$ substrates by reactive MBE. Structural characterization by XRD and TEM revealed that the samples studied are of high quality with nearly atomically abrupt interfaces. We have observed folded acoustic phonons at the expected frequencies using UV Raman spectroscopy.

**13:03**
**V41 8 Site-Selective Studies of Er-doped $SiO_2$/SRO layers** ZACKERY FLEISCHMAN, VOLKMAR DIEROLF, *Physics, Lehigh University* YANLI ZHANG, MARVIN WHITE, *ECE, Lehigh University* Er-doped $SiO_2$ has attracted much attention as a possible pathway to realizing Si-based optoelectronic devices. Of particular interest is how the presence of silicon nanocrystals af-

fects the Er emission in this host material. In samples containing nanocrystals, there are three possible environments for the Er defect to occupy: within, near, and far from the nanocrystal silicon; each environment having the possibility for clustered and nonclustered Er. We present site-selective photoluminescence results obtained from samples with and without nanocrystals to analyze the spectral differences between these two types of samples. We can spectrally identify the different Er environments by directly comparing the results from the two types of samples. We observed Er clustering sites which become dominant as the activation anneal temperature increases. This Er clustering site emission is decreased in the samples containing nanocrystals, indicating that the excess silicon inhibits the formation of clusters. Despite our good site-selectivity, we were unable to find any special spectral signature of nanocrystal-related Er suggesting that their local environment is similar to that of isolated Er ions in $SiO_2$.

**13:15**

**V41 9 First principles theory of the local dielectric permittivity: Application to surfaces and interfaces** NING SHI, RAMPI RAMPRASAD, *Department of Materials Science and Engineering, Institute of Materials Science, University of Connecticut, 97 N. Eagleville Road, Storrs, CT 06269* A new computationally efficient method has been developed within the framework of density functional theory to aid in the study of the dielectric properties of multi-component systems, with explicit treatment of surface and interface effects. The local polarization and permittivity functions, induced due to a finite external electric field, are introduced to describe variation of the dielectric response over length scales of the order of interatomic distances. Specifically, we have determined the position dependent dielectric permittivity profiles for Si-$SiO_2$ and $SiO_2$ -polymer systems. We find that at regions close to surfaces and interfaces, the dielectric permittivity is enhanced compared to the corresponding bulk values, while in interior regions it approaches the corresponding bulk values. The calculated optical and static dielectric constant values of these systems are in excellent agreement with experimental results, and other more involved computational treatments.

**13:27**

**V41 10 Surface Micromachined Ferroelectric MEMS Devices: Correlating Device Performance with Film Microstructure*** JENNIFER RUGLOVSKY, MATTHEW DICKEN, KENNETH DIEST, MOHAMED EL-NAGGAR, SHARLOTTE BOLYARD, DAVID GOODWIN, GURUSWAMI RAVICHANDRAN, KAUSHIK BHATTACHARYA, HARRY ATWATER, *California Institute of Technology* The realization of free-standing ferroelectric thin film devices compatible with CMOS processing is a priority in achieving sophisticated MEMs systems. To release an active film from a silicon substrate with a back-etch technique requires the removal of hundreds of microns of the substrate as well as a suitable and robust mask for the device layer. A more flexible and process compatible technique is surface micromachining. We present work utilizing a $XeF_2$ etch process for surface micromachining silicon with a resistant patterned oxide layer to create free-standing ferroelectric MEMs structures. With surface patterning, we are able to realize both bridge and cantilever geometries. Lead titanate thin films grown by MOCVD for the active layer will be discussed. The devices have been synthesized in three different thin film microstructures: 1) poorly oriented, 2) fiber textured, and 3) biaxially textured. The realization of such a continuum of microstructures allows the switching mechanism to be better resolved and for the correlation between macroscopic device performance and microscopic properties to be more fully understood.

**V41 11 Interaction between ferroelectric nanodots: a first-principles-based study** S. PROSANDEEV,* I. PONOMAREVA, I. NAUMOV, I. KORNEV, L. BELLAICHE, UNIVERSITY OF ARKANSAS TEAM, We have performed Monte-Carlo simulations within a first- principles-based effective Hamiltonian approach to investigate the consequences (if any) of the interaction between nanodots made of lead titanium zirconate. We found that two dots under open circuit electrical boundary conditions weakly interact with each other, implying that they both adopt a vortex structure for their dipoles that is very similar to the one occurring in a single isolated dot. The situation is dramatically different if the first dot is polarized (e.g., by being under an external field) while the second dot is still under open circuit condition. In that case, the dots interact stronger, with this interaction causing the development of a relatively small spontaneous polarization in the second dot and, more importantly, being able to influence the direction of the toroid moment in this second dot – which is of technological importance. We further show how this last interaction, and its consequences, depend on the geometry and shape of the two dots, and reveal that all the striking features can be well understood within a multipole expansion of the field produced by the lattice polarization vortex in the free dot. This work is supported by DOE grant DE- FG02-05ER46188, by ONR grants N00014-01-1-0365, N00014-04-1- 0413 and N00014-01-1-0600, and by NSF grants DMR-0404335 and DMR-9983678.

**V41 12 *Ab-initio* theory of nanoscale capacitors at finite bias** MASSIMILIANO STENGEL, *Materials Department, University of California, Santa Barbara* NICOLA SPALDIN, We present a novel technique for calculating the properties of an electric field applied to a periodic heterostructure with alternating metallic and insulating layers. This scheme allows us to investigate fully from first- principles the microscopic properties of a thin-film capacitor at finite bias potential. We demonstrate how the capacitance and local permittivity profiles can be readily obtained by performing calculations for the Ag(100)/MgO(100) and $SrTiO_3$(100)/$SrRuO_3$(100) systems. Applications range from the emerging field of electronic devices based on ferroelectric materials, to the *ab-initio* simulation of electrochemical cells.

**14:03**

**V41 13 Electrophoresis of Ferroelectric Nanoparticles** XIYA LIU, DRAGOMIR DAVIDOVIC, SCHOOL OF PHYSICS, GEORGIA TECH TEAM, We have studied the electrophoresis of ferroelectric nanoparticles(Ba1-xSrxTiO3). We used de-ionized (DI) water as solvent and an optical microscope to observe the motion of suspended ferroelectric nanoparticles driven by AC electric fields. The immediate start and stop of motion were noticed when the driving electric field was turned on and off, which was similar to dielectricphoresis. Higher voltage generated higher speed as expected. In some instances, the dielectric constant $\varepsilon$ of ferroelectric materials can increase greatly, which makes it pos-

sible that a low driving voltage (no larger than 10V) could induce a relatively high speed. At room temperature, we studied the frequency dependence of the motion speed. By comparing a serial of captured motion movies, we found that higher speeds were corresponding to lower frequencies of driving AC electric field. Further, we use well defined electrodes made by electron-beam lithography and high-vacuum deposition, which may regulate the electric field distribution. Consequently, we can characterize the electric force applied on those nanoparticles.

**V42 1 Brotherly Advice: Letters from Hugo to Paul Ehrenfest in his Final Years** PAUL HALPERN, *University of the Sciences in Philadelphia* At the start of the 1930s, theoretician Paul Ehrenfest spent much of his time traveling through America and Europe while engaged in a steady stream of lectures. This traveling phase coincided with a frantic and intense period of negative self-examination, financial difficulty, and various other personal concerns that would ultimately lead to his 1933 suicide. Throughout these final years, he kept up a steady correspondence with his brother Hugo, a physician based in Saint Louis. Ten years older than Paul, Hugo freely doled out frank psychological advice about subjects ranging from the proper treatment of children to the dangers of self-pity. Through a look at some of the letters exchanged between the two brothers, this talk will examine the role Hugo played during the dark final years of Paul Ehrenfest's life.

**11:39**
**V42 2 E. U. Condon: Science, Religion, and Scientific Responsibility** MICHAEL DAY, *Lebanon Valley College* In the spring of 1947, Walter Michels, a long-time friend and professor of physics at Bryn Mawr College, introduced Condon to Quakerism. In December of that year, Condon was accepted into membership in the Religious Society of Friends. The main purpose of this talk is to consider Condon's views on science and religion that he began setting forth in 1948. Further, Condon's views, which emphasize the ''harmony of science and religion,'' are compared and contrasted with the views of I. I. Rabi and Arthur Compton on science and religion. The talk concludes with a discussion of Condon's views on the responsibilities of scientists. In certain ways, Condon's views on science, religion, and scientific responsibility represent a philosophical minimalism with respect to their commitments.

**12:03**
**V42 3 Particles and Waves in Classical Dynamics** RONALD MICKENS, Two central concepts in classical dynamics involve the notions of ''particles'' and ''waves.'' However, their definitions must take into consideration two aspects related to how they may be characterized: 1) physical properties and 2) their mathematical formulation within particular dynamic theories. An issue of particular importance is that these concepts are abstractions of physical phenomena and may not correspond to any actual physical system component. We first examine the concepts of ''particles'' and ''waves'' from the perspective of how they have been defined in textbooks, scientific dictionaries, handbooks, research monograms, etc. From these readings and their analysis, we formulate definitions based on how these concepts are represented in the general framework of classical dynamics. Our tentative conclusion is that this procedure allows particle and waves systems to be unambiguously defined.

**12:27**
**V42 4 CUNY Doctoral Students Expand Access to Advanced Placement Physics in Urban High Schools** PAULA FEKETE, AMISH KHALFAN, *Hunter College, CUNY* VICTOR STROZAK, *Center for Advanced Study in Education, The Graduate Center, CUNY* The CUNY GK-12 Fellows Program addresses the need to increase the participation of low-income and underrepresented minority students in high-school-level Advanced Placement (AP) courses in mathematics and sciences, particularly in urban schools. The project provides a unique opportunity for doctoral science and math students to work with AP teachers and students in public high schools in the Bronx, NY. The project has demonstrated that doctoral science students can be a valuable resource to both teachers and students and that their presence in the classroom can greatly enhance instruction at this level. Participation in the program also enhances the fellows' communication and teaching skills and deepens their awareness of issues in urban science and math education. We present the results of our work in Advanced Placement Physics during the project's first three years.

**12:39**
**V42 5 High School Visitation Program in New York City for Materials Science and Engineering Outreach** SIU-WAI CHAN, IRVING HERMAN, JUSTINE HERRERA, *Columbia University* MRSEC TEAM, We report on a school science outreach program that we have carried out since 1999 under the National Science Foundation funded Materials Research Science and Engineering Center (MRSEC) at Columbia University. Under this program, we have made 34 visits to twenty New York City public high schools and middle schools and have reached over three thousand students. The demographic of the schools are around 81% historically underrepresented minorities (37% African Americans and 44% Hispanic Americans) and around 55% female. This report shows how a similar program can be set up in an urban area, which can directly address the vital shortage of youths going into science, engineering and mathematics (SEM) careers. Logistics and experiences of running the program are described. Lessons learned and certain important issues of the program are addressed for an easy adaptation in a new city.

**12:51**
**V42 6 Using nanotechnology to illustrate concepts at the secondary school level** M.S. RZCHOWSKI, S.J. RUTHERFORD, C.M. FOLKMAN, C.B. EOM, *University of Wisconsin-Madison* E. MONTALVO, J. STARTEK, E. SEDA, *SESO, Mayaguez, Puerto-Rico* Although nanotechnology is beginning to permeate many aspects of modern society, most people have only a limited awareness of these advances. Here we describe a program in which nanotechnology is used as a vehicle to communicate basic ideas of nanoscale phenomena and materials at the secondary school level. Secondary school teachers from the SESO K-12 school in Mayaguez Puerto Rico participated in a summer nanotechnology workshop at the University of Wisconsin-Madison, where they learned basic aspects of nanotechnology through tuto-

rials and laboratory participation, and developed teaching modules and lesson plans. These materials were incorporated into the curriculum at SESO. We discuss the organization and evaluation of the workshop at UW-Madison, and the implementation and evaluation of the nanotechnology modules at SESO.

**13:03**

**V42 7 Let physics substantiate music and music enhance physics—give principle to the other disciplines.** HUI-YIING CHANG, *Texas State University* A conventional practice in K-12 education is to synchronize the arts and the sciences. Physics, traditionally been considered the mother of the sciences, and music, the mother of the arts, are interdependent and help to establishing a complete understanding of the other disciplines. Intense musical expression is attained when progression aims towards infinity. Motions are made in curves across time, imitating physical phenomena. The meaning of each element is enhanced according to the relative duration and dynamics of its context. Complete musical expression considers the three dimensions of space-length, breadth and height- and the three dimensions of time- past, present and future when balancing the instrumental parts and developing the structural elements. Overall, equilibrium is sought for like gravitational forces as expressed in equations. In learning processes, sensing precedes reasoning. Music attunes one to sensitive reactions towards the environment while physics substantiates the concepts by imposing a hierarchical order, the highest form of which is elegantly beautiful and most effectively expressed in music.

**13:15**

**V42 8 The Art Speed of Light** JAN WOJCIK, The Roman poet Horace predicted correctly his phrase aere perennius, would last ''longer than bronze'' because the Ode he wrote travels to the eye at nearly the speed of light regardless of the rate of the decay of the paper it's written on. John Keats's 19th century Ode predicted correctly the youthful figures he saw on a bronze age Grecian Urn moved in ''slow time'' aging little from the time of painting to the time of his viewing in the British museum-and to ours today of the same urn. The youthful images of the Keystone Kops have aged slower than their twins– their mortal actors. Discoveries about light's speed occurred synchronously with the engineering of telegraph and radio transmissions in the 19th century-which allowed anyone an experience of what Physics had discovered. Einstein's privotal papers appeared in the same year as the first feature film shot and transmitted at the speed of light regardless of the aging of the film stock. Experiencing the light-like speed of art in Keat's ode, Cubism, Bob and Ray's radio, the Keystone Kops provides an aesthetic, visceral understanding of Einstein's Twin's Paradox about the dilation of time.

**13:27**

**V42 9 Online Muon Capture and Decay Experiment*** MEGAN ALEXANDER, DANIEL MINER, WOJTEK SKULSKI, FRANK WOLFS, *Department of Physics and Astronomy, University of Rochester, Rochester NY, 14627* With the aid of the internet, the classic muon lifetime experiment has been made globally accessible. Our muon detector consists of a 2000 $cm^3$ plastic scintillator and 2″ phototube. The muon signals trigger a digital signal processor, which samples the waveform every 25 ns during an 8 microsecond period following the trigger. Signals characteristic of muons that stop and decay in the detector contain two pulses: one from the muon itself, and one from the decay products. The muon lifetime is obtained from the time difference between these pulses. The digitized data are sent to the host computer via a USB link, and fed to a website (http://wolfspc.pas.rochester.edu/muon). The website provides access to the muon waveforms, a lifetime histogram, and energy spectra. Raw data are available for download and can be imported and processed by programs such as Excel or MATLAB. The site allows the user to watch the incoming data in real time, carry out data analysis of a fraction or all of the data collected since November 2005, and explore the underlying particle physics concepts.

*Work funded by a grant from the APS for the World Year of Physics 2005 and a grant from the National Science Foundation under Grant No. PHY-024283.

## SESSION V43: ATOMIC/MOLECULAR STRUCTURE AND AMO PROCESSES ON SURFACES AND IN CONDENSED MATTER

**Thursday Morning, 16 March 2006**
**346, Baltimore Convention Center at 11:15**
**M. Safronova, University of Delaware, presiding**

**11:15**

**V43 1 Oscillating Mechanical Electron Cloud Due to Nuclear Vibration** STEWART BREKKE, *Northeastern Illinois University (former grad student)* The nucleus is vibrating rapidly thereby creating a mechanical sphere of charge as the electrons vibrate due to the moving electric field. The mechanical sphere of charge reconciles the Bohr concept of a circular orbit with Schrodinger's idea of an electon cloud in which the electron is a DeBroglie wave surrounding the nucleus. If the electron is vibrating rapidly in itself as well as due to the vibrating electric field of the nucleus we also have an electon cloud. The resulting mechanical electron cloud is a combination of the two vibrational components. Effectively, there is a vibrating sphere of electronic charge surrounding the nucleus. If r, the distance to the electron from the center of the nucleus minus the Amplitude of nuclear vibration, Acos2($\pi$)ft, then a spherical shell of charge S = 4 ($\pi$)(r - Acos2($\pi$)ft)$^2$ is created.

**11:27**

**V43 2 Hydrogen Molecule in the Frame of the Three-Body Santilli-Shillady Model** RAUL PEREZ-ENRIQUEZ, *Departamento de Fisica, Universidad de Sonora* J. MARIN, R. RIERA, *Departamento de Investigación en Física, Universidad de Sonora* We analyze the charge distribution structure of a Hydrogen molecule under the Restricted Three-body Santilli-Shillady Model. Using the stable isoelectronium model, a particle with $M = 2\,m_e$ and $q = -2\,e$, we found a compatible ground state of $H_2$ which overcomes the problems of that developed by Aringazin and Kucherenko. Our model makes use of energies and bond lengths of the ground state of Hydrogen as calculated by Kolos and Wolniewicz in 1968, and assumes that the isoelectronium is restricted to move over a confined region of space around the nuclei. This compatible ground state can be obtained following the Ley-Koo solution to Schrödinger equation for Hydrogen molecular ion confined by a spheroidal box and we think it could be used for a better understanding of phenomena associated with correlated electrons in molecular bonds as it is observed in double photoionization and neutron scattering experiments. The self consistency of our results comes right from the correlation between

the protons bond length, $R$, and the size of the spheroidal box, $a = 1/2\,\xi_0 \cdot R$.

**11:39**

**V43 3 Explicitly Correlated Wavefunctions for Few-Body Problems*** FRANK E. HARRIS, *Quantum Theory Project, U. of Florida and Dept. of Physics, U. of Utah* Explicitly correlated wavefunctions enable far more compact, yet accurate descriptions of few-body systems than are possible using basis functions built from orbital products. The most efficient functions of this type contain all the interparticle distances as exponentials. Progress in evaluating the matrix elements for such a basis is reviewed for three and four-body systems, with particular attention to the difficult analytical problems posed by the four-body system and the challenges associated with highly singular integrals in the three-body system (which arise in the computation of relativistic effects). An alternative basis is provided by Gaussians in all the interparticle distances; recent contributions toward systematizing the use of such functions are also reported. Application of the exponential basis to the He isoelectronic series is described; the results differ from those reported by others in that their quality does not decrease with increasing nuclear charge $Z$. This feature permits an improved characterization of the coefficients in the $1/Z$ expansion. Also disscused is the cancellation of divergences in the combinations of individually divergent integrals arising in the treatment of relativistic effects in the He system.

*Supported by U.S. National Science Foundation Grant PHY-0303412

**11:51**

**V43 4 Lattice Regularized Diffusion Monte Carlo Simulations of Iron Dimer** MICHELE CASULA, *Department of Physics, University of Illinois at Urbana-Champaign, 1110 W. Green Street, Urbana, Illinois 61801, USA* LEONARDO GUIDONI, *Università degli Studi di Roma ''La Sapienza,'' Physics Department,* SANDRO SORELLA, *International School for Advanced Studies (SISSA), Via Beirut 2-4, 34014 Trieste, Italy* Transition metal compounds play a crucial role in various fields, ranging from biomolecular reactions to magnetic solid state properties. On the other hand, the strong dynamic correlation present in the unfilled d-shell makes the predictions of the density functional theory unreliable and requires the use of post-Hartree-Fock methods, limited however to small systems. The Lattice Regularized Diffusion Monte Carlo (LRDMC) method, recently introduced [M. Casula, C. Filippi, and S. Sorella, Phys. Rev. Lett. 95, 100201 (2005)], seems to be an effective alternative, since it can provide accurate results with a favorable size scaling. One of the main advantages of this framework is the possibility to include non-local potentials in a consistent variational scheme, substantially improving both the accuracy and the computational stability upon previous non-variational diffusion Monte Carlo approaches. Here, we apply the LRDMC framework to the iron dimer, by using a fully optimized Jastrow geminal wave function as guiding state. Despite its simplicity, its neutral and anionic ground states are controversial, and we try to clarify their symmetry by comparing our LRDMC results with experimental spectroscopic data.

**12:03**

**V43 5 Regionally specific hyperfine polarization of Rb atoms at micron/submicron distance from the Pyrex glass surfaces in optical pumping cells*** K. ZHAO, Z. WU, *Department of Physics, Rutgers University, Newark, NJ 07102* We made *regionally specific* measurement of the hyperfine polarization of Rb atoms in the vicinity ( $\sim 10^{-5}$ cm) of coated and uncoated Pyrex glass surfaces in optical pumping cells. This is in contrast to the previous hyperfine polarization studies, where the quantity measured is the bulk hyperfine polarization, which depends on surface interactions *averaged over the entire cell surfaces*. We probe the hyperfine polarization of the Rb atoms in the vicinity of cell surfaces using the evanescent wave of a weak laser beam. We find that the polarization in the vicinity of uncoated surfaces is significantly lower than that in the bulk. The polarization decreases rapidly with decreasing distance from the surface. By contrast, the polarization in the vicinity of a silicone coated Pyrex glass surface is independent of the distance from the cell surface and is equal to the bulk polarization. Regionally specific measurement of the hyperfine polarization as a function of the penetration depth of the evanescent wave allows us to deduce the hyperfine polarization, its normal gradient and normal gradient coefficient at the cell surface. We present the values of these quantities for three representative uncoated cells.

**12:15**

**V43 6 Q-factor spoiling of a fused silica microsphere** PABLO BIANUCCI, JOHN ROBERTSON, ANDREAS MULLER, C. K. SHIH, *The University of Texas at Austin* When a planar transparent surface if brought close to a microsphere resonator, the induced leakage will result in a decrease of the Q-factor of the resonant modes. We present a systematic study of the Q-factor spoiling on a fused silica microsphere using a tapered optical fiber as a waveguide and a cleaved fiber as a planar surface. The Q-spoiling is measured as function of the distance between the microsphere and the cleaved fiber. Different modes show quite different deterioration rate for the Q-value as a function of sphere-fiber distance. This Q-decay rate is directly related to the evanescent nature of the cavity modes.

**12:27**

**V43 7 Radiation Patterns of Electric Dipoles Close to a Plane Interface*** LAN LUAN, PAUL SIEVERT, JOHN KETTERSON, *Northwestern University* The radiation pattern of an electric dipole is modified when located in the vicinity of a dielectric or metal interface. We have investigated this phenomenon through numerical simulations and direct measurements. Our simulations are based on the Sommerfeld integral formalism. The effects of the dipole position and orientation, the dielectric constants of the media, and the observation position on the radiation pattern for TE and TM modes were studied. On the experimental side, we used fluorescent molecules to simulate the electric dipoles. The angular distribution of the fluorescence emission was recorded. Both our simulations and the experiments showed that the dipole radiation pattern is strongly modified from the free space form. Our results are potentially important for optical signal collection associated with spectroscopic studies of molecules bound to a surface.

**12:39**

**V43 8 Quadrupole $nd \rightarrow nl$ resonances in valence ns-photoelectron angular distributions from half-filled shell atoms.*** VALERIY DOLMATOV, *University of North Alabama* Nondipole photoelectron angular distributions from atoms have

become an itad hoc topic of intensive research in recent years. To date, such distributions have largely remained unstudied, with a few exceptions, in open-shell atoms in view of difficulties in handling such atoms. Therefore, we have unfolded a theoretical program focusing on studies of nondipole photoelectron angular distributions from open-shell atoms. In the present work, we choose the Mn($3d^5 4s^2$, $^6$S) atom as a case study owing to its relative ''simplicity'' because its open $3d^5$ subshell is only half-filled. We explore features of nondipole angular asymmetries for valence 4s-photoelectrons in a region of $3d \rightarrow nl(l = 0,2,4)$ quadrupole resonances. A removal of a 4s electron leaves the Mn atom either in a $3d^5 4s,(^7S)$ or $3d^5 4s,(^5S)$ final state. It is found that, due to demonstrated exclusive for a half-filled shell atom electron correlation effects, resonance enhancements of 4s nondipole angular asymmetry parameters depend markedly on final state terms of the atom, both in their magnitudes and shapes, with one of them overshooting the other by almost an order of magnitude at the resonance maximum, and with both of them far overshooting the dipole approximation value of 2. A ''spin-polarized'' RPAE has been employed in this study.

*The NSF financial support PHY-0456480 is acknowledged.

**12:51**

**V43 9 Cooperative Emission from Semiconductor Quantum Wells in High Magnetic Fields*** D. H. REITZE, Y. D. JHO, X. WANG, *Physics Dept., University of Florida* J. KONO, *Dept. of Electrical and Computer Engineering, Rice University* A. A. BELYANIN, V. V. KOCHAROVSKY, *Physics Department, Texas A&M University* G. SOLOMON, *Solid State Laboratories, Stanford University* X. WEI, *NHMFL* Stochastically oriented, spectrally-peaked emissions is generated in $In_{0.2}Ga_{0.8}As/GaAs$ multiple quantum wells (QW). Using intense 150 fs, 775 nm pulses for excitation, we investigate the spatial and temporal characteristics of the emission in dense magneto-plasmas in high magnetic fields (30 T) and at carrier densities approaching $10^{13}$ cm$^{-2}$. Above a threshold intensity and magnetic field, the emission from Landau levels exhibit anomalous narrow features appearing asymmetrically on the high-energy side of the peaks. An examination of the spot size dependence of emission strength relative to the coherence length, temperature dependence of threshold magnetic field, and differential transmission spectra suggest that the inter-LL emission arises from the spontaneous polarization of the dense magneto-plasma.

*Supported by the NSF through grant DMR-0325499 and by the NHMFL through an IHRP grant.

**13:03**

**V43 10 Dielectric Modification of the Casimir force between a gold sphere and a silicon surface** FENG CHEN, UMAR MOHIDEEN, *Department of Physics, University of California, Riverside, CA 92521* The Casimir force (retarded van der Waals force) can become very large at micron and nano distance scales and can affect the performance and fabrication of microelectromechanical (MEMS) and nanoelectromechanical systems (NEMS). Here we demonstrate that it is possible to modify the Casimir force in the microelectromechanical systems, through alteration of the dielectric properties of the silicon boundary. This will open new opportunities for the application of the Casimir force in MEMS and NEMS. This experiment also helps improve our understanding of the Casimir force between dielectric surfaces.

**13:15**

**V43 11 Analysis of van der Waals Interaction Energies from Quantum Chemistry: Aromatic Clusters and Rare Gas Dimers** STEPHEN GARRISON,* *National Institute of Standards and Technology, NIST Center for Theoretical and Computational Nanosciences* INEZ GONZALEZ, *University of Akron, Department of Chemistry* CARLOS GONZALEZ, *National Institute of Standards and Technology, NIST Center for Theoretical and Computational Nanosciences* MANUEL MARQUEZ, *Philip Morris USA Research Center* EDWARD LIM, *University of Akron, Department of Chemistry* The weak van der Waals (vdW) interactions in aromatic clusters and rare gas systems are studied using ab initio quantum chemistry and the Hartree-Fock Dispersion (HFD) method. The results, extrapolated to the complete basis set limit and along with comparisons to experiment, are used to understand and explain a fortuitous cancellation of errors in the benzene interaction calculations. Additionally, interesting results are found for the all-electron calculations for argon.

*I am also with the Interdisciplinary Network of Emerging Science and Technologies (INEST) Group

**13:27**

**V43 12 Energy Distribution of Cluster Assemble with Isomers** SONGBAI YE, LOUIS BLOOMFIELD, BLOOMFIELD LAB TEAM, The internal energy of cluster assemble without isomers will be a single-peak distribution in thermal equilibrium. However, if it has several isomers and each isomer has different state density distribution, the internal energy distribution will be structured in certain circumstance. By destroying the equilibrium of isomer populations and observing the building-up of the new equilibrium, we can gain information of the internal energy of the cluster assemble. We can also study the change of the internal energy of the cluster assemble by selectively burning some isomers before we proceed the deplete-probe method. This presentation is based upon work supported by the National Science Foundation under Grant No. DMR-0405203.

## SESSION V44: KONDO PHYSICS AND LUTTINGER LIQUIDS

**Thursday Morning, 16 March 2006**
**347, Baltimore Convention Center at 11:15**
**K. Ingersent, University of Florida, presiding**

**11:15**

**V44 1 Quantum Phase Transition in an Anisotropic Kondo Lattice** M.T. GLOSSOP, K. INGERSENT, *U. Florida* The Kondo lattice model (KLM), which captures the competition between Kondo screening of localized moments by conduction electrons and their ordering due to the RKKY interaction, is of interest in the context of non-Fermi-liquid behavior in quantum critical heavy-fermions. An important issue concerns the possibility of a local quantum critical point (QCP) — where Kondo screening is itself critical at the magnetic ordering transition — recently invoked [1] to explain anomalous properties of, e.g., $CeCu_{5.9}Au_{0.1}$. We study the anisotropic KLM using the extended dynamical mean-field theory (EDMFT), which maps the KLM onto a self-consistent Bose-Fermi Kondo model (BFKM). Whether a local QCP arises as a self-consistent EDMFT solution of the KLM is a

contentious issue that we seek to resolve. Separate studies [2,3], both employing Quantum Monte Carlo (QMC) to solve the BFKM, have reached opposite conclusions, but limitations of QMC at low temperatures $T$ obscures the picture at $T = 0$. We address this matter, providing reliable $T = 0$ solutions using our extension of [4] Wilson's numerical renormalization group method to solve the BFKM. We present results for both paramagnetic and antiferromagnetic phases, shedding light on the nature of the QPT. Supported by NSF Grant DMR-0312939. [1] Q. Si, S. Rabello, K. Ingersent, and J. L. Smith, Nature **413**, 804 (2001). [2] J-X Zhu, D. R. Grempel and Q. Si, Phys. Rev. Lett. 91, 156404 (2003). [3] P. Sun and G. Kotliar, Phys. Rev. Lett. 91, 037209 (2003). [4] M. T. Glossop and K. Ingersent, Phys. Rev. Lett. 95, 067202 (2005).

**11:27**

**V44 2 Zero temperature phase diagram of the periodic Anderson model** LORENZO DE LEO, *Rutgers University* MARCELLO CIVELLI, *Rutgers University* GABRIEL KOTLIAR, *Rutgers University* We study the phase diagram of the periodic Anderson model using a cluster extension of DMFT to take into account non-local effects generated by the RKKY exchange. We employ exact diagonalization in order to access the zero temperature regime which was previously unexplored. In particular we focus our attention away from half filling where the competition between the localization of the heavy electrons and their magnetic ordering could result in a quantum critical point with unusual properties. We also consider the effect of a direct hopping between the *f*-electrons in order to understand if an indipendent tuning of the RKKY interaction influences the character of the transition.

**11:39**

**V44 3 Non-Fermi-liquid phase in a frustrated Kondo trimer*** KEVIN INGERSENT, DOHYUNG SEO, *U. of Florida* ANDREAS LUDWIG, *U. of California, Santa Barbara* IAN AFFLECK, *U. of British Columbia* The Kondo model for three antiferromagnetically coupled half-integer spins exhibits a non-Fermi-liquid phase that is stable against magnetic fields and against particle-hole symmetry breaking [1,2]. This phase has been argued [3] to describe the low-energy physics of equilateral Cr trimers on Au (111) surfaces [4]. It also has potential realizations in quantum-dot devices of triangular symmetry. We report properties of this phase obtained using the boundary conformal field-theory (CFT) technique, including characteristic signatures in the conductance, and apply CFT and renormalization-group methods to examine the phase's behavior under various perturbations. [1] B. C. Paul and K. Ingersent, cond-mat/9607190. [2] K. Ingersent, A. W. W. Ludwig, and I. Affleck, cond-mat/0505303 (Phys. Rev. Lett., in press). [3] B. Lazarovits et al., Phys. Rev. Lett. 95, 077202 (2005). [4] T. Jamneala, V. Madhavan, and M. F. Crommie, Phys. Rev. Lett. 87, 256804 (2001).

*Supported by NSF, NSERC, and the Canadian Institute for Advanced Research

**11:51**

**V44 4 Egxact ground states for the periodic Anderson model at half filling in two dimensions** ZSOLT GULACSI,* *University of Debrecen, Department of Theoretical Physics, Hungary* Recently, starting from a procedure based on the decomposition of the Hamiltonian in positive semidefinite operators, exact ground states have been deduced for the periodic Anderson model at finite value of the interaction at 1/4 and 3/4 filling even in three dimensions (PRL 91,186401,(2003); PRB 72,075130, (2005)), the method being so powerfull that its application for disordered systems, at the same values of the filling, and two dimensions, is also possible (PRB 69, 054204, (2004)). Herewith we extend the procedure such to be applicable at half filling as well, in the presence of finite on-site Hubbard interaction acting at the level of the correlated band. The extensions lead to a method which uses extended operators, (e.g. linear combinations of the starting fermionic operators acting along the whole system), and also sublattice operators, in constructing the ground state wave functions. The ground states describing conducting spin-singlet states, are presented in two dimensions.

*Research supported by Grant OTKA-T037212 of the Hungarian Scientific Research Fund and Alexander von Humboldt Foundation

**12:03**

**V44 5 Dynamic Magnetic Response of Heavy Fermion Semimetals** PETER RISEBOROUGH, *Temple University* We have calculated the dynamical magnetic response of a model of a heavy fermion semimetal, which is characterized by a narrow gap in the f density of states and a low conduction electron density of states at the Fermi energy. The model is used to fit optical absorbtion measurements on $CeRu_4Sb_{12}$ performed by Dordevic *et al.*, Phys. Rev. Lett. **86**, 684 (2001). The temperature dependence of the dissipative part of the magnetic response is compared with the experimentally determined inelastic neutron scattering cross-section of $CeRu_4Sb_{12}$ measured by Adroja *et al.* Phys. Rev. B **68**, 099426 (2003).

**12:15**

**V44 6 Magnetic Quantum Phase Transitions of a Kondo Lattice Model with Ising Anisotropy** JIAN-XIN ZHU, *Theoretical Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA* STEFAN KIRCHNER, QIMIAO SI, *Department of Physics & Astronomy, Rice University, Houston, Texas 77005-1892, USA* DANIEL R. GREMPEL, *CEA-Saclay/DRECAM/SPCSI, 91191 Gif-sur-Yvette, France* RALF BULLA, *Theoretische Physik III, Elektronische Korrelationen und Magnetismus, Universitaet Augsburg, 86135 Augsburg, Germany* We study the Kondo Lattice model with Ising anisotropy, within an extended dynamical mean field theory (EDMFT) in the presence or absence of antiferromagnetic ordering. The EDMFT equations are studied using both the Quantum Monte Carlo (QMC) and Numerical Renormalization Group (NRG) methods. We discuss the overall magnetic phase diagram by studying the evolution, as a function of the ratio of the RKKY interaction and bare Kondo scale, of the local spin susceptibility, magnetic order parameter, and the effective Curie constant of a nominally paramagnetic solution with a finite moment. We show that, within the numerical accuracy, the quantum magnetic transition is second order. The local quantum critical aspect of the transition is also discussed.

**12:27**

**V44 7 Coherence in the two-impurity Kondo problem** LIJUN ZHU, C.M. VARMA, *University of California, Riverside* We use the Wilson's renormalization group method to investigate the splitting of the even and odd Kondo resonances in the problem of two interacting Kondo impurities which presages the band-width or the coherence scale in the heavy-Fermion lattice. A finite splitting requires both potential scattering V which lifts particle-hole degeneracy and a difference between the exchange in the even and the odd parity channels(Je-Jo)[1]. We also investigate the elimi-

nation of the quantum critical point in the two-impurity Kondo problem[2] due to loss of particle-hole symmetry. [1] I. Affleck and A. W. W. Ludwig, Phys. Rev. Lett. 68, 1046(1992). [2] B. A. Jones, C. M. Varma, and J. W. Wilkins, Phys. Rev. Lett. 61, 125(1988).

**12:39**

**V44 8 Large temperature renormalization of anomalous Luttinger exponent in $Li_{0.9}Mo_6O_{17}$*** FENG WANG, S.-K. MO, J.W. ALLEN, J.V. ALVAREZ, *U. of Michigan* G.-H. GWEON, *Lawrence Berkeley National Lab* J. HE, *U. of Tennessee* R. JIN, R. MANDRUS, *Oak Ridge National Lab* H. HÖCHST, *SRC, U. of Wisconsin* $Li_{0.9}Mo_6O_{17}$ is unique as a quasi-1 dimensional metal for which both photoemission spectroscopy (PES) [1] and tunneling [2] find Luttinger liquid (LL) power law behaviors in spectra near the Fermi energy $E_F$, albeit with differing values of the anomalous exponent $\alpha$, $\approx$ 0.9 at temperature 300K and $\approx$ 0.6 below 50K, respectively. New T-dependent PES spectra from T = 300K down to 15K can be well fit by finite-T LL theory, with $\alpha$ varying continuously from $\approx$ 0.9 to $\approx$ 0.6, showing consistency of PES and tunneling. We find that its incommensurate Fermi wavevector would preclude such a large renormalization of $\alpha$ with T for $Li_{0.9}Mo_6O_{17}$ were it not for interband dynamics and residual interaction scattering that can occur only because there are two (nearly degenerate) bands crossing $E_F$. We also discuss implications of the theory for further experiments. [1] G.-H. Gweon et al, Phys. Rev. B **68**, 195117 (2003). [2] J. Hager et al, Phys. Rev. Lett. **95**, 186402 (2005).

*Supported at U. Mich. by the U.S. NSF Grant(DMR-03-02825)

**12:51**

**V44 9 Finite temperature ac conductivity of disordered Luttinger liquids** ANDREAS GLATZ, *Materials Science Division, Argonne National Laboratory, Argonne, Illinois 60439, USA* BERND ROSENOW, *Physics Department, Harvard University, Cambridge, Massachusetts 02138, USA* THOMAS NATTERMANN, *Institut fuer theoretische Physik, Universitaet zu Koeln, 50937 Koeln, Germany* Due to the strong effect of interactions in one spatial dimension, elementary charge excitations of a Luttinger liquid are plasmons. Backscattering of electrons from a random impurity potential creates single particle excitations, which strongly interact with these plasmons. In this way, backscattering from the impurity potential is modified by interactions and acquires a strong energy dependence first described in [1]. Based on a finite temperature renormalization group (RG) calculation [2], we determine the ac conductivity and include both the renormalization of the impurity strength and of the charge dynamics. The latter was neglected in [1], where the conductivity was calculated using the effective impurity strength obtained from the RG. We discuss the full frequency and temperature dependence of the conductivity and compare our results with those of [1]. [1] T. Giamarchi and H.J. Schulz, Phys. Rev. B 37, 325 (1988). [2] A. Glatz and T. Nattermann, Phys. Rev. Lett. 88, 256401 (2002).

**13:03**

**V44 10 Dynamics of Strongly Correlated 1D Fermi Gases** RAZVAN TEODORESCU, *Columbia University* Dynamics of special collective modes in cold, degenerate Fermi gases are investigated through bosonization. The study applies to a variety of 1D or quasi-1D systems of fermions, including opticaly trapped cold gases and nanowires.

**13:15**

**V44 11 Tunneling, charge spreading, and the infrared catastrophe in conductors** KELLY PATTON, MICHAEL GELLER, *The University of Georgia* In many strongly correlated and low-dimensional electron systems the tunneling density of states (DOS) is suppressed near the Fermi energy; for example, the Luttinger-liquid characterization of one-dimensional conductors predicts that the DOS vanishes as a power law. Here we establish a connection between these DOS anomalies and the infrared catastrophe. The infrared catastrophe can occur during a tunneling event in systems where the relaxation of the newly introduced charge is inhibited by low dimensionality or other localizing effects. This catastrophe is known to be responsible for the x-ray edge spectra of metals, the Anderson orthogonality catastrophe, and the Kondo effect. By expressing the exact Green's function as a functional average of non-interacting Green's functions over of all space and time dependent potentials, we can appropriately treat the potentials responsible for the infrared catastrophe. The resulting interacting Green's function is the product of the noninteracting Green's function and $e^{-S}$, where $S$ is interpreted as a classical electrostatic action of a charge density spreading in time. These results give justification to other previously introduced phenomenological charge spreading theories. We apply this formalism to the Tomonaga-Luttinger, Calogero-Sutherland and other models.

**13:27**

**V44 12 Boundary Green's Function for Spin-incoherent Interacting Electrons in One Dimension** PAATA KAKASHVILI, *Chalmers University of Technology* HENRIK JOHANNESSON, *Göteborg University* Recently the spin-incoherent regime of 1D strongly interacting, very low density electrons has attracted a lot of interest[1,2]. For sufficiently low densities the potential energy dominates the kinetic energy, driving the system towards a Wigner crystal and leading to an exponentially small spin exchange energy. One can then easily reach the spin-incoherent regime where the exchange energy is much less than the temperature. The physics of the spin-incoherent regime has been addressed using Bethe's Ansatz and a bosonized path integral approach, revealing that the spin incoherence dramatically influences the correlations of charge excitations. We have generalized the description to account for the presence of a boundary. By calculating the exact Green's function we find that the charge sector exponent is highly sensitive to the boundary, strongly modifying the tunneling of electrons close to it. Our approach also allows for a detailed description of the crossover between boundary and bulk regimes. 1. V.V. Cheianov and M.B. Zvonarev, PRL 92, 176401 (2004) 2. G.A. Fiete and L. **V44 13 Phonon Effects on Spin-Charge Separation in One Dimension*** CHANG-QIN WU, WEN-QIANG NING, HUI ZHAO, *Department of Physics, Fudan University, Shanghai 200433, China* HAI-QING LIN, *Department of Physics and Institute of Theoretical Physics, The Chinese University of Hong Kong, Shatin, Hong Kong, China* Phonon effects on spin-charge separation in one dimension are investigated through the calculation of one-electron spectral functions in terms of the recently developed cluster perturbation theory together with an optimized phonon approach. It is found that the retardation effect due to the finiteness of phonon frequency suppresses the spin-charge separation and eventually makes it invisible in the spectral function. A signature of electrons pairing in weak interaction regimes was found to be consistent with the existence of a metallic phase proposed recently

by Clay and Hardikar [Phys. Rev. Lett. **95**, 096401 (2005)]. By a comparison between our result and the experimental data of TTF-TCNQ, it is observed that electron-phonon interaction must be taken into account even in the strongly correlated system.

**V44 14 Dynamic Properties of 1-D Ising Chain in a Random Transverse Field*** XUN JIA, SUDIP CHAKRAVARTY, *Department of Physics, University of California at Los Angeles* We considered a one dimensional spin-1/2 Ising chain in a random transverse magnetic field. Dynamic structure factor $S(k,\omega)$ at $T = 0$ is numerically computed by mapping to Jordon-Weigner fermions. Two types of distributions of magnetic fields are introduced into our model. With rectangular distribution, single branch of dispersion relation is observed, and disorder tends to broaden the dispersion peak and close the excitation gap. With a binary distribution, a non-dispersing branch at almost zero energy is recovered. This is reminiscent of neutron scattering measurement in $LiHoF_4$, although this is a three-dimensional system with long-range dipolar coupling between the electronic spins, which are in turn coupled to the nuclear spins through the hyperfine interactions. The implications of this similarity will be discussed.

**14:03**

**V44 15 Stripe Glass from Competing Short and Long Range Interactions** GERGELY ZIMANYI, CHRIS PIKE, RICHARD SCALETTAR, *Physics Department, UC Davis* We investigate a film of dipoles oriented perpendicular to the film. The system's behavior is related to inhomogeneous non-Fermi liquid states, recently studied by Kivelson and Spivak and by Schmalian and Wolynes. The competition of short range ferromagnetic and long range antiferromagnetic interactions causes the formation of stripes. The system has an ordered stripe-crystal phase. However, this phase is avoided unless an extremely slow annealing protocol is utilized. Without any quenched disorder during normal annealing protocols the frustrated competing interactions self-generate a stripe-glass state. The stripe glass exhibits aging, manifesting itself in waiting-time dependent correlations. A scaling analysis of the aging is presented. The long time behavior shows stretched exponential behavior, the relaxation time surprisingly exhibiting a simple activated form. Dynamical inhomogeneities are identified, both frozen domains and instantaneous crystallites.

## SESSION V45: SPIN STRUCTURE AND PHASE TRANSITIONS: THEORY

**11:15**

**V45 1 Disorder and ferromagnetism in a graphene sheet** NUNO M.R. PERES, *Universidade do Minho, Portugal* FRANCISCO GUINEA, *Instituto de Ciencia de Materiales de Madrid. CSIC* ANTONIO H.C. NETO, *Boston University* We study the presence of ferromagnetism in the phase diagram of the two-dimensional honeycomb lattice close to half-filling (graphene) as a function of the strength of the Coulomb interaction and doping. We show that exchange interactions between Dirac fermions can stabilize a ferromagnetic phase at low doping when the coupling is sufficiently large. In clean systems the zero temperature phase diagram shows both first order and second order transition lines and two distinct ferromagnetic phases: one phase with only one type of carriers (either electrons or holes) and another with two types of carriers (electrons and holes). Using the coherent potential approximation we argue that disorder further stabilizes the ferromagnetic phase.

**11:27**

**V45 2 The exchange instability in a graphene bilayer** JOHAN NILSSON, ANTONIO CASTRO NETO, *Boston University* NUNO PERES, *Univ. Minho* FRANCISCO GUINEA, *ICMM* We study the problem of the formation of electron-hole pockets in a graphene bilayer (two layers of graphite). By means of a variational calculation in a simple model we show that pockets can be formed due to the combined effects of the Coulomb interaction and a coherent nearest neighbor hopping within the planes and between the layers. The variational calculation shows that the non-interacting ground-state is unstable and that a small net ferromagnetism can be obtained. Upon doping the system away from half filling the instability goes away above a critical value of the doping. We also discuss how modifications to the model such as the inclusion of screening and disorder will affect the instability.

**11:39**

**V45 3 Spin Liquid States on the Triangular Lattice: A Projective Symmetry Group Analysis of Schwinger Boson States** FA WANG, ASHVIN VISHWANATH, *UC Berkeley* Recent numerical and experimental results on quantum spin systems on the triangular lattice have revealed several unusual phenomena. Motivated by these developments, we apply the Projective Symmetry Group Analysis, previously used to classify spin liquid states obtained within a fermionic spin representation, to Schwinger bosons mean field states on the triangular lattice. We find several distinct $Z_2$ spin liquid states, but restricting attention to states with non-vanishing nearest neighbor amplitudes we find only two candidates. The first (zero-flux state) is the well known state introduced by Sachdev, which on condensation of spinons leads to the 120 degree ordered state. The other solution which we call the Pi-flux state has not previously been discussed. It is found to be stable against order up to a much larger value of the quantum parameter than the zero-flux state, which makes it an attractive candidate spin liquid state. When spinon condensation does occur, the ordering wavevector is at the Brillouin zone edge centers, different from the 120 degree state. While the zero-flux state is more stable with just nearest neighbor exchange, we find that the introduction of either next-neighbor antiferromagnetic exchange or four spin ring exchange tends to favor the Pi-flux state.

**11:51**

**V45 4 Spin current and spiral spinons in the Heisenberg spin chain*** YUPENG WANG,[†] *Institute of Physics, Chinese Academy of Sciences* The twisted boundary magnetic field effects on the one dimensional antiferromagnetic spin chains with spin half and spin one are studied via the density matrix renormalization group method. A spin voltage controlled by the twisted boundary fields as well as the spin current are observed for the spin half chain. The

correlation functions reveal the spiral nature of spin structure for both ground state and the spinon excitations for the spin half case. For the spin one chain, a kink is generated in the ground state and the midgap state is induced by small boundary fields.

**12:03**
**V45 5 Partial order in MnSi?** JOHN HOPKINSON, HAE-YOUNG KEE, *University of Toronto* Motivated by a recent neutron scattering study of MnSi, we study the ferromagnetic Heisenberg model with Dzyaloshinskii-Moriya interactions on the 3D corner-shared triangle lattice, the magnetic sublattice of MnSi. For classical spins we find evidence of a partially ordered state: degenerate states form a sphere with a fixed radius in momentum space. Further, for a metallic system, we propose an assignment of the Moriya vectors following an RKKY derivation of Fert and Levy. We calculate the structure factor within the mean field approximation and test this result against classical monte carlo calculations. We discuss the connection of our results to phenomenological Landau-Ginzburg treatments of the Dzyaloshinskii-Moriya coupling on this lattice.

**12:15**
**V45 6 No dominance of RKKY interaction in 4f-magnets** GERMAN SAMOLYUK, VLADIMIR ANTROPOV, *Ames Laboratory* It is a common belief that in the rare earth materials the dominating exchange mechanism is the magnetic coupling between localized 4fmoments mediated by nearly free conduction electrons resulting in so-called indirect coupling or RKKY interaction. In addition, several experimental proofs have been published in the past. We reanalyzed the validity of this statement from a point of view of realistic atomic and solid state electronic structure. The experimental proofs have been reanalyzed as well. In general, we found that no theoretical validation of RKKY dominance in 4f-magnets exist and all experimental evidences cannot rule out other mechanisms. We claim that the direct interatomic exchange between conduction electrons must be always taken into account.

**12:27**
**V45 7 New classification of magnets** VLADIMIR ANTROPOV, *Condensed Matter Theory, Ames Laboratory, Ames, IA, 50011* Standard methods classify magnets using their magnetic long range order at T=0 (ferromagnets, antiferromagnets and so on). Some classifications can be created inside those groups as well. In addition, there is a very attractive and widely used qualitative localized-itinerant picture, which, however, does not have any real criteria behind. I would like to introduce a rather universal and possible quantitative classification using the idea of magnetic short range order, which we recently found theoretically and which has been for years observed experimentally in many materials.

**12:39**
**V45 8 Exact Diagonalization Study of the Quantum Antiferromagnet $Cs_2CuCl_4$*** OOKIE MA, J. B. MARSTON, V. F. MITROVIĆ, M.-A. VACHON, *Brown University* We exactly diagonalize a model of the quantum antiferromagnet $Cs_2CuCl_4$. The quasi two-dimensional material is one of only two strong candidate systems that may exhibit a spin-liquid phase[1]. To compare with NMR experiments we calculate the total magnetization for clusters of up to 24 sites as a function of temperature and the applied magnetic field. The spin-1/2 degrees of freedom reside on an anisotropic triangular lattice; in addition to the usual nearest-neighbor Heisenberg exchange, interactions of the Dzyaloshinskii-Moriya type must also be included[2]. We investigate the potential importance of additional higher-order terms[3].

*Supported in part by NSF DMR-0213818.

**12:51**
**V45 9 An ab initio study of the giant magnetocaloric effect in MnAs*** HYEJUNG KIM, YIA-CHUNG CHANG, SAHRAOUI CHAIEB, *University of Illinois at Urbana-Champaign* MnAs is one of the materials which show a giant magnetocaloric effect. Electronic and magnetic properties of MnAs in NiAs structure and hypothetical zinc-blende structure are studied using a full potential linear augmented-Slater-type-orbital (LASTO) method within the local spin density approximation. Total energies and magnetic moments as a function of volume as well as band structures are in agreement with previous calculations employing different methods such as full potential linearized augmented plane wave method and a plane-wave pseudopotential implementation. Exchange coupling parameters are determined with a frozen magnon approach. Using the exchange coupling parameters obtained, a mean-field theory is applied to calculate the quantities of interest such as the magnetic entropy and free energy as a function of temperature and the critical temperature, to evaluate the giant magnetocaloric effect in MnAs.

**V45 10 Spatially Anisotropic d=3 Ising, XY Magnetic and Percolation Systems: Exact Renormalization-Group Solutions of Hierarchical Models** AYKUT ERBAŞ, *Koç U. and ITU* ASLI TUNCER, *ITU* BURCU YÜCESOY, *ITU* A. NIHAT BERKER, *Koç U. and MIT* Hierarchical lattices that constitute spatially anisotropic systems are introduced. These lattices provide exact solutions for hierarchical models and, simultaneously, approximate solutions for uniaxially or fully anisotropic $d = 3$ physical models. The global phase diagrams, with $d = 2$ and $d = 1$ to $d = 3$ crossovers, are obtained for Ising, XY magnetic models and percolation systems, including crossovers from algebraic order to true long-range order.[1] Our approach has been applied to spatially anisotropic $d = 3$ tJ models of electronic conduction.[2] 1. A. Erbaş, A. Tuncer, B. Yücesoy, and A.N. Berker, Phys. Rev. E **72**, 026129 (2005). 2. M. Hinczewski and A.N. Berker, cond-mat/0504741.

**13:15**
**V45 11 Simulation of magnetization configurations with constricting magnetization boundary conditions in 2 and 3-D soft-hard magnetic structures*** JONG HAN, HEMACHANDER SUBRAMANIAN, *State University of New York at Buffalo* A soft magnet embedded with hard-magnetic spheres/cylinders magnetized to constrict the soft magnets magnetization creates a system

with multiple minima and related hysterisis effects. Due to many distinct magnetic structures in the soft-magnetic region at fixed magnetization on hard-magnets, frustration develops even in simple hard-magnetic arrays coupled via ferromagnetic exchange interaction. This presentation reports the simulation of such systems. We observed multiple minimum energy configurations and transitions between them in an externally applied magnetic field and/or change in hard magnets magnetization. Hysteresis effects due to the above changes are observed. Electron transport through these systems can generate interesting magneto-resistance effects.

**13:27**

**V45 12 Topological transition in a two-dimensional model of liquid crystal** ANA ISABEL FARIÑAS-SANCHEZ, RICARDO PAREDES V, BERTRAND BERCHE, Simulations of nematic-isotropic transition of liquid crystals in two dimensions are performed using an O(2) vector model characterized by nonlinear nearest neighbor spin interaction governed by the fourth Legendre polynomial $P_4$. The system is studied through standard finite-size scaling and conformal rescaling of density profiles of correlation functions. A topological transition between a paramagnetic phase at high temperature and a critical phase at low temperature is observed. The low temperature limit is discussed in the spin wave approximation and confirms the numerical results.

**SESSION V46: DEFECTS AND IMPURITIES IN SI/GE**

**V46 1 Pathway connecting the four-interstitial ground state and chain in silicon** YAOJUN DU, *Wake Forest University* THOMAS LENOSKY, *879 Meadowview Dr, Columbus OH 43224* STEFAN GOEDECKER, *University of Basel* RICHARD HENNIG, JOHN WILKINS, *The Ohio State University* Dimer searches, minima hopping and nudged elastic band (NEB) calculations try to identify the lowest pathway connecting the two important silicon four-interstitial structures: $I_4$-chain and ground state. First, 400 tight-binding dimer searches reveal several local minima. However, the minima have high DFT formation energies and no pathway connecting chain and ground state is found. Second, we fit a classical modified embedded atom method potential to a database of interstitial clusters. Minima hopping using this potential finds several structures with DFT energies between chain and ground state but no pathway connecting them. Finally, we construct a pathway between chain and ground state with small displacements. The NEB energy barrier with DFT from chain to ground state is 0.6 eV. This indicates that during annealings the $I_4$-chain decays into the nearly immobile ground state, implying that chain structures predominate only for longer chains.

**11:27**

**V46 2 Recombination rate annealing following transient neutron irradiation*** HAROLD HJALMARSON, PETER SCHULTZ, NORMAND MODINE, *Sandia National Laboratories* Neutron irradiation of bipolar transistors generates defects by displacing silicon atoms. For each displacement collision, a pair of defects is created, the interstitial atom and the vacancy left behind. These defects reduce transistor gain by increasing the recombination rate of electrons and holes thereby increasing the base current of these devices. After the radiation ceases, these defects undergo reactions that produce composite defects that are less effective at carrier recombination. In this presentation, we discuss simulations of the temporal evolution of these defects and the carrier recombination rate. We find that the initial carrier recombination rate is dominated by recombination at interstitials in p-type silicon and vacancies in n-type silicon. For p-type silicon, the short-time annealing is controlled by athermal diffusion of interstitials, and this diffusion rate, which is governed by carrier recombination at the interstitial, can be controlled by injection of minority carrier electrons. Our results will be compared with experimental data.

**11:39**

**V46 3 Theory of the Cyclotron Resonance in Si and Ge** SHIGEJI FUJITA, ROBERT SIMION, ROHIT SINGH, *University at Buffalo, SUNY* SEIICHI WATANABE, *Hokkaido University* A quantum theory is developed for the cyclotron resonance (CR) in silicon(Si) and germanium(Ge). The angular dependent CR peaks for heavy ''holes'' are analyzed, using the Dresselhaus-Kip- Kittel (DKK) formula: $\omega = (\omega_t^2 cos^2\theta + \omega_t\omega_l sin^2\theta)$, $\omega_t \equiv eB/m_t$, $\omega_l \equiv eB/m_l$.Their Fermi surfaces for Si(Ge) are spheroids oriented along $\langle 100 \rangle$ axes with the transverse mass $m_t = 0.46(0.29)m$ and the longitudinal mass $m_l = 1.03(0.78)m$.The fluted energy surfaces represented by the quartic dispersion relations used by DKK were avoided.The CR should be observed only, when a substantial number of conduction electrons with a quadratic dispersion relation resonate at a single frequency.

**11:51**

**V46 4 Stability of strained monohydride H:Si(105) and H:Ge(105) surfaces** CRISTIAN V. CIOBANU, *Colorado School of Mines* RYAN M. BRIGGS, *Colorado School of Mines* We report atomic scale studies of the effect of applied strain and hydrogen environment on the reconstructions of the (105) Si and Ge surfaces. Surface energy calculations for monohydride-terminated (001) and (105) reconstructions reveal that the recently established single-height rebonded model is unstable not only with respect to (001), but also in comparison to other monohydride (105) structures. This finding persists for both Si and Ge, for applied biaxial strains from -4% to 4%, and for nearly the entire relevant domain of the chemical potential of hydrogen, thus providing a thermodynamics perspective on the recently observed H-induced destabilization of the Ge(105) surface.

**12:03**

**V46 5 Using Si(100) - 2 x 1:H as a Platform for Patterned Silicon Growth** MATTHEW M. SZTELLE, *Department of Electrical and Computer Engineering and Beckman Institute for Advanced Science and Technology, University of Illinois, Urbana,*

*Illinois* SCOTT W. SCHMUCKER, *Department of Electrical and Computer Engineering and Beckman Institute for Advanced Science and Technology, University of Illinois, Urbana, Illinois* JOSEPH W. LYDING, *Department of Electrical and Computer Engineering and Beckman Institute for Advanced Science and Technology, University of Illinois, Urbana, Illinois* An ultra-high vacuum scanning tunneling microscope (UHV-STM) is used to create patterns at the atomic level by desorbing hydrogen atoms from the Si(100) – 2 x 1:H surface thereby creating a clean silicon template for selective area chemical vapor deposition (CVD). Disilane ($Si_2H_6$) gas, when introduced, repassivates the clean silicon pattern with an inert mix of hydride and silicon-hydride species. Subsequent layers can be grown through repeated patterning allowing controlled silicon growth at the nanometer scale. Amorphous silicon growth has been demonstrated at room temperature with nanometer scale control over feature sizes. Results will also be presented on our attempts to grow single crystal silicon features by performing these experiments at elevated temperatures to promote silicon surface diffusion.

**12:15**

**V46 6 Hole mobility in SiGe alloys from first principles.** SIAN JOYCE, FELIPE MURPHY-ARMANDO, *Tyndall National Institute, Lee Maltings, Prospect Row, Cork, Ireland* STEPHEN FAHY, *Tyndall National Institute and Dept. of Physics University College Cork, Ireland* First principles density functional theory is used to calculate the mobility of holes in $Si_{1-x}Ge_x$ alloys as a function of alloy composition. The alloy host is modelled within the virtual crystal approximation (VCA) using supercell techniques. The scattering matrix for carrier scattering in the presence of a Ge or Si substitutional atom in the VCA lattice is determined from the resultant energy splitting in the valence bands. The effect of the spin-orbit interaction is included in these calculations. The mobility is obtained from the scattering rate using the Boltzmann transport equation in the relaxation time approximation.

**12:27**

**V46 7 First-principles calculation of phonon scattering of n-type carriers in SiGe alloys** FELIPE MURPHY ARMANDO, STEPHEN FAHY, *Tyndall National Institute, University College Cork* We calculate the scattering matrix due to phonons in a $Si_{1-x}Ge_x$ random substitutional alloy using first principles density functional theory. The electron-phonon matrix elements are obtained from linear response theory in supercells containing up to 128 atoms. We calculate the n-type carrier mobility from the scattering rates of phonon and alloy scattering using the Boltzmann transport equation. Results are compared to experiments.

**12:39**

**V46 8 MEIS study of As and Sb implantation in Si(001) with excess vacancy concentration and SIMOX.** MATEUS DALPONTE, HENRI BOUDINOV, *UFRGS, Brazil* LYUDMILA GONCHAROVA, ERIC GARFUNKEL, TORGNY GUSTAFSSON, *Rutgers University, USA* We have studied the behavior of dopants (As and Sb) in Separation-by-IMplanted-OXygen (SIMOX) and in vacancy-rich layers in bulk Si(100). The vacancy layers were created by 240 keV $O_2^+$ or $N_2^+$ ion implantation at 400°C with a dose of $2.5x10^{16}$ $cm^{-2}$. Each of the O or N pre-implanted samples was then implanted at 20 keV at room temperature with only one of the dopants to a dose of $5x10^{14}cm^{-2}$. The samples were then annealed either using Rapid Thermal Annealing (RTA) or Furnace Annealing (FA) and characterized using Medium Energy Ion Scattering (MEIS) in both channeling and random directions. Bulk Si samples without O or N pre-implantation were also prepared for reference. The results showed marked differences in dopant diffusion between all of the samples, for instance, faster diffusion of As in the N pre-implanted compared to the O pre-implanted ones. Also, diffusion is faster for Sb in SIMOX than in Si without N or O pre-implantation. Another observed effect was that both dopants presented stronger Transient Enhanced Diffusion (TED) in the N pre-implanted samples. These differences might be associated with the structure of the vacancies (large clusters in SIMOX and point defects in the O or N pre-implanted samples) as well as with chemical effects of O or N in the pre-implanted samples.

**12:51**

**V46 9 DFT calculations of formation energy and properties of Frenkel pairs in Si** MATTHEW J. BECK, S. T. PANTELIDES, *Department of Physics and Astronomy, Vanderbilt University, Nashville, TN* The formation of vacancy-interstitial pairs (Frenkel pairs) underlies many materials processes, including the production of defects by irradiation or ion implantation. Here we present the results of density functional calculations of the formation and properties of Frenkel pairs in Silicon for various pair configurations. The detailed relaxations and overall stability of these pairs against recombination, even at large separations, are strongly dependent on the transfer of charge among the vacancy and interstitial states in the Si band gap, and are highly sensitive to the interstitial configuration. The results are discussed with respect to their implications for models of radiation-induced defect damage and related processes. This work was supported in part by AFOSR grant FA9550-05-1-0306.

**13:03**

**V46 10 Effect of Hydrogen on the Migration Processes of Dislocations in Silicon** NORIHISA OYAMA, TAKAHISA OHNO, *NIMS* It was reported that the dislocation glide mobility in Si is enhanced by irradiation with H plasma. In this work, we perform the first-principles total-energy calculations, and investigate the effect of H on the migration processes of dislocations in Si. We found that the most stable site in the dislocation core is not located at the bond center (BC) site but at the back-bond (BB) site. By interacting with a H atom, the formation energy of a kink becomes negative, and the dislocation is spontaneously bent. As a result, the activation energy of dislocation motion decreases by 1.1eV. The migration processes of the kinks are discussed in the presentation. This study was supported by RSS21 project and Grant-in-Aid for Scientific Research (No.17064017) of MEXT of the Japanese government. The calculations in this work were carried out partly using the Numerical Materials Simulator in National Institute for Materials Science (NIMS), and partly using the NEC-SX5 at Cybermedia Center, Osaka University.

**13:15**

**V46 11 Self-trapping-enhanced carrier recombination at light-induced boron-oxygen complexes in silicon** SHENGBAI ZHANG, MAO-HUA DU, HOWARD BRANZ, RICHARD CRANDALL, *National Renewable Energy Laboratory* First-principles study of the $BO_2$ complex in B-doped Czochralski silicon reveals a self-trapping-enhanced carrier recombination mechanism that contrasts with the standard fixed-level Shockley-Read-Hall model for recombination. An $O_2$ dimer distant from the boron causes only a slow carrier recombination, which is, nevertheless, enough to drive the $O_2$ diffusion under light to form the $BO_2$ complex. We find that the $BO_2$ and $O_2$ produce nearly identical

defect levels in the bandgap. Despite that, recombination at the $BO_2$ is substantially faster than that at the $O_2$, because the charge state of the latter inhibits a key step in the recombination, namely, the capture of the hole. This work was supported by the U. S. Department of Energy, BES and EERE, under Contract No. DE-AC39-98-GO10337.

**13:27**

**V46 12 Energy gain by defect formation: a new tight binding annealed model for a-Si** JOSEPH FELDMAN, *Naval Research Laboratory and George Mason University* NOAM BERNSTEIN, *Naval Research Laboratory* MARCO FORNARI, *Central Michigan University* DIMITRIS PAPACONSTANTOPOULOS, *Naval Research Laboratory and George Mason University* We have obtained a new structure of a-Si by annealing with QM forces a Wooten CRN type 216 model. The annealing was done for 1.2 ns (1.2 million time steps) and the NRL tight binding method was employed. We obtain the total energy, electronic density of states, and force constants of the model. Whereas the starting model had no coordination defects several were present in the final model. As expected these defects were found to give rise to states in the gap as determined both by charge self-consistent TB calculations and DFT (pseudopotential) calculations, where the latter were performed on related ''relaxed'' models within DFT. The final model was of lower total energy than the starting model, both within the TB method and within the psedopotential method. The normal mode properties based on our force constant determination within TB will also be discussed.

**13:39**

**V46 13 Effect of e-h Pairs on the Stability of Bond-Center Hydrogen in Silicon** NAGESWARA RAO SUNKARANAM, *Department of Physics and Astronomy, Vanderbilt University* SRIRAM DIXIT, *Interdisciplinary Materials Science Program, Vanderbilt University* GUNTER LUPKE, *Department of Applied Science, College of William and Mary* NORMAN TOLK, *Department of Physics and Astronomy, Vanderbilt University* LEONARD FELDMAN, *Department of Physics and Astronomy & Interdisciplinary Materials Science Program, Vanderbilt University* Hydrogen injected into silicon at low temperature resides in the bond-centered site, $H^+$ [BC]. This is the most fundamental hydrogen related defect in many covalent semiconductors. Thermal annealing shows $H^+$ [BC] stability up to 150K, and correlates with Si vacancy migration. We report the first observation of the decay of $H^+$ [BC] due to e-h pairs induced by energetic ions. Thin single crystal silicon films containing $H^+$ [BC] ( $\sim 35\mu$m) were fabricated to permit subsequent transmission of energetic protons, creating high e-h pair concentrations and minimal displacement damage. In-situ infrared studies revealed a 90% reduction of $H^+$ [BC] sites after a 1.8 MeV proton dose of $50\mu C/cm^2$ at 80K. Recombination of e-h pairs at defect sites is known to cause vacancy diffusion providing another mechanism for loss of $H^+$ [BC]. Our results show the effect of e-h pairs on $H^+$ [BC] stability. We interpret this in terms of the e-h pair/vacancy interaction.

**SESSION V47: SPECTROSCOPY AND TRANSPORT IN 2D SEMICONDUCTORS**

**V47 1 Magnetotunneling Spectroscopy in InGaAs Double-well Structures** Y. LIN, *National Tsing Hua University, Taiwan* A.K.M. NEWAZ, E.E. MENDEZ, *SUNY at Stony Brook* J. NITTA, *Tohoku University, Japan* We have used magnetotunneling spectroscopy to elucidate the mechanism of electron tunneling in double-well (DW) heterostructures whose current-voltage ($I - V$) characteristics are quite different from the $\delta$-function-like shapes expected from energy- and momentum-conservation laws. Our DW tunneling structure consisted of two $In_{0.53}Ga_{0.47}As$ wells 53 Å and 82 Å wide, confined by $In_{0.52}Al_{0.48}As$ barriers with thickness of 100 Å, 53 Å and 100 Å. Without magnetic field, at $T = 4.2$K the $I - V$ characteristics had several distinct regions, each one quasi- triangular in shape and corresponding to the alignment of states in adjacent wells. Under a field ($H \leq 14$T) parallel to the current, each region revealed strong features that shifted to higher voltages with increasing field and are related to Landau levels from states in individual wells. The field dependence of those features yielded, in addition to the band parameters, the zero-field energies of the states at representative voltages of the $I - V$ characteristics. In the physical picture that emerges from the analysis, electrons tunnel via the two wells as long as in each of them there are states below the emitter's Fermi energy, without any consideration to in-plane momentum (or Landau-level index) conservation. This conclusion is supported by remarkably similar results we have also obtained in GaAs-GaAlAs double- well structures.

**V47 2 Shot Noise in Coherently Coupled GaAs-AlGaAs Double-Well Resonant-Tunneling Diodes** A.K.M. NEWAZ, W. SONG, B. NIELSEN, E.E. MENDEZ, *SUNY at Stony Brook* R. HEY, H. KOSTIAL, H.T. GRAHN, *Paul Drude Institute, Berlin* We have found experimentally that, regarding shot-noise, there is no difference between coherent and sequential resonant tunneling, in contrast with calculations that predict that the suppression of noise in a coherent-tunneling process should be larger. Our measurements were done at 4.2 K in GaAs-AlGaAs Double-Well Resonant-Tunneling Diodes (DWRTD) grown by molecular beam epitaxy on $n^+$GaAs substrates. Each AlGaAs barrier at the two ends of each structure was 100 Å, while the central barriers were 60 Å (uncoupled DWRTD), 20 Å and 15 Å (coupled DWRTDs) thick, depending on the sample. In all cases, the two quantum wells between the barriers were 53 Å and 80 Å wide, each well having two confined quantum states. The current-voltage characteristics of the diodes exhibited current peaks associated with voltage-induced alignment of states in adjacent wells. In the coupled DWRTDs each peak split into two, as a result of symmetric and anti- symmetric wavefunctions being extended to both wells. Noise measurements revealed a shot noise power spectrum up to about 50% smaller than that of Poissonian noise $2eI$, regardless of whether the wells were coupled or uncoupled. Our results support those calculations in multiple-barrier structures that predict that the shot-noise reduction should be independent of whether the electronic transport is sequential or coherent.

**V47 3 Observation of a periodic structure in quantum rings using Scanning Gate Microscopy** F. MARTINS, B. HACKENS, T. OUISSE, J.F. MOTTE, M. STARK, H. SELLIER, J. CHEVRIER, S. HUANT, *CNRS, UJF, Grenoble, France* V. BAYOT, *CERMIN, UCL Belgium* S. BOLLAERT, X. WALLART, A. CAPPY, *IEMN, France* Recent advances in scanning gate microscopies (SGM) have made it possible to image electron flow in nanostructures, using the tip as a moving gate (M.A. Topinka et al., Science 289, 2323 (2000)). Our experiment focuses on quantum rings (QR), patterned from a two-dimensional electron gas (2DEG) buried close to the sample surface (25 nm). We can therefore reach a very small tip-sample distance, thereby improving the imaging resolution. Furthermore, the absence of metallic gates on the top of our sample allows to probe the electron flow directly inside the QR. The SGM images, obtained at 4.2 K, reveal striking periodic oscillations of the resistance along the QR circumference as the tip scans over the sample surface. These oscillations respect the radial symmetry of the QR, and their periodicity is much larger than the Fermi wavelength. We analyze the influence of the tip-induced perturbation on the 2DEG by changing the tip voltage (both in accumulation and depletion regimes) and the tip-sample distance.

**V47 4 Scanning gate microscopy on Aharonov-Bohm rings in a magnetic field: experiments and simulations** B. HACKENS, F. MARTINS, T. OUISSE, J.F. MOTTE, M. STARK, H. SELLIER, J. CHEVRIER, S. HUANT, *CNRS, UJF, Grenoble, France* V. BAYOT, *CERMIN, UCL Belgium* S. BOLLAERT, X. WALLART, A. CAPPY, *IEMN, France* We use low temperature scanning gate microscopy to study the electron dynamics inside Aharonov-Bohm (AB) rings in the phase-coherent regime. Our samples are prepared by etching from high-mobility two-dimensional electron systems 25 nm below the surface (B. Hackens et al., Phys. Rev. Lett. 94, 146802 (2005)). The bias applied on the AFM tip, as it is scanned over the AB ring, induces a local perturbation of the electric potential experienced by the electrons, thereby affecting the ring resistance. In particular, we observe in detail the effect of small variations of the perpendicular magnetic field in different regimes (up to B=6 T). As we plot these resistance variations as a function of the AFM tip position, we observe resistance modulations which have the spatial symmetry of the ring, and an amplitude equal to that of the AB oscillations. This strongly suggests that our resistance maps are closely linked to the periodic modulations of the electron probability density. Finally, we also performed simulations of the electron wavefunctions in AB rings, as well as of the electron transmission through the AB rings. Including the effect of the perturbating potential of the tip in such simulations, we get valuable informations which help to explain our experimental results.

**V47 5 Optical Imaging for the Determination of Minority Carrier Transport*** DAVID LUBER, *Naval Postgraduate School* FRANK BRADLEY, NANCY HAEGEL, A scanning electron microscope technique is used, in combination with an optical imaging system, to measure minority carrier diffusion length in a heavily doped GaAs double heterostructure. Both diffusion and drift of charge are imaged. A diffusion length of $\sim$ 3.2 - 4 $\mu$m is measured, corresponding to a minority carrier mobility of 950-1480 $cm^2/Vs$ in p-type material, doped $\sim$ 5 x $10^{18}$ $cm^{-3}$, in good agreement with theoretical predictions. Drift and diffusion behavior are also studied in more heavily doped regimes where plasmon scattering is expected to play a significant role. Measurements will be presented as a function of doping level, local electric field and sample temperature. We explore the limitations on determination of the diffusion length due to effects such as the finite nature of the excitation volume and photon recycling near the point of generation and compare approaches for extracting key material parameters. The technique offers a flexible approach to direct measurement of various transport properties and is applicable to a range of luminescent materials and multilayer devices. Examples from high resolution mapping of non-uniform electric field distributions will also be presented.

**V47 6 Transverse magnetic focusing and spin-dependent reflection experiments in InSb- and InAs-based heterostructures** HONG CHEN, J.J. HEREMANS, *Department of Physics, Virginia Tech* J.A. PETERS, J.T. BEARDSLEY, *Department of Physics and Astronomy, Ohio University* N. GOEL, S.J. CHUNG, M.B. SANTOS, *Department of Physics and Astronomy, University of Oklahoma* W. VAN ROY, G. BORGHS, *IMEC, Leuven, Belgium* We report on mesoscopic spin-dependent ballistic transport in InSb/InAlSb and InAs/AlGaSb heterostructures, characterized by strong spin-orbit interaction. Spin-orbit interaction in two-dimensional electron systems can lead to spin-splitting in semiclassical ballistic trajectories and in spin-dependent reflection of carriers. We experimentally demonstrate the spin reflection in open and closed ballistic geometries optimizing scattering off a lithographic barrier. Further, experimentally obtained transverse magnetic focusing spectra can be interpreted as demonstrating both spin-split ballistic transport and spin-dependent reflection for higher order peaks involving carrier reflection off the barrier. NSF DMR-0094055 (JJH), DMR-0080054, DMR-0209371 (MBS).

**V47 7 Effect of dc and ac excitations on the longitudinal resistance of a two-dimensional electron gas in highly doped GaAs quantum wells*** JINGQIAO ZHANG, ALEXEY BYKOV, SERGEY VITKALOV, *The City College of New York* A. K. KALAGIN, A. K. BAKAROV, *Institute of Semiconductor Physics, 630090 Novosibirsk, Russia* Linear AC (888 Hz) resistance of highly mobile two dimensional electrons in GaAs heavily doped quantum wells is studied at different magnitude of dc and ac (10 KHz to 20 GHz) excitations. In the DC excitation regime the differential resistance oscillates with the dc current and external magnetic field similar to that observed earlier in AlGaAs/GaAs heterostructures. At external ac excitations the resistance is also found to be oscillating with the magnetic field. However the form of the oscillations is considerably different from the dc case. We show that at frequency below 100 KHz the difference is result of a specific average of the dc differential resistance during the period of the external ac excitations.

**V47 8 Thermodynamic and transport properties of two-dimensional GaAs systems near the apparent metal-insulator**

**transition** E.A. GALAKTIONOV, G.D. ALLISON, A.K. SAVCHENKO, S.S. SAFONOV, *University of Exeter, UK* M.M. FOGLER, *UCSD* M.Y. SIMMONS, D.A. RITCHIE, *Cavendish Lab, Cambridge, UK* An extensive study of the charge compressibility and resistance of two-dimensional electron and hole systems is reported. A total of five GaAs samples were examined, two 2DEGs and three 2DHGs. All samples have high mobilities but vary in spacer, doping, and other growth parameters. The inverse compressibility is found to have a negative minimum at a sample-dependent carrier concentration followed by an upturn to large positive values as the concentration decreases. This behavior is shown to agree quantitatively with the theory of nonlinear screening of the random impurity potential, for both types of carriers, despite a ten-fold difference in their $r_s$ parameters. The region of the apparent metal-insulator transition (MIT) where $\partial R/\partial T$ changes sign, and the position of the inverse compressibility minimum can differ by as much as 50%. Their relative positions vary with sample and cooldown. No thermodynamic anomalies at the apparent MIT are detected. In a range of $T$ where both the capacitance and the resistance of 2DHG samples were studied, the latter exhibits a scaling characteristic of the percolation transition. The corresponding percolation threshold is different from the MIT but agrees quantitatively with the percolation point deduced from the analysis of the compressibility.

**V47 9 Evidence for coherent transport in GaAs hole open quantum dots.** S. FANIEL, B. HACKENS, A. VLAD, C. GUSTIN, L. MOLDOVAN, S. MELINTE, V. BAYOT, *Cermin, Universite Catholique de Louvain, Louvain-la-Neuve, Belgium* M. SHAYEGAN, *Department of Electrical Engineering, Princeton University, Princeton, New Jersey 08544* We report magnetotransport measurements in GaAs hole open quantum dots. Our samples were fabricated from a *p*-type GaAs quantum well with a density of $2.2 \times 10^{15} m^{-2}$ and a mobility of $35 m^2$/Vs. Two different dots were patterned using e-beam lithography and wet etching. A top gate was added in order to control the dots openings and the hole density. The measurements were performed down to 30 mK with the magnetic field applied perpendicular to the plane of the two- dimensional system. We observed large, reproducible conductance fluctuations associated with the coherent transport of holes inside the dots at lowest temperatures which vanish above 500 mK. From the variance of these fluctuations and from the Random Matrix Theory, we extracted the hole dephasing time $\tau_\varphi$. The temperature dependence of the calculated $\tau_\varphi$ lies between a $T^{-1}$ and $T^{-2}$ behavior and exhibits a saturation at very low temperature which is similar with $\tau_\varphi$ measured in 2D electron systems[1].

**V47 11 Anisotropic thermopower and planar Nernst effect in Ga1-xMnxAs*** YONG PU, JING SHI, *Dept. of Physics, UC-Riverside* We have carried out the thermopower and magneto-thermopower measurements on three Ga1-xMnxAs (x=0.039, 0.049, and 0.059) samples above and below their Curie temperatures. Below the Curie temperature, we have observed magnetic field dependence in both parallel (longitudinal) and perpendicular (transverse) directions to the temperature gradient. The magnetic field dependence does not depend on the relative orientation between the temperature gradient and crystallographic direction of the GaAs. The transverse thermopower or the planar Nernst effect, shows abrupt jumps as the magnetization switches between the four-fold symmetry axes, which resembles the giant planar Hall effect found in similar materials. Although the longitudinal thermopower is not sensitive to the same switchings of the magnetization, it has a strong magnetic field dependence as the magnetization rotates. We have measured both effects vs. the magnetic field orientation with respect to the temperature gradient. Similar to the origin of the giant planar Hall effect, we attribute the longitudinal and transverse effects to the anistropic magneto-thermopower. We interpret the both effects in the context of the anisotropic transport.

**V47 12 Long-Lived Coherent Cyclotron Oscillations in a 2D Electron Gas** X. WANG, R. SRIVASTAVA, A. BARKAN, D. M. MITTLEMAN, J. KONO, *Department of Electrical and Computer Engineering, Rice University* J. L. RENO, *Sandia National Laboratories* DEPARTMENT OF ELECTRICAL AND COMPUTER ENGINEERING, RICE UNIVERSITY TEAM, SANDIA NATIONAL LABORATORIES COLLABORATION, We have used the technique of time-domain THz spectroscopy to study coherent charge dynamics in a high-mobility two-dimensional electron gas (2DEG) in quantizing magnetic fields. By analyzing the magnetic field dependence of the transmitted THz waveform, we successfully extracted the real and imaginary parts of the dynamic conductivity at various magnetic fields and temperatures for a GaAs/AlGaAs 2DEG with a 1.5 K mobility of $3.7 \times 10^6$ cm$^2$/Vs. We observed pronounced coherent cyclotron oscillations persisting more than 50 picoseconds and 20 periods. From the frequency and decay time of these oscillations, we can directly determine the cyclotron mass and phase coherence time. The basic phenomenon observed can be understood as the free induction decay of a coherent superposition between the lowest unfilled Landau level and the highest filled Landau level induced by the incident coherent THz pulse. Finally, we discuss the possibility of using this technique to overcome the saturation effect, which is

known to prevent the determination of true cyclotron resonance linewidths in high-mobility ( $> 10^5$ $cm^2/Vs$) 2DEG measured with conventional far-infrared techniques using CW and incoherent sources.

**13:39**
**V47 13 Modulation of two-dimensional electrons in Si/SiGe heterostructures using atomic-layer-deposited gate dielectric** T. M. LU, K. LAI, *Princeton University* P. D. YE, *Purdue Univeristy* W. PAN, *Sandia National Lab* D. C. TSUI, S. LYON, *Princeton University* M. MUHLBERGER, F. SCHAFFLER, *Univ. Linz* Field effect transistors (FETs) have been fabricated using Atomic-Layer-Deposited (ALD) $Al_2O_3$ as gate dielectric on the Si/SiGe heterostructures to modulate the density of the two-dimensional (2D) electrons in the strained silicon channel [1]. Magnetotransport measurements taken at 0.3K show that the 2D density (n) can be uniformly tuned by the gate voltage (VG) with virtually no leakage current and negligible gate hysteresis. The characteristic of modulation using ALD $Al_2O_3$ as gate dielectric is shown to be better than that using Pd Schottky barrier or the PECVD $SiO_2$ dielectric. We also performed a numerical simulation that solves the one-dimensional Poisson-Schrodinger equations self-consistently for different $V_G$s. The measured n vs. $V_G$ relation can be reproduced in our calculation by assuming a density of $0.6\times 10^{13} eV^{-1}cm^{-2}$ of the surface states. [1] K. Lai et al., Appl. Phys. Lett. 87, 142103 (2005)

**V47 14 Hysteresis and saturation of intersubband absorption by electrons on helium** DMITRI RYVKINE, *Michigan State University* MICHAEL LEA, *Royal Holloway, University of London, Egham, Surrey TW20 0EX, UK* MARK DYKMAN, *Michigan State University* We propose a mechanism, develop a theory, and provide experimental data that demonstrate hysteresis of resonant inter-subband absorption by a quasi two-dimensional electron system on the surface of helium. The electrons form a strongly correlated nondegenerate electron liquid. The absorption occurs at the frequency of the transition from the ground to the first excited state of motion normal to the helium surface. The lifetime of the excited state is extremely long, 0.1 $\mu$s at 0.3 K, leading to strong absorption nonlinearity even for low radiation intensity [1]. Besides absorption saturation, radiation-induced occupation of the excited subband causes a shift of the resonant transition frequency. We show that this shift leads to absorption hysteresis with varying radiation frequency or intensity. As a result of electron correlations, the in-plane motion in all subbands is described by the same electron temperature, which is found self-consistently. The results bear on quantum computing with electrons on helium, since they demonstrate resonant transitions responsible for a single-qubit operation; the hysteresis results from the same mechanism that leads to two-qubit operations. 1. E. Collin et al., Phys. Rev. Lett. 89, 245301 (2002)

## SESSION W1: ARPES IN HIGH TC SUPERCONDUCTORS

**W1 1 Laser ARPES, the sudden approximation, and quasiparticle-like peaks in $Bi_2Sr_2CaCu_2O_{8+d}$.**
DAN DESSAU, *University of Colorado, Boulder*

A new low photon energy regime of angle resolved photoemission spectroscopy is accessed with lasers and used to study the superconductor $Bi_2Sr_2CaCu_2O_{8+d}$. The low energy increases bulk-sensitivity, reduces background, and improves resolution. Crucial aspects of the data such as the dispersion, superconducting gaps, and the bosonic coupling kink are found to be robust to a possible breakdown of the sudden approximation. We observe spectral peaks which are sharp on the scale of their binding energy - the clearest evidence yet for quasiparticles in the normal state. The very sharp spectral peaks and high statistics enables detailed investigations of the temperature and energy dependences of the lineshapes, giving critical insights into the nature of the scattering mechanisms in these materials. We thank collaborations with J. D. Koralek, J.F. Douglas, N.C. Plumb, Z. Sun, A.V. Fedorov, M. Murnane, H. Kapteyn, S. Cundiff, Y. Aiura, K. Oka, and H. Eisaki.

**15:06**
**W1 2 What is the ''glue'' for high temperature superconductivity?**
TONICA VALLA, *Brookhaven National Laboratory*

It has been 20 years since the high-temperature superconductivity (HTSC) was discovered in $La_{2-x}Ba_xCuO_4$, by Bednorz and Müller. Since then, many different HTSC compounds, all containing copper-oxide planes, were synthesized and HTSC became one of the most studied problems in science. However, the mechanism of HTSC still remains unknown. Recent advancements in Angle-Resolved Photoemission Spectroscopy (ARPES) have enabled a direct probing of effects of interactions between electrons and different bosonic excitations in a system, raising the expectations that a ''pairing boson'' responsible for HTSC could finally be identified. Here, we will present the study of single-particle excitations in two different cuprates: $Bi_2Sr_2CaCu_2O_{8+\delta}$, a high-temperature superconductor with $T_C = 91$ K and $La_{1.875}Ba_{0.125}CuO_4$, a system with suppressed superconductivity ($T_C \leqslant 2.5$ K) due to the spin/charge ordering. The extracted self-energies and single-particle gaps will be compared and possible coupling mechanisms will be discussed. This work was supported by the DOE under contract number DE- AC02-98CH10886.

**15:42**
**W1 3 Dispersion Anomalies and High Frequency Optical Conductivity in Cuprate Superconductors.***
ANDREY CHUBUKOV, *University of Wisconsin*

We argue that the shape of the dispersion along the nodal and antinodal directions in the cuprates can be understood as a consequence of the interaction of the electrons with collective spin excitations. In the normal state, the dispersion displays a crossover at an energy where the decay into spin fluctuations becomes relevant. In the superconducting state, the antinodal dispersion is strongly affected by the $(\pi,\pi)$ spin resonance and displays an S-shape whose magnitude scales with the resonance intensity. For nodal fermions, relevant spin excitations do not have resonance behavior, rather they are better characterized as a gapped continuum. As a consequence, the S-shape becomes a kink, and superconductivity does not affect the dispersion as strongly. We also analyzed recent infrared conductivity data in the normal state. We find that the high frequency behavior, which has been suggested as evidence for quantum critical scaling, is well described by the same interaction with overdamped collective modes. From explicit calculations, we find a frequency exponent for the modulus of the conductivity, and a phase angle, in good agreement with experiment.

*In collaboration with M. Norman (Argonne Natl Lab).

**16:18**
**W1 4 ARPES Investigation of Quasiparticle Renormalization in Cuprates.**
TANJA CUK, *Stanford University*

We investigated by Angle-Resolved-Photoemission-Spectroscopy the renormalization of the bands in Bi2212 as a function of doping, including underdoped ($T_c$ =85K), optimally doped ($T_c$ = 94K), andoverdoped($T_c$ = 65K) samples. We identified the sharp energy scale seen in the superconducting state with the $B_{1g}$ bond buckling mode, the out-of-phase vibrations of the in-plane oxygen. More recently, we compare doping dependent data to a theoretical calculation involving the identified modes, including both temperature and momentum dependence. This comparison brings insights to the doping induced spectral changes in the overdoped regime, in connection to some recent discussions. We will also present complimentary pressure dependent Raman scattering and X-Ray diffraction data showing how the $B_{1g}$ mode renormalizes with metallization of the insulating parent compound of Bi2212. The pressure variable allows a continuous assessment of the electron−phonon coupling lambda, based on both phonon frequency and lineshape, across the phase diagram. Finally, we discuss ways to test whether these mode couplings have a direct bearing on superconductivity.

**16:54**
**W1 5 ARPES Study of Nodal Quasiparticles Using Low-Energy Tunable Photons.**
AKIHIRO INO, *Graduate School of Science, Hiroshima University*

Low-energy quasiparticle excitations govern the thermodynamic properties of a superconductor both in the zero-field and vortex-mixed states. For a *d*-wave superconductor, nodal quasiparticles are crucial excitations starting from zero energy. So far, however, the nodal quasiparticle dynamics of high-Tc cuprates has been controversial. For example, it has been reported by an angle-resolved-photoemission (ARPES) experiment that the marginal-Fermi-liquid behavior persists into the superconducting state without appreciable change in the scattering rate, while microwave conductivity increases upon the superconducting transition. Here, we show a new ARPES result that solves the controversies with unprecedented momentum-resolution. Low-energy tunable photons have enabled us to resolve a small nodal bilayer splitting clearly, and to reveal the detailed temperature- and energy-dependence of the scattering rate, indicating the behaviors unique to the nodal quasiparticles. Due to the opening of the *d*-wave gap, the nodal scattering rate is remarkably suppressed, and shows a linear energy dependence. The difference in the energy-linear term between the bilayer-resolved scattering rates hints the nature of impurities involved. This work was done in collaboration with T. Yamasaki, T. Kamo, K. Yamazaki, H. Anzai, M. Arita, H. Namatame, M. Taniguchi, Grad. Sch. of Science and Hiroshima Synchrotron Radiation Center, Hiroshima Univ., A. Fujimori, Dept. of Complexity Science and Engineering, Univ. of Tokyo, Z.-X. Shen, Dept. of Physics, Applied Physics and SSRL, Stanford Univ., M. Ishikado, K. Fujita, and S. Uchida, Dept. of Physics, Univ. of Tokyo.

## SESSION W2: IMAGING CHARGE AND SPIN AND SEMICONDUCTORS
**Thursday Afternoon, 16 March 2006; Ballroom III, Baltimore Convention Center at 14:30**
**Robert Westervelt, Harvard University, presiding**

**14:30**
**W2 1 Imaging Transport Resonances in the Quantum Hall Effect.**
GARY STEELE, *MIT*

We image charge transport in the quantum Hall effect using a charge accumulation microscope. Scanning a charge sensitive tip just above the surface of a very high mobility AlGaAs/GaAs heterostructure, we measure the charging underneath the tip that results from applying an ac voltage to the 2D electron system (2DES). Applying a dc bias voltage

to the tip induces a highly resistive ring-shaped incompressible strip (IS) in the 2D electron system (2DES) that moves along with the tip. This IS acts as a barrier that prevents charging of the region under the tip. At certain tip positions, short-range disorder in the 2DES creates a quantum dot island inside the IS that enables breaching of the IS barrier by means of resonant tunneling through the island. The images that result show striking ring shapes that directly reflect the shape of the IS. Within the ring shaped features, we also observe striations that arise from Coulomb Blockade of the quantum dot island. Varying the magnetic field, the tunneling resistance of the IS varies significantly, and takes on drastically different values at different filling factors. Measuring this tunneling resistance provides a unique *microscopic* probe of energy gaps in the quantum Hall system. To better understand the origin of the transport resonances, we have completed a series of simulations that show that the native disorder from remote ionized donors can create islands in the IS. Comparing the simulations with the experimental images provides a direct view of the disorder potential of a very high mobility 2DES. The experiments and simulations reveal the potential importance of single-electron resonant tunneling to bulk transport in the quantum Hall effect.

**15:06**
**W2 2 Terahertz Imaging of cyclotron emission from quantum Hall conductors.**
SUSUMU KOMIYAMA, *Department of Basic Science, University of Tokyo*

Microscopy of extremely weak terahertz (THz) waves via photon-counting method is reported. A quantum-dot photon detector [1] is incorporated into a scanning terahertz microscope [2]. By using a quantum Hall detector [3] as well, measurements cover the intensity dynamic range more than five orders of magnitude. The minimum intensity reaches as lo as 10-21watt (one photon per one second). Applying the measurement system to the study of semiconductor quantum Hall (QH) devices, we image cyclotron radiation emitted by non-equilibrium electrons generated in QH electron systems. Owing to the unprecedented sensitivity, a variety of new features of electron kinetics are unveiled [4]. It is stressed that the present approach is in marked contrast to the THz- wave applications recently discussed extensively in a wide variety of fields including clinic, security, and environment. In the vast majority of those applications, room-temperature operation is implicit. The intensity of treated THz radiation is hence well beyond the level of 300K blackbody radiation (roughly 10[l]m-7 watts or 10 [1] 4 photons/s per square centimeter in a 1/10 relative bandwidth). From the scientific viewpoint, however, detecting extremely weak THz waves from an object without external illumination such as applied in the present work is of strong importance, because the microscopic kinetics of an object can be probed only in such a passive method. Besides semiconductor electric devices studied here, we will also discuss possible applications of the present method for molecular dynamics, microthermography, and cell activities. [1] S. Komiyama et al., Nature 403, 405 (2000). [2] K. Ikushimaetal, Rev. Sci. Instrum. 74, 4209 (2003). [3] Y. Kawanoetal, J. Appl. Phys. 89, 4037 (2001). [4] K. Ikushimaetal, Phys. Rev. Lett. 93, 146804 (2004).

**15:42**
**W2 3 Imaging coherent electron flow in a two-dimensional electron gas.***
BRIAN LEROY, *Kavli Institute of Nanoscience, Delft University of Technology*

Images of electron flow through a two-dimensional electron gas can be obtained at liquid He temperatures using scanning probe microscopy. Near a quantum point contact (QPC), the images show angular lobe patterns characteristic of the wavefunctions in the QPC. At distances greater than one micron from the QPC, narrow branches of electron flow are observed due to the cumulative effect of small angle scattering. All of the images are decorated by interference fringes spaced by half the Fermi wavelength demonstrating that the flow is coherent. To determine the origin of the interference fringes, an imaging interferometer is created by adding a circular reflecting gate. The strength and position of the interference fringes can then be controlled by the voltage on this reflecting gate. Using the interferometer, we show that the interference fringes are due to backscattering to the QPC. Both experiments and theory demonstrate that the interference signal is robust against thermal averaging.

*In collaboration with A.C. Bleszynski, K.E. Aidala, M.A. Topinka, R.M. Westervelt, A. Kalben, S.E.J. Shaw and E.J. Heller, Harvard University; K.D. Maranowski and A.C. Gossard University of California Santa Barbara.

**16:18**
**W2 4 Imaging Magnetic Focusing in a Two-Dimensional Electron Gas.***
KATHERINE AIDALA, *Harvard University*

Using a liquid-He cooled scanning probe microscope (SPM), we have directly imaged cyclotron orbits of electrons in a two-dimensional electron gas (2DEG) traveling between two side-by-side quantum point contacts (QPCs). The images show magnetic focusing when the spacing between the QPCs is an integer multiple of twice the cyclotron radius. An image is created by deflecting electrons away from their original trajectories using a capacitively coupled SPM tip, and recording the change in conductance as the tip is raster scanned above the surface. The cyclotron orbits are clearly visualized, as well as fringes that demonstrate the coherent nature of the flow. Classical and quantum simulations show

how electrons are deflected by the tip to produce the image. With an applied magnetic field, the simulated images of magnetic focusing agree very well with the measured images. The simulations also show the effect of small angle scattering due to the ionized donor atoms. Fully quantum simulations show that interference fringes can be produced. Imaging and understanding the motion of electrons in magnetic fields is useful for the development of devices for spintronics and quantum information processing.

*In collaboration with Robert E. Parrott, T. Kramer, M. Stopa, E.J. Heller, R.M. Westervelt, M.P. Hanson and A.C. Gossard. Supported in part by ARO grant W911NF-04-1-0343.

**W2 5 STM and AFM: Which is Better for Surface Structural Analysis? Non-contact AFM Studies on Ge/Si(105) Surface.**
YUKIO HASEGAWA, *Institute for Solid State Physics, The University of Tokyo*

Scanning tunneling microscopy (STM) has been utilized to determine surface atomic structure with its highly resolved images. Probing surface electronic states near the Fermi energy ($E_F$), STM images, however, do not necessarily represent the atomic structure of surfaces. It has been believed that atomic force microscopy (AFM) provides us surface topographic images without being disturbed by the electronic states. In order to prove the surpassing performance, we performed noncontact (nc) AFM on the Ge/Si(105) surface [1], which is a facet plane of the ''hut'' clusters formed on Ge-deposited Si(001) surface. It is found that STM images taken on the surface, either filled- or empty-state images, do not show all surface atoms because of the electronic effect; some surface atoms have dangling bond states below $E_F$ and other surface atoms have states above $E_F$ . [2]. In a nc-AFM image, on the other hand, all surface atoms having a dangling bond are observed [3], directly representing an atomic structure of the surface. Electronic information can also be obtained in AFM by using a Kelvin-probe method. From atomically resolved potential profile we obtained, charge transfer among the dangling bond states is directly demonstrated. These results clearly demonstrate that highly-resolved nc-AFM with a Kelvin-probe method is an ideal tool for analysis of atomic structures and electronic properties of surfaces. ## SESSION W3: TOPOLOGICAL ASPECTS OF ELECTRON TRANSPORT IN SOLIDS
**Thursday Afternoon, 16 March 2006; Ballroom I, Baltimore Convention Center at 14:30**
**Shoucheng Zhang, Stanford University, presiding**

**14:30**
**W3 1 Berry Phase and Dissipationless Currents in Solids.**
NAOTO NAGAOSA, *The University of Tokyo*

It is now recognized that the electronic band structures in solids are characterized by nontrivial quantum topological nature associated with Berry phase. This situation is analogous to the quantum Hall system under the strong magnetic field, but occurs in almost every material even without the magnetic field. Anomalous Hall effect in ferromagnets is a representative example, where the anomalous velocity induced by Berry phase leads to the transverse motion of the electrons to the applied electric field. In paramagnetic materials, on the other hand, the Kramers degeneracy makes the Berry connection non-Abelian. The spin dependent anomalous velocity leads to the spin Hall effect in semiconductors such as GaAs. These charge and spin currents are distinct from the usual transport current since it is not due to the deviation from the equilibrium electron distribution in momentum space, but is driven by the anomalous velocity of all the occupied states in equilibrium. Therefore it is essentially dissipationless. However, in real situation, the disorder effect and contact to the leads introduces the dissipation. This aspect is discussed in detail using the Keldysh formalism for each problem. Ideas of anomalous Hall insulator and spin Hall insulator are also proposed to avoid this dissipation. Applications to optical phenomena are also discussed. This work has been done in collaboration with Z. Fang, S. Murakami, K. Ohgushi, M. Onoda, S. Onoda, K. Sawada, R. Shindou, N. Sugimoto, K. Terakura, and S.C. Zhang.

**15:06**
**W3 2 Fermi Liquid Berry Phase Theory of the Anomalous Hall Effect.***
F. D. M. HALDANE, *Princeton University*

Charged Fermi liquids with broken time-reversal symmetry have an intrinsic anomalous Hall effect that derives from the Berry phases accumulated by accelerated quasiparticles that move on the Fermi surface. The intrinsic Hall conductivity is given by a new fundamental geometric Fermi liquid formula that can be regarded as the derivative with respect to magnetic flux density of the Luttinger fomula relating the density of mobile charge carriers to the k-space volume enclosed by the Fermi surface. This formula can be derived by an integration-by-parts of the Karplus-Luttinger free-electron band-structure formula to yield a topological (QHE) part plus a geometrical part expressed completely at the Fermi surface, and which has a natural generalization to interacting Fermi liquid quasiparticles (QP's). The QP Berry phases are properties of the *eigenstates* of the (exact) single-particle Green's function at the Fermi surface, which is a Hermitian matrix with Bloch-state eigenvectors; the Berry phases derive from the variation on the Fermi surface of the spatially-periodic factor of the QP Bloch state that characterizes how the total QP amplitude is distributed among the different electronic orbitals in the unit cell. In the case of 3D ferromagnetic metals, the Berry phases derive from the interplay of exchange splitting with spin-orbit coupling (both must be present). Remarkably, the new formula also applies to Fermi-liquid analogs such as the 2D composite fermion (CF) fluid in the half-filled lowest Landau level: in this case, the QP is a bound electron+vortex composite and not a Bloch state. This QP structure varies on the CF Fermi surface in a way that exactly gives the expected result $\sigma^{xy} = e^2/2h$, unaffected by any Fermi surface anisotropy, thus explaining how a quantized value of $\sigma^{xy}$ persists even though the CF Fermi liquid is *not* an incompressible FQHE state. The geometric anomalous Hall effect formula suggests a more intrinsic geometric description of the Fermi surface, where the Fermi vector $\boldsymbol{k}_F(\mathbf{s})$ is only one of a number of properties that vary on a curved $(D-1)$-dimensional Fermi surface manifold parametrized by curvilinear coordinates $\mathbf{s}$; other properties include the Berry curvature field $\mathcal{F}(\mathbf{s})$, quasiparticle mean free path $\ell(\mathbf{s})$, etc. The new formula also naturally takes into account non-trivial (multiply-connected) Fermi surface topology and open orbits.

**15:42**
**W3 3 The Quantum Spin Hall Effect.**
CHARLES KANE, *University of Pennsylvania*

We show that the intrinsic spin orbit interaction in a single plane of graphene converts the ideal two dimensional semi metallic groundstate of graphene into a quantum spin Hall (QSH) state [1]. This novel electronic phase shares many similarities with the quantum Hall effect. It has a bulk excitation gap, but supports the transport of spin and charge in gapless ''spin filtered'' edge states on the sample boundary. We show that the QSH phase is associated with a $Z_2$ topological invariant, which distinguishes it from an ordinary insulator [2]. The $Z_2$ classification, which is defined for any time reversal invariant Hamiltonian with a bulk excitation gap, is analogous to the Chern number classification of the quantum Hall effect. We argue that the QSH phase is topologically stable with respect to weak interactions and disorder. The QSH phase exhibits a finite (though not quantized) dissipationless spin Hall conductance even in the presence of weak disorder, providing a new direction for realizing dissipationless spin transport. [1] C.L. Kane and E.J. Mele, Phys. Rev. Lett. **95**, 226801 (2005). [2] C.L. Kane and E.J. Mele, Phys. Rev. Lett. **95**, 146802 (2005).

**16:18**
**W3 4 Spintronics, propagating mode, (quantum) spin transport, and new electron liquids.**
B. ANDREI BERNEVIG,* *Department of Physics, Stanford University, Stanford, CA 94305*

The field of spintronics deals with the physics of the electron-spin in semiconductors, metals, insulators and other materials. Among these, the systems which are characterized by strong spin-orbit coupling hold a special place and exhibit a plethora of new phenomena. In classical transport in semiconductors, a propagating spin-charge collective mode appears that is qualitatively different from the diffusive charge transport. The propagating spin-charge mode is the hallmark of spin-orbit coupled systems with a Fermi surface. The Boltzmann transport equations are qualitatively different from the diffusive normal behavior. Three dimensional bulk transport will be analyzed for the first time. In semiconductors without spin-orbit coupling, an orbital Hall effect (similar to the spin-Hall effect) is present in which electrons selectively occupy different orbitals depending on their direction of motion. In quantum transport, a spatially varying spin-orbit coupling is equivalent to a Landau level problem in which electrons of opposite spin feel opposite magnetic fields, thereby exhibiting a quantum Spin-Hall effect. Time-reversal symmetry is unbroken. In these spin Hall insulators, the quantum spin transport takes place through edge states that cross the bulk gap and the Fermi level. The electron liquid on the edges is a helical liquid, in which spin is correlated with chirality, and represents a new class of one-dimensional liquids different from the Luttinger spinless, spinful or chiral liquids. I will also briefly discuss the possibility of three-dimensional quantization in systems with spin-orbit coupling. New experiments are needed and proposed to verify these predictions.

**SESSION W4: CARBON NANOTUBE DISPERSIONS**
**Thursday Afternoon, 16 March 2006; 308, Baltimore Convention Center at 14:30**
**Ramanan Krishnamoorti, University of Houston, presiding**

**14:30**
**W4 1 From Networks to Nematics – Carbon Nanotubes as Soft Matter.**
ERIK K. HOBBIE, *NIST*

Carbon nanotubes represent just one example of an emerging paradigm in condensed matter physics and materials science: traditionally ''hard'' materials appearing in new ''soft'' applications and environments. In part, this trend being is being fueled by the desire to exploit solution and fluid-based approaches, such as self assembly and flow processing, in an effort to streamline the engineering and commercialization of new materials and applications. In this talk I will review our recent work on dispersing, aligning and manipulating carbon nanotubes in complex fluids and polymer melts. Due to the large aspect ratios and strong attractive interaction potentials intrinsic to such materials, a number of scientific and technical challenges become immediately apparent. In particular, I will focus on the subtle interplay of rheological influences, such as externally applied shear and elongation stresses, with the inherent ''stickiness'' of carbon nanotube suspensions and melts, where the latter typically favors the formation of disordered networks or ''gels'' over the more desirable liquid-crystalline order. For simple shear, the strength of the applied stress is found to be a critical factor in dictating carbon nanotube morphology, which varies from a quiescent network to macroscopic aggregates to a fully dispersed, flow-aligned (para)nematic state. Although we find remarkably low loading thresholds for elastic percolation, our results highlight a fundamental dilemma for the engineering of conducting carbon nanotube polymer composites; dispersion stability will often be achieved at the expense of electrical conductivity.

**15:06**
**W4 2 Single-walled carbon nanotubes in strong acids: controlling solubility and the liquid crystal phase.**
MATTEO PASQUALI, *Depts. of Chemical & Biomolecular Engineering and Chemistry, Carbon Nanotechnology Laboratory, Rice University*

Single Walled Nanotubes (SWNTs) have remarkable electrical, thermal, and mechanical properties. Neat, well-aligned SWNT fibers and sheets could be the ultimate building blocks of strong, ultra-light multifunctional materials for aerospace applications, and could yield electromechanical actuators and sensors with unprecedented performance. After the achievement of scalable production of SWNTs, the difficulty of processing pristine SWNTs by liquid-phase methods has been the single most important roadblock to manufacturing macroscopic materials composed solely of SWNTs. Here we show that SWNTs dissolve at high concentration in acids; the SWNTs are stabilized because acids protonate their sidewalls, balancing wall-wall van der Waals forces. Acid strength controls the phase behaviour. At low concentration, SWNTs in acids dissolve as individual tubes which behave as Brownian rods. At higher concentration, SWNTs form a highly unusual nematic liquid phase consisting of spaghetti-like self assembled supermolecular strands of mobile, solvated tubes in equilibrium with a dilute isotropic phase. At even higher concentration, the spaghetti strands self-assemble into a polydomain nematic liquid crystal, where the domains are entangled with each other. Under anhydrous condition, the liquid crystalline phase can be processed into continuous highly aligned fibers of pure SWNTs without the aid of surfactants or polymers. By using a new fluorescent staining technique, we measure the rotational diffusivity and persistence length of SWNTs suspended in water with the aid of surfactants, and show that SWNTs behave as Brownian rods.

**15:42**
**W4 3 Phase Behavior of Carbon Nanotube Suspensions.**
PHILIPPE POULIN, *Centre de Recherche Paul Pascal - CNRS*

We study the phase behavior of nanotube suspensions stabilized by surfactants or amphiphilic polymers. The control of the composition of the solutions allows the interaction potential between the nanotubes to be finely tuned. As a consequence, it is possible to quantitatively analyze important phenomena such as percolation or liquid crystalline phase transitions. In particular, we describe how the percolation of rod-like particles is quantitatively decreased in the presence of attractive interactions [1]. We show that rod-like particles respond much more strongly than spheres to attractive interactions; strengthening thereby the technological interest of carbon nanotubes to achieve low percolation thresholds for electrostatic dissipation or electromagnetic shielding. By contrast, carbon nanotubes which experience repulsive interactions can spontaneously order and form liquid crystalline solutions [2]. Aligning and packing nanotubes is a major challenge to obtain macroscopic materials with improved properties. We will briefly discuss at the end of the presentation,

our latest results concerning the fabrication of fibers aligned nanotubes [3]. In particular, we will present new treatments of these fibers which lead to unusual mechanical properties and shape memory effects with giant stress recovery [4].

**W4 4 Carbon Nanotube Suspensions: some underlying issues.***
ALAN WINDLE, *Department of Materials Science, University of Cambridge*

Entropy of mixing of rigid particles in a suspending medium is determined on a per-particle basis and thus, for a given weight fraction will decrease with increasing particle size. In the case of carbon nanotubes, the entropy contribution to mixing will thus be small compared with the interparticle forces which comprise the enthalpic energy contribution to any thermodynamic equilibrium. These forces will generally be short range with the exception of electrostatic forces in the cases that the particles carry a charge. The ability to form carbon nanotube suspensions depends on both the chemical affinity between the medium and the tubes and, it appears, the size of the medium molecules. Surface treatments of the nanotubes have been developed both using covalently attached functional groups and surfactants, and each strategy has been successfully applied to both multi and single wall CNTs. Because carbon nanotubes are long, thin, rigid and comparatively straight, they have been shown to self assemble into liquid crystalline phases showing all the attributes of conventional systems. The relationship between such CNT systems and the conventional Flory phase diagram will be described, as will the exploitation of these phase equilibria to fractionate nanotubes on the basis of mesogenicity. The use of liquid crystalline phases as a basis for the processing of carbon nanotubes into aligned assemblies such as fibres will also be outlined.

**W4 5 Processes for Dispersing Single Wall Carbon Nanotubes in Polymers and How to Determine Their Spatial and Alignment Distributions.**
KAREN I. WINEY, *University of Pennsylvania*

We are currently designing and making polymer nanocomposites with single wall carbon nanotubes (SWNT) to obtain improved mechanical properties, electrical conductivity, flammability, and thermal conductivity. Our coagulation method is broadly applicable to nanocomposites using readily-soluble thermoplastics such as polystyrene and poly (methyl methacrylate). A variation of this method has been developed for nanotube/polymer composites based on high-density polyethylene. Nylon-based composites are prepared using our adaptation of an itin situ interfacial polymerization method. Epoxy-based SWNT composites are prepared using either shear mixing with multi-step thermal treatments or an infiltration method using a freestanding SWNT network. Recent studies have explored the use of solid-state shear pulverization to disperse SWNT. Rheology is employed to evaluate the spatial distribution of SWNT based on the onset of solid-like behavior associated with the formation of a SWNT network. Morphological tools including various microscopy methods, x-ray scattering and Raman imaging, are used to evaluate both dispersion and alignment. The resulting spatial and alignment distributions of SWNT depend on the composite fabrication method and any subsequent processing, such as melt fiber spinning to effectively align SWNT. Examples will be given detailing the importance of (1) SWNT dispersion on flammability and thermal conductivity and (2) SWNT alignment on electrical conductivity.

## SESSION W5: A CENTURY OF CRITICAL PHENOMENA

**W6 2 Prospects of Mid Infrared Silicon Raman Laser.**
BAHRAM JALALI, *University of California Los Angeles*

Mid wave infrared (MWIR) lasers in the wavelength range of 2-5$\mu$m form an important tool for free space communications, bio-chemical detection and certain medical applications. Most organic chemicals and biological agents have unique signatures in the MWIR and can be detected using these lasers. The strong water absorption peak at 2.9$\mu$m renders such a laser attractive for surgery and dentistry. Solid state lasers comprising OPO-based nonlinear frequency converters and Raman lasers have been the popular choice for these applications. However, the low damage threshold, poor thermal conductivity and high cost limit the commercial availability of these sources. The recent demonstration of the first silicon Raman laser in 2004 combined with excellent transmission of silicon in the mid-IR suggests that silicon should be considered as a MWIR Raman crystal. In the near IR, where current silicon Raman lasers operate, free carriers that are generated by two photon absorption (TPA) create severe losses. TPA vanishes in the MWIR regime ($\lambda > 2.25$ $\mu$m), hence eliminating the main problem with silicon Raman lasers. This combined with (i) the unsurpassed quality of

commercial silicon crystals, (ii) the low cost and wide availability of the material, (iii) extremely high optical damage threshold of 1-4 GW/cm$^2$ (depending on the crystal resistivity), and (iv) excellent thermal conductivity renders silicon a very attractive Raman crystal. Moreover, integrated waveguide and resonator technologies can lead to device miniaturization. This talk discusses the MWIR silicon laser and its applications.

**W6 4 Nonlinear Optics in Silicon—Applications in Optical Communication Systems.**
THOMAS MURPHY, *University of Maryland*

Silicon photonics is quickly becoming an important and active research area, primarily because of the desire to leverage existing silicon fabrication technology and the potential for integration with conventional silicon electronic components. In this talk, I will discuss nonlinear optical effects in silicon, and ways in which they can be employed in optical telecommunication systems. The nonlinear effect that we have been exploring is two-photon absorption: a process in which two photons are simultaneously absorbed in a silicon photodiode to generate a single electron-hole pair. Unlike many other nonlinear processes, two-photon absorption does not require phase matching, and can occur over a very broad wavelength range with an ultrafast (fs) response time. In silicon, two-photon absorption can be observed at wavelengths from 1100 to 2200 nm, a range that spans the entire spectrum presently used in fiber telecommunications. For years, two-photon absorption was regarded as a deleterious effect in nonlinear optics, because it consumes the optical signal that was meant to produce a nonlinear phase shift. More recently, researchers have found ways to exploit two-photon absorption effects for optical signal processing. For example, if the electrical carriers produced by two-photon absorption are collected by an en external electrical bias circuit, the resulting photocurrent can be directly used in a number of nonlinear processing functions including optical autocorrelation, cross-correlation, quality monitoring, demultiplexing, optical sampling, and clock recovery. In this presentation, I will review the recent applications of two-photon absorption in communication systems, and describe ongoing research being conducted at the University of Maryland. In particular, we have found an explanation for the polarization dependence that is often observed in two-photon absorption, and we have developed a new way to overcome this dependence. As an example of how two-photon absorption can be used in a real communication system, we have demonstrated an 80 Gb/s optical clock recovery system based upon two-photon absorption in a silicon photodiode, and we deployed the system in a 1000 km fiber transmission experiment.

**14:30**
**W7 1 Nucleation and growth of cell contacts.***
DANIEL RIVELINE, *Laboratoire de Spectrométrie Physique, UMR 5588, Grenoble*

Living cells develop adhesive contacts with their environments. We present experiments which are dedicated to measure geometric and density evolutions of these contacts in living cells. We focus on two contacts: focal contacts, formed between a cell and the extracellular matrix, and adherens junctions, assembled between neighbouring cells. Both include: (i) a transmembraneous protein dictating the given adhesive junction assembly, (ii) a specific protein complex with tens of different components, (iii) an actin cytoskeletal structure. Our experiments involve the observations of fluorescently labelled proteins of these contacts in living cells, local force application, force measurements, and optical development such as evanescent wave excitation. These adhesive cellular entities are usually described as a result of activation of signalling events. However cell adhesive contacts can be seen as discrete itparticles aggregates, which undergo nucleation and growth like in a first order phase transition. We will show that self-assembly processes are indeed imposing contacts

shapes and dynamics. Far from being two antagonistic ways of describing cells dynamics, signalling pathways and cell self-assembly complement each other to dictate contacts shapes. In addition, eventhough focal contacts and adherens junctions involve different proteins, we will show that they share common features such as mechanosensitivity. Via these contacts, cells behave as climbers seeking to probe the resistance of their environment in order to reinforce appropriately specific adhesive areas.

**15:42**
**W7 3 Cell morphologies depend on substrate rigidity.**
PAUL JANMEY, *University of Pennsylvania*

Extracellular matrices and intracellular cytoskeletons are composed mainly of open meshworks formed by semi-flexible polymers linked by accessory proteins in networks with specific geometries. The viscoelastic properties of such networks often differ strongly from those of flexible polymer gels and are characterized by relatively large elastic moduli for low volume fractions, increased rigidity at increasing strains, and in some cases, negative normal stresses when deformed in simple shear. Cell structure and function depend on the stiffness of the surfaces on which cells adhere as well as on the type of adhesion complex by which the cell binds its extracellular ligand. Most cell types, including fibroblasts and endothelial cells, switch from round to spread morphology as stiffness is increased between 1000 and 10,000 Pa. In contrast, other cells types such as neutrophils do not require rigid substrates in order to spread, and neurons extend processes better on soft (50 Pa) materials than on stiffer gels. Differences in rigidity sensing and response can be exploited to design soft matrices optimized for growth and differentiation of specific cell types.

**16:18**
**W7 4 Physics of adhesion and elasticity of biological cells.***
S.A. SAFRAN, *Dept. Materials and Interfaces, Weizmann Institute of Science, Rehovot, Israel 76100*

Forces exerted by adherent cells are important for many physiological processes such as wound healing and tissue formation. By pulling on their environment, cells sense rigidity gradients, boundaries and strains induced by the presence of other cells. Many cell types respond to these signals by actively adjusting the magnitude and direction of the adhesions that connect cells to surfaces or to each other. These adhesions are formed from membrane-bound integrin proteins and other cytoplasmic proteins that form condensed domains that grow in the direction of externally applied or internal, cytoskeletal forces. We present a model for the adsorption of adhesion proteins from the cell interior to the adhesion site and the resulting, force-sensitive anisotropic growth. The theory couples the mechanical forces to the non- linear adsorption dynamics and predicts the growth velocities of the back and front of the adhesion in qualitative agreement with experiment. The adhesion forces generated by a collection of cells in a tissue significantly alter the overall elastic response of the system. We model an ensemble of cells by an extension of the treatment of dielectric response of polar molecules to elastic interactions. By introducing the elastic analogy of the dielectric constant of the medium, we are able to predict the average cell polarization, their orientational order, and the effective material constants.

**W7 5 Cell mechanics and human disease states.**
SUBRA SURESH, *MIT*

This presentation will provide summary of our very recent studies exploring the effects of biochemical factors, influenced by foreign organisms or itin vivo processes, on intracellular structural reorganization, single-cell mechanical response and motility of a population of cells in the context of two human diseases: malaria induced by Plasmodium falciparum merozoites that invade red blood cells, and gastrointestinal cancer metastasis involving epithelial cells. In both cases, particular attention will be devoted to systematic changes induced in specific molecular species in response to controlled alterations in disease state. The role of critical proteins in influencing the mechanical response of human red bloods during the intra-erythrocytic development of P. falciparum merozoites has also been assessed quantitatively using specific protein knock-out experiments by recourse to gene inactivation methods. Single-cell mechanical response characterization entails such tools as optical tweezers and mechanical plate stretchers whereas cell motility assays and cell-population biorheology characterization involves microfluidic channels. The experimental studies are accompanied by three-

dimensional computational simulations at the continuum and mesoscopic scales of cell deformation. An outcome of such combined experimental and computational biophysical studies is the realization of how chemical factors influence single-cell mechanical response, cytoadherence, the biorheology of a large population of cells through microchannels representative of in vivo conditions, and the onset and progression of disease states.

## SESSION W8: FOCUS SESSION: NONLINEAR ELECTROKINETICS

**W8 1 Electro-Convective and Non-Equilibrium Electro-Osmotic Instability of Electric Conduction from an Electrolyte Solution into a Charge Selective Solid.**
ISAAK RUBINSTEIN, *Blaustein Institutes for Desert Research, Ben-Gurion University of the Negev*

Electro-convection is reviewed as a mechanism of mixing in the diffusion layer of a strong electrolyte adjacent to a charge-selective solid, such as an ion exchange (electrodialysis) membrane or an electrode. Two types of electro-convection in strong electrolytes may be distinguished: bulk electro-convection, due to the action of the electric field upon the residual space charge of a quasi-electro-neutral bulk solution, and convection induced by electro-osmotic slip, due to electric forces acting in the thin electric double layer of either quasi-equilibrium or non-equilibrium type near the solid/liquid interface. According to recent studies, the latter appears to be the likely source of mixing in the diffusion layer, leading to 'over-limiting' conductance in electrodialysis. Electro-convection near a uniform charge selective solid/liquid interface sets on as a result of hydrodynamic instability of one-dimensional steady state electric conduction through such an interface. We discuss instabilities of this kind appearing in the full electro-convective and limiting non-equilibrium electro-osmotic formulations. The short- and long-wave aspects of these instabilities are discussed along with the wave-number selection principles and possible sources of low frequency excess electric noise experimentally observed in these systems.

**15:06**
**W8 2 Nonlinear Surface Transport in the Thin Double-Layer Limit** KEVIN CHU, *Princeton University* MARTIN BAZANT, *Massachusetts Institute of Technology* At high applied electric fields, ionic transport within the double layer plays a significant role in the overall response of electrokinetic systems. It is well-known that surface transport processes, including surface electromigration, surface diffusion and surface advection, may impact the strength of electrokinetic phenomena by affecting both the zeta-potential and the magnitude of the tangential electric field. Therefore, it is important to include these effects when formulating the effective boundary conditions for the equations that govern electrokinetic flow outside of the double layer. In this talk, we discuss the application of a general formulation of ''surface conservation laws'' for diffuse boundary layers to derive effective boundary conditions that capture the physics of electrokinetic surface transport. Previous analyses (e.g. Deryagin & Dukhin 1969) are only valid for weak applied fields and are based on a linearization of the concentration and potential about a reference solution, but our results are fully nonlinear and hold at large applied fields as long as the double layer is sufficiently thin. We compare our nonlinear surface transport theory with existing linear analogues and apply it to the canonical problem of induced-charge electro-osmosis around a metal sphere or cylinder in a strong DC field.

**W8 3 Experiments on Nonlinear Electrokinetic Pumps in Microfluidics*** JOHN PAUL URBANSKI, TODD THORSEN, *Department of Mechanical Engineering, MIT* JEREMY A. LEVITAN, MARTIN Z. BAZANT, *Department of Mathematics, MIT* Nonlinear electrokinetic pumps are attractive in the development of portable and flexible microfluidic analysis systems, since they operate without moving parts using low (battery powered) alternating potentials. Since the discovery of AC electro-osmosis (ACEO) in the late 1990s, there has been much work in designing and building two-dimensional, periodic micro-electrode geometries, which exploit broken symmetry to rectify AC forcing and produce steaming flow over a surface. Building on this work, we exploit more general principles of induced-charge electro-osmosis (ICEO) in three-dimensional electrode geometries to enhance pumping in microfluidic devices. Our fabrication efforts are guided by theoretical analysis and simulations using the standard low-voltage theory, which, in some cases, predict flow rates faster than existing planar ACEO pumps by an order of magnitude (for the same voltage and feature size). We test various microfabricated pump geometries in a microfluidic loop following the methodology of Studer et al (2004). We are also measuring the strong effect of solution chemistry (e.g. ion valence and concentration) on ICEO flow to guide further developments in the theory of nonlinear electrokinetics.

**W8 4 Microfluidic pumps based on Induced Charge Electroosmosis and flow Field Effect Transistor phenomena*** GAURAV SONI, TODD SQUIRES, CARL MEINHART, *University of California Santa Barbara* We are developing AC electrokinetic micropumps to drive electrically conductive biological fluids in microchannels. These pumps work on the principles of Induced Charge Electroosmosis (ICEO) and flow Field Effect Transistor (flowFET) phenomena. AC (as well as DC) electric fields can induce electrical double layer on a polarizable surface and in turn, cause fluid motion by moving this layer. However, when the polarizable surface is electrically floating, symmetric vortices are observed on the surface. Symmetry of this flow leads to zero net pumping. In order to achieve pumping, we apply a second AC signal to the polarizable surface. When the magnitude of this second AC signal is different from the floating potential of the surface, unidirectional flow is observed i.e., pumping is achieved by modulating the induced zeta potential of the surface. Pumping caused by modulation of zeta potential is also known as flowFET phenomenon and has been shown to work with DC electric fields by other community members. We show a detailed study of flowFET with AC electric fields.

*Supported by an Army grant: 8-487859-25500.

**W8 5 Nonlinear studies of AC electrokinetic micropumps** HENRIK BRUUS, LAURITS H. OLESEN, *Technical University of Denmark* ARMAND AJDARI, *Ecole Superieure de Physique et de Chimie Industrielles* Recent experiments have demonstrated that AC electrokinetic micropumps permit integrable, local, and fast pumping (velocities $\sim$ mm/s) with low driving voltage of a few volts only. However, they also displayed many quantitative and qualitative discrepancies with existing theories. We therefore extend the latter theories to account for three experimentally relevant effects: ($i$) vertical confinement of the pumping channel, ($ii$) Faradaic currents from electrochemical reactions at the electrodes, and ($iii$) nonlinear surface capacitance of the Debye layer. We report here that these effects indeed affect the pump performance in a way that we can rationalize by physical arguments.

**15:54**

**W8 6 Electric field driven motion of flexible polyelectrolytes*** TAK SHING LO, *Levich Institute, City College of CUNY* BORIS KHUSID, *Dept. of Mechanical Engineering, NJIT* ANDREAS ACRIVOS, JOEL KOPLIK, *Levich Institute, City College of CUNY* Our work aims to study dielectrophoresis of biomolecules in micro/nano-fluidics using molecular dynamics (MD) simulations. Our model combines electrohydrodynamics with molecular theories for the macromolecule polarization caused by the distortion of the counterion cloud. Unlike most available MD studies of polyelectrolytes, solvent atoms are explicitly represented in our model, so that hydrodynamic interactions are included naturally with no ad hoc assumption. The polyelectrolyte is modeled as a negatively charged bead-spring chain. The charges interact through the Coulomb potential and other molecular interactions are included via Lennard-Jones potentials. We study the transport properties of flexible polyelectrolytes suspended in a solvent, with or without added salt, under the action of DC or AC electric fields. MD data provide the information needed to compute the dipole moments of the molecule and the surrounding double layer, which are required for understanding the dielectrophoretic behavior of these molecules in nanoscopic channels.

**W8 7 Anomalous ionic transport at nanometer-scale electrodes** DIEGO KRAPF, *Delft University of Technology* BERNADETTE QUINN, MENG-YUE WU, HENNY ZANDBERGEN, CEES DEKKER, SERGE LEMAY, We probe the transport of charged species in high ionic strength solutions on the scale of a few nanometers by monitoring electrochemical reactions at correspondingly sized electrodes. The electrical current through the nanoelectrode provides a direct measure of the flux of ions across the diffuse double layer. Because both the concentration gradient and the electric field are localized in the immediate vicinity of the nanoelectrode, this provides very local information. Furthermore, when the electrode dimensions are in the order of a few nanometers, very steep concentration gradients are achieved. To carry out these experiments, we have developed a method for fabricating nanoelectrodes with a well-defined size and geometry. A pore is first drilled in an insulating membrane with a focused electron beam and it is then filled with a noble metal yielding conically shaped, convex electrodes with radii as small as 2 nm. We observe pronounced non-linearities of ion flux versus concentration when transport is localized within a region smaller than 10 nm in size. We numerically calculate the predicted ion flux using the Stern-Poisson-Nernst-Planck formalism. We show that our observations cannot be explained using this widely applied mean-field description of ionic transport.

**16:18**

**W8 8 Nonlinear Electroosmosis and Biomolecule Electrokinetic Trapping Induced by Ion Selective Nanofluidic Channels** YING-CHIH WANG, *Dept. of Mech. Eng., MIT* JONGYOON HAN, *Bio. Eng. Division, Dept. of EECS, MIT* This paper describes a nanofluidic device that can concentrate dilute biomolecule by electrokinetic trapping mechanism. This device has nanofluidic channels with a depth down to 40 nm, therefore, having significant Debye layer overlap. Depending on the strength of the applied potential across the nanochannel, one can observe phenomena such as concentration polarization; charge depletion and nonlinear electrokinetic flow in the adjacent microfluidic channel using fluorescent microscopy. By manipulating the electric field, the device can generate an extended space charge region, maintained for several hours, within a microchannel as a mean to collect and trap biomolecules. Our studies demonstrate such device can achieve up to 10 million fold sample preconcentration within 30 minutes. Besides, if applied a higher potential, a much faster chaotic flow can be seen in the microchannel adjacent to nanochannels. This kind of nonlinear electrokinetic flow is often called the electroosmosis of the second kind or induced-charge electroosmosis in electrode and ion exchange membrane studies. The presented device can be used as either a preconcentrator or an injector to other separation and detection systems preferred its performance and integrabilty. Also, it is an ideal experimental platform for studying such nonlinear electrokinetic effects, by directly tracking molecules in situ.

**16:30**
**W8 9 Modeling of Selectively Permeale Vesicle Membrane in Electrolytes: An Energetic Variational Formulation** CHUN LIU, ROLF RYHAM, *Dept of Math, PSU* We introduce a self consistent coupled system to model the deformation of selectively permeable vesicle membranes in electrolytes via an energetic variational formulation. The equations governing a diffuse charge system and the evolution of the vesicle membrane are coupled with the momentum equations of the electrolyte through the Lorentz force along with the induced elastic forces due to the membrane bending energy. The force coupling and charge flux selectivity are consequences of the energetic balance and competition of kinetic, electric and membrane elastic bending energy. We will also present some numerical simulation results of the system.

**16:42**
**W8 10 Reversible Transitions on Electrically-Tunable Nanostructured Superhydrophobic Surfaces** TOM KRUPENKIN, J. ASHLEY TAYLOR, PAUL KOLODNER, MARC HODES, JOANNA AIZENBERG, *Bell Labs, Lucent Technologies* Recently demonstrated electrically tunable nanostructured superhydrophobic surfaces provide a promising new way of manipulating liquids at both micro and macro scales. Dynamic control over the interaction of liquids with the solid substrate is of great interest to many research areas ranging from biology and chemistry to physics and nanotechnology. In this work the reversibility of the electrically induced superhydrophobic – hydrophilic transition on nanostructured surfaces is addressed. Recently demonstrated approach based on momentarily induction of film boiling in a very thin layer of liquid adjacent to the solid-liquid interface is discussed. The dependence of the hydrophilic – superhydrophobic transition on the topography of the nanostructured layer, as well as on the energy and duration of the electrical pulse is investigated. Several emerging applications of these surfaces, including lab-on-a-chip, chemical microreactor, and on-chip power sources are discussed.

**W8 11 Nonlinear alternating current susceptibilities of rotating microparticles in electrorheological fluids*** KIN WAH YU, *Chinese University of Hong Kong* J.P. HUANG, W.J. TIAN, *Fudan University* A perturbation approach [1] has been employed to investigate the nonlinear alternating current (AC) responses of the rotating microparticles in electrorheological (ER) fluids under AC or direct current electric fields. The shear flow of ER fluids exerts a torque on the particles and leads to the rotational motion of the particles about their centers [2]. We show that the dynamic effects can play a significant role in the AC responses. Our results can be conveniently interpreted in the dielectric dispersion spectral representation [3], thus offering a convenient method to determine the relaxation time and the rotation velocity of the ER particles by measuring the nonlinear AC responses. **17:06**
**W8 12 Electrophoresis in bounded doamins** EHUD YARIV, *Technion* Electrophoretic motion is usually described by a linear model, based upon the smallness of the applied field relative to the equilibrium field in the screening Debye layer surrounding the particle. This model, in turn, leads to the Smoluchowski's slip condition and eventually results in mobility relations. The mobility concept is valid provided the external electric force is neglected — a procedure superficially supported by the net electric neutrality of the combined particle-layer system. In this talk, however, I will show that this force does not vanish in general. Accordingly, a consistent scheme is formulated for analyzing the nonlinear motion of a particle in an applied field. This motion is illustrated in two contexts: rotation of non-spherical particles, and drift of a spherical particle away from a planar wall. I will also describe an analogy to incompressible and inviscid fluid motion. This analogy enables for experimental verification of three-dimensional potential flow solutions.

**17:18**
**W8 13 How accurate is the Poisson-Boltzmann theory for monovalent ions near highly charged interfaces?*** WEI BU, ALEX TRAVESSET, DAVID VAKNIN, *Ames Laboratory, Iowa State University* Monovalent ion distributions next to highly charged interfaces were determined by synchrotron surface X-ray sensitive techniques. A lipid phosphate (dihexadecyl hydrogenphosphate) was spread as a monolayer at the air-water interface, containing CsI at various concentrations. Using anomalous reflectivity off and at the $L_3$ $Cs^+$ resonance, we provide, for the first time, spatial counterion distributions ($Cs^+$) next to the negatively charged interface over a wide range of ionic concentrations. We argue that at low salt concentrations and for pure water the enhanced concentration of hydroniums $H_3O^+$ at the interface leads to proton-transfer back to the phosphate group by a high contact-potential, whereas high salt concentrations lower the contact-potential resulting in proton- release and increased surface charge-density. The experimental ionic distributions are in excellent agreement with a renormalized-surface-charge Poisson-Boltzmann theory without fitting parameters or additional assumptions.

**W9 1 Strain maps with ppm resolution for single crystal wafers obtained from x-ray rocking curve maps** ALBERT MACRANDER, YUNCHENG ZHONG, JOSEF MAJ, YONG CHU, *Argonne National Laboratory* SZCZESNY KRASNICKI, *Carnegie Institute* A double crystal (+,−) x-ray technique has been used to obtain separate maps of strain and tilt across single crystal samples of high crystalline perfection. Rocking curves were ob-

tained for each pixel of a CCD detector and from these data angular shifts of the rocking curve center were mapped. By using data for two azimuthal rotations, that is, by combining data from two diffraction conditions separated by 180° rotation around the diffraction vector, we obtained separately the tilt and the strain. Data for diamonds has been obtained to demonstrate the technique in the case of a symmetric reflection[1]. Extensions of the method to asymmetric reflections in order to also extract strains parallel to the surface[2] will be discussed. Also a correction for wavelength dispersion in the case of different d-spacings for first and second crystals will be discussed. This work was supported by DOE Basic Energy Sciences-Materials Science, under contract No. W-31-109-ENG-38 and by NSF under contract No. EAR-0421020. [1] A.T. Macrander et al., Applied Physics Letters, 87, 194113 (2003). [2] V. Swaminathan and A.T. Macrander, ''Materials Aspects of GaAs and InP Based Structures,'' Prentice Hall, 1991, ISBN 0-13-346826-7.

**W9 2 Is Resonant X-ray Scattering Sensitive to the Electronic Structure of the CDW State?** J.-D. SU, *School of Applied and Engineering Physics, Cornell University, Ithaca, NY 14853* J.D. BROCK, *School of Applied and Engineering Physics, Cornell University, Ithaca, NY 14853* K.D. FINKELSTEIN, *Cornell High Energy Synchrotron Source, Ithaca, NY 14853* The strong ''white-line'' observed at the Ta $L_{III}$ x-ray absorption edge (9.881KeV) in 1*T*-$TaS_2$ indicates resonance with the 2p $\rightarrow$ 5d atomic transition. Theories of the charge density wave (CDW) state in $TaS_2$ highlight the special role played by the 5d states of the thirteen Ta atoms in each unit cell of the super-lattice in forming the reconstructed conduction bands of the CDW state. By measuring the resonant diffraction at the CDW satellites, we combine this additional periodicity with the resonant scattering to amplify and isolate the x-ray signal from the CDW. Then, by studying the behavior as the system goes through the incommensurate-commensurate transition, we probe the sensitivity of this resonant x-ray scattering technique to changes in the electronic structure near the Fermi surface.

**W9 3 Diffraction by Distorted Object – A Unified Description of Coherent X-ray Diffraction and Imaging.*** QUN SHEN, *Argonne National Laboratory* XIANGHUI XIAO, *Argonne National Laboratory* It is well-known that a diffracted or scattered wave by an object can be simply described by a Fourier transform of the electron density distribution of the object. This, in principle, is true only in the so-called far-field regime. In the near-field regime, evaluations of wave field amplitudes become more complicated and Fresnel diffraction and imaging effects have to be taken into account. In this paper, we present a unified diffraction theory that is valid in both far-field and near-field regime. Using the concept of a 'phase-chirped' distorted object, where Fresnel-zone construction is embedded on an original object, we show that the Fourier transform of this distorted object can be used to evaluate Fresnel coherent diffraction images or phase-contrast images from objects. This approach is valid continuously from the near-field to the far-field regimes. In addition, the distorted-object approach extends the applicability of Fourier-based iterative phasing algorithm that is already established for far-field diffraction into the near-field holographic regime where phase retrieval had been difficult in high-resolution structural imaging of noncrystalline specimens. Imaging in near-field also possesses the advantage that it can eliminate twin image ambiguity that may exist in far-field diffraction.

**W9 4 Recovering Ancient Inscriptions by X-ray Fluorescence Imaging** JUDSON POWERS, NORA DIMITROVA, *Cornell University* RONG HUANG, *Advanced Photon Source* DETLEF-M. SMILGIES, DON BILDERBACK, *Cornell High-Energy Synchrotron Source* KEVIN CLINTON, ROBERT THORNE, *Cornell University* For many ancient cultures including those of the Mediterranean, carved stone inscriptions provide our most detailed historical record. Over the ages the surfaces of many of these inscriptions have been eroded so that the original text can no longer be distinguished. A method that allowed at least partial recovery of this lost text would provide a major breakthrough for the study of these cultures. The scope of analytical techniques that can be applied to stone tablets is limited by their large size and weight. We have applied X-ray fluorescence imaging to study the text of ancient stone inscriptions [1]. This method allows the concentrations of trace elements, including those introduced during inscription and painting, to be measured and mapped. The images created in this way correspond exactly to the published text of the inscription, both when traces of letters are visible with the naked eye and when they are barely detectable. [1] J. Powers et al., Zeitschrift für Papyrologie und Epigraphik 152: 221-227 (2005).

**W9 5 Site specific valence band structure of $SrTiO_3$ determined with X-ray standing waves** JORG ZEGENHAGEN, SEBASTIAN THIESS, TIEN-LIN LEE, *ESRF, France* FRANCOIS BOTTIN, *CEA/DIF, France* Structure and chemical composition define the properties of materials, notably band structure and electronic characteristics of solids. Ab initio calculations deliver frequently reliably predictions, which are, however, difficult to verify, in particular in view of the direct relationship between atomic and electronic structure. Combining the x-ray standing wave (XSW) technique with X-ray photoelectron spectroscopy (XPS) is a unique tool in this sense. It is used here to identify unambiguously parts of the valence band of $SrTiO_3$, which can be assigned to Sr, Ti, or O-sites of the lattice. The XSW/XPS measurements were performed in UHV at the ID32 insertion device beamline at the ESRF using a (001) oriented, atomically clean $SrTiO_3$ crystal. Traversing the (111) and (112) Bragg reflections and recording the valence band for different standing wave positions within the lattice unit cell, the site specific contributions could directly be identified. Obtained experimental results are in very good agreement with theory, by utilizing as adjustable parameters the X-ray absorption cross sections of the valence electrons.

**W9 6 CMR Manganite Sensors for Total Energy Measurements of the Linear Coherent Light Source Pulsed X-ray Laser** RAJESWARI M. KOLAGANI,* G.J. YONG, D.E. COX, R. MUNDLE, A. DAVIDSON III, V.N. SMOLYANINOVA, E. TA-

LANOVA, D. SCHAEFER, *Towson University* S. FRIEDRICH, O. DRURY, Z. ALI, L. LI, L. OTT, *Lawrence Livermore National Labs* L. YONG, *Motorola Labs* TOWSON UNIVERSITY TEAM, LAWRENCE LIVERMORE NATIONAL LABORATORY TEAM, MOTOROLA LABS COLLABORATION, We are developing CMR manganite thin film bolometric sensors for total energy measurements of the Linear Coherent Light Source (LCLS) pulsed free electron x-ray laser (FEL). This application requires the sensor array to be fabricated on a low Z substrate capable of withstanding the pulse impact of 2 mJ in $\sim$ 200 femtoseconds, without the thermal expansion exceeding the yield strength, when the back side of the substrate is irradiated. Si is a potential candidate for meeting this requirement though its stability for long term exposure is a concern that needs to be tested. Optimal operating temperature of the sensor is estimated to be $\sim$ 100 K-200 K, based on finite element simulations of the temperature evolution in the sensor pixel. Our initial work has identified $Nd_{1-x}Sr_xMnO_3$ as the manganite material suitable for the LCLS sensor. We will present our materials development efforts towards LCLS sensor design as well as simulations of the sensor response.

**W9 7 Verification and Application of a New Analysis Method for X-ray Diffraction Microscopy*** ROBERT SUTER, CHANGSHI XIAO, DANIEL HENNESSY, *Department of Physics, Carnegie Mellon Univeristy* ULRICH LIENERT, *Advanced Photon Source, Argonne National Laboratory* X-ray diffraction microscopy has been used to determine microstructure maps of bulk polycrystalline material. Data are collected at the Advanced Photon Source beamline 1-ID using line focused 50keV x-rays. Diffracted beams are imaged with a CCD camera and are tracked through space so that orientation, point-of-origin, and shape of individual grains are encoded. Analysis uses a computer simulation of the measurement and sample to generate calculated diffraction patterns; orientations of sample space area elements are adjusted to obtain a match to the data. We illustrate data and analysis using a thin silicon wafer sample. We then show images of several layers of an aluminum polycrystal. The ability to obtain such images in a non-destructive way opens the possibility of measurements of the response to external stimuli of ensembles of individual grains. Our analysis is amenable to inclusion of complex scattering rules such as will be needed to study defected materials.

**W9 8 Nanometer Focusing X-rays With Multiple Kinoform Lenses*** KENNETH EVANS-LUTTERODT, AARON STEIN, *Brookhaven National Laboratory* NATIONAL SYNCHROTRON LIGHT SOURCE TEAM, It has been suggested that for refractive optics operating at photon energies of order 10 keV, that the resolution is limited to the wavelength divided by the critical angle. Using a compound kinoform lens consisting of individually optimized kinoform lenses, we investigate the possibility of exceeding this limit. Single-dimensional, kinoform lens stacks in deep-etched silicon have been fabricated that in principle can exceed the critical angle limit. These optics have been tested and the results will be presented. Additionally we present calculations that show that the resolution of radially-symmetric kinoform lenses is limited only by x-ray wavelength.

**W9 11 Electron structure factor: a unique quantity in probing material's properties.*** JIN-CHENG ZHENG, LIJUN WU, YIMEI ZHU, *Center For Functional Nanomaterials, Brookhaven National Laboratory, Upton, New York 11973* Electron diffraction is very sensitive to valence charge distribution compared with x-ray at small scattering angles due to the near cancellation of the scattering from the positively charged nucleus and the negatively charged electrons. Thus, small changes in electron density can lead to considerable variations in the scattering amplitude. The well known divergence at small scattering vector for Coulomb scattering leads to strong measurable scattered intensities. How-

ever, the advantage of the accurate measurement using quantitative electron diffraction has not been well appreciated. We propose here that the accurate measured electron structure factor can be a unique quantity in probing properties of materials. We demonstrate this by examining the sensitivity of electron structure factor to valence charge distribution, chemical composition variations, and charge / orbital orderings in many functional materials. We also show that the accurately measured low-order electron structure factors can be used to test first principles theories, especially to optimize exchange-correlation functionals.

**W9 12 $^3$He neutron spin filters for polarized neutron scattering.** WANGCHUN CHEN, JULIE BORCHERS, YING CHEN, KEVIN O'DONOVAN, ROSS ERWIN, JEFFREY LYNN, CHARLES MAJKRZAK, SARAH MCKENNEY, THOMAS GENTILE, *NIST, Gaithersburg, Maryland* Polarized neutron scattering (PNS) is a powerful tool that probes the magnetic structures in a wide variety of magnetic materials. Polarized $^3$He gas, produced by optical pumping, can be used to polarize or analyze neutron beams because of the strong spin dependence of the neutron absorption cross section for $^3$He. Polarized $^3$He neutron spin filters (NSF) have been of great interest in PNS community due to recent significant improvement of their performance. Here I will discuss successful applications using $^3$He NSFs in polarized neutron reflectometry (PNR) and triple-axis spectrometry (TAS). In PNR, a $^3$He NSF in conjunction with a position-sensitive detector allows for efficient polarization analysis of off-specular scattering over a broad range of reciprocal space. In TAS, a $^3$He NSF in combination with a double focusing pyrolytic graphite monochromator provides greater versatility and higher intensity compared to a Heusler polarizer. Finally I will present the results from patterned magnetically-coupled thin films in PNR and our first ''proof-of-principle'' experiment in TAS, both of which were performed using $^3$He NSF(s) at the NIST Center for Neutron Research.

**W9 13 A low and hyperthemal energy UHV ion beamline for surface scattering spectroscopies** M.P. RAY, S.A. MOODY, C.E. SOSOLIK, *Clemson University Department of Physics and Astronomy* We are using a differentially pumped beamline to provide well- collimated, monoenergetic beams of noble gas and alkali-metal ions that range in energy from $<$ 10eV to 10keV. These ion beams are scattered from a surface (e.g. Cu(001)) to study charge transfer effects, energy loss, and the excitation of surface phonons and excitons. The ion beam is focused into a UHV scattering chamber that possesses capabilities for studying and characterizing samples using LEED, Auger spectroscopy, and a Kelvin probe for work function measurements. Recent additions to this setup include replacing diffusion pumps with turbo pumps as well as the addition of a fast entry load-lock sample exchange system. Our current research is focused on developing a source to produce an ion beam of $C_{60}$ as well as studying charge transfer and energy loss effects at the low and hyperthermal energy range. Also, we are investigating chemicurrents associated with Schottky diodes in this energy regime.

**W10 1 Synthesizing Metal Nanowires that Detect Molecules.**
REGINALD M. PENNER, *Department of Chemistry, University of California, Irvine, CA 92697-2025 USA*

Noble metal nanowires have attributes including strength, ductility, and chemical stability, that make them attractive candidates for chemical sensing applications. However, in contrast to semiconductor nanowires, the conductivity of metal nanowires is not expected to be responsive to ''charge gating'' induced by the presence at the surface of the nanowire of bound ions. Consequently the properties of metal nanowires for chemical sensing have not been explored. We have developed a new method for preparing arrays of noble metal nanowires that involves the electrodeposition of metals (palladium, silver, platinum and gold) onto stepped graphite surfaces. Under the conditions employed for nanowire growth, metal is deposited selectively at step edges on the graphite surface leading to the formation of polycrystalline nanowires that are up to 1 mm in length and 30-500 nm in diameter. These nanowires adhere weakly to the graphite surface, and arrays of hundreds of wires may be transferred onto glass surfaces using a simple embedding process. These transferred nanowires can form the basis for chemical sensors in which the resistance of the nanowire array is modulated by molecules that chemisorb at the surfaces of these metals. Two examples involve palladium nanowires in the presence of hydrogen, and silver nanowires in the presence of amines. For both of these systems, the changes in resistance ($\Delta R/R_o$) can be 1000% or more, but the mechanism response for the resistance changes are completely different. What is the origin of these enormous and unexpected resistance changes? In this talk, we focus attention on this issue and we discuss the prospects for developing practical chemical sensors based on these novel mechanisms.

**W10 2 Novel Metallic Surface Arrays for SERS and Surface Forces Experiments** MARGO GRACA, JEFF TURNER, SUNG CHUL BAE, STEVE GRANICK, *Departments of Physics, Chemistry, and Materials Science and Engineering, University of Illinois at Urbana-Champaign* Nanofabrication techniques based on FIB (dual-beam focused ion beam lithography) and utilizing a novel solid masking scheme have produced extended arrays of coinage metal nanostructures on muscovite mica and semiconductor wafers. First, the FIB process is used to drill holes in the mask with various alternative shapes, from circles to squares to triangles. Their size is variable from $<$ 100nm to many microns, and their spacing and arrangement are also easily varied. These novel structures were used for two emerging applications. First, we demonstrate nanostructured ''forest'' patterns, arranged perpendicular to the solid, with a high aspect ratio in height to cross-section. Alternatively, these new structures were embedded into hollow spaces within the solid substrate, producing a physically flat yet itchemically rough surface capable of electronic field enhancement. We demonstrate the ability of these new structures to enhance a Raman (SERS) signal with applications to nanoplasmonics.

**15:18**
**W10 3 Scattering T-matrix theory for surface enhanced Raman scattering in clusters of nanoscale metal particles** KARAMJEET ARYA, Very large enhancements up to 14 orders of magnitude in the Raman cross-section from a molecule adsorbed on a single cluster of a few nanaoscale metal particles has been reported recently. The enhancement is believed mainly due to the enhanced electric field because of the excitation of the localized surface plasmon modes. We have developed a Green's function theory using scattering t-matrix approach in the wave-vector space to solve the Maxwell equations for the enhanced field near a metal particle cluster. The large enhancement in the field is due to the multiple scattering of the local modes of the individual metal particles that has been included exactly. We have considered clusters of different shape and size, for example, clusters of two, three, or four spherical particles forming a liner chain, a triangle or a square. Examples of clusters formed on the glass and metal plates are also discussed. We find the enhancement in the Raman cross section can reach up to 10 orders of magnitude for silver particle clusters and is in a broad frequency range. The results for gold particle clusters are also presented.

**W10 4 Ordered Pore Arrays in Arrays in Alumina: Fabrication and Application Issues.***
ULRICH GOESELE, *Max Planck Institute of Microstructure Physics*

Ordered two-dimensional arrays of nanopores in alumina have become a popular model system in nanotechnology because of its ease of fabrication and versatility in terms of geometrical parameters and of using it as template for a variety of materials. The presentation will cover the original two-step approach by Masuda published in Science in 1995 for selfordered pore arrays without long range order as well as nanoimprint and interference lithography approaches for long range ordered pore arrays. Guided self-assembly will also be covered. Metal filling of the pores by electrochemical deposition methods for magnetic storage applications and wetting of the pores by polymers which allows the fabrication of complex tube structures will be discussed. A novel method to get segmented nanotubes consisting e.g. of various gold and nickel segments will be described. Finally, the potential of atomic layer deposition in combination with porous alumina will be touched upon.

**W10 5 Fabrication of and application of anodic alumina film with custom-designed nanochannel arrays** NAI-WEI LIU, *Institute of Atomic and Molecular Sciences, Academia Sinica, Taipei, Taiwan, Republic of China* ANINDYA DATTA, CHIH-YI LIU, CHENG-YI PENG, HUAI-HSIEN WANG, SHR-BIN WU, TSU-SHIN CHAN, CHEN-FENG HSU, JUEN-KAI WANG, YUH-LIN WANG, *National Taiwan University, Taipei, Taiwan, Republic of China* Among the strategies for growing one-dimensional straight nanostructure such as nanorods and nanowires, a viable approach is to grow the materials into templates with aligned nanochannels. Recently, porous anodic aluminum oxide (AAO) film has become an attractive template material for its self-aligned array of nanochannels. In this work, we have demonstrated, for the first time, a focused ion beam (FIB) direct-write lithographic method for selectively closing part of the channels of an ordered array on an AAO film creates a custom-designed nanochannels array. The initial ordered arrays are fabricated by FIB lithographic guiding techniques while the closure of the nanochannels within certain area is achieved by FIB bombardment of the AAO film. Besides, arrays of Ag-nanoparticles grown on anodic alumina nanochannels with precisely tunable gaps (5-25 nm) are exploited for surface-enhanced Raman spectroscopy. The enhancement becomes significant for gaps below 10 nm and turns dramatic when gaps reach an unprecedented value of 5 nm. The results are quantitatively consistent with theories based on collectively coupled surface plasmon.

**W10 6 Novel Solid State Fabrication Techniques*** T. L. MOORE, *Department of Physics, University of Maryland, College Park, MD 20742* D. R. HINES, *Laboratory for Physical Sciences, University of Maryland, College Park, MD 20742* E. GOMAR-NADAL, E. D. WILLIAMS, *Department of Physics, University of Maryland, College Park, MD 20742* We have electrochemically fabricated high dielectric coatings and nanowires in porous membranes. TEM images showed the nanowires to contain grains of

single crystallinity. I-V characteristics of dielectric coatings have been investigated to optimize resistivity for minimum thickness. We will report on transport properties of structures constructed using these novel components. The feasibility of incorporating these electrochemically prepared solid state structures in nanoimprinted pentacene thin-film transistors will be evaluated.

**W10 7 Confined self-organization of a lattice of surface magic-cluster and its structure determination** HSUAN-HAO CHANG, MING-YU LAI, YUH-LIN WANG, CHING-MING WEI, INSTITUTE OF ATOMIC AND MOLECULAR SCIENCES COLLABORATION, DEPARTMENT OF PHYSICS, NATIONAL TAIWAN UNIVERSITY COLLABORATION, The ability to create an ensemble of nanostructures with specific size, shape, and arrangement on particular positions in space is one of the most important issue in the exploration nanoscience and realization nanotechnology. We have been exploring methods to set an initial structure of a substrate surface, which provides desirable constrains to self-organization process and lead to the formation of arrays of nanostructures with identical size and structure. A two dimensional lattice of Ga surface-magic-clusters (SMC), i. e. clusters exhibiting enhanced stability at certain sizes on a particular surface, has created by using the Si(111)-7x7 surface as a confining template. The structure of the individual SMC is determined by a combination of STM, density-functional calculations, and dynamic low energy electron diffraction. The diffraction method is applicable because the SMCs have identical size/structure and form an ordered array with the exact translational symmetry. The unprecedented detailed structure information provided by the diffraction measurement is consistent with direct microscopic imaging and theoretical calculations.

**W10 8 Reversible adsorption of Au nanoparticles on $SiO_2$/Si: an in situ ATR-IR study*** D. ENDERS, *KIP, Heidelberg Univ.* T. NAGAO, *NIMS, Tsukuba, Japan* A. PUCCI, *KIP, Heidelberg Univ.* T. NAKAYAMA, *NIMS, Tsukuba, Japan* Adsorption and desorption of Au nanoparticles (AuNP) on the (aminopropyl)triethoxysilan (APTES) treated $SiO_2$/Si surface was monitored by itin situ attenuated total reflection (ATR) infrared spectroscopy in combination with a liquid flow cell. With increasing the AuNP coverage at the surface, the absorption by water vibration was increased due to surface enhanced infrared absorption (SEIRA). Repulsive electrostatic forces between the incoming AuNP and the already adsorbed AuNP layer lead to saturation at submonolayer coverage of the surface. We clarified that the adsorption process can be described very well by a diffusion limited first-order Langmuir-kinetics model. Furthermore, we show that the AuNPs desorb from the surface when they are exposed to the solution of aminoethanethiol (AET).

**W11 1 Chemical Functionalities in the non-scalable size-regime.**
UELI HEIZ, *Technische Universität München, Lehrstuhl für Physikalische Chemie I, Garching*

The reactivity and optical properties of nanoscale systems are mainly dominated by quantum-size effects that govern the electronic spectra of clusters, by the structural dynamical fluxionality of clusters, as well as by impurity-doping effects. In this talk these fundamental and unique cluster properties will be illustrated by specific examples obtained from molecular beam experiments in the gas phase and experiments on size-selected clusters on surfaces. Where possible, concepts for their understanding are given. Specifically, in the first part of the talk new results on the optical properties of small gold clusters on amorphous silica will be presented, where Cavity Ringdown Spectroscopy is used to measure optical transitions of clusters at surfaces with extremely high sensitivity. In the second part of the talk a new approach for obtaining thermodynamic properties of chemical reactions by using micromechanical devices is introduced and an overview of results on the catalysis of gold clusters is presented. By combining these experimental data with ab-initio calculations, a picture of the peculiar catalytic behavior of gold is now emerging.

**W11 2 Structure and Reactivity of $M_xS_y^+$ (M= Mo,W) Clusters with CO in the Gas Phase: an Experimental and DFT Study** MELISSA PATTERSON, JAMES LIGHTSTONE, *Stony Brook University* MICHAEL WHITE, *Stony Brook University / Brookhaven National Laboratory* We have recently constructed a cluster deposition apparatus which employs a magnetron sputtering source for generating gas-phase cation clusters of pure metals and metallic compounds. Of particular interest are clusters of the transition metal sulfides, $M_xS_y^+$ (M = Mo, W), which are known in their bulk form to be active catalysts for a wide range of heterogeneous reactions. The work reported here examines the gas-phase reactivity of small transition metal sulfide clusters as a first step towards investigations of model catalysts prepared by size-selected deposition. Specifically, we have used density functional theory (DFT) along with mass spectroscopy and gas-phase collision studies to examine the structure and stability of small sulfide clusters, $M_xS_y^+$ (x/y = 2/6, 3/7, 4/6, 5/7, 6/8, 7/10, 8/12). The

number of metal sites was probed through the formation of adducts with CO, which was introduced into a hexapole collision cell. Calculated binding energy curves for the addition of CO onto available metal sites were compared with experiment to give insight as to which geometry for the bare clusters fit best. Results will be presented for the calculated structures and stabilities of the prominent clusters as well as their adducts.

**W11 3 Oxidation of CO on various $Fe_2O_3$ surfaces: A Theoretical Study** ANIL KANDALAM, PURU JENA, SHIV KHANNA, BAPPA CHATTERJEE,* *Virginia Commonwealth University* B.V. REDDY, *Philip Morris USA* Recent experiments indicate that $Fe_2O_3$ nanoparticles can oxidize CO to $CO_2$ in the absence or presence of $O_2$. Depending on the size and experimental conditions, a $Fe_2O_3$ nanoparticle can have different faces that correspond to bulk surfaces of various orientations; which in turn can affect the catalytic activity of the nanoparticle. Hence, an understanding of the reaction pathways, transition barriers, and the feasibility of CO oxidation on bulk surfaces of different orientations are critical to optimize the selection of nanoparticles. Theoretical investigations of the oxidation of CO on various $Fe_2O_3$ surfaces using gradient corrected density functional approach has been carried out. BPW91 functional form and double numeric basis set (DNP), as implemented in Dmol3 code are employed here. Different $Fe_2O_3$ (corundum) faces/surfaces are modeled by a cluster where the edge atoms are saturated by H atoms to simulate the effect of the infinite surface. Results corresponding to the reaction of CO with (100) and oxygen terminated (0001) surfaces at various surface sites; oxidation of CO, both in the presence as well as absence of oxygen, will be presented and discussed.

**W11 4 Efficient Low-Temperature Oxidation of Carbon-Cluster Anions by $SO_2$** ANDREW LEAVITT, *University of West Georgia* RICHARD WYWRAS, WILLIAM WALLACE, *Georgia Institute of Technology* DANIEL SERRANO, *University of West Georgia* MELISSA ARREDONDO, *Georgia Institute of Technology* LOGAN LESLIE, FAROOQ KHAN, *University of West Georgia* ROBERT WHETTEN, *Georgia Institute of Technology* Carbon-cluster anions, $C_N^-$, are very reactive toward $SO_2$ (sticking probability of $0.012 \pm 0.005$ for $C_{27}^-$ at 25 $^o$C), in contrast to their inertness toward other common atmospheric gases and pollutants. In flow-reactor experiments at ambient temperature and near atmospheric pressure, primary adsorption of $SO_2$ by the carbon cluster anions, $N = 4 - 60$, yields $C_NSO_2^-$ or $C_{N-1}S^-$. The inferred elimination of neutral $CO_2$ is also detected as meta-stable decay in collision-induced dissociation. At higher temperatures, the reaction of $SO_2$ with nascent carbon clusters yields $C_{N-1}SO^-$ as well as undetected CO. Such carbon clusters are formed in sooting flames and may act as nuclei for the formation of primary soot particles, and serve as models for the local structural features of active soot particle sites for black-carbon soot. The facile generation of reactive carbon-sulfide and –sulfinate units may therefore have implications for understanding the health and environmental effects attributed to the coincidence of soot and $SO_2$.

**W11 5 Oxidation of magnesia-supported Pd-clusters leads to the ultimate limit of epitaxy with a catalytic function.** MICHAEL MOSELER, *Fraunhofer Institute for Mechanics of Materials*

Oxide-supported transition metal clusters and nanoparticles have recently attracted significant attention due to their important role as components of model-catalysts, sensors, solar-cells and magnetic recording devices. For small clusters, functionality and structure are closely interrelated. However, knowledge of the structure of the bare cluster is insufficient since the interaction with the chemical environment might cause drastic structural changes. Here we show by ab initio simulations based on the density functional theory that the reaction with molecular oxygen transforms small, non-crystalline, magnesia-supported Pd-clusters to crystalline $Pd_xO_y$ nano-oxide clusters that are in epitaxy with the underlying support [1]. Restructuring of the Pd backbone is controlled by the electrostatic interaction with magnesia leading to a strong reduction of the $O_2$dissociation barrier. The supported $Pd_xO_y$ clusters are likely to serve as Mars-van-Krevelen oxygen reservoirs in catalytic oxidation reactions as observed previously for PdO overlayers and demonstrated here for the oxidation of CO molecules. **W11 6 Size effects on catalytic activity of supported metal clusters** TIANPIN WU, WILLIAM KADEN, SCOTT ANDERSON, *Chemistry/U of Utah* Size-selected cluster deposition is used to prepare and study model catalysts with size-selected gold and iridium clusters supported on single crystal oxide supports. Chemistry is found to be strongly size-dependent and a combination of ion scattering and xray photoemission is used to probe the origins of the effects.

**16:30**

**W11 7 The origin of catalytic activity of supported noble-metal nanoparticles** S.N. RASHKEEV, A.R. LUPINI, S. J. PENNYCOOK, S.T. PANTELIDES, *Oak Ridge National Laboratory* Supported Au nanoparticles $< 5$ nm show a sharp rise in the low-temperature catalytic oxidation of CO while the reverse occurs for Pt nanoparticles. Subsequent experimental and theoretical investigations focused on Au nanoparticles and reached conflicting conclusions, attributing the enhanced Au activity to particular nanoscale features such as perimeter sites and low-coordination atoms, or to a particular bilayer structures, independent of particle size. Here we report atomically-resolved Z-contrast images of on $TiO_2$-supported Au nanoparticles and theoretical results on an ensemble of rutile- and anatase- supported Au and Pt nanoparticles. We

show that high catalytic activity requires that (i) reaction barriers are small, (ii) reaction barriers are smaller than desorption energies of reacting molecules. As nanoparticle size is reduced, attached molecules induce reconstruction of Au clusters, resulting in looser Au-Au bonding and higher desorption energies and smaller reaction barriers for the attached molecules. Pt clusters get tighter by attached molecules, resulting in larger reaction barriers. The bilayer gold structures (M. S. Chen and D. W. Goodman, Science **306**, 252 (2004)) are extremely active because local reconstruction significantly reduces coordination of Au atoms. This work was supported in part by DOE Grant DE-FC02-01CH11085 and by DOE Division of Chemical Sciences under contract No. DE-AC05-00OR22725 with ORNL.

**W11 8 Supported Gold and Platinum Clusters: Stability under Vacuum and Hydrogen at Elevated Temperatures; Optical Properties*** STEFAN VAJDA, RANDALL WINANS, GREGORY BALLENTINE, ALEXANDRE BOUHELIER, JEFFREY ELAM, BYEONGDU LEE, MICHAEL PELLIN, SOENKE SEIFERT, GEORGE TIKHONOV, GARY WIEDERRECHT, *Argonne National Laboratory* The Achilles heal of supported clusters remains their low stability at elevated temperatures or when exposed to reactive gases. In this paper, the stability of $Au_n$ and $Pt_n$ clusters (n=6-10) supported on $SiO_2$, $Al_2O_3$ & $TiO_2$ films is addressed. The clusters were heated in vacuum and in $H_2$ atmosphere, their stability monitored by synchrotron grazing incidence small angle X-ray scattering. Pt clusters supported on $Al_2O_3$ did not undergo sintering in vacuum and when exposed to hydrogen during a lengthy heat treatment reaching 400°C; Au clusters on $SiO_2$ remained stable up to 350°C. These temperatures are considerably higher than those characteristic for the onset of the catalytic activity of these clusters. Results on heat-induced structural isomerization of clusters will be shown. Single-particle UV-VIS spectra of Au-particles obtained by dark-field microscopy will be presented as well.

**W11 9 Clusters at Surfaces Studied with Low-Temperature STM and UPS*** T. IRAWAN, S. KRAUSE, M. BIELETZKI, H. HÖVEL, *Universität Dortmund, Experimentelle Physik I, 44221 Dortmund, Germany* C. YIN, B. V. ISSENDORFF, *Universität Freiburg, Fakultät für Physik, 79104 Freiburg, Germany* We study the electronic structure of cluster/surface systems and the nature of charge transfer processes between the cluster and the surface. STM/STS and UPS on size selected large clusters in contact with a surface will be combined with photoemission on the same clusters in the gas phase. For metal islands (Au, Pb) on different surfaces (HOPG, Au(111) and Pb(111)) we observed significant energetic shifts in UPS if the islands were decoupled from the surface by a thick rare gas layer and different materials for the substrate and the islands were used [1]. In addition we measure mass spectra of size selected Ag clusters with a cluster machine consisting of a magnetron sputter gas aggregation source, a differential pumping stage with a cryo pump and a high transmission infinite range mass selector. In current experiments we extend these studies to the deposition of mass selected clusters on rare gas layers and different substrate systems. For these samples low-temperature STM and UPS will be compared with photoemission on the same clusters in a free cluster beam. [1] T. Irawan, D. Boecker, F. Ghaleh, C. Yin, B. v. Issendorff and H. Hövel, Appl. Phys. A (published online Sept. 2005)

**W11 10 Size-Selected $Au_n$ and $Ag_n$ Nanoclusters on Rutlie $TiO_2$(110)-1x1 Surfaces Probed by UHV-STM.*** STEVE BURATTO, XIAO TONG, LAUREN BENZ, STEEVE CHRETIEN, PAUL KEMPER, HORIA METIU, MICHAEL BOWERS, *University of California, Santa Barbara* Catalysis of the oxidation of CO and small olefins by $Au_n$ and $Ag_n$ nanoclusters on oxide supports is known to be strongly dependent on the size of the cluster and its interaction with the oxide surface. In our group we have probed this size dependence by depositing size-selected clusters of $Ag_n^+$ and $Au_n^+$(n = 1-7) from the gas phase onto single crystal rutile $TiO_2$ (110) (1x1) surfaces at room temperature under soft-landing ( $<$ 2 eV/atom) conditions. We analyze the clusters on the surface using ultra-high vacuum scanning tunneling microscopy (UHV-STM) and compare the resulting structures with theory. In the case of $Au_n^+$, $Ag^+$and $Ag_2^+$ clusters deposited under soft-landing conditions we observe large, sintered clusters indicating high mobility for these species on the surface. For $Au_n^+$ ($n \geqslant 2$) and $Ag_n^+$ ($n \geqslant 3$) clusters deposited under soft-landing conditions, however, we observe a high density of intact clusters bound to the surface and no sintered clusters indicating that these species have very limited mobility on the surface. For the intact clusters we can also observe the binding site and geometry of the cluster in the STM image and compare these with structures calculated using density functional theory (DFT) as well as with structures observed in the gas phase.

*The work was supported by the AFOSR DURINT program.

**W11 11 Angle-resolved photoemission of Au clusters on graphite: quantized surface states on cluster facets*** H. HÖVEL, I. BARKE, *Universität Dortmund, Experimentelle Physik I, 44221 Dortmund, Germany* We present an experimental study for the electronic properties of metal clusters on surfaces. For the specific case of the confined Shockley surface state on the top (111) facets of gold clusters on graphite [1] we were able to detect the quantized electronic structure with two independent experimental techniques, scanning tunneling spectroscopy (STS) and ultraviolet photoelectron spectroscopy (UPS). Here we present new UPS data and their analysis which shows a quantitative agreement if we compare the density of states, extracted from the STS spectra by averaging over the cluster size distribution, with the UPS spectra using a deconvolution to compensate the dynamic final state effect [2] which leads to a systematic asymmetric broadening of all valance band UPS features [3]. **W12 1 Influence of interfacial structure on the charge transfer between adsorbed $C_{60}$ and Cu(111)** WOEI WU PAI, J.H. LIN, *Center for Condensed Matter Sciences, National Taiwan University, Taipei 106, Taiwan R.O.C.* A.D. ZHAO, X.Q. ZHANG, X.D. XIAO, *Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong* $C_{60}$ adsorption on metal surfaces typically incurs different amount of charge transfer from the substrate to the molecules. The charge transfer amount has never been found to approach that of optimally doped fulleride, e.g., $K_3C_{60}$, in which three electrons occupy the $C_{60}$ LUMO states. Here we demonstrate that $C_{60}$ adsorbed on Cu(111) render a nearly optimally doped fullerene film. The critical factor to produce such strong charge transfer is the identification of interfacial reconstruction in which a $C_{60}$ most probably resides in a monolayer pit consisting of seven removed Cu atoms. A direct comparison of low temperature (77 K, 4 K) STS on $C_{60}$ regions with and without interfacial reconstruction reveals drastic differences in charge transfer amount. Our STM/STS results are also consistent with a recent photoemission study [1] showing the optimal doping characteristic of the same system. This study thus demonstrates the importance of interfacial structure, which is often based on assumption, on prominent properties of molecular thin films. [1] C. M. Cheng, K. D. Tsuei, unpublished.

**14:42**
**W12 2 Coverage dependent supramolecular structures: 2D phases of $C_{60}$:ACA monolayers on Ag(111)*** BO XU, CHENGGANG TAO, ELLEN WILLIAMS, JANICE REUTT-ROBEY, *University of Maryland* The dependence of supramolecular structures on fractional molecular coverage in a 2-component adlayer has been investigated using scanning tunneling microscopy. A series of acridine-9-carboxylic acid (ACA) surface structures emerges sequentially when deposited on Ag(111) at room temperature. At low molecular coverage ($\theta < 0.4ML$), ACA forms a two-dimensional gas phase. Ordered ACA structures appear with increased coverage: firstly a chain structure composed of ACA molecules linked by O–H $\cdots$ N hydrogen bonds ($\theta > 0.4ML$), then a dimer structure composed of ACA dimers linked by carboxyl-carboxyl hydrogen bonds ($\theta \sim 1.0ML$). The structures of the $C_{60}$:ACA binary system depend on the coverage of pre-deposited ACA. When the initial ACA coverage is between 0.4 ML and 0.8 ML, subsequent $C_{60}$ deposition results in a hexagonal cooperative structure with $C_{60}$ period nearly three times as large as the normal $C_{60}$ 2-D packing of 1 nm, and exists in enantiopure domains. A $C_{60}$ quasi-chain structure is formed when the initial ACA coverage is above 0.8 ML. Parallel $C_{60}$ chains are separated in space by the ACA dimer structure. Chemically reasonable molecular packing model are presented based on the observed STM images.

**14:54**
**W12 3 Step fluctuations on Ag(111) surfaces with $C_{60}$*** CHENGGANG TAO, TIM STASEVICH, TED EINSTEIN, ELLEN WILLIAMS, *Physics Department, University of Maryland, College Park* STM has been used to characterize fluctuation properties of segments of step edges partly covered by $C_{60}$ on Ag(111) at room temperature. The distribution of $C_{60}$ at step edges exhibits a step orientation dependence: low-symmetry step edges are more favorable for $C_{60}$ binding. The temporal correlation functions of step segments between $C_{60}$-covered step regions scale as a power law, with an average exponent of $0.23 \pm 0.02$, indicating that fluctuations of these ''confined'' steps are consistent with step-edge diffusion limited fluctuations. Parameters extracted from temporal correlation and autocorrelation analysis consistently indicate that close-packed steps have smaller fluctuation magnitude and higher step mobility than low-symmetry steps. The measured system sizes of step segments with different lengths show at most a weak step-length dependence. Fluctuation features thus yield the surprising conclusion that $C_{60}$ molecules are not acting as pinning points that constrain mass transport along the step edges.

**W12 4 Self-intermixed patterns of perylene derivatives** MEIKE STOEHR, MARKUS WAHL, TOMAS SAMUELY, *University of Basel, Switzerland* THOMAS A. JUNG, LUTZ H. GADE, *University of Heidelberg, Germany* Self-assembled systems are in the focus of nanotechnology research because of their potential use in the ''bottom-up'' creation of functional supramolecular structures. Potential applications of such systems include several functional groups. Therefore, the intermixing of different molecular compounds will become a key issue. In our approach we made use of H-bonding to form well-ordered intermixed patterns of two different perylene derivatives - PTCDA and DPDI. In an UHV-setup thin films of DPDI and PTCDA were prepared by evaporation on Ag(111). The sample characterization was carried out with a homebuilt STM. For a ratio of 1:1 and a total coverage of about one monolayer, an ordered intermixed pattern was observed. Each PTCDA molecule is interacting via H-bonding with four neighbouring DPDI molecules and vice versa. Furthermore, different intermixed patterns were observed depending on the ratio of the molecules and on the total coverage.

**W12 5 Directed self-assembly of virus particles at nanoscale chemical templates** SUNG-WOOK CHUNG, CHIN LI CHEUNG, *Lawrence Livermore National Laboratory* ANJU CHATTERJI, TIANWEI LIN, JACK JOHNSON, *Scripps Research Institute* JIM DE YOREO, *Lawrence Livermore National Laboratory* Because viruses can be site-specifically engineered to present catalytic, electronic, and optical moieties, they are attractive as building blocks for hierarchical nanostructures. We report results using scanned probe nanolithography to direct virus organization into 1D and 2D patterns and itin situ AFM investigations of organization dynamics as pattern geometry, inter-viral potential, virus flux, and virus-pattern interaction are varied. Cowpea Mosaic Virus was modified to present surface sites with histidine (His) or cysteine (Cys) groups. Flat gold substrates were patterned with 10-100nm features of alkyl thiols terminated by Ni-NTA or meleimide groups to reversibly and irreversibly bind to the Hys and Cys groups, respectively. We show how assembly kinetics, degree of ordering and cluster-size distribution at these templates depend on the control parameters and present a physical picture of

virus assembly at templates that incorporates growth dynamics of small-molecule epitaxial systems and condensation dynamics of colloidal systems. This work was performed under the auspices of the U. S. Department of Energy by the University of California, Lawrence Livermore National Laboratory under Contract No. W-7405-Eng-48.

**W12 6 Enhanced Chemisorption of $Cu(hfac)_2$ on Parylene Surface by $N_2$ Plasma Treatment** S. PIMANPANG, P.-I WANG, D.-X. YE, J. S. JUNEJA, G.-C. WANG, T.-M. LU, *Dept. of Physics, Rensselaer Polytechnic Inst., Troy, NY 12180* The metallization of polymers has been intensively studied due to its wide industrial applications. We report a study of interfacial interaction of metalorganic $Cu(hfac)_2$ with the Parylene surface. Parylene is a low k dielectric polymer prepared by a chemical vapor deposition technique. The as-deposited Parylene surface is shown to be hydrophobic with a measured water droplet contact angle $\sim$ 72°. However, after the $N_2$ plasma treatment, the water droplet contact angle decreases to $\sim$ 40° due to the formation of oxygen and nitrogen functional groups on the surface, as observed by x-ray photoelectron spectroscopy (XPS). These functional groups improve $Cu(hfac)_2$ chemisorption on the plasma treated Parylene surface. Further studies by XPS show that chemisorption of $Cu(hfac)_2$ is self-limiting up to 20 sec of $Cu(hfac)_2$ precursor exposure time. The enhancement of chemisorption of metalorganic precursors on the polymer surface is an important step for chemical vapor deposition or atomic layer deposition of metal. [a]Supported by Thai govt. fellowship (SP) and SRC (JSJ).

**W12 7 Surface Dynamics in thin films of a small organic glass-former** STEPHEN SWALLEN, MARIE MAPES, KENNETH KEARNS, MARK EDIGER, *University of Wisconsin - Madison* SUSHIL SATIJA, *NIST* Enhanced dynamics of molecules near the free surface of thin supported films have been measured using neutron reflectivity. Thin films of the small molecule glass former tris-naphthylbenzene were vapor deposited with subnanometer initial surface roughness, allowing diffusion rates to be measured between isotopically labeled layers. Measured dynamics suggest a mobile surface layer of about 4 nm with a significant decrease in Tg. This can be compared with recent measurements in polymeric systems which find thick active layers and Tg shifts up to 30 K.

**15:54**

**W12 8 Topography and Wetting of Dotriacontane Films on Graphite Surfaces*** MATTHEW SIMPSON, MENGJUN BAI, KLAUS KNORR, HAIDING MO, HASKELL TAUB, *U. Mo.-Columbia* STEVEN EHRLICH, *Brookhaven Nat. Lab.* ULRICH VOLLKMANN, *P. U. Católica Chile* FLEMMING HANSEN, *Tech. U. Denmark* We have used Atomic Force Microscopy (AFM) in the noncontact mode and synchrotron x-ray diffraction to investigate the structure, morphology, and wetting of dotriacontane ($n$-$C_{32}H_{66}$ or C32) films deposited from a heptane solution onto highly-oriented pyrolytic graphite (HOPG). Consistent with previous neutron diffraction measurements,[1] the x-ray patterns indicate one to two layers immediately adjacent to the HOPG surface in which the molecules are oriented with their long axis parallel to the interface. Above these parallel layers, the AFM images show a partial layer of C32 molecules oriented with their long axis perpendicular to the surface. Upon heating above room temperature, we observe the area occupied by the perpendicular monolayer first to increase and then to decrease. Just above the bulk melting point, the perpendicular monolayer dewets the underlying parallel layers as we have found for C32 films adsorbed on a $SiO_2$substrate. [1]K. W. Herwig, B. Matthies, and H. Taub, Phys. Rev. Lett. **75**, 3154 (1995).

*Supported by Grant Nos. NSF DMR-0411748, DOE W-7405-Eng-82 and W-31-109-Eng-38, and FONDECYT 1010548 and 7010548.

**W12 9 Ellipsometric Measurements of Dotriacontane Films Adsorbed on Au(111) Surfaces*** P. SOZA, V. DEL CAMPO, E. CISTERNAS, M. PINO, U.G. VOLKMANN, H. TAUB, F.Y. HANSEN, We have conducted ellipsometric and stray light intensity measurements on dotriacontane ($n$-$C_{32}H_{66}$ or C32) films adsorbed on Au(111) substrates in air as a function of temperature in order to determine their optical thickness and surface roughness. The C32 films were deposited from a heptane ($n$-$C_7H_{16}$) solution onto the gold surface. Our large, atomically flat gold substrates were produced by the method reported by Hegner et al.[1] in which gold films grown on mica are glued onto Si(100) wafers. For films of 25 Å thickness, our ellipsometry measurements show a decrease of about 75% in the height of the monolayer substep compared to the same film adsorbed on $SiO_2$substrates.[2] This substep is believed to be contributed by a monolayer phase in which the molecules are oriented with their long axis perpendicular to the surface. The substep decrease may be interpreted as reduction in the number of molecules in this phase or possibly a tilting of the molecules. [1]M. Hegner et al., Surf. Sci. **291**, 39 (1993). [2]U.G. Volkmann et al., J. Chem. Phys. **116**, 2107 (2002).

**W12 10 Comparison of Thickness and Morphology of Dotriacontane Films on $SiO_2$/Si Surfaces Vapor-deposited in High Vacuum with those Deposited from Solution*** E. CISTERNAS, P. SOZA, V. DEL CAMPO, E. RAMIREZ, U.G. VOLKMANN, *P. U. Católica Chile* H. TAUB, *U. Mo.-Columbia* F.Y. HANSEN, *Tech. U. Denmark* We have used Very High Resolution Ellipsometry (VHRE) and Atomic Force Microscopy in the noncontact mode to compare the thickness and morphology of dotriacontane ($n$-$C_{32}H_{66}$ or C32) films deposited by two different methods on Si(100) wafers coated with their native oxide. During deposition, the substrate temperature was held below the bulk melting point of C32. As monitored by VHRE, the film thickness of different samples was found to be in the range 20 Å to 400 Å. Films deposited by physical vapor deposition from a Knudsen cell in high vacuum are optically smooth and homogeneous, while deposition by dip-coating from a heptane solution also results in optically smooth but less homogeneous layers. Heating/cooling cycles were performed on these two sample types while conducting VHRE and stray light intensity measurements in order to compare the wetting behavior and surface roughness of C32 as a function of film thickness on both hydrophilic and hydrophobic $SiO_2$/Si surfaces.

**W12 11 Controlling growth kinetics and morphology of crystal surfaces through biomolecular interactions** JIM DE YOREO, ROGER QIU, *Lawrence Livermore National Laboratory* SELIM ELHADJ, PATRICIA DOVE, *Virginia Tech* GERMAINE FU, DANIEL MORSE, *University of California at Santa Barbara* ALAN SALTER, ANDRZEJ WIERZBICKI, *University of South Alabama* The complex shapes and hierarchical designs of biomineralized nanostructures arise from biomolecular controls over crystallization. One prevailing view is that mineral-associated macromolecules are responsible for nucleating and stabilizing non-equilibrium polymorphs and morphologies through interactions at crystal surfaces. Here we report results of itin situ AFM and molecular modeling investigations of calcite growth in the presence of acidic amino acids, polypeptides, and proteins associated with biomineral formation. We show how the sterochemical relationship between modifier and crystal lattice lead to step-specific interactions and how those interactions account for the changes in kinetics and morphology. We analyze the results in terms of classic physical models of crystal growth and epitaxy and show that there are important deviations from those classic models that stem, in part, from the low kink density of steps on calcite. This work was performed under the auspices of the U.S. Department of Energy by the University of California, Lawrence Livermore National Laboratory under contract No. W-7405-Eng-48.

**W12 12 Mixing in a Solid Monolayer: $SF_6$ + $C_2F_6$ on Graphite*** G. B. HESS, *Univ. of Virginia* B. L. ELLIS, YIZE LI, We have studied mixing of $SF_6$ and $C_2F_6$ in a solid monolayer film on graphite by admitting one gas to the cell to a pressure between monolayer condensation and saturation, then slowly admitting the other gas. The total coverage is monitored by ellipsometry and the condition of the individual adsorbates is determined by infrared absorption spectra. In particular, shifts in absorption lines due to dynamic dipole coupling indicate the local environment of molecules of each species. At 75 and 80 K there is no detectable solubility of $C_2F_6$in a dense $SF_6$ monolayer, then a layer of nearly pure $C_2F_6$condenses on top. At 86 K there is limited solubility of $C_2F_6$ in dense $SF_6$, followed by appearance of a second $C_2F_6$–rich phase in the monolayer. At 90 K and above, $C_2F_6$ appears to replace $SF_6$ by continuous substitution; thus there appears to be a 2-D solid consolute critical point near 90 K. If $SF_6$ is added to a higher-temperature, low-density $C_2F_6$ layer, the $C_2F_6$ molecules are rapidly compressed from flat or tilted orientation to axes perpendicular to the substrate, then are continuously diluted.

**W12 13 Energetic Study of the Flip-flop Motion of P(VDF-TrFE)*** XUEWEN WANG, LEI CAI, JIANDI ZHANG, *Florida International University* P. A. DOWBEN, *University of Nebraska-Lincoln* Ferroelectric copolymer P(VDF-TrFE) has attracted significant attention in material science and technology due to its excellent electromechanical properties and easy manipulation of the individual monomer or monomer clusters resulting in the change of the such properties. Theoretical aspect of the switching dynamics of P(VDF-TrFE) has been investigated by using the density function theory and compared with experimental results. Through calculation, we find a simple flipping of the individual monomer with lower energy that involves no change of the bond length and the bond angle of –C–C–, –C–H–, and –C–F–. These consist with the experimental results obtained with STM. We compare the STM image before and after the flipping of the monomers. Except the observation of the lattice shift at the boundary, we find no other structure distortion and no change in the inter- and intra- chain spacing.

**W12 14 Exploiting Photo-induced Reactions in Polymeric Thin Films to Create Hierarchically Ordered, Defect-free Materials** RUI TRAVASSO, OLGA KUKSENOK, ANNA BALAZS, *University of Pittsburgh* Computer simulations reveal how photo-induced chemical reactions in polymeric thin films can be exploited to create long-range order in materials whose features range from the sub-micron to the nanoscale. The process is initiated by shining a spatially uniform light on a 2D photosensitive AB binary blend, which thereby undergoes both a reversible chemical reaction and phase separation. When a well-collimated, higher intensity light is rastered over the sample, the system forms defect-free, spatially periodic structures, which resemble the phases of microphase-separated diblock copolymers. We then add a non-reactive homopolymer C, which is immiscible with both A and B. This component localizes in regions that are irradiated with a higher intensity light and one can effectively write a pattern of C onto the AB film. Rastering over the ternary blend with the collimated light now leads to hierarchically ordered patterns of A, B and C. The findings point to a facile, non-intrusive process for manufacturing high quality polymeric devices in a low-cost, efficient manner.

**W16 1 Extraordinary Electrical Conductance in GaAs-In Hybrid Structures*** YUN WANG, K.A. WIELAND, S.A. SOLIN, *Washington University in St.Louis* Following the demonstration of extraordinary magnetoresistance (EMR)in semiconductor-metal hybrids[1], it has been realized that EMR is but one example of a general class of EXX phenomena that can be geometrically enhanced by the judicious choice of sample geometry. Two other EXX phenomena reported recently are extraordinary piezoconductance, EPC, and extraordinary Optoconductance, EOC. Here we address a fourth EXX phenomena, extraordinary electrical conductance, EEC. We develop a new design concept for an EEC sensor, which is a van der Pauw plate structure of Si-doped GaAs with a non-magnetic metallic shunt on top so that the external E field is perpendicular to the interface. EEC arises from the current redistribution between the shunt and GaAs when an external E field lowers the Schottky barrier at the interface. This allows more electrons to tunnel through and results in a larger conductance. We compare the response of a sample with a Schottky barrier to an unshunted sample and to a shunted sample with an Ohmic contact.

The conductance of each sample was measured as a function of temperature, bias current and external perturbing field. In addition, we will compare the EEC structure to the Schottky diode structure to illustrate the advantages of an EEC sensor for static charge imaging.

**W16 2 High-power mid-infrared interband cascade lasers** MIJIN KIM, CHUL SOO KIM, CHADWICK CANEDY, WILLIAM BEWLEY, JAMES LINDLE, IGOR VURGAFTMAN, JERRY MEYER, *Code 5613, Naval Research Laboratory, Washington DC 20375* We have grown and fabricated interband cascade lasers (ICLs) with ''W'' active regions. The ICL structures were etched into 140-$\mu$m-wide ridges, with 100-$\mu$m-wide metal strips deposited in the middle, and operated epitaxial-side-up. Initial devices displayed lasing thresholds as low as 12 A/cm$^2$ at 78 K, series resistance as low as 0.21 m$\Omega \cdot$ cm$^2$, and a voltage efficiency of 96%. Cavity length studies on a series of ICLs with 5, 10, and 15 stages determined that the internal losses at 78 K were 16, 27, and 37 cm$^{-1}$, respectively, while the internal efficiencies were $\approx$ 80% in all cases. Pulsed operating temperatures as high as 300 K were obtained, and a 5-stage device with 0.5 mm cavity length had a wallplug efficiency per facet of $\approx$ 20% without facet coatings. A 3-mm-long laser with high-reflection (95%) and antireflection (5%) coatings produced $>$ 1.1 W of cw output power at 78 K.

**14:54**

**W16 3 Single-Mode Distributed-Feedback ''W'' Diode and Interband Cascade Lasers in the Mid-Infrared** CHUL SOO KIM, MIJIN KIM, CHADWICK CANEDY, WILLIAM BEWLEY, JAMES LINDLE, IGOR VURGAFTMAN, JERRY MEYER, *Code 5613, Naval Research Laboratory, Washington DC 20375* To obtain spectrally pure output, we have fabricated narrow index–guided ridges with lateral distributed-feedback (DFB) line gratings on both ''W'' diode and interband cascade lasers. The ''W'' diode structure containing a GaSb *p*-SCH etch-stop layer was chemically etched into a 5 $\mu$m ridge and a first-order DFB grating constructed on both side walls of the ridge. For the interband cascade laser, a first-order top DFB grating was patterned on top of a chemically-etched ridge that was 15 $\mu$m wide. The low-loss DFB mode was roughly resonant with the gain peak at $T =$ 165 K for the ''W'' diode and at $T =$ 110 K for the interband cascade laser. The sidemode suppression ratios were definitely $>$ 20 dB for both devices, and all of the features above 30 dB appeared to result from instrument noise rather than actual parasitic modes. Just beyond the stop band on the long-wavelength side of the ''W'' diode DFB, a series of longitudinal modes became apparent at $>$ 30 dB suppression. For the narrow-ridge waveguide DFB devices, the temperature ranges over which single-mode lasing were successfully obtained were 140-162 K for the ''W'' diode, for which $\lambda = 3.195 \sim 3.202$ $\mu$m (0.29 nm/K), and 110-125 K for the interband cascade laser, for which $\lambda = 3.452 \sim 3.456$ $\mu$m (0.27 nm/K).

**W16 4 High Resolution 2D dopant profiling of FinFET structures and Silicon-based Devices using Scanning Probe Microscopies** A. KHAJETOORIANS, *UT at Austin Physics Dept.* X.D. WANG, *APRDL, Freescale Semiconductor* J. LI, *UT at Austin Physics Dept.* D. GARCIA-GUTIERREZ, *UT at Austin Dept. of Chem. Engr.* J. DENYSZYN, *UT at Austin: Texas Materials Inst.* H. CELIO, D. PHAM, A. DIEBOLD, *International SEMATECH* J. GOODENOUGH, *UT at Austin: Texas Materials Inst.* M. JOSE-YACAMAN, *UT at Austin Dept. of Chem. Engr.* C.K. SHIH, *UT at Austin Dept. of Physics* The ability to perform dopant/junction profiling with high spatial resolution is critical for development of future generation devices such as FinFET structures. Among various forms of scanning probe microscopy, scanning tunneling microscopy (STM) has demonstrated direct atomic imaging of dopant atoms on GaAs (110) surfaces. More recently, scanning thermoelectric microscopy (SThEM) (H.K. Lyeo et al itScience v.303 p816 (2004)) has been applied to profile GaAs $p - n$ junction with unprecedented spatial resolution. The key challenge to successfully apply these techniques to silicon-based devices is to prepare a surface that is both chemically and electronically passivated. Here we present our progress toward this goal. We present STM and SThEM studies on Si $p - n$ junction devices including FinFET structures. We also present in-depth profiling of fin structures using scanning capacitance (SCM) and conductive atomic force microscopy (C-AFM) (Khajetoorians itet al APL (submission)).

**W16 6 Electron relaxation through multiphonon processes in a double quantum dot** VASILIOS STAVROU, *Dept. of Physics and Astronomy, University of Iowa, Iowa City, IA 52242-1479* XUEDONG HU, *Department of Physics, State University of New York at Buffalo, NY 14260-1500* We theoretically study the relaxation of the electron orbital states of a double quantum dot system due to two-phonon processes. In particular, we calculate how the relaxation rates depend on the separation distance between the quantum dots, the strength of quantum dot confinement, and the lattice temperature. Our results show interesting crossovers in the relative strength of different scattering channels as temperature is

varied. Furthermore, although at low temperatures two-phonon processes are much weaker compared to one-phonon processes in relaxing electron orbital states, at room temperature they are as important as one-phonon processes.

**15:42**

**W16 7 Dark current generation in a confined and depleted region of silicon** JAMES LAVINE, DANIEL MCGRATH, *Eastman Kodak Company* Dark current generation degrades the performance of silicon solid-state imagers. The present study examines whether a depleted region with defects supplies dark current to a photodiode when it is separated by a neutral region. Thermally-excited electron-hole pairs appear in the depleted region, which is confined by infinite potential barriers in two dimensions and a triangular potential well in the third. The triangular well has ground states of 0.036 and 0.058 eV for electric fields of 0.1 and 0.2 MV/cm, respectively. Lateral dimensions of 0.1 to 1.0 micrometers lead to high electron densities, which quench further dark current generation before excited states are occupied. As a result, the electrons must diffuse against the strong electric field and are unlikely to reach the photodiode. The same potential barrier accelerates the holes and creates electron-hole pairs by impact ionization. The electron would be generated near the top of the potential barrier. However, the probability that the hole acquires sufficient energy is 0.00001 for 0.2 MV/cm and 0.0028 for 0.3 MV/cm, based on J. S. Marsland in Solid-State Electronics 30, 125 (1987). If the defect is a gold atom at 55 C, this leads to 0.0056 and 1.6 electrons/s.

**15:54**

**W16 8 Measuring Ionization and Athermal Phonons: Detectors of the Cyrogenic Dark Matter Search*** KYLE SUNDQVIST, *University of California, Berkeley* FOR THE CDMS COLLABORATION, The Cryogenic Dark Matter Search (CDMS) is a search for weakly-interacting massive particles (WIMPS) in the halo of our galaxy. WIMPs are a favored solution to the dark matter problem in cosmology and particle physics. We will describe how CDMS measures simultaneously the number of charge carriers and the energy in athermal phonons created by particle interactions in Ge and Si crystals at a temperature of 50 mK. Together these distinct signals create a signature response for each event, allowing candidate WIMP interactions with nuclei to be discriminated from electromagnetic radioactive background which interacts with electrons. Combining this method with additional information contained in the athermal phonon signal shape, CDMS has achieved a sensitivity roughly ten times better than any other experiment in the world. These techniques introduce a number of unique challenges. Bias levels must remain at only a few volts, else the secondary phonons emitted by the drifted carriers dominate the original phonon signal. The neutralization of charge-trapping sites, even at concentrations of only $\sim 10^{10} cm^{-3}$, is of primary importance to the performance of charge collection. We present the methods of crystal neutralization, subsequent characterization, and representative phenomena encountered in practice.

**W16 9 Resistive all boron carbide neutron detectors*** ELLEN DAY, MANUEL DIAZ, CAROLINA ILIE, SHIREEN ADENWALLA, *Mechanical Engr., Physics and Astronomy and CMRA, Univ. of Nebraska-Lincoln* Semiconducting boron carbide is a promising material for true solid-state neutron detection [1]. An all boron carbide (BC) layer was deposited on sapphire ($Al_2O_3$) with sputtered Chrome/Gold electrical contacts. Resistance vs. temperature measurements indicate a $T^{-3/2}$ dependence and a band gap of $\sim$ 0.17eV. X-ray diffraction measurements confirm the similarities in crystal structure of the films grown on $Al_2O_3$ and Si. Detection area ranged from $0.25mm^2$ to $1mm^2$ and the thickness of the films ranged from 280nm to 600nm. Neutron detection measurements show no sharp spectral peaks but a long high energy tail which increased in counts as the reactor power was increased, in agreement with both monte carlo simulations and simple model calculations [2]. The low thermal neutron capture cross section of Al and O ensures that the entire neutron signal observed is from the resistive boron carbide layer, thus demonstrating the fabrication of an all boron carbide neutron detector. We show plots as a function of reactor power and thickness. [1] B.W. Robertson, S. Adenwalla, A. Harken, et al., Appl. Phys. Lett. **80**, 3644 (2002). [2] C. Lundstedt, A. Harken, E. Day, B. W. Robertson, S. Adenwalla, submitted to NIM.

**W16 10 What should neutron spectra from boron carbide devices look like?*** CARL LUNDSTEDT, ELLEN DAY, SHIREEN ADENWALLA, *Physics and Astronomy, Mechanical Engineering and CMRA, University of Nebraska-Lincoln, Lincoln, NE 68588* GEANT4 (Geometry ANd Tracking) monte carlo modeling was performed on boron based neutron detectors [1]. Two different detector geometries were used. Geometry 1 consisted of a boron carbide (BC) layer placed on a Silicon (Si) layer in a cylindrical design with thermal neutrons of energy 0.025eV incident on the BC face. Geometry 2 was a rudimentary calorimeter made by sandwiching a moderator material between two BC/Si layers. The energy deposition spectra for the BC/Si device of various BC layer thicknesses for geometry 1 are presented as well as the spectra for geometry 2. In geometry 2, by changing the moderator material and thickness, higher energy neutrons may be detected, due to thermaization of neutrons in the moderator material. We show results for incident neutrons ranging in energy from 0.025eV to 2.5MeV. [1] C. Lundstedt, A. Harken, E. Day, B. W. Robertson, S. Adenwalla, submitted to NIM.

*Work is funded by the State of Nebraska, ONR [N00014-04-1-0605] and NASA.

**W16 12 Alpha-Energy-Deposition-Profiling of Radioisotope $p-i-n$ Diodes for Power Generation** CORY CRESS, RYNE RAFFAELLE, *NanoPower Research Labs, R.I.T.* The high energy density and long half-life of certain alpha-emitting radioisotopes enables viable and long-lived power supplies to be fabricated on the micro-scale. A design incorporating an InGaP $p-i-n$ photovoltaic (PV) device that directly converts the kinetic energy of the alpha-particles into electricity represents both a scalable and efficient microsystem design. To better understand the relationship between the alpha-energy-deposition-profile (ADEP) and the maximum power conversion efficiency for this device structure, we have performed two systematic studies. In these studies, I-V characteristics for the InGaP PV device under alpha-flux are measured as a function of alpha source distance, and as function of aluminum film thickness (10 nm to 10 $\mu$m) which is deposited onto the surface of the PV device. Both techniques will alter the ADEP in relation to the active region of the PV device. These experimental results are compared to a theoretical model which utilizes Monte Carlo simulations and numerical calculations to determine the ADEP for the same device configuration. The understanding gained from this analysis has direct implications towards the fabrication of radioisotope microbatteries with structural characteristics that enable optimal power conversion efficiencies to be achieved.

**16:54**
**W16 13 Analysis of microwave-frequency field patterns in an externally-driven Single-Electron Transistor*** BRYAN HEMINGWAY, ANDREI KOGAN, *University of Cincinnati* We report a numerical study of electromagnetic field patterns that emerge in a Single-Electron Transistor (SET) device driven by a microwave-frequency signal. In an SET, an electronic droplet (quantum dot) containing a few electrons is connected to two macroscopic conductors via tunnel barriers, and DC current measurements are used to investigate the quantum properties of the lead-dot system. Our goal is to develop a method for a well-controlled excitation of few-electron devices with microwaves. Such capability is needed for investigating the intrinsic time scales of Kondo-correlated electrons, not accessible in static experiments. We study realistic model geometry of an SET defined lithographically on a semiconductor heterostructure such as GaAs/AlGaAs. We find that at frequencies $\sim$ 10 GHz and above, the microwave voltages across the sub-micron features of the SET can be drastically different from those applied to the large-scale pads and depend in a complex and sensitive way on the excitation frequency, thus presenting a challenge for dynamic transport experiments with SETs. We discuss possible strategies for resolving the problem.

**W16 14 The effect of negative electron affinity emitter materials on space charge mitigation of vacuum thermionic energy conversion devices** JOSHUA SMITH, *North Carolina State University* GRIFF BILBRO, *North Carolina State University* ROBERT NEMANICH, *North Carolina State University* Vacuum thermionic energy conversion (TEC) devices provide a way to convert heat directly into electrical work. The negative space charge effect has been an effect that significantly degrades the performance of these devices, requiring small interelectrode spacings for reasonable performance. Recently, Nitrogen doped, Hydrogen terminated, ultra-nanocrystalline diamond films have been investigated as possible candidates for low operating temperature, low work function emitter materials. Furthermore, these materials exhibit a so-called negative electron affinity (NEA) where the vacuum level lies below the conduction band minimum of the material. As a result of this NEA property, the distribution of thermionically emitted electrons will have some nonzero minimum initial velocity. A model was developed to determine the effect that the NEA property of these types of emitters have on mitigation of the space charge effect. The model shows that a TEC with an NEA emitter material will have comparable performance with a non-NEA emitter TEC with a smaller gap. Thus, it is possible to use NEA emitters to relax the requirement of a small gap distance.

**W18 1 Phonon sideband in optical spectra of C13 carbon nanotubes.**
SHIGEO MARUYAMA, *Dept. of Mech. Eng., The University of Tokyo*

Photoluminescence (PL) of single-walled carbon nanotubes (SWNTs) has been widely used for the measurement of chirality distribution of single-walled carbon nanotubes (SWNTs). However, there are unassigned peaks in the 2-D photoluminescence map plotted as a function of emission and excitation photon energy. In order to clarify the origin of these peaks, we have studied photoluminescence (PL) and resonant Raman scattering of single-walled carbon nanotubes (SWNTs) consisting of carbon-13 ($SW^{13}CNTs$) synthesized from a small amount of isotopically modified ethanol [1]. There was almost no change in the Raman spectra shape for $SW^{13}CNTs$ except for a downshift of the Raman shift frequency by the square-root of the mass ratio 12/13. By comparing photoluminescence excitation (PLE) spectra of $SW^{13}CNTs$ and normal SWNTs, the excitonic phonon sideband due to strong exciton-phonon interaction was clearly identified with the expected isotope shift [2]. The PLE line shape and energy difference from $E_{ii}$ are remarkably similar to the excitonic phonon sideband predicted by Perebeinos itet al. for (7, 5) and (6, 5) nanotubes. In addition to these phonon sideband features, we also found low-intensity 'pure electronic' features whose origin has never been elucidated. In order to examine these 'pure electronic' features, polarized PLE measurements on individually-dispersed SWNTs

aligned in a gelatin-based thin film. By comparing optical transitions of SWNTs for incident light parallel or perpendicularly polarized to the nanotube axis, we have attributed these features to excitation by perpendicularly polarized light to the nanotube axis. The measured absorption energies of perpendicularly polarized light are compared with cross-polarized version of the Kataura plot. [1] S. Maruyama and Y. Miyauchi, AIP Conf. Proc. 786, 2005, 100-105. **W18 2 Raman Studies of Exciton-Phonon Coupling in Single-Walled Carbon Nanotubes** STEPHEN DOORN, *Los Alamos National Lab* SERGUEI GOUPALOV, SATISHKUMAR CHIKKANNANAVAR, Significant chirality-dependent effects on nanotube Raman intensities have recently been observed whose origins lie in the chirality dependence of exciton-phonon coupling. We present resonance Raman excitation data that demonstrates this dependence in radial breathing mode (RBM) intensities for both E11 and E22 excitation. For E22 excitation, intensities for (n-m)mod 3 = -1 chiralities are significantly more intense than for (n-m)mod 3 = +1, with more complex behavior in E11 excitation. We discuss the results in terms of a new theoretical analysis of exciton-phonon coupling that accurately describes the observations with simple intuitive analytical expressions. Relative intensities can be easily predicted using a newly introduced parameter that is also able to explain a number of anomalies in the observations. We also present the first direct comparison of E11 vs. E22 intensities for a number of chiralities. This comparison yields the ratio of the decay rates for the excited and ground excitonic states serving as intermediate states in the Raman process under E22 and E11 excitations, respectively.

**W18 3 Resonance Raman Spectroscopy of 1.2< dt < 2.0 nm Diameter Single Wall Carbon Nanotubes in the E33S and E44S Optical Range*** PAULO A. T. ARAÚJO, *UFMG* S.K. DOORN, *Los Alamos National Lab* A.G. SOUZA FILHO, *UFC* J.JIANG, *Tohoku University* R. SAITO, *Tohoku University* S. MARUYAMA, *Tokyo University* M.A. PIMENTA, *UFMG* A. JORIO, *UFMG* This work uses Resonant Raman Spectroscopy with excitation laser energy from 1.26 to 2.98 eV to measure the E33S and E44Soptical transition energies, for single wall carbon nanotubes (SWNTs) with diameters in the range 1.2 < dt < 2.0 nm. We identify the families of (2n+m) = constant and analyse the radial breathing mode (RBM) frequencies, the E33S and E44S energies and intensities as a function of (n,m). The excitonic effects are weaker in the E33S and E44S , the energies being blue-shifted when compared with earlier predictions. We also study the relation between the RBM intensity and tube chirality, clearly showing that the RBM Raman spectrum is less intense for armchair tubes.

**W18 4 Raman spectroscopy and imaging of surface and suspended carbon nanotubes*** KATE KAMINSKA, *NRC, Ottawa* JACQUES LEFEBVRE, *NRC, Ottawa* D. GUY AUSTING, *NRC, Ottawa* JEFFERY BOND, *University of Ottawa* PAUL FINNIE, *NRC, Ottawa* Freely suspended single walled carbon nanotubes show enhanced photoluminescence and Raman signals compared with those from nanotubes on surfaces. We prepared suspended carbon nanotubes by chemical vapor deposition on lithographically patterned substrates. The nanotubes were of the order of 100 microns in length with suspended segments ranging from 1 to 20 microns. Individual nanotubes and bundles were characterized with both Raman spectroscopy and scanning electron microscopy. Raman signals from suspended and non-suspended segments of the same nanotube were detected with up to a tenfold signal enhancement observed for the suspended segments. The effect of suspension is clearly illustrated in spatially resolved confocal images of nanotubes extending over many microns.

**W18 5 Effects of collective excitations on the G-band and RBM modes in the Raman spectra of metallic unfilled and filled carbon nanotubes** SAURABH GAYEN, *Drexel University* SURJYO BEHERA, SHYAMALENDU BOSE, *Drexel University* The Raman spectra of a single-wall carbon nanotube (SWNT) consist of three types of modes; (i) the high frequency G-mode arising out of tangential oscillations of carbon atoms, (ii) D-mode due to the defects in the nanotube and (iii) the low frequency radial breathing mode (RBM) resulting out of radial oscillations of the carbon atoms. In this paper we theoretically investigate the effects of collective oscillations of electrons (plasmons) on the G and RBM modes in the Raman spectra of a filled and unfilled metallic SWNT. Inclusion of plasmon and the filling (rattler) atom produces four peaks in the Raman spectra in general. The positions and relative strengths of the Raman peaks [1] depend upon phonon frequencies of the nanotube and that of the filling atoms, the plasmon frequency, the strength of the electron-phonon interaction, strength of the interactions between the nanotube phonons and rattler phonon and radius of the nanotube [2]. Usually the intensity of the G-mode is higher than that of RBM. For heavier filling atoms the frequency of the rattler phonon is lower in value, which may broaden the peak to such an extent that it may disappear in the background spectrum altogether. 1.S.M. Bose et al., Physica B **351**, 129 (2004) 2. S.M. Bose, S.Gayen and S. Behera, Phys. Rev. B **72**, 153402 (2005).

**W18 6 Chirality dependence of Raman intensity of single wall cabon nanotubes*** RIICHIRO SAITO, JIE JIANG, KENTARO SATO, *Tohoku UNIV. and CREST JST* ADO JORIO, *UFMG* GEORGII SAMSONIDZE, GRACE CHOU, GENE DRESSELHAUS, MILDRED DRESSELHAUS, *MIT* We present calculated Raman intensity of radial breathing modes (RBM), and other first and second order Raman signals as a function of (n,m) with exciton wavefunctions. Because of strong k dependent electron-phonon and electron-photon matrix elements, the Raman intensity shows (2n+m) family pattern. Within the extended tight binding calculation, we make exciton Kataura-plot for RBM. The Raman intensity is enhanced by localized wavefunction of the bright exciton which decreases with increasing energy and diameter. We will further discuss disorder induced D-band Raman intensity with some experimental results.

**W18 7 Carbon Nanotube Population Analysis from Raman and Photoluminescence Intensities*** ADO JORIO, *UFMG* C. FANTINI, *UFMG* P.A.T. ARAUJO, *UFMG* M.A. PIMENTA, *UFMG* D.A. HELLER, *UIUC* M.S. STRANO, *UIUC* M.S. DRESSELHAUS, *MIT* Y. OYAMA, *Tohoku Univ.* J. JIANG, *Tohoku Univ.* R. SAITO, *Tohoku Univ.* Large efforts are now being directed to developing synthesis or manipulation processes able to generate single-wall carbon nanotubes (SWNT) with well-defined geometric structure, i.e. $(n,m)$ indices. The $(n,m)$ population in a SWNT sample can be obtained from intensity analysis of photoluminescence excitation (PLE) and Resonance Raman spectroscopy (RRS) experiments, after the information is corrected to account for the $(n,m)$ dependence of the RRS and PLE efficiency. In the absence of standard single-wall carbon nanotube samples with well-known (n,m) population, we provide both a photoluminescence excitation (PLE) and resonance Raman scattering (RRS) analysis that together can be used to check the calculations for PLE and RRS efficiency. We show that available models describe well the chirality dependence of the intensity ratio, confirming the differences between type 1 and type 2 semiconducting tubes and the existence of a node in the radial breathing mode intensity for type 2 carbon nanotubes with chiral angles between 20° and 25°. The method is used to characterize SWNT samples grown by the CoMoCAT, HiPco and alcohol-CVD processes.

**W18 8 Optical studies of finite length effects in short DNA-wrapped carbon nanotubes** SHIN GRACE CHOU, *Chemistry, MIT* H. SON, *EECS, MIT* EDUARDO BARROS, *EECS/Physics, UFC, Brazil/MIT* GEORGII G. SAMSONIDZE, *EECS, MIT* MING ZHENG, *Experimental Station, Dupont Central Research and Development* RIICHIRO SAITO, *Department of Physics, Tohoku University and CREST JST, Japan* GENE DRESSELHAUS, *Francis Bitter Magnet Laboratory, MIT* MILDRED DRESSELHAUS, *EECS/Physics, MIT* In this study, a systematic resonance Raman study was carried out on samples of DNA-wrapped SWNTs with average lengths between 50 and 100nm using multiple laser excitation energies. The different Raman features have been studied in detail as a function of nanotube length and laser excitation energies. The ratio of the D-band to G-band intensities has been found to increase with decreasing average SWNT length and decreasing laser excitation energy. As the nanotubes becomes much shorter than 1/4 wavelength of light, distinct finite length effects are also observed in overtone and intermediate frequency modes between 400 and 1500cm$^{-1}$. The MIT authors acknowledge supports under the Dupont-MIT Alliance, and NSF Grant DMR 04-05538.

**W18 9 $(n, m)$-dependent environmental effect on photoluminescence of single-walled carbon nanotubes** YUTAKA OHNO, *Nagoya Univ., PRESTO/JST* SHINYA IWASAKI, *Nagoya Univ.* YOICHI MURAKAMI, *Univ. of Tokyo* SHIGERU KISHIMOTO, *Nagoya Univ.* SHIGERU MARUYAMA, *Univ. of Tokyo* TAKASHI MIZUTANI, *Nagoya Univ.* NAGOYA UNIV. COLLABORATION, PRESTO/JST COLLABORATION, UNIV. OF TOKYO COLLABORATION, The photoluminescence (PL) map was measured for 20 chiralities of single-walled carbon nanotubes (SWNTs) suspended in air, and the $E_{11}$ and $E_{22}$ were compared to the results reported for SDS-wrapped SWNTs [1]. The $E_{11}$ and $E_{22}$ are mostly blueshifted by a few tens of meV, except for $E_{22}$ of type-II near zigzag SWNTs which show a redshift. The energy shifts of $E_{11}$ and $E_{22}$ from those of SDS-wrapped SWNTs, $\Delta E_{11}$ and $\Delta E_{22}$, show clear dependence on the chirality, in particular on the chiral angle rather than the diameter. $E_{11}$ and $E_{22}$ show different dependences on the chiral angle between type-I and type-II SWNTs. In the case of type-I SWNTs, $\Delta E_{11}$ is lager for the larger chiral angle whereas $\Delta E_{22}$ is smaller for the larger chiral angle. In contrast, type-II SWNTs shows the opposite dependences. The difference between type-I and type-II disappears for the SWNTs with the chirality near armchair. The chiral angle dependence of environmental effect can be explained by difference in effective mass. [1] R. B. Weisman itet al. itNano Lett. **3** 1235(2003).

**W18 10 Raman Scattering from few-layer Graphene Films** A. GUPTA, *Dept. of Physics, The Pennsylvania State University* P. JOSHI, T. SRINIVAS, *Dept. of Electrical Engineering, The Pennsylvania State University* PETER EKLUND, *Department of Physics, The Pennsylvania State University, University Park, PA 16802 USA* Few layer-graphene sheet ($n$GL's) films, where n is the number of graphene layers, are new two-dimensional sp$^2$ carbon systems that have been shown to produce exciting Fractional Quantum Hall phenomena. We report here on the first Raman scattering (RS) results of $n$GLs. $n$GLs with lateral dimensions of $\sim$ 1-3 $\mu$m were prepared by chemical delamination of graphite flake or HOPG and then transferred from solution onto substrates (mica, pyrex,In/pyrex and Au/pyrex). RS spectra have been collected on $n$GL's with n=1, 2, 3 and compared with the graphite. Graphite exhibits two $E_{2g}$ interlayer modes at 42 cm$^{-1}$ and 1582 cm$^{-1}$. The Raman spectra of (n=1-3) $n$GLs were found to exhibit peaks at 1350 cm$^{-1}$ and 1620 cm$^{-1}$, i.e., near frequencies associated with high phonon density of states. The high frequency $E_{2g}$ band is found to split into two bands when the $n$GL is supported on metallic substrates (In,Au). In both these cases, we observe bands at 1583 cm$^{-1}$, $\sim$ 1592 cm$^{-1}$ rather than one band at 1581 cm$^{-1}$when the nGL is on insulating pyrex. The splitting of the interlayer band when on metallic substrates is identified with charge transfer between the nGL and the substrate. The phonon density of states scattering observed does not appear to be due to disorder in the basal plane.

**W18 11 Resonance Raman Study of Linear Carbon Chains Formed by the Heat Treatment of Double-Wall Carbon Nanotubes** C. FANTINI, *UFMG, Brazil* E. CRUZ, *IPICYT, Mexico* A. JORIO, *UFMG, Brazil* M. TERRONES, H. TERRONES, *IPICYT, Mexico* G. VAN LIER, J-C. CHARLIER, *Un. Cath. de Louvain, Belgium* M. S. DRESSELHAUS, *MIT, USA* R. SAITO, *Tohoku Un., Japan* Y. A. KIM, T. HAYASHI, M. MARAMATSU, M. ENDO, *Shinshu Un., Japan* M. A. PIMENTA, *UFMG, Brazil* The Raman spectra of carbon nanotubes exhibit weak features in the spectral range between 1600 and 2000 cm$^{-1}$ that are ascribed to a second-order Raman process. However, the observation of unusual and strong spectral features around 1850 cm$^{-1}$ have been reported recently in the Raman spectra of carbon nanotube systems, and have been ascribed to the vibration of one-dimensional chains of carbon atoms. We study the resonance behavior of the unusual Raman feature known as the coalescence-inducing mode (CIM), observed at $\sim$ 1850 cm$^{-1}$, in samples of double-wall carbon nanotubes annealed at high temperatures. Resonance Raman spectra taken with many different laser energies show that the intensity of the CIM band exhibits a maximum around 2.20 eV. By

comparing the experimental results with first principles calculations for the vibrational frequency and the energy gap, we propose that the CIM feature is associated with short carbon chains with an odd number of atoms, interconnecting the nanotube surfaces.

**W18 12 Raman Scattering Study of the Thermal Conversion of SWNTs into Graphitic NanoRibbons.** U.J. KIM, H.R. GUTIÉRREZ, PETER EKLUND, *Department of Physics, The Pennsylvania State University, University Park, PA 16802 USA* Thermal processing of purified bundled SWNTs in vacuum at high temperatures has been found to lead to a series of important structural transformations: SWNT coalescence (1400 [r]C-1600 [r]C), formation of MWNTs ( $\sim$ 1600-1800 [r]C) and the formation of a new filamentary allotrope, i.e., Graphitic Nanoribbons (GNRs). HRTEM indicates that GNRs are collapsed MWNTS. ARC and HiPCO SWNTs go through the first two transformations, but only ARC material transforms to GNRs. At the highest temperatures, the ARC material is almost completely transformed into GNRs. Here we present the results of Raman scattering experiments on these carbon filaments after high temperature heat treatment (HTT) for $\sim$ 6 hr. For coalesced SWNTs, the structural order in the tube walls is sufficient to observe new low frequency radial (R) Raman modes ( $\sim$ 100 $cm^{-1}$) identified with the diameter-doubled tubes. We can conclude that small diameter tubes (d$<$ 1.4 nm) are preferentially lost in the range HTT$\sim$ 1600-1800 [r]C. After HTT$\sim$ 1800 [r]C, the formation of MWNTs occurs via massive bond rearrangement of coalesced SWNTs, and this transformation is observed in Raman as a broadening of the high frequency bands and a loss of R-band intensity. A few isolated SWNTs with d $\sim$ 1.3-1.5 nm were found to survive HTT$\sim$ 2000 [r]C, but not HTT$\sim$ 2200 [r]C.

**W18 13 Coherent phonon oscillations from micelle-suspended single-walled carbon nanotubes** E. HAROZ, J. SHAVER, J. KONO, R. HAUGE, R. SMALLEY, *Rice Univerisity-USA* Y.S. LIM, *Rice University-USA, Konkuk University-Korea* K.J. LEE, J.H. KIM, *Chungnam National University-Korea* S. DOORN, *Los Alamos National Laboratory-USA* Time-domain oscillations were generated via degenerate pump- probe spectroscopy from individual single-walled carbon nanotubes (SWNTs) dispersed in aqueous media using ultrafast excitation pulses from a Ti:sapphire laser over the range of 710- 860 nm. Fast Fourier transform of such oscillations reveals the observation of coherent phonons (CP) corresponding to the radial breathing mode (RBMs) of 16 distinct (n,m) SWNTs. Comparison to Resonance Raman scattering (RRS) experiments indicates excellent agreement with observed RBMs, with significantly narrower linewidths seen for CP. Additionally, different RBM intensity behavior is observed within 2n+m families compared to RRS. Finally, we have directly observed two-peak maxima, separated by tens of meV, in the excitation profile for a given RBM. A possible origin of this two-peak structure is discussed. This technique represents a novel method for (n,m) characterization as well as electronic structure probing.

**W19 1 Shot noise and s-o coherent control of entangled and spin polarized electrons.** J. CARLOS EGUES, *University of Sao Paulo and University of Basel* GUIDO BURKARD, *University of Basel* DANIEL SARAGA, *University of Basel* JOHN SCHLIEMANN, *University of Regensburg and University of Basel* DANIEL LOSS, *University of Basel* We extend our previous work on shot noise for entangled and spin polarized electrons in a beam-splitter geometry with spin-orbit (s-o) interaction in the incoming leads. Besides accounting for both the Dresselhaus and the Rashba spin-orbit terms, we present general formulas for the shot noise of singlet and triplets states derived within the scattering approach. We determine the full scattering matrix of the system for the case of leads with two orbital channels coupled via a weak s-o interaction inducing channel anti-crossings. We show that this inter-band coupling gives rise to an additional modulation angle which allows for further coherent control of the electrons. We also derive explicit shot noise formulas for a variety of correlated pairs (e.g., Bell states) and lead spin polarizations. Interestingly, the singlet and each of the triplets defined along the quantization axis perpendicular to lead 1 and in the plane of the beam splitter display distinctive shot noise for injection energies near the channel anti-crossings – one can tell apart all the triplets through noise measurements. Finally, we find that backscattering within lead 1 reduces the visibility of the noise oscillations. This work was supported by NCCR Nanoscale Science, EU-Spintronics, CNPq, Swiss NSF, DARPA, ARO, and ONR (to appear in PRB).

**W19 3 Theory of spin noise spectroscopy of itinerant fermions** SIMON KOS, *University of Cambridge* ALEXANDER BALATSKY, *Los Alamos National Laboratory* SCOTT CROOKER, *Los Alamos National Laboratory* PETER LITTLEWOOD, *University of Cambridge* DWIGHT RICKEL, *Los Alamos National Laboratory* DARRYL SMITH, *Los Alamos National Laboratory* We study the noise of spin magnetization in a region within a system of fermions in different regimes of temperature (degenerate/non-degenerate) and disorder (ballistic/diffusive), with and without spin-flip processes included, and with no particle-particle interactions. We obtain a single spectral line, ana-

lyze the dependence of its width and spectral weight on the parameters of the system and the size of the region of interest, and discuss conditions for the maximal effect. We compare our results to the recent measurements of spin noise of alkali-gas vapor and of conduction electrons in a GaAs epilayer.

**15:06**
**W19 4 Spin-resolved shot noise in multichannel spin-orbit coupled quantum wires** RALITSA DRAGOMIROVA, BRANISLAV NIKOLIĆ, *University of Delaware* The characterization of spin-dependent transport via shot noise has recently attracted considerable attention in semiconductor spintronics. The key quantity that makes it possible to obtain the shot noise of both spin currents and spin-polarized charge currents is the correlation function between the spin-resolved charge currents. We extend the Landauer-Büttiker scattering formalism to obtain the spin-resolved shot noise for arbitrary polarization of the injected current and apply it to two-probe multichannel quantum wire with the Rashba spin-orbit interaction. We find that the Fano factor of the charge shot noise is non-zero even for ballistic transport and increases with the strength of the Rashba spin-orbit coupling due to enhancement of the backscattering at the lead-wire interface. In disordered quantum wires this effect enhances the Fano factor beyond the standard $F = 1/3$ shot noise suppression.

**W19 5 Valley-Kondo Effect in Transport Through a Silicon Quantum Dot** SHIUEYUAN SHIAU, *Department of Physics. UW, Madison* The Anderson model is applied to transport through a silicon quantum dot with infinite Coulomb interaction U with the valley degeneracy taken into account. At zero temperature, we study the conductance in the Kondo regime as a function of applied magnetic field, using the variational method developed by Gunnarsson and Schönhammer. The conductance peaks show a characteristic evolution due to the interplay of Zeeman splitting and valley splitting.

**15:30**
**W19 6 Time-dependent multiple scattering approach for a single finger-gate in a Rashba-type quantum channel.** LU-YAO WANG, *Department of Electrophysics, National Chiao-Tung University, Hsinchu 30010, Taiwan* C.S.TANG TEAM,* C.S. CHU TEAM,† We consider a Rashba-type quantum channel (RQC) consisting of one AC-biased finger-gates (FG) that orient perpendicularly and located above the RQC. Such an AC-biased FG gives rise to a local time-modulation in the Rashba coupling parameter, and generates a dc spin current (SC). A static potential is located inside or outside the FG in the RQC and the backscattering effect is studied. We use analytical time-dependent multiple scattering approach to treat the effect of the SC suppression due to a static potential in the RQC.

**W19 7 Spin-current detector by a periodic array of quantum dots with Rashba Hamiltonian** JUN-QIANG LU, X.-G. ZHANG, *Center for Nanophase Materials Sciences, and Computer Science and Mathematics Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831* SOKRATES T. PANTELIDES, *Department of Physics and Astronomy, Vanderbilt University, Nashville, TN 37235 and Oak Ridge National Laboratory, Oak Ridge, TN 37831* Electron diffraction by a periodic array of quantum dots is studied using the Rashba Hamiltonian and a plane wave-based Green function method. A transverse charge current is found due to the asymmetric spatial diffraction of a spin-polarized electron injection. The spin-polarization of the forward electon current is maintained after passing through the array. Such an array can be used as a non-magnetic spin-current detector. Detailed results in terms of the parameters relevant to experimental design, such as the size of the quantum dots, strength of the spin-orbit coupling, are presented.

**15:54**
**W19 8 Effect of Coulomb interaction on the spin-galvanic mode in a two dimensional electron gas with Rashba spin-orbit interaction.** GERNOT GUNTHERODT, *Physikal. Institut IIA, RWTH Aachen, 52056 Aachen, Germany* YAROSLAW B. BAZALIY, STUART S. P. PARKIN, *IBM Almaden Research Center, 650 Harry Road, San Jose, CA 95120* B. V. BAZALIY, *Appl. Mathematics Inst., Natl. Academy of Science, Donetsk, Ukraine* Recently a new propagating mode of coupled charge and spin oscillations was predicted in a two dimensional electron gas with a sufficiently strong Rashba interaction. We show [cond-mat/0511534] that Coulomb interaction qualitatively modifies the spectrum and increases the characteristic wavelength of this mode by orders of magnitude, but does not suppress it. An absorption experiment that can conclusively detect the presence or absence of such a propagating mode is proposed.

**16:06**
**W19 9 Quantum coherence oscillations in InSb and InAs** J.A. PETERS, *Department of Physics, Ohio University* HONG CHEN, J.J. HEREMANS, *Department of Physics, Virginia Tech* N. GOEL, S.J. CHUNG, M.B. SANTOS, *Department of Physics and Astronomy, University of Oklahoma* W. VAN ROY, G. BORGHS, *IMEC, Leuven, Belgium* Quantum oscillation phenomena in parallel arrays of loops have been investigated in InSb/AlInSb and InAs/AlGaSb heterostructures, notable for their strong spin-orbit interaction. The arrays consist of parallel lines of hexagonal lattice cells, forming linear concatenations of loops. From the h/2e periodicity, the dominance of Altshuler-Aronov-Spivak (AAS) oscillations is deduced. Measurement of the temperature dependence of the oscillations enables the extraction of spin and phase coherence lengths in InSb and InAs. The spin coherence lengths show a weak drop with increasing temperature, akin to the mobility mean free path behavior, and consistent with a dominant Elliott-Yafet related spin relaxation mechanism in both heterostructures. The phase coherence lengths follow a power law without observed saturation at the lowest temperatures. NSF DMR-0094055 (JJH), DMR-0080054, DMR-0209371 (MBS).

**16:18**
**W19 10 Rashba spin-orbit and lateral local confinement effects in quasi-two-dimensional electronic systems** GABRIELE GIULIANI, STEFANO CHESI, *Purdue University* We consider the effects of lateral confinement on a two dimensional electron gas in the presence of different types of spin-orbit coupling as applied to the electrons and holes in *GaAs* heterostructures. Both the linear and cubic Rashba spin-orbit coupling mechanisms have been studied. We show that confinement leads to interesting spin polarization effects that can in principle be observed by transport measurements across a quantum point contact.

**16:30**
**W19 11 Response Functions and Collective Oscillations of a Two Dimensional Electron Gas in the Presence of Rashba Spin-Orbit Coupling** GEORGE SIMION, GABRIELE F. GIULIANI, *Physics Department, Purdue University* Various response functions and the spectrum of the collective excitations of a two dimensional electron liquid in the presence of Rashba type spin-orbit coupling have been studied within time dependent mean field formalism. Of particular interest are the results concerning the in-plane and out-of- plane spin susceptibility of the paramagnetic phase and the corresponding spin excitations. As an by product of this analysis we have derived an exact analytical expression for the static density response function which corrects formulas previously appeared in the literature. Approximate analytical expressions have also be derived for the low frequency, long wave length dependence of the same function.

**16:42**
**W19 12 Mean field phase diagram of a two dimensional electron liquid with Rashba spin-orbit** STEFANO CHESI, GABRIELE GIULIANI, *Purdue University* By a combination of analytic an numerical techniques we have mapped out the mean field phase diagram of a two dimensional electron liquid in the presence of Rashba or Dresselhaus spin-orbit. Although inhomogeneous solutions can be found that minimize the total energy, we have carried out a systematic study of the spatially homogeneous phases in the $(r_s, \alpha)$ diagram (with $r_s$ the density parameter and $\alpha$ the strength of the spin-orbit coupling). The scenario is intriguing for a number of broken symmetry states have been unraveled that can be characterized by suitable momentum space occupation numbers $n_{\mathbf{k}}$ and local spin quantization axes $\hat{s}_{\mathbf{k}}$. While at high densities the system is as expected paramagnetic, at lower densities (or larger $\alpha$ values) markedly different ferromagnetic phases exist with spontaneous polarization oriented perpendicular or parallel to the plane of motion that are characterized by non trivial spin textures in momentum space. Of particular interest is a phase transition between an isotropic paramagnetic state to an anisotropic ferromagnetic one that occurs in the large $\alpha$ limit. The relation between the various phase transitions and the differential instabilities signaled by the in plane and out of plane spin susceptibilities will be discussed.

**16:54**
**W19 13 Cubic Dresselhaus Spin Orbit Coupling in Small Quantum Dots*** JACOB J. KRICH, BERTRAND I. HALPERIN, *Harvard University* Due to the suppression of linear spin-orbit effects in small quantum dots in two-dimensional electron systems, the cubic Dresselhaus spin-orbit coupling can play a significant role in such phenomena as the variance of conductance through a dot. We characterize the different spin-orbit coupling terms by the strength of the anti-crossings they induce in the eigenstates of a closed quantum dot as an in-plane magnetic field is increased, and we perform numerical simulations in a chaotic billiard model to estimate the RMS anti-crossing energy. We investigate the conditions under which the cubic Dresselhaus effects may be measurable and significant for realizable dot configurations.

**W19 14 g-factor anisotropy in p-type GaAs/AlGaAs quantum point contacts** SUNANDA KODUVAYUR, LEONID ROKHINSON, *Purdue University* In this work we report the influence of lateral confinement on the effective Lande **g**-factor for holes in GaAs. For 2D hole gas grown along crystallographic direction other than the high symmetry [100] or [111], mixing of heavy and light hole subbands leads to anisotropic g-factor depending on the direction of the in-plane magnetic field.Further lateral confinement of the holes into 1D channel modifies g-factor depending on the strength and direction of the confining potential. We investigate **g**-factor in quantum point contacts (QPC) fabricated on 2D hole gas on $[\bar{3}11]$A GaAs by AFM lithography using the local anodic oxidation technique. Several QPCs are oriented along the major $[\bar{2}33]$ or $[\bar{1}10]$ axis. In-plane **B** is predominantly acting on the spin part of the Hamiltonian and the magnitude of the Zeeman splitting can be obtained from energy level spectroscopy combined with the critical fields at which half-integer steps in the conductance (in units of $2e^2/h$) appear. The **g**-factor is found to be strongly modified compared to the values reported for a 2D hole gas and has strong dependence on the quantized momentum normal to the current flow (number of filled energy levels in the point contact). Thus the g-factor can be modulated electrostatically, providing an extra degree of control of spintronic devices.

**17:18**
**W19 15 The effect of interactions on the geometrical structure of the Fermi surface in systems with spin-orbit interactions** VICTOR GALITSKI, *Physics Department, University of Virginia* The spectrum of many electronic systems contains band degeneracies, which can be thought of as monopoles in momentum space leading to a non-trivial topological structure of the Fermi surface. This structure is characterized by two quantities: curvature and metric, which, being gauge invariant, are in principle observable in experiment. In electronic systems with spin-orbit interactions, the Berry's curvature determines the so-called spin Hall conductivity, which may be related to observable spin accumulation near the edges. We consider Rashba, Dresselhaus, and Luttinger models and study the effect of interactions on the topology of the Fermi surface in these systems. We find that interactions renormalize the spin-orbit couplings but in certain cases do not change the Berry's phase structure. This suggests that the non-trivial geometry of the Fermi surface is a true Fermi liquid property.

**14:42**

**W20 2 ''Lorentz force'' acting on a ray of light in multiferroics** KEI SAWADA, NAOTO NAGAOSA, *CREST, Department of Applied Physics, the University of Tokyo* We theoretically propose that optical analogue of a Lorentz force acting on a ray of light is realized in multiferroic materials showing an optical magnetoelectric effect. The toroidal moment $\vec{T} = \Sigma_j \vec{r}_j \times \vec{S}_j$ plays a role of ''vector potential'' while its rotation corresponds to a ''magnetic field'' for photons. Hence the light is subject to the Lorentz force when propagating through the domain wall region of the ferromagnetic or ferroelectric order. Realistic estimate on the magnitude of this effect is given.

**14:54**

**W20 3 Enhanced optical magnetoelectric effect in a patterned polar ferrimagnet*** N. KIDA, *ERATO-JST* Y. KANEKO, *ERATO-JST* J.P. HE, *ERATO-JST* M. MATSUBARA, *CERC-AIST* H. SATO, *CERC-AIST* T. ARIMA, *ERATO-JST and Tohoku Univ.* H. AKOH, *CERC-AIST* Y. TOKURA, *ERATO-JST, CERC-AIST, and Univ. Tokyo* A simple method to dramatically enhance the optical magnetoelectric (ME) effect, i.e., nonreciprocal directional birefringence, is proposed and demonstrated for a polar ferrimagnet $GaFeO_3$ as a typical example. We patterned a simple grating with a pitch of 4 $\mu$m on a surface of $GaFeO_3$ crystal and used the diffracted light as a probe. Optical ME modulation signal for Bragg spot of the order $n = 1$ becomes gigantic in the photon energy 1–4 eV and reaches 1–2% of the bare diffracted light intensity in a magnetic field of 500 Oe. This is amplified by more than three orders of magnitude compared to that for the reflection of bulk $GaFeO_3$. Fabricating a photonic crystal will make it possible to lead a new route for the practical use of the optical ME effect.

**W20 4 Magnetoelectric effects in multiferroics.**

ALOIS LOIDL, *Center for Electronic Correlations and Magnetism, University of Augsburg*

Magneto-electric phenomena were investigated in two different multiferroic systems: The strong coupling of dielectric and magnetic properties and the simultaneous occurrence of long-range magnetic and ferroelectric order are discussed for rare earth manganites and sulfo spinels. A phase diagram of $Eu_{1-x}Y_xMnO_3$ is established, which recovers the main features of the well-known magneto-electric phase diagram for the pure rare earth manganites $RMnO_3$. Here a variety of magnetic and electric phases emerge with varying rare earth ions R. As function of temperature and external magnetic field, also Y doped $EuMnO_3$compounds undergo a sequence of different magnetic and polar phase transitions for varying effective ionic radii of the rare earth ions. Special attention is paid to the occurrence of fundamentally new hybrid spin-electromagnetic excitations, which we name electromagnons and are characterized as spin waves that can be excited by an ac electric field. These excitations are identified in $Eu_{1-x}Y_xMnO_3$with x = 0.2, in $GdMnO_3$, and in $TbMnO_3$. Specifically in $GdMnO_3$ the electromagnons can easily be suppressed by external magnetic fields and allow tuning the index of refraction by moderate fields. In the second part we discuss the simultaneous appearance of colossal magnetoresistance (CMR) and colossal magneto-capacitance (CMC) effects in chromium sulfo spinels. In $CdCr_2S_4$ ferromagnetism of localized Cr spins evolves at 85 K, while polar order is established below 130 K. The onset of ferroelectric order is neither accompanied by the occurrence of soft modes nor by structural changes which break the inversion symmetry of the high-temperature cubic phase. $HgCr_2S_4$ becomes ferroelectric close to 70 K while a complex antiferromagnetic order is found below 25 K. CMR and CMC effects are specifically strong in the mercury compound, as moderate magnetic fields of only 0.1 T induce ferromagnetism at much higher temperatures. We speculate that the occurrence of ferroelectricity in these multiferroic compounds is rather of electronic than of ionic origin.

**W20 5 A neutron scattering study on a ferrimagnetic magnetocapacitance system $Mn_3O_4$** JAE-HO CHUNG, *NIST Center for Neutron Research & University of Maryland* JUNG HWA KIM, SEUNG-HUN LEE, *University of Virginia* TAKURO KATSUFUJI, *Waseda University* The low-temperature phase of the tetragonal $Mn_3O_4$ has long been known as a ferrimagnet with the Yafet-Kittel structure. The long-range ferrimagnetic order first develops at 41.2 K, upon cooling, and a commensurate cell-doubling magnetic order occurs along the *b*-axis at 32.7 K. Recently magnetocapacitance behaviors were observed in $Mn_3O_4$. We present our high-resolution neutron scattering data to show that $Mn_3O_4$ undergoes an additional lattice distortion around 25 K. Peak broadening of selected reflections suggests that the crystal structure becomes pseudo-orthorhombic at low temperatures. Relation between the lattice distortion and magnetism will also be discussed.

**W20 6 Magnetodielectric consequences of phase separation in the colossal magnetoresistance manganite $Pr_{0.7}Ca_{0.3}MnO_3$** R.S. FREITAS, *Department of Physics and Materials Research Institute, Pennsylvania State Univeristy, University Park PA 16802* J.F. MITCHELL, *Materials Science Division, Argonne National Laboratory, Argonne IL 60439* P. SCHIFFER, *Department of Physics and Materials Research Institute, Pennsylvania State*

*Univeristy, University Park PA 16802* We have studied the low-frequency dielectric properties of the phase-separated manganite $Pr_{0.7}Ca_{0.3}MnO_3$ as a function of applied magnetic field in the low temperature phase-separated state. The dielectric constant is strongly field dependent and also depends on the magnetic field history of the sample. The dielectric behavior appears to be associated with the hopping of polaronic charge carriers, and we can derive the field dependent hopping energy barrier from the frequency dependence of the dielectric constant. This analysis allows us to associate the metal-insulator transition observed in this material with the field-induced suppression of the polaron activation energy. Reference: Phys. Rev. **W20 7 Dielectric anomalies in $CoCr_2O_4$** G. LAWES, *Wayne State University* B. MELOT, K. PAGE, C. EDERER, *UCSB* M.A. HAYWARD, *Oxford* TH. PROFFEN, *LANL* R. SESHADRI, *UCSB* We investigate the magnetic,dielectric, and thermodynamic properties of $CoCr_2O_4$ polycrystalline samples. AC susceptibility and specific heat measurements show the existence of two distinct magnetic transitions in this material. Neutron scattering experiments confirm a ferrimagnetic ordering transition at $T_c = 95$ K and a transition to a spiral magnetic phase below $T_N$ 25 K. We observe a significant dielectric anomaly coincident with the onset to long-range spiral magnetic order, and a separate feature with significant thermal hysteresis above T=50 K. We associate this higher temperature dielectric anomaly with short-range spiral magnetic order, and discuss these results in the context of utilizing magnetodielectric couplings to capacitively probe short range magnetic structures.

**W20 8 Mossbauer Spectroscopy Investigation of Substituted Cobalt Ferrites ($CoM_xFe_{2-x}O_4$, where M = Mn or Cr, and x = 0.0-0.8)*** JOHN SNYDER, CHESTER LO, YEVGEN MELIKHOV, PAUL MATLAGE, *MSE Dept and CNDE, Iowa State Univ, Ames IA* KELLY KRIEBLE, *Physics Dept, Moravian College, Bethlehem PA* In order to enable applications of substituted cobalt ferrites for strain sensing, magnetostrictive actuating, and ''multiferroic'' composites, more basic knowledge is needed concerning how cation substitution affects the atomic level environments, distributions, and interactions of the cations. In this study, the local environments of the Fe atoms in two series of substituted cobalt ferrites ($CoM_xFe_{2-x}O_4$, where M = Mn or Cr, and x = 0.0-0.8) have been investigated using Mossbauer spectroscopy. Results of both series show two distinct six-line hyperfine patterns, indicating Fe in A (tetrahedral) and B (octahedral) sites. They can be identified by isomer shift and hyperfine distribution width. Both series show some similar behavior: with increasing substitution, magnetic hyperfine field decreases and hyperfine field distribution width increases for both A and B sites. B-site hyperfine fields and distribution widths are more affected than A. All of these effects are more pronounced for Cr-substitution than for Mn. Results are consistent with a model of Mn or Cr ions substituting into B-sites and displacing Co ions onto A sites. It would appear that Cr has an even stronger B-site preference than Mn, and displaces more of the Co to the A sites.

**W20 9 Preparation and properties of single phase $PbTi_{1-x}Mn_xO_3$ perovskites at high Mn concentrations.** STANISLAV STOUPIN, CARLO SEGRE, SOMA CHATTOPADHYAY, *Physics Division, Illinois Institute of Technology* Recent observation of multiferroic properties in the $PbTi_{0.5}Fe_{0.5}O_3$ perovskite material raises questions about the electronic and structural driving forces causing the coupling between ferroelectric and ferromagnetic properties. It is known that the Jahn-Teller distortion of oxygen octahedra due to d orbital occupancy inhibits formation of the ferroelectric double well potential in $ABO_3$ perovskites. Thus, the presence of a ferroelectric distortion in $d^n$ magnetic transition metal perovskite oxide is an unexpected result. We report observation of tetragonal structure (XRD) in a similar $PbTi_{1-x}Mn_xO_3$ system. The material is prepared using the sol-gel method with various Mn concentrations. In this study, we access a range of concentrations starting from a relatively high value of x=0.1 in order to introduce considerable amount of magnetic sites into the system. Reduction in the tetragonal ratio (c/a) is observed with increase in x as expected. Further characterization of the material involves magnetoelectric measurements and X-ray Absorption Spectroscopy. Preliminary results are discussed.

**W20 10 Colossal magnetocapacitance and scale-invariant dielectric response in mixed phase manganites** RYAN RAIRIGH, AMLAN BISWAS, ARTHUR HEBARD, *Dept. of Physics, University of Florida, Gainesville, FL 32611-8440* We are studying thin-film capacitors utilizing $(La_{0.5}Pr_{0.5})_{0.7}Ca_{0.3}MnO_3$ (LPCMO) as the base electrode, AlOx as the dielectric and Al as the counter-electrode. The LPCMO films exhibit itcolossal magnetoresistance (CMR). Likewise, the capacitance changes by three orders of magnitude in the region of the resistance drop. These itcolossal magnetocapacitance (CMC) effects are related to magnetic field induced changes in the relative extent of coexisting ferromagnetic metal and charge ordered insulating phases. The widths of the hysteresis loops, in capacitance and resistance, are about the same, but the center of the capacitance loop is shifted 20 K below the center of the resistance loop. When the LPCMO resistance is at a maximum (low capacitance) the electrode comprises filamentary conductors threading an insulating medium. In this region log-log Cole-Cole plots reveal an intrinsic dielectric response in which the data plotted as a function of frequency ($\omega$) collapse onto single straight lines, implying scale-invariance over a wide range of $\omega$, magnetic field and temperature.

**W20 11 Epitaxial thin films of novel multiferroic double perovskites.** A. VENIMADHAV, QI LI, *Department of Physics, Pennsylvania State University, PA16801* Recently multiferroic materials have attracted great interest. However, relatively a few pure multiferroic compounds are currently known. Here we show the exploration of design of multiferroic properties in double perovskites by combining the ferrolectrisity driven by the Bi lone pairs and selectively choosing the 3d transition metals following Goodenough-Kanamori's rules to bring in ferromagnetism. We present growth issues in stabilizing the single phase, epitaxial thin films of new double perovskite multiferroic systems such as $Bi_2NiMnO_6$, $Bi_2FeCrO_6$and $La_2NiMnO_6$by pulsed laser deposition. Targets of these compositions were synthesized by solid state method with 15% of excess Bi in the composition to compensate the volatility of Bi during the deposition. We also present the synthesis of $Bi_2FeCrO_6$by growing a superlattice structures from

individual targets of Bi $FeO_3$ and $BiCrO_3$. In the cubic double perovskites, cations show rock salt kind of ordering in the (111) direction and hence growing these films on STO (111) substrates has an advantage. We present the growth, structural and multiferroic properties in these double perovskite thin films.

**W20 12 First-principles exploration of multiferroic oxides with double-perovskite structure** TAMIO OGUCHI, TATSUYA SHISHIDOU, YOSHITAKA URATANI, *ADSM, Hiroshima University* Multiferroics have attracted much attention recently because of their novel properties. There are a few known as ferromagnetic and ferroelectric materials, particularly with perovskite-type crystal structure. Ferroelectrics should be insulating and likely ionic. Furthermore, it is widely recognized that covalent bonds between the cation and anion orbitals are crucial to realize atomic displacements to a noncentrosymmetric structure. As for magnetism, most of magnetic perovskite oxides usually have an antiferromagnetic order (mostly frustrating) due to a superexchange coupling. According to the Kanamori-Goodenough rule for the superexchange coupling, certain combinations of the transition-metals ions ($d^3$-$d^5$ and $d^3$-$d^8$ configurations) may possibly give a ferromagnetic coupling by the 180° superexchange mechanism. In this study, we explore possible co-existence of spontaneous electric polarization and ferromagnetic ordering from first principles, by focusing bismuth double-perovskite oxides $Bi_2BB'O_6$ ($B$,$B'$ = 3$d$ ions) as target materials. Ferromagnetic and ferrimagnetic solutions are obtained for cubic $Bi_2MnNiO_6$, $Bi_2CrFeO_6$ and $Bi_2CrCuO_6$ with nearly gapped electronic structure. Quite recently, $Bi_2MnNiO_6$ has been successfully synthesized by a high-pressure technique and revealed multiferroic properties. Possible multiferroic properties of $Bi_2MnNiO_6$ with the observed monoclinic structure are investigated in detail.

**W20 13 Magnetoelectric gyrator** DWIGHT VIEHLAND, JUNYI ZHAI, JIEFANG LI, *Virginia Tech* M.I. BICHURIN, *Novgorod State University, Russia* VIRGINIA TECH TEAM, NOVGOROD STATE UNIVERSITY TEAM, As well-known [1], an ideal gyrator would be an unusual device with respect to other network elements. It would have the unique properties of (i) antireciprocity, and (ii) being capable of acting like an impedance inverter. Here, for the first time, we report the design and study of such an ideal gyrator. Our ideal gyrator consists of a trilayer composite of Terfenol-D/PZT/Terfenol-D operated in a L-L mode at its electromechanical resonance (f≈ 80kHz). Measurements have shown that magnetoelectric (ME) susceptibility of our composite is comparable with its permeability and permittivity, and that the gyration coefficient achieves a value 0.9. In addition, we have observed a 180o phase-shift between an input current and an output voltage, or vice versa, and proved that our ME laminate behaves as an impedance inverter. We believe that our gyrator may enable resolutions to numerous important and complex network problems. [1] B.D.H. Tellegen, Phillips Research Reports 3, 81 (1948). **W21 1 Dielectric Dispersion Effects in Liquid Crystals.*** OLEG LAVRENTOVICH, *Liquid Crystal Institute, Kent State University* YE YIN, MINGXIA GU, SERGIJ SHIYANOVSKII, As the switching speed in practical LC devices is pushed from the currently common 10 ms to sub-millisecond levels, it is important to take into account the effects associated with the finite rate with which the electric displacement changes in the external electric field. We discuss two important general consequences of the dielectric relaxation phenomenon: (1) Non-local time relationship between the electric displacement and the electric field [1]. In a quickly changing electric field, orientation of the liquid crystal depends not only on the instantaneous value of the electric field, but also on the previous values of the field and previous orientations of the material. (2) Dielectric heating. [1] Y. Yin, S.V. Shiyanovskii, A.B. Golovin, and O. D. Lavrentovich, itPhys. Rev. Lett. **95**, 087801 (2005) .

**W21 2 Using micro-focus synchrotron X-ray diffraction to probe textured liquid crystal samples*** RONALD PINDAK, BRANDON CHAPMAN, *Brookhaven National Lab* RUITING WANG, ISHTIAQUE SYED, GIOVANNI CARBONE, CHARLES ROSENBLATT, *Case Western Reserve Univ.* MICHI NAKATA, CHRISTOPHER JONES, NOEL CLARK, *Univ. of Colorado* SHIN-WOONG KANG, *Kent State Univ.* SATYENDRA KUMAR, *National Science Foundation* JULIE CROSS, *Argonne National Lab* 16 KeV X-rays from a bend magnet source at Sector 20 of the Advanced Photon Source were micro-focused by Kirkpatrick-Baez mirrors to a 14$\mu$m x 14$\mu$m cross-section and used in conjunction with an in-situ polarizing optical microscope to measure the diffraction from select areas in textured liquid crystal samples between thin glass plates. The technique will be described and its utility illustrated by three examples: (1) measuring the orientational deformation of smectic-A liquid crystal layers under the bend strain imposed by an AFM-scribed polymer alignment film, (2) mapping the concentration dependence of the liquid crystal phases exhibited by suspensions of short DNA oligomers of 6 to 16 base-pairs, and (3) selecting local monodomain regions from a globally unaligned conducting porphyrin-derivative sample for structural determination of its liquid crystal phases.

**W21 3 Impurity Induced Cross-over from Continuous to First-order Nematic-to-Smectic A Phase Transitions in a Liquid Crystal.** JAN THOEN, KATLEEN DENOLF, BERT VAN ROIE, CHRIST GLORIEUX, *Lab. Akoestiek en Thermische Fysica, Dept. Natuurkunde en Sterrenkunde, Katholieke Universiteit Leuven, Celestijnenlaan 200 D, B-3001 Leuven, Belgium* We used adiabatic scanning calorimetry (ASC) to study the impact of adding small amounts of cyclohexane on the N-SmA transition of the liquid crystal octylcyanobiphenyl (8CB). The transition re-

mains continuous upto a mole fraction of cyclohexane near 0.05, where at a tricritical point the transition becomes first- order with latent heats increasing with mole fraction of cyclohexane. Along the continuous part of the N-SmA transition line the effective specific heat capacity critical exponent increases from 0.31 for 8CB to 0.50 at the tricritical point. Ongoing experiments with other non-mesogenic impurities will also be reported.

**W21 4 Phase morphology of a disk-sphere dyad molecule.** LI CUI, JEFFREY COLLET, LEI ZHU, *Polymer Program, Institute of Materials Science and Department of Chemical Engineering, The University of Connecticut, Storrs, CT 06269-3136* A disk-sphere dyad molecule was synthesized by attaching a discotic triphenylene molecule to a spherical polyhedral oligomeric silsesquioxane (POSS) molecule via esterification reaction. The self-assembly behavior of the dyad molecule was studied by differential scanning calorimetry, polarized light microscopy, X-ray diffraction (XRD), and transmission electron microscope. Two-dimensional (2D) XRD results showed the dyad molecules self-assembled into a lamellar structure, which composed of a crystalline POSS layer and a discotic-nematic triphenylene double-layer. The POSS layer consisted four layers of ABCA-stacked spherical molecules. The liquid crystalline triphenylene molecules were parallel and staggered in the double-layer. Computer simulation of the XRD intensity confirmed the proposed structural model. Compared with that of the POSS crystal in bulk (melting point at ca 220 $^{o}$C), the melting temperature of POSS crystal was dramatically decreased to 67 $^{o}$C, possibly due to effects of the asymmetry molecular shape and plasticization of the discotic triphenylene moieties between POSS layers.

**15:18**

**W21 5 Excitation-Enhanced Optical Reorientation in Pure Liquid Crystalline Materials** THAI V. TRUONG, YUEN-RON SHEN, *Department of Physics, University of California, Berkeley* Electronic excitation with polarized light necessarily creates complementary orientational anisotropies from the excited and ground-state molecules. If the intermolecular interaction with the surrounding experienced by the excited-state molecules is different from that experienced by the ground-state molecules, a net excitation-induced orientational anisotropy will develop, enhancing the molecular reorientation provided directly by the optical field. This effect is analogous to that observed in dye-doped liquid crystals (LC) when dye molecules are excited. We report here the study of the effect in a pure isotropic LC medium. We use an optical pump-probe method to observe the excitation-induced reorientational dynamics. As the system relaxes back from picosecond pulse excitation, an increase in the orientational anisotropy of the ground-state molecules is observed, signifying the enhanced optical reorientation due to the state-dependent intermolecular interaction. The observed dynamics is well predicted by a mean-field model describing the intermolecular interaction between LC molecules. This work was supported by NSF

**15:30**

**W21 6 Effect of disorder on a nematic-smectic A phase transition*** SIMON LAROCHELLE, MEHMET RAMAZANOGLU, *Dept. of Physics, University of Toronto* ROBERT J. BIRGENEAU, *Dept. of Physics, University of Toronto and Dept. of Physics, University of California Berkeley* Using X-ray scattering, we studied the nematic to smectic A phase transition of the liquid crystal butyloxybenzilidene-octylaniline (4O.8) confined in an aerosil gel. The aerosil particles introduce quenched randomness in the system by providing pinning centers to the liquid crystal molecules. We find that the introduced disorder destroys the long range nature of the phase transition, and that the transition becomes similar to a transition in a finite-size system. Finite low temperature correlation lengths of the ordered moments are measured and the order parameter follows a power law behavior with respect to the reduced temperature in a limited temperature range. We also show evidence for a shift of the effective order parameter critical exponent $\beta$ with increasing disorder.
