**K26 2 Single Human Plasma Fibrinogen Molecule Imaging by PEEM and AFM** XIANHUA KONG, JACOB GARGUILO, CRISSY RHODES, ROBERT NEMANICH, Human Plasma Fibrinogen (HPF), which is a protein involved in thrombosis, was studied by photoelectron emission microscopy (PEEM) and Atomic Force Microscopy (AFM). PEEM, using the spontaneous emission output of the Duke OK-4 free electron laser (FEL), clearly reveals the trinodular structure of the single fibrinogen molecule absorbed on oxidized silicon substrates. Moreover, PEEM images excited using various wavelengths between 249 and 310 nm reveal ionization thresholds of 4.6 eV for HPF. In addition, hydrogen-terminated silicon (H-Si) substrates and oxidized silicon substrates serving as model hydrophobic and hydrophilic surfaces were used to investigate the absorption coverage difference of fibrinogen molecules using ambient AFM. The images show that the fibrinogn absorption on H-Si substrates is significantly greater than that on the oxidized substrates.

**K26 3 Probing the low-resolution dynamics of biopolymers under force** RUXANDRA DIMA, *University of Massachusetts* CHANGBONG HYEON, D. THIRUMALAI, *IPST, University of Maryland* Single molecule force experiments are a major source of information for probing the structure and the dynamics of biopolymers. While the response of a biopolymer to the application of force, which is readily obtained from the force versus the extension curve, provides a glimpse of the underlying energy landscape, the much more interesting molecular-level behavior is not as easy to extract. In this context, we introduce a minimal model suitable for simulating the dynamics under force of biomolecules for long time-scales and with modest computational expenses. We will show that forced unfolding pathways predicted using this minimal model on systems that are challenging to simulate with conventional methods correlate very well with the results of recent force-unfolding experiments. Our findings underline the importance of understanding the interplay between tension propagation and the molecular relaxation time in pulling experiments.

**K26 4 Motion of single MreB bacterial actin proteins in Caulobacter show treadmilling in vivo*** W.E. MOERNER, SOYEON KIM, *Stanford University* ZEMER GITAI, *Princeton University* ANIKA KINKHABWALA, HARLEY MCADAMS, LUCY SHAPIRO, *Stanford University* Ensemble imaging of a bacterial actin homologue, the MreB protein, suggests that the MreB proteins form a dynamic filamentous spiral along the long axis of the cell in Caulobacter crescentus. MreB contracts and expands along the cell axis and plays an important role in cell shape and polarity maintenance, as well as chromosome segregation and translocation of the origin of replication during cell division. In this study we investigated the real-time polymerization of

MreB in Caulobacter crescentus using single-molecule fluorescence imaging. With time-lapse imaging, polymerized MreB could be distinguished from cytoplasmic MreB monomers, because single monomeric MreB showed fast motion characteristic of Brownian diffusion, while single polymerized MreB displayed slow, directed motion. This directional movement of labeled MreB in the growing polymer implies that treadmilling is the predominant mechanism in MreB filament formation. These single-molecule imaging experiments provide the first available information on the velocity of bacterial actin polymerization in a living cell.

**K26 5 Co-operative unfolding of protein domains** BUDDHAPRIYA CHAKRABARTI, *Lyman Laboratory of Physics, Harvard University, Cambridge MA 02138* TANNIEMOLA B. LIVERPOOL, *Department of Applied Mathematics, University of Leeds, LS2 9JT, UK.* ALEX J. LEVINE, *Department of Chemistry, University of California at Los Angeles, Los Angeles, CA 90095* How well does the worm-like chain force extension curve fit single-molecule protein unfolding data? Careful analysis of dynamic force spectroscopy data for different proteins [1] suggests that the compliance of a protein is generically larger than that predicted by the worm-like chain model. We propose that the observed excess compliance is due to pre-transitional conformational rearrangements within the protein domain that occur before the more dramatic failure of the domain as a whole. Using a generalization of the formalism introduced by Evans and Ritchie [2], we study protein–unfolding kinetics in our model where these internal conformational rearrangements are represented by a number of interacting Ising-type variables, which cooperatively escape over a barrier to the unfolded state. From this model, we predict a relation between the statistics of the fluctuations of the peak domain–unfolding force and the deviations of the force extension curves from the worm-like chain prediction. We suggest that, by using this approach, one can extract further details on the domain–unfolding pathway from extant force spectroscopy data. [1] D. J. Brockwell (private communication). [2] E. Evans, and K. Ritchie, Biophys. J., **72** 1541 (1997).

**K26 6 Quantitative analysis of tethered particle motion** PHILIP NELSON, *Dept. of Physics, Univ. Pennsylvania* CHIARA ZURLA, *Dept. of Biology, Univ. Milan* DARREN SEGALL, *Div. of Engr. and Applied Science, Caltech* DORIANO BROGIOLI, *Dept. of Biology, Univ. Milan* ROB PHILLIPS, *Div. of Engr. and Applied Science, Caltech* DAVID DUNLAP, *Dept. of Cell Biology, Emory Univ.* LAURA FINZI, *Dept. of Physics, Emory Univ.* Tethered particle motion (TPM) is a single-molecule technique that consists in tethering a bead to a slide through a DNA molecule. The Brownian amplitude of motion of the bead provides information about the conformational changes of the DNA molecule. We describe an improved experimental protocol, and a data analysis algorithm to extract quantitative conclusions from the data. We then apply a theoretical model for the statistics of the bead motion, which are quite different from those of a free polymer. Our experimental data for chain extension versus tether length are in good agreement with the model, showing that TPM is a useful tool for monitoring large conformational changes such as DNA looping. Moreover, we present the first experimental determination of the full probability distribution function of bead displacements, and find excellent agreement with theory over a range of tether lengths. Knowing this distribution a priori enhances our ability to extract events such as loop formation from observed time series.

**K26 7 The Role of Fluctuations in Enzymatic Activity.** STEVEN CHU, *Lawrence Berkeley National Laboratory*

In ''What is Life,'' a set of lectures delivered in 1944, Erwin Schrodinger states '' . . . from all we have learnt about the structure of living matter, we must be prepared to find it working in a manner that **cannot** be reduced to the ordinary laws of physics [not because] there is any 'new force', . . . but because the construction is different from anything we have yet tested in the physical laboratory.'' I will briefly discuss how this prediction fared 60 years after these lectures were given. With the advent of molecular, structural and single molecule biology, we are developing an increasingly mechanistic understanding of bio-molecular systems. The molecular machinery of life is imbedded in a viscous fluid where friction and thermal fluctuations are huge. In particular, studies of RNA enzymes such as the ribosome and other ribozymes show that their construction and operation itis different than human designed machines that work in an environment where fluctuations and dissipation or minimized.

**K26 10 Using a Microcantilever Array for Detecting DNA Melting** SIBANI BISWAL, *UC Berkeley* DIGVIJAY RAORANE, *UC Berkeley* ALISON CHAIKEN, *HP Labs* ARUN MAJUMDAR, *UC Berkeley* Microcantilever based sensors translate changes in Gibbs free energy due to macromolecular interactions into mechanical responses. We utilize the microcantilevers to observe surface stress changes in response to thermal dehybridization of surface grafted double stranded DNA oligonicleotides. We begin by immobilizing and hybridizing 20, 25, and 30 base pair DNA strands. Once the cantilever is heated, the DNA undergoes a transition as the complementary strand melts which results a cantilever deflection change. This deflection is due to changes to the electrostatic, ionic, and hydration interaction forces between the remaining immobilized DNA strands. For example, using a 20mer DNA strand in a 50 mM PBS buffer, the cantilever deflection shows an abrupt discontinuity at T $\sim$ 39$^o$C. When the salt concentration is lowered to 25 mM, we see a shift in the discontinuity to a lower temperature, T $\sim$ 30$^o$C. We also observe that DNA strands grafted onto the cantilever melt at lower temperatures compared to bulk solution due to the interactions between neighboring strands and the surface. We are also probing how base mismatches affect the cantilever deflection. This new technique has allowed us to probe DNA melting dynamics and leads to a better understanding of the stability of DNA complexes on surfaces.

**K26 11 Exploring the Electrical Conductivity of Cytochrome P450 by Nano-Electrode and Conductive Atomic Force Microscopy*** DEBIN LI, JIANHUA GU, YEWHEE CHYE, DAVID LEDERMAN, *Dept of Physics, West Virginia University* JAROD KABULSKI, PETER GANNETT, *Basic Pharmaceutical Sciences, West Virginia University* TIMOTHY TRACY, *Dept of Experimental and Clinical Pharmacology, University of Minnesota* There is a growing interest in measuring the conductivity of electron-transfer proteins. The cytochrome P450 (CP450) enzymes represent an important class of heme-containing enzymes. Immobilizing CP450 enzymes on a surface can be used for studying a single enzyme with respect to electron transfer. The spin state of the heme iron can change upon binding of a substrate. In our experiment, CP450 (diameter $\sim$ 5 nm) has been bonded to a metal surface. Nano-electrodes (gap $<$ 10 nm) were fabricated by defining a bridge via e-beam lithography and then breaking the junction by electromigration at low temperatures. We have examined the electronic properties of CP450 by itself and after binding CP450 with flurbiprofen. The room temperature I-V conductivity is reminiscent to cyclic voltammetry measurements, indicating the presence of strong ionic transfer. At lower temperatures (100 K) the I-V characteristics indicate electronic transport dominated by tunneling processes. The conductive AFM is an additional method used to examine the enzyme's electronic properties. The results from two methods will be discussed.

**K26 12 Traveling wave tracking of individual molecular motors** IRENE DUJOVNE, M. VAN DEN HEUVEL, *Kavli Inst. of NanoScience, Delft University of Technology* C. SYMONDS, G. CAPPELLO, *Institut Curie, Paris, France* CEES DEKKER, *Kavli Inst. of NanoScience, Delft University of Technology* Insight into the mechanisms of motility can be obtained by the study of the movement of motor proteins along biological filaments. Optical tweezer techniques are now able to track the motion of motor proteins with nanometer spatial resolution and 1-10 Hz bandwidth. Recently, G. Cappello developed an optical technique to track the movement of beads with sub-nanometer and microsecond resolution [1]. A unique aspect of this technique, based on total-internal-reflection traveling wave, is that no force is applied on the object under study. In this work we present modifications of this optical technique with the goal of larger scattering intensities that allow shorter acquisition times. Here we present this system to the study of microtubules traveling on kinesin-coated structures. The impact of fabricated nanostructures on the scattering intensities is discussed together with the feasibility of the application of this experimental scheme to the study of DNA-processing enzymes. 1 L. Busoni, A. Dornier, Jean-Louis Viovy, J.Prost, and G. Cappello, J. Appl. Phys. 98, 064302 (2005).

**K26 13 Steering and Trapping Multiple Particles by Feedback Flow Control: Theory and Experiments** MIKE ARMANI, SATEJ CHAUDHARY, ROLAND PROBST, BENJAMIN SHAPIRO, On the macro scale, feedback control is routinely applied to improve performance and enable new tasks in complex and uncertain systems operating in noisy environments. Our lab has focused on applying feedback control ideas to systems on the micro scale. We show how to combine micro-fluidics and feedback control to independently steer multiple particles with micrometer accuracy in two spatial dimensions. The particles are steered by creating a spatially and temporally varying fluid flow that carries all the particles from where they are to where they should be at each time step. Our control loop comprises sensing, computation, and actuation to steer particles along user-input trajectories, to hold particles in place, or both. Particle locations are identified in real-time by an optical system and sent to a control algorithm that then determines the electrode voltages necessary to create a flow field to carry all the particles to their next desired locations. The process repeats at the next time instant. We have demonstrated flow steering of multiple particles at once both in simulations and in experiments. The steering algorithm is robust to uncertainty and works even when conditions of the particles (size, surface charge), conditions of the buffer (pH, temperature, electro-chemistry, impurities), and attributes of the devices (errors in fabrication geometry, parasitic pressure flows driven by surface tension) vary and/or are unknown.

**K27 1 Long-range excitations in time-dependent density functional theory** DAVID G. TEMPEL, NEEPA T. MAITRA, *Hunter College of CUNY* Within TDDFT linear response, an adiabatic approximation such as ALDA to the exchange correlation kernel is most often used. It is local in time, or when considered in the frequency domain, frequency independent. We show that this neglected frequency dependence leads to drastic consequences for all excitations of a heteroatomic molecule composed of two open shell fragments at large separation. Strong frequency dependence of the kernel is needed for excitations of both local and charge transfer character. The needed frequency dependence arises from static correlation due to the step in the Kohn Sham potential between the fragments. An approximate kernel is derived to undo the static correlation and restore excited molecular dissociation curves at large separation. Leading order polarization and local dynamic correlation effects are also included. Future challenges for TDDFT will be discussed including molecular Feshabch resonances in stretched systems.

**K27 2 A physical interpretation of the Kohn-Sham energy in time-dependent current-density functional theory** ROBERTO D'AGOSTA, *Department of Physics, University of California - San Diego* GIOVANNI VIGNALE, *Department of Physics and Astronomy, University of Missouri - Columbia* It is well known that in static density functional theory the Kohn-Sham energy plays a fundamental role because it gives, by construction, the ground state energy of the system under study. In time-dependent density functional theory, it is not possible to attach to the Kohn-Sham energy the same physical interpretation. For example we know that for an isolated system the Kohn-Sham energy can be ''dissipated'' while the total energy of the real system is conserved.[1] However, the Kohn-Sham energy can be given a new physical interpretation as the maximum work that can be extracted from the system and it is related to the production of entropy during the time evolution of the system.[1] Project supported by NFS Grant No. DMR-0313681 [1]R. D'Agosta and G. Vignale, accepted by Phys. Rev. Lett., cond-mat/0508175.

**K27 3 Memory and exact exchange in time-dependent density-functional theory*** HARSHANI O. WIJEWARDANE, CARSTEN A. ULLRICH, *Department of Physics and Astronomy, University of Missouri-Columbia* Most applications in time-dependent density-functional theory (TDDFT) are being carried out using adiabatic approximations, such as the ALDA, for the exchange-correlation potential $V_{\rm xc}(r,t)$ at time $t$. In these approximations, the previous history of the system at times $t' < t$ is ignored in constructing $V_{xc}(r,t)$. In this talk, we consider the exact exchange potential in TDDFT and show that it has a memory. The exact exchange potential is obtained from the time-dependent optimized effective potential (TDOEP) method. We solve the associated TDOEP integral equation in space and time for a quantum well with two occupied subbands. We compare exact results with the KLI, Slater and ALDA approximations, discussing the memory effects and their relation to the elasticity of the electron liquid.

**K27 4 The Generating-Coordinate Method in Static and Time-Dependent Density Functional Theory*** EDNILSOM ORESTES, *Instituto de Quimica de Sao Carlos, Universidade de Sao Paulo and Department of Physics and Astronomy, University of Missouri-Columbia* A. B. F. DA SILVA, *Instituto de Quimica de Sao Carlos, Universidade de Sao Paulo* KLAUS CAPELLE, *Instituto de Fisica de Sao Carlos, Universidade de Sao Paulo* CARSTEN A. ULLRICH, *Department of Physics and Astronomy, University of Missouri-Columbia* The generating-coordinate method represents a many-body wave function as a superposition of non-orthogonal Kohn-Sham Slater determinants arising from different Hamiltonians. This method provides additional variational degrees of freedom in the calculation of static and dynamical properties of electronic systems. We present results for atomic ground- and excited- state energies for various choices of generating coordinates. We then apply our variational approach to discuss a particularly challenging problem in TDDFT, the calculation of correlated double-ionization processes. We present results for single- and double-ionization probabilities of a strongly driven two-electron Hookes atom.

**K27 5 The quantum defect: the true measure of TDDFT results for atoms** META VAN FAASSEN, KIERON BURKE, *Department of Chemistry and Chemical Biology, Rutgers University* We apply quantum defect theory to (time-dependent) density-functional calculations of Rydberg series for some closed shell atoms. We will compare several potentials by considering the quantum defect instead of the excitation energies. The quantum defect has the property of amplifying errors, allowing us to show that results that seem accurate from tables of excitation energies are not always so, especially for larger values of the principle quantum number $n$. In this way the quantum defect provides the appropriate tool for comparing time-dependent density-functional results for atoms.

**15:30**
**K27 6 Atom-Atom Scattering with TDDFT - Beyond the Born-Oppenheimer Approximation.*** RYAN M. HATCHER, ALAN R. TACKETT, MATTHEW J. BECK, SOKRATES T. PANTELIDES, *Vanderbilt University* We report results of calculations of atom-atom scattering going beyond the Born-Oppenheimer (B-O) approximation. We use time-dependent density functional theory with an adiabatic approximation to the scalar exchange-correlation potential in the local-density approximation. We use pseudopotentials, keeping the nearest approach larger than the core radius. The ions are treated as classical particles while the electrons have full freedom to evolve off their instantaneous ground state. If radiative energy loss is not included, energy is conserved; part of the initial ion kinetic energy is transferred to

electrons and stays there after separation, a clear sign of effects beyond the B-O approximation. Results of treating radiative losses at two levels of approximation will be discussed. Further results of ongoing calculations of scattering of a Si atom by a solid Si matrix will be described.

**15:42**

**K27 7 Effects of core-valence interaction in the screened-exchange density functional method*** BYOUNGHAK LEE, LIN-WANG WANG, *Lawrence Berkeley National Lab* We present a new development for the screened-exchange (sX) density functional method using a planewave basis. In the screened-exchange density functional method, an explicit screened exchange interaction term is included in the total energy expression. When implemented with a planewave basis, the LDA derived norm-conserving pseudopotentials have usually been used without any change for the sX calculation. While this works well for valence *s* and *p* orbitals with the same quantum numbers, we found that there is a problem when *d* orbitals with a different quantum number are included. This is due to an error in the exchange integral between *d* and *s*, *p* orbitals stemming from the use of pseudowavefunctions. As a result, the calculated bulk electronic structures have much smaller band gaps compared to all electron sX calculations and experiments. We propose a scheme to correct the *d-s/p* exchange integrals using atomic orbital projection operators. We test our scheme on ZnTe, CdSe, and GaAs, and discuss the effects of shallow core states in comparison with other implementations such as the full potential linearized augmented planewave method. We will also compare our scheme with other Hartree-Fock pseudopotentials.

**K27 8 Non-Uniqueness of Local Effective Potential Energy in Density Functional Theory** VIRAHT SAHNI, XIAO-YIN PAN, *The Graduate School, CUNY* MARLINA SLAMET, *Sacred Heart University* As a consequence of the first Hohenberg-Kohn (HK) theorem, in the mapping from a *ground* state of an interacting system to an S system of noninteracting fermions with equivalent density, the effective potential energy of the latter is *unique*. But it is so *only* if these fermions are in their *ground* state. It can be shown via Quantal Density Functional Theory,[1] that the *ground* state density of an interacting system can also be reproduced by S systems that are in an *excited* state. Hence, in principle, there are an infinite number of functions that can reproduce a *ground* state density. Similarly, in the mapping from an *excited* state of the interacting system to an S system with equivalent density, the state of the latter is *arbitrary*. Hence, there are an infinite number of functions that can reproduce the excited state density. The latter proves the lack of a first HK theorem for *excited* states. The difference between the potential energy functions in either case is due solely to Correlation-Kinetic effects.

**16:06**

**K27 9 Dynamical exchange-correlation potentials beyond the local density approximation*** JIANMIN TAO, GIOVANNI VIGNALE, *University of Missouri* Approximations for the static exchange-correlation (xc) potential of density functional theory (DFT) have reached a high level of sophistication. By contrast, time-dependent xc potentials are still being treated in a local (although velocity-dependent) approximation [G. Vignale, C. A. Ullrich and S. Conti, PRL **79**, 4879 (1997)]. Unfortunately, one of the assumptions upon which the dynamical local approximation is based appears to break down in the important case of d.c. transport. Here we propose a new approximation scheme, which should allow a more accurate treatment of molecular transport problems. As a first step, we separate the exact adiabatic xc potential, which has the same form as in the static theory and can be treated by a generalized gradient approximation (GGA) or a meta-GGA. In the second step, we express the high-frequency limit of the xc stress tensor (whose divergence gives the xc force density) in terms of the exact static xc energy functional. Finally, we develop a perturbative scheme for the calculation of the frequency dependence of the xc stress tensor in terms of the ground-state Kohn-Sham orbitals and eigenvalues.

**K27 10 Beyond the LDA in density functional theory: empirical Laplacian-based models for the exchange-correlation energy.** ANTONIO C. CANCIO, *Ball State University* M.Y. CHOU, *Georgia Tech* We report recent work in developing a simple GGA-level density functional theory using primarily the Laplacian of the density $\nabla^2 n$ as an input beyond the LDA, obtained by a fit to the exchange-correlation energy density of the Si crystal and atom[1]. Preliminary tests of this model with LDA pseudopotentials for several solids and molecules show a modestly improved treatment of structural properties over that of conventional GGA's, particularly for covalently bonded systems. We discuss an all-electron generalization of our model constructed by fitting to all-electron data for the energy density and potential of closed-shell first row atoms (He, Be, Ne)[2]. The use of $\nabla^2 n$ trivially avoids the singularity in the Kohn-Sham potential that gradient-based models suffer due to the cusp in electron density at the nucleus. Using an expansion in $1/\nabla^2 n$ we are able to fit exchange energy densities in the cusp region with a great degree of accuracy, while obtaining reasonable potentials.

**K27 11 Local self-interaction correction in LSMS.** MARKUS EISENBACH, G. M. STOCKS, *ORNL* While local density approximation (LDA) calculations have proven to be exceptionally successful for performing first principles calculations materials generally thought of as being strongly correlated (e.g. transition metal oxides) are poorly described. However, for many of these systems, it is now clear that an important factor in this failure is the self-interaction error that results in an unphysical Coulomb interaction of an electron with itself. This error can be readily accounted for by use of self-interaction corrected (SIC) LDA [1,2]. Here we report on our implementation of the recently developed local SIC (L-SIC) formulation developed by Lüders et al. [3] and which is particularly well suited to multiple scattering theory based electronic structure methods. Here we will describe

the implementation of L-SIC in our order-N locally self-consistent multiple scattering (LSMS) code as well results for example applications f-electron and TMO systems. 1. J. P. Perdew & A. Zunger, PRB 23, 5048 (1981). 2. Z. Szotek et al., J. Phys.:CM 16, S5587-S5600 (2004). 3. M. Lüders et al., PRB 71 205109 (2005). **K27 12 One-to-one Correspondence of the Normalization and Coulomb Hole Sum Rules for Approximate Wave Functions.[1]**
XIAO-YIN PAN, VIRAHT SAHNI, LOU MASSA, *The Graduate School, CUNY* For approximate wave functions, we prove the theorem that there is a one-to-one correspondence between the constraints of normalization, and of the Fermi-Coulomb and Coulomb hole sum rules. This correspondence is surprising because normalization depends on the probability of finding an electron at some position, whereas the Fermi-Coulomb/Coulomb hole sum rules depend on the probability of two electrons staying apart due to Pauli-Coulomb/Coulomb correlations. We demonstrate the theorem by example using wave function functionals[2]. The significance of the theorem for DFT lies in the fact that the extensively employed LYP correlation energy functional[3] is based on a wave function (that of Colle-Salvetti[4]) which satisfies the Coulomb hole sum rule only approximately, and that wave function is therefore not normalized. 1 Supported by RF CUNY 2 X.-Y. Pan*et al*, Phys. Rev. Lett. **93**, 130401 (2004) 3 C. Lee *et al*, Phys. Rev. B **37**, 785 (1988) 4 R. Colle and O.Salvetti, Theor. Chim. Acta **37**, 329 (1975).

**K27 13 Wave Function Arbitrariness of Noninteracting Fermion Model in Quantal Density Functional Theory[1](QDFT)**
MARLINA SLAMET, *Sacred Heart University* VIRAHT SAHNI, *The Graduate School, CUNY* In the QDFT mapping from a *ground* or *excited* state of the interacting system to one of noninteracting fermions in a particular *excited* state with equivalent density, there is an arbitrariness in the wave function of the model system. For example, in the case of a two-electron atom, the mapping to the excited singlet $2^1S$ state of the model system, there are three wave functions that lead to the *same* density: two single Slater determinants of the orbitals that are eigen functions of only $S_z$, and a linear combination of Slater determinants of these orbitals that is an eigen function of both $S_z$ and $S^2$. Neither of the wave functions is more appropriate than the other, since all three wave functions deliver the same density. However, based on the choice of wave function, the structure of the corresponding Fermi and Coulomb holes, and therefore the values of the resulting Pauli and Coulomb correlation energies, will differ. Their sum, the Fermi-Coulomb holes, and the Pauli-Coulomb energy, remains unchanged. The wave function arbitrariness will be demonstrated via the Hooke's atom. 1 *Quantal Density Functional Theory*, V. Sahni (Springer-Verlag, 2004).

**K27 15 Ions on the verge of ionization*** VAZGEN SHEKOYAN, *Rutgers University, Department of Physics and Astronomy* KIERON BURKE, *Rutgers University, Department of Chemistry and Chemical Biology* The behavior of negative ions on the verge of ionization is studied. Electron-electron correlation plays a significant role for negative ions, especially for the outermost electron. Answering questions such as what negative ions exist, what the behavior of its electronic density is at the ionization threshold or why negative ions are particularly hard to treat in Density Functional Theory(DFT) are important. A general formalism (a differential equation for the square root of the electronic density) has been developed to treat such systems. It has been applied on a 1-d model of 2-electron negative ion, and its behavior on the verge of ionization has been studied in detail.

**K28 2 Polymer Vesicles in Biomimetic Applications.**
MARIA SANTORE, *UMass Amherst Polymer Science and Engineering*

The performance of phospholipid vesicles in targeted pharmaceutical delivery is greatly improved by the addition of water-soluble polymeric tethers. The resulting solvated brush resists protein adsorption and access of biological entities

to the hydrophobic membrane core, evading immune response. Polymeric vesicles have, due to their increased stability and greater variability in chemical and mechanical properties, huge potential relative to lipsomes. They may ultimately form the basis for artificial cells and scavengers, or in non-biomedical applications, distributed microreactors. To this end, we explore the incorporation of biomimetic features in polymer lamellae: membrane phase separation and ''rafts,'' bending fluctuations and budding, triggered release, and dynamic engulfment. Vesicle phase separation, bending, lamellar disruption, and lamellar wetting all are rooted in block copolymer and polymer brush physics. For instance, vesicles blended from two block copolymers, polystyrene-co-poly(ethylene oxide) (PS-PEO) and poly(butadiene)-PEO (PBD-PEO) exhibit no macroscopic phase separation, though blends of PS and PBD at the same molecular weight do. This represents either an upward shifting of the UCST or a suppression of large-scale morphology. Also interesting is the ability of PS-PEO to form robust, vesicle-sized, capsules carrying aqueous phase cargo. While we doubt the true vesicular nature of these structures, they are often robust to passing of a liquid-air contact line. Their morphology is highly dependent on copolymer composition. The capsules are subject to buckling instabilities and in some instances, glassy fracture with sudden content release. Lamellar physics also plays an important role in the scavenging and adhesion capabilities of polymer vesicles: While the density of adhesive groups on the chain ends of incorporated tethers acts in ways easy to anticipate, engulfment dynamics depends dramatically on dynamic membrane bending.

**K28 3 Transition from Unilamellar to Bilamellar Vesicles Induced by an Amphiphilic Biopolymer** SRINIVASA RAGHAVAN, JAE-HO LEE, *Department of Chemical and Biomolecular Engineering, College Park, MD 20742* GREGORY PAYNE, *Center for Biosystems Research, University of Maryland Biotechnology Institute, College Park, MD 20742* VIVEK AGARWAL, ARIJIT BOSE, *Department of Chemical Engineering, University of Rhode Island, Kingston, RI 02881* We report some unusual structural transitions upon the addition of an amphiphilic biopolymer to unilamellar surfactant vesicles. The polymer is a hydrophobically modified chitosan and it embeds its hydrophobes in vesicle bilayers. We study vesicle-polymer mixtures using small-angle neutron scattering (SANS) and cryo-transmission electron microscopy (cryo-TEM). When low amounts of the polymer are added to unilamellar vesicles of itca. 120 nm diameter, the vesicle size decreases by about 50%. Upon further addition of polymer, lamellar peaks are observed in the SANS spectra at high scattering vectors. Using a model developed by Nallet et al., we show that the SANS data corresponds to a co-existence of unilamellar vesicles and bilamellar vesicles (i.e., vesicles with two bilayers). The transition to bilamellar vesicles as well as the changes in unilamellar vesicle size are further confirmed by cryo-TEM. A mechanism for the polymer-induced transition from uni- to bilamellar vesicles is proposed.

**K28 4 Temperature and pH Response of PB-P(Lys) Block Copolymer Assemblies** DANIEL A. SAVIN, KAY E. GEBHARDT, GOPAL R. VENKATACHALAM, *University of Vermont* Amphiphilic block copolymers consisting of poly(butadiene) and poly(L-lysine) (PB-P(Lys)) were synthesized and their solution properties studied using dynamic light scattering and transmission electron microscopy. We exploit secondary structure changes that occur in the P(Lys) chain to observe changes in solution morphology as a function of solution conditions. At high pH, the P(Lys) chain assumes either an $\alpha$-helical or a $\beta$-sheet conformation depending on temperature, while at lower pH the side chains become protonated, resulting in an expanded coil configuration. In these studies, four molecular weights and compositions of PB-P (Lys) were studied. For short P(Lys) blocks, these block polymers assemble into vesicles that swell with decreasing pH. For longer P(Lys) blocks, cylindrical micelles are formed that undergo a morphological shift to spherical micelles with decreasing pH.

**K28 5 Understanding the Self-Assembly of Amphiphilic Diblock Copolypeptides for Controlled Biomaterial Design** LISA PAKSTIS, *Univ. of Delaware* ANDREW NOWAK, ERIC HOLOWKA, TIMOTHY DEMING, *UCLA* DARRIN POCHAN, *Univ. of Delaware* Copolypeptides with a hydrophilic lysine (K) block and a hydrophobic leucine (L) block were designed to self-assemble due to their amphiphilic nature and the defined secondary structure of the hydrophobic block. In aqueous solution, these copolypeptides assemble into stiff, porous hydrogels at low volume fractions of polymer (vol. fraction polypeptide (0.5 wt%). Assembly is dictated by the secondary structure of the hydrophobic block and the polyelectrolytic character of the hydrophilic block, as revealed through microscopy and neutron scattering experiments. Understanding the self-assembly mechanism of amphiphilic diblock copolypeptides has led to the formation of a disparate range of materials. Vesicles can be produced by inducing curvature at the interface between the hydrophilic to hydrophobic blocks by altering either the charge density or the molecular weight of the polypeptide. Manipulation of the assembly kinetics, by dissolution of the polypeptide into an organic solvent with subsequent addition of water followed by evaporation of the organic component, produces twisted fibrils and hexagonal platelets. Characterization of these materials demonstrates that assembly is intrinsically controlled on the nanoscale by molecular design, most importantly by the presence of the alphahelical hydrophobic block, and can also be influenced by assembly kinetics and manipulation of electrostatic interactions of the charged blocks.

**K28 6 Laminated, Nontwisting Beta-Sheet Fibrils Constructed via Peptide Self-Assembly** MATTHEW S. LAMM, *University of Delaware - Department of Materials Science and Engineering* KARTHIKAN RAJAGOPAL, *University of Delaware - Department of Chemistry and Biochemistry* JOEL P. SCHNEIDER, *University of Delaware - Department of Chemistry and Biochemistry* DARRIN J. POCHAN, *University of Delaware - Department of Materials Science and Engineering* A de novo designed peptide has been characterized that self-assembles into beta-sheet fibrils exhibiting a nontwisted, laminated morphology. The laminated morphology is constituted by 2.5nm wide filaments that laterally associate to form flat fibril laminates exceeding 100nm in width and microns in length. The height of each fibril is determined by the length of exactly one peptide momomer in an extended beta-strand conformation, approximately 7nm. Once formed, these fibrils are highly stable over a range of temperatures and pH and exhibit characteristics similar to those of amyloid fibrils. Kinetic

parameters of pH and temperature can be used to affect the rate of beta-sheet formation and, consequently, the degree of lamination. Finally, the importance of peptide sequence on the resultant fibril morphology is demonstrated via rational peptide design and discussed in the context of current theories of fibril twisting.

**16:30**
**K28 7 Physical Properties of Anionic Peptide Amphiphile Fibers Grown in the Presence of Cationic Proteins** MEGAN GREENFIELD, MONICA OLVERA DE LA CRUZ, SAMUEL STUPP, *Northwestern University* We analyze the structure and mechanical properties of fibers formed by anionic peptide amphiphiles (PA) in the presence of cationic proteins with varying charge. The PA molecules, which are composed of a hydrophobic alkyl tail, a beta-sheet forming region, and a hydrophilic epitope region, self-assemble into cylindrical micelles in water at 1% weight concentration in the presence of multivalent salts. The fibers grow in one dimension by forming an internal beta sheet along the middle segment; the hydrophobic tail hides inside the micelle and the epitope region is exposed to the water. Rheology and electron microscopy are used to investigate the physical properties of the resulting PA gels. The correlation between the charge of the cationic proteins used for gelation and the resulting PA gel's structure and mechanical properties are discussed.

**16:42**
**K28 8 Dewetting instability during formation of polymerosomes from block-copolymer-stabilized double emulsions** RYAN HAYWARD, *University of Massachusetts, Amherst* ANDREW UTADA, DAVID WEITZ, *Harvard University* We study the formation of polymer vesicles, or polymerosomes, from double emulsion droplets of controlled architecture produced via a microfluidic device. A volatile organic solvent containing an amphiphilic diblock copolymer is employed as the middle phase of a water-in-oil-in-water emulsion. The block copolymer assembles at the oil-water interfaces, stabilizing the interior water droplet against coalescence with the exterior aqueous phase. Upon evaporation of the organic solvent, a thin vesicle of the block copolymer is formed. We find that the presence of excess diblock copolymer in the oil phase gives rise to a dewetting phenomenon, in which the shrinking oil droplet partially wets a thin film of solvated block copolymer. This yields acorn-like morphologies similar to those commonly encountered in systems of three immiscible fluids, ultimately resulting in an inhomogeneous polymerosome structure. We propose that the dewetting may be driven by a depletion effect due to the excess diblock copolymer.

**16:54**
**K28 9 Condensed States of a Semiflexible Copolymer in a Poor Solvent: Figures of Eight and Discrete Toroids** DAVID WILLIAMS, ERNESTO HERNANDEZ-ZAPATA, IRA COOKE, *Australian National University* We examine the problem of a semiflexible (stiff) copolymer chain in a selective solvent. In the homopolymer case toroids often result. In the copolymer case the phase diagram is much richer. One can obtain striped toroids, figure eights, cages and many other stuctures. We will present simple analytical results for some of these along with computer simulations showing a variety of morphologies. One major result, is that for copolymers the structures must be discrete so the size of the toroids is effectively quantised.

**SESSION K29: PROTEINS STRUCTURE AND FUNCTION**

**K29 1 Biochemical Reversal of Aging** JOHN T.A. ELY, *Radiation Studies, University of Washington* We cite our progress on biochemical reversal of aging. However, it may be circa 2 years before we have necessary substances at low cost. Meanwhile, without them, a number of measures can be adopted providing marked improvement for the problems of aging in modern societies. For example, enzymes are needed to excrete toxins that accelerate aging; Hg is the ultimate toxin that disables all enzymes (including those needed to excrete Hg itself). Low Hg level in the urine, due to loss of excretory ability, causes the diagnosis of Hg toxicity to almost always be missed. Hg sources must be removed from the body! Another example is excess sugar; hyperglycemia decreases intracellular ascorbic acid (AA) by competitively inhibiting the insulin- mediated active transport of AA into cells. Thus, immunity is impaired by low leucocyte AA. AA is needed for new proteins in aging tissues. Humans must supplement AA; their need same as in AA-synthesizing mammals.

**14:42**
**K29 2 A Unified Approach to Sickle Hemoglobin Gelation and Phase Separation** F.A. FERRONE, *Drexel University* M.U. PALMA, M.B. PALMA-VITTORELLI, *University of Palermo* Protein aggregation has been identified as a major component in a number of diseases of which the earliest known and most thoroughly studied is sickle cell disease. Because of its direct bearing on pathophysiology, HbS polymer formation has been extensively described. The principal challenge now lies in the need of reconciling well documented but apparently contrasting properties of HbS solutions. These are the purely hard-sphere behavior of HbS under non-gelling conditions (extending to the 7th order in virial coefficients), and the equally well documented existence of a region of liquid-liquid demixing of the solution, from which notable deviations from hard-sphere behavior would be expected. We present a strategy to circumvent this impasse by including explicit and well known activity coefficients in a Flory-Huggins like term in the monomer chemical potential. This preserves the successful thermodynamic treatment of polymer formation while introducing a term leading to a spinodal. The formulation is consistent with known data, and implications for kinetics will be described.

**14:54**
**K29 3 Fluorescence photocycle of GFP studied by trapping phototransformation intermediates** GEORGI GEORGIEV, *Assumption College* TIMOTHY SAGE, *Northeastern University* JASPER VAN THOR, *Oxford University* OXFORD/NORTHEASTERN COLLABORATION, NORTHEASTERN/ASSUMPTION TEAM, The fluorescence photocycle consists involves excited state proton transfer (ESPT) from chromophore to Glu222, ionizing chromophore and neutralizing Glu222. A competing low quantum yield phototransformation process ionizes chromophore, and decarboxylates Glu222. We report spectroscopic measurements on cryotrapped reaction intermediates of the phototransformed GFP that electrostatically mimic intermediates in the fluorescence photocycle. Illumination at 100K leads to ap-

pearance of both a visible absorption band at 497nm, indicating an ionized chromophore in a non-equilibrium environment, and of multiple IR bands due to photogenerated carbon dioxide, confirming the decarboxylation of Glu222. Additional changes in the IR spectrum reflect numerous rearrangements of surrounding side chains and internal water molecules even at 100K. Polarized IR measurements on single crystals, measurements on mutant GFP, and solvent exchange measurements allow us to identify IR difference signals due to Gln69, Cys70, and weakly hydrogen-bonded internal water molecules. These spectroscopic changes highlight the role of the chromophore environment in preventing nonradiative decay of the excited state, and thereby enhancing the quantum efficiency.

**K29 4 Mechanisms of triggering H1 helix in prion proteins unfolding revealed by molecular dynamic simulation*** CHIH-YUAN TSENG, *Dept. of Physics, National Central University* H.C. LEE, *Dept. of Physics and Dept. of Life Science, National Central University* In template-assistance model, normal Prion protein ($PrP^{normalC}$), the pathogen to cause several prion diseases such as Creutzfeldt-Jakob (CJD) in human, Bovine Spongiform Encephalopathy (BSE) in cow, and scrapie in sheep, converts to infectious prion ($PrP^{normalSc}$) through a transient interaction with $PrP^{normalSc}$. Furthermore, conventional studies showed S1-H1-S2 region in $PrP^{normalC}$ to be the template of S1-S2 $\beta$-sheet in $PrP^{normalSc}$, and Prion protein's conformational conversion may involve an unfolding of H1 and refolding into $\beta$-sheet. Here we prepare several mouse prion peptides that contain S1-H1-S2 region with specific different structures, which are corresponding to specific interactions, to investigate possible mechanisms to trigger H1 $\alpha$-helix unfolding process via molecular dynamic simulation. Three properties, conformational transition, salt-bridge in H1, and hydrophobic solvent accessible surface (SAS) are analyzed. From these studies, we found the interaction that triggers H1 unfolding to be the one that causes dihedral angle at residue $Asn^{normal143}$ changes. Whereas interactions that cause S1 segment's conformational changes play a minor in this process. These studies offers an additional evidence for template-assistance model.

**K29 5 Analyzing knots in protein structures** PETER VIRNAU, MEHRAN KARDAR, *Department of Physics, MIT* LEONID MIRNY, *Harvard-MIT Division of Health Sciences & Technology* Although globular homopolymers display an abundance of knots (Virnau et al, J. Am. Chem. Soc. 127, 15102 (2005)), only about one in a thousand protein structures are knotted. Can this absence of entanglement be explained in terms of statistical mechanics or is there an evolutionary bias? Do knots in proteins serve a purpose and how do they actually fold? To elaborate on this, we will present an overview of knotted proteins from the current version of the Protein Data Bank. We will also discuss some particularly intriguing examples of this set.

**15:30**

**K29 6 Designing novel kinases using evolutionary sequence analysis** AREEZ MODY, JOAN WEINER, LAKSHMAN IYER, SHARAD RAMANATHAN, *Bauer Center for Genomics at Harvard University* Cellular pathways with new functions are thought to arise from the duplication and divergence of proteins in existing pathways. The MAP kinase pathways in eukaryotes provide one example of this. These pathways consist of the MAP kinase proteins which are responsible for evoking the correct response to external stimuli. In the yeast *Saccharomyces cerevisiae* these pathways detect pheromones, osmolar stresses and nutrient levels, leading the cell into dramatic changes of morphology. Despite being homologous to each other, the MAP kinase proteins show specificity of function. We investigate the nature of the amino acid sequences conferring this specificity. To this end, we i) search the sequences of similar proteins in other Eukaryote species, ii) make a study of simple theoretical models exploring the constraints felt by these protein segments and iii) experimentally construct, a large suite of hybrid proteins made of segments taken from the homologous proteins. These are then expressed in Yeast cells to see what function they are able to perform. Particularly we also ask whether it is possible to design a new kinase protein possessing new function and specificity.

**15:42**

**K29 7 Phase Diagram for Urate Oxidase** NATHANIEL WENTZEL, JAMES D. GUNTON, *Lehigh University* Urate Oxidase from itAsperigillus flavus has been shown to be a model protein in terms of understanding the effects of PEG on the crystallization of large proteins. Extensive experimental studies based on SAXS (Vivares et al, J. Phys. Chem. B 108, 6498 (2004)) have determined the effects of salt, pH, temperature, and most importantly polyethylene glycol (PEG), on the crystallization of this protein. Recently, some aspects of the phase diagram have also been determined. In this paper we use Monte Carlo techniques to predict phase diagrams for urate oxidase in solution with PEG. The model used includes an electrostatic interaction, van der Waals attraction, and a polymer-induced depletion interaction (Vivares et al, Eur. Phys. J. E 9, 15 (2002)). Results of the simulation are compared with experimental results.

**15:54**

**K29 8 Inter-Domain Dynamics in a Two-Domain Protein Studied by NMR** YAROSLAV RYABOV, *University of Maryland at College Park* DAVID FUSHMAN, Domain orientation and dynamics often play an important role in regulation of multi-domain proteins function. Here we consider a two-domain system, Lys48-linked di-ubiquitin ($Ub_2$), which is the simplest model of the polyubiquitin chain involved in the ubiquitin-proteasome pathway. Under physiological conditions $Ub_2$ adopts a compact conformation, in which the functionally important hydrophobic residues are sequestered at the interface between the two $Ub_2$ domains. Here we present a dynamic model that combines the anisotropic overall rotational diffusion with intra- and interdomain dynamics. This model describes the interdomain motion as a transition between two distinct conformational states. The model is applied to experimental $^{15}N$ relaxation data for Lys48-linked $Ub_2$ acquired at neutral (pH 6.8) and acidic (pH 4.5) conditions. The model provides complete picture of $Ub_2$ domain mobility including domain orientations, time scales of domain motions, and occupation probabilities for both states of $Ub_2$. The obtained results are consistent with independent data on chemical shift perturbation mapping and spin labeling.

**16:06**

**K29 9 Discovering the recognition code bacteria use to sense their environment by tracking co-evolutionary patternsBacteria typically posses tens of distinct signaling pathways that allow the organism to translate diverse environmental conditions into action** ROBERT WHITE, *The Scripps Research Institute (TSRI)* TERRY HWA, *The Center for Theoretical Biological Physics (UCSD)* JIM HOCH, *TSRI* Bacteria typically posses tens of distinct signaling pathways that allow the organism to translate diverse environmental conditions into action. A common signaling mechanism is a bucket brigade of phosphate triggered by the autophosphorylation of ''sensor kinase'' (SK) then passed to a protein called a ''response regulator'' (RR). The phosphorylation state of the RR regulates its function, thereby completing the signaling pathway. In one organism—but in pathways responsible for sensing diverse signals—the domains at which the transfer of the phosphate group occurs show surprising homology to each other. What keeps the organism from getting its signals crossed? We present a detailed bioinformatic study of over 1500 cognate SK/RR pairs that reveals patterns that can be used to predict the presence of evolved crosstalk and shed light on the paralogous divergence of these essential messengers.

**16:18**

**K29 10 Simple Model of Sickle Hemoglobin** ANDREY SHIRYAYEV, XIAOFEI LI, JAMES GUNTON, A microscopic model is proposed for the interactions between sickle hemoglobin molecules based on information from the protein data bank. A Monte Carlo simulation of a simplified two patch model is carried out, with the goal of understanding fiber formation. A gradual transition from monomers to one dimensional chains is observed as one varies the density of molecules at fixed temperature, somewhat similar to the transition from monomers to polymer fibers in sickle hemoglobin molecules in solution. An observed competition between chain formation and crystallization for the model is also discussed. The results of the simulation of the equation of state are shown to be in excellent agreement with a theory for a model of globular proteins, for the case of two interacting sites.

**16:30**

**K29 11 Antifreeze Protein Binds Irreversibly to Ice*** I. BRASLAVSKY, N. PERTAYA, C.L. DI PRINZIO, L. WILEN, *Ohio University, Athens, OH* E. THOMSON, J.S. WETTLAUFER, *Yale University, CT* C.B. MARSHALL, P.L. DAVIES, *Queen's University, ON, Canada* Many organisms are protected from freezing by antifreeze proteins (AFPs), which bind to ice and prevent its growth by a mechanism not completely understood. Although it has been postulated that AFPs would have to bind irreversibly to arrest the growth of an ice crystal bathed in excess liquid water, the binding forces seem insufficient to support such a tight interaction. By putting a fluorescent tag on a fish AFP, we were able to visualize AFP binding to ice and demonstrate, by lack of recovery after photo-bleaching, that it is indeed irreversible. Because even the most avid protein/ligand interactions exhibit reversibility, this finding is key to understanding the mechanism of antifreeze proteins, which are becoming increasingly valuable in cryopreservation and improving the frost tolerance of crops.

*Supported by CIHR, the Bosack and Kruger Foundation, Yale and Ohio Universities.

**16:42**

**K29 12 Fluorescence microscopy studies of the hyperactive antifreeze protein from an insect*** N. PERTAYA, C.L. DI PRINZIO, L. WILEN, *Ohio University, Athens, OH* E. THOMSON, J.S. WETTLAUFER, *Yale University, CT* C.B. MARSHALL, P.L. DAVIES, *Queen's University, ON, Canada* I. BRASLAVSKY, *Ohio University, Athens, OH* Antifreeze proteins (AFPs) protect animals from freezing by binding to extracellular ice and inhibiting its growth. Since the initial discovery of AFPs in fish, non-homologous types have been found in insects, plants, bacteria, fungi, and vertebrates. Different AFP types have diverse structures and varied activities. For example, AFPs produced by insects are much more active in inhibiting ice crystal growth compared to most AFPs found in fish or plants. By putting a fluorescent tag on an insect AFP we were able to visualize AFP binding to ice, to determine the ice crystal surfaces to which the AFP adheres, and to follow the kinetics of AFP binding to ice. We expect this approach will contribute to a better understanding of the mechanism of AFP activity and in particular the hyperactivity of insect AFPs.

*Supported by CIHR, the Bosack and Kruger Foundation, Yale and Ohio Universities.

**16:54**

**K29 13 Self-assembly of type 1 collagen : Interaction between normal and mutant collagen** SEJIN HAN, WOLFGANG LOSERT, *University of Maryland* We investigate the self-assembly of type 1 collagen, termed fibrillogenesis. Fibrillogenesis of type I homozygous mutations revealed a substantial difference in the kinetics, in particular, rapid growth of fibers and the absence of lag time. We developed a technique for differential fluorescent labeling of collagen combined with laser scanning confocal microscopy for time dependent observation of fibrillogenesis kinetics and structural properties in 3D. We observed that co-assembly of heterotrimers (normal) and homotrimers (mutant) in mixtures within the same fibrils during fibrillogenesis, despite their very different fibrillogenesis kinetics. Turbidity measurements of fibrillogenesis of mixture of hetero- and homotrimers showed the normal S-shaped curve with a lag time typical of heterotrimers. We characterized the structural topology of the collagen 3D network through Betti numbers that are primarily describing the connections between different components. We found that homotrimers has fewer intersections per disjoint fiber than normal heterotrimers, demonstrating finer and straighter network structure in images.

**17:06**

**K29 14 MutY: optimized to find DNA damage site electronically?*** JONG-CHIN LIN, DANIEL COX, RAJIV SINGH, Iron sulfur clusters are present in the DNA repair protein MutY in a region highly homologous in species as diverse as *E. Coli* and Homo Sapiens, yet their function remains unknown. In MutY, this mixed valence cluster exists in two oxidation states, $[Fe_4S_4]^{2+/3+}$, with the stability depending upon the presence of DNA. We have studied the electronic structure and stability of these clusters using the local orbital based SIESTA implementation of density functional theory. We find that the iron-sulfur cluster in MutY can undergo 2+ to 3+ oxidation when coupling to DNA through hole transfer, especially when MutY is near an oxoguanine modified base(oxoG). Employing the Marcus theory for electron transfer, we find (i) near optimal Frank-Condon(FC) factor for 2+ transfer to oxoG; (ii) reduced FC factor for transfer to G due to a high oxidation potential; (iii) reduced FC factor with

the mutation L154F; (iv) reduced tunning matrix element with the mutation R149W. Both L154F and R149W mutations dramatically reduce or eliminate repair efficiency. Hence, redox modulation of MutY search and binding appears plausible and may have broader implications for DNA-protein interactions.

**14:30**
**K30 1 Weighing Molecules with Carbon Nanotubes** ABHIJAT GOYAL, TADIGADAPA SRINIVAS, *Department of Electrical Engineering, The Pennsylvania State University, University Park, PA 16802* PETER EKLUND, *Department of Physics, The Pennsylvania State University, University Park, PA 16802* We have constructed a sensitive mass balance by coating a thin quartz transducer with debundled carbon nanotubes. The transducer operates in theshear mode at 29 MHz. Application of the nanotube film to the transducer downshifts the frequency as expected (mass loading), but we observe an unexpected increase in the Q-factor, i.e., the nanotube loading reduces the mechanical losses in the resonator. This nanomechanical resonator is also sensitive to mass loading of the internal pores of the nanotubes. By exposing the nanotube-coated resonator to various gases (e.g., inert gases, N2, SF6, etc.), we are able to easily observe the adsorption/desorption of the gases. At constant temperature and pressure, we observe an interesting M0.45 shift in the resonance frequency, where M is the molecular mass. The mass exponent we observe in these mass-balance experiments results is in good agreement with that published recently [1] on the collision-induced changes in the resistance and thermolectric power of thin nanotube films. The theory behind exponential mass dependence will be discussed and relates to the deformation of the nanotube wall and the residence time of the molecule on the tube wall.

**14:42**
**K30 2 Probing Mechanical Properties of Carbon Nanotubes by Light Scattering** YANG WU, FENG WANG, MINGYUAN HUANG, LIMIN HUANG, MATTHEW Y. SFEIR, LOUIS E. BRUS, STEPHEN O'BRIEN, JAMES HONE, TONY F. HEINZ, *Columbia University, New York, NY 10027* An important capability for studying and exploiting the remarkable mechanical properties of carbon nanotubes is the detection of their physical motion. Here we present a scheme based on light scattering by a nanotube placed slightly off-center of a tightly focused laser beam. The approach permits measurement of the movement of individual single-walled carbon nanotubes with nanometer sensitivity and high detection bandwidth. The method can be readily combined with optical characterization by Rayleigh scattering spectroscopy for studies of well-defined nanotube structures [1]. The technique is demonstrated for suspended pristine nanotubes, as well as for nanotubes modified by mass loading. By passing a current through the nanotube in the presence of a magnetic field, we can apply static and oscillating Lorentz forces. In this fashion, we have produced both static deflection and vibration excitation of nanotubes. Sharply defined nanotube vibrational modes are observed by sweeping the frequency of the driving force. We discuss the nature of these resonances and how to extract fundamental nanotube properties from the measurements. [1] M. Y. Sfeir, Science **306**, 1540 (2004).

**14:54**
**K30 3 Continuum Theory for Nanotube Piezoelectricity** PAUL J. MICHALSKI, NA SAI, E. J. MELE, *University of Pennsylvania* We develop and solve a continuum theory of the piezoelectric response in 1-D nanotubes and nanowires. We find that the piezoelectric response depends on the aspect ratio, the chiral angle, and two dimensionless parameters giving the relative strengths of the two elastic constants to the piezoelectric constant. Solutions for several limiting cases in the parameter space are discussed. The low dimensionality of the model system gives rise to several interesting effects not seen in conventional 3-D systems. We find that a uniform axial stress will induce a spatially non-uniform polarization and a non- linear variation of the electrostatic potential along the tube. The model predicts a strong coupling between longitudinal strain and torsional strain in chiral nanotubes and nanowires. The theory is applied to estimate the piezoelectric response of boron-nitride nanotubes.

**15:06**
**K30 4 Analysis of band-gap formation in squashed armchair CNTs** H. MEHREZ, A. SVIZHENKO, M. P. ANANTRAM, *Mail Stop: 229-1, Center for NanoTechnology and NASA Advanced Supercomputing Division, NASA Ames Research Center, Moffett Field, California 94035-1000* M. ELSTNER, T. FRAUENHEIM, *heoretische Physik, Universitat Paderborn, D-33098 Paderborn, Germany* The electronic properties of squashed arm-chair CNTs are modeled using constraint free density functional tight binding molecular dynamics simulations. Independent from CNT diameter, squashing path can be divided into *three* regimes. In the first regime, the CNT deforms with negligible force. In the second one, there is significantly more resistance to squashing with the force being $\sim 40 - 100$ nN/per CNT unit cell. In the last regime, the CNT looses its hexagonal structure resulting in force drop-off followed by substantial force enhancement upon squashing. We compute the change in band-gap ($E_g$) as a function of squashing and our main results are: (i) $E_g$ initially opens due to interaction between atoms at the top and bottom sides of CNT. The $\pi -$ orbital approximation is successful in modeling the $E_g$ opening at this stage. (ii) In the second regime of squashing, large $\pi - \sigma$ interaction at the edges becomes important, which can lead to $E_g$ oscillation. (iii) Contrary to a common perception, nanotubes with broken mirror symmetry can have *zero* $E_g$. (iv) All armchair nanotubes become metallic in the third regime of squashing. [Phys. Rev. B 71, 155421 (2005)].

**15:18**
**K30 5 Conductivity, Rheology and Processing of Carbon Nanotube Composites** KALMAN MIGLER, *NIST* SAM KHARCHENKO, JAN OBRZUT, JACK DOUGLAS, PAUL START, The primary application for CNT composites is the enhancement of their electrical properties relative to pure polymers. The conductivity is controlled by the alignment and the dispersion of the nanotubes in the polymer matrix during processing. Understanding the interplay between conductivity, processing, alignment and rheology is key their efficient use. We present simultaneous

measurements of the Rheology and conductivity of molten polymer nanotube composites over a range of concentrations near the percolation threshold. We find that simple shear fields can change the conductivity by orders of magnitude. Surprisingly, upon cessation of shear, the conductivity returns to its quiescent value.

**15:30**

**K30 6 Focused electron beam from open-tip single-wall carbon nanotubes** SANGBONG LEE, SEUNGCHUL KIM, JISOON IHM, *School of Physics, Seoul National University, Seoul, Korea* Open-tip single-wall carbon nanotubes can produce focused electron spot in the field emission. We calculate direct evolution of the nanotube wavefunction under applied electric field by solving the time dependent Shrödinger equation in the first principles scheme. (5,5), (10,10), and (12,12) carbon nanotubes are investigated and We obtain the focused spot size of a few angstroms. The spot size of electron beam from the (10,10) tube is smaller than that of the (5,5) or (12,12) tube. We also find that s-like state near the Fermi level contributes most to the field emission current.

**15:42**

**K30 7 Controlling the diameter of carbon nanotubes** T.D. YUZVINSKY, W. MICKELSON, S. ALONI, G.E. BEGTRUP, A. ZETTL, *University of California at Berkeley* We report a method to control the diameter of an individual carbon nanotube. Electronic transport measurements performed in situ reveal a striking dependence of conductance on nanotube geometry. As the diameter of the nanotube is reduced to near zero, we observe negative differential resistance.

**K31 1 Integrated Density of States Lloyd's Formula for Disordered Alloys with Short-Range Order via a KKR-based Dynamical Cluster Approximation*** D. A. BIAVA, SUBHRADIP GHOSH, W. A. SHELTON, D. D. JOHNSON, *Physics and Materials Science and Engineering, University of Illinois Urbana Champaign* Within Korringa, Kohn and Rostoker (KKR) multiple scattering theory, we have formulated[1] a static version of the Dynamic Cluster Approximation (DCA)[2], which is a cluster (or nonlocal) generalization of the coherent potential approximation (NLCPA)[3] that includes environmental effects, including short-range order. Within our KKR-DCA/NL-CPA we present an analytic expression for configurationally-averaged integrated density of states $< N(E) >$ , or generalized Lloyd's formula. We show also that this Lloyd's formula is stationary with respect to changes in the DCA/NLCPA effective medium, providing a rigorous electronic density functional theory and total-energy formalism for (partially) disordered alloys with(out) short-range order that is exact for infinite sized clusters and reduces to the single-site CPA for a cluster size of one. We show applications to various alloys with-(out) short-range order.

**K31 2 New modeling approach for the deformation of fractal hierarchical structures.** CATALIN PICU, MONICA SOARE, *Rensselaer Polytechnic Institute* A new formulation is proposed to address the deformation of multiscale hierarchical structures with a self-similar geometry across scales for which the classical formalism of continuum mechanics either does not apply or it is too expensive from computational point of view. Examples of such structures are porous materials (rocks, aerogels, glasses) in which pores with a wide range of dimensions are found, many biological materials and some of the newly developed nanostructured hierarchical composites. To this end, the equations of solid mechanics are reformulated to include information about the geometry. The procedure to solve boundary value problems with the new formulation will be presented. Examples will be discussed in which the variation of the solution with the number of scales in the hierarchy is studied.

**K31 3 Medium-Range Structural Properties of Vitreous Germania Obtained through First-Principles Analysis of Vibrational Spectra** LUIGI GIACOMAZZI, PAOLO UMARI, ALFREDO PASQUARELLO, *Ecole Polytechnique Fédérale de Lausanne (EPFL), Institute of Theoretical Physics, CH-1015 Lausanne* We analyse the principal vibrational spectra of vitreous $GeO_2$ and derive therefrom structural properties referring to length scales beyond the basic tetrahedral unit. We generate a model structure which yields a neutron structure factor in accord with experiment. The inelastic-neutron, the infrared, and the Raman spectra, calculated within a density-functional approach, also agree with respective experimental spectra. The accord for the Raman spectrum supports a Ge-O-Ge angle distribution centered at 135°. The Raman feature $X_2$ is found to result from vibrations in three-membered rings, and therefore constitutes a distinctive characteristic of the medium-range structure.

**K31 4 Predicting complex ground state structures from first principles: genetic algorithm for finding accurate coarse-grained Hamiltonians.**

VOLKER BLUM, *Fritz-Haber-Institut, Faradayweg 4-6, 14195 Berlin, Germany*

First-principles quantum-mechanical (QM) calculations allow to evaluate many interesting properties of a *given* nanoscale configuration of atoms with high accuracy. However, *predicting* stable structures or finite-$T$ thermodynamic configurational averages with QM accuracy remains a challenge: even for a binary solid with $N$ atoms per unit cell, $2^N$ distinct configurations must be evaluated. Such large numbers of calculations can be made affordable by mapping the QM Hamiltonian onto a computationally simpler ''coarse-grained'' Hamiltonian. The ability to predict ground state structures then depends on the shape of the coarse-grained Hamiltonian, but this shape is not a priori clear. For instance, a few simple assumed generic interactions will allow only a few simple ground states, but any more complex structures will be missed. For the generalized Ising model for binary alloys (cluster expansion), I show how a genetic algorithm[1,2] can identify the leading interactions which characterize a given system. I illustrate the method for the bcc binary alloys of Nb, Ta, Mo, W. A rich spectrum of ground state structures is found, including both well-known and unsuspected complex structures, far beyond what is envisioned from ''usual-suspect'' structure listings or from simple generic interactions. At the same time, order-disorder temperatures are significantly lower than those from simple intuition-based interactions, in agreement with experimental observations for these systems. This work was done at the National Renewable Energy Laboratory, supported by DOE-SC-BES, in collaboration with A. Zunger and G. Hart. [1]G. Hart, V. Blum, M. Walorski and A. **K31 5 Accurate prediction of x-ray absorption spectra using density functional theory*** GIULIA GALLI,[†]DAVID PRENDERGAST,[‡] *Lawrence Livermore National Laboratory* The increasing availability of x-ray absorption spectroscopy measurements for materials in the condensed phase is providing new opportunities to explore the local structure of disordered materials. However, the spectra produced by such experiments rely heavily on theoretical interpretation to infer the underlying atomic structure. We make use of density functional theory calculations to accurately approximate the initial and final state electronic structure associated with the absorption of an x-ray photon in the condensed phase. We outline some efficient computational approaches applied to ordered and disordered systems, concentrating on the K-edge absorption of oxygen. We report simulated x-ray absorption spectra for ice I, liquid water and magnesium oxide. Our results indicate excellent agreement with experiment for ice I and magnesium oxide, and our results for water, modelled using the classical TIP4P potential, indicate a reasonable qualitative agreement with experiment.

**K31 6 A First-principles Investigation of Superprotonic Activity in $CsHSO_4$** BRANDON WOOD, *MIT* NICOLA MARZARI, With the recent push to realize the hydrogen economy, there has been a surge of interest in viable solid-state materials for use as fuel cell electrolytes. Among the candidates are various derivatives of the anhydrous superprotonic conductor $CsHSO_4$, which exhibits reasonably high ionic conductivity at relevant operating temperatures while remaining electronically insulating. However, despite being widely characterized experimentally, a truly atomistic picture of the diffusion pathways and mechanisms in the material is missing. To this end, we have characterized this material with extensive first-principles static and dynamical calculations on 112-atom supercells of $CsHSO_4$. We isolate the dominant atomistic mechanisms involved in the superprotonic behavior and discuss the effect of correlated diffusive events in enhancing proton transport. We also offer a detailed description of the dynamics of the hydrogen bond network topology as the diffusing protons propagate through the lattice structure. The role of our findings in understanding superionic behavior are discussed.

**K31 7 First-principles study of the Hume-Rothery electron concentration rule in Al-Cu-(Fe,Ru)-Si 1/1-cubic approximants*** RYOJI ASAHI, *Toyota Central R&D Labs., Inc.* O.Y. KONTSEVOI, *Northwestern University* U. MIZUTANI, *Toyota Phys.&Chem. Res. Inst.* T. TAKEUCHI, *Nagoya University* A.J. FREEMAN, *Northwestern University* To elucidate the Hume-Rothery electron concentration rule, we determined the self-consistent electronic structures of the $Al_{108}Ru_{24}Cu_6Si_6$ and $Al_{108}Fe_{24}Cu_6Si_6$ 1/1-1/1-1/1 approximants containing 144 atoms in each it Pm-3 cubic unit cell using the full-potential linearized augmented plane wave (FLAPW) method [1], now running on massively parallel computer platforms. A significant pseudogap was found around the Fermi level for both alloys in the calculated densities of states, which should contribute to stabilization of the system. The FLAPW wave functions provide a direct observation of the Brillouin zone resonance in the Fermi surface [2]: a Fourier analysis of the wave functions confirms the Hume-Rothery matching rule $2k_F = K$ where the reciprocal lattice vectors $K$ consist of {543}, {550}, and {710} planes highly degenerate at the $N$ point. Consequently, an effective electron concentration per atom $(e/a)$ was evaluated to be 0.8 for both Ru and Fe in these structures

making a sharp contrast with the previously assumed empirical value of -2.7 proposed by Raynor [3]. [1] Wimmer et al., Phys. Rev. B **24**, 864 (1981). [2] Asahi et al., Phys. Rev. B **72**, 125102 (2005). [3] Raynor, Prog. Metal Phys. **1**, 1 (1949).

**K31 8 High-precision mixed-space cluster expansion for Cu-rich Cu-Pd alloys: Explaining the "$L1_{2''}$" phase*** S. BÄRTHLEIN, S. MÜLLER, *Universität Erlangen−Nürnberg, Germany* G.L.W. HART, *Northern Arizona Univieersity, Flagstaff, Arizona 86011−6010* A. ZUNGER, *National Renewable Energy Lab, Golden, Colorado 80401* A remarkable feature of Cu−Pd alloys is the existence of long−periodic superlattices (LPS) on the Cu−rich side of the phase diagram. Whereas earlier studies did not include necessary information about the diversity of important, but until then inaccessible formation enthalpies, we are able by combining DFT calculations with a mixed−space cluster expansion, genetic algorithms [1] and Monte Carlo to predict the phase stability from millions of possible candidates. Effective interactions were constructed, enabling us to predict the ground state line in order to determine the stable configurations a T=0 K. As a matter of special interest, we investigate the so −called ″L12″ phase, whiche merges as a domain −mixture between the LPS3 and a newly discovered low −temperature phase at xPd=0.125. Examination of the system's short−range order reveals a continuous transition from the domain−mixture to the disordered solid solution. Hence a natural explanation for the existence of this off−stoichiometry phase can be given. [1] G.L.W. Hartetal., Nat. Mater. **4**, 391 (2005)

**K31 9 Nanoscale Patterning of $L1_2$ Chemical Order in $Ni_3Al$ Alloy Processed by Energetic Ions** JIA YE, YOUHONG LI, ROBERT AVERBACK, PASCAL BELLON, JIANMIN ZUO, We recently predicted that alloys forming chemical ordered phases at equilibrium can be forced into stable nanoscale patterns of chemical order by irradiation with energetic particles. We have tested this prediction on the $Ni_3Al$ compound by combining MD and KMC simulations. For 1MeV Kr and 70KeV He ions, MD simulation is used to simulate the disordered zones, which are then incorporated into KMC simulations to reach long irradiation times. We introduce a new method based on scaling behavior of structure factor to identify reliably the transition boundary between patterning and disordered states. These simulations indicate that 1MeV Kr ion irradiation can lead to patterning, whereas 70KeV He ion cannot. These results are compared to experimental results, obtained by performing ion irradiations on $Ni_3Al$ thin films grown by sputtering.

**K31 10 Maximally fast coarsening algorithms** MOWEI CHENG, *Center for Theoretical and Computational Materials Science, National Institute of Standards and Technology* ANDREW RUTENBERG, *Department of Physics and Atmospheric Science, Dalhousie University* We present maximally-fast numerical algorithms for conserved coarsening systems that are stable and accurate with a growing natural time-step $\Delta t = At_s^{2/3}$. We compare the scaling structure obtained from our maximally-fast conserved systems directly against the standard fixed-timestep Euler algorithm, and find that the error scales as $\sqrt{A}$ — so arbitrary accuracy can be achieved. For non-conserved systems, only effectively finite timesteps are accessible for similar unconditionally stable algorithms.

**K31 11 Mesoscopic modeling of the response of human dental enamel to mid-infrared radiation** ANA VILA VERDE, *Department of Chemical Engineering, Penn State University* MARTA RAMOS, *Department of Physics, University of Minho, Portugal* A.M. STONEHAM, *Centre for Materials Research, Department of Physics and Astronomy, University College London, UK* Ablation of human dental enamel, a composite biomaterial with water pores, is of significant importance in minimally invasive laser dentistry but progress in the area is hampered by the lack of optimal laser parameters. We use mesoscopic finite element models of this material to study its response to mid-infrared radiation. Our results indicate that the cost-effective, off-the-shelf $CO_2$ laser at $\lambda = 10.6\ \mu$m may in fact ablate enamel precisely, reproducibly and with limited unwanted side effects such as cracking or heating, provided that a pulse duration of $\approx 10\ \mu$s is used. Furthermore, our results also indicate that the Er:YAG laser ($\lambda = 2.94\ \mu$m), currently popular for laser dentistry, may in fact cause unwanted deep cracking in the enamel when regions with unusually high water content are irradiated, and also provide an explanation for the large range of ablation threshold values observed for this material. The model may be easily adapted to study the response of any composite material to infrared radiation and thus may be useful for the scientific community.

**K31 12 The isotope effect in the ferroelectric phase transition of KDP using *ab-initio* path intergal simulations** VARADHARAJAN SRINIVASAN,* ROBERTO CAR, *Princeton University, Princeton, NJ 08544, US* DANIEL SEBASTIANI, *Max Planck Institute for Polymer Research, Ackermannweg 10 / 55128 Mainz, Germany* We perform *ab-initio* path integral simulations on protonated and deuterated KDP at different temperatures and lattice constants in order to probe the origin of the isotope effect of the ferroelectric phase transition in this material. By taking into account the quantum nature of the proton/deuteron our simulations are capable of distinguishing the direct effects of a pure mass change versus the indirect structural effect in the hydrogen bonding geometry upon deuteration. In reality, the direct and indirect effects amplify each other in a self-consistent manner, leading to the huge isotope effect on the transition temperature. With our calculation we can selectively investigate the manisfestation of the two phenomena. We characterize the ferro and paraelectric phases with the help of a recent modification of the path integral implementation in the CPMD package which enables us to compute momentum distributions of the proton/deuteron both above and below the transition temperature in order to characterize the extent of proton/deuteron delocalization in both phases.

**K32 1 Trends in the structure of neutral, cationic, and anionic Ag and Au clusters from DFT calculations*** IGNACIO L. GARZON, *Instituto de Fisica, UNAM* LUIS A. PEREZ, KARO MICHAELIAN, The physical and chemical properties of small coinage metal clusters, with atomic structures $nd^{10}(n+1)s^1$ ($n=$ 3,4,5 for Cu, Ag and Au, respectively), are of great interest since, for example, can be viewed as a bridge between those existing in the ''simple'' *s*-only alkali metal and the more complicated transition metal clusters. Several theoretical calculations and indirect experimental evidence have shown that $Au_N$ clusters prefer planar structures up to sizes around $N=13$, cage-like structures for the $T_d$ $Au_{20}$ and $I_h$ $Au_{32}$ and low- symmetry (amorphous) configurations for $Au_{55}$. In this work, we present a theoretical study of the structural and electronic properties of Ag and Au neutral, cationic and anionic clusters with up to $N=55$ atoms, using density functional theory in the generalized gradient approximation. A different behavior is found in the physical properties of Ag and Au clusters, mainly due to the stronger relativistic effects present in the Au clusters. Another trend indicates that not only the size (number of atoms) and shape (isomer geometry) of a given cluster determine its properties, but also the charge present in the system may affect the cluster behavior even in the larger sizes with N=55. A discussion of the structural motifs existing in neutral, cationic and anionic Ag and Au clusters with up to N=55 atoms and their connection with recent experimental data will be presented.

**K32 2 Enantiospecific adsorption study at chiral gold nanoclusters from DFT calculations*** XOCHITL LOPEZ-LOZANO, *Instituto de Fisica, UNAM, Mexico.* LUIS A. PEREZ, IGNACIO L. GARZON, Chiral structures have been found as the lowest energy isomers of bare and passivated gold nanclusters from density functional theory (DFT) studies. Recently, experimental evidence on the existence of chiral gold nanoclusters has been published. In this work, DFT calculations are performed to study the adsorption of chiral molecules (like cysteine) on chiral and achiral (icosahedral) $Au_{55}$ clusters. Different locations on the metal cluster surfaces are used to identify the most favorable adsorption sites of the chiral molecule. Enantioselectivity is investigated through the comparison of the binding energies of the (S) and (R)-cysteine molecule adsorbed on the different $Au_{55}$ cluster enantiomers.

**K32 3 Structural and electronic properties of sodium nanoclusters*** LUIS A. PEREZ, *Instituto de Fisica, UNAM* JUAN A. REYES-NAVA, *IPICYT* IGNACIO L. GARZON, *Instituto de Fisica, UNAM* Recent advances on mass selection of sodium nanoclusters and their characterization by photoemission electron spectroscopy [1] have given useful data for a variety of clusters sizes. These data may lead to assignments of the relevant structures by comparing the measured photoelectron spectra (PES) with the electronic density of states (DOS) obtained from DFT calculations. In this work, the lowest energy structures modeled by the many-body Gupta potential, are obtained by using molecular dynamics simulations for $Na_n$ (n= 178, 204, 271, 298-300, 309). DFT calculations were then performed for neutral, positively- and negatively-charged $Na_n$ clusters. A comparison between the DOS of clusters of the same size but different charge will be presented, as well as between the available experimental PES and the theoretical obtained DOS. [1] H. Haberland, T. Hippler, J. Donges, O. Kostko, M. Schmidt, B. von Issendorff, Phys. Rev. Lett. 94, 035701 (2005).

**K32 4 Electron-Stimulated Emission of Na Atoms from NaCl Nanocubes** DAVIDE CERESOLI, TANYA ZYKOVA-TIMAN, *SISSA, Trieste* ERIO TOSATTI, *SISSA and ICTP, Trieste* Emission of neutral cations/anions from solid akali halides can in principle be provoked by donating/subtracting electrons to the surface of alkali halide crystals, but generally constitutes a very endoenergetic process. The amount of energy required is expected to decrease for atoms located in less favorable positions, such as at surface steps and kinks, where the local coordination is smaller. The most favorable case of all should be represented by corner atoms of alkali halides cubes, where ionic binding is the weakest. We carried out first principles density functional calculations and simulations of magic-size neutral and charged NaCl nanocubes, to ascertain the stability and extractibility of neutralized corner ions. We find that detachment of neutral Na atoms upon donation of an excess electron is possible for a very modest energetic cost of the order of 0.6 eV, in line with early experimental observations. The atomic and electronic structure of the resulting $Na^+$ vacancy is analyzed in detail.

**15:18**

**K32 5 Comparison of TDLDA and GW-Bethe-Salpeter Methods for Optical Excitations in Noble Metal Clusters** SHING F. YIP, JUAN C. IDROBO, SERDAR OGUT,* *University of Illinois at Chicago* MURILO TIAGO, JAMES R. CHELIKOWSKY,† *University of Texas at Austin* JINLAN WANG, JULIUS JELLINEK,‡ *Argonne National Laboratory* We perform a comparative analysis of first principles results for optical spectra of $Ag_n$ and $Au_n$ ($n \leqslant 8$) clusters calculated within the time-dependent local density approximation (TDLDA) and the GW-Bethe-Salpeter (GW-BSE) technique. Both the TDLDA and GW-BSE calculations are performed entirely in real space based on the higher-order finite difference *ab initio* pseudopotential method. In the GW-BSE method, the screened Coulomb potential is calculated from the TDLDA polarizability. The convergence of the

results with respect to various computational parameters is carefully examined. In general, the TDLDA and GW-BSE methods are in reasonable agreement with respect to peak positions at low energies, while high-energy excitations and oscillator strengths can be different. The GW-BSE results are found to be in a somewhat better agreement with the available experimental data.

**K32 6 *Ab initio* calculations for the photoelectron spectra of iron clusters*** SHEN LI, *Department of Physics and Astronomy, Rutgers the State University of New Jersey, Piscataway, NJ 08854,USA* MANUEL ALEMANY, *Departamento de Física de la Materia Condensada,Facultad de Física, Universidad de Santiago de Compostela, E-15872, Spain* JAMES CHELIKOWSKY, *Department of Physics and Chemical Engineering, Institute of Computational Engineering and Sciences, University of Texas, Austin, Texas 78712, USA* We studied negatively charged iron clusters $Fe_n^-$ $(n = 3 - 6)$. We use a real-space pseudopotential approach based on the density-functional theory within local spin density approximation. The real space approach assumes no explicit basis. Wave functions are evaluated on a uniform grid; only one parameter, the grid spacing, is used to control the convergence of the electronic properties. Charged states are easily handled in real space, in contrast to method based on supercells where electrostatic divergences require special handling. For each cluster, we determined the ground state structure. To compare with the experimental photoelectron spectra, we calculated the electron binding energies, which include the final state relaxation effects. Our results for the photoelectron spectra, are able to reproduce the main features of the experiments. Our results for the magnetic moment of each cluster agree well with the other theories.

**K32 7 Size Dependence of the Static Polarizabilities and Absorption Spectra of Gold Clusters** SERDAR OGUT, JUAN CARLOS IDROBO,* *University of Illinois at Chicago* JINLAN WANG, JULIUS JELLINEK,† *Chemistry Division, Argonne National Laboratory* We present results for static polarizabilities and absorption spectra for ground state structures of $Au_n$, $n = 2 - 14,20$, clusters calculated within static and time-dependent density functional theory. The static polarizabilities of the clusters with less than 14 atoms exhibit even-odd oscillations. The polarizabilities of $Au_{14}$ and $Au_{20}$ are noticeably lower. This change in the behavior of static polarizability is correlated with the transition from two-dimensional to three- dimensional structures at $n = 14$. The *d* electrons have a large effect on the optical spectra as they quench the oscillator strengths significantly and are heavily involved in low-energy excitations. The calculated spectra are compared with available experimental data and spectra obtained for $Ag_n$ clusters.[1]

**K32 8 Interactions of water and oxygen molecules with gold clusters** SEUNG BUM SUH, BOKWON YOON, MINDE SUN, UZI LANDMAN, *School of Physics. Georgia Institute of Technology, Atlanta, GA 30332-0430* The interaction of water and oxygen molecules with neutral gold clusters, $Au_n$ for n=2-8, is investigated using the first- principles calculations based on the density functional theory with generalized gradient correction. The $O_2$ binding energy, the intramolecular bond-length of $O_2$, and the excess charge on the adsorbed $O_2$ show even-odd alternations as a function of the number of gold atoms, correlating with the vertical electron detachment energy of $Au_n$ . The influence of pre-adsorbed $H_2O$ on the $O_2$ adsorption is pronounced when the $O_2$ is adsorbed with an Au-O bond with the gold cluster and an O-H bond with pre- adsorbed $H_2O$, while the influence is relatively small for $O_2$ adsorbed with double Au-O bonds. Compared to the $O_2$ adsorption in the absence of $H_2O$, the binding energy of $O_2$ are increased by 0.4 eV, and the intramolecular bond- length are stretched by up to 0.03 Å.

**16:06**

**K32 9 Density-Functional Study of $Au_n^-$ $(n = 16 - 24)$: Atomic and Electronic Structures and Interaction with $O_2$** BOKWON YOON, UZI LANDMAN, *Georgia Institute of Technology* PEKKA KOSKINEN, MICHAEL MOSELER, *Fraunhofer Institute for Mechanics of Materials* HANNU HAKKINEN, *University of Jyvaskyla* Anionic gold clusters with 16 to 24 atoms are studied using the Born-Oppenheimer local-spin-density molecular dynamics method. The structures of the ground-state clusters and energetically lowest-lying isomers are 3-dimensional, while the ground-state structures of smaller $Au_n^-$ with up to 14 atoms were reported to be planar (Häkkinen, et al., J. Chem. Phys. 117, 6982 (2002)). The calculated vertical electron detachment energies ($vDE$) are in good agreement with the experimental results (Taylor, et al., J. Chem. Phys. 98, 3319 (1992)); $vDE$'s are smaller for even $n$'s and larger for odd $n$'s, with the exception of $n = 16$. Compared to the other even-numbered clusters, $Au_{16}^-$ exhibits relatively large $vDE$, $vDE(Au_{16}^-)$=4.03 eV. The smallest $vDE$ is measured for $n = 20$, $vDE(Au_{20}^-)$=2.71 eV, The adsorption of $O_2$ to $Au_n^-$ is also sensitive to the cluster size; the $O_2$ adsorption is relatively strong for the even-numbered clusters with the exeption of $Au_{16}^-$. The $O_2$ binding energy, the intramolecular bond-length of $O_2$, and the excess charge on $O_2$ correlate strongly with the vertical electron detachment energy of $Au_n^-$ .

**16:18**

**K32 10 Properties of $Pt_{37}$ and $Pt_6Ru_{31}$ Clusters on Carbon: comparison of theory and experiment*** LIN-LIN WANG, DUANE D. JOHNSON, *Department of Materials Science and Engineering, UIUC* Using DFT calculations, we analyze the structures of self-organizing nanoparticles formed by Pt and Ru-Pt on a carbon support and clarify complex behaviors noted in earlier experimental studies. With clusters deposited via metallo-organic Pt or

PtRu5 complexes and annealed at 670 K in hydrogen atmosphere, the Pt and Pt-Ru based clusters were observed to form fcc(111)-stacked cuboctahedral geometry and essentially bulk-like metal-metal bond lengths, even for the 10-40 atom nanoparticles for which the average coordination number is much smaller than that in the bulk, and that Pt in bimetallic clusters segregates to the ambient surface. We explain these observations and characterize the cluster structures with graphite as a model for the support. Our study reveals the origin of the observed bulk-like metal-metal bond lengths and bond-length disorder, and demonstrates the profound consequences that result from the cluster/support interactions and hydrogen passivation on their structural and electronic properties.

**K32 12 Vibrational Dynamics and Thermodynamics of AgCu nanoparticles*** ABDELKADER KARA, HANDAN YILDIRIM, TALAT S. RAHMAN, *Physics Department, Kansas State University* RICARDO FERRANDO, *INFM and IMEM-CNR, Dipartimento di Fisica dellUniversita' di Genova, via Dodecaneso 33, 16146 Genova, Italy* We present results of a systematic study of the structure, vibrational dynamics and thermodynamics of $Ag_nCu_{34-n}$ nanoparticles including. The starting structure were generated using a structural optimization using a genetic algorithm [1]. Using the embedded atom method potentials, we have calculated the vibrational densities of states for all stoichiometries and the corresponding vibrational free energies, in the harmonic approximations. At 300K, the vibrational free energy is found to behave linearly with the increasing number of Ag atoms in the nanoparticles. The vibrational contributions to the free energy increase from 5.5% for $Ag_0Cu_{34}$ to 8.3% $Ag_{34}Cu_0$. Selected force constants for several nanoparticles were calculated using density functional theory (DFT) and were found to be very close to those determined using EAM potentials. [1] G. Rossi, A. **K32 13 Selective modification of the surface structure of oxide nano-particles using sub-bandgap photons** A. SHLUGER, P. TREVISANUTTO, P. SUSHKO, A. STONEHAM, *Department of Physics and Astronomy, University College London, Gower St., London, WC1E 6BT, UK* M. HENYK, K. BECK, A. JOLY, W. HESS, *Pacific Northwest National Laboratory, P.O.Box 999, Richland, WA 99352 USA* Controlled manipulation of the physical and chemical properties of nano-structured materials requires correlating their spectroscopic properties and reactivity with specific surface sites. We have demonstrated experimentally that laser excitation of MgO nano-crystalline films and nanocube samples with 4.66 eV photons desorbs neutral O and Mg atoms with hyperthermal kinetic energies in the range of 0.1–0.4 eV. Using an ab initio embedded cluster approach we developed the mechanisms for the hyper-thermal emission of atomic species. We demonstrate that the desorption of O atoms from 3-coordinated (3C) surface sites occurs via the following steps: i). an exciton is excited at the 3C site; ii) the exciton is ionized, while the remaining electronic hole is trapped at the 3C O site converting it to an $O^-$ radical; iii) absorption of another 4.66 eV photon in the vicinity of the 3C site forms an excited state, which relaxes with desorption of a neutral O atom. Similar process was identified for Mg-terminated 3C site. The proposed general mechanism can be used to control atomic scale modification of insulating surfaces. [1] P.E. Trevisanutto et al., itSurf. ## SESSION K33: NOVEL MOVING BOUNDARY PROBLEMS
**Tuesday Afternoon, 14 March 2006; 336, Baltimore Convention Center at 14:30**
**Wim Saarloos, Leiden University, presiding**

**14:30**
**K33 1 Nonlinear shape evolution of electromigration-driven single-layer islands.*** JOACHIM KRUG, *University of Cologne*

Electromigration is the transport of matter induced by an electric current in the bulk or at the surface of a conducting material. Electromigration along interfaces and grain boundaries is a central factor limiting the reliability of integrated circuits. This has motivated numerous theoretical studies of the shape evolution of voids in metallic thin films caused by electromigration along the void boundary [1]. In this case the coupling of the void shape to the current distribution in the film leads to a nonlocal moving boundary problem driven by a mass current tangential to the boundary. Here we are concerned with the itlocal version of the problem, which applies to the electromigration of single-layer islands on metallic

surfaces [2]. We show that the introduction of crystal anisotropy in the mobility of atoms along the island boundary induces a rich variety of dynamical behaviors, ranging from spontaneous symmetry breaking to periodic and chaotic modes of island migration [3]. Under suitable physical conditions these phenomena can be reproduced in kinetic Monte Carlo simulations of a realistic microscopic model of the Cu(100) surface. Finally, we discuss recent results on the electromigration of vacancy islands in the kinetic regime dominated by exchange with the adatom diffusion field itinside the island. The talk is based on joint work with P. Kuhn, F. Hausser, A. Voigt and M. Rusanen. [1] M. Schimschak, J. Krug, J. Appl. Phys. **87**, 685 (2000). [2] O. Pierre-Louis, T.L. Einstein, Phys. Rev. **K33 2 Fluctuation-regularized front propagation dynamics in reaction-diffusion systems.***
DAVID KESSLER, *Bar-Ilan University*

We introduce and study a new class of fronts in finite particle number reaction-diffusion systems, corresponding to propagating up a reaction rate gradient. We show that these systems have no traditional mean-field limit, as the nature of the long-time front solution in the stochastic process differs essentially from that obtained by solving the mean-field deterministic reaction-diffusion equations. Instead, one can incorporate some aspects of the fluctuations via introducing a density cutoff. Using this method, we derive analytic expressions for the front velocity dependence on bulk particle density and show self-consistently why this cutoff approach can get the correct leading-order physics.

**K33 3 Spark formation as a moving boundary process.**
UTE EBERT, *CWI Amsterdam and TU Eindhoven*

The growth process of spark channels recently becomes accessible through complementary methods. First, I will review experiments with nanosecond photographic resolution and with fast and well defined power supplies that appropriately resolve the dynamics of electric breakdown [1]. Second, I will discuss the elementary physical processes as well as present computations of spark growth and branching with adaptive grid refinement [2]. These computations resolve three well separated scales of the process that emerge dynamically. Third, this scale separation motivates a hierarchy of models on different length scales. In particular, I will discuss a moving boundary approximation for the ionization fronts that generate the conducting channel. The resulting moving boundary problem shows strong similarities with classical viscous fingering. For viscous fingering, it is known that the simplest model forms unphysical cusps within finite time that are suppressed by a regularizing condition on the moving boundary. For ionization fronts, we derive a new condition on the moving boundary of mixed Dirichlet-Neumann type ($\phi = \epsilon\partial_n\phi$) that indeed regularizes all structures investigated so far. In particular, we present compact analytical solutions with regularization, both for uniformly translating shapes and for their linear perturbations [3]. These solutions are so simple that they may acquire a paradigmatic role in the future. Within linear perturbation theory, they explicitly show the convective stabilization of a curved front while planar fronts are linearly unstable against perturbations of arbitrary wave length. **K33 4 Stalactite Growth as a Free-Boundary Problem.***
RAYMOND GOLDSTEIN, *University of Arizona*

As far back in recorded history as the writings of the Elder Pliny in the first century A.D. are found references to the fascinating structures found in limestone caves, particularly stalactites. Although the subject of continuing inquiry since that time, the chemical mechanisms responsible for their growth have only been well-established since the 19th century, and there has been no quantitative understanding of the morphological evolution of these strange and beautiful forms. In this talk I will describe a synthesis of calcium carbonate chemistry, diffusion, thin-film fluid dynamics, and nonlinear dynamics which shows that stalactites evolve according to a novel geometric growth law which exhibits extreme amplification at the tip. Studies of this model show that a broad class of initial conditions is attracted to an ideal parameter-free shape, not previously known in science, which is strikingly close to a statistical average of natural stalactites. Similar hydrodynamic and geometric considerations lead to a quantitative theory for the shapes of icicles, and an understanding of why stalactites and icicles look so similar, despite the vastly different physics underlying their growth.

**K35 1 Exotic few-particle ground states in charged self-assembled InAs/GaAs quantum dots*** LIXIN HE, GABRIEL BESTER, ALEX ZUNGER, *National Renewable Energy Laboratory, Golden, Colorado 80401* Three-dimensionally confined quantum dots can be loaded with a few carriers. However, unlike real atoms, in self-assembled InAs/GaAs quantum dots, the Coulomb repulsion between holes $J_{hh} \sim$ 15 -25 meV is comparable to the single-particle energy spacing between levels $\Delta\epsilon \sim$ 10 - 20 meV. This opens the possibility of observing stable, exotic spin configurations that defy the rules of atomic physics (Hund's rule and the Aufbau principle). We have applied a combination of atomistic pseudopotential description for the single-particle level structure, with a many-body configuration interaction (CI) description of many-particle effects to predict both electron and hole charged states in InGaAs/GaAs self-assembled quantum-dots. We find that while electron charging follow both the Aufbau principle and Hund's rule, hole charging gives rise to stable but unusual spin configurations. Our theory [1] offer a self-consistent interpretation to recent experimental observations [2], where the simple 2D effective mass parabolic models fail. [1] L. He, G. Bester and A. Zunger, Phys. Rev. Lett. (in press), cond-mat/0505330. [2] Reuter *et al*, Phys. Rev. Lett. **94**, 026808 (2005).

**K35 2 A variational wave function for two-dimensional quantum-dot helium*** M. GOLAM FARUK, *Department of Electrical Engineering and Department of Physics, Prairie View A&M University, Prairie View, Texas 77446* ORION CIFTJA, KEVIN STORR, *Department of Physics, Prairie View A&M University, Prairie View, Texas 77446* We introduce a variational wave function for two-dimensional quantum dot helium (a system of two interacting electrons in a two-dimensional parabolic confinement potential) in an arbitrary perpendicular magnetic field. This variational wave function contains a Jastrow pair correlation factor of displaced Gaussian form in addition to the commonly used Laughlin correlation factor. The Gaussian correlation factor assures the overall quality of the variational wave function at all values of the magnetic field including weak (or zero) and strong magnetic fields. The accuracy of the variational wave function is gauged through exact numerical diagonalization results. We find out that this trial wave function is a very accurate representation of the true ground state for the whole range of magnetic fields.

**K35 3 Spin-Orbit effects in Quantum Dots: Interplay of disorder and interactions** HAKAN E. TÜRECI, Y. ALHASSID, A. DOUGLAS STONE, *Center for Theoretical Physics, Sloane Physics Laboratory, Yale University, New Haven, CT 06520* Disordered or chaotic quantum dots with a large Thouless conductance g provide a tractable experimental and theoretical system for studying electron-electron interactions within the framework of the universal Hamiltonian. In particular, good agreement between theory and experiment is observed for the mesoscopic fluctuations of the conductance in dots with negligible spin-orbit scattering [1]. Here we focus on the effects of a tunable spin-orbit scattering within the universal Hamiltonian model. The presence of spin-orbit scattering was shown to introduce new symmetry limits of the single-particle Hamiltonian [2]. We present results for ground state and finite temperature properties in the crossover regime between symmetries. Furthermore, we study the signatures of a quantum critical regime dominated by collective critical fluctuations [3].

**K35 4 A many-polaron system in a background-charge potential*** F. BROSENS, S. N. KLIMIN, J.T. DEVREESE, *–TFVS, Departement Natuurkunde, Universiteit Antwerpen* The ground state energy of an *N*-polaron system confined to a quantum dot with a neutralizing background charge is investigated within an all-coupling many-body path-integral variational principle taking into account both Fermi statistics of polarons and the electron-electron interaction. The treatment of the ground-state energy is performed for both closed-shell and open-shell systems. The electron-phonon contribution to the ground-state energy as a function of the number of fermions demonstrates a trend to a constant value when increasing *N*. For a finite number of polarons, the dependencies of the ground-state energy and of the polaron contribution on the parameter $r_s^*$, which determines the average fermion density in a quantum dot, are very similar to those for a polaron gas in bulk. Herefrom, we can conclude that the ground-state properties of a polaron gas in bulk can be qualitatively described using a model of a finite number of polarons in a confinement potential provided by a background charge.

**K35 5 Spectroscopy of the Kondo Problem in a Box** DENIS ULLMO, RIBHU KAUL, GERGELY ZARAND, SHAILESH CHANDRASEKHARAN, HAROLD BARANGER, *Duke U, Karlsruhe U, Budapest U, and LPTMS Orsay* We study the spin quantum numbers and energy eigenvalues of the ground state and low lying excitations of a quantum dot with a single spin-S impurity. We prove an exact theorem that allows us to infer the ground state spin for an arbitrary spin-S of the impurity and for even/odd electrons on the quantum dot. Additionally, strong and weak coupling perturbation theory backed up with quantum Monte-Carlo simulations enable us to map out the spin structure of the excited states and the energy splittings between them as the ratio $\Delta/T_K$ is tuned. We propose a simple transport experiment involving the tunneling spectroscopy of a double quantum dot, where these results can be observed. Finally, we make explicit contact with experiment by calculating the transport properties of the proposed double dot device that exhibit signatures of tunneling into the Kondo-correlated state.

**K35 6 Charge Fluctuations in a Nanoscale Structure: Interplay of Kondo and Luttinger Liquid Physics** PAATA KAKASHVILI, *Chalmers University of Technology* HENRIK JOHANNESSON, *Göteborg University* We propose a setup which allows to study the interplay of Kondo and Luttinger liquid physics. It consists of a quantum box, biased by a gate voltage, and side-coupled to a quantum wire by a point contact. Close to the degeneracy points of the Coulomb blockaded box the setup can be described as a Luttinger liquid interacting with an effective Kondo impurity. By applying a magnetic field one drives the system from an effective two-channel to a one-channel situation, allowing for the study of the crossover between the two. Using bosonization and boundary conformal field theory we predict that for the case of spin-polarized electrons the differential capacitance of the box will exhibit distinctive Luttinger liquid scaling with temperature and gate voltage. In the limit of zero field the Luttinger liquid behavior gets masked by two-channel Kondo screening, leading to a logarithmic scaling of the differential capacitance with temperature and gate voltage. These effects should be possible to study experimentally using the recently developed SET electrometer technique.

**15:42**

**K35 7 Universality and non-universality for a time-dependent quantum dot in the Kondo regime** ALI GOKER, PETER NORDLANDER, *Rice University* We employ time-dependent noncrossing approximation for single electron transistor and calculate the transient response of the conductance for a variety of temperatures in infinitesimal bias when the dot-lead tunneling constant is suddenly changed such that the Kondo effect is present in the final state. In non-universal timescale, we see rapid oscillations. The frequency of these oscillations depends on the dot level and their amplitude is modulated by initial and final tunneling constants. We explain this observation qualitatively by exact solution of the resonant level model. In universal timescale, we compute the conductance for two systems which have different Kondo temperatures and test universality. Our results indicate that universality is well preserved as a function of $T/T_K$ in spite of tiny deviations at low temperatures.

**15:54**

**K35 8 Universal Scaling Behavior of the Kondo Effect in a Quantum Dot.** DAVID GOLDHABER-GORDON, ILEANA RAU, *Stanford University* RONALD POTOK, *Harvard University* MICHAEL GROBIS, *Stanford University* At zero temperature, a many-body Kondo singlet forms between a spin-1/2 quantum dot and electrons in nearby, tunnel-coupled reservoirs. This Kondo singlet can be broken by sufficiently large temperature T or bias V across the dot. Differential conductance G(V,T) is predicted to show universal scaling in eV/kT. However, such behavior has not been examined thoroughly in experiments. To address this issue, we have performed detailed transport measurements through a Kondo quantum dot at finite bias and temperature. We will present our results and discuss the scaling behavior seen in this system.

**16:06**

**K35 9 The Two-channel Kondo Effect in a Semiconductor Nanostructure** ILEANA RAU, *Stanford University* RON POTOK, *Harvard University* DAVID GOLDHABER-GORDON, *Stanford University* Quantum dots have proven to be excellent systems for studying the single-channel Kondo effect, the many-body ground state resulting from the interaction between a spin 1/2 quantum dot and a reservoir of conduction electrons. The two-channel Kondo effect is achieved by coupling the dot with equal strength to two independent reservoirs. In this case the reservoirs compete to independently form a Kondo state with the dot, resulting in overscreening of the excess spin. In a new semiconductor double quantum dot geometry, proposed by Y. Oreg and D. Goldhaber-Gordon (1), we observe spin two-channel Kondo physics. Low temperature transport measurements through the smaller of the two dots reveals that the double dot – leads system undergoes a quantum phase transition from one competing single-channel Kondo state to another. By tuning between these two Fermi liquid regimes, we observe the non-Fermi liquid signature of the two-channel Kondo state. I will explore recent experimental progress and open questions. (1) Y. Oreg, D. Goldhaber-Gordon, PRL **90** 136602 (2003).

**16:18**

**K35 10 Jahn-Teller / Kondo Interplay in a Three-Terminal Quantum Dot** R.C. TOONEN, *University of Wisconsin (UW)* H. QIN, *UW* A.K. HUETTEL, *Ludwig-Maximilians-Universitaet* S. GOSWAMI, *UW* D.W. VAN DER WEIDE, *UW* K. EBERL, *Max-Planck-Institut fuer Festkoerperforschung* R.H. BLICK, *UW* The Jahn-Teller effect is the spontaneous geometric distortion of a nonlinear molecular entity. The Kondo effect, an expression of asymptotic freedom, arises from the hybridization between localized states of a magnetic impurity and the itinerant states of its environment. The interplay of these two phenomena has attracted the attention of theorists studying the growth and interactions of heavy-fermion systems. Because of the technical difficulties associated with probing isolated impurities in bulk materials, this composite effect has remained experimentally unexplored. We have investigated co-tunneling transport phenomena in a three-terminal quantum dot with triangular symmetry. Our measurements of anomalous spectral signatures reveal interplay between the Jahn-Teller and Kondo effects. This discovery suggests a means of controlling the correlation of spatially separated pairs of entangled electrons (EPR pairs)—a necessary condition for the physical realization of a quantum computer (DiVincenzo's 7th requirement).

**16:30**

**K35 11 Quantum Dot Coupled to a Mesoscopic Fabry-Perot Resonator.** MICHAEL GROBIS, *Stanford University* ILEANA RAU, *Stanford University* RONALD POTOK, *Harvard University* DAVID GOLDHABER-GORDON, *Stanford University* We will present our study of a quantum dot coupled to a Fabry-Perot resonator. The Fabry-Perot resonator is created by tunnel coupling a lithographically defined two-lead quantum dot to an additional finite reservoir of tunable length. Fabry-Perot oscillations are observed in transport through the quantum dot caused by interference between the direct tunneling path through the dot and the multi-step path that includes tunneling in and out of the finite reservoir. These oscillations are dependent on the phase shifts acquired during the transmission events and the nature of the electron path through the Fabry-Perot cavity. Tuning the quantum dot through a Kondo resonance allows us to extract information about the Kondo transmission phase shift and the nature of Kondo screening cloud in this system.

**16:42 guezsica, Universidad Nacional Autónoma de México**

**K35 12 Electron Dynamics in AC-Driven Quantum Lenses** AREZKY HERNÁNDEZ-RODRíGUEZ, *Instituto de Física, Universidad Nacional Autónoma de México* LILIA MEZA-MONTES, *Instituto de Física, Universidad Autónoma de Puebla* CARLOS TRALLERO-GINER, *Dept. de Física Teórica, Univ. de La Habana* SERGIO ULLOA, *Dept. of Physics and Astronomy, Ohio Univ.* We have applied the Floquet formalism to study the effects of an ac electric field applied to quantum dots with lens shape. The electric field is applied along and perpendicular to the direction of the axial symmetry and the time-dependent Hamiltonian in the effective mass approximation is solved. A complete set of orthonormal functions is found to characterize the physical problem while keeping the full lens symmetry. When the electric field is along the axial symmetry axis, we show that the Hilbert space of solutions is separated into orthogonal subspaces with different $z$-component of the angular momentum. In case of a perpendicular field, the appearance of new dynamical symmetry is studied. We give an explicit analytical representation for the quasi-energy spectrum and electronic states, and show numerical results for different lens parameters and intensity and direction of the electric field. The interplay between the lens shape geometry and the ac driven field (intensity and frequency) are analyzed. Our approach applies to the full range of intensities.

**16:54**

**K35 13 Toward Strong Interactions in Circular Quantum Dots: Correlation Induced Inhomogeneity** AMIT GHOSAL, *University of California Los Angeles* ALEV GUCLU, CYRUS UMRIGAR, *Cornell University* DENIS ULLMO, *LPTMS Orsay* HAROLD BARANGER, *Duke University* Physical properties of the electron gas, which describes conduction electrons interacting via Coulomb forces, change dramatically depending on the balance between the strength of the kinetic energy and the Coulomb repulsion. For weak interactions (high density), the system behaves as a Fermi liquid, with delocalized electrons. In contrast, in the strongly interacting limit (low density), the electrons localize and order in a Wigner crystal phase. The physics at intermediate densities is phenomenally rich and not adequately understood. Here we present a study of the intermediate density electron gas (up to $r_s = 18$) confined to a circular quantum dot containing up to 20 electrons. Using an accurate quantum Monte Carlo technique, we show that the correlation induced by increasing interaction strength smoothly causes, first, ring structure and, then, angular modulation in the pair-density without any signature of a cross-over. The excitation energy for certain high-spin states decreases significantly with $r_s$. Dots with smaller number of electrons are typically more affected by correlation effects.

**17:06**

**K35 14 Kondo Physics in Exactly Solvable SU(4) Double Dots** ROBERT KONIK, *Brookhaven National Laboratory* I study a dot-lead system composed of two quantum dots arranged in series. I consider dots that are both capacitive and tunnel coupled and where the applied gate voltage to the individual dots is unequal. This system admits an exact solution via the Bethe ansatz even in the presence of finite (as opposed to infinite) Coulomb repulsion. From this solution, the transport properties of the dot system can be ascertained analytically. In particular transport can be determined everywhere from the empty orbital to the mixed valence to an SU(4) Kondo regime. While double dots are the focus, natural generalizations to systems with $N > 2$ dots are similarly integrable.

**K36 1 Real Space Observation of Helical Spin Order by Lorentz Microscopy** MASAYA UCHIDA, *ERATO, Japan Science and Technology Agency (JST), Tsukuba, Japan* YOSHINORI ONOSE, *ERATO-JST, Tsukuba, Japan* YOSHIO MATSUI, *AML, National Institute for Materials Science (NIMS), Tsukuba, Japan* YOSHINORI TOKURA, *Univ. Tokyo, Tokyo, Japan* Helical spin order is widely observed and its average structure has been investigated so far in reciprocal space mainly by neutron diffraction. Here the helical spin order and dynamics are visualized in real space by means of Lorentz electron microscopy. Our system of choice is $Fe_{1-x}Co_xSi$, which exhibits a helical spin order with a long period ($> 30$ nm) in a concentration range $0.05 \leqslant x \leqslant 0.8$. The Néel temperature $T_N$ and the helix period for $x = 0.5$ take about 38 K and 90 nm along the [100] direction, respectively. The

helical spin order is due to the Dzyalosinsky-Moriya (DM) interaction because of the lack of centrosymmetry of the lattice. The observations were made by means of a Lorentz transmission electron microscope operated at 300 kV. The magnetization distribution was obtained by the transport of intensity equation (TIE) analysis. The real world of the helical spin order proves to be much richer than expected from the averaged structure, as manifested by variegated magnetic defects like atomic boundary and dislocation in the crystal lattice. By applying magnetic fields we can directly observe the deformation processes of the helical spin order, accompanied by nucleation, movement, and annihilation of the magnetic defects.

**14:42**

**K36 2 Imaging chiral domains and magnetic phase coexistence in holmium metal*** A. CADY, J. C. LANG, D. HASKEL, G. SRAJER, *Argonne National Laboratory* D. B. MCWHAN, *Brookhaven National Laboratory (retired)* In the rare-earth metal holmium, the magnetic moments in the atomic planes form a magnetic spiral structure below $T_N = 133$ K with an incommensurate repeat unit along the crystal c-axis. This spiral structure forms with different chirality in different regions of the samples, giving rise to chiral domains. The pitch of the spiral evolves with temperature decreasing toward six atomic layers as the crystal is cooled to $T = 19$ K where the magnetic moments cant toward the c-axis, and a commensurate conical magnetic structure results. This magnetic phase transition leads to the formation of a second type of domains where the spiral phase coexists with the conical phase over a temperature range of approximately 1 K. We have combined micro-diffraction with phase-retarding x-ray optics to image both types of magnetic domains simultaneously as a function of temperature. Using circularly polarized x-rays, the satellite peaks associated with the magnetic ordering become sensitive to the chirality of the spirals, and the micro-focused beam provides spatial resolution of a couple microns. We will present images of both chiral domains and spiral/conical domains, which have been shown to occur over length scales of many microns.

**K36 3 Inverse Transition of Magnetic Domain Patterns in Ultrathin Fe Films on Cu(001): A Quantitative Analysis** OLIVER PORTMANN, ALESSANDRO VINDIGNI, TUOMAS KNOWLES, ANDREAS VATERLAUS, DANILO PESCIA, *Laboratory for Solid State Physics, ETH Zurich* The magnetization of ultrathin Fe films on Cu(001) is perpendicular to the film plane. Due to the competition between exchange and dipolar interactions such films break up into domains of opposite magnetization. As the temperature is increased, the magnetic domain pattern undergoes an inverse transition[1]: a more ordered stripe phase is found at higher temperatures than a less ordered labyrinthine phase. The domain structure has been imaged by means of a SEMPA (Scanning Electron Microscope with Polarization Analysis). We characterize this pattern sequence quantitatively in terms of domain width, correlations, single-configuration energy and density of defects, directly extracted from SEMPA images. [1] O. Portmann, A. Vaterlaus, and D. Pescia, Nature **422**, 701 (2003).

**15:06**

**K36 4 Magnetic bubble domains in the spin reorientation transition region of Fe/Ni/Cu(001)** J. CHOI, J. WU, T. OWENS, Z. Q. QIU, *Dept. of Phys., UC-Berkeley, Berkeley, CA 94720* C. WON, *MSD, Argonne Nat. Lab., Argonne, IL 60439* Y. Z. WU, *Dept. of Phys. Fudan Univ., Shanghai, P. R. China* A. SCHOLL, A. DORAN, *Advanced Light Source, LBNL, Berkeley, CA 94720* Spin reorientation transition (SRT) in Fe/Ni/Cu(001) system was investigated using photoemission electron microscopy (PEEM). In addition to the previously found stripe domains, we also observed bubble domains within a narrow thickness region of the SRT after applying an in-plane magnetic field. Because of the up-down asymmetry of the bubble domains, a small off-normal component of the in-plane magnetic field is necessary to generate the bubble domains. By applying the magnetic field along different directions related to the sample surface, we found that the bubble domains disappear if the field direction is more than $\sim$ 10 degrees off the sample surface. A temperature dependent study shows that the bubble domains are unstable against annealing and will be converted back to the stripe phase, indicating that the bubble domain phase is a meta-stable phase.

**15:18**

**K36 5 Regular magnetic domain pattern in $TbNi_2B_2C$ due to strong magneto-elastic coupling** A. KREYSSIG, J.-W. KIM, L. TAN, A. I. GOLDMAN, *Ames Laboratory USDOE, Department of Physics and Astronomy, Iowa State University, Ames, IA 50011* C. DETLEFS, *ESRF Grenoble, 38043 Grenoble, France* B. GRENIER, *ILL Grenoble, 38042 Grenoble, France* M. LOEWENHAUPT, *Technische Universitaet Dresden, IFP, D-01062, Germany* $RNi_2B_2C$ compounds are of strong interest due to the competition between superconductivity and magnetism. The crystal electric field effects yield strong magnetoelastic effects. The strongest tetragonal-to-orthorhombic distortion is observed for $TbNi_2B_2C$ with a relative distortion of 0.6 % in the antiferromagnetic state at 1.5 K. The lowering of the symmetry forces the development of domains of two forms, in which the magnetic moment direction are align along the a or b axis, respectively. For both kind of domains, the lattice distortion is opposite in the ab plane. We investigated the resulting domain using scattering techniques. Temperature-dependent topographic x-ray images show that the domains are very large in (110) directions where as they are very narrow in the direction perpendicular in the ab plane. In X-ray and neutron diffraction sattelite reflections are found, which are produced by the regular pattern of domains with dimensions of 10 nm. A model describing this pattern and consequences for magnetic and superconducting properties will be discussed.

**K36 6 Disorder Induced Magnetic Memory** MICHAEL S. PIERCE, *University of Washington* To test theories of random microscopic disorder, we first developed and then applied coherent x-raymetrology to a series of thin multilayer films with perpendicular magnetic anisotropy anddegrees of disorder. We used coherent x-rays to generate speckled scattering patterns. The ''random'' arrangement of the speckles is due to the exact configuration of the magneticin the sample. Changes in the domain structure change the speckles, and comparison of thespeckle patterns provides a quantitative determination of how much the domain structure has. We asked (and answered) two important questions. How is the magnetic domain configuration at one point on the major hysteresis loop related to the configurations at the same point on the loop during subsequent cycles: microscopic

return point memory (RPM)? We found the RPM is partial and imperfect in the disordered samples. How are the magnetic domains at one point on the major loop related to the domains at the inversion symmetric point on the loop, during the same and during subsequent cycles: microscopic complementary point memory (CPM)? We found the CPM is also partial and imperfect in the disordered samples. In addition, we found that RPM is always larger than CPM. No existing theory was capable of reproducing our results. We developed newthat do fit our observations. Our experimental and theoretical results set new benchmarks for work.

**K36 7 Kerr Imaging of Co/Pt multilayers with perpendicular anisotropy** M. ROBINSON, Y. AU, J. KNEPPER, F. YANG, R. SOORYAKUMAR, *The Ohio State University* Co/Pt multilayer films are promising materials for applications such as in high density magnetic recording media. For very thin Co layers these structures exhibit perpendicular magnetization. The exchange coupling between adjacent Co layers is ferromagnetic and the coupling strength oscillates as the nonmagnetic Pt layer thickness ($t_{Pt}$) ranges from 3 to 75°A. In order to understand the magnetization reversal process in these structures, we report on magneto-optical images of a series of $[\text{Co}(4\ \text{Å})/\text{Pt}(t_{Pt})]_N$ multilayers obtained with Kerr microscopy as a function of $t_{Pt}$ and layer repetition N. The images reveal the evolution of the magnetic reversal process that strongly depends on $t_{Pt}$ and therefore on the interlayer coupling. For Co/Pt multilayers with small $t_{Pt}$, e.g., 11 Å, when Co layers are strongly coupled, the whole multilayer switches as a single ferromagnet. As Co layers are farther separated and decoupled, e.g., at $t_{Pt}$ =41 Å, Co layers switch independently and layer by layer switching was observed by Kerr imaging. The response of these distinct magnetic phases to external magnetic fields and their relationship to details of the hysteresis loops will be discussed.

**K36 8 Sagnac type fiber interferometer for magneto-optic Kerr effect measurement at cryogenic temperatures*** JING XIA, *Stanford University* PETER BEYERSDORF, *San Jose State University* MARTIN FEJER, AHARON KAPITULNIK, *Stanford University* We describe a Sagnac type magneto-optical interferometer operating at 1550 nm wavelength in which the fast and slow axis of a single 10-meter long Polarization-Maintaining fiber were used as the Sagnac loop. The last 2 meters of this PM fiber were fed into a cryogenic probe to measure Kerr rotation. This zero-area-Sagnac-loop design is virtually immune to temperature fluctuations and mechanical bending of the fiber, and can work at much lower temperature ( $<$ 1 K) compared to apparatus with optical windows. Most important, no perturbing AC magnetic field is needed. Up to now, we have achieved a Kerr rotation sensitivity of $2.5 \times 10^{-7} rad/\sqrt{Hz}$ down to liquid Helium temperature, with $4\mu W$of optical power at the detector. Drifts of this apparatus were observed to be less than$0.5 \times 10^{-7} rad/Hour$. We studied ferromagnetic transition and magnetic domains of thin (3 to 30 nm) $SrRuO_3$ films by cooling them through Tc in zero fields ( $<$ 5 mG) and measuring polar Kerr rotations.

**K36 9 Fluctuation in the depinning of edge magnetic domains due to edge defects in ultrathin films** ADEBANJO ORIADE, SIU-TAT CHUI, *Bartol Research Institute* Magnetic memory devices utilize an optimal reversal field to change the magnetic state of a magnetic memory element. Edge pinned domains (EPD) can lead to the restoration of the original magnetic state. Failure in reversal can occur when the external field is withdrawn before EPD's are completely depinned [1],[2]. We study, via Monte-Carlo simulations, the reversal of edge pinned domains in NiFe ultrathin films with dimensions $0.33\mu m \times 0.50\mu m \times 50$ Å and $0.20\mu m \times 1.00\mu m \times 50$ Å (aspect ratio 2:3 and 1:5 respectively) at different temperatures. Fluctuations in reversal field were computed relative to that of samples without edge defects, our control. Defects in the edges parallel to the easy axis increase the switching field by an average of 29% in 1:5 samples and 6.7% in 2:3 samples. Defects in the edges perpendicular to the easy axis reduce the switching field by an average of 3.6% in 1:5 samples and 4.2% in 2:3 samples. The averages are quoted for word ($H_{ext,x}$) and digit ($H_{ext,y}$) line fields that result in a net external field at an angle of 5° to 55° to the easy axis (digit line). We show the mechanism for edge pinned domain reversal is by the removal of 180° domain walls. This removal is by the nucleation of solitons propagating from one end of the sample to the other. Most of the time, the upper and lower walls are removed simultaneously from opposite ends. [1] J. Shi et al, Appl. Phys. Lett. 77, 1692 (2000). [2] A. A. Oriade et al, Jour. App. Phys. 97, 023905 (2005).

**16:18**

**K36 10 A study of magnetic domain formation and motion in perpendicularly magnetized ultrathin film using the magnetic ac-susceptibility** NIDAL ABU-LIBDEH, DAVID VENUS, *McMaster University* The Complex, low-frequency ac magnetic susceptibility $\chi$ has been used to study magnetic domain formation and motion in perpendicularly magnetized ultrathin Fe films on a 2ML Ni/W(110) substrate. Analysis of the real and imaginary part of $\chi$ reveals that below a characteristic temperature $T_{sat}$, the stripe-domain density cannot change quickly enough to maintain equilibrium. This is due to the fact that domain wall creation and/or annihilation is itself an activated process, with nucleation energy $E_n$, distinct from the pinning of existing domain walls by defects in film structure, with activation energy $E_a$. $T_{sat}$, is set by the time scale of the measurements, which is determined by the rate of change of temperature (R). The Magnetic susceptibility was recorded as a function of temperature at different heating rates between 0.03 (K/s) to 1 (K/s). Our results show that below heating rate $R_c$(= 0.2 K/s for 1.5ML Fe film) the susceptibility peak temperature ($T_{peak}$) decreases as dT/dR = -200.0 (s). Above $R_c$, the susceptibility peak temperature increases as dT/dR = 16.6 (s). Preliminary model calculation show the movement of $T_{peak}$ is due to the change in $T_{sat}$ as the heating rate changes. $R_c$ is set by the relative values of $E_n$and $E_a$.

**16:30**

**K36 11 Imaging Antiferromagnetic Domain Walls with the Hall Effect*** RAFAEL JARAMILLO, T.F. ROSENBAUM, *University of Chicago* E.D. ISAACS, O.G. SHPYRKO, *Argonne Nat'l. Lab* P.G. EVANS, *University of Wisconsin* G. AEPPLI, *University College, London* Z. CAI, *Advanced Photon Source, Argonne Nat'l. Lab* We find that the Hall effect in the

spin-density-wave state of elemental chromium is sensitive to the underlying magnetic domain structure. A modest hysteresis in the linear Hall coefficient emerges as a function of temperature in the antiferromagnetic phase. By measuring all three components of the resistivity tensor in the plane of the sample we are able to separately consider the effects of domain rearrangement on carrier mobility and density. We also present direct images of hysteretic domain rearrangement, acquired via spatially resolved X-ray charge and magnetic scattering, and we show that these images can be correlated to the transport measurements.

*This material is based upon work supported under a National Science Foundation Graduate Research Fellowship

**16:42**

**K36 12 Anhysteretic magnetization and magnetostriction of thin NiFe films under stress and plastic deformation** PETER FINKEL, ED GARRITY, *Thomson* SAM LOFLAND, *Rowan University* The magnetic properties of thin samples of a thin film NiFe sample under tensile stress are investigated. The magnetostriction contribution to dc magnetization under elastic stress and the effect of the plastic strain on the hysteresis loops are discussed. Also, a role of the plastic deformation interrelated with the elastic stress in the magnetization process is established. An experimental system based on a conventional vibrating sample magnetometer equipped with the specially designed loading fixture and optical resonant spectroscopy tension monitoring technique is used to measure anhysteretic permeability and magnetization curve as a function of stress and temperature. This method used to measure anhysteretic permeability and magnetization curve of Ni-Fe as a function of stress and temperature. Anhysteretic permeability was extracted from the anhysteretic $B - H$ curves constructed by degaussing the sample at given longitudinal (parallel to the stresses) dc field. The large positive magnetostriction constant of FeNi samples leads to higher susceptibility and lower coercivity with tensile stress while the large volume magnetostriction results in reduced saturation magnetization. Large stresses imposed on the sample result in plastic strain of the sample which induces increase in dislocation density and domain wall pinning. This causes the gain in hysteresis loss and coercivity to increase at the highest stresses. We also discuss the effect of the Ni composition on results of the measurements.

**16:54**

**K36 13 Soft magnetic layers for low-field detection in spin-valve and magnetic-tunnel-junction sensors** WILLIAM EGELHOFF, ROBERT McMICHAEL, CINDI DENNIS, MARK STILES, ALEXANDER SHAPRIO, BRIAN MARANVILLE, CEDRIC POWELL, *NIST* We have investigated a wide variety of soft magnetic layers as sense layers for magnetic-field sensors. We find that in thin-film form, some of these soft materials can have susceptibilities approaching those of the corresponding bulk material. In general, the highest susceptibilities occur in tri-layer structures with a non-magnetic film separating two soft magnetic films. The alloy $Ni_{77}Fe_{14}Cu_5Mo_4$ of the mu-metal family is the softest thin-film material we have found, and we can achieve hard-axis susceptibilities of $\sim 10^5$ in tri-layer structures. The hard axis is preferred for magnetic sensors due to its near-linear response. The major impediment we have found to using these very soft layers in low-field sensors is that the susceptibility decreases by almost two orders of magnitude when the soft structure is incorporated in a standard spin valve or magnetic tunnel junction. In this talk, we will illustrate the problem, show how the structural modifications can minimize the problem, discuss the outlook for the complete elimination of the problem, and assess the prospects for significant improvements in thin-film, low-field magnetic sensors.

**17:06**

**K36 14 Minimizing 1/f Noise in Magnetic Sensors Using MEMS Flux Concentrators** ALAN EDELSTEIN, GREG FISCHER, *U.S. Army Research Laboratory* MICHAEL PEDERSEN, WILLIAM BERNARD, *MEMS Exchange* SHU-FAN CHENG, *Naval Research Laboratory* EDMUND NOWAK, *University of Delaware* The 1/f noise of new types of magnetoresistance sensors based on GMR and MTJ limits their sensitivities at low frequencies. Our approach for dealing with this problem is to shift the operating frequency to higher frequencies where the 1/f noise is much lower. The shift is accomplished by placing flux concentrators on MEMS flaps. Springs connecting the flaps are used to establish the proper normal mode. The motion of the MEMS structure, driven to oscillate at 15 kHz by electrostatic comb drives, modulates the field at the position of the sensor. The device was fabricated using SOI wafers, deep reactive ion etching (DRIE), and flip chip bonding. The motion of the permalloy on the MEMS flaps modulates the field by a factor of 2. Driving the motion only requires microwatts of power. Noise measurements indicate that the device is likely to increase the sensitivity of many magnetic sensors at low frequencies by orders of magnitude.

**K36 15 Enhanced coercivity in melt-spun Sm-Co-Fe-Cu ribbons after low temperature aging*** D. SULTANA, M. MARINESCU, Y. ZHANG, G.C. HADJIPANAYIS, *Department of Physics & Astronomy, University of Delaware, 223 Sharp Lab., Newark, DE 19716* MAGNETICS LAB. TEAM, We have studied systematically the influence of the microstructure refinement on the change of coercivity in melt-spun Sm $(Co_{0.45}Cu_{0.4}Fe_{0.15})_5$ alloys after thermal aging. The specimens have been prepared in the form of ribbons with a thickness in the range of 35 - 80 $\mu$m for values of the quenching wheel speed between 5-25 m/s. X-ray diffraction spectra of the as-spun ribbons showed a single phase 1:5 structure. The as-spun ribbons had a coercivity $H_c = 8$ kOe. The as-spun ribbons have been subjected to low temperature aging between 350-400 °C for different periods of time, in Ar atmosphere. Our results showed that the highest coercivity of 44 kOe was obtained in a sample aged at 400 $^o$C for 133 h. Microstructural investigations by transmission electron microscopy reveal that the average grain size of the specimens with the enhanced coercivity is about 500 nm. In order to have an insight into the mechanism of the coercivity enhancement, we are investigating the microchemistry at the grain boundaries by energy dispersive X-ray analysis and measuring the change in the Curie temperature through thermomagnetic measurements.

**K37 1 Ultrafast, Time-Resolved Quasiparticle Dynamics in Hg-Based High Temperature Superconductors** X. LI, M. KHAFIZOV, R. SOBOLEWSKI, *University of Rochester, Rochester, NY 14627* S. CHROMIK, V. STRBIK, *Slovak Academy of Sciences, SK-84104 Bratislava, Slovakia* D. DE BARROS, P. ODIER, *CNRS, F-38042 Grenoble, France* We present our all optical and optoelectronic time-domain studies of the quasiparticle and Cooper pair dynamics in Hg-based superconductors. The samples were mixed phase (Hg-1212 and Hg-1223), *c*-axis-oriented thin films, fabricated by magnetron sputtering, followed by itex-situ mercuration. The films exhibited the onset of the superconducting transition at $T_c = 123$ K and the zero-resistance at 110 K. Far below $T_c$, our femtosecond pump-probe spectroscopy studies clearly demonstrated the bi-molecular-type relaxation of photoexcited quasiparticles, governed by the direct Cooper pair formation process. At temperatures close to $T_c$, we observed a severe phonon bottleneck, and the quasiparticle relaxation time was limited by the phonon anharmonic decay/escape process. The photoresponse studies performed on current-biased microbridges, illuminated by femtosecond optical pulses demonstrated the picosecond nonequilibrium response on top of the much slower bolometric signal.

**14:42**
**K37 2 Time-resolved infrared spectroscopy of superconducting NbTiN films*** H. ZHANG, D.H. REITZE, C.J. STANTON, D.B. TANNER, *Department of Physics, University of Florida* R.P.S.M. LOBO, *ESPCI-CNRS* G.L. CARR, *Brookhaven National Laboratory* Time-resolved, pump-probe measurements of superconducting thin NbTiN films were performed at the National Synchrotron Light Source, Brookhaven National Laboratory. Near-infrared Ti:sapphire laser pulses break Cooper pairs, producing an excess of non-thermal quasiparticles. The recombinations of these excess quasiparticles are probed by time-synchronized, far-infrared, synchrotron pulses, with a time resolution of order 200 picoseconds. The main process probed is the bottleneck between gap-edge quasiparticles and excess $2\Delta$ phonons. (The phonons, generated by recombination of quasiparticles into Cooper pairs, are pairbreaking, producing gap-edge quasiparticles.) We will report the temperature, magnetic field, and laser fluence dependence of the spectrum-averaged far-infrared photoinduced transmission and reflection. We will also report the changes in the photoinduced far-infrared transmission spectrum.

**K37 3 Finite bandwidth effects in time-domain measurements of fast electronic processes** OFER NAAMAN, JOSÉ AUMENTADO, *NIST, 325 Broadway, Boulder CO., 80305* Using rf reflectometry, we have observed individual quasiparticle tunneling events in a superconducting single- charge transistor. These events follow a Poisson process on microsecond time scales. We show that when the measurement is done with a finite bandwidth receiver, the experimentally observed process is no longer Poissonian, and the measured transition rates always underestimate those in the underlying system. We will present a model that accounts for bandwidth effects in these time-domain measurements, and show how to obtain the underlying rates from their measured values. We compare the results of our model to simulated and experimental data. We argue that these effects, which are significant even if the receiver is 10 times faster than the process, are a general feature in time domain experiments.

**15:06**
**K37 4 Determination of electron−phonon interaction parameters from time−domain terahertz spectroscopy** J. STEVEN DODGE, M. A. GILMORE, SAEID KAMAL, D. M. BROUN, *Simon Fraser University* We present an analytical framework for determining metallic electron−phonon interaction parameters from time−domain terahertz spectroscopy measurements in the normal state. We apply this analysis to the case of lead, where we obtain values that are consistent with existing estimates. We discuss the statistical and systematic errors that limit the uncertainty in the parameter estimates.

**15:18**
**K37 5 Hole doping in $YBa_2Cu_3O_{6+\delta}$ from polarization dependent x-ray absorption spectroscopy** DAVID HAWTHORN, DARREN PEETS, KYLE SHEN, SUMAN HOSSAIN, GEORGE SAWATZKY, *University of British Columbia* THOMAS KROLL, *IFW-Dresden* JONATHAN DENLINGER, *Lawrence Berkeley National Lab* RUIXING LIANG, DOUG BONN, WALTER HARDY, *University of British Columbia* We present detailed polarization dependent x-ray absorption spectroscopy (XAS) measurements of the cuprate $YBa_2Cu_3O_{6+\delta}$ as a function of oxygen concentration for ($0 \leqslant \delta \leqslant 1$). By adding O into the chain layer of YBCO, holes are doped into both the $CuO_2$ planes and $CuO_3$ chains. The presence of O induced states is directly observed by measurements of the O K edge and Cu L edge XAS, which probes unoccupied states in the O $2p$ and Cu $3d$ orbitals respectively. Owing to the different symmetry of the Cu d orbitals in the planes ($d_{x^2-y^2}$) and chains ($d_{y^2-z^2}$), the contribution to the total XAS from the chains and planes is clearly separated by measuring the polarization dependence of the x-ray absorption. Comparison to LDA calculations of the unoccupied density of states are used to obtain a quantitative measure of the hole doping in the planes and chains as a function of O concentration. In addition, the doping of holes into the $CuO_2$ planes as a function of degree of oxygen order in the chains is observed by measuring $YBa_2Cu_3O_{6.5}$ in both the chain ordered (ortho II) and chain disordered phases. This provides direct evidence for the role of chain ordering on hole doping in YBCO.

**15:30**
**K37 6 Doping Dependence of Resonant Inelastic X-ray Scattering (RIXS) in Electron and Hole-doped Cuprates*** ARUN BANSIL, ROBERT MARKIEWICZ, *Northeastern University* YINWAN LI, DONG QIAN, ZAHID HASAN, *Princeton University* Resonant inelastic X-ray scattering (RIXS) can in principle access all intra- and inter-band transitions over a wide range of energies and momenta. For these reasons, RIXS is emerging as an important probe of Mott gap physics in strongly correlated materials. Here we discuss evolution of RIXS spectra in electron and hole doped cuprates within the framework of a three-band model Hamiltonian [1]. The theoretical predictions are compared and

contrasted with the corresponding experimental results in NCCO and LSCO [2]. Interband (magnetic) transitions are found to shift to lower energy with increasing doping, while intraband features appear away from half-filling and spread over a wider energy range as the bandwidth grows with doping. Higher energy features arising from transitions deeper within the cuprate valence band complex will also be discussed. 1: R.S. Markiewicz and A. Bansil, cond-mat/0506474. 2: M.Z. Hasan, *et al.*, cond-mat/0406654.

**K37 8 Electronic Excitations in the Resonant X-Ray Scattering Spectra of $La_2CuO_4$*** DAVID ELLIS, *Department of Physics, University of Toronto* JOHN HILL, *Department of Physics, Brookhaven National Laboratory* SHUICHI WAKIMOTO,† *Department of Physics, University of Toronto* DIEGO CASA, *CMC-CAT, Advanced Photon Source, Argonne National Laboratory* THOMAS GOG, *CMC-CAT, Advanced Photon Source, Argonne National Laboratory* YOUNG-JUNE KIM, *University of Toronto* Resonant inelastic X-Ray scattering (RIXS) experiments were done on the insulating cuprate $La_2CuO_4$ (LCO), tuning the incident energy to the copper k-edge at 8.99 keV to probe excitations on the order of an eV. With an energy resolution of 130 meV, a number of new features in the electronic excitations could be resolved. The momentum dependence of these features was studied in detail. In LCO, distinct peaks were seen above 2 eV, the first of which is associated with the charge-transfer excitation between the copper and the neighboring oxygen atoms. The amplitude of this peak decreased with increasing momentum transfer q, and energy increased with an observed dispersion of at least 0.2 eV. These results were interpreted using a 1-band model calculation. Also seen was a non-dispersive feature at 1.8 eV thought to be an orbital d-d excitation.

**K37 9 Quantum melting of the hole crystal in the spin ladder of $Sr_{14-x}Ca_xCu_{24}O_{41}$** ANDRIVO RUSYDI, *University of Hamburg* P. ABBAMONTE, *UIUC* H. EISAKI, *AIST* Y. FUJIMAKI, S. UCHIDA, *University of Tokyo* G. BLUMBERG, *Bell Laboratories* M. RUEBHAUSEN, *University of Hamburg* G.A. SAWATZKY, *UBC* The ''spin ladder'' is a reduced-dimensional analogue of the high temperature superconductors that was predicted to exhibit both superconductivity and an electronic charge density wave or ''hole crystal'' (HC). Both phenomena have been observed in the doped spin ladder system $Sr_{14-x}Ca_xCu_{24}O_{41}$ (SCCO), which at x = 0 exhibits a HC which is commensurate at all temperatures. To investigate the effects of discommensuration we used resonant soft x-ray scattering (RSXS) to study SCCO as a function of doped hole density, $\delta$. The HC forms only with the commensurate wave vectors $L_L = 1/5$ and $L_L = 1/3$ (Not at 1/4!) and exhibits a simple temperature scaling $\tau_{1/3}/\ \tau_{1/5} = 5/3$. For incommensurate values the HC ''melts.'' During this study, the distribution of holes in ladder ($n_L$) and chain ($n_c$) of SCCO are redetermined as a function of $x$ using polarization-dependence x-ray absorption spectroscopy (XAS). An interpretation of polarization dependent XAS is proposed. Based on our interpretation, for $x = 0$, the estimation of $n_L$ and $n_c$ is 2.8 and 3.2, respectively. The number of holes in the ladder is linearly increasing with $x$. For $x = 11$, the estimation of $n_L$ and $n_c$ is 4.4 and 1.6, respectively. This number of holes is matching well with the model of paired of holes needed to explain the RSXS result.

**K37 10 Shedding New Light on Spin Excitations: Magnon-Magnon Scattering in a High-$T_c$ Parent Compound Using Soft X-rays** B. FREELON, *LBNL- UC Berkeley* P.G. MEDAGLIA, A. TEBANO, G. BALESTRINO, *INFM COHERENTIA Tor Vergata* P.A. GLANS, T.E. LEARMONTH, K. SMITH, *Boston University* K. OKADA, *Okayama University* A. KOTANI, *RIKEN-Spring8* D.E. KILCOYNE, B. RUDE, I. FURTADO, J.-H. GUO, *LBNL* The struggle to understand high-temperature superconductivity (HTSC) has taken place in the field of condensed matter physics for a relatively long time. The difficulty in discovering a HTSC mechanism seems to originate from the confluence of two very complicated problems; electron correlation and quantum magnetism. Novel techniques that specifically probe the electronic or magnetic behavior of these materials are highly sought. We report the direct observation of spin-flip (SF) excitations using resonant inelastic soft x-ray scattering (RIXS). The antiferromganetic (AFM) charge transfer insulator, $CaCuO_2$, was irradiated by soft x-rays tuned to the Cu M-edge ( $\sim$ 75 eV). Magnon-magnon (2 spin-flips) excitations were revealed as low-energy loss (0.39 eV) features in photon-in/photon-out experiments. The process is analogous to 2-magnon laser Raman scattering. Collected RIXS spectra provide a measurement of the 2 spin-flip excitation energy and the extraction of the AFM exchange of $CaCuO_2$. These results mark the first report of two-spin-flip magneto-optical excitations revealed through Raman scattering using x-rays. This work reveals the utility of RIXS as a new probe of the spin structure in strongly correlated electron materials.

**K37 12 Doping dependence of the coupling of electrons to bosonic modes in the single-layer high-temperature superconductor, $Bi_2Sr_2CuO_6$*** W. MEEVASANA, D.H. LU, F. BAUMBERGER, W.S. LEE, T. CUK, J. ZAANEN, Z.-X. SHEN, *Stanford University* N.J.C. INGLE, K.M. SHEN, *U. of British Columbia, Canada* J.R. SHI, *U. of Texas, Austin* H. EISAKI, *Nanoelectronic Research Institute, AIST, Japan* T.P. DEVEREAUX, *U. of Waterloo, Canada* N. NAGAOSA, *CREST, U. of Tokyo, Japan* S. SAHRAKORPI, M. LINDROOS, R. S. MARKIEWICZ, A. BANSIL, *Northeastern University* A recent highlight in the study of high-$T_c$ superconductors is the observation of band renormalization/self-energy effects on the quasiparticles in the form of kinks in their dispersions as measured by photoemission, interpreted as signatures of collective bosonic modes coupling to the electrons. Here we compare for the first time the self-energies in an optimally doped and strongly overdoped, non-superconducting single-layer Bi-cuprate, $Bi_2Sr_2CuO_6$. Besides a strong overall weakening we also find that weight of the self-energy in the overdoped system shifts to higher energies. We present evidence that this might well be related to the coupling to c-axis phonons which are unscreened at optimal doping, being particularly sensitive to the rapid change of the c-axis screening in this doping range. We also discuss doping dependencies of the FS maps and dispersions in terms of the corresponding band structure and one-step photointensity computations.

**K37 13 Unusual photoemission resonances of oxygen-dopant induced states in $Bi_2Sr_2CaCu_2O_{8+x}$** P. RICHARD, Z.-H. PAN, M. NEUPANE, Z. WANG, H. DING, *Department of Physics, Boston College, Chestnut Hill, MA 02467* A. V. FEDOROV, *Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA 94720* T. VALLA, P. D. JONHSON, G. D. GU, *Physics Department, Brookhaven National Laboratory, Upton, NY 11973* A rising interest for the doping impurities in cuprates have been stimulated by a recent STM report on $Bi_2Sr_2Ca_1Cu_2O_{8+x}$ [McElroy *et al.*, Science **309**, 1048 (2005)], which identified oxygen dopants and investigated their local influence on the $CuO_2$ plane electronic properties. The nature of the perturbation induced by the dopants, which is of crucial importance, is thus questioned by these results. In order to investigate further this issue, we have performed an angular-resolved photoemission study of underdoped, optimally doped and overdoped $Bi_2Sr_2Ca_1Cu_2O_{8+x}$ samples using a wide photon energy range (14 - 100 eV). We report the presence of a non-dispersive peak, which we assign to a local impurity state similar to the one observed by STM and attributed to oxygen dopants. Unusual resonances in the peak intensity are observed around 50 and 75 eV for both the nodal and anti-nodal orientations, which suggest a hybridization of the local state with in-plane Cu.

**SESSION K38: SUPERCONDUCTIVITY—MESOSCOPICS AND THEORY**

**K38 1 Charge dynamics in a single electron trap** JULIE WYATT, *Yale University* ROBERT SCHOELKOPF, *Yale University* We report on measurements made using a radio frequency single electron transistor (RF-SET) capacitively coupled to a small metallic island to study the dynamics of single tunneling events. A circuit consisting of two small metallic islands and two tunnel junctions provides an architecture with which to tune the tunneling rates of single electrons up to the micro-second time scale. Thermal and cotunneling (quantum tunneling) events as well as the cross-over between the two regimes can be studied with this system. Characterization of devices will be shown including stability diagrams and the dependence of tunneling rates on bias conditions.

**14:42**

**K38 2 Measuring the Quantum Capacitance of a Differential Single Cooper-Pair Box*** MATTHEW SHAW, JUSTIN SCHNEIDERMAN, *University of Southern California* PER DELSING, *Chalmers University of Technology, Microtechnology and Nanoscience, MC2* HANS BOZLER, *University of Southern California* PIERRE ECHTERNACH, *Jet Propulsion Laboratory, California Institute of Technology* We present a simple method for measuring the quantum capacitance (QC) of a charge qubit based on a Differential Single Cooper-Pair Box using a Differential Radio-Frequency Single Electron Transistor. Measurement of the QC, which is proportional to the second derivative of the energy bands, can in principle be used for state readout at the degeneracy point, where decoherence due to charge fluctuations is at a minimum. The QC is measured by examining the response of the qubit to a small-amplitude AC excitation. Using this technique, we make an independent measurement of the qubit energy relaxation time. Although we have performed this experiment with a differential SCB and differential charge readout, the technique can easily be applied to a conventional SCB.

**K38 3 A solid-state refrigerator for cooling cm-scale payloads below 300 mK*** N.A. MILLER, D.R. SCHMIDT, J.A. BEALL, W.D. DUNCAN, G.C. HILTON, G.C. O'NEIL, L.R. VALE, K.D. IRWIN, J.N. ULLOM, *National Institute of Standards and Technology (NIST) - Boulder* State-of-the-art x-ray and infrared sensors require bath temperatures near 100 mK. Currently, the two main options for cooling devices below 300 mK are the dilution refrigerator and adiabatic demagnetization refrigerator. We have developed a compact, lightweight alternative. Solid-state refrigerators based on Normal metal/Insulator/Superconductor (NIS) tunnel junctions can cool from temperatures near 300 mK to below 100 mK. The physical cooling mechanism is the preferential tunneling of the highest energy (hottest) electrons through a biased NIS junction. Recently, we have cooled both thin-film and bulk thermistors from 320 to 240 mK. Here, we present progress towards NIS refrigerators capable of cooling user-supplied payloads. In particular, we demonstrate a NIS-based refrigerator capable of

cooling 6 x 6 $mm^2$ silicon chips. This refrigerator, in combination with a $^3$He cryostat (base temperature $\sim$ 300 mK), forms a simple, compact cooling platform for ultralow temperature x-ray and infrared sensors. NIS refrigerators are fabricated lithographically on wafers, making the technology inherently scaleable to wafer-sized detector arrays.

**K38 4 Quantum Calorimetry for Nonproliferation*** B. L. ZINK, *NIST* J. N. ULLOM, J. A. BEALL, K. D. IRWIN, W. B. DORIESE, R HORANSKY, W. DUNCAN, G. C. HILTON, C. D. REINTSEMA, D. R. SCHMIDT, L. R. VALE, *NIST Quantum Sensors Project, Boulder CO* High resolution $\gamma$-ray spectroscopy is an important tool for non-destructive analysis of nuclear materials and is often used by safeguards inspectors to help verify the inventories of nuclear materials held around the world. The energy spectrum of photons emitted from isotopes of uranium or plutonium in the 40 $-$ 1000 keV energy range give unique signatures that, if accurately measured, give inspectors important information about the age and enrichment of the material and therefore its intended purpose. In this talk I will describe our recent demonstration of a $\gamma$-ray spectrometer based on a superconducting transition-edge sensor microcalorimeter detector. This device has more than an order of magnitude better energy resolution than standard high resolution $\gamma$-ray detectors. We present high-resolution $\gamma$-ray spectra of Pu isotopic mixtures, describe the physics of the microcalorimeter and overview our plans for a realistic spectrometer for meeting real-world challenges such as measuring the mass of plutonium in spent nuclear fuel.

**K38 7 Dynamics of a Nanomechanical Resonator Coupled to a Superconducting Single Electron Transistor*** MILES BLENCOWE, *Dartmouth College* JARA IMBERS, *University of Nottingham* ANDREW ARMOUR, *University of Nottingham* We present an analysis of the dynamics of a nanomechanical resonator coupled to a superconducting single electron transistor (SSET) in the vicinity of the Josephson quasiparticle (JQP) and double Josephson quasiparticle (DJQP) resonances. For weak coupling and wide separation of dynamical timescales, we find that for either superconducting resonances the dynamics of the resonator are given by a Fokker-Planck equation, i.e., the SSET behaves effectively as an equilibrium heat bath, characterised by an effective temperature, which also damps the resonator and renormalizes its frequency. Depending on the gate and drain-source voltage bias points with respect to the superconducting resonance, the SSET can also give rise to an instability in the mechanical resonator marked by negative damping and temperature within the appropriate Fokker-Planck equation. Furthermore, sufficiently close to a resonance, we find that the Fokker-Planck description breaks down. We also point out that there is a close analogy between coupling a nanomechanical resonator to a SSET in the vicinity of the JQP resonance and Doppler cooling of atoms by means of lasers.

**K38 8 Dipolon Theory of Superconducting Regular and Pseudo- Energy Gap Parameters at Finite Temperature and Transition Temperatures $T_C$ and $T^*$ in High-Temperature Superconductors** RAM SHARMA, *University of Illinois at Chicago, Chicago, IL* First temperature dependent regular and pseudo- energy gap parameters and regular ($T_C$)and pseudo-($T^*$) transition temperatures have been obtained arising from the same physical origin by developing many-body field-theoretic techniques making use of dipolon propagator and electron Green's function with dressed dipolons as mediators of superconductivity, screened Coulomb repulsion, nonrigid electron energy bands, retardation and damping effects and electron-hole asymmetry, as an extention of our previous zero temperature formalism [1]. The theory contains all essential and important electron correlations. The Migdal vertex correction is found to be small ( $\sim$ 1%). Our calculated results of temperature dependent regular and pseudo-energy gap parameters and regular ($T_C$) and pseudo- ($T^*$) transition temperatures for Bi-cuprates agree well with available experimental data. In comparison it is concluded that the models (such as the Hubbard and t-j models) should contain additionally electron correlations due to dipolons to visualize superconductivity. 1. R.R. Sharma, Phys. Rev. **B 63**, 054506, (2001).

**16:06**
**K38 9 Bad Screening and Applicability of Migdal's Theorem to Layered Cuprates** ALEXEI ABRIKOSOV, *Materials Science Division, Argonne National Laboratory, USA* A proof is presented, that in the model of high-$T_c$ layered cuprates with long-range phonon-mediated attraction, due to bad screening of Coulomb forces, the ''Migdal's theorem,'' permitting to neglect vertex corrections, still holds, despite the absence of the small ''adiabatic parameter.'' The calculation of the superconducting critical temperature for this model permits to explain the high values of $T_c$ observed in experiment. This work was supported by the Department of Energy under the contracts # W-31-109-ENG-38.

**K39 1 Kondo Physics and Strongly Correlated Superconductivity in Model Fullerene Conductors.*** MICHELE FABRIZIO, *International School for Advanced Studies (SISSA) and The Abdus Salam Center for Theoretical Physics (ICTP)*

The effects of electronic correlations on superconductivity are investigated by means of Dynamical Mean Field Theory (DMFT) in a model for alkali doped fullerenes. It is shown that the proximity to a Mott transition actually amplifies the *s*-wave phonon-mediated pairing mechanism built into the model. It leads to a superconduting pocket adjacent the Mott insulator with a superconducting gap which is huge in comparison with the corresponding BCS value.The physical properties of this strongly correlated superconductor are compatible with the experimental data available on fullerenes. Yet, contradicting the common belief for fullerenes, superconductivity in this model is not of the BCS-type nor is the normal state a conventional Fermi-liquid. We find on the contrary several aspects which rather resemble those of cuprate superconductors, such as an increase of Drude weight accompaning the onset of superconductivity. We identify the origin of these anomalies to the unconventional properties displayed by the Anderson impurity model for a $C_{60}^{n-}$ molecule onto which the lattice model maps within DMFT. We also argue that this behavior should be common to other models that contain pairing mechanisms able to survive inside the Mott insulator, which translate within DMFT into impurity models where Kondo screening competes against an internal mechanism that tends to freeze the impurity in a low-spin state.

**K39 2 Renormalization Group approach to anisotropic-pairing superconductivity** RAFAEL ROLDAN, *Instituto de Ciencia de Materiales de Madrid, CSIC, Spain* SHAN-WEN TSAI, *Physics Dept., Univ. of California, Riverside* The Renormalization Group (RG) approach to interacting fermions [R. Shankar, *Rev. Mod. Phys.* **66** 129 (1994)] has been extended to the case where both electron-electron and electron-phonon interactions are present [S.-W. Tsai *et al*, *Phys. Rev. B* **72** 054531 (2005)]; [S.-W. Tsai *et al*, cond- mat/0505426]. There Eliashberg's equations are derived for the case of a two dimensional Hubbard model with a circular Fermi surface (FS) in the presence of isotropic Einstein phonons. However, there are materials where the isotropic electron-phonon coupling is not a good approximation. In this work we study the problem of superconductivity mediated by anisotropic electron-phonon couplings, and derive a generalization of the Eliashberg's equations for this case. We solve, for the case of a circular FS, the flow equations for the interaction vertices in the particle-particle channel up to one loop, taking into account the retardation effects due to the presence of phonons. Retardation effects lead to important corrections to the imaginary part of the self-energy. For a generic anisotropic electron- phonon coupling these corrections are momentum dependent and the RG flow equations for superconducting couplings with different symmetries become coupled. We find an instability of the Fermi liquid state towards superconductivity for various momentum-dependent el-ph couplings, with competition between superconducting channels with different symmetries of the order parameter.

**K39 3 Correlations in Dynamic Hubbard Model: A DMRG Study** FATIH DOGAN, FRANK MARSIGLIO, *University of Alberta, Edmonton, Canada* The Dynamic Hubbard model has been introduced to study how holes behave in the Hubbard Model with dynamic degrees of freedom modelled by pseudo-spins. It has previously been analyzed using exact diagonalization on small clusters. However the lattice sizes used are not sufficiently large to understand the behaviour of the system in the thermodynamic limit. We present our analysis using the density-matrix-renormalization- group (DMRG) to understand the behaviour of two holes for different system sizes. We observed a decrease in kinetic energy, and an increase in the effective nearest neighbor attraction, even for moderate on-site repulsion, which indicates pairing of the holes through effective nearest neighbor attraction.

**K39 5 Fermi surface splittings in multilayered high-$T_c$ cuprates with charge imbalance** M. MORI, T. TOHYAMA, S. MAEKAWA, *IMR, Tohoku Univ; CREST, JST* Cuprate superconductors have layered structure of $CuO_2$ planes, which makes conducting blocks separated by an charge- reservoir block. Multilayered high-$T_c$ cuprates, e.g., $Ba_2Ca_3Cu_4O_8(O_{1-y}F_y)_2$ and $HgBa_2Ca_4Cu_5O_y$, have two kinds of $CuO_2$ planes in a unit cell; the outer-pyramidal-coordinated-planes (OP's) and the inner-square-coordinated-planes (IP's). The carrier density in the OP is generally different from that in the IP. We call such an inhomogeneous charge-distribution [**lq**]charge imbalance'. We study doping dependence of interlayer hoppings, $t_\perp$, in such a charge-imbalance system in the Gutzwiller approximation. When the double occupancy is forbidden in the $CuO_2$ plane, an effective amplitude of $t_\perp$ is shown to be proportional to the square root of the product of doping rates in adjacent two planes. Therefore, the charge imbalance in more than three-layered cuprates results in two different values of $t_\perp^{\rm eff}$, i.e., $t_{\perp 1}^{\rm eff} \propto t_\perp\sqrt{\delta_{\rm IP}\delta_{\rm IP}}$ between IP's, and $t_{\perp 2}^{\rm eff} \propto t_\perp\sqrt{\delta_{\rm IP}\delta_{\rm OP}}$ between IP and OP, where $\delta_{\rm IP}$ ($\delta_{\rm OP}$) is the doping rates in IP (OP). Fermi surfaces are calculated in the four-layered $t$-$t'$- $t''$-$J$ model by the mean-field theory. The order parameters, the renormalization factor of $t_\perp$, and the site- potential making the charge imbalance between IP and OP are self-consistently determined for several doping rates. We show the interlayer splitting of the Fermi surfaces, which may be observed in the angle resolved photoemission spectroscopy measurement. *cond-mat/0511249.

**15:54**

**K39 6 Effective theory of underdoped cuprates and the puzzle of superfluid density** IGOR HERBUT, *Simon Fraser University* I will discuss the recently proposed low-energy description of fluctuating d-wave superconductors (I. F. Herbut, PRL 94, 237001 (2005)), and its implications for the evolution of the superfluid density with doping and temperature. Recent experiments find that while the T=0 superfluid density becomes reduced by more than two orders of magnitude by going from optimal to extremely underdoped regime in single crystals of YBCO, the slope of the temperature dependence stays roughly the same. This apparent violation of the Ioffe-Larkin rule, argued otherwise rather generally to hold in the underdoped regime, is explained as being due to the particular form of the bosonic (fluctuation) term, which resembles the condensate of the weakly interacting layered Bose gas. This suggests that, its linear appearance notwithstanding, the reduction of the superfluid density with temperature in extremely underdoped cuprates may be due to phase fluctuations over most of the temperature range. Further experimental tests of this idea will be proposed.

**16:06**

**K39 7 Magnetic Origin of the Tetragonal-Orthorhombic Phase Transition in the Cuprates** JIANGPING HU, *Purdue University* CHEN FANG, STEVEN KIVELSON, *Stanford University* STUART BROWN, *UCLA* It is shown that a quasi two dimensional (layered) Heisenberg antiferromagnet with fully frustrated interplane couplings generically exhibits two thermal phase transitions with lowering temperature – an upper transition (''order from disorder without order'') in which the lattice point-group symmetry is spontaneously broken, and a lower Neel transition at which spin-rotational symmetry is broken. We therefore suggest that it may primarily be the magnetic interactions between planes, rather than strains associated with a mismatch of ionic radii, that are responsible for the tetragonal to orthorhombic (T-O) structural phase transition seen in many of the cuprates.

**16:18**

**K39 8 A 4D-XY model of the superfluid density of strongly underdoped cuprate superconductors** ANDREW IYENGAR, *Indiana University* MARCEL FRANZ, *University of British Columbia* A new phenomenology is proposed for the superfluid density of strongly underdoped cuprate superconductors based on data for ultra-clean single crystals of YBCO. The data feature a puzzling departure from Uemura scaling and a decline of the slope as the $T_c = 0$ quantum critical point is approached. We argue that the proximity of a Mott insulator drives quantum fluctuations of the superconducting phase which are described by a (3+1)-dimensional XY model. The subsequent renormalization of the superfluid density is computed using variational methods and then studied systematically as a function of c-axis anisotropy, interaction strength, and doping. We find that non-critical phase fluctuations explain key features of the new cuprate phenomenology, which is expected to fail in the true critical regime.

**16:30**

**K39 9 Microscopic Spectral Model of High Temperature Superconductors** J.C. PHILLIPS, *Dept. of Physics and Astronomy, Rutgers University* The self-organized dopant percolative filamentary model [1], entirely orbital in character (no spins), explains the evolution with doping of Fermi arcs observed by ARPES, including the abrupt transitions in quasiparticle strength observed near optimal doping in cuprate high temperature superconductors [2]. Similarly abrupt transitions are also observed [3] in time-resolved picosecond relaxation spectroscopy at 1.5 eV, and these are explained as well, using no new assumptions and no adjustable parameters. The anomalous ''precursive'' temperature-dependent strains observed by EXAFS [4] are associated with relaxation of filamentary ends. [1] J. C. Phillips, Phys. Rev. Lett. 88, 216401 (2002). [2] T. Yoshida, X. J. Zhou, T. Sasagawa et al., Phys. Rev.

Lett. 91, 027001 (2003). [3] N. Gedik, M. Langer, J. Orenstein et al., Phys. Rev. Lett. 95, 117005 (2005). [4] N. L. Saini and H. Oyanagi, Phys. C 412, 152 (2004).

**K39 10 Pairing in Marignal Fremi Liquid and Luttinger Liquid in Terms of the Bethe-Salpeter Equation** YURIY MALOZOVSKY, *Department of Chemistry and Physics, Southeastern Louisiana University* The pairing between two fermions in the fermionic systems with the smeared Fermi distribution is considered in terms of the Bethe-Slapeter equation. The examples of the systems with the smeared Fermi distribution are the marginal Fermi liquid and the Luttinger liquid where the quasiparticle pole is absent in the Green's function. Although the pairing between two fermions in the systems with the smeared Fermi distribution is, in general, absent, the pairing similar to the Cooper's pairing can occur and the conditions for such pairing to exist are discussed.

**16:54**

**K39 11 High-$T_c$ superconductivity does not originate in cuprate-planes.*** JOHN D. DOW, *Arizona State U.* $CuO_2$ planes are not needed for high-$T_c$ superconductivity, as demonstrated by $Sr_2YRuO_6$ and $Ba_2YRuO_6$, weakly doped on Ru sites with Cu, with onset $T_c$'s of 49K and 93K, but no cuprate-planes. $Gd_{2-z}Ce_zSr_2Cu_2RuO_{10}$ and $GdSr_2Cu_2RuO_8$ do not superconduct in their cuprate- planes, which are magnetic, but in their SrO layers (with onset $T_c \approx 45$K). High-temperature superconductivity resides in SrO, BaO, or interstitial oxygen regions, not in cuprate-planes. In $YBa_2Cu_3O_7$, Harshman *et al.* [1], using muon spectroscopy, found *s*-wave character, not *d*-wave character (to better than one percent) which measures the *superconducting* layers. This contradicts scanning tunneling microscopy and photoemission, which claim *d*-wave behavior after measuring *near-surface* layers (which often do not superconduct). High-temperature superconductivity originates in the BaO, SrO, or interstitial oxygen regions, not in the cuprate planes. [1] D. R. Harshman, *et al.*, Phys. Rev. **B 69,** 174505 (2004).

**K39 13 Unconventional Pairing in 2D lattice with an ''Inherent Gap''** RENYUAN LIAO, KHANDKER QUADER, *Department of Physics, Kent State University* We investigate superconducting pairing in 2D lattice with an ''inherent gap.'' In this calculation, we take this gap to be a constant, and thus similar to that in semiconductors. We consider different pairing symmetries, namely, s-wave, extended-s-wave, p-wave and d-wave. We calculate superconducting gap parameters, critical temperatures, chemical potential, etc in terms of interaction strength and filling factor. There is a sharp transition fom the ''inherent gapped state'' to a superconducting state for half filling f=1/2, corresponding to the undoped case. For finite doping, the transition becomes a smooth crossover. We also explore other features, such as the effect of phase fluctuations and the resulting Kosterlitz-Thouless transition; tunneling density of states, etc.

**K40 1 Decoherence in Josephson Qubits.**
ROBERT McDERMOTT, *UC Santa Barbara*

The Josephson junction can be thought of as an artificial atom, with energy levels determined by the circuit design parameters and bias. This system shows great promise for quantum computing, since it should be straightforward to scale to many-qubit circuits using standard integrated circuit technology. To date, however, device performance has been severely limited by coupling of the qubit to spurious materials defects. Here I discuss a recent breakthrough which has enabled striking improvements in phase qubit coherence and visibility, and which has deep implications for other Josephson qubits. I present a model of qubit decoherence induced by two-level defect states, and describe an intimate connection between intrinsic (low-temperature and low-power) dielectric loss and qubit performance: coupling to individual defects in the tunnel barrier of the Josephson junction results in a loss of visibility of coherent qubit oscillations, while coupling to a continuum of defects in the wiring dielectric leads to energy relaxation from the qubit $|1>$ to the $|0>$ state. Optimization of the phase qubit proceeds along two lines. The first approach involves a novel circuit architecture

which promotes statistical avoidance of resonant defects, and leads to dramatic enhancements in qubit visibility and measurement fidelity. The second approach is to explore novel high-Q dielectrics for qubit circuits. Recent improvements in materials have led to a factor of 30 increase in qubit coherence time. I describe progress in the development of novel epitaxial dielectrics grown on epitaxial refractory metal underlayers for qubit applications. These results open the door to the realization of many-qubit algorithms in superconducting circuits.

**K40 3 Using Phase Qubits to Evaluate Dielectrics Materials*** J.A. STRONG, M.S. ALLMAN, K. CICAK, JEFFREY S. KLINE, SEONGSHIK OH, K.D. OSBORN, G. PROKOPENKO, M.A. SILLANPAA, A.J. SIROIS, J.D. WHITTAKER, *National Inst. of Standards and Tech. - Boulder* JOHN M. MARTINIS, *UC Santa Barbara* D.P. PAPPAS, R.W. SIMMONDS, *National Inst. of Standards and Tech. - Boulder* It has been known since the late 1970's that Amorphous insulating materials contain defects that can be modeled as a bath of interacting two-level fluctuators. Measurements of LC oscillator microwave circuits have identified these two-level systems as an inherent energy loss mechanism in Josephson phase qubits. By developing methods to reduce the volume of dielectric material in the fabrication of Josephson phase qubits, we have been able to conclusively show that the energy relaxation time can be improved in these systems. Furthermore, by using a different dielectric material with less intrinsic low temperature loss, it is possible to further improve this situation. In addition, we have fabricated new phase qubits which have strong coupling to substrate materials in an effort to evaluate loss from different substrates. We show that substrate materials with high crystalinity result in qubits with improved relaxation times.

**K40 4 Further Microwave Resonator Studies of Loss Mechanisms to Improve Qubits*** K.D. OSBORN, M.S. ALLMAN, K. CICAK, JEFFREY S. KLINE, SEONGSHIK OH, G. PROKOPENKO, M.A. SILLANPAA, A.J. SIROIS, J.A. STRONG, J.D. WHITTAKER, *National Inst. of Standards and Tech. - Boulder* JOHN M. MARTINIS, *UC Santa Barbara, Dept. of Physics* D.P. PAPPAS, R.W. SIMMONDS, *National Inst. of Standards and Tech. - Boulder* Microwave resonators have been previously used to identify materials that limit the coherence time of Josephson phase qubits. For example, amorphous silicon dioxide was found to exhibit an unsaturated loss tangent of 0.005 in resonators at low temperatures. Minimized use of this dielectric has shown improved phase qubit performance as well as using lower loss materials like silicon-nitride. Furthermore, superconducting aluminum, the major superconductor used in many present types of qubits, forms a native surface oxide which may also contribute to dielectric loss. To prevent any native oxides on superconducting circuits, we have fabricated resonators with superconducting wiring that has been covered with a thin layer of gold. We will measure the power dependence of resonant peaks in these circuits in order to determine losses in these systems as well as investigate various substrate materials and compare these results to losses from silicon-oxide and silicon-nitride.

**K40 5 Ohmic and step noise from a single trapping center hybridized with a Fermi sea†*** ROGERIO DE SOUSA, K. BIRGITTA WHALEY, *Department of Chemistry and Pitzer Center for Theoretical Chemistry, University of California, Berkeley, CA 94720-1460, USA* FRANK K. WILHELM, JAN VON DELFT, *Department Physik, CeNS, and ASC, Ludwig-Maximilians-Universität, Theresienstrasse 37, D-80333 München, Germany* We show that single electron tunneling devices such as the Cooper-pair box or double quantum dot can be sensitive to the zero-point fluctuation of a single trapping center hybridized with a Fermi sea. If the trap energy level is close to the Fermi sea and has line-width $\gamma > k_B T$, its noise spectrum has an Ohmic Johnson-Nyquist form, whereas for $\gamma < k_B T$ the noise has a Lorentzian form expected from the semiclassical limit. Trap levels above the Fermi level are shown to lead to steps in the noise spectrum that can be used to probe their energetics, allowing the identification of individual trapping centers coupled to the device. **K40 6 Quasiparticle Poisoning in a Cooper-Pair Box** B. S. PALMER, C. A. SANCHEZ, A. NAIK, M. A. MANHEIMER, *Laboratory for Physical Sciences* J. F. SCHNEIDERMAN, *Department of Physics, University of Southern California* P. M. ECHTERNACH, *Jet Propulsion Laboratory* F. C. WELLSTOOD, *Center for Superconductivity Research, Department of Physics, University of Maryland* We have used a single-electron transistor (SET) to measure the Coulomb staircase of a single Cooper-pair box (CPB) from a temperature of 30 mK to 300 mK. At the lowest temperature, the data shows that the CPB, which is fabricated from $Al/AlO_x/Al$ tunnel junctions, is poisoned by nonequilibrium quasiparticles. As the temperature is increased from 30 to 150 mK, the width of the odd step in the staircase, which corresponds to a quasiparticle on the island of the box, decreases linearly with temperature. Above 180 mK, the width of the odd step increases,

eventually producing a staircase with 1ite steps. The low-temperature poisoning is consistent with the assumptions of Aumentado et al. that quasiparticles are spontaneously generated in the leads.[1] For particular gate voltages it is energetically favorable to have a nonequilbrium quasiparticle occupy a state on the island; hence poisoning the pure 2e staircase. The data above 180 mK is consistent with the quasiparticle states of the island being thermally populated.

**K40 7 Kinetics of the superconducting charge qubit in the presence of a quasiparticle** R. LUTCHYN, L. GLAZMAN, A. LARKIN, *U of Minnesota* We investigate the energy and phase relaxation of a superconducting qubit caused by a quasiparticle. In our model, the qubit is an isolated system consisting of a small island (Cooper-pair box) and a larger superconductor (reservoir) connected by a Josephson junction. If such system contains an odd number of electrons, then even at lowest temperatures a single quasiparticle is present in the qubit. The quasiparticle resides in the reservoir with an overwhelming probability, but its quick round-trips to the box lead to the relaxation of the qubit. We derive master equations governing the evolution of the qubit coherences and populations. We find that the kinetics of the qubit can be characterized by two time scales - quasiparticle escape time from reservoir to the box $\Gamma_{in}^{-1}$ and quasiparticle relaxation time $\tau$. The former is determined by the normal-state conductance $g_T$ of the Josephson junction and one-electron level spacing $\delta_r$ in the reservoir ($\Gamma_{in} \sim g_T \delta_r$), and the latter is due to electron-phonon interaction. The phase coherence is damped on the time scale of $\Gamma_{in}^{-1}$. The qubit energy relaxation depends on the ratio of the two characteristic times, $\tau$ and $\Gamma_{in}^{-1}$, and also on the ratio of temperature $T$ to the Josephson energy $E_J$. In the limit $\Gamma_{in}\tau \gg 1$ and $T \ll E_J$, the relaxation of the qubit populations occurs in two stages. In the first stage, $t \sim 1/g_T\delta_r$, the initial population of the excited state changes only by a small amount $\sim (T/E_J)1/2$. This quasi-stationary state relaxes to full equilibrium over a longer time scale $t \sim \tau(E_J/T)^{1/2}$.

**16:18**

**K40 8 Charge motion near metallic single electron transistors on oxidized Si substrates** K. R. BROWN, L. SUN, B. E. KANE, *University of Maryland* Many proposals for spin qubits in semiconductors rely on spin-charge conversion combined with charge measurement for determination of the final state. In pursuit of such a measurement for donor spins in Si we have performed systematic experiments using Al-$AlO_x$-Al single electron transistors (SETs) on doped, oxidized Si substrates. One of the first priorities has been to identify other sources of charge motion that could disguise or overwhelm the signals from donors. We have identified reproducible peaks in the ac susceptibility of our samples as a function of electric field, similar to the response that would be expected from donor electrons moving between two different states. Nevertheless, preliminary results indicate that these peaks are associated with defects above the interface and not with charge motion in the Si itself. We will discuss planned device refinements to eliminate these and other defects and to isolate donor electron signals.

**16:30**

**K40 9 Design of a metallic SET gated by lateral Schottky gates for measurements of electric-field-dependent ionization of donors** LUYAN SUN, K. R. BROWN, B. E. KANE, *Laboratory for Physical Sciences, University of Maryland* Spins associated with donors in silicon are ideally suited as qubits for a solid state quantum computer due to their long coherence times and potential scalability. One method for spin measurement incorporates electric-field-dependent ionization of two-electron systems to distinguish singlet and triplet spin states. Therefore the electric field at donor sites needs to be known accurately. The electric field can be applied via a heavily doped back gate, but sharp density profiles are difficult to obtain both with ion implantation (due to straggle) and with molecular beam epitaxy. To resolve this issue, we have fabricated lateral PtSi Schottky gate devices. Schottky gates should make the transition from conducting layer to intrinsic Si far more abrupt. They can also tune the Fermi level in the substrate, so that we can populate donors in the substrate by applying an appropriate bias and shining an LED. By studying the Coulomb blockade peak spacing of an Al/$AlO_x$/Al SET while sweeping a nearby Schottky gate, we can identify the flat band condition. We will present preliminary data for the filling and emptying of $Si/SiO_2$ interface states and for the determination of electric field below the SET island from such devices.

**K40 10 Experimental demonstration of an oscillator stabilized Josephson flux qubit** R. H. KOCH, G. A. KEEFE, F. P. MILLIKEN, J. R. ROZEN, C. C. TSUEI, J. R. KIRTLEY, D. P. DIVINCENZO, *IBM Research, Yorktown Heights, NY 10598* We experimentally demonstrate the use of a superconducting transmission line, shorted at both ends, to stabilize the operation of a tunable flux qubit. Our qubit consists of three Josephson junctions and three loops coupled to a fixed-length superconducting transmission line. The bare qubit has two control parameters, the flux and the control flux. This allows the qubit to have a tunable difference frequency between the ground and first excited states and at the same time to be biased at a degenerate point with respect to the flux parameter. This condition can be met for a wide range of junction critical currents. This flexibility of our structure is a very desirable property for a scalable qubit. To stabilize the operation of our qubit and increase its coherence time, we couple the bare qubit to the lowest mode of a superconducting transmission line, which we model as a harmonic oscillator. Using harmonic oscillator stabilization and pulsed dc operation, we have observed Larmor oscillations with a single shot visibility of 90 percent and a coherence time of 100 ns. In another qubit the visibility was 60 percent and there was no measurable visibility reduction after 35 ns.

**K40 11 Design and Implementation of Devices for Flux Qubit Entanglement Experiments*** PAUL REICHARDT, TRAVIS HIME, *University of California, Berkeley* BRITTON PLOURDE, *Syracuse University* TIMOTHY ROBERTSON, CHENG-EN WU, *University of California, Berkeley* ALEXEY USTINOV, *University of Erlangen-Nuremberg* JOHN CLARKE, *University of California, Berkeley* We report measurements on two superconducting flux qubits coupled to a readout Superconducting QUantum Interference Device (SQUID). The chosen device parameters allow for the implementation of a fast, controllable qubit coupling scheme based on variations in the current bias of the readout SQUID in the zero-voltage state. The devices have Al-AlOx-Al

tunnel junctions and were fabricated with e-beam lithography on a single substrate. Two on-chip flux bias lines allowed independent flux control of any two of the three elements. By applying microwave radiation, we observed resonant excitation of each qubit and thereby individually mapped out energy dispersions for both qubits. These dispersions displayed the expected hyperbolic dependence with tunnel splittings of 9.0 ± 0.2 GHz, which agreed well with the calculated and measured device parameters. Single qubit coherence properties including relaxation times, Rabi oscillations, Ramsey fringes, and echoes were also measured.

**K40 12 Variable Coupling of Two Flux Qubits*** T. HIME, *University of California, Berkeley* P.A. REICHARDT, B.L.T. PLOURDE, *Syracuse University* T.L. ROBERTSON, *University of California, Berkeley* C.-E. WU, A.V. USTINOV, *University of Erlangen-Nuremberg* JOHN CLARKE, *University of California, Berkeley* We report observations of variable coupling of two flux qubits. The qubits are coupled inductively to each other and to a readout Superconducting Quantum Interference Device (SQUID). By applying microwave radiation to the device, we observed resonant absorption in each of the qubits when the level splitting in the qubit matched the energy of the microwave photons. Using the two on-chip flux bias lines we adjusted the bias of each qubit so that the energy levels of the two qubits were equal; we then observed a splitting of the resulting absorption peak characteristic of coupling between the qubits. We varied the coupling between the qubits by changing the current bias in the SQUID in the zero voltage state, thereby changing its dynamic inductance and thus modifying the effective mutual inductance between the qubits. We compare the resulting changes in splitting with our predictions. This controllable coupling should be extendable to many qubits.

**K40 13 Actively Tuned and Spatially Trapped Polaritons** RYAN BALILI, DAVID SNOKE, *Department of Physics and Astronomy, University of Pittsburgh* LOREN PFEIFFER, KENNETH WEST, *Bell Labs, Lucent Technologies* The resulting eigenstate of the strong coupling of light and excitons in a two-dimensional semiconductor microcavity produces the quasiparticles called polaritons. Owing to their light mass and bosonic character, these particles are predicted to Bose condense at much higher temperatures and lower densities than their atomic counterparts. However, standard methods of producing strongly coupled semiconductor microcavities are very inefficient. Only tiny regions of the microcavity wafer end up in the strong coupling regime due to the wedge of the layer thicknesses formed during the growth process. Here we present a method to actively control the exciton coupling with cavity photon modes and at the same time create an in-plane spatial trap for polaritons, which is necessary for two-dimensional BEC. The exciton energy of quantum well excitons in a semiconductor microcavity is actively tuned using applied stress. Starting with the quantum well exciton energy higher than the cavity photon mode, stress is used to reduce the exciton energy and bring it into resonance with the photon mode. At the point of zero detuning, line narrowing and strong increase of the photoluminescence are seen. By the same means, an in-plane harmonic potential for the polaritons is created, which allows trapping, potentially making possible BEC of polaritons analogous to trapped atoms. Drift of the polaritons into this trap is also demonstrated.

**K41 2 NMR quadruopole spectra of PZT from first-principles*** DANDAN MAO, *College of William and Mary* ERIC J. WALTER, *College of William and Mary* HENRY KRAKAUER, *College of William and Mary* High performance piezoelectric materials are disordered alloys, so it can be difficult to determine the local atomic geometry. Recently, high field NMR measurements have shown great promise as a microscopic probe of ABO3 perovskite-based alloys[1] by their ability to resolve line-splittings due to nuclear quadrupolar coupling with the electric field gradient (EFG) at the nucleus. We report first-principles LDA calculations of the EFG's in monoclinic and tetragonal $Pb(Zr_{0.5}Ti_{0.5})O_3$ systems using the linear augmented planewave (LAPW) method, and we compute NMR static powder spectra for $^{91}Zr$, $^{47}Ti$, and $^{17}O$ atoms as a function of applied strain. With decreasing $c/a$ ratio PZT converts from tetragonal to monoclinic symmetry. We observe that the calculated NMR spectra show dramatic deviations with decreasing $c/a$ from that in tetragonal $P4mm$ well before the electric polarization begins to rotate away from the [001] direction. This indicates that NMR measurements

can be a very accurate probe of local structural changes in perovskite piezoelectrics.

**K41 3 A First Principles Approach to Modelling $Ba_{(1-x)}Ca_{(x)}ZrO_3$** JOSEPH BENNETT, ILYA GRINBERG, ANDREW RAPPE, *University of Pennsylvania* Dielectric properties are often optimized by varying material composition, so there is a need to understand the impact of doping on the local structure and properties of a material. One study showed that the dielectric constant of $BaZrO_3$ (BZ) can be increased by up to 50% by doping with small amount of Ca [1]. This is interesting because $CaZrO_3$ (CZ) actually has a lower epsilon than BZ. We use first principles methods to characterize the local structure of $Ba_{(1-x)}Ca_{(x)}ZrO_3$ (BCZ) at various compositions and compute the contribution to the dielectric response of each normalized mode at 0 K. There arise low frequency phonon modes related to Ca-O motions and a transformation of Raman modes to IR modes caused by the introduction of Ca. [1] Levin, I. et al. J Sol. State Chem. 175 (2003) 170-181.

**K41 4 Pressure-Induced Ferroelectric-to-Relaxor Crossover in PSN and Isomorphs.***
EUGENE VENTURINI, *Sandia National Laboratories*

We discuss the influences of pressure (P) and bias field on the dielectric properties and phase behavior of a single crystal of the chemically-disordered ABB'$O_3$ perovskite $Pb(Sc_{0.5}Nb_{0.5})O_3$ or PSN. On cooling from high temperatures (T), PSN first enters a relaxor (R) state and then spontaneously transforms to a ferroelectric (FE) phase at a temperature $T_c$ substantially below the maximum in the dielectric susceptibility. The R state indicates the presence of polar nanoregions, arising from the B-site chemical disorder, that increase in size with decreasing T. At ambient P, these regions grow to macroscopic size, leading to a first-order FE transition at $T_c$. Hydrostatic P offers a unique method to systematically decrease the dielectric polarizability of PSN by reducing the unit cell volume and, hence, increasing the frequency of the soft transverse optic phonon modes. As P increases, the size of the polar regions decreases, enhancing the R state at the expense of the FE phase. It appears that the FE phase vanishes somewhat above the highest P reached in the experiments, making the R state the ground state of the crystal at reduced volume. This suggests a T-P phase diagram with a $T_c$(P) phase line that terminates between 10 and 15 kbar in a manner akin to a critical point; however, in the case of PSN this feature represents a FE-to-R crossover. In contrast, a biasing electric field favors the FE phase over the R state, and the data indicate that the R state vanishes above 5 kV/cm. Additional insight is provided by comparison to dielectric results on isomorphous $Pb(Sc_{0.5}Ta_{0.5})O_3$ in both its compositionally ordered and disordered forms.

**K41 5 Dielectric Behavior of Compositionally Graded Ferroelectrics** MOHAMED EL-NAGGAR, KAUSHIK DAYAL, DAVID GOODWIN, KAUSHIK BHATTACHARYA, *California Institute of Technology* Graded ferroelectric thin films offer the possibility of engineering the dielectric response by spatial variations in composition. While a homogenous ferroelectric material achieves very high dielectric constants near the phase transition, heterogeneous compositions can result in high dielectric responses over a wide range of temperatures. This can be understood as an ''aggregate'' response of the graded film, and has been experimentally observed. It is a promising candidate for tunable microwave applications that benefit from temperature-insensitivity. We examine this issue through a continuum model that accounts for the spatial variation in properties and the long-range electrostatic interaction. This model is applied to graded Barium Strontium Titanate and Lead Barium Titanate films in a single-domain system where the polarization gradient is normal to the film surface. We examine the effect of grading and the geometry of electrode/ferroelectric layers on the dielectric behavior with temperature and provide results that are useful as design tools for functionally graded devices.

**15:54**
**K41 6 Origin of Curie temperature non-linearity in ferroelectric $BiBO_3$-$PbTiO_3$ solid solutions** ILYA GRINBERG, *Department of Chemistry, University of Pennsylvania* ANDREW M. RAPPE, *Department of Chemistry, University of Pennsylvania* We use first-principles density functional theory calculations to investigate compositional trends in ferroelectric $BiBO_3$-$PbTiO_3$ solid solutions. We find that cation displacements which give rise to ferroelectricity in these materials follow a linear relationship with the average displacive characteristics of the B-site. The transition temperatures in these materials are well correlated with polarization magnitudes computed from our calculations. The coupling between composition of the B-site and A- and B-site displacements explains the highly nonlinear and sometimes non-monotonic dependence of the Curie temperature ($T_c$) on composition observed in these materials.

**16:06**
**K41 7 Atomistic simulation of strained $BaTiO_3$/$SrTiO_3$ superlattices** SILVIA TINTE, *NIST, MD* MARCELO SEPLIARSKY, *IFIR, Argentina* BENJAMIN P. BURTON, *NIST, MD* The $BaTiO_3$(BT)/$SrTiO_3$(ST) superlattice is one of the most intensively studied because of the possibility of polarization enhancement by manipulating strain and layer thicknesses. In this work, we apply an

atomistic-level description to explore the structural, polar and dielectric properties of epitaxial 001-oriented BT/ST superlattices. The shell-model potentials used here have previously described well the phase diagram and properties of BT perfect crystals and ST in the high-temperature limit, and in combination, these potentials reproduced the FE properties of $Ba_xSr_{1-x}TiO_3$ random solid solutions. Here, we focus on asymmetric BT/ST superlattices with in-plane lattice parameter matched to a ST substrate, and periods ranging from 6 to 18 unit cells. These structures have strain induced tetragonal symmetry at low temperature with polarization along the modulation direction and transform to a paraelectric phase at high temperature. Ferroelectric transition temperatures and static dielectric constant are reported as functions of the BT/ST ratio. Also, we show values for local strain and local spontaneous polarization.

**K41 8 Effects of Pressure and Electric Field on the Relaxational Dielectric Properties of $K_{0.97}Li_{0.03}O_3$ (KLT-3)*** GEORGE SAMARA, ROBERT GRUBBS, EUGENE VENTURINI, *Sandia Labs* LYNN BOATNER, *Oak Ridge* The temperature dependence of the dielectric response of KLT-3 shows no evidence of a thermodynamic phase transition, but reveals two prominent relaxational features associated with the off-center $Li^+$ ion, one attributed to the hopping of the $Li^+$ dipole and the other with the reorientation of $Li^+$ - $Li^+$ ion pair. Both relaxations are Debye-like and follow Arrhenius kinetics, the energy barriers decreasing with pressure. While pressure favors the relaxational behavior, a biasing itdc electric field favors long-range order of the dipolar system. The interplay between pressure and field provides additional insight. Pressure suppresses the magnitude of the $\varepsilon'(T)$ response over the whole temperature range The results allow evaluation of the contributions of the soft mode and of the $Li^+$ dipoles to the measured $\varepsilon'(T)$ response.

**K41 9 Ferroelectricity in $PbTiO_3$ and $BaTiO_3$ under Pressure** R.E. COHEN, Z. WU, *Carnegie Institution of Washington* First-principles total energy and linear response calculations reveal a complicated pressure-induced phase transition sequence for $PbTiO_3$ (PT) under pressure. The previously proposed $P4mm$-to-$Cm$-to-$R3m$-to-$Pm\bar{3}m$ transition sequence [1] is not complete because only zone-center ($\Gamma$) instabilities and pressures $P$ less than 30 GPa were considered. Recently Kornev *et al.* reported an unexpected enhancement of ferroelectric instability at high pressures [2]. Our computations confirm this result, and in addition, the zone-boundary R-point rotational instability is enhanced with pressure. Preliminary results show $R3m$-to-$R3c$-to-$R\bar{3}c$-to-$R3c$ phase transitions in PT for 18 GPa $< P <$ 120 GPa due to the competition and interaction of zone-center and zone-boundary instabilities. On the other hand, there is no instability in cubic $BaTiO_3$ for $P >$ 10 GPa up to 120 GPa, resulting in a single $R3m$-to-$Pm\bar{3}m$ transition at 0 K. We are investigating whether the covalency of Pb is responsible for the unusual enhancement of ferroelectricity under high pressure. The electromechanical coupling constants become enormous in the transition regions from the tetragonal to high pressure phases for PT, suggesting that the large coupling in PT solid solutions such as PZT, PMN-PT, and PZN-PT, simply tune this transition to zero pressure [1]. Supported by ONR. [1] Z. Wu and R. E. Cohen, Phys. Rev. Lett. **95**, 037601 (2005). [2] Kornev *et al.*, Phys. Rev. Lett. **95**, 196804 (2005).

**K41 10 A-site driven ferroelectricity in $K_{0.5}Li_{0.5}NbO_3$** DANIEL I. BILC, D.J. SINGH, *Condensed Matter Sciences Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA* Mixed A-site ferroelectric materials have gained recent attention. Here we report density functional calculations of $K_xLi_{1-x}NbO_3$ perovskite supercells in order to understand the interplay between various lattice instabilities with size mismatch on the A-site and the role of the A and B site ions in this case. The calculations were done using the general potential LAPW method. For x=0.5, we find a ferroelectric ground state, even though the average tolerance factor is significantly smaller than unity and there is no stereochemically active A site ion. This is due to frustration due to the very different ionic radii of K and Li. We find very large off-centering of the Li ions, which distinguishes this compound. Relative to this the Nb off-centering is quite small. This is in contrast to most perovskite ferroelectrics where there is significant off-centering of all ions, and resulting cooperativity. Also because of the large Li off-centering it contributes strongly to the anisotropy between tetragonal and rhombohedral ground states, yielding a tetragonal ground state. Normally the anisotropy is determined by the interplay of B site off-centering and strain coupling. This work was supported by the Office of Naval Research and the Department of Energy.

**16:54**

**K41 11 Effective Hamiltonian study of $PbSc_{1/2}Nb_{1/2}O_3$ under pressure** ERIC COCKAYNE, SILVIA TINTE, BENJAMIN P. BURTON, *NIST* UMESH V. WAGHMARE, *JNCASR* In general, increasing pressure depresses the transition temperature $T_{FE}$ of ferroelectric transitions, and sufficient pressure yields a FE $\rightarrow$ paraelectric (PE) transition. A more complicated behavior is observed for disordered $PbSc_{1/2}Nb_{1/2}O_3$ (PSN). At atmospheric pressure, PSN exhibits relaxor ferroelectric (RFE) properties within a small temperature range before transforming to a FE phase at low temperatures. Pressure of approximately 1.5 to 2.5 GPa induces a low-temperature RFE state without a RFE/FE phase boundary.[E. L. Venturini et al.] To investigate the effects of pressure on phase transitions in PSN, we used a first-principles based effective Hamiltonian. Our effective Hamiltonian includes a local field term arising from the charge difference between the $Sc^{3+}$ and $Nb^{5+}$ ions. Under pressure, the local field term changes little, while the FE well depths decrease, increasing the relative importance of the local fields. Molecular dynamics simulations show that $T_{FE}$ decreases with temperature and that the phase transition broadens.

**17:06**

**K41 12 Pressure-induced phase transitions in $PbTiO_3$*** MUHTAR AHART, P. DERA, R. E. COHEN, RUSSELL J. HEMLEY, *Carnegie Institution of Washington* We have investigated $PbTiO_3$ under pressure in a diamond anvil cell for temperatures of 20K to 300K using micro-Raman spectroscopy and x-ray diffraction. The Raman spectra show large changes: three peaks, centered at 200, 240 and 250 $cm^{-1}$ disappeared above 20, 19 and 17 GPa at 20, 47 and 77 K, respectively. Furthermore, a new peak centered at 300 $cm^{-1}$ appears above transition points. The disappearance of peaks and the appearance of new peaks are consistent with theo-

retical calculations of Z. Wu et al., Phys. Rev. Lett. 95, 37601, 2005, and suggest a zone boundary instability at high pressures. The experimental results also indicate that pressure induced phase transitions at low temperature are reversible. At room temperature the first order Raman spectrum disappears above 12 GPa consistent with a transition to the cubic phase, but x-ray diffraction data suggests a rhombohedral or monoclinic phase between the tetragonal and cubic phases, consistent with the predictions of Z. Wu et al. The experimental results provide a new phase diagram for $PbTiO_3$.

**K41 13 Electronic structure and lattice distortion in $PbMg_{1/3}Nb_{2/3}O_3$** MALLIGA SUEWATTANA, DAVID SINGH, *Oak Ridge National Laboratory* We investigated the local structural distortions of PMN($PbMg_{1/3}Nb_{2/3}O_3$) within the density functional theory using the linearized augmented plane-wave method. Structural relaxations were performed on 30 atom unit cells with B-cations arranged in 1:1 chemical ordering along [111]. The direction and magnitude of Mg and Nb off-centering within $O_6$ octahedral cages and Pb within its cage as well as electronic structures were examined. The results are discussed in terms of the Nb 4d - O 2p and Pb 6p - O 2p hybridizations and their interplay. A significant role is found for the on-site Ewald potential of different Nb sublattices, which is correlated with the off-centering. †This work was supported by ONR and DOE.

**K42 1 Shock Hugoniot Calculations of Dense Liquid Helium*** BURKHARD MILITZER, *Carnegie Institution of Washington* By combining two first-principles computer simulation techniques, path integral Monte Carlo and density functional molecular dynamics, the properties of dense liquid helium are studied. From the equation of state we derive the shock Hugoniot curves. Results at low pressures agree well with gas gun experiments. For higher pressures, we predict that helium is compressible to more than five times its initial density. This behavior is in contrast to hydrogen, for which we predicted a maximum compression ratio of only 4.25. In the case of helium, the conditions for 5-fold compression are attainable with existing shock facilities. Studying this material will enable us to verify new experimental and theoretical techniques, and may help us to understand the existing controversy in the experimental shock results for deuterium. The characterization of dense liquid hydrogen and helium allows us to build models describing the interior of Giant Planets and answer fundamental questions of their evolution.

**K42 2 Simulations of dense hydrogen and hydrogen-helium mixtures at conditions relevant to gas planet interiors*** ISAAC TAMBLYN, *Dalhousie University* JAN VORBERGER, *Carnegie Institution of Washington Geophysical Laboratory* BURKHARD MILITZER, *Carnegie Institution of Washington Geophysical Laboratory* STANIMIR A. BONEV, *Dalhousie University* The principle components of all gas giants are hydrogen and helium. In order to improve models describing the formation and evolution of planets such as Jupiter and Saturn, we investigate the properties of these materials under extreme conditions. itAb initio molecular dynamics simulations are performed on both pure hydrogen and hydrogen-helium mixtures. The equation of state and structural properties of these liquids are determined at characteristic temperatures, pressures, and mixing ratios relevant for the interior of Jupiter-like planets. Results are compared with previous investigations, both experimental and theoretical, with improvements highlighted. In particular, effects originating from the dissociation of molecular hydrogen are discussed.

*Work supported by Carnegie Canada and the NSERC of Canada.

**14:54**

**K42 3 Hydrogen-Helium Mixtures under Giant Gas Planet Conditions** JAN VORBERGER, *Geophysical Laboratory, Carnegie Institution of Washington, Washington D.C.* ISAAC TAMBLYN, STANIMIR A. BONEV, *Dalhousie University, Halifax, Canada* BURKHARD MILITZER, *Geophysical Laboratory, Carnegie Institution of Washington, Washington D.C.* We use density functional molecular dynamic simulations to investigate equilibrium properties of mixtures of hydrogen and helium. We consider a range of temperature, density and mixing ratio which enables us to study the equation of state for these mixtures under extreme conditions relevant, e.g., for giant gas planets. We focus on the atomic and molecular phase of hydrogen helium mixtures. We consider the structure of the liquid and how the presence of helium influences the bond length and suppresses the dissociation of the hydrogen molecules. We present binary distribution functions illustrating that helium leads to lower dissociation in the system. We will demonstrate constraints concerning the validity of the linear mixing rule. We will show comparisons to different methods and present results for Jupiters isentrope.

**15:06**

**K42 4 Equation of state and electronic structure of liquid Helium at high pressure** LARS STIXRUDE, *University of Michigan* RAYMOND JEANLOZ, *University of California at Berkeley* As the second most abundant element, the properties of fluid Helium form an important part of our understanding of stellar and giant planetary structure. Yet the physics of Helium at pressure-temperature conditions characteristic of these bodies is uncertain. We perform first principles molecular dynamics simulations of fluid Helium over a wide range of pressure ( $<$ 1 Gbar) and temperature ( $<$ 5 eV). The simulations are based on finite-temperature density functional theory in the generalized gradient approximation, and are performed in the canonical ensemble with a Nose thermostat. We find that both temperature and compression have a strong influence on the electronic structure as revealed by the band gap. At a density of 1 g $cm^{-3}$ the band gap varies from 20 eV for the static crystal to 0 for the fluid at 4 eV. The gap is closed at all temperatures for density greater than 20 g $cm^{-3}$. We find that the equation of state varies smoothly through the band gap closure transition with no indication of a high-order phase transformation. The decrease in band gap with increasing tempera-

ture at constant density results from enhanced mixing of 1s- and 2s-like states with increasing disorder (i.e., enhanced vibrational amplitudes and melting) that has profound implications for understanding the deep interiors of planets.

**15:18**

**K42 5 Raman spectroscopy of hot compressed hydrogen and nitrogen - implications for the intramolecular potential** ALEXANDER F. GONCHAROV, *Geophysical Laboratory, Carnegie Institution of Washington* JONATHAN C. CROWHURST, *Lawrence Livermore National Laboratory* Raman measurements of molecular hydrogen, deuterium, and nitrogen have been made under simultaneous conditions of high temperature and high static pressure. Measurements have been made on hydrogen and deuterium to 50 GPa and 1600 K, and on nitrogen to 50 GPa and 2000 K. In all three materials the familiar molecular stretching mode (vibron) is accompanied in the high temperature Raman spectra by one or more lower frequency peaks due to transitions from excited vibrational states. We find the frequency differences between these bands decreases with pressure, implying that the anharmonicity of the corresponding part of the intramolecular potential also decreases. This is accompanied by an increase in the measured line widths of the bands that is consistent with a decrease of the depth of the potential and an approaching molecular dissociation.

**K42 6 First-principles study of the effect of helium on the onset of dissociation in liquid hydrogen** KYLE CASPERSEN, SEBASTIEN HAMEL, TADASHI OGITSU, FRANÇOIS GYGI, *University of California Davis* ERIC SCHWEGLER, *Lawrence Livermore National Laboratory* The onset of molecular dissociation in liquid hydrogen under high-pressures is known to occur abruptly, possibly involving a first-order liquid-liquid phase transition [1,2]. We have examined this transition in detail by performing a series of large-scale first-principles molecular dynamics simulations of liquid hydrogen and mixtures of hydrogen with small concentrations of helium. In addition, we have examined the electronic properties of hydrogen-helium mixtures by using hybrid density functional theory to analyze snapshots from our molecular dynamics simulations. This work was performed under the auspices of the U.S. Department of Energy by the University of California, Lawrence Livermore National Laboratory under contract No. W-7405-Eng-48. [1] S. Scandolo, PNAS 100, 3051 (2003). [2] S.A. Bonev, et al. Phys. Rev. B 69, 014101 (2004).

**K42 7 Reentrant Phase Diagram in Ortho-Para Mixtures of Solid $H_2$ at High Pressure** BALAZS HETENYI,* *SISSA, Trieste (Italy)* SANDRO SCANDOLO, *The Abdus Salam ICTP and INFM-CNR Democritos, Trieste (Italy)* ERIO TOSATTI, *SISSA, ICTP, and Democritos, Trieste (Italy)* Quantum effects dominate the low temperature phase diagram of solid molecular hydrogen in a wide range of pressures from ambient up to about 100 GPa. Important differences exist in the behavior of pure even-$J$(para-$H_2$ and ortho-$D_2$), and odd-$J$ (ortho-$H_2$ and para-$D_2$) species, but little is known about the phase diagram of ortho-para mixtures. We develop a multiorder parameter mean-field formalism for systems of coupled quantum rotors and apply it to solid $H_2$ and $D_2$. For a thermal distribution of ortho-para molecules we find an anomalous reentrant orientational phase transition in the pressure - temperature phase diagram of both systems [Hetenyi et al., PRL 94, 125503 (2005)]. The correlation functions of the order parameter indicate short-range order at low temperatures. As the temperature is increased the correlation increases along the phase boundary. We also find that even extremely small itodd-$J$concentrations (1%) can trigger short-range orientational ordering.

**K42 8 Observability of a projected new state of matter: a metallic superfluid hydrogen*** EGOR BABAEV, *Cornell University* ASLE SUDBO, *NTNU Trondheim* N.W. ASHCROFT, *Cornell University* Dissipationless quantum states, such as superconductivity and superfluidity, have attracted interest for almost a century. A variety of systems exhibit these macroscopic quantum phenomena, ranging from superconducting electrons in metals to superfluid liquids, atomic vapours, and even large nuclei. It was recently suggested that liquid metallic hydrogen could form two new unusual dissipationless quantum states, namely the metallic superfluid and the superconducting superfluid. Liquid metallic hydrogen is projected to occur only at an extremely high pressure of about 400 GPa, while pressures on hydrogen of 320 GPa having already been reported. The issue to be adressed is if this state could be experimentally observable in principle. We propose experimental probes for detecting it and discuss recent developments in superconducting/superfluid properties of the projected metallic state of hydrogen or its isotopes.

**16:06**

**K42 9 Observation of a metallic superfluid in a numerical experiment*** ASLE SUDBO, JO SMISETH, EIVIND SMORGRAV, EGOR BABAEV, *Norwegian University of Science and Technology* We report the observation, in Monte Carlo simulations, of a novel type of quantum ordered state: *the metallic superfluid*. The metallic superfluid features ohmic resistance to counter-flows of protons and electrons, while featuring dissipationless co-flows of electrons and protons. One of the candidates for a physical realization of this remarkable state of matter is hydrogen or its isotopes under high compression. This adds another potential candidate to the presently known quantum dissipationless states, namely superconductors, superfluid liquids and vapours, and supersolids.

**K42 11 Scaling fields and equation of state near the liquid-liquid critical point in supercooled water** DAPHNE FUENTEVILLA, MIKHAIL ANISIMOV, *University of Maryland, College Park* We have developed a scaled parametric equation of state to describe and predict thermodynamic properties of water in supercooled conditions. The equation of state is built on the assumption that in the supercooled water an additional critical point, the critical point of liquid-liquid separation, does exist. Although this second critical point of water is not accessible experimentally, the pre-critical anomalies affect thermodynamic and transport properties of water in the metastable and even in stable regions and can be observed experimentally. Our approach is based on the principle of critical-point universality. The equation of state is universal in terms of theoretical scaling fields and belongs to the three-dimensional Ising-model class of universality. The theoretical scaling fields are postulated to be analytical combinations of physical fields (pressure and temperature). The proposed equation of state enables us to accurately locate the ''Widom line'' (the locus of stability minima) and the position of the critical point, as well as to predict the thermodynamic properties in the regions that are not accessible to experiments.

**16:42**

**K42 12 The metastable limit of isentropically compressed water** D.H. DOLAN, *Sandia National Laboratories* M.D. KNUDSON, *Sandia National Laboratories* J.P. DAVIS, *Sandia National Laboratories* C. DEENEY, *Sandia National Laboratories* C. HALL, *Sandia National Laboratories* Although freezing is normally a slow process, it can be observed on very short time scales using isentropic compression techniques. For isentropic compression beyond 2 GPa, liquid water becomes metastable with respect to the ice VII phase and can freeze on nanosecond time scales if heterogeneous nucleation sites are present [D.H. Dolan et al., J. Chem. Phys. **123**, 64702 (2005)]. Such nucleation sites are typically found on the surfaces of crystalline and amorphous silica windows used to compress a water sample; in the absence of such windows, water remains in a metastable liquid state for some time. Recent gas gun and Z machine experiments at Sandia National Laboratories suggest a sharp metastable limit for isentropically compressed water, beyond which the liquid phase rapidly transforms to a solid without the aid of a nucleating window. This rapid transition is expected because the liquid phase is increasingly unfavorable at high pressure, but has not been previously observed. Comparison of the new freezing observations with prior results reveals stark qualitative differences, suggesting that this newly observed freezing is very different from a heterogeneously nucleated transition.

**K42 13 Infrared study of high-pressure HD: observation of the A-phase*** AKOBUIJE CHIJIOKE, ISAAC SILVERA, *Lyman Laboratory of Physics, Harvard University, Cambridge MA 02138* Infrared absorption was used to investigate the phase diagram of solid HD up to pressures of 156 GPa at temperatures ranging from 4 to 200K. A re-entrant phase line between the low-pressure and broken-symmetry phases (BSP) was observed, in agreement with Raman scattering results, with a 0 K transition pressure of $\sim$ 65-70 GPa. A phase transition was observed with an onset at $\sim$ 154 GPa (at 5K), consistent with the transition to the A-phase, previously observed in $H_2$ and $D_2$. The infrared spectra in the compressed low-pressure and BSP phases complement existing Raman spectra in these phases.

**K42 14 Water in $MgSiO_3$ melt at high pressure** MAINAK MOOKHERJEE, LARS STIXRUDE, *University of Michigan* The presence of water is thought to play important role in modifying the equilibrium and transport properties of earth materials including silicate liquids. In our study we want to address the following questions: How does the presence of water modifies density of melts? What is the partial molar volume of water in melts? What structural species of $H_2O$ are present at high pressure? In order to address these issues we explore the high-pressure behaviour of hydrous $MgSiO_3$ melt with 11 wt% $H_2O$, using first principles molecular dynamics simulation, based on local density approximation (LDA) and the plane-wave-pseudopotential method. The simulations are performed in the canonical ensembles with periodic boundary conditions and a Nose' thermostat. Melting was confirmed by the radial distribution function displaying no long-range order. By comparing our results with that of the anhydrous counterpart (Stixrude and Karki, 2005), we find that the partial molar volume of water decreases along the 3000 K isotherm from 20 cc/mol at 2 GPa to 6.6 cc/mol at 80 GPa. The water component is substantially more compressible than the silicate component. The partial molar volume of water is much less than the volume of pure water at the same conditions (Pitzer and Sterner, 1994), indicating a difference in structure. Analysis of our simulations shows a range of $H_2O$ species including hydroxyls, water molecules and H-O-H-O groups.

**K42 15 Optical studies of compressed silane up to 40 GPa** VIKTOR V. STRUZHKIN, XIAOJIA CHEN, OLGA DEGTYAREVA, MUHTAR AHART, YANG SONG, HANNS-PETER LIERMANN, JIAN XU, HO-KWANG MAO, RUSSELL J. HEMLEY, *Geophysical Laboratory, Carnegie Institution of Washington, Washington, DC 20015* Under sufficiently strong compression, hydrogen is believed to be a metal and eventual superconductor with high transition temperatures. Despite an unrelenting experimental assault at ultra-high pressures, dense solid hydrogen has so far defined all attempts at metallization. Recently, Ashcroft suggested that the dense group IVa hydrides would undergo a transition to eventual metallic and superconducting states at pressures considerably lower than may be necessary for hydrogen. We have performed the vibrational study of silane at high pressures up to 31.6 GPa by Raman spectroscopy. By using the fully symmetrical stretching mode as a probe for exploring the phase transition, we find one fluid-solid transition at around 4.0 GPa and two solid-sold transitions near 6.5 GPa and 26.5 GPa at 300 K. After 26.5 GPa, the solid silane becomes opaque. Our x-ray diffraction data also confirmed the high-pressure phase transitions. Moreover, the observed high-pressure structure is irreversible. Although there is no evidence for possible metallization in this pressure regime from our IR measurements, the observation of black hydrogen in solid silane is significant since the pressure used is ten times smaller than that in solid hydrogen.

**K43 1 Population of closed-channel molecules in trapped Fermi gases with broad Feshbach resonances*** QIJIN CHEN, K. LEVIN, *University of Chicago* We compute the fraction of closed-channel molecules in trapped atomic Fermi gases, over the entire range of accessible fields and temperatures. We use a two-channel model of BCS–Bose-Einstein condensation (BEC) crossover theory at general temperature $T$, and show that this fraction provides a measure of the $T$ dependent pairing gap. Our calculations, containing no free parameters, are in good quantitative agreement with recent low $T$ measurements in $^6$Li. We present readily testable predictions for the dependencies of the closed-channel fraction on temperature and Fermi momentum. Reference: arXiv:cond-mat/0505689; Phys. Rev Lett. 95, Dec 31, 2005.

**K43 2 Quantum Monte Carlo Simulations of Dilute Fermion Gases at Finite Temperature** VAMSI AKKINENI, DAVID CEPERLEY, *University of Illinois at Urbana-Champaign* NANDINI TRIVEDI, *The Ohio State University* In a system of fermions with attractive interactions at low temperature, the crossover from the BCS regime to a molecular BEC, with increasing interaction strengh, is a problem of particular interest in many-body physics. The development of successful experimental techniques to trap and cool dilute gases of fermionic alkali atoms, and to tune the effective inter-atomic interaction over a wide range, have opened exciting possibilities for studying the physics of interacting fermions in this crossover region. The composition of the ground state, nature of fermion pairs, nature of excitations, pairing energy scale, and the pairing and condensation transitions are all important considerations in this crossover regime. Ab initio quantum simulations are invaluable tools for obtaining accurate values of various physical quantities of interest. We utilize the Restricted Path Integral Monte Carlo (RPIMC) technique to calculate to the energy, pairing energy, and the superfluid density at the unitarity point. We present these results along with an estimate of the critical temperature for the superfluid transition.

**14:54**
**K43 3 Evolution from BCS to BEC superfluidity in p-wave Fermi gases** MENDERES ISKIN, CARLOS SA DE MELO, *Georgia Institute of Technology* We consider the evolution of superfluid properties of a three dimensional $p$-wave Fermi gas from weak (BCS) to strong (BEC) coupling as a function of scattering volume. We analyse the order parameter, quasi-particle excitation spectrum, chemical potential, average Cooper pair size and the momentum distribution in the ground state ($T = 0$). We also discuss the critical temperature $T_c$, chemical potential and number of unbound, scattering and bound fermions in the normal state ($T = T_c$). Lastly, we derive the time-dependent Ginzburg-Landau equation for $T \approx T_c$ and extract the Ginzburg-Landau coherence length.

**15:06**
**K43 4 Many body exchange effects close to the s-wave Feshbach resonance in two component Fermi systems: is a triplet superfluid possible?** SERGIO GAUDIO, *Los Alamos National Laboratory and Department of Physics, Boston College* JASON JACKIEWICZ,*KEVIN BEDELL, *Boston College* We suggest that the fluctuations close to a Feshbach resonance in a two component Fermi gas can result in an effective p-wave attractive interaction. On the BCS side of the resonance, the magnitude of this effective interaction is comparable to the s-wave interaction, therefore leading to the possibility of a spin-triplet superfluid in the range of temperatures of actual experiments. We compare the results for our effective scattering length to the mean field result and to the observed binding energy. Finally, we show that by including particle-hole exchange in the fluctuations, the divergence of the effective scattering length disappears.

*now at Max Planck Institute, Katlenburg-Lindau, Germany

**15:18**
**K43 5 Spin noise spectroscopy to probe quantum states of ultracold fermionic atom gases** BOGDAN MIHAILA, SCOTT CROOKER, KRASTAN BLAGOEV, DWIGHT RICKEL, *Los Alamos National Laboratory* PETER LITTLEWOOD, *Cavendish Laboratory, Cambridge University, UK* DARRYL SMITH, Physical systems are often studied by measuring their response to an external perturbation. Measuring the intrinsic noise of a physical system can provide the same information as measuring its response to a perturbation, but noise spectroscopy measurements often disturb the physical system less strongly and scale more favorably with system size reduction. For quantum systems at very low temperature, noise from quantum fluctuations in the ground state of an observable that does not commute with the Hamiltonian can be used as a probe of the system properties. We describe the use of electron spin noise spectroscopy to probe the quantum states of ultracold fermionic atomic gases. The electron spin is not a good quantum number of the atomic gases and fluctuations of electron spin can be measured using optical Faraday rotation. We show that electron spin noise spectroscopy gives unique signatures for different models describing the interatomic interactions in the ultracold fermionic gases, can be used to probe the BCS/BEC crossover in these systems, and weakly disturbs the atomic gases. Measurements of spin noise in classical Boltzmann gases of alkali atoms are used to estimate the expected signal strength for spin noise measurements in ultracold atom systems and to show that these measurements are tractable.

**15:30**
**K43 6 Atomic Fermi gases with unequal spin populations** MEERA PARISH, *University of Cambridge* We investigate the properties of a gas of fermionic atoms where the two spin populations are unequal. By considering how the ground state evolves as a function of inter-atomic interaction and population imbalance, we will determine what the measurable differences are between the various theoretical models of the BCS-BEC crossover in atomic gases.

**15:42**
**K43 7 Spontaneous Vortices in Imbalance Populated Fermion Gas, Finite Size System** JUNG-JUNG SU, YUN-PIL SHIM, REMBERT DUINE, ALLAN H. MACDONALD, *Department of Physics, University of Texas at Austin* Atomic Fermion gases with mismatched densities have attracted much interest recently both experimentally and theoretically. These gases are related to super-

conductors in a magnetic field, to color superconductivity in high density QCD and to other systems. The main focus of recent research is on the possibility of unusual pairing states, the Larkin-Ovchinnikov-Fulde-Ferrel(LOFF) [1] phase, the Deformed Fermi surface(DFS) [2] and other states have been suggested in the past few years. We work specifically on two-dimensional systems with circular hard walls which contain atoms with two different hyperfine states and different populations. In addition to phase separation, a phenomenon that has already been observed [3], we consider the possibility of the spontaneous formation of vortices and giant vortices in some regions of parameter space. [1] Qinghong Cui, C.-R. Hu, J.Y.T. Wei, and Kun Yang, cond-mat/0510717 [2] A. Sedrakian et al., cond-mat/0404577 [3] R. Hulet, preprint.

**K43 8 Superfluid properties across the BEC/BCS transition*** JACQUES TEMPERE, JOZEF DEVREESE, *Universiteit Antwerpen* The superfluid properties of a Bose-Einstein condensate (BEC) and of the Bardeen-Cooper-Schrieffer (BCS) state are reasonably well understood. Recent experimental breakthroughs allow investigating the transition region between the BEC and BCS limits. In this contribution, we apply the path-integral formalism to study how the vortex core size, the superfluid critical velocity and the pair-pair scattering length vary in the crossover region. These quantities depend on the interaction strength of the atoms and change quantitatively from BEC to BCS side. In particular we discuss how the pair-pair scattering length obtained here relates to the mean-field results and to the four-body scattering result.

**K43 9 Relaxation and persistent oscillations of the order parameter in the non-stationary BCS theory** EMIL YUZBASHYAN, *Center for Materials Theory, Rutgers University, Piscataway, New Jersey 08854, USA* OLEKSANDR TSYPLYATYEV, *Physics Department, Lancaster University, Lancaster LA1 4YB, UK* BORIS ALTSHULER, *Physics Department, Columbia University, New York, New York 10027, USA* We determine the limiting dynamics of a fermionic condensate following a sudden perturbation for various initial conditions. We demonstrate that possible initial states of the condensate fall into two classes. In the first case, the order parameter asymptotes to a *constant* value. The approach to a constant is oscillatory with an inverse square root decay. This happens, e.g., when the strength of pairing is abruptly changed while the system is in the paired ground state and more generally for any *nonequilibrium* state that is in the same class as the ground state. In the second case, the order parameter exhibits persistent oscillations with several frequencies. This is realized for nonequilibrium states that belong to the same class as excited stationary states. Our *classification* of initial states extends the concept of excitation spectrum to nonequilibrium regime and allows one to predict the evolution without solving equations of motion.

**16:18**

**K43 10 Dynamical properties of the pairing gap in ultra-cold Fermi gases** MAXIM DZERO, *DOE Ames Laboratory* EMIL YUZBASHYAN, *Rutgers University* We study the dynamics of a condensate of an atomic ultra-cold Fermi gas following an abrupt change in the pairing strength. At long times the order parameter asymptotes to a constant value, which we determine exactly. Under certain conditions, the system reaches a novel steady state with peculiar properties.

**16:30**

**K43 11 Exploring the Possibility of Collapse in a Degenerate Fermi Gas*** J. VON STECHER, S. T. RITTENHOUSE, C. H. GREENE, *Department of Physics and JILA, University of Colorado, Boulder, Colorado 80309-0440* M. J. CAVAGNERO, *Department of Physics and Astronomy, University of Kentucky, Lexington, Kentucky 40506-0055* Trapped ultracold atomic gases with tunable attractive interactions can, in principle, collapse to a deep many-body bound state. Mean-field theories have predicted collapse of Bose-Einstein condensates with negative scattering length $a$ [1], which has been confirmed experimentally [2]. Mean field treatments of degenerate Fermi gases have also predicted collapse [3]. In a recent study, we proposed [4] a hyperspherical coordinate treatment of a two-component degenerate Fermi gas in an isotropic oscillator trap, for which the atoms interact through a zero-range pseudopotential. Ref. [4] predicts a ($T = 0$) collapse at $k_f a = -1.21$. Using Monte Carlo methods, we study variationally the collapse for different two body finite range interactions. We introduce Jastrow-type correlations in the many-body wave function, which allows us to test the validity of the mean-field approach and the zero-range interaction. [1] E. V. Shuryak, Phys. Rev. A 54, 3151 (1996). [2] E. A. Donley et al, Nature 412, 295-299 (2001). [3] M. Houbiers et al, Phys. Rev. A 56, 4864 (1997). [4] S. T. Rittenhouse et al, arXiv:cond-mat/0510454.

**K43 12 Viscous relaxation and transport in a 2d Fermi liquid*** DMITRY NOVIKOV, *Princeton University* Long-wavelength transport and relaxation properties of interacting systems are naturally described in terms of hydrodynamic modes. Here we focus on the viscosity of the two-dimensional (2d) interacting fermions. It is well-known that the viscosity of a clean Fermi liquid in three dimensions is proportional to the quasiparticle lifetime, scaling as $E_F/T^2$. We find that for the 2d fermions, the viscosity is logarithmically enhanced by the factor of $\ln(E_F/T)$, that arises from the phase-space restrictions for quasiparticle scattering in two dimensions. In particular, these restrictions enforce the dominant contributions of the collisions between quasiparticles from opposite sides of the Fermi surface, the effect specific to the 2d geometry. We discuss the effects of viscous modes that can manifest themselves in the electron transport in the metallic phase, and in the momentum relaxation of cold fermion gases.

**14:30**
**K44 1 Metals and insulators at infinite temperature** DAVID HUSE, *Princeton University* VADIM OGANESYAN, *Yale University* Numerical exact diagonalization results for spectral correlations and finite temperature transport of strongly disordered and interacting lattice fermions are presented. We study the finite temperature metal-insulator transition recently proposed by Basko and collaborators (condmat/0506617) focussing in particular on establishing the existence of the insulating phase.

**14:42**
**K44 2 Magnetism near the percolation transition in two-dimensional electron systems** KEIVAN ESFARJANI, MAHDI FAZELI, *Department of Physics, Sharif University of Technology, Tehran, IRAN* BILAL TANATAR, *Department of Physics, Bilkent University, Ankara, Turkey* Recent thermodynamic measurements on two-dimensional (2D) electron systems have found divergence in the magnetic susceptibility and appearance of ferromagnetism as the electron density is lowered. The critical density for these phenomena coincides with the metal-insulator transition (MIT) recorded in transport measurements. Based on density functional calculations within the local spin-density approximation, we have investigated the compressibility and magnetic susceptibility of a 2D electron gas in the presence of remote impurities. A correlation between the minimum in the inverse capacitance, which is identified with the percolation transition, and the maximum of magnetization and magnetic susceptibility was found. This is also coincident with the MIT point based on values we obtain for the inverse participation ratio.

**14:54**
**K44 3 Melting of the electron Wigner Crystal: Theory of the metal-insulator transition in two dimensions (2DMIT)** JOHN JANIK, SERGEY PANKOV, VLADIMIR DOBROSAVLJEVIC, *NHFML/FSU National High Magnetic Field Laboratory and Department of Physics, Florida State University, Tallahassee, FL 32310* Past theoretical work in explaining the 2D metal-to-insulator transition at $T = 0$ has focused on perturbative approaches around the Fermi Liquid state, and has met with limited success [1]. Starting from the opposite limit we propose a charge transfer model with vacancy-interstitial pair formation as the mechanism for the phase transition. A new picture of the phase diagram has emerged [2], which our theory explains. At low carrier density we find an insulating phase with short-range order, at high density a metallic phase with no order, and a persistent intermediate density metallic phase with short range order. Our theory also explains the experimentally observed strong effective mass enhancements, as the metal-insulator transition is approached from the metallic side. 1. Abrahams, E., Kravchenko, S. V., and Sarachik, M. P., Rev. Mod. Phys. 73, 251-266 (2001). 2. Falakshahi, H. & Waintal, X., Phys. Rev. Lett. 94, 046801 (2005).

**15:06**
**K44 4 Transport of GaAs two-dimensional holes in strong Coulomb interaction regime** JIAN HUANG, D.C. TSUI, *Princeton University* L.N. PFEIFFER, K.W. WEST, *Bell Labs, Lucent Technologies* We report experimental findings on the 2D holes in a GaAs/AlGaAs heterojunction insulated-gate field-effect transistor in the strong interaction regime ($E_{ee} > > E_F, kT$) with the carrier densities (p) varying from $7 \times 10^9\ cm^{-2}$ to $7 \times 10^8\ cm^{-2}$. Though the temperature dependence of the resistivity ($\rho$) resembles that observed in typical 2D Metal-to-Insulator Transition (MIT), there are two things strikingly different. First, for each density, a kink/dip appears in the $T$-dependence of the conductivity ($\sigma$) around a characteristic temperature which we call $T_c$. In the $T_c$-$p$ relation, there is a sudden change at a characteristic density which is the same as the critical density $p_c$ where the apparent MIT is observed. The linear $T_c$-$p$ at high densities suggests that $T_c$s for $p > p_c$ correspond to the Fermi temperature $T_F$s. However, $T_c$ shows little $p$- dependence at $p < p_c$ ($p_c = 4 \times 10^9\ cm^{-2}$). Second, $T_c$ divides the $\sigma$-$T$ into a linear part for $T > T_c$ and a power-law part for $T < T_c$. The $\sigma$ is finite at the base temperature of 35mK even for the lowest density $7 \times 10^8\ cm^{-2}$. These results rule out the possibility of hopping transport, or the insulator of a pinned Wigner crystal.

**K44 5 Metal-insulator transition in 2D: comparison between experiment and Punnoose-Finkelstein's theory*** S. ANISSIMOVA, A. A. SHASHKIN, S. V. KRAVCHENKO, *Northeastern University* T. M. KLAPWIJK, *TU Delft* New theory of the 2D metal-insulator transition (Punnoose and Finkelstein, Science 310, 289 (2005)) explains all most striking features of this phenomenon — temperature- independent separatrix between metallic and insulating phases, destruction of the metallic state by magnetic field, critical behavior of the spin susceptibility and dramatic enhancement of the effective mass in the vicinity of the transition. We will report detailed comparison between our experiments and this theory.

*Supported by NSF and PRF

**K44 6 Hall coefficient and magnetoresistance of 2D spin-polarized eletron system*** EUYHEON HWANG, *University of Maryland* SANKAR DAS SARMA, *University of Maryland* Recent measurements of the Hall resistance show that the Hall coefficient is independent on the applied in-plane magnetic field which gives rise to the spin-polarization of the system. We calculate the weak-field Hall coefficient and the magnetoresistance of a spin polarized system based on the screening theory. We solve the coupled kinetic equations of the two carrier system including electron-electron interaction. We find that the in-plane magnetic field dependence of the Hall coefficient can be suppressed by the weakening of the screening and the electron-electron interaction. However, the in-plane magnetoresistance is barely affected by the electron-electron interaction.

*Supported by US-ONR, LPS-NSA, and NSF.

**K44 7 Unified scaling picture for electronic transport in two-dimensions at low temperatures*** DAVID NEILSON, *University of Camerino* D.J. WALLACE GELDART, *Dalhousie University* We focus on generic features of the phase diagram for the 2D metal-insulator transition phenomenon. The diagram has a line of critical points corresponding to a conducting region (but not necessarily Fermi-liquid-like). The line terminates at a critical end point which controls an extended quantum critical region encompassing not only the conventional quantum critical sector but also a wide range of low temperature data extending deep into the insulator region. This permits us to unify analysis of transport data from the insulating region and the quantum critical sector, and allows us to determine the $z$ and $\nu$ critical exponents from a single experiment. We present strong evidence for the connection between data in the quantum critical sector and insulating critical region, pointing to the presence of a quantum critical point.

**K44 8 Temperature-Dependent Weak Field Hall Resistance in 2D Carrier Systems** THEODORE CASTNER,* *University of Rochester* Das Sarma and Huang [1] have attempted to explain the T- dependent Hall coefficient $R_H(T)$ of Gao et al. [2] for the 2D GaAs hole system solely with the T-dependent Hall factor $r_H(T) = <\tau^2>/<\tau>^2$. They employed $R_H = r_H(T)/en$ with n the total hole density which is independent of T. However $r_H = 1$ at T=0 and $r_H > 1$ at finite T. Thus $r_H(T)$ cannot explain the observed decrease of $R_H(T)$ with increasing T. Employing the known relation $R_H(T) = r_H/ep_i(T)$, where $p_i(T)$ is the itinerant hole density, one can explain the decrease in $R_H$ with increasing T with $p_i(T)$ increasing faster than $r_H(T)$. Using the mobility data $[\mu(T) \alpha <\tau>]$ one can determine $r_H(T)$, which differs from the calculated curves in [1] in that it is asymmetrical about $r_{H,max}$. Using the Hall data and $r_H(T)$ inferred from the data one can obtain the increase in $p_i(T)$ with T and compare it with calculations of $p_i(T)$ done with Fermi Liquid theory taking account of the soft Coulomb gap in the density-of-states. This approach gives good agreement, but doesn't take account of inhomogeneity. Other features of the Gao et al. data will be discussed. 1. S. Das Sarma and E.H. Huang, Phys. Rev. Lett. 95, 0164011 (2005) 2. X.P.A. Gao et al., Phys. Rev. Lett. 93, 256402 (2004).

**K44 9 The transmission of a quantum particle through 2D disordered clusters.** MD ISLAM, HISAO NAKANISHI, *Purdue University* We study quantum percolation model in two dimensions by directly calculating the conductance of finite disordered clusters. In extrapolating to the limit of very large clusters we find evidence that states are localized for any amount of disorder except at the limit of zero disorder where resonance transmission may occur. The nature of localization, however, depends on the amount of disorder present in the clusters. When disorder exceeds certain critical value, transmission decreases exponentially with the size of the clusters whereas below that value it is consistent with power laws. We also investigate how the energy affects the transmission in 2D disordered systems.

**16:18**

**K44 10 Mean-field description of Anderson localization transition** JINDRICH KOLORENC, *Center for High Performance Simulation and Department of Physics, North Carolina State University, Raleigh, NC 27695-8202* VACLAV JANIS, *Institute of Physics, Academy of Sciences of the Czech Republic, Na Slovance 2, CZ-18221 Praha 8, Czech Republic* The Anderson model of noninteracting disordered electrons is studied in high spatial dimensions. In this limit the coupled Bethe-Salpeter equations determining two-particle vertices (parquet equations) reduce to a single algebraic equation for a local vertex. We find a disorder-driven bifurcation point in this equation signaling vanishing of electron diffusion and onset of Anderson localization. There is no bifurcation in $d = 1,2$ where all states are localized. In dimensions $d \geqslant 3$ the mobility edge separating metallic and insulating phase is found for various types of disorder and compared with results of other treatments.

**16:30**

**K44 11 Anomalously Localized States at the Anderson Transition** HIDEAKI OBUSE, *Condensed Matter Theory Laboratory, RIKEN, Wako, Saitama 351-0198, Japan* KOUSUKE YAKUBO, *Department of Applied Physics, Graduate School of Engineering, Hokkaido University, Sapporo 060-8628, Japan* Anomalously localized states (ALS) at the critical point of the disorder induced metal-insulator transition, namely, the Anderson transition, are investigated. ALS are states in which most of amplitudes of a wave function concentrate on a narrow spatial region even in a metallic phase. While the existence of ALS in the metallic phase was analytically predicted and confirmed by numerical and experimental works, ALS at the critical point are far from understood due to lack of proper analytical methods describing critical phenomena of this phase transition. In this work, it is numerically shown that ALS exist at the critical point of the Anderson transition in both the three-dimensional orthogonal class and the two-dimensional symplectic class by quantifying non-multifractality of critical wave functions due to a characteristic length originating in their concentration nature of ALS. These results may suggest that the existence of non-multifractal states at criticality is generic in many disordered systems.

**K44 12 New Glassy Phases of Electrons in Disordered Potentials** ROGER HAYDOCK,* *University of Oregon* NIGEL GOLDENFELD, *University of Illinois at Urbana-Champaign* Critical disorders are found analytically for the Anderson model of independent electrons in two and three-dimensional random potentials. At large disorders the states are exponentially localized, then with decreasing disorder the model goes through a sequence of less strongly localized phases ending with power-law localization just above the transition to extended states. These results follow from an analytic transformation of the Anderson model into augmented space where disorder is removed from matrix-elements by constructing a basis of extended states correlated with the potential. For different disorders, the states are dominated asymptotically by different sectors of augmented space, and these sectors are identified by path-counting.

**K44 13 Noise in an Electron Glass, Amorphous Indium Oxide** STEPHEN ARNASON, *University of Massachusetts Boston* Amorphous Indium Oxide is a material that manifests a rich spectrum of physical phenomena. It undergoes both the disorder driven and the magnetic field driven superconductor to insulator transitions. In addition, in highly disordered samples, it shows electron glass behavior, where correlations amongst the electrons leads to memory and aging effects. It is hypothesized that this glassy behavior is the consequence of a hierarchy of multielectron relaxation processes. To study this hierarchical relaxation we are measuring conductance fluctuations in samples in the glassy regime, where the spectrum of fluctuations is related to the relaxation processes, leading to a 1/f type of spectral dependence.

**K44 14 Proposal for a pre-exponential dependent Efros-Shklovskii regime** MIGUEL RODRIGUEZ, ISMARDO BONALDE, ERNESTO MEDINA, *Centro de Fisica, IVIC, Caracas, Venezuela* We address the variable range hopping regime in the range for which the measured temperatures are of the order of the characteristic Mott or Efros-Shklovskii temperatures $T_M$ and $T_{ES}$ respectively. In such a range present theories imply $R_{hop}/\xi < 1$ where $R_{hop}$ is the hopping length and $\xi$ is the localization length. Using the Mott optimization procedure, including prefactor corrections in the wavefunction overlap, we obtain expressions for the dependence on temperature for the typical hopping length and the resistivity in an Anderson insulator with coulombic interactions. Such expressions lead to a regular Efros-Shklovskii law when $T << T_{ES}$ while for $T \sim T_{ES}$ they can lead to a meaningful pre-exponential dominated regime such that $R_{hop}/\xi > 1$. We propose that the optimization procedure can consistently explain contradictory results in the critical regime and recent experimental results showing a maximum in resistivity due to a interplay between prefactor and exponential terms.

**K44 15 Universal and Non-universal Behavior at the Metal Insulator Transition.*** ERIK HELGREN, LI ZENG, DAMIEN QUERLIOZ, FRANCES HELLMAN, DEPT. OF PHYSICS, UC BERKELEY TEAM, A metal-insulator transition in amorphous metal semiconductor alloys is known to exist at dopant concentrations much higher ( $\sim$ 12 at. %) than their crystalline counterparts [1]. We have studied the MIT in alloys grown using MBE for a series of semiconductor matrices, Si, Ge and both C and H-C (hydrogenated carbon) for various dopants (magnetic Gd and non-magnetic Y and Nb), as a function of concentration and magnetic field tuning. We compare the temperature dependence of the DC conductivity in the magnetically doped systems to the non-magnetic systems and to crystalline doped semiconductors (i.e. Si:P). Results are discussed in terms of a theoretical model that incorporates both disorder and electronic correlations [2]. This model correctly describes many universally observed aspects including the remarkably similar temperature dependence of the metallic and insulating DC conductivity of crystalline and amorphous systems, despite the vastly different disorder and electron concentration. There are however very significant variations in the prefactors that control the magnitude of the conductivity, which we correlate with the microscopic physics of each system. [1] F. Hellman et al. **K45 1 Thermal and Magnetic Properties of Ferromagnetic $YbPt_2$*** MOO SUNG KIM, *University of Michigan* MARCUS BENNETT, *University of Michigan* MEIGAN ARONSON, *University of Michigan* JASMINE MILLICAN, *Louisiana State University* JULIA CHAN, *Louisiana State University* We present the results of magnetization and heat capacity measurements carried out on needle-like single crystals of $YbPt_2$. Above 250 K, the magnetic susceptibility is well described by a Curie-Weiss expression with a moment of 3.35 $\mu_B$ per Yb and a Weiss temperature of 73 K, indicating ferromagnetic interactions among almost localized moments. At the lowest temperatures, the magnetization is increasingly nonlinear in field, approaching a saturation value of 3.5 $\mu_B$/Yb at 1.8 K. However, an Arrott plot analysis indicates that ferromagnetic order occurs at a much lower temperature, approximately 0.85 K. Above $\sim$ 10 K,we find that the heat capacity $C = \gamma T + \beta T^3$, with $\gamma = 0.358$ J/mol-K$^2$, while between 10 K and 3 K, C/T drops by a factor of four, perhaps due to the opening of a gap at the Fermi surface. A large anomaly is found in the heat capacity at 0.83 K, suggesting that the transition to the ferromagnetic state is weakly first order. Our results imply that $YbPt_2$ is a rare example of a heavy fermion ferromagnet.

*Work at the University of Michigan supported by the National Science Foundation.

**14:42**
**K45 2 Magnetic Field Suppression of Ferromagnetism in $Yb_2Pt_3$** MARCUS BENNETT, *University of Michigan* DMITRY SOKOLOV, *University of Michigan* WILLIAM GANNON, *University of Michigan* MEIGAN ARONSON, *University of Michigan* CARL HENDERSON, *University of Michigan* JASMINE MILLICAN, *Louisiana State University* JULIA CHAN, *Louisiana State University* We have measured the heat capacity, resistivity and magnetization of single crystals of $Yb_2Pt_3$ grown from Pb flux. The magnetization is anisotropic and strongly non linear with field, with an Arrott plot analysis indicating ferromagnetic order. The zero field AC susceptibility is peaked at 2.4 K, where the zero field heat capacity shows a first order paramagnetic to ferromagnetic transition. This transition is suppressed by magnetic field, disappearing at a critical point, 1.75 T and 1.3 K. The zero field resistivity shows a metallic temperature dependence, and for all fields we find $\rho(T,H) = \rho_0(H) + A(H)T^2$ at sufficiently low temperature. The coefficient, A(H), has a strong maximum for H=1.75 T. It is remarkable that the application of a magnetic field decreases $T_C$ in $Yb_2Pt_3$, contradicting conventional expectations.

**K45 5 Quantum critical behaviour of heavy Fermion CeNi2Ge2*** BILAL ZOGHBI, *Kent State University* ALMUT SCHROEDER, *Kent State University* COLLIN BROHOLMS, *Johns Hopkins University* Neutron scattering data of CeNi2Ge2 collected at SPINS at NIST will be presented to characterize the magnetic correlations and dynamics close to an antiferromagnetic quantum critical point (AF QCP). The dynamical susceptibility $\chi''$(q,E) has been measured in a temperature range 0.1K$<$ T $<$ 30K. While the q-independent fluctuations remain unchanged for T$<$ 30K, the enhanced susceptibility $\Delta\chi''$ close to the wavevector q=(0.5,0.5,0), shows a relaxation rate following the absolute temperature kBT down to 5K but then remains finite towards the lowest T = 0.1 K. The Lorentzian linewidth is reduced to about 0.4 meV, a factor of ten smaller than the rate observed in the q- independent spectrum. The energy, q, and T dependence of $\Delta\chi''$ shows characteristics of the fluctuations expected close to an AF QCP in 3 dimensions, stating that CeNi2Ge2 lies beside the AF QCP.

**K45 6 Time-resolved optical spectroscopy of the itinerant antiferromagnets $UMGa_5$ (M=Ni, Pt)** EE MIN ELBERT CHIA, HAE JA LEE, *MST-CINT, Los Alamos National Laboratory* ERIC BAUER, NAMJUNG HUR, *MST-10, Los Alamos National Laboratory* RICHARD AVERITT, ANTOINETTE TAYLOR, *MST-CINT, Los Alamos National Laboratory* JOHN SARRAO, *MST-10, Los Alamos National Laboratory* We present time-resolved optical conductivity measurements of the itinerant antiferromagnets $UNiGa_5$ ($T_N$=85K) and $UPtGa_5$ ($T_N$=25K), as well as the parent material $UGa_3$, using a pump-probe technique. The relaxation time $\tau$ diverges near $T_N$, which we attribute to the opening of a spin gap. $\tau$ also diverges at the lowest temperatures, which is similar to that shown by the heavy fermion $YbAgCu_4$, but with no blocking of electron-phonon scattering within the DOS peak. The transient amplitude exhibits a sign change at $T_N$, whose temperature dependence is also consistent with the appearance of a spin gap. We will also attempt to analyze our data using the Rothwarf-Taylor model.

**15:42**

**K45 7 Ferromagnetism and Crystalline Electric Field Effects in Cubic $UX_2Zn_{20}$ (X=Co, Rh, Ir)** E.D. BAUER, *LANL* F. RONNING, A. SILHANEK, N. HARRISON, J.D. THOMPSON, J.L. SARRAO, R. MOVSHOVICH, M.F. HUNDLEY, M. JAIME, *LANL* E. DANIEL, *Cidade Universitaria* C.H. BOOTH, *LBNL* The properties of a new class of cubic $UX_2Zn_{20}$ (X=Co, Rh, Ir) heavy fermion compounds have been investigated by means of magnetic susceptibility, specific heat, electrical resistivity, and x-ray absorption spectroscopy. Both $UCo_2Zn_{20}$ and $URh_2Zn_{20}$ show peaks in $C(T)$ and $\chi(T)$ at $\sim$ 5-10 K suggesting the presence of crystalline electric field (CEF) effects in these materials, i.e., a localized $5f^2$ configuration of uranium. In addition, measurements in high magnetic fields up to 40 T are consistent with a CEF model of a nonmagnetic ground state and a magnetic first excited state separated by $\sim$ 20 K. In contrast, $UIr_2Zn_{20}$ exhibits a first-order ferromagnetic transition at $T_c$=2.75 K with a saturation moment $\mu_{sat}$=0.5 $\mu_B$ in the ferromagnetic state. All compounds in this series are heavy fermion materials with enhanced electronic specific heat coefficients $\gamma \sim$ 150-300 mJ/molK$^2$. The physical properties of $UX_2Zn_{20}$ (X=Co, Rh, Ir) will be discussed.

**K45 8 NMR Probes Two Kinds of HO Effects in $URu_2Si_2$ Single Crystals*** O.O. BERNAL, J. SEUNGHUN, *California State University, Los Angeles* A.P. REYES, P.L. KUHNS, *National High Magnetic Field Lab, Tallahassee* D.E. MacLAUGHLIN, *University of California, Riverside* J.A. MYDOSH, *Institute of Physics II, University of Cologne, Germany* T.J. GORTENMULDER, *Kamerlingh Onnes Lab, Leiden University, The Netherlands* We performed $^{29}$Si NMR experiments in two single crystals of $URu_2Si_2$ for $4 < T <$ 50 K and $9 < H <$ 15 T. Crystal # 1 (50 mg) had an irregular trapezoidal shape with base dimensions of $\sim$ 6 (major) and $\sim$ 4 (minor) mm, height $\sim$ 4 mm, and 1 mm thickness. Crystal # 2 (10 mg) was rectangular: 2 mm by 3 mm, with a 0.5 mm thickness. We will describe NMR spectra from $T$ sweeps at orientation angles of 90° (Crystal # 1) and 70° (Crystal # 2) between the corresponding crystal's $c$-axis and $H$. Our results for Crystal #1 indicate a homogeneous, field- independent internal field, increasing from zero just below $T_0$ = 17.5 K@ and reaching a value of order 5 G at the lowest temperatures. Crystal #2 displayed a different kind of hidden order effect. In this case, the NMR intensity dropped continuously with decreasing $T$, becoming a minimum at $T_0$. We will describe the NMR conditions used to acquire the signal in the two cases, and discuss possible ways to understand the results.

**K45 9 Ordered states of $URu_2Si_2$ under hydrostatic pressure** J. R. JEFFRIES, N. P. BUTCH, J. PAGLIONE, M. B. MAPLE, *Department of Physics and Institute for Pure and Applied Physical Sciences, University of California, San Diego* Oriented single crystalline samples of $URu_2Si_2$ have been synthesized and investigated under nearly hydrostatic pressure via electrical resistivity and ac susceptibility measurements. The heavy fermion compound $URu_2Si_2$ exhibits three distinct ordered states as a function of temperature and pressure: ''hidden order'' (HO), in which the order parameter has yet to be determined; antiferromagnetism (AFM), which seemingly develops out of the HO state at $P \leqslant 15$ kbar; and superconductivity (SC), which exists at ambient pressure. Careful measurements of the HO transition, occurring at $T_{HO} \sim 16.5$ K at ambient pressure, have been performed at several different pressures, yielding a *P-T* phase diagram for the HO state as a function of pressure. In addition, measurements of the superconducting critical temperature, $T_c \sim 1.4$ K at ambient pressure, and the upper critical field $H_{c2}$ have been performed at low temperatures using a $^3$He-$^4$He dilution refrigerator, revealing the superconducting *H-T-P* phase diagram. Possible correlations between the HO, AFM, and SC states will be discussed. This research was supported by the National Nuclear Security Administration under the Stewardship Science Academic Alliances program through DOE Research Grant No. DE-FG52-03NA00068.

**K45 10 Hall Effect Evolution Across a Field-Induced Quantum Critical Point in $U(Ru_{0.96}Rh_{0.04})_2Si_2$** YOON SEOK OH, KEE HOON KIM, *School of Physics and CSCMR, Seoul National University* N. HARRISON, P. A. SHARMA, *NHMFL-LANL* H. AMITSUKA, *Hokkaido University* J. A. MYDOSH, *Leiden University* The heavy fermion compound $U(Ru_{0.96}Rh_{0.04})_2Si_2$ has been recently identified as a unique system in which a magnetic field-induced quantum critical point (QCP) is avoided by the creation of a single magnetic phase [1]. To further understand the nature of phase formation across the putative QCP, we have measured the Hall effect of $U(Ru_{0.96}Rh_{0.04})_2Si_2$ between 0.6 and 30K using a 50T mid-pulse magnet. We find that the Hall coefficient $R_H$ abruptly increases inside the new phase formed between 28 and 38T, around $B_{QCP} \sim$ 34T, evidencing formation of a gap in the Fermi surface. Furthermore, low temperature $R_H$ at $B >$ 38T is much smaller than that at $B <$ 28T, indicating the different Fermi surface area in each Fermi liquid states. While the field-induced phase disappeared above 9.5K, $R_H$ still exhibits a broad maximum near $B_{QCP}$, signaling a finite temperature crossover of the Fermi surface change. All of above findings are consistent with an electronic structure evolution from a heavy fermion to spin-polarized Fermi liquids across $B_{QCP}$. [1] K. H. Kim *etal.*, Phys. Rev. Lett. **93**, 206402 (2004).

**16:30**

**K45 11 Irreversible dynamics of the phase boundary in $U(Ru_{1-x}Rh_x)_2Si_2$** VICTOR FANELLI, *Dep. of Phys. and Astron., University of California, Irvine, CA and MST-NHMFL, LANL, Los Alamos, NM* A.V. SILHANEK, M. JAIME, N. HARRISON, *MST-NHMFL, LANL, Los Alamos, NM* C.D. BATISTA, *T11, LANL, Los Alamos, NM* H. AMITSUKA, *Grad. School of Science, Hokkaido University, Japan* L. BALICAS, *NHMFL-FSU, Tallahassee, FL* J.L. SARRAO, *MST, LANL, Los Alamos, NM* J.A. MYDOSH, *II Physikalisches Institut, Universitat zu Koln, Germany* Specific heat and magneto-caloric effect measuments on the systems: $U(Ru_{1-x}Rh_x)_2Si_2$ and $Yb_{1-x}Y_xIn\ Cu_4$ were carried out at high magnetic fields. Thermodynamic similarities are found at the phase boundary into the magnetic field-induced phase (phase II) of the former and at the valence transition of the latter. We show that the irreversible properties of the transition into the phase II of $U(Ru_{1-x}Rh_x)_2Si_2$ are very similar to that associated with the valence transition of $Yb_{1-x}Y_xIn\ Cu_4$. To explain these results, we propose a bootstrap mechanism by which lattice degrees of freedom within phase II become coupled to the 5f-electron hybridization, giving raise to a valence change at the transition.

**16:42**

**K45 12 Neutron scattering studies of itinerancy and ''hidden order'' in $URu_2Si_2$** C.R. WIEBE, J.A. JANIK, *Florida State University/NHMFL* G.J. MACDOUGALL, G.M. LUKE, J.D. GARRETT, *McMaster University* Y. QIU, J.R.D. COPLEY, *CHRNS, NIST* C. BROHOLM, *Johns Hopkins University* W.J.L. BUYERS, *CNBC,Chalk River* The heavy fermion superconductor $URu_2Si_2$ has been of interest for the last two decades but the nature of the ''hidden order'' in the phase below $T_0 = 17.5$ K has not been identified. The large specific heat jump at this temperature cannot be accounted for by the weak ordered moment which is only a fraction of a Bohr magneton on the uranium site (0.03 $\mu_B$). In recent neutron scattering experiments we set new limits for the maximum size of an ordered moment which could be observed in the ''hidden order'' phase, and we investigated the possibility of orbital currents. Furthermore, our experiments have unveiled a new feature in the inelastic spectrum – the precursor phase above 17.5 K exhibits incommensurate fluctuations that are highly correlated in Q and extend to high energies. This suggests that (1) the spins are itinerant, rather than localized and (2) these excitations must play a role in the heat capacity anomaly at the phase transition, as they become gapped at incommensurate wavevectors below $T_0$ and cover a large region of phase space. Implications of these new measurements will be discussed.

**16:54**

**K45 13 Region of Quantum Critical Behavior in $Ce(Ru_{1-x}Rh_x)_2Si_2$*** G.R. STEWART, J.S. KIM, D.J. MIXSON, D. BURNETTE, *Dept. of Physics, Univ. of Florida* The magnetic phase diagram of $Ce(Ru_{1-x}Rh_x)_2Si_2$ is quite rich, with a spin density ordering temperature approaching T=0 around $x_{QCP} = 0.4$ and with - from the Rh rich side where $T_N$ of $CeRh_2Si_2$ is 36 K - a long range, local moment ordering temperature approaching T=0 at approximately $x_{QCP} = 0.6$. Specific heat data down to 0.04 K for a number of compositions indicate a itregion of non-Fermi liquid behavior between x=0.4 and 0.6 associated with the two quantum critical points. The nature of the nFl temperature dependence in the specific heat changes from Moriya-like weak spin fluctuation behavior at the Ru rich side to strong fluctuation, $C/T \propto \log T$ behavior at the Rh rich end. How this smooth progres-

sion of behavior with increasing x provides insights into our understanding of non-Fermi liquid behavior in general will be discussed. The disagreement in the literature over whether C/T is Moriya-like or follows logT at x=0.5 is resolved in favor of the former temperature dependence.

**K45 14 Magnetic ordering and valence instability in Kondo system $CeMn_{2-x}Cu_xSi_2$** GAN LIANG, SHELLEY KEITH, JESSE VERNON, *Sam Houston State University* F. YEN, *University of Houston* The transition from a 3d-antiferromagnetically ordered mixed valence system to a Kondo lattice system has been studied for the $CeMn_{2-x}Cu_xSi_2(0 \leqslant x \leqslant 1)$ series. The Ce $L_3$-edge x-ray absorption result shows that the series evolves from a Ce mixed valence system at $x = 0$ to a nearly trivalent system at $x = 2$. The resistivity results show that in the low Ce valence region ($x$ greater than 1.0), the system exhibits a crystalline-field modified Kondo lattice behavior. In the high valence region, however, the system displays a behavior of the prototype mixed valence compound $CePd_3$. Magnetization (M) data were taken in both zero-field-cooled (ZFC) and field cooled (FC) processes. It is found that for $0 \leqslant x < 0.4$, Neel temperature decreases rapidly with the increase of the Cu concentration $x$. In the range of $x$ from $0.4 \leqslant x < 0.8$, ferromagnetic phase is observed below 150 K, and both the ordering temperature $T_c$ and Qurie-Weiss temperature $\theta$ decrease with the increase of $x$. For $x \geqslant 0.8$, the $M$ (T) curves are reversible and display paramagnetic behavior. Thus, the system is non-magnetic as it approaches heavy-fermion compound $CeCu_2Si_2$. Finally, a magnetic phase diagram is proposed for this compound series.

**K45 15 Deviations from Drude response in $CaRuO_3$** SAEID KAMAL, STEVE DODGE, *Department of Physics, Simon Fraser University, B.C., V5A-1S6, Canada* DONG-MIN KIM, CHANG-BEOM EOM, *Department of Materials Science and Engineering, University of Wisconsin-Madison, Madison, Wisconsin 53706* We report on the low frequency optical conductivity measurements of epitaxial thin films of $CaRuO_3$, obtained with time-domain terahertz spectroscopy. We find that the conductivity does not follow a simple Drude form, even at low temperatures and frequencies; alternative power-law forms also fail to describe it adequately. To achieve a good fit to the experimental data, we find it necessary to use a multi-component model consisting of multiple *Drude* terms and a finite frequency Lorentzian. This parameterization allows us to set an upper bound on the free-carrier spectral weight, from which we can set a lower bound on the renormalized mass of $m^*/m \cong 10$. If the scattering is assumed to be isotropic, our results imply a frequency dependence in the mass enhancement and scattering rate that extends well below terahertz frequencies. However, our results are also consistent with frequency-independent carrier dynamics that vary strongly over the Fermi surface.

## SESSION K46: SPECTROSCOPY OF SEMICONDUCTORS

**Tuesday Afternoon, 14 March 2006**
**349, Baltimore Convention Center at 14:30**
**Giti Khodaparast, Virginia Polytechnic Institute and State University, presiding**

**14:30**

**K46 1 Microwave cyclotron resonance of two-dimensional holes in GaAs/AlGaAs quantum wells on (100) substrates** HAN ZHU, K. LAI, D. C. TSUI, N. P. ONG, *Princeton University* M. MANFRA, L. PFEIFFER, K. WEST, *Bell Labs* Cyclotron resonance at microwave frequencies is used to measure the band mass ($m_b$) of two-dimensional holes (2DHs) in the $GaAs/Al_xGa_{1-x}As$ quantum wells grown on (100) GaAs substrates [1]. The measured $m_b$ shows strong dependences on both the 2DH density ($p$) and the well width ($W$). For a fixed $W$, in the density range ($0.4\times 10^{11}$ to $1.1\times 10^{11}cm^{-2}$) studied here, $m_b$ increases with $p$, consistent with previous studies of the 2DHs on the (311)A surface [2]. However, the density dependence is significantly weaker on the (100) surface than that on the (311)A surface for the same well width of 30nm. For a fixed $p = 1.1\times 10^{11}cm^{-2}$, $m_b$ increases from $0.22m_e$ at $W = 10$nm to $0.54\ m_e$ at $W = 20$nm, and stays around $0.51m_e$ for $W$ up to 1000nm. With the transport measurement at 0.3K in the dark, the DC scattering time $\tau_{DC}$ deduced for $p = 1.1\times 10^{11}cm^{-2}$ shows a maximum of 0.6ns at $W = 20$nm. [1] M. J. Manfra *et al.*, Appl. Phys. Lett. 86, 16 (2005). [2] W. Pan *et al.*, Appl. Phys. Lett. 83, 3519 (2003).

**14:42**

**K46 2 Magnetoplasmons and cyclotron resonance in a two-dimensional electron gas** GERARD MARTINEZ, *Grenoble High Magnetic Field Laboratory* C. FAUGERAS, *Thales Group, Paris, France* YU. A. BYCHKOV, *L. D. Landau Institute, Moscow, Russia* A. RIEDEL, R. HEY, K.J. FRIEDLAND, *Paul Drude Institute, Berlin, Germany* Cyclotron resonancen (CR) transitions in quasi two-dimensional electron gas (2DEG) are known to involve magnetoplasmons (MP) dispersion. It has been recently [1] possible to derive in the frame of the MP picture, assuming the Hartree-Fock approximation, the magneto conductivity response of such systems for any value of the filling factor $\nu$ and including non-parabolicity effects. As compared to the one-electron picture, the MP theory predicts specific behavior of the response concerning both the oscillator strength as well as the energy variation of the CR transitions as a function of $\nu$. These predictions are confronted to absolute magneto-transmission results obtained on high mobility 2DEG embedded in GaAs quantum wells. It is shown that the MP theory reproduces quite well the experimental findings for $2n+1 < \nu < 2n+2$ whereas clear discrepancies appear for $2n < \nu < 2n+1$. The possible origin of these discrepancies are discussed. [1] Yu. A. Bychkov and G. Martinez, Phys. Rev. B**72**, 195328 (2005).

**14:54**

**K46 3 Infrared Magneto-Optical Probe of Landau Levels of Graphite in the Extreme Quantum Limit** DIMITRI BASOV, ZHIQIANG LI, WILLIE PADILLA, *UCSD* SASA DORDEVIC, *University of Akron* KENNETH BURCH, *UCSD* YONG-JIE WANG, *National High Magnetic Field Laboratory* UCSD COLLABORATION, UNIVERSITY OF AKRON COLLABORATION, NATIONAL HIGH MAGNETIC FIELD LABORATORY COLLABORATION, We present a systematic investigation of the ab plane magneto- reflectance R($\omega$,H) of highly oriented pyrolytic graphite (HOPG) in magnetic fields up to 18T, with magnetic field parallel to the c axis of the sample. A linear magnetic field dependence of the Landau level energies is observed in contrast to the square root field dependence predicted by Dirac fermion description of the quasiparticles in HOPG. We show that the conventional graphite band model can quantitatively account for the totality of the magneto-optical data. We also find that the resonance linewidth of the lowest inter-Landau-level transition shows an unconventional linear field dependence. These results provide new insights into the magneto- transport of HOPG.

**15:06**

**K46 4 Ultrahigh spatial and spectral resolution photoluminescence experiments on excitons bound to the isoelectronic nitrogen impurities in GaAs.** DENIS KARAISKAJ, ANGELO MASCARENHAS, *Center for Basic Science, National Renewable Energy Laboratory, 1617 Cole Boulevard, Golden, Colorado 80401, USA* Optical spectroscopy with diffraction limited resolution allows the measurement of luminescence from single impurity centers. Selectively studying individual centers makes it possible to unveil their otherwise concealed polarization anisotropy, identify their particular configuration, map their spatial distribution, and demonstrate the presence of diversity of local environments [1]. Experiments on several single nitrogen impurity pairs in GaAs allowed us to gain valuable insight into their orientation, distribution, and local environment. The nanoscale photoluminescence experiments have been combined with ultrahigh spectral resolution studies in order to better understand the optical transitions of excitons bound to nitrogen pairs in GaAs. The high spectral resolution studies have revealed a new excitonic transition originating most likely from excitons bound to two or more nitrogen impurity atoms, unprecedented since the discovery of isoelectronic impurity bound excitons in the sixties [2]. The temperature dependence demonstrates that all involved transitions originate from the same center, while the polarization dependent studies give insight into the orientation of the different nitrogen atoms in the cluster. [1] S. Francoeur, J. F. Klem, and A. Mascarenhas, Phys. Rev. Lett. **93**, 067403 (2004). [2] D. G. Thomas and J. J. Hopfield, Phys. Rev. **150**, 680 (1966).

**15:18**

**K46 5 Nuclear spin-lattice relaxation in n-GaAs close to the metal-insulator transition** W.G. MOULTON, JUN LU, M.J.R. HOCH, P.L. KUHNS, *National High Magnetic Field Laboratory* Dynamic nuclear polarization is of considerable interest in semiconductors particularly in GaAs. Nuclear spin-lattice relaxation interactions are important in the polarization process. The coupling of electron and nuclear spins in n-GaAs close to the metal-insulator (MI) transition changes significantly as the dopant concentration n increases through the MI critical concentration $n_C = 1.2\text{x}10^{16}$ cm$^{-3}$. The changes correspond to the evolution of localized donor states into itinerant states close to the bottom of the conduction band. Measurements of the $^{71}$Ga relaxation rates $^{71}W$ made as a function of magnetic field (1 – 13 T) and temperature (1.5 – 300 K) for n-GaAs samples with n = $5.9\text{x}10^{15}$, $7\text{x}10^{16}$ and $2\text{x}10^{18}$ cm$^{-3}$ show marked changes in the relaxation behavior with n. Korringa-like relaxation is found in the metallic samples for $T < 30$ K and power law dependence at lower n. For $T > 30$ K phonon-induced nuclear quadrupolar relaxation is dominant. Knight shift measurements made on the $2\text{x}10^{18}$cm$^{-3}$ sample using magic-angle spinning, confirm a small value for the hyperfine coupling constant and permit comparison of the Korringa product with predictions. At lower n, local moments play an important role in relaxation producing striking changes in the $H$ dependence of $^{71}W$. A model will be presented.

**15:30**

**K46 6 Low-temperature scanning tunneling spectroscopy of Si(111) 7x7 near the Fermi energy** SHENGYONG QIN, DAEJIN EOM, CHIH-KANG SHIH, *Department of Physics, the University of Texas at Austin, Austin TX 78712* Si(111) 7x7 is probably the most widely studied surface in surface sciences. Scanning tunneling microscopy/spectroscopy (STM/S) have been applied extensively to and have provided very detailed understanding of the atomic and electronic structures of this surface, revealing adatom, dangling bond and backbond states. Most spectroscopic studies however, have focused on the electronic structures far away from the Fermi energy. The metallic nature of this surface, however, makes it interesting to explore the electronic states near Fremi energy. Moreover, theoretical studies of this surface suggested important correlation effects. By using a low temperature STM (about 5K), we reported studies of electronic structures near the Fermi energy. In addition to the real-space distribution of density of states directly revealed by STS, Fourier analysis is used to obtain k-space electronic structures. We confirm that the surface is metallic with appreciable DOS, however with a small gap (about 0.15 eV) below the Fermi energy. Moreover, Fourier space analysis reveals what appears to be a Fermi surface in the extended zone scheme, although further investigation is needed to confirm this observation.

**15:42**

**K46 7 Electrostatic potential screened by a two-dimensional electron system: A real-space observation by scanning tunneling spectroscopy** MASANORI ONO, YOSHIHIRO NISIGATA, TAKAHIRO NISHIO, TOYOAKI EGUCHI, *The Institute for Solid State Physics, The University of Tokyo* YUKIO HASEGAWA, *The Institute for Solid State Physics, The University of Tokyo; PRESTO, Japan Science and Technology Agency* Scanning tunneling spectroscopy at 5K was used to investigate the electrostatic potential profile on the Si(111)-$\sqrt{3}\times\sqrt{3}$ Ag surface at subnanometer spatial resolution. The potential was measured from an energy-level shift of electronic states on the surface. The potential images obtained reveal that the potential drops around the steps and Ag adsorbates, upon which positive charges are presumably accumulated. The profiles of the reduced potentials are explained with the screening of potential due to the charges by two-dimensional electron gas (2DEG) existing on the surface. The Friedel oscillation, which results from the screening and has a period of the half Fermi wavelength of the 2DEG, was also observed in the potential images as well.

**15:54**

**K46 8 Phonon Confinement and Laser Heating Effects on Germanium Nanowires.** ROMANEH JALILIAN, *University of Louisville, Department of Physics* HARI CHANDRASEKHAR, MAHENDRA SUNKARA, *University of Louisville, Department of Chemical Engineering* GAMINI SUMANASEKERA, *University of Louisville, Department of Physics* We explore the combined effects of phonon confinement, local heating and stress on the Raman spectra of Germanium nanowires with varying diameters. Germanium nanowires were synthesized using spontaneous nucleation and basal growth from gallium droplets. The asymmetric broadening and downshifting of the first order Raman band is studied as a function of average diameter, local temperature of the nanowires. This basic phenomenological model with a modified confinement function incorporated with thermal effects and stress are in agreement with our experimental results. Fano-resonance effect was excluded from this study.

**16:06**

**K46 9 Optical and Electronic Properties of Ge-Sb-Te films*** HENG LI, *University of Utah* P. C. TAYLOR, *Colorado School of Mines* Amorphous and crystalline films in the system Ge-Sb-Te are of interest because of their use in reversible phase change optical storage media or electrical switches. These applications utilize differences in optical or electrical properties between the crystalline and amorphous phases of the same material. The most commonly employed composition is $Ge_2Sb_2Te_5$, which lies along the pseudobinary tie line GeTe-$Sb_2Te_3$. We present data on amorphous films of GeTe, $Sb_2Te_3$, $Ge_2Sb_2Te_5$, and $Ge_2Sb_2Te_7$ grown by rf sputtering and examine the effects of growth rate and oxygen impurities on the optical and electronic properties. For Ge2Sb2Te5, the optical gap decreases with increasing growth rate, and the inverse slopes of the exponential band tails (Urbach tails) extending into the gap also decrease with increasing growth rate (i.e., the band tails become sharper at slower growth rate). The increase of the optical gap for oxygen concentrations greater than about $10^{21}$ $cm^{-3}$ is almost certainly due to the presence of oxygen at levels approaching alloy compositions. On the other hand, the sharpening of the band tail absorption is probably due to increased diffusion on the surface during growth with decreasing growth rate.

**K46 10 Structural, Vibrational, and Electronic Properties of Ternary SiGeSn Alloys*** VIJAY R. D'COSTA, JOSÉ MENÉNDEZ, ANDREW V.G. CHIZMESHYA, JOHN TOLLE, JOHN KOUVETAKIS, *Arizona State University* The recent demonstration of ternary SiGeSn alloys represents a significant breakthrough that adds new levels of flexibility to the design of microelectronic and optoelectronic devices based on group-IV materials. We present a systematic experimental and theoretical study of the structural, vibrational, and electronic properties of this material. X-ray reciprocal lattice maps are used to determine the equilibrium lattice constant of the alloys, whose composition is measured independently by Rutherford Backscattering. It is found that the system follows Vegard's law quite closely, in contrast to GeSn alloys, which show evidence for bowing in the compositional dependence of the lattice constant. The Raman spectrum shows the three standard Si-Si, Ge-Si, and Ge-Ge peaks found in GeSi alloys. No evidence for Sn-Ge or Sn-Si modes is seen, but the three observed peaks shift in frequency as a function of the Sn concentration. The energy of the direct optical transitions display significant bowing as a function of the alloy composition. The dominant source of bowing appears to be the simultaneous presence of Si and Sn atoms in the ternary alloy.

**K46 11 Two-photon Photoemission Electron Microscopy Imaging of $TiO_2$** GANG XIONG, ALAN JOLY, WAYNE HESS, S. CHAMBERS, T. KASPAR, KENNETH BECK, *Pacific Northwest National Laboratory, P O Box 999, Richland, WA 99352, USA* Photoemission electron microscopy (PEEM) utilizing two-photon excitation was used to image a novel $TiO_2$ thin film sample grown by molecular beam epitaxy. The $TiO_2$ thin film consists of small (50-100 nm) $TiO_2$ rutile nanocrystallites embedded in an epitaxial anatase $TiO_2$ film. Individual rutile crystallites can be identified from the anatase background, in part due to the work function difference and morphology contrast. For both phases the photoelectron signals result from electrons at the surface defect levels in the gap rather than valence band electrons. We compare the two-photon PEEM images excited by p- and s-polarized light. The greater image intensity excited by p-polarized light can be attributed to a stronger refracted wave and is further enhanced by the two-photon effect. How the differences in optical refraction, absorption and photoelectron yield affect the contrast between rutile nanocrystallites and anatase background is discussed. We summarize the contrast mechanisms for PEEM imaging and discuss the role of the complex dielectric constant in PEEM contrast mechanisms. Enhanced photoemissions from localized regions are also discussed.

**16:42**

**K46 12 Electron Paramagnetic Resonance Study of Amorphous $V_2O_5$** D.B. BAKER, K. HARTMAN, K.C. MAYNES, P.H. BUNTON, *William Jewell College* S. FELLER, *Coe College* Vitreous $V_2O_5$ is generally non-stoichiometric when cooled from above the melt, leading to the formation of paramagnetic $V^{4+}$ ions. At low temperature ( $\sim$ 120 K), previous workers have observed well-resolved EPR spectra associated with these centers. By contrast, recent results from our laboratory show EPR spectra that remain broad ( $\sim$ 20 mT, peak-to-peak) from ambient down to 120 K, with no apparent hyperfine interactions. EPR spin counting analyses also indicate high concentrations ( $\sim$ $10^{20}$ spins/$cm^3$) of paramagnetic centers, suggesting that linewidths are limited by spin-spin relaxation of the electron spin system. In addition, current results reveal that EPR signal intensities increase more rapidly than $(\text{Temperature})^{-1}$, as indicated by monitoring signal intensities over the temperature range from 120-300 K. In particular, when temperature is decreased by a factor of two (from 240 to 120 K), signal intensity increases by a factor of approximately 10. Such observations indicate the possibility of superparamagnetic or spin glass behavior within the amorphous $V_2O_5$ system. In order to further investigate the magnetic behavior of amorphous $V_2O_5$, several experimental EPR parameters are evaluated over the temperature range from 120-370 K.

**16:54**
**K46 13 Analysis of Reflectivity Measurements*** WILLIAM KARSTENS, *Saint Michael's College* D. Y. SMITH, *University of Vermont and Argonne National Laboratory* Reflectivity measurements over a limited wavelength range do not uniquely determine a material's optical constants. To achieve the latter, reflectivity must be known over a sufficient range to apply phase dispersion analysis, or reflectivity at several angles of incidence must be measured in order to solve Fresnel's equations. An approximate alternative is to fit reflectivity data with a model for the optical constants that is consistent with the material's known, or at least plausible, electronic and/or phonon structure. We have explored this procedure for analysis of IR and visible reflectivity of crystalline, amorphous, and porous silicon using both theoretical and empirical models. Limitations of this procedure, especially at the extremes of the measured range will be discussed.

**L7 1 Mis-folding and self-association: opportunities for alternative modes of self-recognition during the folding of TIM barrel proteins.***
C. ROBERT MATTHEWS, *University of Massachusetts Medical School*

The $(\beta\alpha)8$ or TIM barrel motif is one of the most common in biology, represented in all three super-kingdoms of life. Detailed thermodynamic and kinetic analysis of the folding reactions of three members of the TIM barrel family of proteins reveal a common propensity to mis-fold to an off-pathway intermediate in less than a few milliseconds. The unfolding of this stopped-flow burst-phase intermediate controls access to an on-pathway intermediate that is highly-populated at moderate denaturant concentrations. Curiously, the equilibrium intermediate for two of the three nominally monomeric proteins spontaneously adopts a dimeric form; the native state of the third also dimerizes at micromolar concentrations. The early mis-folding reactions may reflect the rapid access to non-native folds enabled by the simple, repetitive $\beta\alpha$ topology of this motif. The propensity of stable forms, either intermediate or native, to form dimers may reflect a segment-swapping mechanism enabled by the modular folding of these single structural domain proteins. Off-pathway intermediates and non-native dimers serve as examples of important, alternative intra- or inter-molecular self-recognition events.

**L7 5 Single Molecule Dynamics Reveals the Role of Flexibility in Bio-molecular Recognition.**
JIN WANG, *SUNY at Stony Brook*

With combined single molecule study of flexible protein binding with an energy landscape inspired microscopic model, we found strong evidences of a new paradigm that bio-molecular recognition is determined by flexibilities in addition to structures. The single-molecule study show conformational fluctuations of the protein complex that involves bound and loosely bound states, which can be quantitatively explained in our model as a result of cooperative binding. Theoretical predictions on the key residues are consistent with mutational experiments. The combined study provides a test ground for fundamental mechanisms and insights for future explorations on recognition with large conformational changes.

**SESSION M50: INTELLIGENT DESIGN: ITS IMPACT AND RESPONSES TO IT**

**M50 1 Legal Perspectives on Religion in Public School Science Classes.**
JEREMY GUNN, *American Civil Liberties Union*

In the 1920s, state legislatures in the United States became involved in enacting laws prohibiting the teaching of evolution in public schools. The famous itTennessee v. John Scopes trial of 1925 was the most famous test case to determine the constitutionality the first phase of the laws. Scopes was convicted of violating one such law and many of these anti-evolution laws continued to be in effect for the next forty years. During the 1950s, for a number of reasons, the teaching of evolution became more common as the anti-evolution laws were either repealed or ignored. In 1968, the Supreme Court in *Epperson v. Arkansas* ruled that the prohibition of the teaching of evolution was unconstitutional. Since the itEpperson decision, there have been several other federal court decisions that have considered the constitutionality of allowing religious theories to be taught in the science curriculum. For all practical purposes, federal courts since 1968 have prohibited the teaching of creationism. The new current battleground is on the issue of intelligent design. The first court decision on intelligent design, from Dover, Pennsylvania, is expected by January 2006. The significance of this decision, and the fallout from it, will be discussed. In many ways, the current controversy over the teaching of intelligent design may be only the tip of a far larger public controversy involving the roles of science, law, politics, and religion. Suggestions will be made as to how the scientific community can contribute to the legal and cultural issues that underlie this debate.

**20:06**
**M50 2 Science and Society Under Attack: The Need for Political As Well As Scientific Responses.**
MARSHALL BERMAN, *Sandia National Laboratory, retired, and past Vice-President of the New Mexico State Board of Education*

Today science and scientists are under attack. This is not new in human history. Copernicus delayed publishing for fear of possible persecution. Bruno was burned at the stake. Galileo was forced to recant. Darwin worked for 20 years without publishing his ideas, perhaps out of fear of possible consequences. In the US today, fundamentalist evangelicals have launched an attack on science, from intelligent design creationism, to stem cell research, global warming, vaccines to prevent cervical cancer, even museums that show exhibits on evolution. In the $21^{st}$ century, this medieval mentality must be strenuously resisted. Rational thought can co-exist with religious faith, unless extremism becomes the norm. Scientists have often ignored politics in their pursuit of new knowledge. But they must understand that public opinion is strongly influenced by non-scientific elements of society, from the pulpit, from politicians and bureaucrats, from a scientifically illiterate public, and from a media that frequently treats all points of view as equal, when they are most certainly not. Will science eventually be required to pass muster for religious fundamentalists in the near future?

**20:42**
**M50 3 APS Activities with Other Professional Societies.**
FRANCIS SLAKEY, *American Physical Society*

In 1981, the APS Council issued a statement that opposed ''equal time'' presentation in public school science classes of creationism and evolution. The statement clarified that ''Scientific inquiry and religious beliefs are two distinct elements of the human experience. Attempts to present them in the same context can only lead to misunderstandings of both.'' The APS Council revisited the issue in 1999 when a school board in Kansas attempted to eliminate the Big Bang, among other issues, from the science curriculum. Since that time, the APS has been more directly involved in confronting efforts that would dilute the teaching of science in public school science classes. This talk will review the APS activities and describe a developing multi-science society activity.

# APS MARCH MEETING 2006

March 13–17, 2006
Baltimore Convention Center
Baltimore, MD

## General Information

Welcome to the Annual March Meeting of the American Physical Society. All scientific sessions and some APS-sponsored sessions will be held at the Baltimore Convention Center (BCC). APS affiliated meetings and satellite meetings will be held at the Marriott Waterfront Hotel, headquarters hotel for the meeting. Consult the schedule of APS affiliated and satellite meetings, in this Bulletin for exact locations.

An outstanding scientific program has been planned by the March Meeting Program Committee. The five-day program consists of approximately 6,900 papers to be presented in invited, contributed, focus and poster sessions. A larger, enhanced exhibit show will complement the scientific program. Attendees are encouraged to visit with exhibitors who will be displaying the latest products, instruments and equipment, computer software, as well as science publications related to the research and application of physics.

## Participating APS Units

**Divisions:** Condensed Matter Physics (DCMP); Materials Physics (DMP); Polymer Physics (DPOLY); Chemical Physics (DCP); Biological Physics (DBP); Fluid Dynamics (DFD); Computational Physics (DCOMP); Atomic, Molecular and Optical Physics (DAMOP); Laser Science (DLS).

**Topical** Groups: Instrument and Measurement Science (GIMS); Magnetism and Its Applications (GMAG); Quantum Information, Concepts, and Computation (GQI); Shock Compression of Condensed Matter (SCCM); Statistical and Nonlinear Physics (GSNP).

**Forums:** Industrial and Applied Physics (FIAP); Physics and Society (FPS); History of Physics (FHP); International Physics (FIP); Education (FEd); Graduate Student Affairs (FGSA).

## Registration Location/Hour

Pratt Street Lobby
Baltimore Convention Center (BCC)

The APS Registration Desk will open and close at the following times.

| | |
|---|---|
| Sunday, March 12 | • 1:00pm –7:00pm |
| Monday, March 13 | • 7:00am – 5:00pm |
| Tuesday, March 14 | • 7:00am – 5:00pm |
| Wednesday, March 15 | • 7:00am – 4:00pm |
| Thursday, March 16 | • 7:30am – 3:00pm |
| Friday, March 17 | • 7:30am – 10:00am |

## Badge Monitoring

All attendees must register for the meeting. Attendees must wear their badges at all times. Security personnel will be checking for badges before allowing admission to the sessions. Attendees without badges will not be admitted to sessions or exhibits. If you have lost your badge, please go to the APS registration desk for a new one. We will give you one replacement badge free. After that replacement badges will be charged $10.00.

## Wireless Connection at the Convention Center

The Baltimore Convention Center has wireless internet connection available free of charge, sponsored by the American Physical Society.

## APS Job Fair

Whether you are looking for a job or recruiting, the American Physical Society Annual March Meeting Job Fair is the place to be! The Job Fair will provide job seekers and hiring managers with unsurpassed recruitment and networking opportunities. Last year, we assisted hundreds of job seekers and more than 50 employers.

*March 12 –16*
*Job Fair Schedule*

| | | |
|---|---|---|
| *March 12* | • | Employer/Job Seeker on-site pre-registration and check-in<br>1:00pm – 4:00pm |
| March 13 | • | Job Fair hours of operation<br>10:00am – 5:00pm |
| March 14 | • | Job Fair hours of operation<br>10:00am – 5:00pm |
| March 15 | • | Job Fair hours of operation<br>10:00am – 4:00pm |
| March 16 | • | Last day to view/search jobs and résumés online |

Join in with hundreds of individuals specializing in the following areas:

*Computational Physics*
*Insulators and Detectors*
*Polymeric and Organic Materials*
*Metals History and Physics*
*Statistical and Nonlinear Physics*
*Phase Transitions and Strongly Correlated Systems*
*Artificially Structured Materials*
*Surface, Interfaces and Thin Films*
*Physics and Society Magnetism*

*International Physics Instrumentation and Measurement*
*Quantum Information, Concepts and Computation*
*Education Chemical Physics*
*Biological Physics*
*Superconductivity*
*Fluids*
*Complex Structured Materials*
*Industrial and Applied Physics*

## Job Seekers utilize the Job Fair services to:

- Network with technical staff and human resource recruiters
- Post your résumé and search open positions
- Interview for positions

## Employers utilize the Job Fair services to:

- Showcase your company with a Recruitment Booth
- Advertise open positions
- Interview qualified job seekers
- Search résumés specific to this meeting

*For more information contact abrice@aip.org*

## APS Store

| | |
|---|---|
| Monday – Wednesday | • 9:30am – 5:00pm |
| Thursday | • 9:30am – 1:00pm |

Come browse our t-shirts, bumper stickers, and more.

## APS Exhibit Show/APS Lounge

*Exhibit Hall E*

| | |
|---|---|
| Monday, March 13 | • 10:00am – 5:00pm |
| Tuesday, March 14 | • 10:00am – 5:00pm |
| Wednesday, March 15 | • 10:00am – 4:00pm |

The annual exhibit show days are Monday through Wednesday. The exhibits are an important adjunct to the meeting, offering information on a wide variety of physics-related products and services. In addition, book and periodical publishers will be participating as exhibitors. The poster sessions, and food concessions will be located in the exhibit hall, as will the E-mail Pavilion. A wine and cheese reception will be held in the exhibit hall on Monday and Tuesday from 4:00pm – 5:00pm. Plan to stop by to visit the exhibits, view the posters and enjoy the refreshments. **NOTE:** *You must wear your badge to be admitted to the exhibit hall.*

## APS Membership Booth

The APS Membership Booth is located near APS Registration in the Pratt Street Lobby. Membership Department staff will be on hand to answer questions about APS Membership and journal subscriptions.

## E-mail Service

E-mail service will be available on Monday, Tuesday and Wednesday in the Exhibit Hall during exhibit hours only. E-mail will be available on Thursday and Friday in the Pratt Street Lobby. Email stations will be available for your use during the following hours:

| | |
|---|---|
| Monday, March 13 | • 10:00am – 5:00pm (exhibit hall) |
| Tuesday, March 14 | • 10:00am – 5:00pm (exhibit hall) |
| Wednesday, March 15 | • 10:00am – 4:00pm (exhibit hall) |
| Thursday, March 16 | • 7:00am – 6:00pm (Pratt Street Lobby) |
| Friday, March 17 | • 7:00am – 12:00noon (Pratt Street Lobby) |

Please be advised that e-mail access is provided as a service to attendees, and that we cannot provide unlimited access to e-mail stations, both in terms of the number of stations provided and the length of time that they are available.

## Speaker-Ready Room

*BCC/Room 330*

The speaker-ready room will be open as follows:

| | |
|---|---|
| Sunday, March 12 | • 1:00pm – 7:00pm |
| Monday, March 13 | • 7:00am – 5:00pm |
| Tuesday, March 14 | • 7:00am – 5:00pm |
| Wednesday, March 15 | • 7:00am – 5:00pm |
| Thursday, March 16 | • 7:00am – 5:00pm |
| Friday, March 17 | • 7:00am – 12:00noon |

## Press Room

*Press Room: BCC/Room 334*
*News Conference Room: BCC/Room 333*

| | |
|---|---|
| Monday through Thursday | • 8:00am – 5:00pm |
| Friday | • 8:00am – 12:00noon |

Phone: 410–649–6498
Fax: 410–649–6494

## Press Conference Room

*BCC/Room 333*

A schedule of news conferences can be obtained from the Press Room (Room 334).

## City Information Desk

The Baltimore Convention and Visitors Bureau will host an information desk in the BCC/Pratt Street Lobby:

| | |
|---|---|
| Sunday, March 12 | • 2:00pm – 6:00pm |
| Monday, March 13 | • 11:00am – 5:00pm |
| Tuesday, March 14 | • 11:00am – 5:00pm |

Stop by to inquire about restaurants in the city and sightseeing.

## Business Center

The Baltimore Convention Center business center is located off the Pratt Street Lobby across from Room 333. The business center offers a full range of services and is open Monday through Friday 8:30am – 4:30pm.

## Hotel List - March Meeting

- Marriott Waterfront Hotel (HQ)
  700 Aliceanna Street
  *Bussing provided to and from Convention Center*
- Sheraton Inner Harbor
  300 South Charles Street
  *Within walking distance*
- Days Inn
  100 Hopkins Place
  *Within walking distance*
- Renaissance Harborplace Hotel
  202 East Pratt Street
  *Within walking distance*
- Hyatt Regency Baltimore
  300 Light Street
  *Connected to Center*
- Holiday Inn
  301 West Lombard Street
  *Within walking distance*
- Wyndham Inner Harbor
  101 West Fayette Street
  *Within walking distance*

# PRE-MEETING PROGRAMS

**DPOLY Short Course – Baltimore Convention Center (BCC)**
Polymers in Existing and Emerging Patterning Technologies (no on-site registration – you must be pre-registered to attend this course)
**Room 304**
Saturday March 11 • 8:30am – 5:00pm
Sunday March 12 • 8:30am – 3:00pm

**Tutorials – Baltimore Convention Center (BCC)**
*(No on-site registration – you must be pre-registered to attend a tutorial)*
**Sunday, March 12**
**Baltimore Convention Center**
**Morning Tutorials #1–4**
*8:30am –12:30pm*
T1 Spintronics: What's New – Room 307
T2 Molecular Magnetics – Room 301
T3 Current Interpretations of Quantum Mechanics – Room 302
T4 Thermoelectric Energy Conversion – Room 303

**Afternoon Tutorials #5–8**
*1:30pm – 5:30pm*
T5 Solid State Implementations of Cavity QED – Room 301
T6 Spallation Neutron Sources – Room 302
T7 Forefront Methods and Limits of Lithography – Room 303
T8 Polymeric Templating – Room 305

**Professional Skills Development for Women Physicists**
**Sunday, March 12**
*8:00am – 5:00pm*
*Reception 5:00pm – 6:30pm*
Marriott Waterfront Hotel/Dover A (workshop)
Marriott Waterfront Hotel/Grand Salon I (reception)
This one-day workshop will offer training on persuasive negotiation and communication skills for tenure track and newly-tenured women physicists. Workshop will be led by professional facilitators using an interactive format that encourages highly personal learning. Lunch will be provided and a reception for participants will follow the workshop. Limited to 30 participants. Pre-registration required.

**Workshop on Opportunities in Biology for Physicists**
**Organized by APS Division of Biological Physics**
**Sunday, March 12**
*8:00am – 5:00pm*
Lunch break on your own.
BCC/Room 310
Biology is a rapidly changing field that has been making tremendous strides forward in recent years. Biology is changing from a descriptive to a quantitative and conceptually profound field. This workshop will showcase a sample of the rich opportunities in biology for physicists. It is aimed at physicists, especially graduate students and postdocs, who are curious about how a background in physics can provide a unique perspective of biological systems. We believe that physicists will make a substantial contribution to this revolution by working together with biologists.

**Invited speakers include:**
- William Bialek (Princeton)
- Steven Block (Stanford) (tentative)
- Robijn Bruinsma (UCLA)
- Hans Frauenfelder (Los Alamos)
- Klaus Lehnertz (Bonn)
- Yale Goldman (Penn)
- Boris Shraiman (Santa Barbara) (tentative)
- Charles Stevens (Salk Institute)
- Zuzanna Siwy (Irvine)
- Sunney Xie (Harvard)

Co-chairs of Organizing Committee:
Dean Astumian, DBP Vice Chair, astumian@maine.edu
Clare Yu, cyu@uci.edu

On-site registration is available but payable in cash only – no credit cards or checks.
Students: $50
Post Docs: $75
Regular Members: $100

**Special Workshop: Quantum Mechanics with Interactive Computer-based Tutorials**
Sponsored by the APS Forum on Education
**Sunday, March 12**
1:30pm – 5:30pm
BCC/Room 306
• No cost to attend the workshop - all are welcome.
Although quantum mechanics is one of the most widely taught topics on the college/university level in the physical sciences, the teaching of quantum mechanics has not changed significantly since the 1940s. This workshop will present recently developed computer-based curricular material that has shown to improve understanding of traditional quantum topics and that makes many heretofore inaccessible topics in quantum mechanics accessible to undergraduate and graduate students. Participants will receive a CD containing curricular material from the Quantum Interactive Learning Tutorials (QUILT) project as well as a collection of ready to run Java programs from the Open Source Physics (OSP) project. All programs are freely distributable under the GNU GPL license.
This workshop will benefit anyone teaching or planning to teach quantum mechanics as well as computational physicists wishing to adopt the OSP Java libraries for their own teaching and research. We will discuss the general pedagogical and technical issues in the design of interactive computer-based tutorials as well as how OSP programs can be adapted to your local situation. Additional information can be obtained at www.opensourcephysics.org

**Speakers:**
- Chandralekha Singh, University of Pittsburgh
- Wolfgang Christian, Davidson College
- Mario Belloni, Davidson College

**Career Workshop**
**Sunday, March 12**
*3:00pm – 7:00pm*
BCC/Room 308

Attendance is free. All are welcome.

# PRE-MEETING PROGRAMS

**NRC/NAS Town Meeting**
**Sunday, March 12**
*7:30pm – 9:30pm*
Marriott Waterfront Hotel, Grand Ballroom Salon V

**Condensed Matter and Materials Physics In the Next Decade**

M. A. Kastner, Chair, Solid State Sciences Committee of the National Research Council and Department of Physics, MIT

• The National Research Council (NRC) will soon appoint a committee to carry out a decadal study of condensed-matter and materials physics called CMMP2010. The study, which will result in an NRC report, is supported by the NSF and DOE. The committee will assess the current and future opportunities of our field. It will identify the most important fundamental scientific problems, as well as problems whose solutions are likely to help meet national or societal needs. It will also examine the current status and future needs for resources that will be necessary to solve these problems, such as small and large facilities, individual and multi-investigator research support, as well as university, national and industrial laboratories. After a brief introduction to the work done so far, under the auspices of the Solid State Sciences Committee, attendees will be invited to offer their views about issues to which the panel should pay special attention.

# APS MEETINGS / EVENTS
***(In chronological order)***

**Contact Congress**
**Mon-Thurs 9:00am–6:00pm**
Sponsored by DCMP and DMP
BCC/Pratt Street Lobby

Worried about the slashing of NSF, DOE and NASA funding? Concerned about the dearth of science literacy in our high-schoolers? Anxious about where the country's security is heading? YOU can have an impact on national science policy! Come write your representatives in Congress to let them know how you feel about science issues of interest to you. The most important letters that a Member of Congress receives are the ones from his or her constituents – you elect them, and you matter. The American Physical Society feels that it is incumbent on all of us to interact with the government, to offer technical assistance where we can, and to remind our Members of Congress that scientists have much to offer the country, in areas of basic science R&D funding, education, and energy policy. We have set up computers in the entrance area where you can send a letter to your Senators and Representatives - you can use our template or write your own letter on issues that matter to you. If the state of affairs in Washington, DC, interests you, we have another way for you to get involved: the APS "Physics and Government Network," a group of APS members who volunteer to contact their representatives in Congress a few times a year at critical junctures. PGNet signup fliers will be available at the registration desk and at the "Contact Congress" computers. Come help make science more visible in Congress!

**Awards Program**
**Monday, March 13**
*5:45pm – 6:30pm*
BCC/Room 309
Prizes and awards will be bestowed on individuals for outstanding contributions to physics. Please plan on attending the Awards Program and join us in honoring these individuals. See page 829 for a list of award and prize winners. The Awards Program will be followed by the Welcome Reception at 6:45pm.

**Welcome Reception**
**Monday, March 13**
*6:45pm – 8:00pm*
BCC/Ballroom II

All Attendees welcome.

## *Special Symposium:*

**Emerging Emergent Phenomena (Session F50)**
**Monday, March 13**
Sponsored by DCMP
*8:00pm – 10:00pm*
Marriott Waterfront Hotel, Grand Ballroom Salons V-VI

Session Chair: Leo Kadanoff, University of Chicago
*Speakers:*
- Edward Witten: Emergent Phenomena In Particle Physics
- Susan J. Lolle: Revisiting Mendel and the Paradox of Gene Restoration
- Albert Laszlo Barabas: Complex Networks: From the Internet to Biology
- Bernard Sadoulet: Condensed Matter Physics and the Nature of Dark Matter in the Universe

**Wine and Cheese Reception**
**Monday and Tuesday • 4:00pm – 5:00pm**
BCC/Exhibit Hall E

**APS Journal Editors Panel Discussion**
**Tuesday, March 14**
*2:30pm – 3:30pm*
BCC/Room 337
All are invited to a panel discussion with the Editors of the American Physical Society journals. The panel will include Editors from Physical Review Letters, Physical Review B, and Physical Review E. They will briefly discuss some current issues facing the journals such as how to express appreciation for good refereeing, possible inclusion of popular abstracts in PRL to make Letters accessible to physicists in all fields, the challenge posed by open access, etc. The Editors look forward to hearing opinions on these and other issues. They will also respond to questions and comments. The Panel Discussion will be followed by the Meet the Editors Reception.

**Meet the Journal Editors of AIP and APS**
**Tuesday, March 14**
*3:30pm – 5:30pm*
BCC/Camden Lobby

The Editors of the AIP and APS journals cordially invite you to join them for conversation and refreshments. Your questions, criticisms, compliments, and suggestions about the journals are welcome. We hope you will be able to join us.

**Journals of the American Institute of Physics:**
- Applied Physics Letters
- Chaos
- Journal of Applied Physics
- The Journal of Chemical Physics
- Journal of Mathematical Physics
- Physics of Fluids
- Physics of Plasmas
- Review of Scientific Instruments

**Journals of the American Physical Society:**
- Physical Review A
- Physical Review B
- Physical Review E
- Physical Review Focus
- Physical Review Letters
- Reviews of Modern Physics

# APS MEETINGS / EVENTS
*(In chronological order)*

### *Special Symposium:*

**Intelligent Design: Its Impact and Responses to It**
**Tuesday, March 14**
*7:30pm – 9:30pm*
Marriott Waterfront Hotel/Grand Ballroom Salon V

Session Chair: Robert Eisenstein
Speakers:

- Jeremy Gunn, ACLU - Dover, PA Case
- Marshall Berman - Action at the Local Level
- Cory Dean, New York Times - Media Coverage
- Francis Slakey, APS Office of Public Affairs - APS Activities

**Congressional Visits during March Meeting 2006**
**Congressional Visits Office –**
**BCC/East Pratt Show Office, Lower Level**

The APS Office of Public Affairs (OPA) is organizing Congressional visits during the 2006 APS March Meeting in Baltimore. The advantageous location of this year's Meeting provides an exciting opportunity to have attendees from as many districts and states as possible travel down to Washington, DC to educate Congress on the importance of science research funding. The visit days are scheduled for Wednesday, March 15th and Thursday March 16th.

Carrying the message to individual offices remains one of the best means of influencing a Member of Congress. The timing of these visits is excellent since Congress will have just started its considerations of the appropriations for the next fiscal year. In addition to influencing Congress, we hope that participants see first-hand the importance of informing their elected officials about what physicists do. While our members are getting more active in this regard and more APS meeting attendees write letters at the Contact Congress computers, there is much more to do.

OPA will assist the participants in all aspects of the congressional visits from scheduling to follow up. Leading up to the meeting, OPA will contact participants to inform them of the organizational logistics of the visits and provide a means of coordination of their meetings on the Hill with other participants in their state or district. During the March Meeting, briefings will be held in Baltimore in the evenings preceding the visits to outline a common message, offer advice on how to conduct an effective meeting, and cover the logistics of a congressional visit. We will also provide materials to be left with each office that will present useful talking points and have state specific information. Shuttle bus transportation to and from the Meeting and Washington, DC will be provided for participants.

We would like you and all APS members to view Congressional visits as part of developing a relationship with an office rather than a one-time event. We would hope that you would follow up with the Congressional office at opportune times, make visits to the home offices and perhaps invite staff or Members of Congress to visit their labs. You may also become resources for a Member's office.
For more information visit the Congressional Visits office as noted above.

**Session on Refereeing**
**Wednesday, March 15**
*9:30am – 11:00am*
BCC/Room 337

Editors from Physical Review Letters and the Physical Review will provide useful information and tips for referees. Following short presentations from the editors, there will be a moderated discussion where questions relevant to refereeing will be addressed. Refreshments will be served.

**Estate Planning Seminar**
**Wednesday, March 15**
*1:00pm – 2:00pm*
BCC/Room 301

### *Special Symposium:*

**Perspectives on our Energy Future**
**Wednesday, March 15**
*7:30pm – 9:00pm*
Marriott Waterfront Hotel/Grand Ballroom Salon V

Session Chair: George Crabtree, Argonne National Laboratory
Speakers:

- Steven E. Koonin, Chief Scientist, BP
- Patricia Dehmer, Office of Basic Energy Sciences, DOE

**Physics Sing-a-Long/Listen-a-Long**
**Wednesday, March 15**
9:00pm – 10:00pm
Grand Salon II, Marriott Waterfront Hotel

**Changing Dynamics of Industrial Research as a Consequence of Global Trends (Session V19)**
Sponsored by APS and AIP
**Thursday, March 16**
BCC/Room 316

Session Chair: Mark Bernius, The Dow Chemical Company
Speakers:

- **Alan Taub**: General Motors' R&D: Managing Innovation Globally
- **Hans Stork**: Not Only Texas is Flat …
- **Mark Durcan**: Micron R&D: Global Scope and Nano-Scale in N-Dimensions
- **Abel Weinrib**: Leap Ahead: Global R&D at Intel
- **Thomas Feist**: Sustaining Breakthrough Research in a Changing Global Environment

# APS EVENTS FOR SPECIAL GROUPS

***(In chronological order)***

**Companions Breakfast**
**Monday, March 13**
*8:00am – 9:30am*
Marriott Waterfront Hotel/Dover A

Companions of the attendees of the March Meeting are invited to a complimentary breakfast to meet other companions and learn about the city of Baltimore. Presentations will be made by a representative of the Baltimore Convention and Visitors Bureau. At the breakfast you will receive information about the sites and attractions in the city.

**SPS Undergraduates and Mentors Gathering**
**Monday, March 13**
*1:50pm – 2:20pm*
BCC/Room 345

Undergraduates and their mentors, as well as graduate school representatives, are especially invited to hear the student presentations and mingle with the presenters during this gathering. The event is sandwiched between two exciting undergraduate research sessions - B42 and D42 in room 345. Light refreshments will be available for those attending the talks.

**CSWP/FIAP Networking Breakfast for Women in Physics**
**Tuesday, March 14**
*7:30am – 9:30am*
Marriott Waterfront Hotel, Grand Ballroom Salon VII
$20 (pre-registration only)

The Committee on the Status of Women in Physics (CSWP) and the Forum on Industrial and Applied Physics (FIAP) will host a networking breakfast for women in physics. All are welcome, both men and women. Thanks to the generosity of FIAP, the breakfast is free for physics students who pre-register. Only a limited number of walk-ins can be accepted.

**High School Physics Teachers Day**
**Tuesday, March 14**
*8:00am – 2:30pm*
Marriott Waterfront Hotel, Grand Ballroom Salons II–III

In conjunction with the 2006 March Meeting, the APS Department of Education & Outreach is sponsoring a High School Physics Teachers' Day for teachers in the Baltimore region. For more information contact Ed Lee: lee@aps.org

*The day's program includes:*

- Hands-on workshops presenting innovative, class room-ready activities
- Research talks on cutting-edge physics
- A welcoming breakfast, and a chance to network with fellow teachers
- Lunch with a physicist

**Congressional Visits Meeting**
**Tuesday, March 14**
*5:00pm – 6:30pm*
BCC/Room 337

**DCMP/DMP/DCOMP Fellows & Awards Reception**
**Tuesday, March 14**
*5:30pm – 7:00pm*
Marriott Waterfront Hotel/Grand Salon VI

**FIP Reception**
**Tuesday, March 14**
*6:30pm – 8:00pm*
Marriott Waterfront Hotel/Dover C

**Students Lunch with the Experts**
**Wednesday, March 15**
*1:00pm – 2:30pm*
BCC/Ballroom II

Students can sign up on-site to enjoy a complimentary box-lunch while participating in an informal discussion with an expert on a topic of interest to them. Sign-up will take place beginning on Monday, March 13 at 1:00pm at the APS registration desk, and will be on a first-come, first-served basis. Attendance is limited to eight students per topic.
See page 828 for list of topics and experts.

**Congressional Visits Meeting**
**Wednesday, March 15**
*5:00pm – 6:30pm*
BCC/Room 311

**Status of Funding Opportunities in NSF's Division of Materials Research**
**Wednesday, March 15**
*5:00pm – 7:00pm*
BCC/Room 338

**Student Reception**
**Wednesday, March 15**
*5:30pm – 6:30pm*
BCC/Ballroom II
Sponsored by the Forum on Graduate Student Affairs (FGSA)

All students are welcome. Plan to attend and socialize with your fellows and enjoy the refreshments. The Forum on Graduate Student Affairs (FGSA) will present a short program.

# APS EVENTS FOR SPECIAL GROUPS

***(In chronological order)***

## APS Unit Business Meetings

### SUNDAY, MARCH 12

**GSCCM Business Meeting**
*3:00pm – 4:00pm*
Falkland Room, Marriott Waterfront Hotel

### TUESDAY, MARCH 14
### 5:30pm – 6:30pm

**DPOLY Business Meeting**
BCC/Room 315

**FIAP Business Meeting**
BCC/Room 312

**FIP Business Meeting**
Marriott Waterfront Hotel, Galena

**DCP Business Meeting**
BCC/302

**GSNP Business Meeting**
BCC/Room 336

**GMAG Business Meeting**
BCC/Room 320

**GQI Business Meeting**
BCC/Room 343

**GIMS Business Meeting**
BCC/Room 301

### TUESDAY, MARCH 14
### 7:00pm–8:00pm

**DCMP Business Meeting**
Marriott Waterfront Hotel/Dover A

**DMP Business Meeting**
Marriott Waterfront Hotel/Dover B

### WEDNESDAY, MARCH 15

**FED Business Meeting and Reception**
*5:30pm – 7:00pm*
Marriott Waterfront Hotel/Grand Ballroom Salon III

**DCOMP Business Meeting**
*6:30pm – 730pm*
Marriott Waterfront Hotel, Dover C

# SATELLITE MEETINGS

***(ancillary events sponsored by non-APS groups)***

**Sunday, March 12**
**High Magnetic Field Laboratory Users Group**
*5:00pm – 9:00pm*
Marriott Waterfront Hotel/Grand Ballroom Salon X

**Sunday, March 12**
**Socialize with Science - Oxford Instruments**
*7:00pm – 9:00pm*
Marriott Waterfront Hotel/Grand Salons VIII–IX

**Monday, March 13**
**Discussions and Updates on the Nanoscale Ordered Materials Diffractometer at the Spallation Neutron Source (NOMAD)**
11:00am – 2:00pm
Marriott Waterfront Hotel/Dover C

**Tuesday, March 14**
**Research Corporation Reception**
*5:00pm – 7:00pm*
Marriott Waterfront Hotel/Grand Ballroom Salon I

**Tuesday, March 14**
**Alumni Reunions**
*6:00pm – 8:00pm*
Marriott Waterfront Hotel
- Cornell University, Grand Ballroom Salons IX–X
- University of Illinois, Grand Ballroom Salons II–III
- Michigan State University, Bristol
- IBM, Grand Salon VIII
- Brown University, Falkland
- State of Florida Universities, Harborside Ballrooms AB
- Sigma Pi Sigma, Essex B
- Brandeis Alumni Reunion, Essex C

**Tuesday, March 14**
**Chinese Academy of Sciences Reception**
*6:00pm–8:00pm*
Marriott Waterfront Hotel/Essex A

**Tuesday, March 14**
**American Chapter of the Indian Physics Association**
*7:30pm – 9:30pm*
Marriott Waterfront Hotel/Grand Ballroom Salon IV

**Wednesday, March 15**
**RSI Editorial Board Meeting**
*12:00noon – 2:00pm*
Marriott Waterfront Hotel/Grand Salon IX

**Wednesday, March 15**
**Status of Funding Opportunities in NSF's Division of Materials Research**
*5:00pm – 7:00pm*
BCC/Room 338

**Wednesday, March 15**
**MRFM Workshop**
**(Magnetic Resonance Force Microscopy)**
*6:30pm – 10:30pm*
Marriott Waterfront Hotel/Atlantic Room

# STUDENTS LUNCH WITH THE EXPERTS

**Wednesday, March 15**
*1:00pm – 2:30pm*
Ballroom II

Students can sign up on-site to enjoy a complimentary box-lunch while participating in an informal discussion with an expert on a topic of interest to them. Topics are listed below. Sign-up will take place beginning on Monday, March 13 at 1:00pm at the APS registration desk, and will be on a first-come, first-served basis. Attendance is limited to eight students per topic/expert. You must show your ticket and badge at the door, and sit at the table for which you have a ticket.

Lunch topics
sponsored by:

| | | |
|---|---|---|
| **1. DMP** | **Jaqueline Krim** | **Nanotribology: Applications and Implications of Friction at the Atomic Scale** |
| 2 DMP | Lynn Boatner | Smart Nanocomposite Materials and How to Make Them |
| **3. DFD** | **Ray Goldstein** | **Biological Physics** |
| 4. DFD | Wolfgang Losert | Complex Fluids from Sand to Cells |
| **5. DFD** | **Dave Weitz** | **Squishy Physics** |
| 6. FPS | Francis Slakey | The Issue of Intelligent Design |
| **7. GMAG** | **Jeff Childress** | **Research in Magnetic Recording - Industrial and Academic Perspectives** |
| 8. GMAG | Jim Rhyne | Neutron Scattering Insights into Condensed Matter Systems |
| **9. DCMP** | **Allen Goldman** | **Superconductivity** |
| 10. DCMP | Art Ramirez | Frustrated Magnetism |
| **11. DCMP** | **Gwyn P. Williams** | **Careers in the National Labs: Development of the Jefferson Lab FEL** |
| 12. DCMP | David Awschalom | Spin Dynamics and Spin Coherence in Condensed Matter Systems (Spintronics) |
| **13. DCMP** | **Julia Phillips** | **Sandia & Los Alamos Center for Integrated Nanotechnologies** |
| 14. DCMP | Alan Dorsey | Supersolids |
| **15. DCMP** | **Garnett Bryant** | **Quantum Nano-optics and Quantum Dots** |
| 16. DCMP | Arthur F. Hebard | Magnetism in Reduced Dimensions: Ultra Thin Films and Thin-Film Interfaces |
| **17. DCMP** | **Christopher Homes** | **Optical Spectroscopy of Superconductors** |
| 18. DCMP | Richard Newrock | One Dimensional Conductance: Coulomb Drag and Luttinger Liquids |
| **19. DCMP** | **Eric Shirley** | **Optical Properties of Materials: From Basic Theory to Industrial Impact** |

# 2006 PRIZES AND AWARDS

**Award Session (Session E5)**
**Monday, March 13**
*5:45pm – 6:45pm*
*BCC/309*

## Biological Physics Prize

**Alfred G. Redfield**
*Brandeis University*

"For his seminal contributions to the theory and technical development of nuclear magnetic resonance spectroscopy, and for pioneering applications of this technique to the study of biological molecules."

## Lars Onsager Prize

**Rodney Baxter**
*Australian National University*

"For his original and groundbreaking contributions to the field of exactly solved models in statistical mechanics, which continue to inspire profound developments in statistical physics and related fields."

## Oliver E. Buckley Prize

**Noel A. Clark**
*University of Colorado*

**Robert Meyer**
*Brandeis University*

"For groundbreaking experimental and theoretical contributions to the fundamental science and applications of liquid crystals, particularly their ferroelectric and chiral properties."

## George E. Pake Prize

**Charles B. Duke**
*Xerox Innovation Group*

"For groundbreaking theoretical contributions to the understanding of tunneling in solids, and inelastic scattering of low-energy electrons in solids, and for his outstanding contributions to Xerox Corporate Research both as an intellectual leader and research manager."

## Frank Isakson Prize

**Roberto Merlin**
*University of Michigan*

"For original contributions to spontaneous Raman and ultrafast spectroscopy of fundamental excitations in solids."

## Earle K. Plyler Prize

**Mark Johnson**
*Yale University*

"For the applications of spectroscopic methods towards the understanding of solvation on the microscopic scale, especially the solvation of protons and hydroxide anions by water."

## James C. McGroddy Prize

**Hongjie Dai**
*Stanford University*

**Alex Zettl**
*University of California, Berkeley*

"For developing novel synthesis pathways for preparing carbon and boron nitride nanotubes and for pioneering applications of these for sensing, electronics and nanomechanics."

## Polymer Prize

**Ludwik Leibler**
*Ecole Superieure de Physique et Chimie Industrielles, Paris*

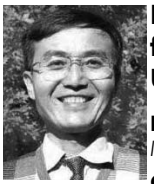
"For outstanding theoretical contributions to the fundamental understanding of self-assembly of diblock copolymers and gels, and wetting."

# 2006 PRIZES AND AWARDS

## Aneesur Rahman Prize

**David Vanderbilt**
*Rutgers University*

"For his conceptual breakthroughs in his development of the ultrasoft pseudopotential and the modern theory of polarization, and their impact on first-principles investigations of the properties of materials."



## Prize to a Faculty Member for Research in an Undergraduate Institution

**Rainer Grobe**
*Illinois State University*

**Q. Charles Su**
*Illinois State University*

"For their outstanding effort at creating a successful and renowned optical theory research program at Illinois State University, and for their exemplary involvement of undergraduates in this research."

## David Adler Lectureship Award

**James Chelikowsky**
*University of Texas*

"For his creative and outstanding research in computational materials physics and for his effectiveness in communicating research results through lectures and publications."

## LeRoy Apker Award

**Nathaniel Craig**
*Harvard University*

**Matthew Paoletti**
*Bucknell University*

"Tunable Nonlocal Spin Control in a Coupled Quantum Dot System."
"Experimental Studies of the Effects of Chaotic Mixing on an Advection-Reaction-Diffusion System."

## Edward A. Bouchet Award

**Angel Garcia**
*Rensselaer Polytechnic Institute*

"For his contributions to the understanding of the role of water in the dynamics and folding of proteins through computer simulations."

Photo not available

## John H. Dillon Medal

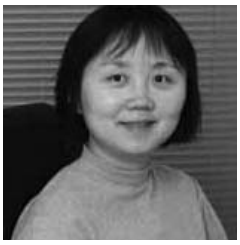
**Kenji Urayama**
*Kyoto University*

"For insightful experiments that probe the nature of polymer networks."

## Keithley Award

**Frances Hellman**
*University of California, Berkeley*

"In recognition of using emerging micromachining techniques to significantly extend the range of calorimetry into the realm of nano-scale science, by construction of Si based microcalorimeters capable of operating in extreme environments with unprecedented sensitivity and accuracy."



## Maria Goeppert-Mayer Award

**Hui Cao**
*Northwestern University*

"For her groundbreaking contributions to the experimental studies of coherent light generation and transport in disordered media, including her invention of microlasers based on disordered media."

Photo not available

## Nicholas Metropolis Award

**Joseph A. Barranco**
*University of California, Berkeley*

"For the development of computational techniques to handle 3D compact vortices in rotating shear flows, and for the application of these techniques to solve longstanding problems in the theory of planet and star formation."

**Additional Awards:**

**Marshak Lectureship Award: Zohra ben Lakhdar (Session D3)**

**Beller Lectureship Award: Pierre-Gilles de Gennes (Session Y29)**

Each year, the APS Committee on International Scientific Affairs (CISA) will award the APS Beller and Marshak Lectureships to bring distinguished foreign scientists to speak at the March and April meetings.

The Beller Lectureship was endowed by Esther Hoffman Beller for the purpose of bringing distinguished physicists from abroad as invited speakers at APS meetings. The Marshak Lectureship, endowed by Ruth Marshak, in honor of her late husband and former APS president, Robert Marshak, provides travel support for physicists from a developing country or Eastern Europe invited to speak at APS meetings.

# FOCUS SESSIONS

**DAMOP**
A43 - Focus Session: Strongly Interacting Fermi Gases and the BCS - BEC Crossover I
D43 - Focus Session: Vortices and Vortex Lattices in Fermi and Bose Superfluid Gases
H43 - Focus Session: Strongly Interacting Fermi Gases and the BCS - BEC Crossover II
U43 - Focus Session: Novel Phases in Low Dimensional Quantum Gases

**DAMOP/GQI**
W43 - Focus Session: Cold Atoms in Optical Lattices

**DBP**
G26 - Focus Session: Trapping of Nanoscale Biological Objects
G29 - Focus Session: Physical and Engineering Constraints on the Function of Biological Systems
H29 - Focus Session: Physical Aspects of Morphogenesis: Computational Approaches
N29 - Focus Session: Physical Models of Ion Channel Function
R26 - Focus Session: Counterion Dynamics in Charged Biopolymer Systems
R28 - Focus Session: Biological Networks: Structure, Dynamics and Function
W26 - Focus Session: Biological Photophysics
Y26 - Focus Session: Physics of Physiological Systems

**DBP/DCMP**
K26 - Focus Session: Single Molecule Biophysics I

**DBP/DCP**
P26 - Focus Session: Protein Dynamics in Folding and Function

**DBP/DFD**
N26 - Focus Session: DNA and Protein Analysis with Micro and Nano Fluidics

**DBP/DPOLY**
B26 - Focus Session: Single Molecule Biophysics: DNA & RNA
D26 - Focus Session: Dynamics of Nuclei Acid-Protein Interaction: Single Molecule
U29 - Focus Session: Nonequilibrium Fluctuation in Biomolecules and Artificial Nanodevices
Y29 - Focus Session: Noise and Fluctuation in Biological Systems

**DBP/GSNP**
B29 - Focus Session: Micro-Organism Motility
A39 - Focus Session: Magnesium Diboride and Related Compounds: Multi Gap Superconductivity
D15 - Atomic Tunneling, Films, Nanostructures
H39 - Focus Session: Josephson Junctions and Pairing State Symmetry

**DCMP/DCOMP**
*G39* - Focus Session: Superconductivity: Theory and Computation I

**DCMP/GSCCM**
R42 - Focus Session: Plasticity and Phase Transitions

**DCOMP**
D27 - Focus Session: Novel Computational Algorithms I
G27 - Focus Session: Novel Computational Algorithms II

**DCOMP/DFD**
V8 - Focus Session: Simulations Using Particles

**DCOMP/DCMP**
K39 - Focus Session: Superconductivity: Theory and Computation II
P39 - Focus Session: Superconductivity: Theory and Computation (Mainly First Principles)
V39 - Focus Session: Superconductivity: Theory and Computation III
Z39 - Focus Session: Superconductivity: Theory and Computations (Mostly Phonons)

**DCOMP/DMP**
B32 - Focus Session: Computational Nanoscience I
D32 - Focus Session: Computational Nanoscience II
G31 - Focus Session: Simulation of Complex Materials I
H31 - Focus Session: Simulation of Complex Materials II
H32 - Focus Session: Computational Nanoscience III
K31 - Focus Session: Simulation of Complex Materials III
K32 - Focus Session: Computational Nanoscience IV
R32 - Focus Session: Computational Nanoscience V

**DCOMP/GSCCM/DMP**
N42 - Focus Session: Simulations of Matter at Extreme Conditions I
U42 - Focus Session: Simulations of Matter at Extreme Conditions II
W42 - Focus Session: Simulations of Matter at Extreme Conditions III

**DCOMP/GQI**
P40 - Focus Session: Pathways to Practical Quantum Computing I
R40 - Focus Session: Pathways to Practical Quantum Computing II

**DCOMP/GQI/DAMOP**
U40 - Focus Session: Pathways to Practical Quantum Computing III

**DCP**
A10 - Focus Session: Physical Chemistry of Nanoscale Systems I
A11 - Focus Session: Promises and Challenges in Chemical Dynamics I
B10 - Focus Sessions: Physical Chemistry of Nanoscale System II
B11 - Focus Session: Promises and Challenges in Chemical Dynamics II
D10 - Focus Session: Physical Chemistry of Nanoscale System III
D11 - Focus Session: Promises and Challenges in Chemical Dynamics III
G10 - Focus Sessions: Physical Chemistry of Nanoscale System IV
G11 - Focus Session: Promises and Challenges in Chemical Dynamics IV
H10 - Focus Session: Frontiers in Computational Chemical Physics I
H11 - Focus Session: Chemical and Spectroscopic Applications of Nonlinear Optics I
K10 - Focus Session: Frontiers in Computational Chemical Physics II
K11 - Focus Session: Chemical and Spectroscopic Applications of Nonlinear Optics II

# FOCUS SESSIONS

N10 - Focus Session: Frontiers in Computational Chemical Physics III
N11 - Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects I
N13 - Focus Session: Ultrafast and Ultrahigh Field Chemistry I: Strong Field Phenomena
P10 - Focus Session: Frontiers in Computational Chemical Physics IV
P11 - Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects II
P13 - Focus Session: Ultrafast and Ultrahigh Field Chemistry II: Quantum Control
R10 - Focus Session: Surfaces and Interfaces in Electronic Materials I
R11 - Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects III
R13 - Focus Session: Ultrafast and Ultrahigh Field Chemistry III: Ultrafast Processes
U10 - Focus Session: Surfaces and Interfaces in Electronic Materials II
U11 - Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects IV
V10 - Focus Session: Surfaces and Interfaces in Electronic Materials III
V11 - Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects V
W10 - Focus Session: Surfaces and Interfaces in Electronic Materials IV
W11 - Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects VI

**DCP/DBP**

A13 - Focus Session: Spectroscopy of Biomolecules from Isolated Molecules to Cell Environoment I
B13 - Focus Session: Spectroscopy of Biomolecules from Isolated Molecules to Cell Environoment II
D13 - Focus Session: Spectroscopy of Biomolecules from Isolated Molecules to Cell Environoment III
G13 - Focus Session: Spectroscopy of Biomolecules from Isolated Molecules to Cell Environoment IV

**DFD**

H21 - Focus Session: Microfluidic Physics I

**DFD/DBP**

R21 - Focus Session: Biological Hydrodynamics I
U28 - Focus Session: Biological Hydrodynamics II

**DFD/GSNP**

P8 - Focus Session: Jets, Shocks & Splashes

**DMP**

A18 - Focus Session: Carbon Nanotubes: Synthesis and Growth I
A35 - Focus Session: Nanoscale Thermal, Thermoelectricity and Mass Transport: Measurement and Characterization
A46 - Focus Session: Wide Bandgap Semiconductors I
B18 - Focus Session: Carbon Nanotubes: Synthesis, Processing and Characterization
B35 - Focus Session: Nanoscale Thermal, Thermoelectricity and Mass Transport: Theory and Simulation
B46 - Focus Session: Wide Band Gap Semiconductors II
D18 - Focus Session: Carbon Nanotubes: Synthesis and Growth II
D35 - Focus Session: Thermal Transport and Thermoelectricity in Nanotubes and Graphene
D38 - Focus Session: Magnesium Diboride and Related Compounds: Properties of Doped and Irradiated MgB2
D46 - Focus Session: Wide Band Gap Semiconductors III
G18 - Focus Session: Carbon Nanotubes: Electronic and Optical Properties I
G37 - Focus Session: Nanoscale Materials Physics of Phase Transitions I
G38 - Focus Session: Magnesium Diboride and Related Compounds: Carbon Alloying of MgB2
G40 - Focus Session: Materials for Quamtum Computing I
H18 - Focus Session: Carbon Nanotubes: Electronic and Optical Properties II
H36 - Focus Session: Single Molecule Conductance
H37 - Focus Session: Nanoscale Materials Physics of Phase Transitions II

Y20 - Focus Session: Ruddlesden-popper Phase Manganites
Z19 - Focus Session: Spin Dynamics in Quantum Dots
Z20 - Focus Session: Novel Ferromagnetic Semiconductors II

**GMAG/DMP/DCOMP**
D23 - Focus Session: MAG.THY I / Spin Structures and Dynamics
G23 - Focus Session: MAG.THY II / Transport & General
N23 - Focus Session: MAG.THY III: Oxides and Phase Transitions
W23 - Focus Session: MAG.THY IV / ab initio Studies

# FOCUS SESSIONS

*Focus Sessions (cont'd)*

**GMAG/FIAP**
R23 - Focus Session: Theory and Simulation for Information Storage Applications
Y22 - Focus Session: Coupled Thin-Film Structures for Magnetic Recording
Z22 - Focus Session: FePt Nanoparticles for Information Storage

**GMAG/FIAP/DMP**
A22 - Focus Session: Current Driven Magnetization Dynamics I
B22 - Focus Session: Current Driven Magnetization Dynamics II
K22 - Focus Session: Magnetization Dynamics
P22 - Focus Session: Spin Transport in Metals
U22 - Focus Session: Magnetic Tunneling I
V22 - Focus Session: Magnetic Tunneling II

**GSCCM/DCMP**
H42 - Focus Session: Dynamic Compression

**GSNP**
A33 - Focus Session: Econophysics
H8 - Focus Session: Jamming in Glasses, Grains, and Gels I
K8 - Focus Session: Jamming in Glasses, Grains and Gels II
N33 - Focus Session: Instabilities & Turbulence in Complex Fluids
N35 - Focus Session: Organization of Complex Networks
V33 - Focus Session: Social Networks

**GSNP/DBP**
P7 - Focus Session: Physics of Transcriptional Regulatory Networks
U26 - Focus Session: Cytoskeletal Dynamics

**GSNP/DFD**
B8 - Focus Session: Granular Materials Near Jamming
W8 - Focus Session: Nonlinear Electrokinetics

**GQI/DCMP**
D40 - Focus Session: Foundations of Quantum Theory
V40 - Focus Session: Linear Optics Quantum Computation

# POSTER SESSIONS

**Poster Sessions**
*Exhibit Hall*
Poster sessions will be held Monday, Tuesday and Wednesday. Posters will be on display from 10:00am to 5:00pm on Monday and Tuesday and from 10:00am to 4:00pm on Wednesday. Authors should be in attendance at the times listed below. APS is not responsible for poster materials that are left in the exhbiti hall after the session is over. No A/V is allowed in poster sessions.

**C1: Poster Session 1**
**Monday, March 13**
Authors in attendance from 2:00pm – 5:00pm
(DPOLY Session from 11:15am – 2:15pm)

Posters 1-99: DPOLY Posters I
Posters 100-152: Biological Physics
Posters 153-184: Chemical Physics
Posters 185-215: Statistical and Nonlinear Physics
Posters 216-256: Artificially Structured Materials
Posters 257-270: Instrumentation and Measurements

**J1: Poster Session II**
**Tuesday, March 14**
Authors in attendance from 2:00pm – 5:00pm

- Posters 1-19: Metals
- Posters 20-48: Semiconductors
- Posters 49-65: Insulators and Dielectrics
- Posters 66-88: Superconductivity
- Posters 89-147: Magnetism Poster
- Posters 148-195: Complex Structured Materials
- Posters 196-245: Fluids and Soft Matter Poster
- Posters 246-259: Phase Transitions and Strongly Correlated Systems
- Posters 260-292: Surfaces, Interfaces and Thin Films

**Q1: Poster Session III**
**Wednesday, March 15**
Authors in attendance from 1:00pm – 4:00pm
(DPOLY Session from 11:15am – 2:15pm)

- Posters 1-97: DPOLY Posters II
- Posters 98-122: Applications
- Posters 123-144: General Theory
- Posters 145-154: General Physics
- Posters 155-157: Quantum Fluids and Solids
- Posters 158-173: Atomic, Molecular & Optical (AMO) Physics
- Posters 174-186: Physics Education
- Posters 187-199: Quantum Information, Concepts, and Computation
- Posters 200-333: Post-Deadline Posters

# PROGRAM FORMAT

**Program Time-Blocks**

Normally contributed and invited sessions at APS general meetings are three hours in length - three sessions per day at 8:00am, 11:15am, and 2:30pm. The time blocks are designated in alpha order beginning with time-block "A" on Monday at 8:00am, and ending with "Z" designating the 11:15 time-block on Friday.

**Session Codes**

The number following the alpha that designates the time-block represents the sequential numbering of the sessions within the time-block. Session A1 is one of several sessions taking place in parallel in the first time-block on Monday. The number following the decimal in the session code represents the sequence of the papers to be presented in that session. For *example:* B3.004 = Time-block B (Monday at 11:15am); Session 3 (of several) within that time-block; and the 4th paper to be presented in that session.

**Poster Codes**

The poster sessions will take place on Monday, Tuesday, and Wednesday in the Exhibit Hall. A breakdown of the topics presented in each category is listed on page 835.

- Monday poster sessions = Sessions C1
- Tuesday poster session = Sessions J1
- Wednesday poster sessions = Sessions Q1

Each poster presentation (board) within each poster session is numbered sequentially.

## GUIDELINES FOR SPEAKERS

**Oral Presentations**

Please arrive at least 15 minutes prior to the scheduled time of your talk. Contributed papers are allocated 12 minutes each - 10 minutes for presentation and 2 minutes for questions from the audience, unless otherwise specified. Invited papers are allocated 36 minutes - 30 minutes for presentation and 6 minutes for questions from the audience.

Note: Occasionally (and unfortunately) the chair for a session may not appear, in which case we ask that the first presenter serve as chair of the session.

**Poster Presentations**

If you are presenting a poster, please be sure to have your poster up prior to 10:00am on the day of your poster presentation to which you have been assigned, and taken down immediately at the end of the day. You must be on hand at the beginning of the poster session (see epitome for times). APS will not be responsible for posters left up after the end of each poster session. No A-V is allowed in the poster sessions. Posters will be on display between the hours of 10:00am to 5:00pm Monday, Tuesday; 10:00am to 4:00pm, Wednesday. Consult the Poster Session Schedule for exact times and a breakdown of poster topics.

## GUIDELINES FOR SESSION CHAIRS

- Prior to the session, check the Corrigenda distributed with the Bulletin, as well as the Program-Changes Board in the registration area to see if any papers in the session you are chairing have been withdrawn.
- Arrive at the meeting room about 15 minutes prior to the start of the session and familiarize yourself with the controls for lights, microphones, A-V equipment and the timer. Technicians will be on hand to assist. If you encounter problems, you should immediately alert the Meetings Manager and/or the A-V specialist.
- Start the session on time. Briefly introduce yourself, announce the first paper and author, and start the timer.
- Please adhere to the time schedule listed in the Bulletin, so that simultaneous sessions are as closely synchronized as possible. Many attendees move from session to session in order to hear specific papers.

Note: any time used by the speaker and/or technicians to set up laptops for LCD (Powerpoint) presentations is deducted from the time allocated for the talk.

- The allotted time for contributed papers is 12 minutes; for invited papers - 36 minutes. If you are chairing a session that includes both contributed and invited papers please be aware of the different times allocated for each and set the timer as follows:

*Contributed papers* - set timer for 8 minutes to give initial warning, then set the final bell to go off 2 minutes later. When this time is up, allow 2 additional minutes for questions relating to the paper, thank the speaker and promptly introduce the next paper and speaker.

Invited papers - set timer for 25 minutes for initial warning, and the final bell to ring 5 minutes later. Then set the timer for 6 additional minutes for questions from the audience.

Explain the timing system to the audience prior to the start of the session, and as often during the session as you think necessary.

- The By-Laws of the Society request that speakers be asked to stop when their allotted time is up in a courteous but firm manner. Keep in mind that the session must end on time, and that the last speaker has just as much right to an audience as does the first speaker.
- Should a speaker fail to appear, you must wait 12 minutes before going on to the next speaker. At the end of the session, call again for the regularly scheduled paper, if time allows.
- When two or more papers are submitted by an author, only one of these will be assigned a scheduled presentation time within that session. It is assumed that the first author listed in the abstract is the person who will present the paper at the meeting. A second abstract submitted by the same author is automatically assigned to a poster.
- If any problems arise that you are unable to handle relative to successfully chairing the session, please inform the A-V tech in the room, or go immediately to the APS registration desk to alert the APS staff.

**General A-V Policy**

In keeping with our legally binding contract with our A-V vendor, speakers are not permitted to bring their own projection equipment for use at the meeting.

**Standard A-V in all Sessions**

The standard A-V package consists of an LCD projector, overhead projector, screen, laser pointer and 2 lapel microphones – one for the chair and one for the speakers. Any additional A-V equipment must be rented by the speaker directly through APS's designated A-V provider located in Rooms 331-332. The speaker is responsible for the cost of renting any additional equipment.

# PROGRAM FORMAT

**Policy and Guidelines on Use of LCD Projectors**

The responsibility for a smooth, technically trouble-free presentation ultimately rests with the presenter. Speakers who plan to use LCDs must do the following:

• Bring your own laptop computer, power cord, and any proprietary cords required for your computer. Do not bring your own projector to the meeting. NOTE: APS is not responsible for the security of personal laptop computers.

• Visit the Speaker-Ready room located in Room 330 to run through the presentation to ensure a smooth and technically trouble-free talk. Testing your presentation in the Speaker-Ready room prior to your presentation is strongly recommended to minimize equipment compatibility difficulties. Remember that time used to set up equipment reduces the time you have to make your presentation.

• Bring a back-up vu-graph presentation in case there are set-up difficulties with the LCD equipment.

# PROGRAM FORMAT & UNIT ACRONYMS

**Divisions**

DAMOP ..... Division of Atomic, Molecular and Optical Physics
DAP ..... Division of Astrophysics
DBP ..... Division of Biological Physics
DCP ..... Division of Chemical Physics
DCMP ..... Division of Condensed Matter Physics
DCOMP ..... Division of Computational Physics
DFD ..... Division of Fluid Dynamics
DLS ..... Division of Laser Science
DMP ..... Division of Materials Physics
DNP ..... Division of Nuclear Physics
DPB ..... Division of the Physics of Beams
DPF ..... Division of Particles and Fields
DPP ..... Division of Plasma Physics
DPOLY ..... Division of Polymer Physics

**Topical Groups**

GFBS ..... Few Body Systems Topical Group
GFC ..... Precision Measurement and Fundamental Constants Topical Group
GGR ..... Gravitation
GHP ..... Topical Group on Hadronic Physics
GIMS ..... Instrumentation and Measurement
GMAG ..... Magnetism and Its Applications Topical Group
GPAP ..... Topical Group on Plasma Astrophysics
GQI ..... Quantum Information, Concepts and Computation
GR ..... Gravitation Topical Group
GSNP ..... Statistical and Non-linear
GSCCM ..... Shock Compression of Condensed Matter

**Forums**

FEd ..... Forum on Education in Physics
FGSA ..... Forum on Graduate Student Affairs
FHP ..... Forum on History of Physics
FIAP ..... Forum on Industrial and Applied Physics
FIP ..... Forum on International Physics
FPS ..... Forum on Physics and Society

**Committees**

COM ..... Committee on Minorities
CSWP ..... Committee on the Status of Women in Physics

# MARCH EXHIBIT SHOW GUIDE 2006

The following is a list of exhibitors participating in the March Meeting 2006. For complete information on exhibiting companies and their booth numbers, consult the Pocket Epitome/Exhibitor Guide distributed at registration. Please take time during the meeting to visit the exhibits. You must wear your badge to be admitted to the exhibits.

**APS Exhibit Hours:**
Monday, March 13 • 10:00am–5:00pm
Tuesday, March 14 • 10:00am–5:00pm
Wednesday, March 15 • 10:00am–4:00pm

A&N Corporation
ADE Phase Shift
Advanced Research Systems, Inc.
AIP Education & Society of Physics Students
AJA International, Inc.
Ambios Technology
American Institute of Physics
American Magnetics Inc.

# *Epitome of the March Meeting 2006*

**15:00 SUNDAY AFTERNOON 12 MARCH 2006**

1B GSCCM: **GSCCM Business Meeting**
Falkland, Marriott Waterfront Hotel

**19:30 SUNDAY EVENING 12 MARCH 2006**

1A **NAS Town Meeting**
Grand Ballroom Salon V, Marriott Waterfront Hotel

**8:00 MONDAY MORNING 13 MARCH 2006**

A1 DCMP: **Quantum Properties of Superconducting Nanowires**
*Sachdev, Tian, Rogachev, Khlebnikov, Arutyunov*
Ballroom IV, Baltimore Convention Center

A2 DCMP: **Magnetic-Ferroelectric Coupling in Multiferroics**
*Cheong, Vajk, Harris, Chu, Mostovoy*
Ballroom III, Baltimore Convention Center

A3 DCMP: **Bilayer 2D Systems: Interlayer Drag and Spontaneous Coherence**
*Pillarisetty, Das Sarma, Kivelson, Simon, Pellegrini*
Ballroom I, Baltimore Convention Center

A4 DPOLY: **Particle Self Assembly**
*Crocker, Starr, Hammond, Douglas, Walker*
308, Baltimore Convention Center

A5 DMP/ FIAP: **Advanced Materials for Energy Applications**
*Dresselhaus, Kanatzidis, Christensen, Mavrikakis, Schubert*
309, Baltimore Convention Center

A6 DCOMP: **Frontiers of Computational Materials**
*Asta, Johnson, Marzari, Hart, Kolmogorov*
310, Baltimore Convention Center

A7 DBP: **Bacterial Flagellar Dynamics, Polymorphism, and Conformational Spread**
*Powers, Stark, Darnton, Shaevitz*
307, Baltimore Convention Center

A8 DFD/ GSNP: **Pattern Formation and Nonlinear Dynamics**
314, Baltimore Convention Center

A9 DCMP: **Electronic Structure on Surfaces and in Reduced Dimensions**
301, Baltimore Convention Center

A10 DCP: **Focus Session: Physical Chemistry of Nanoscale Systems I**
*Nesbitt, Van Duyne*
302, Baltimore Convention Center

A11 DCP: **Focus Session: Promises and Challenges in Chemical Dynamics I**
*Shapiro, Lin*
303, Baltimore Convention Center

A12 DMP/ DCMP: **Focus Session: Steps, Growth, and Smoothing**
*Margetis*
304, Baltimore Convention Center

A13 DCP/ DBP: **Focus Session: Spectroscopy of Biomolecules from Isolated Molecules to Cell Environment I**
*Anfinrud, Spence*
305, Baltimore Convention Center

A15 DCMP: **Metals: 1D, 2D, 3D**
311, Baltimore Convention Center

A16 FIAP: **Focus Session: Hydrogen Storage I**
*Frederick Pinkerton*
312, Baltimore Convention Center

A17 FIAP: **Focus Session: Structure and Properties of Nanoscale Oxide Films**
*Pennycook, Freund*
313, Baltimore Convention Center

A18 DMP: **Focus Session: Carbon Nanotubes: Synthesis and Growth I**
*Hata*
315, Baltimore Convention Center

A19 GMAG/DMP: **Focus Session: Optical and Electrical Spin Generation in Semiconductors**
*Sipe*
316, Baltimore Convention Center

A20 DMP/GMAG: **Focus Session: Complex Oxide Thin Films Surfaces and Interfaces I: Superlattice Fabrication and Properties**
*Varela*
317, Baltimore Convention Center

A21 DFD: **Colloids I: Emulsions, Foams, and Suspensions**
318, Baltimore Convention Center

A22 GMAG/FIAP/DMP: **Focus Session: Current Driven Magnetization Dynamics I**
*Pufall*
319, Baltimore Convention Center

A23 GMAG: **Strongly Correlated Electrons I**
320, Baltimore Convention Center

A24 DPOLY: **Semi-Crystalline and Structured Polymers**
321, Baltimore Convention Center

A25 DPOLY/DMP: **Focus Session: Organic Field Effect Transistors**
*Marks*
322, Baltimore Convention Center

A26 DBP: **Biomolecular Computation**
323, Baltimore Convention Center

A28 DPOLY: **Polymer Blends**
325, Baltimore Convention Center

A29 DBP: **Experimental Techniques in Biophysics**
326, Baltimore Convention Center

A30 DPOLY: **Focus Session: Block Copolymer Dynamics**
*Morse*
327, Baltimore Convention Center

A31 DCMP: **Metallic Nanostructures**
328, Baltimore Convention Center

A32 DCMP: **Fullerenes**
329, Baltimore Convention Center

A33 GSNP: **Focus Session: Econophysics**
*Yakovenko*
336, Baltimore Convention Center

A35 DMP: **Focus Session: Nanoscale Thermal, Thermoelectric and Mass Transport: Measurement and Characterization**
*Fon*
338, Baltimore Convention Center

A36 DCMP: **Structural, Optical, and Electronic Properties of Nanostructures**
339, Baltimore Convention Center

A38 DCMP: **Superconductivity—Vortex Matter**
341, Baltimore Convention Center

A39 DMP: **Focus Session: Magnesium Diboride and Related Compounds: Multi Gap Superconductivity**
342, Baltimore Convention Center

A40 TGQI/DCMP: **Quantum Entanglement**
343, Baltimore Convention Center

A41 DCMP: **Quantum Fluids and Solids**
344, Baltimore Convention Center

A42 DMP/DCOMP: **Focus Session: Planetary Materials I**
*Gironcoli, Lin*
345, Baltimore Convention Center

A43 DAMOP: **Focus Session: Strongly Interacting Fermi Gases and the BCS-BEC Crossover I**
*Denschlag*
346, Baltimore Convention Center

A45 GMAG: **Cuprates and Nickelates**
348, Baltimore Convention Center

A46 DMP: **Focus Session: Wide Bandgap Semiconductors I**
*Wetzel*
349, Baltimore Convention Center

**11:15 MONDAY MORNING**
**13 MARCH 2006**

B1 DCMP: **DCMP/DCOMP Prize Session**
*Clark, Meyer, Merlin, Vanderbilt*
Ballroom IV, Baltimore Convention Center

B2 DCMP: **Solid Helium**
*Clark, Beamish, Dai, Reatto, Ceperley*
Ballroom III, Baltimore Convention Center

B3 GSNP: **Uncovering the Structure of Complex Networks**
*Newman, Guimera, Vicsek, Muñoz, Almaas*
Ballroom I, Baltimore Convention Center

B4 DMP/ FIAP: **Advances in ZnO Materials Physics and Applications**
*Van de Walle, Tsukazaki, Brillson, Hsu, Norton*
308, Baltimore Convention Center

B5 FPS: **Nuclear Proliferation & Nuclear Terrorism**
*Cirincione, Fetter, Park, Carter*
309, Baltimore Convention Center

B6 DCMP: **Spin-Based Quantum Computing**
*Hanson, Ghosh, Flatté, Finley, Burkard*
310, Baltimore Convention Center

B7 DBP/ DCMP: **Bionanotechnology: Application and Fundamental Aspects of Processes at Nano-scale**
*Eisenberg, Kosztin, Stein, Yu, Kohli*
307, Baltimore Convention Center

B8 GSNP/ DFD: **Focus Session: Granular Materials Near Jamming**
*Campbell, Daniels*
314, Baltimore Convention Center

B9 DCMP: **Phase Transitions, Dynamics, and Excitations**
301, Baltimore Convention Center

B10 DCP: **Focus Sessions: Physical Chemistry of Nanoscale System II**
*El-Sayed, Dexheimer*
302, Baltimore Convention Center

B11 DCP: **Focus Session: Promises and Challenges in Chemical Dynamics II**
*Jortner, Brus*
303, Baltimore Convention Center

B12 DCMP/ DMP: **Quantum Metal Films and Overlayer Structures**
304, Baltimore Convention Center

B13 DCP/ DBP: **Focus Session: Spectroscopy of Biomolecules from Isolated Molecules to Cell Environment II**
*de Vries, Jarrold, Jockusch*
305, Baltimore Convention Center

B15 DCMP: **Metals: Lattice, Low D, Phonons**
*Burin*
311, Baltimore Convention Center

B16 FIAP: **Focus Session: Molecular-Scale Electronics I**
*Champagne*
312, Baltimore Convention Center

B17 FIAP: **Focus Session: Phase Transitions and Domains in Ferroelectric Nanostructures I**
*Levanyuk*
313, Baltimore Convention Center

B18 DMP: **Focus Session: Carbon Nanotubes: Synthesis, Processing and Characterization**
*Arnold*
315, Baltimore Convention Center

B19 GMAG/ DMP: **Focus Session: Transition Metal Oxide Ferromagnetic Semiconductors**
*Ogale*
316, Baltimore Convention Center

B20 GMAG/ DMP: **Focus Session: Phase Competition and Separation in Pervoskite Oxides**
*Wu*
317, Baltimore Convention Center

B21 DFD: **Colloids II: Colloidal Crystals, Gels, and Glasses**
318, Baltimore Convention Center

B22 GMAG/ FIAP/ DMP: **Focus Session: Current Driven Magnetization Dynamics II**
*Beach*
319, Baltimore Convention Center

B23 GMAG: **Quantum Spin Chains I**
320, Baltimore Convention Center

B26 DBP/ DPOLY: **Focus Session: Single Molecule Biophysics: DNA & RNA**
*Nelson*
323, Baltimore Convention Center

B28 DBP: **Experimental Techniques in Biomaterials Science**
325, Baltimore Convention Center

B29 DBP/ GSNP: **Focus Session: Micro-Organism Motility**
*Bodenschatz*
326, Baltimore Convention Center

B31 DCMP: **Insulating Nanostructures**
328, Baltimore Convention Center

B32 DCOMP/ DMP: **Focus Session: Computational Nanoscience I**
*Roundy*
329, Baltimore Convention Center

B33 GSNP: **Financial Markets and Other Applications of Statistical Physics**
336, Baltimore Convention Center

B35 DMP: **Focus Session: Nanoscale Thermal, Thermoelectric and Mass Transport: Theory and Simulation**
*Heinze*
338, Baltimore Convention Center

B36 DCMP: **Electronic Properties of Nanowires**
339, Baltimore Convention Center

B37 DCMP: **High-Tc: STM and Pseudogap**
340, Baltimore Convention Center

B38 DCMP: **Superconducting Devices and Applications**
341, Baltimore Convention Center

B39 DCMP: **Superconductivity—Magnetic Properties**
342, Baltimore Convention Center

B40 TGQI/ DCMP: **Topics in Quantum Foundations**
343, Baltimore Convention Center

B42 **SPS Undergraduate Research I**
345, Baltimore Convention Center

B43 DAMOP: **BEC in Trapped Atomic Gases**
346, Baltimore Convention Center

B46 DMP: **Focus Session: Wide Band Gap Semiconductors II**
*Wright*
349, Baltimore Convention Center

**13:30 MONDAY AFTERNOON 13 MARCH 2006**

B34 **Session on Authoring**
337, Baltimore Convention Center

**14:00 MONDAY AFTERNOON 13 MARCH 2006**

C1 **Poster Session I**
Exhibit Hall 2:00pm–5:00pm (DPOLY session: 11:15am–2:15pm), Baltimore Convention Center

**14:30 MONDAY AFTERNOON 13 MARCH 2006**

D1 DCMP: **Fluctuation and Relaxation Near Jamming**
*Langer, Makse, Abate, Silbert, Losert*
Ballroom IV, Baltimore Convention Center

D2 DCMP: **Quantum Hall Effect in Graphene**
*Kim, Geim, Sharapov, De Heer*
Ballroom III, Baltimore Convention Center

D3 FIP: **Scientists from Developing Countries: Is There an Effective Way to Support Meaningful Research?**
*Kofane, Ben lakdar, de Brito Cruz, M'Passi-Mabiala*
Ballroom I, Baltimore Convention Center

D4 DPOLY/ DMP: **Organic Electronics**
*Friend, Martin, Loo, Chabinyc, Lin*
308, Baltimore Convention Center

D5 FIAP: **Catalysis and Complexity: Ken Hass Memorial**
*Schneider, Wolverton, Carlsson, Davis*
309, Baltimore Convention Center

D6 DCOMP: **Simulating Hydrogen Storage: From Current Challenges to Future Promises**
*Johnson, Tse, Zhao, Jena, Goddard*
310, Baltimore Convention Center

D7 GMAG: **New Results in Geometrically Frustrated Magnets**
*Mendels, Moessner, Gardner, Schiffer, Lunkenheimer*
307, Baltimore Convention Center

D8 DFD/GSNP: **Patterns and Instabilities I**
314, Baltimore Convention Center

D9 DBP: **Methods in Nanobiotechnology**
*Roukes, Austin, Michl, Wiseman, Hla*
301, Baltimore Convention Center

D10 DCP: **Focus Session: Physical Chemistry of Nanoscale System III**
*Leone, Xie*
302, Baltimore Convention Center

D11 DCP: **Focus Session: Promises and Challenges in Chemical Dynamics III**
*Kawasaki*
303, Baltimore Convention Center

D12 DCMP/DMP: **Morphological Evolution and Instabilities**
304, Baltimore Convention Center

D13 DCP/DBP: **Focus Session: Spectroscopy of Biomolecules from Isolated Molecules to Cell Environment III**
*Baumgart, Ha*
305, Baltimore Convention Center

D15 DCMP: **Focus Session: Atomic Tunneling, Films, Nanostructures**
*Enss*
311, Baltimore Convention Center

D16 FIAP: **Focus Session: Negative Refractive Index I**
*Brueck*
312, Baltimore Convention Center

D17 FIAP: **Focus Session: Phase Transitions and Domains in Ferroelectric Nanostructures II**
*Gregg*
313, Baltimore Convention Center

D18 DMP: **Focus Session: Carbon Nanotubes: Synthesis and Growth II**
315, Baltimore Convention Center

D19 GMAG/DMP: **Focus Session: Semiconductor Spin Injection and Detection**
*Crowell*
316, Baltimore Convention Center

D20 DMP/GMAG: **Focus Session: Multiferroics I**
317, Baltimore Convention Center

D21 DFD: **Colloids III: Particles at Interfaces and in Confined Geometries**
318, Baltimore Convention Center

D22 GMAG/DMP: **Focus Session: Magnetic Nanopatterns**
*Chien*
319, Baltimore Convention Center

D23 GMAG/DMP/DCOMP: **Focus Session: MAGTHY I/Spin Structures and Dynamics**
*Dobrovitski*
320, Baltimore Convention Center

D25 DPOLY: **Focus Session: Particle Dynamics and Organization; Polymer Tethers and Interfacial Segregation**
*Smith*
322, Baltimore Convention Center

D26 DBP/DPOLY: **Focus Session: Dynamics of Nuclei Acid-Protein Interaction: Single Molecule**
*Wang, Wuite*
323, Baltimore Convention Center

D27 DCOMP: **Focus Session: Novel Computational Algorithms I**
*Hu, Aspuru-Guzik*
324, Baltimore Convention Center

D28 DPOLY: **Block Copolymer Thin Films**
325, Baltimore Convention Center

D29 DBP/GSNP: **Molecular Machines and Motors**
*Flood, Goldman*
326, Baltimore Convention Center

D30 DPOLY: **Multiphase Polymer Materials**
327, Baltimore Convention Center

D31 DCMP: **Properties of Semiconducting Nanostructures**
328, Baltimore Convention Center

D32 DCOMP/DMP: **Focus Session: Computational Nanoscience II**
329, Baltimore Convention Center

D33 DMP/GSNP: **Focus Session: Friction, Fracture and Deformation I**
*Dickinson*
336, Baltimore Convention Center

D35 DMP: **Focus Session: Thermal Transport and Thermoelectricity in Nanotubes and Graphene**
*Shi*
338, Baltimore Convention Center

D38 DMP: **Focus Session: Superconductivity—Properties of Doped and Irradiated Magnesium Diboride and Related Compounds**
*Putti*
341, Baltimore Convention Center

D39 DCMP: **Spin Properties of Superconductors**
342, Baltimore Convention Center

D40 TGQI/DCMP: **Focus Session: Foundations of Quantum Theory**
*Hardy*
343, Baltimore Convention Center

D42 SPS: **SPS Undergraduate Research II**
345, Baltimore Convention Center

D43 DAMOP: **Focus Session: Vortices and Vortex Lattices in Fermi and Bose Superfluid Gases**
*Zwierlein*
346, Baltimore Convention Center

D45 GMAG: **Strongly Correlated Electrons on Triangular Lattices**
348, Baltimore Convention Center

D46 DMP: **Focus Session: Wide Band Gap Semiconductors III**
*Huang*
349, Baltimore Convention Center

## 17:45 MONDAY EVENING 13 MARCH 2006

E5 **APS Prizes and Awards Ceremony**
309, Baltimore Convention Center

## 18:45 MONDAY EVENING 13 MARCH 2006

E6 **Welcome Reception**
Ballroom II, Baltimore Convention Center

## 20:00 MONDAY EVENING 13 MARCH 2006

F50 DCMP: **Emerging Emergent Phenomena**
*Witten, Lolle, Barabási, Sadoulet*
Grand Salons V-VI, Marriott Waterfront Hotel

## 8:00 TUESDAY MORNING 14 MARCH 2006

G1 **Nobel Prize Symposium and Special Prize Session**
*Hänsch, Hall, Glauber, Su, Grobe*
Ballroom IV, Baltimore Convention Center

G2 DCMP: **Quantum Criticality in Cuprates**
*Chamon, Tallon, Shibauchi, Lake, Broun*
Ballroom III, Baltimore Convention Center

G3 DCMP: **Coupled Superconducting Qubits**
*Shnirman, Martinis, Schuster, Plantenberg, Morpurgo*
Ballroom I, Baltimore Convention Center

G4 DPOLY: **Polymer Physics Prize**
*Leibler, Möller, Fredrickson, Candau, Colby*
308, Baltimore Convention Center

G5 DMP/FIAP: **Advanced Materials for Solar Energy Utilization**
*Lewis, Kurtz, Yong, Moore, Carlson*
309, Baltimore Convention Center

G7 GSNP: **Shear-Induced Patterns in Complex Fluids and Granular Matter**
*van Saarloos, Reichmann, Register, Davidovitch, Jaeger*
307, Baltimore Convention Center

G8 DFD/GSNP: **Patterns and Instabilities II**
314, Baltimore Convention Center

G10 DCP: **Focus Sessions: Physical Chemistry of Nanoscale System IV**
*Yang, Xia*
302, Baltimore Convention Center

G11 DCP: **Focus Session: Promises and Challenges in Chemical Dynamics IV**
*Shafer-Ray*
303, Baltimore Convention Center

G12 DCMP/DMP: **Self-Assembled Nanostructures: Growth and Patterning**
304, Baltimore Convention Center

G13 DCP/DBP: **Focus Session: Spectroscopy of Biomolecules from Isolated Molecules to Cell Environment IV**
*Zwier, Hochstrasser, Mons*
305, Baltimore Convention Center

G15 DCMP: **Mechanical Properties of Metals**
311, Baltimore Convention Center

G16 FIAP: **Focus Session: Negative Refractive Index II**
*Narimanov*
312, Baltimore Convention Center

G17 FIAP: **Focus Session: Emerging Research Devices and Materials for Microelectronics Industry I**
*Vogel*
313, Baltimore Convention Center

G18 DMP: **Focus Session: Carbon Nanotubes: Electronic and Optical Properties I**
*Spataru*
315, Baltimore Convention Center

G19 GMAG/DMP: **Focus Session: III-V Magnetic Semiconductors I**
*Poggio*
316, Baltimore Convention Center

G20 DMP/GMAG: **Focus Session: Complex Oxide Thin Films Surfaces and Interfaces II: Surfaces and Theory**
317, Baltimore Convention Center

G21 DFD: **Colloids IV: Polymeric and Colloid-Polymer Systems**
318, Baltimore Convention Center

G22 GMAG/DMP: **Focus Session: Magnetic Nanoparticles I**
*Leslie-Pelecky*
319, Baltimore Convention Center

G23 GMAG/DMP/DCOMP: **Focus Session: MAGTHY II/ Transport & General**
*Yao*
320, Baltimore Convention Center

G24 DPOLY: **Polymer Nanomaterials I**
321, Baltimore Convention Center

G25 DPOLY: **Structure and Dynamics of Functional Macromolecules**
322, Baltimore Convention Center

G26 DBP: **Focus Session: Trapping of Nanoscale Biological Objects**
*Cohen, Gratton*
323, Baltimore Convention Center

G27 DCOMP: **Focus Session: Novel Computational Algorithms II**
*Bai, Baroni*
324, Baltimore Convention Center

G28 DPOLY: **Focus Session: Microphysical Properties of Block Copolymer Aggregates I**
*Discher*
325, Baltimore Convention Center

G29 DBP: **Focus Session: Physical and Engineering Constraints on the Function of Biological Systems**
*Lezon, Doyle*
326, Baltimore Convention Center

G30 DPOLY/DMP: **Focus Session: Electronic Transport in Organic Films**
*De Feyter, Charra*
327, Baltimore Convention Center

G31 DCOMP/DMP: **Focus Session: Simulation of Complex Materials I**
*Wagner*
328, Baltimore Convention Center

G32 DMP/GMAG: **Focus Session: Orbital/Charge Order in Complex Oxides**
*Ye*
329, Baltimore Convention Center

G33 GSNP: **GSNP Student Award Session and Glasses**
336, Baltimore Convention Center

G34 DFD: **Glassy Dynamics and Jamming**
337, Baltimore Convention Center

G35 DCMP: **Nanoparticles, Nanotubes and Nanocrystals: Optical and Structural Properties**
338, Baltimore Convention Center

G37 DMP: **Focus Session: Nanoscale Materials Physics of Phase Transitions I**
*Dawber*
340, Baltimore Convention Center

G38 DMP: **Focus Session: Superconductivity—Carbon Alloying of Magnesium Diboride and Related Compounds**
*Wilke*
341, Baltimore Convention Center

G39 DCMP/ DCOMP: **Focus Session: Superconductivity: Theory and Computation I**
*Scalapino*
342, Baltimore Convention Center

G40 DMP: **Focus Session: Materials for Quantum Computing I**
343, Baltimore Convention Center

G41 DCMP: **Supersolid**
344, Baltimore Convention Center

G42 FEd: **Physics Education Research and Undergraduate Education**
345, Baltimore Convention Center

G44 DCMP: **Charge-Density Waves**
347, Baltimore Convention Center

G45 GMAG: **Phase Transitions in Ruthenates**
348, Baltimore Convention Center

G46 FIAP: **QHE, Including Graphene**
349, Baltimore Convention Center

## 11:15 TUESDAY MORNING 14 MARCH 2006

H1 GQI: **Quantum Information, Concepts and Computation**
*Blatt, Yamamoto, Raizen, Gisin, Whaley*
Ballroom IV, Baltimore Convention Center

H2 DCMP: **Spin Liquids in 2D Frustrated Quantum Magnets**
*Coldea, Alicea, Kanoda, Motrunich, Lee*
Ballroom III, Baltimore Convention Center

H3 DCMP: **Soft Interfaces**
*Quere, Zhang, Stebe, Hilgenfeldt, Gopal*
Ballroom I, Baltimore Convention Center

H4 DCMP: **Physics for Everyone and Depletion Forces In Vitro and Out of Equilibrium**
*Dahlberg, Falco, Schwartz, Snir, Lewis*
308, Baltimore Convention Center

H5 FEd/ FGSA/ FPS/ CSWP: **Forum: What Has Actually Changed in Physics Departments in the Situation for Women, Graduate Students and Other People?**
309, Baltimore Convention Center

H6 DCOMP: **The Response of Extended Systems to Electrical and Magnetic Fields: Novel, Theoretical, and Computational Methods**
*Thonhauser, MacDonald, Cai, Umari, Ghosez*
310, Baltimore Convention Center

H7 DBP: **Nanopore Biophysics**
*Kasianowicz, Dekker, Movileanu, Li, Aksimentiev*
307, Baltimore Convention Center

H8 GSNP: **Focus Session: Jamming in Glasses, Grains, and Gels I**
*Maloney*
314, Baltimore Convention Center

H10 DCP: **Focus Session: Frontiers in Computational Chemical Physics I**
*Lin, Angel*
302, Baltimore Convention Center

H11 DCP: **Focus Session: Chemical and Spectroscopic Applications of Nonlinear Optics I**
*Eisenthal, Shultz*
303, Baltimore Convention Center

H12 DCMP/ DMP: **Thin Film Growth and Interfaces**
304, Baltimore Convention Center

H13 DCP: **Colloid and Polymer Interfaces**
305, Baltimore Convention Center

H15 DCMP: **Metals: Electronic Structure, Fermiology, Transport**
311, Baltimore Convention Center

H16 FIAP: **Focus Session: Hydrogen Storage II**
*Ahn*
312, Baltimore Convention Center

H17 FIAP: **Focus Session: Emerging Research Devices and Materials for Microelectronics Industry II**
*Coufal*
313, Baltimore Convention Center

H18 DMP: **Focus Session: Carbon Nanotubes: Electronic and Optical Properties II**
*Lienau, Chang*
315, Baltimore Convention Center

H19 GMAG/ DMP: **Focus Session: III-V Magnetic Semiconductors II**
*Burch*
316, Baltimore Convention Center

H20 GMAG: **Frustration in 3D**
317, Baltimore Convention Center

H21 DFD: **Focus Session: Microfluidic Physics I**
*Paoletti*
318, Baltimore Convention Center

H22 GMAG/ DMP: **Focus Session: Nanoparticles and Nanocomposites**
*Wang*
319, Baltimore Convention Center

H23 GMAG/ DMP/ FIAP: **GMR and AMR**
320, Baltimore Convention Center

H24 DPOLY: **Polymers at Interfaces**
321, Baltimore Convention Center

H25 DPOLY: **Focus Session: Particle Dynamics and Organization**
322, Baltimore Convention Center

H27 DCOMP: **Computational Methods: Multiscale Modeling**
324, Baltimore Convention Center

H28 DPOLY/ DMP: **Focus Session: Energetics and Transport in Conjugated Organics**
*Silva*
325, Baltimore Convention Center

H29 DBP: **Focus Session: Physical Aspects of Morphogenesis: Computational Approaches**
*Brodland, Jiang*
326, Baltimore Convention Center

H30 DPOLY: **Padden Award Symposium**
327, Baltimore Convention Center

H31 DCOMP/ DMP: **Focus Session: Simulation of Complex Materials II**
*Ogitsu*
328, Baltimore Convention Center

H32 DCOMP/ DMP: **Focus Session: Computational Nanoscience III**
*Zhang*
329, Baltimore Convention Center

H33 DMP/ GSNP: **Focus Session: Friction, Fracture and Deformation II**
*Gnecco*
336, Baltimore Convention Center

H35 DCMP: **Electronic Properties of Quantum Wells and Superlattices**
338, Baltimore Convention Center

H36 DMP: **Focus Session: Single Molecule Conductance**
*Weber*
339, Baltimore Convention Center

H37 DMP: **Focus Session: Nanoscale Materials Physics of Phase Transitions II**
*Albrecht*
340, Baltimore Convention Center

H38 DCMP: **Superconductivity—Disordered Thin Films and Quantum Phenomena**
341, Baltimore Convention Center

H39 DCMP: **Focus Session: Superconductivity—Josephson Junctions and Pairing State Symmetry**
*Klemm*
342, Baltimore Convention Center

H40 DMP: **Focus Session: Materials for Quantum Computing II**
*Buhrman*
343, Baltimore Convention Center

H41 DMP: **Dielectric, Ferroelectric, and Piezoelectric Oxides I**
344, Baltimore Convention Center

H42 GSCCM/ DCMP: **Focus Session: Dynamic Compression**
*Hayes, Minich*
345, Baltimore Convention Center

H43 DAMOP: **Focus Session: Strongly Interacting Fermi Gases and the BCS-BEC Crossover II**
*Regal*
346, Baltimore Convention Center

H44 DCMP: **Quantum Phase Transitions**
347, Baltimore Convention Center

H45 DCMP: **Theoretical Methods in Strongly Correlated Electron Systems**
348, Baltimore Convention Center

H46 DMP: **Focus Session: Wide Band Gap Semiconductors IV**
*Qian*
349, Baltimore Convention Center

## 14:00 TUESDAY AFTERNOON 14 MARCH 2006

J1 **Poster Session II**
Exhibit Hall, 2:00pm–5:00pm, Baltimore Convention Center

## 14:30 TUESDAY AFTERNOON 14 MARCH 2006

K1 DAMOP: **Optical Frequency Clocks and Experimental Quantum Optics**
*Gill, Udem, Ye, Bergquist, Haroche*
Ballroom IV, Baltimore Convention Center

K2 DCMP: **Exotic Ordering in Spinels**
*Croft, Horibe, Khomskii, Sushkov, Radaelli*
Ballroom III, Baltimore Convention Center

K3 DCMP: **Electron Doped High Tc Superconductors**
*Dagan, Blumberg, Takahashi, Motoyama, Naito*
Ballroom I, Baltimore Convention Center

K4 DMP/ CSWP: **DMP/CSWP Prize Symposium**
*Chelikowsky, Cao, Dai, Zettl*
308, Baltimore Convention Center

K5 FIAP: **Microelectronics for Mid-Infrared through Terahertz**
*Gmachl, Prober, Shaner, Tredicucci, Schmidt*
309, Baltimore Convention Center

K6 COM: **Minorities in the Nanosciences**
*Mason, James, Noveron, Stokes*
310, Baltimore Convention Center

K7 DBP: **New Methods and Algorithms for Biomolecular Modeling**
*Darve, Sagui, Thorpe, Tuckerman, Yang*
307, Baltimore Convention Center

K8 GSNP: **Focus Session: Jamming in Glasses, Grains and Gels II**
*Blair*
314, Baltimore Convention Center

K10 DCP: **Focus Session: Frontiers in Computational Chemical Physics II**
*Reuter*
302, Baltimore Convention Center

K11 DCP: **Focus Session: Chemical and Spectroscopic Applications of Nonlinear Optics II**
*Shen, Simpson, Morita*
303, Baltimore Convention Center

K12 DMP/DCMP: **Focus Session: Magnetic Thin Films and Narrow Gap Semiconductors**
*Weitering*
304, Baltimore Convention Center

K13 DCP: **Atomic And Molecular Processes at Solid Surfaces**
305, Baltimore Convention Center

K16 FIAP: **Focus Session: Molecular-Scale Electronics II**
*Karna*
312, Baltimore Convention Center

K17 FIAP: **Focus Session: Si, Ge and SiGe Nanostructures**
*Ross, Kamins*
313, Baltimore Convention Center

K18 DPOLY: **Focus Session: Dillon Medal Symposium**
*Urayama*
315, Baltimore Convention Center

K19 GMAG/DMP: **Focus Session: III-V Magnetic Semiconductors III**
*van Schilfgaarde*
316, Baltimore Convention Center

K20 DMP/GMAG: **Focus Session: Multiferroics II—Hexagonal Systems**
*Fennie*
317, Baltimore Convention Center

K21 DFD: **Colloids V**
318, Baltimore Convention Center

K22 GMAG/FIAP/DMP: **Focus Session: Magnetization Dynamics**
*Rasing*
319, Baltimore Convention Center

K23 GMAG: **Quantum Magnets: BEC and 2D**
320, Baltimore Convention Center

K24 DPOLY: **Polymer Nanomaterials II**
321, Baltimore Convention Center

K25 DPOLY: **Polymer Electrolytes and Conduction**
322, Baltimore Convention Center

K26 DBP/DCMP: **Focus Session: Single Molecule Biophysics I**
*Chu*
323, Baltimore Convention Center

K27 DCOMP: **Density Functional Theory**
324, Baltimore Convention Center

K28 DPOLY: **Focus Session: Microphysical Properties of Block Copolymer Aggregates II**
*Santore*
325, Baltimore Convention Center

K29 DBP: **Proteins Structure and Function**
326, Baltimore Convention Center

K30 DMP: **Carbon Nanotubes: Applications and Novel Phenomena**
327, Baltimore Convention Center

K31 DCOMP/DMP: **Focus Session: Simulation of Complex Materials III**
*Blum*
328, Baltimore Convention Center

K32 DCOMP/DMP: **Focus Session: Computational Nanoscience IV**
329, Baltimore Convention Center

K33 GSNP: **Novel Moving Boundary Problems**
*Krug, Kessler, Ebert, Goldstein, Karma*
336, Baltimore Convention Center

K34 **Panel Discussion**
337, Baltimore Convention Center

K35 DCMP: **Electronic Properties and the Kondo Effect in Quantum Dots**
338, Baltimore Convention Center

K36 GMAG: **Magnetic Domains and Applied Magnetic Materials**
339, Baltimore Convention Center

K37 DCMP: **Superconductivity—Time Resolved Optical and Inelastic X-ray Scattering in Cuprates**
340, Baltimore Convention Center

K38 DCMP: **Superconductivity—Mesoscopics and Theory**
341, Baltimore Convention Center

K39 DCOMP/DCMP: **Focus Session: Superconductivity—Theory and Computation II**
*Fabrizio*
342, Baltimore Convention Center

K40 DMP: **Focus Session: Materials for Quantum Computing III**
*McDermott*
343, Baltimore Convention Center

K41 DMP: **Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides II**
*Venturini*
344, Baltimore Convention Center

K42 DMP/DCOMP: **Focus Session: Planetary Materials II**
345, Baltimore Convention Center

K43 DAMOP: **Trapped Fermi Gases**
346, Baltimore Convention Center

K44 DCMP: **Transport in Disordered Electronic Systems**
347, Baltimore Convention Center

K45 DCMP: **Heavy Fermions: Experiment**
348, Baltimore Convention Center

K46 FIAP: **Spectroscopy of Semiconductors**
349, Baltimore Convention Center

**17:30 TUESDAY EVENING**
**14 MARCH 2006**

L9 GIMS: **GIMS Business Meeting**
301, Baltimore Convention Center

L10 DCP: **DCP Business Meeting**
302, Baltimore Convention Center

L16 FIAP: **FIAP Business Meeting**
312, Baltimore Convention Center

L18 DPOLY: **DPOLY Business Meeting**
315, Baltimore Convention Center

L23 GMAG: **GMAG Business Meeting**
320, Baltimore Convention Center

L29 DBP: **DBP Business Meeting**
326, Baltimore Convention Center

L33 GSNP: **GSNP Business Meeting**
336, Baltimore Convention Center

L40 TGQI: **TGQI Business Meeting**
343, Baltimore Convention Center

L48 FIP: **FIP Business Meeting**
Galena, Marriott Waterfront Hotel

**17:45 TUESDAY EVENING**
**14 MARCH 2006**

L7 DBP: **Flexible Molecular Recognition: The New Paradigm**
*Matthews, Kern, Taylor, Jennings, Wang*
307, Baltimore Convention Center

**19:00 TUESDAY EVENING**
**14 MARCH 2006**

L49 DCMP: **DCMP Business Meeting**
Dover A, Marriott Waterfront Hotel

L50 DMP: **DMP Business Meeting**
Dover B, Marriott Waterfront Hotel

**19:30 TUESDAY EVENING**
**14 MARCH 2006**

M50 FPS: **Intelligent Design: Its Impact and Responses to It**
*Gunn, Berman, Slakey, Dean*
Grand Salon V, Marriott Waterfront Hotel

**8:00 WEDNESDAY MORNING**
**15 MARCH 2006**

N1 DCMP: **Topological Phases and Quantum Computing**
*Kitaev, Hermele, Freedman, Stern, Fendley*
Ballroom IV, Baltimore Convention Center

N2 DCMP: **Nanoscale Crystals**
*Craig, Alivisatos, Drndic, Krauss*
Ballroom III, Baltimore Convention Center

N3 DCMP: **Insulating Cobaltates: Mottness on a Triangular Lattice**
*Gasparovic, Hasan, Zandbergen, Balicas, Imai*
Ballroom I, Baltimore Convention Center

N4 DPOLY/DMP: **Polymer Crystallization**
*Cheng, Hsiao, Ungar, Muthukumar, Granasy*
308, Baltimore Convention Center

N5 FIAP: **Pake and AIP Industrial Physics Prizes**
*Duke, Semerjian, Palffy-Muhoray, Lubell, Edelstein*
309, Baltimore Convention Center

N6 DAMOP: **Fermi Superfluid Gases: Non-equal Spin Polarization (FFLO State) and p-Wave pairing**
*Son, Yip, Hulet, Diener, de Melo*
310, Baltimore Convention Center

N7 DCOMP: **Recent Advances in the Computation of Optical and Transport Properties of Nanostructures**
*Weissker, Bester, Gebauer, Sanvito, Pecchia*
307, Baltimore Convention Center

N8 DFD: **Granular Flows**
314, Baltimore Convention Center

N10 DCP: **Focus Session: Frontiers in Computational Chemical Physics III**
*Cui*
302, Baltimore Convention Center

N11 DCP: **Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects I: Helium Nanodroplets I**
*Drabbels, Tiggesbäumker*
303, Baltimore Convention Center

N12 DMP/ DCMP: **Focus Session: Alloy and Interface Composition**
*Hannon*
304, Baltimore Convention Center

N13 DCP: **Focus Session: Ultrafast and Ultrahigh Field Chemistry I: Strong Field Phenomena**
*Jones, Yamanouchi*
305, Baltimore Convention Center

N16 FIAP: **Focus Session: Hydrogen Storage III**
*Yildirim*
312, Baltimore Convention Center

N17 FIAP: **Focus Session: Semiconductors for THz and IR I**
*Perera*
313, Baltimore Convention Center

N18 DMP: **Focus Session: Carbon Nanotubes: Transport I**
*Strunk*
315, Baltimore Convention Center

N19 GMAG/ DMP: **Semiconductor Spin Transport**
316, Baltimore Convention Center

N20 DMP/ GMAG: **Focus Session: Complex Oxide Thin Films Surfaces and Interfacess III: New Materials, New Techniques, and Effects of Strain**
317, Baltimore Convention Center

N21 DFD: **Microfluidic Physics II**
318, Baltimore Convention Center

N22 GMAG/ DMP: **Focus Session: Magnetic Vortices and Exchange Biased Thin Films**
*Roshchin*
319, Baltimore Convention Center

N23 GMAG/ DMP/ DCOMP: **Focus Session: MAGTHY III: Oxides and Phase Transitions**
*Schulthess*
320, Baltimore Convention Center

N24 DPOLY: **Structure and Dynamics in Polymer Thin Films**
321, Baltimore Convention Center

N25 DPOLY/ DMP: **Focus Session: Organic Photovoltaics**
*Inganäs*
322, Baltimore Convention Center

N26 DBP/ DFD: **Focus Session: DNA and Protein Analysis with Micro and Nano Fluidics**
*Riehn, Hansen*
323, Baltimore Convention Center

N27 DCOMP: **Electronic Structure I**
324, Baltimore Convention Center

N28 DPOLY: **Polymer Adsorption and Surface Modification**
325, Baltimore Convention Center

N29 DBP: **Focus Session: Physical Models of Ion Channel Function**
*Gillespie, Coalson*
326, Baltimore Convention Center

N30 DPOLY: **Block Copolymer Phase Behavior**
*327, Baltimore Convention Center*

N31 DCMP: **Carbon Nanotubes: Theory**
*328, Baltimore Convention Center*

N32 DMP/ DPOLY: **Focus Session: Carbon Nanotubes: Composites and Applications**
*Baughman*
329, Baltimore Convention Center

N33 GSNP: **Focus Session: Instabilities & Turbulence in Complex Fluids**
*Sureshkumar*
336, Baltimore Convention Center

N35 GSNP: **Focus Session: Organization of Complex Networks**
*Mendes*
338, Baltimore Convention Center

N36 DMP: **Focus Session: Optical Properties of Nanostructures with S, Se, Te, and Ge**
339, Baltimore Convention Center

N37 DMP: **Focus Session: Nanoscale Fabrication, Assembly and Semiconductor Nanowires**
*Misra*
340, Baltimore Convention Center

N38 DCMP: **Transport Properties of High-Tc Superconductors**
341, Baltimore Convention Center

N39 DMP: **Focus Session: Superconductivity—Thin Films and Junctions Magnesium Diboride and Related Compounds**
*Xi*
342, Baltimore Convention Center

N41 DCMP: **Insulating and Dielectric Oxides**
344, Baltimore Convention Center

N42 DCOMP/ GSCCM/ DMP: **Focus Session: Simulations of Matter at Extreme Conditions I**
*Johansson*
345, Baltimore Convention Center

N43 DAMOP: **Quantum Optics and Strong Field Physics**
346, Baltimore Convention Center

N44 DCMP: **Quantum Criticality and Nematic Ordering**
347, Baltimore Convention Center

N45 DCMP: **Exotic Phases in Strongly Correlated Systems**
348, Baltimore Convention Center

N46 FIAP: **Semiconductor Devices/ Semiconductors General**
349, Baltimore Convention Center

## 9:30 WEDNESDAY MORNING 15 MARCH 2006

N34 **Session on Referreeing**
337, Baltimore Convention Center

## 11:15 WEDNESDAY MORNING 15 MARCH 2006

P1 DCMP: **Electron Transport in Single Molecules**
*Tao, Yao, Flensberg, Wolkow, Bar-Joseph*
Ballroom IV, Baltimore Convention Center

P2 DCMP: **The Electronic Properties of Overdoped Cuprates: The Clean Gateway to High-Tc Superconductivity**
*Hussey, Damascelli, Slezak, Taillefer, van der Marel*
Ballroom III, Baltimore Convention Center

P3 FEd: **Physics Teacher Preparation at a Crisis: Innovative Programs Addressing a National Need**
*Heron, Marder, Stewart, Finkelstein, Hein*
Ballroom I, Baltimore Convention Center

P4 GIMS: **Keithley Award Session**
*Hellman, Jach, Fortune, Migliori*
308, Baltimore Convention Center

P5 DFD: **Shedding Light on the Enigma of the Transition to Turbulence in Pipes and other Shear Flows**
*Mullin, Henningson, Waleffe, Kerswell, Tumin, Eckhardt*
309, Baltimore Convention Center

P6 GMAG: **Quantum Spin Dynamics in Molecular Nanomagnets**
*Waldmann, Chudnovsky, Sessoli, Harmon, Park*
310, Baltimore Convention Center

P7 GSNP/DBP: **Focus Session: Physics of Transcriptional Regulatory Networks**
*You, Buchler, Li, Huang, Vazquez*
307, Baltimore Convention Center

P8 DFD/GSNP: **Focus Session: Jets, Shocks & Splashes**
*Xu, Lohse*
314, Baltimore Convention Center

P10 DCP: **Focus Session: Frontiers in Computational Chemical Physics IV**
*Martinez*
302, Baltimore Convention Center

P11 DCP: **Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects II: Helium Nanodroplets II, Aerosols, and Miscellaneous**
*Signorell*
303, Baltimore Convention Center

P12 DCMP/DMP: **Metal Islands and Clusters**
304, Baltimore Convention Center

P13 DCP: **Focus Session: Ultrafast and Ultrahigh Field Chemistry II: Quantum Control**
*Silberberg, Girard*
305, Baltimore Convention Center

P16 FIAP: **Focus Session: Molecular-Scale Electronics III**
*Janes*
312, Baltimore Convention Center

P18 DMP: **Focus Session: Carbon Nanotubes: Opto-Electronics**
*Chen*
315, Baltimore Convention Center

P19 GMAG/DMP: **Focus Session: Spin Interference and Spin Hall Effect**
*Sih*
316, Baltimore Convention Center

P20 DMP/GMAG: **Focus Session: Cobaltites, Nickelates and Vanadates**
317, Baltimore Convention Center

P21 DFD: **Microfluidic Physics III**
318, Baltimore Convention Center

P22 GMAG/FIAP/DMP: **Focus Session: Spin Transport in Metals**
*Garzon*
319, Baltimore Convention Center

P23 GMAG: **Quantum Spin Chains II**
320, Baltimore Convention Center

P26 DBP/DCP: **Focus Session: Protein Dynamics in Folding and Function**
*Mildvan, de Alba, Miller, Summers, Campbell, Hall, Pastor, Redfield*
323, Baltimore Convention Center

P27 DCOMP: **Electronic Structure II**
324, Baltimore Convention Center

P29 DBP: **Biomolecular Structure and Functions**
326, Baltimore Convention Center

P30 DPOLY/DMP: **Focus Session: Organic Interfaces**
*Rosei*
327, Baltimore Convention Center

P31 DCMP: **Nanotubes: Theory and Experiment**
328, Baltimore Convention Center

P32 GMAG: **Spin Glasses**
329, Baltimore Convention Center

P33 DMP/GSNP: **Focus Session: Friction, Fracture and Deformation III**
*Falk*
336, Baltimore Convention Center

P35 DCMP: **Nanostructure Fabrication, Quantum Point Contacts, and Single Electron Transistors**
338, Baltimore Convention Center

P36 DMP: **Focus Session: Plasmon Resonances in Nanostructures**
339, Baltimore Convention Center

P38 DCMP: **Superconductivity—Optical Spectroscopy of Cuprates**
341, Baltimore Convention Center

P39 DCOMP/DCMP: **Focus Session: Superconductivity—Theory and Computation (Mainly First Principles)**
*Mazin*
342, Baltimore Convention Center

P40 DCOMP/TGQI: **Focus Session: Pathways to Practical Quantum Computing I**
*DiVincenzo*
343, Baltimore Convention Center

P41 DMP: **Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides III**
*Dierolf*
344, Baltimore Convention Center

P42 DMP/ DCOMP: **Focus Session: Planetary Materials III**
345, Baltimore Convention Center

P43 DAMOP: **Novel Phases in Quantum Gases**
346, Baltimore Convention Center

P44 DCMP: **Organic Conductors**
347, Baltimore Convention Center

P45 DCMP: **Structural and Ferroelectric Phase Transitions**
348, Baltimore Convention Center

P46 FIAP: **FQHE**
349, Baltimore Convention Center

## 13:00 WEDNESDAY AFTERNOON 15 MARCH 2006

Q1 **Poster Session III**
Exhibit Hall, 1:00pm–4:00pm (DPOLY session: 11:15am–2:15pm), Baltimore Convention Center

## 14:30 WEDNESDAY AFTERNOON 15 MARCH 2006

R1 DCMP DBP: **Cytoskeletal Dynamics and Mechanics**
*Svitkina, Julicher, Gopinathan, Gardel, Storm*
Ballroom IV, Baltimore Convention Center

R2 DCMP: **Fractional Quantum Hall Systems**
*Csathy, Gallais, Peterson, Kim, Schulze-Wischeler*
Ballroom III, Baltimore Convention Center

R3 DCMP: **Lateral Spin Transport**
*Ji, Bauer, Valenzuela, Otani*
Ballroom I, Baltimore Convention Center

R4 DPOLY: **Ionic, Dipolar and H-bonding Polymers**
*Breedveld, Dormidontova, Pochan, Cremer, Prabhu*
308, Baltimore Convention Center

R5 FGSA/ FIAP: **Paths from Academics to Employment**
*Czujko, Silbernagel, Seiler, Stanton, Garg*
309, Baltimore Convention Center

R6 CSWP: **U.S. Women in Physics: An International Perspective**
*Michelman-Ribeiro, Whitten, Horton, Ong, Hodari*
310, Baltimore Convention Center

R7 DBP/ FEd/ FPS: **The Experimental and Theoretical Foundations of Evolution**
*Keymer, Deem, Fisher, Lenski, Shapiro*
307, Baltimore Convention Center

R8 DFD: **Monolayers, Membranes & Microemulsions**
314, Baltimore Convention Center

R9 GIMS: **Imaging, Signal Detection and Processing**
301, Baltimore Convention Center

R10 DCP: **Focus Session: Surfaces and Interfaces in Electronic Materials I**
*Wieckowski, Switzer*
302, Baltimore Convention Center

R11 DCP: **Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects III: Molecular Clusters**
*Johnson*
303, Baltimore Convention Center

R12 DCMP/ DMP: **Dynamics at Silicon Surfaces**
304, Baltimore Convention Center

R13 DCP: **Focus Session: Ultrafast and Ultrahigh Field Chemistry III: Ultrafast Processes**
*Schafer, Villeneuve, Matsumoto*
305, Baltimore Convention Center

R16 FIAP: **Thermoelectrics**
312, Baltimore Convention Center

R17 FIAP: **Focus Session: Semiconductors for THz and IR II**
*Zhang*
313, Baltimore Convention Center

R18 DMP: **Focus Session: Carbon Nanotubes: Transport II**
*Roche*
315, Baltimore Convention Center

R19 GMAG/DMP: **Focus Session: Spin Hall Effect and Spin Transport**
*Engel*
316, Baltimore Convention Center

R20 DMP/GMAG: **Focus Session: Multiferroics III: Perovskites**
317, Baltimore Convention Center

R21 DFD/DBP: **Focus Session: Biological Hydrodynamics**
*Aranson*
318, Baltimore Convention Center

R22 GMAG/DMP: **Focus Session: Biomagnetism and Exchange Biased Thin Films**
*Hoffmann*
319, Baltimore Convention Center

R23 GMAG/FIAP: **Focus Session: Theory and Simulation for Information Storage Applications**
*Schrefl*
320, Baltimore Convention Center

R24 DPOLY: **Block Copolymer Applications**
321, Baltimore Convention Center

R25 DPOLY: **Adhesion and Viscoelasticity in Polymer Thin Films**
322, Baltimore Convention Center

R26 DBP/DPOLY: **Focus Session: Counterion Dynamics in Charged Biopolymer Systems**
*Wong, Netz*
323, Baltimore Convention Center

R27 DCOMP: **Many-Body/Strongly Correlated**
324, Baltimore Convention Center

R28 DBP: **Focus Session: Biological Networks: Structure, Dynamics and Function**
*El-Samad, Suel*
325, Baltimore Convention Center

R29 DBP: **Biomolecular Structure and Function**
326, Baltimore Convention Center

R30 DPOLY: **Polymer Nanocomposites**
327, Baltimore Convention Center

R31 DCMP: **Properties of Carbon Nanotubes**
328, Baltimore Convention Center

R32 DCOMP/DMP: **Focus Session: Computational Nanoscience V**
*Tangney*
329, Baltimore Convention Center

R33 DMP/GSNP: **Focus Session: Friction, Fracture and Deformation IV**
*Houston*
336, Baltimore Convention Center

R34 DFD: **Turbulence**
337, Baltimore Convention Center

R36 DMP: **Focus Session: Optical and X-ray Properties of Nanostructures**
*Vasiliev*
339, Baltimore Convention Center

R37 DMP: **Focus Session: Nanoscale Conductance Theory I**
*Baranger*
340, Baltimore Convention Center

R38 DCMP: **Superconductivity—Optical Spectroscopy of Cuprates: IR Hall Effect**
341, Baltimore Convention Center

R39 DCMP: **Superconductivity—Sodium Cobaltate**
342, Baltimore Convention Center

R40 DCOMP/TGQI: **Focus Session: Pathways to Practical Quantum Computing II**
*Laflamme*
343, Baltimore Convention Center

R41 DMP: **Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides IV**
*Streiffer*
344, Baltimore Convention Center

R42 DCMP/GSCCM: **Focus Session: Plasticity and Phase Transitions**
*Robinson, Lorenz*
345, Baltimore Convention Center

R43 DAMOP: **One Dimensional Bose Gases**
346, Baltimore Convention Center

R44 DCMP: **Experimental Studies of 115 Materials**
347, Baltimore Convention Center

R45 DCMP: **Strong Correlation in Metals: Mott Transition**
348, Baltimore Convention Center

R46 FIAP: **Electronic and Optical Properties of Semiconductors: First Principals**
349, Baltimore Convention Center

**17:30 WEDNESDAY EVENING 15 MARCH 2006**

S48 FED: **FED Business Meeting & Reception**
Grand Ballroom Salon III, Marriott Waterfront Hotel

**17:45 WEDNESDAY EVENING 15 MARCH 2006**

T7 DBP: **Physics, Chemistry and Biology of the Hydrophobic Effect**
*Li, Widom, Chandler, Truskett*
307, Baltimore Convention Center

**18:30 WEDNESDAY EVENING 15 MARCH 2006**

S49 DCOMP: **DCOMP Business Meeting**
Dover C, Marriott Waterfront Hotel

**19:30 WEDNESDAY EVENING 15 MARCH 2006**

T50 **Perspectives on our Energy Future**
*Koonin, Dehmer*
Grand Salon V, Marriott Waterfront Hotel

**8:00 THURSDAY MORNING 16 MARCH 2006**

U1 DCMP: **Spin Liquids and Superconductivity near the Mott Transition**
*Lee, Schmalian, Tremblay, Mook, Bourges*
Ballroom IV, Baltimore Convention Center

U2 DCMP: **Quantum Magnets in High Magnetic Fields**
*Broholm, Grenier, Zheludev, Hagiwara, Essler*
Ballroom III, Baltimore Convention Center

U3 DCMP: **Nanomechanical Architecture of Strained Thin Films**
*Prinz, Liu, Schmidt, Blick*
Ballroom I, Baltimore Convention Center

U4 DPOLY: **Lithography**
*Willson, Dammel, Nealey, Jones, Hinsberg*
308, Baltimore Convention Center

U5 FHP: **Low Temperature Physics, A Historical Perspective**
*Wheeler, Donnelly, Meyer, Lee*
309, Baltimore Convention Center

U6 DCOMP: **Strong Electronic Correlation in Solids: Applications of the LDA+U method**
*Louie, Janotti, Lichtenstein, Kunes, Cococcioni*
310, Baltimore Convention Center

U7 FIAP: **Nanoscale Pattern Generation and Lithography**
*Hector, Smith, Baglin, Kim, Russell*
307, Baltimore Convention Center

U8 DFD: **Granular Materials**
314, Baltimore Convention Center

U9 GIMS: **Scanning Probe Microscopy**
301, Baltimore Convention Center

U10 DCP: **Focus Session: Surfaces and Interfaces in Electronic Materials II**
*Buriak, Wang*
302, Baltimore Convention Center

U11 DCP: **Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects IV: Metal Clusters I**
*Duncan, Woeste*
303, Baltimore Convention Center

U12 DMP/ DCMP: **Focus Session: Electrochemical and Related Growth**
*Wang*
304, Baltimore Convention Center

U16 FIAP: **Nanotechnology: Applications and Measurements**
312, Baltimore Convention Center

U17 DBP: **Physics and Imaging in Medicine**
*Amols, Soares, Baird, Gueye*
313, Baltimore Convention Center

U18 DMP: **Focus Session: Carbon Nanotubes: Transport III**
*Ferrari*
315, Baltimore Convention Center

U19 GMAG/ DMP: **Focus Session: Semiconductor Spin Nanostructures for Quantum Computing**
*Mizel*
316, Baltimore Convention Center

U20 DMP/ GMAG: **Focus Session: Metal-Insulator Transition and Electron Phonon Coupling in Perovskites**
*Alvarez*
317, Baltimore Convention Center

U21 DFD: **Liquid Crystals I**
318, Baltimore Convention Center

U22 GMAG/ FIAP/ DMP: **Focus Session: Magnetic Tunneling I**
*Yang*
319, Baltimore Convention Center

U23 GMAG: **Frustration in 2D**
320, Baltimore Convention Center

U24 DPOLY: **Liquid-Crystalline Polymers**
321, Baltimore Convention Center

U25 DPOLY/ DMP: **Focus Session: Oligoacene Semiconductors**
322, Baltimore Convention Center

U26 GSNP/ DBP/ DPOLY: **Focus Session: Cytoskeletal Dynamics**
*Danuser*
323, Baltimore Convention Center

U27 DCMP: **Computational Methods: Monte Carlo/Molecular Dynamics I**
324, Baltimore Convention Center

U28 DBP/ DFp: **Focus Session: Biological Hydrodynamics II**
*Groisman, Brenner*
325, Baltimore Convention Center

U29 DBP/ DPOLY: **Focus Session: Nonequilibrium Fluctuation in Biomolecules and Artificial Nanodevices**
*Astumian, Janko*
326, Baltimore Convention Center

U30 DPOLY: **Focus Session: Mechanical Properties: Deformation, Rupture and Failure**
*Marder*
327, Baltimore Convention Center

U31 DCMP: **Nanotubes, Experiment**
328, Baltimore Convention Center

U33 GSNP: **Dynamics and Systems Far From Equilibrium**
336, Baltimore Convention Center

U35 DCMP: **Nanowires**
338, Baltimore Convention Center

U36 DMP: **Focus Session: Optical Properties of Nano-Dots, Holes, and Wires**
339, Baltimore Convention Center

U37 DMP: **Focus Session: Nanowire and Nanodot Quantum Devices**
*Doh*
340, Baltimore Convention Center

U38 DCMP: **1-D Superconductors and Organics**
341, Baltimore Convention Center

U39 DCMP: **Superconducting Proximity Effect—S/N and S/F**
*Eschrig*
342, Baltimore Convention Center

U40 DCOMP/ TGQI/ DAMOP: **Focus Session: Pathways to Practical Quantum Computing III**
*Cirac*
343, Baltimore Convention Center

U41 DCMP: **Dielectrics: Response Properties**
344, Baltimore Convention Center

U42 DCOMP/ GSCCM/ DMP: **Focus Session: Simulations of Matter at Extreme Conditions II**
*Ashcroft*
345, Baltimore Convention Center

U43 DAMOP: **Focus Session: Novel Phases in Low Dimensional Quantum Gases**
*Porto, Ho*
346, Baltimore Convention Center

U44 DCMP: **Models of Strongly Correlated Electrons**
347, Baltimore Convention Center

U45 DCMP: **Structural, Surface and Other Phase Transitions**
348, Baltimore Convention Center

U46 FIAP: **Optical Properties of Semiconductors: Excitons and Phonons**
349, Baltimore Convention Center

**11:15 THURSDAY MORNING 16 MARCH 2006**

V1 DCMP: **Quantum Hall Edges**
*Grayson, Yang, Rezayi, Roddaro, Papa*
Ballroom IV, Baltimore Convention Center

V2 DCMP: **Excitons in Single-Walled Carbon Nanotubes**
*Lanzani, Sheng, Zhao, Mirlin, Reich*
Ballroom III, Baltimore Convention Center

V3 DCMP: **Nonequilibrium Nano-oscillators**
*Cleland, Chan, Dykman, Vijayaraghavan, Clerk*
Ballroom I, Baltimore Convention Center

V4 DAMOP: **Dynamics and Non-equilibrium Phenomena in Optical Lattices**
*Batrouni, Polkovnikov, Weiss, Rigol, Minguzzi*
308, Baltimore Convention Center

V5 DMP: **Surfaces and Interfaces of Correlated Oxides**
*Kawasaki, Ahn, Santamaria, Bozovic, Mannhart*
309, Baltimore Convention Center

V7 GSNP/DBP: **Noise in Biological Systems**
*Cluzel, Tu, Levine, Setayeshgar, Sourjik*
307, Baltimore Convention Center

V8 DCOMP/DFD: **Focus Session: Simulations Using Particles**
*Koplik, Cottet*
314, Baltimore Convention Center

V9 GIMS: **Magnetic Force Microscopies**
301, Baltimore Convention Center

V10 DCP: **Focus Session: Surfaces and Interfaces in Electronic Materials III**
*Uosaki, Wei*
302, Baltimore Convention Center

V11 DCP: **Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects V: Metal Clusters II**
*Schooss, Cheshnovsky*
303, Baltimore Convention Center

V12 DMP/DCMP: **Focus Session: Wetting and Hard-Soft Interfaces**
*Cicero*
304, Baltimore Convention Center

V16 FIAP: **Nanotechnology: Biological and Polymer**
312, Baltimore Convention Center

V17 DBP: **Medical Physics Panel Discussion**
313, Baltimore Convention Center

V18 DMP: **Focus Session: Carbon Nanotubes: Transport IV**
*Gruner*
315, Baltimore Convention Center

V19 APS/AIP: **The Changing Dynamics of Industrial Research as a Consequence of Global Trends**
*Taub, Stork, Durcan, Weinrib, Feist*
316, Baltimore Convention Center

V20 GMAG/DMP: **Focus Session: Semiconductor Spin Dynamics: Optics**
*Hall*
317, Baltimore Convention Center

V21 DFD: **Liquid Crystals II: Nano & Bio**
318, Baltimore Convention Center

V22 GMAG/FIAP/DMP: **Focus Session: Magnetic Tunneling II**
319, Baltimore Convention Center

V23 GMAG: **Spin Waves**
320, Baltimore Convention Center

V24 DPOLY: **Charged and Ion-Containing Polymers: Properties**
321, Baltimore Convention Center

V25 DPOLY: **Polymer Composites—Nanotubes and Nanoclays**
*Dhinojwala*
322, Baltimore Convention Center

V26 DBP: **Cellular Biomechanics**
323, Baltimore Convention Center

V27 DCOMP: **Computational Methods: Monte Carlo/Molecular Dynamics II**
324, Baltimore Convention Center

V28 DPOLY: **Rheology of Biopolymer Solutions**
325, Baltimore Convention Center

V29 DBP/ DCMP: **Nonlinear Phenomena & Pattern Formation in Biology**
326, Baltimore Convention Center

V30 DPOLY: **Focus Session: Mechanical Properties: Microscale Deformation and Failure**
*Sue*

350, Baltimore Convention Center

## 14:30 THURSDAY AFTERNOON 16 MARCH 2006

W1 DCMP: **ARPES in High Tc Superconductors**
*Dessau, Valla, Chubukov, Cuk, Ino*
Ballroom IV, Baltimore Convention Center

W2 DCMP: **Imaging Charge and Spin and Semiconductors**
*Steele, Komiyama, LeRoy, Aidala, Hasegawa*
Ballroom III, Baltimore Convention Center

W3 DCMP: **Topological Aspects of Electron Transport in Solids**
*Nagaosa, Haldane, Kane, Bernevig*
Ballroom I, Baltimore Convention Center

W4 DPOLY: **Carbon Nanotube Dispersions**
*Hobbie, Pasquali, Poulin, Windle, Winey*
308, Baltimore Convention Center

W5 FHP: **A Century of Critical Phenomena**
*Sengers, Voronel, Ahlers, Fisher, Kadanoff*
309, Baltimore Convention Center

W6 FIAP: **New Applications of Silicon in Photonics and Biomedicine**
*Manalis, Jalali, Lipson, Murphy, Vlasov*
310, Baltimore Convention Center

W7 DBP/ DPOLY: **Physics of Cell Elasticity, Interactions and Tissue Formation**
*Riveline, Bruinsma, Janmey, Safran, Suresh*
307, Baltimore Convention Center

W8 GSNP/ DFD: **Focus Session: Nonlinear Electrokinetics**
*Rubinstein*
314, Baltimore Convention Center

W9 GIMS: **X-ray, Light, and Particle Scattering and Diffraction**
301, Baltimore Convention Center

W10 DCP: **Focus Session: Surfaces and Interfaces in Electronic Materials IV**
*Penner, Goesele*
302, Baltimore Convention Center

W11 DCP: **Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects V: Nanocatalysis, Supported Clusters I**
*Heiz, Moseler*
303, Baltimore Convention Center

W12 DCMP/ DMP: **Molecules on Surfaces**
304, Baltimore Convention Center

W16 FIAP: **Semiconductor Applications**
312, Baltimore Convention Center

W18 DMP: **Focus Session: Carbon Nanotubes: Electronic and Optical Properties III**
*Maruyama*
315, Baltimore Convention Center

W19 GMAG/ DMP: **Focus Session: Semiconductor Spin Transport: Noise/Theory**
316, Baltimore Convention Center

W20 DMP/ GMAG: **Focus Session: Multiferroics IV**
*Loidl*
317, Baltimore Convention Center

W21 DFD: **Liquid Crystals III**
318, Baltimore Convention Center

W22 GMAG/ DMP: **Focus Session: Magnetic Nanoparticles II**
*Dvorak*
319, Baltimore Convention Center

W23 GMAG/ DMP/ DCOMP: **Focus Session: MAGTHY IV/ab initio Studies**
*Stepanyuk*
320, Baltimore Convention Center

W24 DPOLY: **Focus Session: Lithography**
*Soles, Jonas*
321, Baltimore Convention Center

W25 DPOLY: **Gels and Networks**
322, Baltimore Convention Center

W26 DBP: **Focus Session: Biological Photophysics**
*Zhong, Venugopalan*
323, Baltimore Convention Center

W28 DPOLY/ DMP: **Focus Session: Ordered Optoelectronic Organics**
325, Baltimore Convention Center

W29 DBP: **Biological Networks and System Biology**
326, Baltimore Convention Center

W30 DPOLY/ DBP: **Focus Session: Biopolymers at Interfaces**
*Ober*
327, Baltimore Convention Center

W31 DCMP: **Nanotubes: Devices**
328, Baltimore Convention Center

W32 DCMP: **Glassy and Amorphous Systems**
329, Baltimore Convention Center

W33 DFD: **Nonequilibrium and Templated Assembly**
336, Baltimore Convention Center

W34 DFD: **Fluid Structure & Properties**
337, Baltimore Convention Center

W36 DMP: **Focus Session: Optical Properties of Nanostructures of Si & GaAs**
*Chou, Dal Negro*
339, Baltimore Convention Center

W37 DMP: **Nanoscale Conductance Theory II**
340, Baltimore Convention Center

W38 DCMP: **Flux Pinning and Critical Currents**
341, Baltimore Convention Center

W39 DCMP: **Superconductivity—Josephson Junctions and Qubits**
342, Baltimore Convention Center

W40 TGQI/ DAMOP: **Quantum Communication, Cryptography and Computation**
343, Baltimore Convention Center

W41 DCMP: **Cold Fusion**
344, Baltimore Convention Center

W42 DCOMP/ GSCCM/ DMP: **Focus Session: Simulations of Matter at Extreme Conditions III**
*Streitz*
345, Baltimore Convention Center

W43 DAMOP/ GQI: **Focus Session: Cold Atoms in Optical Lattices**
*Demler*
346, Baltimore Convention Center

W45 GMAG: **Spin Structure in Magnetic Materials**
*348, Baltimore Convention Center*

W46 FIAP: **Compound Semiconductor Defects and Dopants**
349, Baltimore Convention Center

W47 FIAP: **Quantum Transport in Semiconductors: Theory and Experiment**
350, Baltimore Convention Center

**8:00 FRIDAY MORNING 17 MARCH 2006**

Y1 DCMP/ DBP: **Engineering Biomolecules and Circuits by Rational Design and Genetic Selection**
*Hwa, Guet, Goulian, Liao, Noireaux*
Ballroom IV, Baltimore Convention Center

Y2 DCMP: **Electrostatic Levitation and High Energy X-rays**
*Rogers, Hyers, Goldman, Fadley, Lee*
Ballroom III, Baltimore Convention Center

Y4 GMAG: **High TMR MgO Tunneling and Spin Momentum Transfer Materials, Physics, and Devices**
*Parkin, Yuasa, Fuchs, Huai, Sun*
308, Baltimore Convention Center

Y5 FIAP: **New Functionalities in Glasses and Nanomaterials**
*Chakravorty, Gopalan, Jain, Kieffer, Mazur*
309, Baltimore Convention Center

Y6 DCOMP: **Is the Hubbard/t-J Model a High Temperature Superconductor?**
*Pryadko, Putikka, Troyer, Ogata*
310, Baltimore Convention Center

Y7 DCMP: **Challenges and Issues in Nanowire Nanodevices**
*Friedman, Hashizume, Cobden, Aono*
307, Baltimore Convention Center

Y8 DFD: **General Fluid Dynamics**
*Barranco*
314, Baltimore Convention Center

Y12 DCMP/ DMP: **Oxide Surface and Interfaces**
304, Baltimore Convention Center

Y16 FIAP: **Optics and Optoelectronics**
312, Baltimore Convention Center

Y18 DMP: **Focus Session: Carbon Nanotubes: Adsorption and Gas Surface Interactions with Carbon Nanotubes**
315, Baltimore Convention Center

Y19 GMAG/ DMP: **Focus Session: Novel Ferromagnetic Semiconductors I**
*Saito*
316, Baltimore Convention Center

Y20 GMAG/ DMP: **Focus Session: Ruddlesden-popper Phase Manganites**
*Hayward*
317, Baltimore Convention Center

Y22 GMAG/ FIAP: **Focus Session: Coupled Thin-Film Structures for Magnetic Recording**
*Thiele*
319, Baltimore Convention Center

Y23 GMAG: **Single Molecule Magnets**
320, Baltimore Convention Center

Y24 DPOLY: **Polymer Melts & Solutions: Structure & Solubility**
321, Baltimore Convention Center

Y25 DPOLY: **Charged and Ion-Containing Polymers: Computation**
322, Baltimore Convention Center

Y26 DBP: **Focus Session: Physics of Physiological Systems**
*Ben-Jacob*
323, Baltimore Convention Center

Y28 DPOLY/DMP: **Focus Session: Magnetic and Doping Effects in Cojugated Organics**
325, Baltimore Convention Center

Y29 DBP/DPOLY: **Focus Session: Noise and Fluctuation in Biological Systems**
*van Oudenaarden, de Gennes*
326, Baltimore Convention Center

Y30 DPOLY/DBP: **Focus Session: Biopolymers I: Phase Transitions**
*Garcia, Onuchic*
327, Baltimore Convention Center

Y31 DCMP: **Quasicrystals, Adsorption on Quasicrystals, Porous and Random Materials**
329, Baltimore Convention Center

Y33 GSNP: **Statistical Physics: Dynamics and Transitions**
336, Baltimore Convention Center

Y37 DMP: **Focus Session: Probing Novel Nanostructures**
*Fölsch*
340, Baltimore Convention Center

Y38 DCMP: **Superconductivity—Vortex Lattices and Pinning Center Arrays**
341, Baltimore Convention Center

Y39 DCMP: **Superconductivity—Materials and Processing**
342, Baltimore Convention Center

Y40 TGQI/DCMP: **Solid State Quantum Computing I**
343, Baltimore Convention Center

Y45 GMAG: **Magnetic Phase Transitions**
348, Baltimore Convention Center

Y46 FIAP: **Bilayers, Wigner Crystals**
349, Baltimore Convention Center

## 11:15 FRIDAY MORNING 17 MARCH 2006

Z1 DCMP: **Strong Interaction Effects in Small Conductors**
*Petta, Matveev, Steinberg, Fiete, LeHur*
Ballroom IV, Baltimore Convention Center

Z2 DCMP: **Resonant Inelastic X-ray Scattering in Complex Oxides**
*Kim, Hancock, Ishii, Ghiringhelli, Li*
Ballroom III, Baltimore Convention Center

Z4 DPOLY/DBP: **Biopolymers**
*Vogel, Sheetz, Perkins, Greer, Horkay*
308, Baltimore Convention Center

Z7 DBP: **Synchrony and Complexity in Brain Activity and Function**
*Towle, Nadkarni, Schiff, Lehnertz, Zochowski*
307, Baltimore Convention Center

Z18 DMP: **Focus Session: Carbon Nanotubes: Double Wall Nanotubes, Sheets and Chains**
*Kuzmany*
315, Baltimore Convention Center

Z19 GMAG/DMP: **Focus Session: Spin Dynamics in Quantum Dots**
*Abstreiter*
316, Baltimore Convention Center

Z20 GMAG/DMP: **Focus Session: Novel Ferromagnetic Semiconductors II**
317, Baltimore Convention Center

Z22 GMAG/FIAP: **Focus Session: FePt Nanoparticles for Information Storage**
*Weller*
319, Baltimore Convention Center

Z23 GMAG: **Strongly Correlated Electrons II**
320, Baltimore Convention Center

Z24 DPOLY: **Polymer Melts & Solutions: Rheology & Dynamics**
321, Baltimore Convention Center

Z25 DPOLY: **Molecular Dynamics: Theory and Simulation**
322, Baltimore Convention Center

Z26 DBP: **Radiation Therapy and Medical Imaging Techniques**
323, Baltimore Convention Center

Z28 DBP/GSNP: **Methods of Statistical Physics, Population Dynamics and Epidemiology**
*Brockmann*
325, Baltimore Convention Center

Z31 DCMP: **Complexed Structured Materials, Glasses and Clathrates**
329, Baltimore Convention Center

Z33 GSNP: **Statistical and Nonlinear Physics**
336, Baltimore Convention Center

Z37 DMP: **Focus Session: Nanoscale Conductance Theory III**
340, Baltimore Convention Center

Z38 DCMP: **High Tc Cuprates: ARPES**
341, Baltimore Convention Center

Z39 DCOMP/DCMP: **Focus Session: Superconductivity—Theory and Computations (Mostly Phonons)**
342, Baltimore Convention Center

Z40 TGQI/DCMP: **Solid State Quantum Computing II**
343, Baltimore Convention Center

Z45 GMAG: **Mostly Spinels**
348, Baltimore Convention Center

Z46 FIAP: **2D Multi-Valley Systems: QHE Experiment**
349, Baltimore Convention Center

# MAIN TEXT

**SESSION N1: TOPOLOGICAL PHASES AND QUANTUM COMPUTING**
**Wednesday Morning, 15 March 2006; Ballroom IV, Baltimore Convention Center at 8:00**
**Eduardo Fradkin, University of Illinois, presiding**

**8:00**
**N1 1 Protected qubits and quantum computation using Josephson junctions.**
ALEXEI KITAEV, *Caltech & Microsoft*

Several schemes of topological protection have been proposed, in which qubits are realized as degenerate ground states of quantum many-body systems so that all likely perturbations are exponentially suppressed. In the realm of Josephson junction physics, this approach was pioneered by Doucot, Vidal, Ioffe, and Feigelman in 2002. I will report a variation of their scheme that offers greater robustness and flexibility. Its key element is a ''quantum transformer,'' a superconducting current mirror operated in the quantum regime. This is a four-terminal device whose energy depends only on $\phi_1 - \phi_2 + \phi_3 - \phi_4$, with exponentially small ''error terms'' like $\cos(\phi_1 - \phi_4)$. The qubit is implemented by connecting terminal 1 with 3 and 2 with 4. I will describe a realization of the basic element, qubit measurements and unitary gates, and also discuss some parameter tradeoffs.

**8:36**
**N1 2 Quantum critical phases in two dimensions: U(1) spin liquids.**
MICHAEL HERMELE, *Physics Department, Massachusetts Institute of Technology*

Usually, we expect that stable phases of matter can be described in terms of quasiparticle excitations that interact only weakly at low energies. However, it is now clear that certain quantum spin liquids dramatically violate this expectation, but can nonetheless exist as stable zero-temperature phases in two-dimensional systems. These are the critical or algebraic spin liquids, which have no broken- symmetry ordering, but support gapless spin-carrying excitations. These states are promising candidates for the longstanding goal of the unambiguous experimental detection of a quantum spin liquid state; they have been suggested to play a role in certain strongly correlated materials, and they possess a variety of striking, and measurable, properties. I will discuss recent work on the simplest algebraic spin liquids. These are a type of two-dimensional U(1) spin liquid, and can be described at low energies by gapless Dirac fermions (spinons) coupled to a compact U(1) gauge field (photon). I will outline an argument that establishes the stability of these states in a large-N limit, and thus resolved a longstanding controversy. Next, I will discuss some of the remarkable properties of these states, and conclude with a discussion of open issues.

**9:12**
**N1 3 Non-Abelian topological phases.**
MICHAEL FREEDMAN, *Microsoft*

I will discuss the role of topology in the storage and processing quantum information. Chern-Simons theories in their chiral and doubled versions will be discussed. The Fractional quantum hall effect is the leading example of topological phases and may be home to striking nonabelian examples such as the $\nu = 5/2$ state. These examples will be considered within a larger mathematical framework.

**9:48**
**N1 4 Proposed experiments to probe the non-abelian $\nu = 5/2$ quantum Hall state.***
ADY STERN, *Weizmann Institute of Science*

We propose several experiments to test the non-abelian nature of quasi-particles in the fractional quantum Hall state of $\nu = 5/2$. One set of experiments studies interference contribution to back-scattering of current, and is a simplified version of an experiment suggested recently by Das Sarma et al. A second set looks at thermodynamic properties of a closed system. A third set looks at electronic transport in an array of immobile quesi-particles. The first two sets are only weakly sensitive to disorder-induced distribution of localized quasi-particles.

*Work done with B.I. Halperin (Harvard) and E. Grosfeld (Weizmann).

**10:24**
**N1 5 Realizing non-Abelian statistics in time-reversal invariant systems.**
PAUL FENDLEY, *University of Virginia*

Motivated by the search for a quantum computer robust against errors, much theoretical effort has been devoted to finding systems with quasiparticles obeying non-abelian statistics. I discuss a general method of constucting quantum loop gases with such behavior, focusing in particular on the simplest time-reversal-invariant model (P. Fendley and E. Fradkin, Phys. Rev. B 72 (2005) 024412 [cond-mat/0502071]). The quasiparticles of this model are called ''Fibonacci anyons,'' and their braiding is related to SO(3) Chern-Simons theory. I also discuss the quantum critical point governing the transition from a topological phase to a conventionally-ordered phase.

**SESSION N2: NANOSCALE CRYSTALS**
**Wednesday Morning, 15 March 2006; Ballroom III, Baltimore Convention Center at 8:00**
**Dmitri Talapin, Lawrence Berkeley Laboratory, presiding**

**8:00**
**N2 1 LeRoy Apker Award (2005): Tunable Nonlocal Spin Control in a Coupled Quantum Dot System.**
NATHANIEL CRAIG, *Stanford University*

The effective interaction between magnetic impurities in metals that can lead to various magnetic ground states often competes with a tendency for electrons near impurities to screen the local moment (known as the Kondo effect). The simplest system exhibiting the richness of this competition, the two-impurity Kondo system, was realized experimentally in the form of two quantum dots coupled through an open conducting region. We demonstrate nonlocal spin control by suppressing and splitting Kondo resonances in one quantum dot by changing the electron number and coupling of the other dot. The results suggest an approach to nonlocal spin control that may be relevant to quantum information processing.

**8:36**
**N2 2 Electrical Transport Through a Single Semiconductor Nanocrystal Tetrapod.**
A. PAUL ALIVISATOS, *University of California, Berkeley, and Lawrence Berkeley National Laboratory*

Semiconductor nanocrystal tetrapods represent a unique complex nanostructure of interest for multiterminal electrical and electromechanical studies. We demonstrate by single electron transport measurements the electronic coupling between the nanotetrapod core quantum dot and the four arm quantum rods. Either ionic or covalent bonding-type of coupling can exist when the interaction between quantum dot at the junction and arm rods is weak or strong. In addition, we demonstrate a new integrated single electron transistor scheme enabled by the unique coupled nanotetrapod systems: one arm can be used as a sensitive arm-gate to control the electrical transport through the whole system. The work here reveals that nanotetrapods and other branched colloidal nanocrystals represent a new class of chemically controlled ''artificial molecules'' of coupled quantum dots.

**9:12**
**N2 3 Controlled assembly and electronics in semiconductor nanocrystal-based devices.**
MARIJA DRNDIC, *University of Pennsylvania*

I will discuss the assembly of semiconductor nanocrystals (CdSe and PbSe) into electronic devices and the basic mechanisms of charge transport in nanocrystal arrays [1-4]. Spherical CdSe nanocrystals show robust memory effects that can be exploited for memory applications [1]. Nanocrystal memory can be erased electrically or optically and is rewritable. In PbSe nanocrystal arrays, as the interdot coupling is increased, the system evolves from an insulating regime dominated by Coulomb blockade to a semiconducting regime, where hopping conduction is the dominant transport mechanism [2]. Two-dimensional CdSe nanorod arrays show striking and anomalous transport properties, including strong and reproducible non-linearities and current oscillations with dc-voltage [4]. I will also discuss imaging of the charge transport in nanocrystal-based electronic devices. Nanocrystal arrays were investigated using electrostatic force microscopy (EFM) and transmission electron microscopy (TEM) [3]. Changes in lattice and transport properties upon annealing in vacuum were revealed. Local charge transport was directly imaged by EFM and correlated to nanopatterns observed with TEM. This work shows how charge transport in complex nanocrystal networks can be identified with nm resolution [3]. This work was supported by the ONR grant N000140410489, the NSF grants DMR-0449553 and MRSEC DMR00-79909, and the ACS PRF grant 41256-G10. References: 1) Fischbein M. **9:48**
**N2 4 Localized charge of single CdSe quantum rods and the role of lattice imperfections.**
TODD KRAUSS, *University of Rochester*

The local electronic structure of colloidal semiconductor nanoparticles is of significant fundamental and technical interest. Electrostatic force microscopy was used to determine that single CdSe quantum rods (QRs) have a permanent polarization surface-charge density, an unexpected observation for supposedly well-shaped, neutral dielectric particles. To investigate the source of the surface charge, we performed electron nanodiffraction studies with a scanning transmission electron microscope (STEM). Electron nanodiffraction patterns suggest that rotations exist between various ''sections'' of individual QRs, and that the rotation axes may form substantial angles with the c-axis. Thus, the surface charge results from the slight angle between the QR sides and the direction of internal electric polarization. Despite the large dipole moment expected for CdSe QRs, none was observed. The unavoidable presence of permanently charged surfaces on CdSe QRs has the potential to impede the development of novel devices incorporating these materials.

## SESSION N3: INSULATING COBALTATES: MOTTNESS ON A TRIANGULAR LATTICE
**Wednesday Morning, 15 March 2006; Ballroom I, Baltimore Convention Center at 8:00**
**Patrick Lee, Massachusetts Institute of Technology, presiding**

**8:00**
**N3 1 Neutron scattering study of novel magnetic order in $Na_{0.5}CoO_2$.***
GORAN GASPAROVIC, *MIT*

The layered sodium cobaltates, $Na_xCoO_2$, have attracted much recent attention, due to their unusual thermodynamic properties, as well as the recent discovery of superconductivity in the hydrated composition. These strongly correlated systems exhibit a rich electronic phase diagram as a function of sodium doping, $x$. A particularly intriguing insulating phase is realized at $x = 1/2$, featuring a long range sodium order, a metal-insulator phase transition at 51 K, and a magnetic ordering transition at 88 K. We present polarized and unpolarized neutron scattering measurements of the magnetic order in single crystals of $Na_{0.5}CoO_2$. Our data indicate that below $T_N = 88$ K the spins form a novel antiferromagnetic pattern within the CoO2 planes, consisting of alternating rows of ordered and non-ordered Co ions. The domains of magnetic order are closely coupled to the domains of Na ion order, consistent with such a two-fold symmetric spin arrangement. Magnetoresistance and anisotropic susceptibility measurements further support this model for the electronic ground state.

*Work done in collaboration with R. A. Ott, J.-H. Cho, F. C. Chou, Y. Chu, J. W. Lynn, and Y. S. Lee. Supported by DOE DE-FG02-04ER46134, and NSF MRSEC DMR02-13282.

**8:36**
**N3 2 Quasiparticles, Fermi surface topology and Phase transitions in $Na_xCoO_2$.***
M. ZAHID HASAN, *Dept. of Physics, Princeton University, Princeton, NJ*

Recently discovered triangular cobaltate class is a novel realization of doped Mott insulators on a triangular spin- lattice. This system exhibits superconductivity, spin-density- waves, charge-order, metal-insulator phase transitions and colossal thermopower as well as Mott and Band insulation. We employ state-of-the-art ARPES to uncover the nature of electron motion in the cobaltates over the phase diagram. Quasiparticle dynamics (Fermi velocity, bandwidth, FS topology, correlation parameters, quasiparticle coherence) we extract from the data provides valueable insights into the novel phases of matter realized on this first realization of a triangular lattice Mott system. Low-T metal-insulator (order-disorder) phase transition will be discussed in this presentation.

*Work in collaboration with D. Qian, R.J. Cava, Z. Hussain and A. Fedorov. This work is supported by U.S. DOE, NSF and Princeton Center for Complex Materials and partially carried out at the Advanced Light Source.

**9:12**

**N3 3 Sodium Ion Ordering in double-layered and triple-layered $Na_xCoO_2$.**

HENNY ZANDBERGEN, *Dept. of Chemistry and Princeton Materials Inst., Princeton University; National Centre for HREM, Dept. of Nanoscience, Delft University of Technology*

The layered sodium cobalt oxide $Na_xCoO_2$ is studied by electron diffraction for a wide range of sodium contents, $0.15 < x < 0.75$. This range in compositions is obtained by removal of Na by various methods for the starting materials $Na_{0.7}CoO_2$, and $Na_{1.0}CoO_2$ The structure of $Na_xCoO_2$ is based the stacking of triangular O-Co-O layers with Na planes. The Co atoms are in edge-sharing $CoO_6$ octahedra. For the starting compound $Na_{0.7}CoO_2$, the $Na^+$ ions are in a trigonal prismatic coordination whereas for $Na_{1.0}CoO_2$ the $Na^+$ coordination is octahedral. Prismatic coordination occurs when the close packed oxygen planes directly adjacent to the Na plane have the same projection into the basal plane (A-Na-A), whereas octahedral coordination of Na occurs when the directly adjacent oxygen planes have different projections (A-Na-B) into the basal plane. Due to this difference in stacking the a axis is about 1.08 nm and 1.65 nm for $Na_{0.7}CoO_2$ and $Na_{1.0}CoO_2$respectively. For $Na_{0.7}CoO_2$ as well as $Na_{1.0}CoO_2$a series of superstructures are observed, which can be explained with ordered Na ion-Na vacancy superlattices. The structural principle for some of the observed ordering schemes, particularly near $x=0.5$, is, surprisingly, the presence of lines of Na ions and vacancies rather than simply maximized Na-Na separations. With $Na_{0.7}CoO_2$ as starting material, the most strongly developed superlattice is found for the composition $Na_{0.5}CoO_2$. With $Na_{1.0}CoO_2$ as starting material, the most strongly developed superlattice is found for the compositions $Na_{0.75}CoO_2$and $Na_{0.5}CoO_2$. In particular the superstructure $Na_{0.75}CoO_2$of is very complicated. In collaboration with M.L. Foo, Department of Chemistry and Princeton Materials Institute, Princeton University, Princeton, NJ 08544 USA; Q. Xu and V. Kumar, National Centre for HREM, Department of Nanoscience, Delft University of Technology, Rotterdamseweg 137, 2628 AL Delft, The Netherlands ; L. Viciu, Department of Chemistry and Princeton Materials Institute, Princeton University; Q. Huang, NIST Center for Neutron Research, NIST, Gaithersburg, MD 20899; and R.J. Cava, Department of Chemistry and Princeton Materials Institute, Princeton University.

**N3 4 Magnetic-Field-Induced Suppression of the Charge Ordered State in $Na_{0.5}CoO_2$ and the observation of Shubnikov−de Haas Oscillations in $Na_xCoO_2$.**

LUIS BALICAS, *National High Magnetic Field Lab*

We performed electrical transport measurements at low temperatures and high magnetic fields in $Na_xCoO_2$ single crystals for both $x = 0.5$ and $x = 0.3$. For $x = 0.5$ Shubnikov de Haas oscillations corresponding to only 1% of the area of the orthorhombic Brillouin zone (BZ) were clearly observed, indicating that most of the original Fermi surface vanishes at the charge ordering (CO) transition. While in-plane magnetic fields were found to strongly suppress the charge ordered state observed for $x = 0.5$ via a field-induced strongly hysteretic transition. When the external fields are rotated within the conducting planes, we observe angular magnetoresistance oscillations whose periodicity changes from two-to six-fold at the transition suggesting the reconstruction of the Fermi surface of this material. These facts indicate that the charge order is a delicate one, more akin to a charge-density-wave, and consistent with the small gap observed in the optical conductivity. While for $x = 0.3$ we clearly observe quantum oscillatory phenomena for two frequencies $f_1 \cong 480$ and $f_2 \cong 800$ T corresponding respectively to only 0.8 and 1.36% of the first Brillouin zone (FBZ), with very weak indications of possible additional frequencies. These values contrast markedly with what is predicted by band structure calculations for $x = 0.3$, i.e., 2.26% and 22.3% of the FBZ for the pockets resulting from the $e_g'$ and the $a_{1g}$ bands, respectively. We speculate that the Na superstructures seen for both concentrationsm re-define the Brillouin zone and thus the geometry of the Fermi surface explaining perhaps such discrepancies.

**N3 5 $^{17}O$ and $^{59}Co$ NMR Studies of Strongly Correlated Electrons in $Na_xCoO_2$.**

TAKASHI IMAI, *McMaster University*

The anomalous electronic properties of triangular-lattice system $Na_xCoO_2$ has been attracting strong interest over the last several years since the discovery of superconductivity in hydrated $Na_{1/3}CoO_2 \cdot {}_{4/3}[H_2O]$. The electronic phase diagram of these materials is quite rich, as the physical properties depend very strongly on Na concentration. Here we report our $^{17}O$ and $^{59}Co$ NMR studies of the local electronic properties and low-frequency spin dynamics in these materials for a variety of Na concentrations [1,2]. [1] F.L. Ning, T. Imai, B.W. Statt, and F.C. Chou, PRL 93 (2004) 237201. [2] F.L. Ning and T. Imai, PRL 94 (2005) 227004.

**SESSION N4: POLYMER CRYSTALLIZATION**
**Wednesday Morning, 15 March 2006; 308, Baltimore Convention Center at 8:00**
**Freddy Khoury, National Institute of Standards and Technology, presiding**

**8:00**
**N4 1 A new approach to study of the onsets of tethered chain overcrowding and highly stretched brush regime utilizing crystalline-amorphous diblock copolymers.**
STEPHEN CHENG, *Maurice Morton Institute and Department of Polymer Science, University of Akron, Akron, Ohio 44325-3909 USA*

Two series of diblock copolymers, PEO-*b*-PS and PLLA-*b*-PS, were used as templates to generate tethered PS blocks on the single crystal surfaces. Controlled and tunable reduced tethering density, $\tilde{\sigma}$, defined by it$\sigma\pi R_g^2$ (where it$\sigma$ is the tethered chain density), could be achieved in a broad range (up to 24) by changing the molecular weights (MW's) of the crystalline and amorphous blocks and by varying the crystallization temperature ($T_x$) of different PEO-*b*-PS and PLLA-*b*-PS solutions. The $\tilde{\sigma}$ of the tethered PS chains on the crystal surface increased with increasing $T_x$ because at a fixed MW of the PEO or PLLA block, an increase in the lamellar thickness ($d_{CRYST}$) was evidence of a decrease in the number of folds. When we plotted the relationships between $1/d_{CRYST}$ and $T_x$ for these two series of diblock copolymers, sudden and discontinuous changes of the slopes in some of these were observed at $\tilde{\sigma} = 3.7$ ($\tilde{\sigma}$*). This was as a result of the drastic interaction change of the neighboring PS tethered chains. An average reduced surface free energy of the tethered PS chains ($\Gamma^{PS}$) was used as a parameter to characterize the PS tethered chain interactions. The relationship between $\Gamma^{PS}$ and $\tilde{\sigma}$ showed a discontinuous transition at $\tilde{\sigma}$*. This could be identified as the onset of the tethered PS chain overcrowding in solution. This transition indicates that the extra entropic surface free energy created by the repulsion of tethered PS chains started to affect the nucleation barrier of the PEO or PLLA block crystallization. Based on the scaling laws, the onset of highly stretched brush regime could be identified at $\tilde{\sigma} = 14.3$ ($\tilde{\sigma}$**). In the $\Gamma^{PS}$ versus $\tilde{\sigma}$ plot, the transition appears to be continuous. Thus, a crossover regime in the tethered PS chains exists between $\tilde{\sigma}^* = 3.7$ and $\tilde{\sigma}^{**} = 14.3$. It is defined as the regime where the interaction of the tethered PS chains undergo changes from being non-interacting towards penetration to, finally, chain stretching normal to the surface.

**8:36**
**N4 2 Flow-Induced Crystallization Precursor Structure in Entangled Polymer Melt.***
BENJAMIN HSIAO, *Stony Brook University*

Flow-induced crystallization has long been an important subject in polymer processing. Varying processing conditions can produce different morphologies, which lead to different properties. Recent studies indicated that the final morphology is in fact dictated by the initial formation of crystallization precursor structures (i.e., shish kebabs) under flow. In this talk, factors that affect the shish-kebab formation in entangled polymer melts are systematically reviewed, including the concept of coil-stretch transition, chain dynamics, critical orientation molecular weight, phase transition during shish and kebab formations. In particular, recent experimental results from in-situ rheo-X-ray studies and ex-situ microscopic examinations have been presented to illustrate several new findings of flow-induced shish-kebab structures in polymer melts. (1) The shish entity consists of stretched chains (or chain segments) that can be in the amorphous, mesomorphic or crystalline state. (2) The kebab entity mainly arises from the crystallization of coiled chains (or chain segments), which seems to follow a diffusion-control growth process. (3) A shish-kebab structure with multiple shish was seen in the ultra-high molecular weight polyethylene (UHMWPE) precursor. Based on the above results and recent simulation work from other laboratories, a modified molecular mechanism for the shish-kebab formation in entangled melt is presented.

*This work was supported by the National Science Foundation (DMR-0405432).

**9:12**
**N4 3 Curved faces in polymer crystals with asymmetrically spreading growth patches.**
GORAN UNGAR, *U. Sheffield*

Polymer crystals often have curved faces. Understanding such morphology is of major interest since it allows distinction between fundamentally different theories of polymer crystallization. E.g., Sadler's ''roughness-pinning'' theory assumes that the curvature is a result of roughening transition on lateral faces. It has since been shown by Mansfield that the curvature can be explained quantitatively, essentially within the Lauritzen-Hoffman nucleation theory. However, the step propagation rates $v$ implied in their treatment are substantially lower than predicted by the LH theory. The retardation appears to be due to the ''self-poisoning'' or ''pinning'' effect of incorrect chain attachment, effectively demonstrated by the extreme cases of growth rate minima in long-chain monodisperse n-alkanes. Recently crystals of poly(vinylidene fluoride) and alkanes $C_{162}H_{326}$ and $C_{198}H_{398}$ have been found with habits that can be best described as bounded by curved {110} faces. The interesting feature is the asymmetry of the curvature: while the faces are curved at one end, they are straight at the other. We carried out mathematical analysis of the curvature, generalizing the Mansfield model. We

suggest that such asymmetric curvature arises from the propagation rates to the left, $v_l$, and to the right, $v_r$, being different because of the lack of mirror bisecting planes such as (110). By solving appropriate equations with moving boundaries, we obtained the shape of the growth front $y(x,t)$. Calculated crystal habits gave excellent fits to the observed growth shapes of $a$-axis lenticular crystals of long alkanes and PVDF, as well as of single crystals of PEO. This explains some hitherto poorly understood morphologies and, in principle, allows independent measurements of step initiation and propagation rates in all polymers.

**9:48**
**N4 4 New Paradigms for Polymer Crystallization.**
MURUGAPPAN MUTHUKUMAR, *University of Massachusetts*

The ordering process of topologically connected chains into a crystalline state is distinctly different from that of low molar mass substances. One of the key differences arises fundamentally from entropic barriers due to substantial reduction in configurational entropy of the system during the ordering process. We have derived a new theoretical model with the following essential features: (1) For a single lamella, the free energy landscape exhibits many metastable states (separated by free energy barriers), and a globally stable state. Among the metastable states, even the first viable state with its free energy just below that of the melt is long-lived, due to the barrier for thickening. The thickness of this long-lived metastable state increases with temperature. However, if enough time is granted for this metastable state to evolve, then the equilibrium thickness would be reached for each temperature. The equilibrium thickness decreases with temperature, until the approach of the equilibrium melting temperature. The equilibrium melting temperature does not correspond to that of extended chain dimensions. (2) The lateral growth faces a free energy barrier, due to temporal crowding of entangled chains at the growth front. A general formula is derived for the growth kinetics of the growth front, providing a crossover description for crystallization of low and very high molar mass polymer chains. The predictions are compared with available experimental data.

**10:24**
**N4 5 Growth and form of spherulites: A phase field study.**
LASZLO GRANASY, *Research Institute for Solid State Physics and Optics*

Polycrystalline patterns termed spherulites are present in a broad variety of systems including metal alloys, polymers, minerals, and have biological relevance as well (see e.g. semi-crystalline amyloid spherulites and spherultic kidney stones). The fact that similar polycrystalline patterns are observed in systems of very different nature suggests that a minimal model based on coarse-grained fields, which neglects the details of molecular interactions, might be appropriate. Although such a field-theoretic approach disregards most of the molecular scale details of formation, some features such as crystal symmetries can be incorporated via the anisotropies of the model parameters. The rationale for developing such coarse-grained models is the current inability of fully molecular models to address the formation of large scale morphologies. A phase field theory of polycrystalline growth, we developed recently, is applied for describing spherulitic solidification in two and three dimensions. Our model consists of several mechanisms for nucleating new grains at the perimeter of the crystallites, including homogeneous (trapping of orientational disorder and branching in certain crystallographic directions) and heterogeneous (particle-induced nucleation) processes. It will be shown that the diversity of spherulitic growth morphologies arises from a competition between the ordering effect of discrete local crystallographic symmetries and the randomization of the local crystallographic orientation that accompanies crystal grain nucleation at the growth front. This randomization in the crystal orientation accounts for the isotropy of spherulitic growth at large length-scales and long times. We find the entire range of observed spherulite morphologies can be reproduced by this generalized phase field model of polycrystalline growth.

## SESSION N5: PAKE AND AIP INDUSTRIAL PHYSICS PRIZES
**Wednesday Morning, 15 March 2006; 309, Baltimore Convention Center at 8:00**
**Thomas Theis, IBM, presiding**

**8:00**
**N5 1 The Future of Research in Industry.**
CHARLES DUKE,* *Xerox Wilson Center for R&T*

Since 1990 the environment for and execution of industrial research has changed profoundly. See, e.g., R. Buderi, Engines of Tomorrow (Simon and Shuster, New York, 2000); H. W. Chesbrough, Open Innovation (Harvard Business School Press, Boston, 2003); C. B. Duke, Creating Economic Value from Research Knowledge (The Industrial Physicist, Aug-Sept. 2004, pp. 29-31). According to Thomas L. Friedman (''The World is Flat,'' Farrar, Straus and Giroux, New York, 2005) a new global communications-collaboration platform has ''flattened'' the world. National alarms have been

raised about the US capability to compete in this changed environment. See, e.g., ''America's Tech Might Slipping?,'' Business Week, March 14, 2004; ''Globalization and Engineering,'' The Bridge, National Academy of Engineering, Fall 2005; ''Rising Above the Gathering Storm,'' National Academy of Sciences, 2005. In this presentation I indicate why firms perform research and how they generate economic value from it. Then I discuss the profound changes in the environment for these activities since 1990. This leads to a consideration of how firms are modifying their Research and Development activities to deal with this situation. I close by noting implications of these developments on the role of physics and the careers of physical scientists in the 21st century.

*Vice President and Senior Fellow.

**8:36**
**N5 2 NIST Role in Advancing Innovation.**
HRATCH SEMERJIAN, *NIST*

According to the National Innovation Initiative, a report of the Council on Competitiveness, innovation will be the single most important factor in determining America's success through the $21^{st}$ century. NIST mission is to promote U.S. innovation and industrial competitiveness by advancing measurement science, standards, and technology – in ways that enhance economic security and improve the quality of life for all Americans. NIST innovations in measurement science and technology often become the basis for new industrial capabilities. Several examples of such developments will be discussed, including the development of techniques for manipulation and measurement of biomolecules which may become the building blocks for molecular electronics; expansion of the frontiers of quantum theory to develop the field of quantum computing and communication; development of atomic scale measurement capabilities for future nano- and molecular scale electronic devices; development of a lab-on-a-chip that can detect within seconds trace amounts of toxic chemicals in water, or can be used for rapid DNA analysis; and standards to facilitate supply chain interoperability.

**9:12**
**N5 3 Liquid Crystals: From Discovery to Products.**
PETER PALFFY-MUHORAY, *Kent State University*

Liquid crystals, constituting a new phase of matter, were discovered in 1888. They remained a scientific curiousity until the late 1960s, when liquid crystal displays were invented by Heilmeier at RCA and Fergason at Kent State University. Today, LCDs dominate the flat panel display industry, with production primarily in the Far East. In this talk, I will briefly review the history of liquid crystals and LC devices, discuss emerging LC technologies and speculate on their commercial potential. I will outline new directions in liquid crystal research and describe some of the remarkable new products that may result. I will conclude by considering the connection between support for basic and applied research and successful product commercialization.

**9:48**
**N5 4 Benchmarking Competitiveness: Is America's Technological Hegemony Waning?**
MICHAEL S. LUBELL, *CCNY Department of Physics*

For more than half a century, by almost every standard, the United States has been the world's leader in scientific discovery, innovation and technological competitiveness. To a large degree, that dominant position stemmed from the circumstances our nation inherited at the conclusion of the World War Two: we were, in effect, the only major nation left standing that did not have to repair serious war damage. And we found ourselves with an extraordinary science and technology base that we had developed for military purposes. We had the laboratories – industrial, academic and government – as well as the scientific and engineering personnel – many of them immigrants who had escaped from war-time Europe. What remained was to convert the wartime machinery into peacetime uses. We adopted private and public policies that accomplished the transition remarkably well, and we have prospered ever since. Our higher education system, our protection of intellectual property rights, our venture capital system, our entrepreneurial culture and our willingness to commit government funds for the support of science and engineering have been key components to our success. But recent competitiveness benchmarks suggest that our dominance is waning rapidly, in part because other nations have begun to emulate our successful model, in part because globalization has ''flattened'' the world and in part because we have been reluctant to pursue the public policies that are necessary to ensure our leadership. We will examine these benchmarks and explore the policy changes that are needed to keep our nation's science and technology enterprise vibrant and our economic growth on an upward trajectory.

**10:24**
**N5 5 MRI from 400 gauss to 1.5 tesla and beyond.**
WILLIAM EDELSTEIN, *GE Global Research Center (Retired)*

Magnetic Resonance Imaging (MRI) is arguably the most novel and important medical imaging modality since the advent of the X-ray. MRI grew out of the long development of atomic spectroscopy, atomic and molecular beam resonance and, finally, nuclear magnetic resonance (NMR) in condensed matter. The operation and economics of MRI systems depend

on the performance of magnets, pulsed magnetic field gradient windings and rf (radiofrequency) coils. Physics and physicists have made critical contributions to these technologies. Superconducting magnets have come to be the magnet of choice. Magnetic gradient windings present theoretical electromagnetic and practical challenges. The need for rf antennas that resonate at high frequencies while surrounding sizable spatial regions inspired large coils producing uniform rf magnetic fields while minimizing electric field interactions with the imaging subject. This development enabled MRI at high magnetic fields. Additionally it is possible to use arrays of small rf coils to obtain MRI images with the high signal-to-noise ratio of a small surface coil and the field of view of a large coil. We recently investigated the intense acoustic noise (110 dB or more) produced in MRI scanners. Surprisingly, eddy currents induced in the magnet cryostat inner bore make a major contribution to this noise. Calculations indicate that a thin layer of Cu on the outside of the gradient assembly could substantially decrease eddy currents and help reduce noise. GE R&D work was focused on the science underlying MRI, MRI technology and the MRI product. Corporate management sometimes discourages technical publication related to evolving products because it might help rivals. Our practice of extensive publication and participation in open scientific exchange—after filing appropriate patent applications—served as quality control for company science and technology. GE conference presentations and journal publications helped establish technical leadership and determine which ideas were most important. GE scientists built reputations leading to leadership prominent within the MRI technical community. Openness underpinned a highly effective development process that enabled GE to pull ahead of competitors.

## SESSION N6: FERMI SUPERFLUID GASES: NON-EQUAL SPIN POLARIZATION (FFLO STATE) AND P-WAVE PAIRING

**Wednesday Morning, 15 March 2006; 310, Baltimore Convention Center at 8:00**
**Erich Mueller, Cornell University, presiding**

**8:00**
**N6 1 Phase Diagram of Cold Polarized Fermi Gas.**
DAM THANH SON, *University of Washington*

We propose the phase diagram of cold polarized atomic Fermi gas with zero-range interaction. We identify four main phases in the plane of density and polarization: the superfluid phase, the normal phase, the gapless superfluid phase, and the modulated phase. We argue that there exist a Lifshitz point at the junction of the normal, the gapless superfluid and the modulated phases, and a splitting point where the superfluid, the gapless superfluid and the modulated phases meet. We show that the physics near the splitting point is universal and derive an effective field theory describing it. We also show that subregions with one and two Fermi surfaces exist within the normal and the gapless superfluid phases.

**8:36**
**N6 2 Superfluid stability in polarized Fermi atomic gases.**
SUNGKIT YIP, *Inst. Physics, Academia Sinica*

For a two-species atomic Fermi gas with equal populations, it is now widely accepted that a smooth BCS-BEC cross-over occurs when the Feshbach resonance is crossed. However, the situation is very different if the populations of the two species are different. In particular, the uniform state is stable only either (a) for sufficiently negative detuning, where the system is a gapless mixture of Bose condensed pairs and unpaired normal Fermions, or (b) for sufficiently positive detuning, where Fermions are unpaired and the system is in the normal state. No uniform state is stable in between. Phase transition(s) must therefore occur when the resonance is crossed. We discuss the theoretical phase diagram of this system in this talk.

**9:12**
**N6 3 Pairing and Phase Separation in a Polarized Fermi Gas.***
RANDALL HULET,† *Rice University*

BCS pairing can only occur when the Fermi energies of the individual particles are equal. There has been great interest, however, in the consequences of mismatched Fermi energies that may arise in several important situations, including magnetized superconductors or cold dense quark matter at the core of neutron stars. Pairing is qualitatively altered by the Fermi energy mismatch, and there has been considerable speculation regarding the nature and relative stability of various proposed exotic phases. We have created a two-component gas of $^6$Li atoms in which the relative Fermi energies are altered by changing the relative numbers of each component[1]. The BEC/BCS crossover with tunable interactions is realized via a Feshbach resonance. Above a critical number polarization, which depends on the interaction energy, the gas

separates into a superfluid paired core surrounded by a shell of normal unpaired atoms. Below the critical polarization the gas exists in a paired state with asymmetric Fermi surfaces. The critical polarization is largest in the BEC regime, and becomes small in the BCS regime. We also measure the universal interaction parameter $\beta$ for a strongly interacting Fermi gas to be -0.54 (5), in good agreement with recent Monte-Carlo calculations.

*Supported by NSF, ONR, NASA, and the Welch Foundation.

**9:48**
**N6 4 Fermi superfluids with p-wave pairing near a Feshbach resonance.**
ROBERTO DIENER, *Department of Physics, The Ohio State University*

Fermi superfluids with s-wave pairing near an s-wave Feshbach resonance are being extensively studied both theoretically and experimentally. Recently, Feshbach resonances in the p-wave channel have been observed in both $^{40}$K and $^{6}$Li, raising the possibility that fermionic superfluids with p-wave pairing could be attained at low temperatures. Since the pairing wavefunction in this case breaks rotational symmetry, the superfluid properties of this system in the BEC-BCS crossover will be much different from the s-wave case. In particular, I will discuss the symmetry of the ground state as well as the experimental signatures of these novel superfluids as a function of the parameters defining the resonance. Other new results on resonance physics will also be reported.

**10:24**
**N6 5 Evolution from BCS to BEC Superfluidity in Dilute Fermi Gases.***
CARLOS A. R. SA DE MELO, *Georgia Institute of Technology*

I will review briefly some old results [1,2] of the evolution from BCS to BEC superfluidity in dilute Fermi gases, including critical temperature, order parameter amplitude, chemical potential and time dependent Ginzburg-Landau theory for the s-wave channel in three dimensions. Following this discussion, I will present new results for the BCS to BEC evolution of Fermi gases in the p-wave channel [3]. I will make comparisons between s-wave and p-wave superfluidity and point out the main differences between the two cases. Lastly, I will discuss supefluidity of s-wave and p-wave Fermi gases in a restricted two-dimensional geometry (one dimensional optical lattice), where a Berezinkii-Kosterlitz-Thouless-type transition is proposed as the system evolves from the weak to the strong attraction limit. In this case, I will show that spontaneous vortex-antivortex pairs form and that they can condense into a vortex-antivortex lattice at lower temperatures [4]. [1] C. A. R. Sa de Melo, M. Randeria, and J. R. Engelbrecht, PRL 71, 3202 (1993). [2] J. R. Engelbrecht, M. Randeria, and C. A. R. Sa de Melo, PRB 55, 15153 (1997). [3] M. Iskin, and C. A. R. Sa de Melo, cond-mat/0510300 (2005). [4] S. S. Botelho, and C. A. R. Sa de Melo, cond-mat/0509387 (2005).

## SESSION N7: RECENT ADVANCES IN THE COMPUTATION OF OPTICAL AND TRANSPORT PROPERTIES OF NANOSTRUCTURES

**Wednesday Morning, 15 March 2006; 307, Baltimore Convention Center at 8:00**
**Marco Buongiorno Nardelli, North Carolina State University, presiding**

**8:00**
**N7 1 Optical Properties of Nano-Crystallites.***
HANS-CHRISTIAN WEISSKER, *European Theoretical Spectroscopy Facility (ETSF) France and Laboratoire des Solides Irradies, Ecole Polytechnique, France*

The optical properties of nanostructured materials are interesting due to the tunability of the electronic structure, of the lifetimes, and of the excitation spectra. This calls for precise knowledge of the physical effects which create the desired properties. Thereby it is of utmost importance to settle the question as to how many-body effects have to be incorporated in the description of the excitation aspects inherent in any optical process. Static DFT-LDA itab initio calculations have now become possible for systems of about 1000 atoms for the ground state. Time-dependent DFT (TDDFT) can in principle describe excitations as exhibited in optical spectra. However, approximations for the exchange and correlation contributions that are valid in a wide range of situations and efficient enough to be applied to large nanostructures are still to be found. GW calculations deal only with charged (electron addition and removal) excitations. The solution of the Bethe-Salpeter equation (BSE) gives good answers for neutral excitations like absorption but is numerically heavy and so far tractable for rather small systems only. In my talk I will briefly review the state of the calculation of optical

properties. Using bulk semiconductors and Ge, Si, and alloy nanocrystals as illustrations, I will then discuss the following points: Manifestation of confinement effects in various spectra; Importance of surface effects; Interplay between many-body effects and confinement and surface effects; Importance of short- and long-range contributions. How are they adequately described? (Important, e.g., for embedded nanostructures.) These questions will be discussed in view of the optical properties, but also for loss spectra and photo-emission. Methods used are DFT-LDA, TDDFT in various approximations, GW, and BSE.

*Supported by the European Union through the Network of Excellence NANOQUANTA (Contract NMP4-CT-2004-500195).

**8:36**
**N7 2 Atomistic Pseudopotential Calculations of the Electronic and Optical Properties of Self-Assembled Quantum Dots.***
GABRIEL BESTER, *National Renewable Energy Laboratory*

The optical spectrum and the charging energies of semiconductor quantum dots have been recently measured with high accuracy. Both of these experimental techniques probe many-body states that are not directly described by independent particle theories such as the density functional theory. On the other hand, quasi- particle theories that can in principle address the problem, such as GW, are computationally too demanding for the study of nanostructures (as opposed to clusters) where many thousands of atoms are involved. One way to approach this problem is to use the effective mass approximation or the k.p method and choose a confinement potential that reproduces a few known experimental facts (e.g. the splitting between confined levels). These methods can provide a good initial guess but were shown to be too crude to enable a quantitative comparision with recent experiments. We therefore adopt a bottom-up atomistic approach where instead of starting from a simplified approach, such as effective mass, and progressively increase the complexity by adding parameters, we start from the accurate atomistic description (LDA or GW) and work ourselves up using a few well controlled approximations. I will first present the method, namely (i) the scheme that is used to derive the empirical pseudopotentials including the piezoelectric effect, (ii) the choices that have to be made for the basis used to expand the wave functions, (iii) the inclusion of corelations through Bethe-Salpeter-like treatment. I will then present recent applications of the theory to calculate the fine-structure [1] of excitons and charged excitons, the charging spectra of holes [2] and the degree or entanglement stored in a quantum dot molecule [3]. **9:12**
**N7 3 Density Functional Theory of the electrical conductivity of molecular devices.**
RALPH GEBAUER, *The Abdus Salam International Centre for Theoretical Physics (ICTP)*

The theoretical modeling of electrical transport through nanoscale devices is a very challenging task: On one hand, the conduction properties of a molecular junction depend crucially on details of the chemical bonding, particularly at the interface. Such properties are routinely studied using methods based on density-functional theory (DFT). On the other hand, ground-state theories like DFT cannot be directly applied to systems with a finite current, because such devices are out of equilibrium. One possibility to overcome this problem is to study electron transport in the time domain. In the spirit of what is done in semiclassical Boltzmann approaches, one considers the system subject to both an external electrical field and to dissipation due to inelastic scattering. The combined influence of the external driving force and dissipation leads to a steady state with finite current. In this presentation I will first show how time-dependent DFT can be formally extended to dissipative systems, described by a Liouville master equation for the reduced density matrix. In a second step this formalism is then applied to calculate the current-voltage characteristics of molecular junctions, like e.g. carbon nanotubes suspended between metallic contacts.

**N7 4 Self-interaction errors in density functional calculations of electronic transport.**
STEFANO SANVITO, *Trinity College Dublin*

All density functional (DFT) calculations of single-molecule transport to date have used continuous exchange-correlation approximations, such as the local density approximation (LDA) or the generalized gradient approximation (GGA). These usually provide a good description of metallic systems, but fail in predicting the correct I-V curve for molecules weakly coupled to the current/voltage probes. Most of the problem can be attributed to the lack of the derivative discontinuity of the DFT potential in local approximations. These in fact continuously connect the orbital levels for different integer occupations, leading to qualitative errors such as the erroneous prediction of the dissociation of heteronuclear molecules into fractionally charged ions In this talk I will first describe the typical errors arising from neglecting the derivative discontinuity in transport calculations [1], namely the erroneous prediction of metallic transport for insulating molecules. Then I will present a simple and computationally undemanding atomic self-interaction correction scheme for transport. This preserves the computational and conceptual simplicity of standard LDA, and nevertheless re-introduces part of the derivative discontinuity. The method is implemented in our quantum transport code Smeagol [2] (www. smeagol.tcd.ie) and several examples will be given. [1] C. Toher, A. Filippetti, S. Sanvito, and K. Burke, Phys. Rev. Lett. 95, 146402, (2005). [2] A.R. Rocha, V.M. Garcia Suarez, S.W. Bailey, C.J. Lambert, J. Ferrer, and S. Sanvito, cond-mat/0510083.

**N7 5 Electron-vibration interaction in molecular electronics and GW approximation for the e-e interaction in transport theory.**
ALESSANDRO PECCHIA, *Roma 'Tor Vergata'*

The field of molecular electronics has seen a tremendous expansion in recent years, thanks to the realization of ingenious experimental setups and the fundamental achievement of reproducible results and behaviours. Significant progresses have also been made from a theoretical point of view, although the agreement with experiments is still not satisfactory. The challenges for a complete understanding of transport in such systems are still considerable. Inelastic electron tunnelling spectroscopy is becoming very popular in the field thanks to its powerful capability of probing molecular vibrational properties and could provide in the future a valuable characterization tool if correctly related to theoretical calculations. We simulate IETS spectra of various molecules between metal contacts and show the importance of such simulation for the interpretation of the experiments. Particular attention is devoted to the evaluation of Joule heating and thermal dissipation. The problem is tackled within the formalism of NEGF by the calculation of appropriate electron-phonon self-energies. The electron-phonon coupling is derived from the DFTB Hamiltonian. The Power dissipated is calculated from the virtual contact current originated from phonon emission and absorption processes. Preliminary results of thermal dissipations of molecules coupled to Au and Si substrates will be shown. As well known, all DFT methods tend to underestimate the electronic band-gap of semiconducting and insulating materials. In particular the band-gap of conjugated organic molecules is usually underestimated by few electronvolts. However, band-gap corrections are crucial for quantitatively correct calculations of the tunneling current through organic molecules. We show a novel implementation of the itGW correction applied to our DFTB method and show its applications to molecular systems sandwitched in-between electrodes to obtain a first-principle correction of the $e - e$ interaction energy. The resulting self-energy is used to improve the system itGF and to obtain a correction of the tunneling current. We also apply the itGW correction in the context of the computation of the complex band-structures of polymers such as poly-acetylene or poly-phenylene and show how the energy gap and decay lengths of the evanescent states should be corrected by quasi-particle effects.

**N8 1 Assessing a Continuum Description of Wide Shear Zones in Slow Granular Flow by Discrete Element Simulations** JEREMY B. LECHMAN, GARY S. GREST, *Sandia National Laboratories** MARTIN DEPKEN, *Instituut-Lorentz for Theoretical Physics* MARTIN VAN HECKE, *Kamerlingh Onnes Lab* While the rheology of rapid granular flows is becoming well established, slow, dense flows are not well characterized in part because the strain localization (i.e., shear bands) they often exhibit is not easily amenable to continuum descriptions. Recently, a novel experimental system (split-bottom Couette Cell) was developed with promising potential to give new insight into these flows due to its wide, smooth shear zones (Fenistein et al. PRL **92**, 94301). Subsequent experimental and numerical studies have lead to a good understanding of the nature of the flow in this device, which has lead Depken et al. (cond-mat/0510524) to propose a set of testable constitutive relations between the internal stresses and flow field. In particular, they suggest that the bulk, effective friction coefficient between sliding layers of particles is not constant, but has a subtle dependence on the orientation of the layers with respect to the bulk force. Here we present large-scale Discrete Element Simulations to analyze the bulk flow in both circular, above and below the critical height, and linear, where no critical height for slip at the base is found, split-bottom geometries. We check the proposed form of the stress tensor and assess the validity of the claim that the effective friction coefficient depends on the shape of the shear zone with respect to gravity.

**8:12**

**N8 2 Dynamical heterogeneities in dense granular flow: timescales and large-scale particle rearrangements** ALLISON FERGUSON, BULBUL CHAKRABORTY, *Brandeis University* Recent interest in understanding the dynamical arrest leading to a fluid $\rightarrow$ solid transition in both thermal and athermal systems has led to questions about the nature of these jamming transitions (PRL **86**, 111 (2001), Nature **411**, 772 (2001)). It is believed that these jamming transitions are dependent on the influence of extended structures on the dynamics of the system (Science **287**, 627 (2000)). Simulations of steady-state gravity-driven flows of inelastically colliding hard disks show the formation of large-scale linear chains of particles with a high collision frequency even at flow velocities well above the jamming transition (EPL **66**, 277 (2004)). These chains can be shown to carry much of the collisional stress in the system due to a dynamical correlation that develops between the momentum transfer and time between collisions in these ''frequently-colliding'' particles. While measurements of slowly decaying stress correlations yield an average lifetime for these structures which scales inversely with the flow velocity (cond-mat/0505496), distributions of time scales associated with the stress chains may provide more information about their effect on the dynamics of the flowing granular medium. These distributions may be obtained by considering time scales related to large-scale rearrangements of neighbouring particles in analogy with measurements done on supercooled fluids.

**8:24**

**N8 3 Dense granular flows down an inclined plane** ROBERT ECKE, TAMAS BORZSONYI,* *Los Alamos National Laboratory* Granular flow on a rough inclined plane is an important model system in which to study the basic rules of the dynamics of granular materials. Despite intensive study, many features of such flows are still incompletely understood. For uniformly flowing layers at relatively shallow inclination, we consider experimentally the the basic flow rheology of the granular media and propose new scalings to collapse our data for glass beads and rough sand as a function of inclination angle and particle diameter. At steep inclinations above some angle $\theta_s$ ($\tan\theta_s/\tan\theta_r \approx 1.3 - 1.5$, where $\theta_r$ stands for the angle of repose) for flowing grains, numerics and theory predict that the surface roughness is inadequate to dissipate energy gained in the gravitational field, and the flow should continue to accelerate. We report on our experimental results on the properties of granular flows on a steeply inclined plane and define the domains of steady flows. We also discuss the instabilities of such flows leading to spatial patterns.

*Currently at Hungarian Academy of Sciences, Budapest, Hungary.

**8:36**

**N8 4 Transverse Instability of Avalanches in Granular Flows down Incline*** IGOR ARANSON, *Argonne National Laboratory* FLORENT MALLOGGI, ERIC CLEMENT, *ESPCI, France* Avalanche experiments on an erodible substrate are treated in the framework of ''partial fluidization'' model of dense granular flows. The model identifies a family of propagating soliton-like avalanches with shape and velocity controlled by the inclination angle and the depth of substrate. At high inclination angles the solitons display a transverse instability, followed by coarsening and fingering similar to recent experimental observation. A primary cause for the transverse instability is directly related to the dependence of soliton velocity on the granular mass trapped in the avalanche.

**N8 5 Swirling in a Vibrated Monolayer of Rods** VIJAY NARAYAN, SRIRAM RAMASWAMY, *Indian Institute of Science, Bangalore* NARAYANAN MENON, *U. of Massachusetts, Amherst* We report observations of the spatiotemporal behaviour of a vertically vibrated horizontal monolayer of copper rods (aspect ratio $\approx$ 5) etched to a rolling-pin-like shape. The spatial organization of the rods resembles a highly-defected nematic state with large, coherently moving swirls. We measure spatiotemporal correlations of the single-particle and collective velocities, and study the structure and dynamics of the system as a function of density and vibration amplitude. We analyze the observed patterns in the light of theories[1] of orientational ordering, dynamics, and topological defects in systems of driven particles. We make comparisons to related but different experiments[2], as well as to our earlier measurements[3] on similar particles with higher aspect ratio.

**N8 6 Simple Power Law for Transport Ratio with Bimodal Distribution of Coarse Sediment** CHRISTOPHER THAXTON, *Appalachian State University* JOSEPH CALANTONI, *Naval Research Laboratory* Using a discrete particle model, we have simulated sheet flow transport of coarse bimodal sediment distributions in the bottom boundary layer over a range of oscillatory waves and steady currents. The ratio of large grain to small grain diameter was varied as 5:4, 3:2, and 2:1. For each bimodal distribution, the mass ratio $M_L/M_S$ ($M_L$ and $M_S$ are the masses of large and small grains respectively – the total mass was fixed for all runs) was varied from 1/9 up to 9/1. We find that, independent of wave and current forcing for the range of conditions considered, the ratio of large to small grain time-average transport rate obeys the power law $Q_L/Q_S = C(M_L/M_S)^k$, where $Q_L$ and $Q_S$ are the time-average transport rates of the large grains and small grains respectively and $C$ and $k$ are regression constants. A linear regression in log space (including 81 different simulations per diameter ratio) suggests that itk$\approx D_L/D_S$ with $R^2 > 0.9$. The robust nature of the results suggests that the new power law may have a broad range of applications for shear flows of bimodal granular mixtures.

**9:12**

**N8 7 Large scale surface flow generation in driven suspensions of magnetic microparticles.** MAXIM BELKIN, ALEXEY SNEZHKO, IGOR ARANSON, *Materials Science Division, Argonne National Laboratory, 9700 South Cass Avenue, Argonne IL 60439* Nontrivially ordered dynamic self-assembled snake-like structures are formed in an ensemble of magnetic microparticles suspended over a fluid surface and energized by an external alternating magnetic field. These self-assembled multi-segment structures emerge as a result of the collective interaction between the particles oscillations induced by an external magnetic field and the standing waves on the surface of fluid. Surprising large-scale vortex flows

are generated by these snake-like structures. The flows can be as fast as 2 cm/sec and strongly depend on the driving magnetic field parameters. We report on systematical experimental study of the vortex flow properties and generation mechanisms.

**9:24**

**N8 8 Green-Kubo expressions for transport coefficients of a granular fluid.** APARNA BASKARAN, JAMES DUFTY, *Department of Physics, University of Florida* A formal derivation of linear hydrodynamics for a granular fluid is given. The linear response to small spatial perturbations of the homogeneous state is studied in detail using methods of nonequilibrium statistical mechanics. A transport matrix for macroscopic excitations in the fluid is defined in terms of the response functions. An expansion in the wavevector to second order allows identification of all phenomenological susceptibilities and transport coefficients through Navier - Stokes order [1]. The transport coefficients in this representation are the generalization of Helfand and Green-Kubo relations to granular fluids. The analysis applies to a wide range of collision rules. Several differences from the corresponding expressions in the elastic limit are noted. Then, the particular case of inelastic hard spheres is considered and some approximate analytical evaluations illustrated. [1] A preliminary report of these results can be found in J. W. Dufty, A. Baskaran and J. J. Brey cond-matt/0507609.

**9:36**

**N8 9 Dynamics angle and surface flow properties of wet and cohesive granular matter** QING XU, ARSHAD KUDROLLI, *Physics Dept., Clark University* We will discuss an experimental study of the flow of grains mixed with a small amount of liquid using a horizontally rotated drum apparatus, extending on our previous work on the maximum angle of stability of wet granular materials [1]. We focus on the continuous avalanching regime observed at high rotation rates, and examine the shape of the granular surface and depth of flow with imaging techniques as a function of amount, viscosity and surface tension of the liquid. Glass beads with 1mm diameter, and a drum with a diameter 295 mm and a width of 145mm is used to minimize the effect of the boundary. We find that the shape of the surface may be approximated by two linear segments in the upper and lower halves. The slope of the upper segment corresponding to the dynamical angle of repose $\theta_d$ is observed to initially increase with rotation rate and volume fraction of liquid as expected, while the lower segment has an approximately constant slope. Interestingly, $\theta_d$ is observed to peak before decreasing to an approximately constant value as the volume fraction is increased. The rate of increase of $\theta_d$ is observed to decrease with rotation rate and viscosity. The role of the time scale over which wet grains shear past each other and the time over which grains actually come into contact due to lubrication forces on the observed change in scaling will be discussed. **N8 10 Characterizing the banded state of granular material in a rotating drum.*** MICHAEL NEWEY, *University of Maryland* KENNETH DESMOND, *Rochester Institute of Technology* WOLFGANG LOSERT, *University of Maryland* Why do particles of different size segregate axially in a horizontal rotating tumbler? We aim to understand the microscopic mechanisms for axial segregation through direct measurements of the motion of individual particles. Imaging the surface of the flowing layer, we extract flow angles, velocities, drift and diffusion for different particle types and mixtures of particles. Surprisingly, the direction of surface drift and steepest flow angle do not coincide and that surface drift cannot explain the axial segregation in our mixtures. On the other hand, particles in small particle bands flow significantly faster then particles in large particle bands, and this can be observed before visible band formation. We discuss the possible role of velocity differences in the axial segregation process. We characterize the fluidity of the flowing layer from its response to gentle sideways forcing.

*Supported by NASA Grant NAG-32736.

**N8 11 Mechanisms in size segregation of binary granular mixtures** STEPHAN ULRICH, *University of Göttingen* JENNIFER KREFT, MATTHIAS SCHRÖTER, JACK SWIFT, HARRY SWINNEY, *Center for Nonlinear Dynamics, University of Texas at Austin* Shaking of a mixture of large and small particles can lead to segregation. One distinguishes between the Brazil-nut effect (large particles go to the top) and its opposite, the reverse Brazil-nut effect. In this talk, experiments of vertically shaken binary mixtures are presented. Using image analysis, the number of large particles visible at the top and bottom of the granulate are counted to determine the state of segregation. By complementing these results with molecular dynamics simulations, we are able to identify different segregation mechanisms discussed in recent theoretical approaches: a geometrical mechanism called void filling, transport of particles in sidewall-driven convection rolls, and thermal diffusion, a mechanism predicted by kinetic theory.

**10:12**

**N8 12 Upward penetration through a granular medium** D. COSTANTINO, T.J. SHEIDEMANTEL, M.B. STONE, J. COLE, C. CONGER, K. KLEIN, M. LOHR, W. McCONVILLE, Z. MODIG, P. SCHIFFER, *Penn State University* We measure the force needed to push a flat plunger upwards through a granular medium. The plunger begins flush with the base of the grains' container, and we focus upon the force necessary to initiate motion. The data show that this break-out force increases monotonically with plunger diameter and pile height as expected. In contrast to previous measurements of the force needed for vertical penetration from above and of the horizontal drag force, this break-out force has a strong dependence on bead diameter. Research supported by NASA grant NAG3-2384 and the NSF REU program.

**10:24**

**N8 13 Correlation in granular shear flows** GREGG LOIS, *University of California, Santa Barbara* JEAN CARLSON, *University of California, Santa Barbara* We investigate the effects of long-range correlation in simulations of sheared granular materials and develop theories to model force propagation in the dense regime. Measurements of spatial force correlations determine the size of force networks that emerge as the density is increased. The magnitude of the correlation length separates the dilute regime, where kinetic theory holds, from a dense regime where its assumptions break down. In the dense regime we introduce theories that successfully predict constitutive relations for the stress tensor, using geometrical properties of the force networks. Additionally, we observe that the behavior of the contact force distribution at small forces is highly dependent on the size of the force networks.

**10:36**
**N8 14 Shear reversal in granular flows** MASAHIRO TOIYA, *University of Maryland* WOLFGANG LOSERT, *University of Maryland* The reversal of the shear direction in flow of monodisperse and bidisperse granular matter in a shear cell of Taylor-Couette type is characterized experimentally. By changing the boundary conditions we tune the location and width of the shear band in steady state flow. When the shear direction is reversed, the system compacts over a characteristic length of half a particle diameter, and shear forces reach a steady state over a chacteristic length of 1-3 particle diameter. A linear strain is found at the onset of shear reversal before a steady state shear band develops. We associate this extra strain during shear reversal with the displacement needed to jam particles in regions away from the shearband. We find that the strain decreases with increasing particle size for a fixed system size. We also find radial components in average particle velocities at the top surface, suggesting a convection current in the bulk.

**N10 1 Development of effective models for vectorial biological processes.***
QIANG CUI, *UW-Madison*

Progress towards understanding vectorial processes in biological systems using theoretical and computational approaches will be discussed. The specific problems of interest include mechanochemical coupling in the molecular motor myosin and vectorial proton pumping in cytochrome c oxidase. Several related methodological developments will be discussed, which include boundary potential for QM/MM simulations, effective QM methods for treating long-range proton transfers and phosphate chemistry, and coarse-grained models for describing large-scale motions in biomolecules. Quantitative benchmark calculations of these methods have been carried out using both model and realistic biological systems. The application of these methods to myosin and cytochrome c oxidase will be briefly presented.

*Projects were supported via grants from the National Science Foundation and the National Institutes of Health.

**N10 2 Hierarchical Coarse-Grained Models for Polymer Simulations*** SHENG D. CHAO, *Institute of Applied Mechanics, National Taiwan University* Structural and thermodynamic properties of industrial and bioengineering materials can be better investigated using atomistic simulations. However, current large-scale atomistic simulations remain computationally demanding. It is thus desirable to seek alternatives to perform efficient and informative mesoscopic simulations. We have developed a coarse-grained intermolecular force (CGIF) model for polymer nanostructures and nanocomposites. This model can effectively capture the stereochemical response to anisotropic long-range interactions. The coarse-graining procedure forms the basis to perform a hierarchy of simulations starting with the quantum-chemistry calculations to coarse-grained molecular dynamics toward continuum modeling. We have applied this procedure to several cases from alkane to benzene to fullerene. For liquid methane, molecular dynamics simulations using the CGIF model reproduce the structural properties calculated using the atomistic force field. The coarse-grained energetics of benzene clusters has well reproduced the results using electronic structure calculations. The subtle anisotropy in the interaction potential of fullerene dimer is also well represented by the CGIF model and is consistent with that calculated using the Brenner force field.

*This work was supported by the National Science Council of Taiwan, ROC.

**8:48**
**N10 3 Dynamic Phase Transitions in Coupled Motor Proteins** ANATOLY KOLOMEISKY, EUGENE STUKALIN, *Rice University* The effect of interactions on dynamics of coupled motor proteins is investigated theoretically. A simple stochastic discrete model, that allows to calculate explicitly the dynamic properties of the system, is developed. It is shown that there are two dynamic regimes, depending on the interaction between the particles. For strong interactions the motor proteins move as one tight cluster, while for weak interactions there is no correlation in the motion of the proteins, and the particle separation increases steadily with time. The boundary between two dynamic phases is specified by a critical interaction that has a non-zero value only for the coupling of the asymmetric motor proteins, and it depends on the temperature and the transitions rates. At the critical interaction there is a change in a slope for the mean velocities and a discontinuity in the dispersions of the motor proteins as a function of the interaction energy.

**9:00**
**N10 4 Reduced-Dimensional Models for Chemical Dynamics in Complex Environments** RIGOBERTO HERNANDEZ, ALEX V. POPOV, ELI HERSHKOVITS, *School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA 30332-0400* Nonstationary Langevin models have been developed that are capable of capturing feedback between complex environments and the underlying molecular constructs which in turn collectively comprise the environment. Although initial justifications for this formalism were heuristic and phenomenological, in recent work we have shown that in some cases it arises as the projection of a

simple model of a chemical system bilinearly coupled to a harmonic bath with a time-dependent coupling. Moreover, the stochastic model can be used to surmise the diffusion of a tagged particle in a colloidal suspension which swells or shrinks with time. Alternatively, a liquid crystal, modelled as a colloidal suspension of orientable bodies, can also exhibit driven (time-dependent) behavior by way of the rotation of a magnetic field. Once again, the diffusion of a tagged particle under such time-dependence, can be surmised by the stochastic model. Thus these models allow for a substantial reduction of the dimensionality of a complex environment while retaining its multiple-time-scale features.

**N10 5 Structure of Alzheimer's 10-35 $\beta$ peptide from replica-exchange molecular dynamics simulations in explicit water** ANDRIY BAUMKETNER, JOAN-EMMA SHEA, *University of California Santa Barbara* We report a replica-exchange molecular dynamics study of the 10-35 fragment of Alzheimer's disease amyloid $\beta$ peptide, A$\beta$10-35, in aqueous solution. This fragment was previously seen [J. Str. Biol. 130 (2000) 130] to possess all the most important amyloidogenic properties characteristic of full-length A$\beta$ peptides. Our simulations attempted to fold A$\beta$10-35 from first principles. The peptide was modeled using all-atom OPLS/AA force field in conjunction with the TIP3P explicit solvent model. A total of 72 replicas were considered and simulated over 40 ns of total time, including 5 ns of initial equilibration. We find that A$\beta$10-35 does not possess any unique folded state, a 3D structure of predominant population, under normal temperature and pressure. Rather, this peptide exists as a mixture of collapsed globular states that remain in rapid dynamic equilibrium with each other. This conformational ensemble is seen to be dominated by random coil and bend structures with insignificant presence of $\alpha$-helical or $\beta$-sheet structure. We find that, overall, the 3D structure of A$\beta$10-35 is shaped by salt bridges formed between oppositely charged residues.Of all possible salt bridges, K28-D23 was seen to have the highest formation probability, totaling more than 60% of the time.

**9:24**

**N10 6 Orbital Energetics and Molecular Recognition** AARON GEORGE, *Targacept, Inc.* REBECCA HARRIS, VISHALI MOGALLAPU, YONAS ABRAHAM, ROBERTO CAR, *Princeton University* JEFFREY SCHMITT, We present data demonstrating that orbital eigenenergy fluctuation recorded in the course of ab initio molecular dynamics calculations contains information relevant in determining molecular behavior and recognition. A simple scheme is presented that maps these data to molecular descriptors. Using computational drug design as the context, these descriptors are compared with previous electronic eigenvalue descriptor methods with encouraging results. Finally we discuss further methods of mapping electronic structure based molecular dynamics trajectories to Quantitative Structure Activity Relationships (QSAR).

**9:36**

**N10 7 Unrestricted Hartree-Fock Investigation of the Electron Distribution on the Heme System in Azidohemoglobin-$^{57m}$Fe and $^{14}$N Hyperfine Interactions.** ARCHANA DUBEY, H.P. SAHA, LEE CHOW, *UCF, Orlando* R.H. SCHEICHER, *MTU, Houghton* N. SAHOO, R.H. PINK, DIP N. MAHATO, M.B. HUANG, T.P. DAS*, *SUNY Albany* We have a program of investigations in progress on the electronic structure of azidohemoglobin by the first-principles Unrestricted Hartree-Fock procedure to understand the substantial amount of magnetic (g-tensor), magnetic hyperfine, and nuclear quadrupole interaction, data available [1] from electron paramagnetic resonance, Mosbauer and electron-nuclear double resonance measurements. Earlier semi-empirical Self-Consistent Charge Extended Huckel investigations have provided semiquantitative results [2] with different degrees of agreement for the available properties and suggested the need for more accurate and quantitative investigations. Results of our investigations will be presented for the $^{57m}$Fe and $^{14}$N nuclear quadrupole and magnetic hyperfine interaction properties and compared with experimental data. *Also UCF Orlando [1] See Refs. 2-4 listed in Ref.[2]. **9:48**

**N10 8 Polymer dynamics and the folding rates of fast folding proteins** JOHN PORTMAN, *Kent State University* In recent years, minimal models of fast folding proteins has enabled considerable agreement between computation, theory, and experiment. The assumptions associated with most simple models of fast folding proteins (Go-models) give rather robust results in terms of coarse grained description of the transition state ensemble. One aspect of the folding mechanism that has received less attention is describing the conformational dynamics responsible for the folding rate prefactor, $k_0$. Here, we consider the distribution of prefactors of fast folding proteins: does local dynamics influence $k_0$, or can one reasonably expect that $k_0$ is essentially the same regardless of contact order or mean structure of the transition state ensemble. We address this question by considering the folding routes of a wide variety of fast folding proteins using a polymer based model in which structural ensembles are parameterized by the degree of localization about the native structure.

**10:00**

**N10 9 A United Atom Model for Simulation of DNA from Angstroms to Microns in Length** THOMAS KNOTTS IV, NITIN RATHORE, JUAN DE PABLO, *Department of Chemical and Biological Engineering - University of Wisconsin-Madison* For several years, single molecule pulling experiments have given insights into the stability of DNA. Many descriptions of DNA, from atomistic to continuum, have proven successful at reproducing observed behavior. We have found, however, that there is no suitable model for several problems of interest, including viral packaging of DNA and microarray interactions, where the size of the molecules prohibits atomistic representations, but continuum and linear bead-spring models do not contain the required molecular level of detail. Emerging technologies require that mesoscopic models of DNA be developed, capable of describing length scales in the 5 to 500 nm range. One of the main challenges is to preserve a coupling between the phenomena seen at longer length scales (e. g. a persistence length of 50 nm) while incorporating the features needed for smaller scales (e. g. charge effects, geometry, and base specificity). We have developed a coarse grain description of DNA which reduces the complexity of a nucleotide to three interaction sites. The model is capable of describing sequence information,

bubble formation, and salt effects in simulations of DNA up to a few microns in length. The predictions are in remarkable, quantitative agreement with experiment, and shed light into the coupling of multiple length scales and interactions to yield unique behaviors and functions.

**10:12**
**N10 10 Diffusion Monte Carlo applied to weak interactions - hydrogen bonding and aromatic stacking in (bio-)molecular model systems** M. FUCHS, J. IRETA, M. SCHEFFLER, *Fritz-Haber-Institut der MPG, Berlin* C. FILIPPI, *Instituut Lorentz, Univ. Leiden* Dispersion (Van der Waals) forces are important in many molecular phenomena such as self-assembly of molecular crystals or peptide folding. Calculating this nonlocal correlation effect requires accurate electronic structure methods. Usual density-functional theory with generalized gradient functionals (GGA-DFT) fails unless empirical corrections are added that still need extensive validation. Quantum chemical methods like MP2 and coupled cluster are more accurate, yet limited to rather small systems by their unfavorable computational scaling. Diffusion Monte Carlo (DMC) can provide accurate molecular total energies and remains feasible also for larger systems. Here we apply the fixed-node DMC method to (bio-)molecular model systems where dispersion forces are significant: (dimethyl-) formamide and benzene dimers, and adenine-thymine DNA base pairs. Our DMC binding energies agree well with data from coupled cluster (CCSD(T)), in particular for stacked geometries where GGA-DFT fails qualitatively and MP2 predicts too strong binding.

**10:24**
**N10 11 Computational Methods for Enhanced Conformational Kinetics** IOAN ANDRICIOAEI, *University of Michigan* We present and analyze two general method to calculate time-correlation functions from molecular dynamics on scaled potentials or from molecular dynamics with artificial momenta distributions. They are useful for complex systems whose simulations are affected by broken ergodicity. Depending on the value of the scaling factor or of the details of the momentum distributions, correlation functions can be accurately calculated for times that can be orders of magnitude longer than those accessible to current molecular dynamics simulations. We show that the exact value of the correlation functions of the original system can be obtained, in principle, using an action-reweighting scheme based on a stochastic path-integral formalism. Tests on model systems and peptides are exemplified. We also show that free energy profiles using Jarzynski's identity can be more effectively calculated within this scheme.

## SESSION N11: FOCUS SESSION: AEROSOLS, CLUSTERS, DROPLETS: PHYSICS AND CHEMISTRY OF NANOOBJECTS I: HELIUM NANODROPLETS I

**N11 1 Imaging the Photodynamics of Doped Helium Droplets.**
MARCEL DRABBELS, *Institute of Chemical Sciences and Engineering, Swiss Federal Institute of Technology Lausanne, Switzerland*

During the last decade helium nanodroplets have been established as an ideal spectroscopic matrix. Helium droplets are also thought to be ideal low temperature nanoreactors because of their ability to stabilize weakly bound species. As the focus is nowadays shifting to the study of chemical reactions in liquid helium droplets, question related to the energy relaxation and solvation dynamics become more and more prominent. To address these questions experiments have been performed in with species with a well defined kinetic energy distribution have been created via the photodissociation molecules residing inside helium droplets. The velocity distributions of the photofragments that have escaped from the droplets have been determined using ion imaging techniques. The analysis of speed distributions as function of droplet size and precursor has enabled to obtain a consistent picture of the mechanisms underlying the translational motion of these non-thermal species through this quantum liquid. Additional information on the solvation dynamics could be obtained by using non-resonant ionization techniques in these experiments. More recently the translational dynamics of quasi-free electrons in helium droplets has been investigated by means of photoelectron spectroscopy. The results on these experiments indicate that the relaxation of the electrons is governed by the same mechanism responsible for the kinetic energy relaxation of non-thermal neutral molecules.

**N11 2 Photoionization and photoelectron spectroscopy of doped helium nanodroplets** DANIEL NEUMARK, *University of California, Berkeley* Photoionization and photoelectron spectra for helium nanodroplets doped with rare gas atoms and $SF_6$ will be reported. The experiments were conducted using tunable synchrotron radiation at the Advanced Light Source in the photon energy range of 14-26 eV. Time-of-flight mass spectra will be presented, along with photoion and photoelectron images. The results will be compared to previous electron impact ionization data.

**8:48**

**N11 3 Photoinitiated processes in and on liquid helium** ELENA POLYAKOVA, DANIIL STOLYAROV, CURT WITTIG, *Columbia University* Photoinitiated processes that involve molecules in $He_n$ droplets are examined. Excitation to states that contain Rydberg character results in repulsion between the electronically excited embedded molecules and the surrounding helium. Even after the helium has, moved further from the molecular core, the situation is unstable in the sense that the electronically excited species prefer the surface. The timescale for transport to the surface is $<$ 10 itns duration of the laser pulse. The resulting surface-bound species can be ionized, yielding small clusters of the form $He_mNO^+$, where $\langle g \rangle$ is of order 10,000. The possibility of observing high Rydberg states in which the electron is outside the helium droplet will be discussed. A vastly different case of photoexcitation occurs when the excited potential is coupled to a lower one via conical intersection.

**N11 4 Wave packet propagation of alkali dimers attached to helium nanodroplets** FRANK STIENKEMEIER, *Universitaet Freiburg, Germany* PATRICK CLAAS, *Universitaet Bielefeld, Germany* CLAUS-PETER SCHULZ, *Max-Born-Institut Berlin, Germany* Real-time spectroscopy of alkali dimers attached to helium nanodroplets has been studied by femtosecond pump-probe spectroscopy. Wave packet propagation in different electronic states of $Na_2$ and $K_2$ molecules was investigated. The perturbation of the helium environment allows in particular to observe electronic ground state vibrational motion. Furthermore, for the first time wave packets in alkali dimer triplet states are observed. Finally, the slight change of the vibrational structure when desorbing from the helium droplet can be utilized to determine desorption times upon laser excitation.

**N11 5 Metal clusters in helium droplets: Fulfilling the promise** PAUL L. STILES, ROGER E. MILLER,* *University of North Carolina* In 2001 we demonstrated that superfluid helium droplets, coupled to high-resolution infrared spectroscopy, could be used to investigate the intermolecular interactions and structures of metal cluster-adsorbate systems. The HCN-$Mg_n$ (n = 1-6) clusters investigated provided several interesting surprises and taught us many valuable lessons but nevertheless remained a somewhat uninteresting system from the point of view of catalysis and reactivity. Recently, we have overcome some significant experimental challenges and are finally beginning to fulfill the promise of using superfluid helium droplet spectroscopy for the investigation of more ''chemically interesting'' systems. In this talk we will present the infrared spectra of a single HCN molecule bound to copper and silver clusters. From these spectra we were able to obtain information about the adsorbate-metal cluster interactions, as well as obtaining direct structural information through high-resolution spectra.

**N11 6 Adaptive Clustering of Adatoms Around Ionic Dopants in He Droplets: Quantum Calculations** FRANCESCO A. GIANTURCO, *Dept. of Chemistry, University of Rome ''La Sapienza''* The structuring and collocation of individual He atoms as quantum objects around simple atomic and molecular impurities has been the subject of a great number of studies, both experimentally and from the theoretical viewpoint [1,2] since the advent of droplets experiments, where such nanoscopic containers have been exploited to provide a sort of nanocryostat for the analysis of the dopant's spectroscopic behavior [3]. We have carried out computations of potential fields within small clusters which contain a variety of ionic dopants using post-Hartree-Fock, ab initio methods and have further endeavoured to extract from them the corresponding classical and quantum structuring of such impurities within clusters of variable size. For the latter enquiry we have employed both classical optimization methods and Quantum Diffusion Monte Carlo analysis. Results for both atomic ($Li^+$) and molecular ($LiH^+$, $OH^+$, $OH^-$) ionic dopants will be presented at the meeting. [1] J.P. Toennies and A.F. Vilesov, Angewandte Chemie **43**, 2622 (2004). **N11 7 Electron-impact ionization mass-spectrometry of molecules and clusters in a pulsed helium droplet source** SHENGFU YANG, SCOTT BRERETON, ANDREW M. ELLIS, *University of Leicester, UK* A pulsed helium droplet source has been developed and characterized. The nozzle geometry was found to be critical in allowing controlled tuning of helium nanodroplet size by variation of the stagnation pressure and temperature. The average droplet size scales according to a simple $\{p, T\}$ scaling law, placing pulsed helium nanodroplet sources on a par with cw sources for the first time. Using this pulsed source, the ability of helium nanodroplets to impede ion fragmentation in electron impact mass spectrometry has been explored. A number of haloalkanes and $C_1$–$C_6$ alcohols were selected as the target species. The presence of helium alters the fragmentation patterns when compared with the gas phase, with some ion product channels being more strongly affected than others. Parent ion intensities are also enhanced by the helium for alcohols, but only for the two cyclic alcohols studied, cyclopentanol and cyclohexanol, is this effect large enough to transform the parent ion from a minor product (in the gas phase) into the most abundant ion in the helium droplet experiments. The results obtained are difficult to explain solely by rapid cooling of the excited parent ions by the surrounding superfluid helium, although this undoubtedly takes place. A second factor also seems to be involved, a cage effect which favors hydrogen atom loss over other fragmentation channels.

**N11 8 Electron and Ion Emission from Clusters exposed to Strong Laser Fields.**
JOSEF TIGGESBÄUMKER, *Institut of Physics, University of Rostock, Germany*

When clusters interact with intense optical laser pulses energetic and highly charged atomic fragment ions e.g. are generated[1]. In contrast to atoms the efficiency of the process could be enhanced by choosing a pair of optical delayed pulses instead of a single but more intense femtosecond pulse[2]. In metals the stronger charging of the clusters can qualitatively be explained by a plasmon enhanced ionization process. We extended our studies and have made a compared analysis of the emission of highly charged ions and energetic electrons the interaction dynamics of intense femtosecond laser fields with nanometer-sized silver clusters. Using a pair of laser pulses with variable optical delay the time-dependent cluster response is resolved. A dramatic increase both in the atomic charge state of the ions and the maximum electron kinetic energy is observed for a certain delay of the pulses. Corresponding Vlasov calculations on a metal cluster model system indicate that enhanced cluster ionization as well as the generation of fast electrons coincide with resonant plasmon excitation.[3]

**N11 9 Energy and angular momentum densities of states of ripplons on the surfaces of helium nanodroplets and bubbles***
VITALY KRESIN, MICHAEL JOHNSON, *University of Southern California* KLAVS HANSEN, *Gothenburg University* We present an analytical evaluation of the statistical densities of states of surface excitations (ripplons) of (1) isolated liquid-drop helium nanoclusters and (2) large multielectron bubbles in bulk liquid helium [1]. For the former case, the calculation of the energy density of states, $\rho(E)$, can be accurately performed in a micro-canonical ensemble formalism [2] and yields an expression which is extremely close both to the exact numerical calculation and to its fitted form [3]. For case (2) the canonical ensemble formulation is appropriate. For both systems, the calculation is then extended to yield the energy- and angular-momentum- resolved density of states $\rho(E,L)$ (c.f. [3]); in other words, the ripplon moment of inertia is described. [1] J. Tempere, I.F. Silvera, J.T. Devreese, Phys. Rev. Lett. **87**, 275301 (2001). [2] J.U. Andersen, E. Bonderup, K. Hansen, J. **N11 10 Excited states of $He_NH^-$Clusters*** PAULO ACIOLI,† *Physics Department, Northeastern Illinois University* FREDERICO V. PRUDENTE, *Instituto de Fisica, Universidade Federal da Bahia* We use correlation function quantum Monte Carlo (CFQMC) method to compute the excited states of the weakly bonded Helium clusters with the $H^-$ impurity ($He_N$ $H^-$, N=1, . . . ,5). The methodology was tested through comparison with previously published results for the ground state of the system with N=1-11. Our test basis set consists of a standard pair-product ground state multiplied by a polynomial. Our tests for $HeH^-$ and $He_2H^-$ demonstrated very good agreement with previously published discrete variable representation (DVR) results. We believe the lowest excited states of the larger clusters to be of similar quality and they can reveal important properties of these weakly bound systems, mainly on the effect of the impurity on the cluster and vice versa.

**N11 11 Microwave Spectroscopy in Helium Nanodroplets.**
RUDOLF LEHNIG, *University of Alberta* WOLFGANG JAEGER, *University of Alberta* We have implemented a microwave resonator, i.e. a Fabry-Perot cavity, into a helium nanodroplet instrument. The cavity consists of two spherical aluminum mirrors with radius of curvature of 13 cm and diameter of 10 cm. The cavity is mounted in a coaxial fashion into the instrument to maximize the interaction length between radiation and doped helium droplets. The helium droplet beam enters and exits the cavity through a hole in each of the mirrors. One of the mirrors can be adjusted to tune the cavity into resonance. The output of a cw microwave synthesizer can be amplified by a traveling wave tube amplifier to powers of about 25 Watt and is coupled into the cavity through a simple wire hook antenna. Detection is accomplished using the depletion technique. We have measured the spectrum of the J=2-1 transition of carbonylsulfide demonstrating the sensitivity of this method. Power saturation was observed and will be analyzed as will be the observed line width of the transition.

**N12 1 Boron nitride nanostructures: complete layers and nanomeshes** MARTINA CORSO, MARTIN MOERSCHER, SIMON BERNER, THOMAS GREBER, JUERG OSTERWALDER, *Physik-Institut, Universitaet Zuerich, Winterthurerstr. 190, CH-8057, Zuerich, Switzerland* ANDRII GORIACHKO, *Physikalisch-Chemisches Institut, J. L. Unversitaet, D-35392 Giessen, Germany* A highly ordered self-assembled nanomesh grows on a hot (1000 K) Rh(111) surface during 40 L (1 Langmuir=$10^{-6}$ $torr \times s$) of borazine $(HBNH)_3$ exposure [1]. Hexagonal boron nitride (ith–BN) units aggregate to form this double-layer network of 3 nm periodicity and 2 nm hole size. The two layers are offset so that nearly the entire underlying metal surface is covered. This system can be used as a template for supramolecular structures, as demonstrated with $C_{60}$ molecules, or for any purpose where a nanopatterned surface that is stable at high temperatures (1000 K) is needed. One of the driving forces for its formation is the large lattice mismatch of 6.9 % between the ith–BN film and the Rh substrate. The growth of similar nanomeshes on different substrates is investigated, with the purpose to control hole size and shape. It is found that not only the lattice mismatch and the symmetry of the underlying metal play an important role but also the bonding between the nitrogen atoms and the substrate. In fact nanomeshes can be grown on Ru(0001) and on Ir(111) thin films but it does not form on Pd(111) nor on Pd(110). [1] M. Corso et al. Science, 303 (2004) 217.

**N12 2 Measurements of Molecular Dynamics in Atomically Engineered Molecular Nanostructures*** JOSEPH A. STROSCIO, ROBERT J. CELOTTA, *Electron Physics Group, National Institute of Standards and Technology, Gaithersburg, MD 20899-8412* The quantum yield for exciting the motion of a single atom within a molecular nanostructure was measured with atomic spatial resolution. The molecular nanostructures consisted of a series of $CoCu_n$ and $CoCu_nCo$ linear molecules fabricated on a Cu(111) surface. The Co atoms at the end of the molecules were induced to switch between two lattice positions using electron excitation in a scanning tunneling microscope (STM). The electron excitation and quantum yield were found to be spatially localized on an atomic scale. Above an electron energy threshold, the Co atom motion resulted from a predominantly single electron process. By systematically varying the molecular structure, atom motion within the molecule was shown to be dependent on molecular length and composition.

**N12 3 Formation and Vibrational Entropy-Driven Disordering of Mo(100) and W(100) Surface Alloys** M.S. ALTMAN, K.L. MAN, Y.J. FENG, C.T. CHAN, *Hong Kong University of Science and Technology* Atoms that are deposited on a surface of a dissimilar material may either remain on the surface or they may become incorporated in a surface or bulk alloy. Although the energetic differences between alloy and overlayer structures at T = 0 can now be understood from first principles in many systems, the entropic contribution to the system free energy, which governs the equilibrium structure, is less well understood. The formation and stability of Cu, Ag and Au-induced c(2x2) alloys at the Mo(100) and W(100) surfaces have been investigated with low energy electron microscopy and diffraction. The dependence of the c(2x2) diffraction intensity upon metal deposition flux reveals that alloy formation is governed by atomistic processes that are analogous to those that dictate overlayer island nucleation. An order-disorder transition is also observed that converts the surface from ordered alloy to disordered overlayer structure. Combined with knowledge of energetics that is obtained from first principles calculations, a comparison of disordering temperatures for alloys of the different metal species and substrates provides information on the decisive contribution of vibrational entropy to the system free energy. Effective Debye temperatures for metal adatoms are determined that are substantially lower than bulk values, but exhibit the expected mass and bond strength dependence.Vibrational entropy may also play a role in the stability of alloys at other surfaces.

**N12 4 Measuring 3D Alloy Composition Profiles at Surfaces.**
JAMES HANNON, *IBM Research Division*

A key challenge in thin-film growth is controlling structure and composition. Of particular importance is understanding how and why atomic-scale heterogeneity develops during growth. We have used low-energy electron microscopy (LEEM) to measure how the three-dimensional composition of an alloy film evolves with time at the nanometer length scale. By quantitatively analyzing the reflected electron intensity in LEEM, we determine the alloy composition and structure, layer by layer near a surface, with 9 nm lateral spatial resolution. As an example, we show that heterogeneity during the growth of Pd on Cu(001) arises naturally from a generic step-overgrowth mechanism that is likely to be relevant in many growth systems. This work was performed in collaboration with Jiebing Sun (UNH), Karsten Pohl (UNH), and Gary Kellogg (Sandia Labs).

**N12 5 Threading Dislocation Pair Annihilation as a Mechanism for the Growth of Ordered 2D Nanocluster Arrays*** BOGDAN DIACONESCU, KARSTEN POHL, *Physics Department and Material Science Program, University of New Hampshire* The bottom-up approach of growing nanostructured ordered arrays of clusters on the misfit dislocation networks of strained metallic thin films requires a detailed understanding of the nucleation and film-adsorbate interaction processes. In the case of S adsorption on submonolayer Ag / Ru(0001), the Ag's short herring bone rectangular misfit dislocation unit cell of 54Åx40Å (19x16 Ag atoms) reconstructs into a well ordered triangular array of S filled vacancy islands 50Å apart. Atomically resolved VT-STM measurements show that the S cluster growth mechanism involves a local restructuring of the misfit dislocation network of Ag with the final structure free of threading dislocations. The new symmetry and morphology of the composed S/Ag films is obtained via a threading dislocation annihilation mechanism where adjacent and opposite pairs of threading dislocations are replaced by the S filled Ag vacancy islands. The local character of the annihilation process is shown by the conservation of the unit cell size area of 21.5nm$^2$.

**N12 6 Highly-spatial resolved surface structure and composition by LEEM image intensity analysis** J. SUN, *Univ. of New Hampshire* J. B. HANNON, *IBM Research Division* G.L. KELLOGG, *Sandia Natl. Labs* K. POHL, *University of New Hampshire, Department of Physics, Durham, NH 03824* Controlling the local structure and composition of a surface alloy is of great importance in thin film technologies. However, measuring the alloy's heterogeneity is very difficult, because existing experimental techniques either assume lateral homogeneity or have limited subsurface or chemical sensitivity. In this work we have analyzed the electron diffraction intensity vs. incident energy curves of the (00) beam acquired from low-energy electron microscopy (LEEM) images. In contrast to conventional LEED-IV we are able to extract structural and local composition in the surface region with a lateral resolution of 8 nm. Two challenges in applying multiple electron scattering calculations to the analysis of LEEM data are the low and limited electron energy range (10 to 100 eV), which we address by a careful choice of the energy-dependent real and imaginary part of the optical potential. Our analysis of the LEEM IV curves for the clean Cu(001) and Pd/Cu(001) surfaces gives excellent agreement between experimental and best-fit data and good agreement with previous structural investigations. Our new analysis technique is capable of determining surface structure and composition with high accuracy.

**N12 7 Structure of an ultra-thin Ag film on the Al(100) surface*** M. KOPCZYK, *Montana State University* A. KAYANI, *Montana State University* R.J. SMITH, *Montana State University* D.S. CHOI, *Kangwon National University, Chunchon, Korea* The surface structure for one monolayer of Ag deposited on the Al(100) surface at room temperature has been studied using low energy electron diffraction (LEED), ion scattering spectroscopy (ISS) and Rutherford back-scattering spectroscopy (RBS). The Ag coverage was determined with RBS. We conclude that the Ag atoms form two domains of a buckled, quasi-hexagonal structure that is incommensurate with the Al(100) surface unit cell, having a repeat distance of 5 Al(100) interatomic spacings in the [110] direction. The LEED pattern shows a double-domain (5x1) structure with additional intensity in those spots corresponding to a (111) close-packed hexagonal layer. The analysis of the ISS results suggests that the heights of the adsorbed Ag atoms above the Al surface are not all the same, leading to the proposed buckling model. In addition, some Al atoms apparently move from the substrate up into the Ag adlayer.

**N12 9 Disorder and Roughening at Surfaces of Silver/Gold Alloys*** GREGORY DERRY, *Loyola College In Maryland* RUNDONG WAN, *University of Maryland Baltimore County* Attempts to obtain a clean and well-ordered surface in ultrahigh vacuum for several low index faces of a 50 at% silver/gold alloy gave rise to an unexpected phenomenon. After several cycles of sputtering and annealing, the surfaces appeared clean using Auger spectroscopy but yielded low energy electron diffraction spots of poor quality (in the case of AgAu(110), no diffraction was observed at all). Many further time/temperature annealing protocols were attempted with no improvement. In addition to the diffraction results, which indicate a lack of long-range microscopic order at the surface, continued processing resulted in macroscopic roughening of the surfaces. Electron microscopy revealed the presence of features with sizes on the order of microns at the roughened surfaces. Analysis of the lineshapes of the diffuse LEED beams for the AgAu(111) surface indicates that the sizes of the ordered patches on the surface are less than a nanometer. These results will be presented in more detail and possible explanations for this extraordinary behavior will be discussed.

**N12 11 Determination of interface compositions by X-ray three-beam resonance diffraction** H.-H. WU, Y.-R. LEE, C.-M. HSUEH, H.-H. CHEN, S.-L. CHANG, *National Tsing Hua University* X-ray three-beam diffraction$(200/\bar{3}\,\bar{1}\,1)$under resonant conditions is used to measure the concentrations of the constituent elements of the interface between a (100) CdTe thin film and a (100) InSb substrate. The three-beam diffraction profiles versus the azimuth angle of rotation around [200] reveal a wide variety of change in phase shift due to resonance for photon energies in the vicinity of the Cd $L_{III}$ absorption edge. At different momentum transfers $q_r$ along [200], sensitive to the interfacial structure, the phase shift in the resonant state also provides sufficient information about the distributions of Cd and Te concentrations. With theoretical analysis for the crystallographic phase of the structure-factor triplets and the resonance phase shifts involved in the three-beam diffraction, it allows us to determine the composition of Cd and Te as a function of depth normal to the interface. Via the propagation of the secondary$(\bar{3}\,\bar{1}\,1)$reflected beam along the surface, possible interface structures parallel to the surface could also be deduced.

**N12 13 Investigation of the interface structure in sputtered $WSi_2$/Si multilayers by in-situ synchrotron X-ray scattering.** YIPING WANG, HUA ZHOU, LAN ZHOU, RANDALL L. HEADRICK, *University of Vermont, Department of Physics, Burlington, VT 05405* ALBERT. T. MACRANDER, *Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 6043* KARL F. LUDWIG, *Boston University, Department of Physics, Boston, MA 02215* Multilayer X-ray optics have many applications such as X-ray microscopy, X-ray lithography, and X-ray microanalysis. The interface imperfections are critical to the optical performance of the multilayer structures. We report on the growth of $WSi_2$ and Si amorphous thin films by dc magnetron sputtering in a vacuum chamber with $10^{-9}$ Torr base pressure. In-situ synchrotron X-ray scattering with high temporal resolution has been employed to probe the surface and interface roughness evolution during film deposition. X-ray reflectivity simulations were performed using the IMD software package. It is found that the structure of $WSi_2$/Si multilayers is with an alternately smooth and rough interface. While Si layer roughens, $WSi_2$ layer is observed to smooth out an initially rough surface. The ion energy and flux assisting the growth may play a role in inducing this asymmetry in the interface roughness.

**N13 1 Strong-Field Physics with Coherently Prepared Molecular Targets.***
ROBERT JONES, *University of Virginia*

Intense, short laser pulses can create rotational wavepackets in molecules, resulting in transient preferential molecular alignment in a field free environment. The availability of aligned rather than randomly oriented molecular samples is

enabling new strong-field molecular physics experiments which offer additional insight into a variety of complex phenomena. For example, high harmonic generation (HHG) is mediated by electrons that are first tunnel-ionized and then driven back into their parent ions by an intense laser field. Both the initial ionization and recollision events can be strongly dependent on the orientation of the molecular axis with respect to the laser field. Once this dependence is well understood, information regarding the structure of the parent molecule at the instant of the electron/ion recollision might be extracted from the resulting electron and/or photon emission. I will describe methods for manipulating and probing molecular alignment, as well as our recent measurements of the dependence of intense laser ionization rates, HHG yields, and the polarization of high-order harmonics on the alignment of the molecular axis relative to the polarization direction of the intense laser field.

**N13 2 Non-adiabatic Electronic Excitation of Linear Polyenes in the Strong Field Regime** STANLEY SMITH, *Wayne State University, Detroit, MI* XIAOSONG LI, *University of Washington, Seattle, WA* ALEXEI MARKOVICH, DMITRI ROMANOV, ROBERT J. LEVIS, *Temple University. Philadelphia, PA* H. BERNHARD SCHLEGEL, *Wayne State University, Detroit, MI* Using a newly developed unitary transform time-dependent Hartree-Fock (UT-TDHF) algorithm, the electronic response to an ultrashort strong-field laser pulse was studied on a series of molecules – ethylene, butadiene, and hexatriene – in which molecular size and conjugation increase systematically. The evolution of electronic subsystem of molecules exposed to 760 nm $8.75\times 10^{13}$ W/cm$^2$ of 7 fs duration was calculated using the 6-31G(d,p) basis set. Two scenarios are envisioned: in the first, the molecule interacts with the pulse immediately after ionization; in the second, sufficient time elapses for the molecular geometry to relax. The non-adiabatic behavior of the instantaneous dipole moment and the charge distribution in a molecule is more pronounced for the monocations than for the dications or neutrals. For a given charge state and geometry, the non-adiabatic effects increase with the length of the molecule. As Fourier analysis reveals, the residual (after-pulse) oscillations of the dipole moment are mainly due to non-resonant excitations of the lowest excited states with significant oscillator strength. For each molecule, the non-adiabatic coupling is greater for geometry with the lower excitation energies.

**N13 3 A new type of wavelength dependence in strong-field ionization** DMITRI ROMANOV, *Dept. of Physics, Center for Advanced Photonics Research, Temple University* KATHARINE MOORE, RYAN COMPTON, ROBERT J. LEVIS, *Dept. of Chemistry, Center for Advanced Photonics Research, Temple University* It is commonly assumed that in mid-IR region the strong-field ionization approaches quasistatic limit (tunneling, or ADK regime) and ceases to depend on the laser wavelength. Contrary to this notion, ionization yields for the noble gas Xe at intensities from $10^{13}$-$10^{15}$ W cm$^{-2}$ for wavelengths spanning from 800 to 1500nm reveal strong and counterintuitive wavelength dependence. There is an increasing ionization probability in the strong field regime as the excitation wavelength increases from 800nm to 1500 nm at fixed field intensity. The measured thresholds for the ionization event scale approximately as $\lambda^{-2}$. We developed a simple quantitative model that extends through-the-barrier tunneling with single photon ionization from a Rydberg intermediate state and captures the observed wavelength dependence. This wavelength dependence will be reduced to some degree if the ionization occurs in a strong DC electric field that is capable to independently ionize the Rydberg states. The wavelength dependence of ionization rate in the quasitstatic regime is of considerable importance for ascertaining the correct physics for various strong field processes.

**N13 4 Orientation effects in Coulomb explosion of $H_2S$ in intense laser fields studied by coincidence momentum imaging** AKIYOSHI HISHIKAWA, EIJI TAKAHASHI, *Institute for Molecular Science, National Institute for Natural Sciences and The Graduate University for Advanced Studies (SOKENDAI)* The Coulomb explosion of $H_2S$ in an ultrashort intense laser field (12 fs, 0.33 PW/cm$^2$), $H_2S^{3+} \rightarrow H^+ + S^+ + H^+$, has been studied by the coincidence momentum imaging method to study how the nuclear dynamics depends on the molecular orientation with respect to the laser polarization vector. When the molecular plane, defined as the plane spanned by the fragment momentum vectors, is perpendicular to the laser polarization vector ($\varepsilon$), the distribution of the total kinetic energy release E shows a peak at E = 21(1) eV. On the other hand, the distribution peak is observed at a substantially smaller value, E = 15(1) eV, when the molecular plane is perpendicular to $\varepsilon$, showing that the Coulomb explosion dynamics of $H_2S$ depends sensitively on the orientation of the molecular frame to the laser polarization vector. The difference in the peak kinetic energies indicates that the geometrical structure for the perpendicular orientation is less elongated prior to the Coulomb explosion than that for the perpendicular orientation.

**N13 5 Ultrafast hydrogen atom dynamics of small hydrocarbon molecules in intense laser fields - Ejection of H3+ and hydrogen migration.**

KAORU YAMANOUCHI, *The University of Tokyo*

In ultrashort intense laser fields, molecules are decomposed into fragments via a variety of dissociation pathways. Among them, ultrafast migration of hydrogen atoms within molecules as well as efficient ejection of H3+ molecular ions are noteworthy [1]. By referring to our recent studies on small hydrocarbon molecules in intense laser fields [2] by the

coincidence momentum imaging method [3], I will show how ultrafast dynamics of hydrogen atoms are induced within duration of ultrashort intense laser pulses. [1] Y. Furukawa, K. Hoshina, K. Yamanouchi, H. Nakano, Chem. Phys. Lett. 414, 117 (2005). [2] T. Okino, Y. Furukawa, P. Liu, T. Ichikawa, R. Itakura, K. Hoshina, K. Yamanouchi, and H. Nakano, Chem. Phys. Lett. 419, 223 (2005). **N13 6 Femtosecond Laser Ionization of Organic Amines with Very Low Ionization Potential.** TOMOYUKI YATSUHASHI, TAKASHI OBAYASHI, MICHINORI TANAKA, MASANAO MURAKAMI, NOBUAKI NAKASHIMA, *Graduate School of Science, Osaka City University* The interaction between high intensity femtosecond laser and molecules is one of the most attractive areas in laser chemistry and ionization is the most fundamental subject. Theoretical consideration successfully reproduced the ionization behavior of rare gases. However, the understanding of ionization mechanisms of large molecules is difficult more than those of rare gases due to their complexity. Generally speaking, molecules are harder to ionize than rare gases even if they have the same ionization potential. The suppressed ionization phenomena are one of the important features of molecular ionization. Hankin et al. examined 23 organic molecules with ionization potentials between 8.25 and 11.52 eV. We have examined ionization and/ or fragmentation of many organic molecules, including aromatic compounds, halogenated compounds, methane derivatives etc. at various wavelengths below $10^{16}$ $Wcm^{-2}$. In order to investigate the nature of molecular ionization, it is interesting to examine a variety of molecule in a wide range of ionization potential. In this study, we examined several organic amines because we can explore the uninvestigated ionization potential range down to 5.95 eV. In addition to the significant suppression of the ionization rates, stepwise ionization behavior, which was not observed in rare gases, was observed.

**N13 7 All-solid-state, ultraviolet, high power laser system using Ce:LiCAF as a gain medium** NOBUHIKO SARUKURA, *Osaka University* SHINGO ONO, HIDETOSHI MURAKAMI, ALEX QUEMA, ELMER ESTACIO, *Institute for Molecular Science* TSUGUO FUKUDA, *Tohoku University* High peak-power, femtosecond, ultraviolet (UV) lasers have attracted new interest. Chirped pulse amplification (CPA) in the UV region has been demonstrated using Ce:LiCaAlF6 (Ce:LiCAF) crystal as the gain medium. The peak power of the amplified and compressed pulse (115 fs) reached 30 GW at 290 nm. To increase the peak power to the terawatt (TW) level, further pulse compression is desired. Since Ce:LiCAF has a tunability of 281nm to 315nm, it holds promise for 3-fs pulse generation which are required for seeding TW-class Ce:LiCAF lasers. The pulse-width of the frequency-tripled Ti:sapphire regenerative amplifier was measured to be 210 fs. The seed pulses were then focused into a hollow fiber filled with argon to spectrally broaden the pulses due to self-phase-modulation. The pulses were then compressed to 25 fs by dispersion-compensation. The fourth harmonics of a Nd:YAG laser (266 nm) is an ideal pump source as it falls within the absorption band Ce:LiCAF. We have generated 430 mJ fourth harmonics with a total conversion efficiency of 30.5% using Li2B4O7

$$(LB4)crystals.ACe{:}LiCAF$$

double-pass power-amplifier was then designed with a peak energy of 98 mJ for a 13 mJ seed pulse and an extraction efficiency of 25%.

**N13 8 Influence of linear chirp on non-vertical transitions in a dye solution** ELIZABETH CARROLL, ANDREI FLOREAN, PHILIP BUCKSBAUM, ROSEANNE SENSION, *FOCUS Center, University of Michigan, Ann Arbor, MI* KEN SPEARS, *Department of Chemistry, Northwestern University, Evanston, IL* Chirped laser pulses can manipulate vibrational coherences in dye solutions. We show that the effect of linear chirp also depends strongly on the power spectrum of the ultrafast pulse. We use a programmable phase mask to control the spectral phase of 25-fs visible pulses generated in a noncollinear optical parametric amplifier (NOPA). Following chirped pulse excitation of the oxazine laser dye LD690, coherent oscillations are observed in the time-resolved transient absorption. When a vertical transition is excited, negative chirp leads to strong ground state vibrational coherences as resonant stimulated Raman processes are enhanced by the frequency sweep of the laser pulse. When the chirped pulse excitation is higher frequency than the Franck-Condon transition, the optical response of the dye is significantly affected by excited state absorption. In this case, coherences are established in excited states but no chirp-enhancement of the ground state wavepacket is observed.

**N13 9 Terahertz absorption spectrum of water vapor at different humidity at room temperature** XUYING XIN, HAKAN ALTAN, DAVID MATTEN, ANGELAMARIA SAINT, ROBERT ALFANO, *Institute for Ultrafast Spectroscopy and Lasers, Physics Department, the City College of New York* We measured the absorption spectrum of water vapor in 0.2-2.4THz range at different humidity from 17% to 98% at room temperature using Er: doped fiber laser (IMRA America Inc.) based terahertz time-domain spectroscopy. The experiments were performed in a nitrogen-purged cage at atmosphere environment to obtain the reference and water absorption information. The seventeen absorption lines were observed due to water molecular rotations in the ground vibration state. The first three absorption lines at low frequencies increase with humidity, following the Beer-Lambert Law, while some of high frequency lines were found to decrease with humidity. These effects will be discussed. The observed line broadening is due to collisions occurring among water and nitrogen molecules.

**N16 1 Ambient and High Pressure Structural Studies on $TiH_2$*** PATRICIA KALITA, RAVHI KUMAR, ANDREW CORNELIUS, *University of Nevada, Las Vegas* Currently metal hydrides attract intense research interest because of their potential application as hydrogen storage materials. We performed in situ high-pressure synchrotron x-ray diffraction as well as high-pressure Raman spectroscopy studies on $TiH_2$ at pressures up to 20 GPa. Low temperature ambient pressure x-ray diffraction studies were also carried out. A phase transition from a high symmetry cubic structure to a lower symmetry tetragonal structure was observed as temperature is lowered below room temperature. The unit cell parameters as well as the equation of state were calculated. To the best of our knowledge this is the first report of high pressure synchrotron x-ray diffraction as well as high-pressure Raman spectroscopy studies on $TiH_2$.

**N16 2 Optical Spectroscopy of PdO and Pd thin Films under hydrogen exposure*** J.I. AVILA, M. FAVRE, U.G. VOLKMANN, A.L. CABRERA, *Departamento de Fisica, Universidad Catolica de Chile* D. LEDERMAN, *Physics Department, West Virginia University* Palladium oxide (PdO) is a p-type semiconductor with a bandgap appropriate to absorb light in the visible range an thus generating an electrical current. This bandgap, being of the order of 2.5 eV, remains yet not accurately determined. We are currently setting up a new experiment in which we are able to monitor the evolution of reflectivity or transmission, for several wavelengths in the visible spectrum, and the resistivity as a function of the exposure time to hydrogen. We should be able to calculate the evolution of bandgap of the semiconductor as a function of reduction from the reflectivity data. Pd films also change reflectivity properties during hydrogen absorption. The experimental set up consist of a tungsten light, Spectrapro 275 monochromator with a diffraction grid of 1200 lines/mm, and a silicon diode detector. Preleminary results will be shown. Based on these data we expect to depict a model for the changes measured.

**N16 3 First-principles prediction of a new metallic carbon hydride: bcc-$CH_2$*** CESAR CAB, ROMEO DE COSS, GERKO OSKAM, *Department of Applied Physics, CINVESTAV-Merida, Mexico* GABRIEL MURRIETA, *Facultad de Matematicas, UADY, Yucatan, Mexico* GABRIEL CANTO, *CCMC-UNAM, Ensenada, Mexico.* The observation of a new carbon phase in nanoparticles having the body-centered-cubic structure (bcc) has been reported very recently. However, has been suggested that hydrogen is present in the samples forming solid $CH_2$ with the anti-cuprite structure. The structural and electronic properties of bcc-C and bcc-$CH_2$ are unknown. In the present work we have studied the elastic stability and the electronic structure of these systems by means of first-principles total-energy calculations. The results were obtained with the pseudopotentials LCAO method (SIESTA code) and the Generalized Gradient Approximation (GGA) for the exchange-correlation potential. We have evaluated the structural stability via the elastic properties, we find that bcc-$CH_2$ is stable with a lattice parameter very close to the experimental value. In addition, we find that the electronic structure of bcc-$CH_2$ exhibits metallic behavior with a relatively high density of states at the Fermi level. The relevance of this new hydride to the problem of hydrogen storage is discussed.

**N16 5 Ab Initio Thermochemistry and Elastic Properties of Alkaline Earth Hydrides** LOUIS HECTOR, JR., JAN HERBST, *GM R&D Center* WALTER WOLF, PAUL SAXE, *Materials Design* In addition to comprising a scientifically interesting class of materials, the binary alkaline earth hydrides are important components of hydrogen sorption/desorption reactions. Of critical importance for predicting the thermodynamic stability of hydrides is the enthalpy of hydride formation, $\Delta H$, which links the temperature and pressure of hydrogen sorption via the van't Hoff relation. We compare LDA and GGA predictions of the heats of formation and elastic properties of alkaline earth metals and their binary hydrides $BeH_2$, $MgH_2$, $CaH_2$, $SrH_2$, and $BaH_2$ using a plane wave density functional method. Phonon calculations using the direct method enabled prediction of the zero point energies of each material and the 0K and 298K heats of formation. We also computed the 0K and 298K cohesive energies for the alkaline earth metals. Born effective charge tensors were computed via the Berry phase method and enabled prediction of the phonon dispersion curves with LO/TO zone center splittings. It was found that the LO/TO splittings have no effect on the computed zero point energies and heats of formation. The elastic constants were computed with a least squares fitting method using a set of sequentially-applied strains to improve the accuracy of each calculation. Comparison of results from the least squares methodology with prior results using the Hartree-Fock method suggest that the former is substantially more accurate for predicting hydride elastic properties.

**N16 6 Hydrogen uptake and the 18-eletron rule** KIRAN BOGGAVARAPU, ANIL KANDALAM, PURU JENA, *Virginia Commonwealth University* Hydrogen is considered to be an ideal energy carrier in the foreseeable future; however, the key problem is its storage. Solid state materials capable of storing hydrogen with high gravimetric (9 wt %) and volumetric density (70 g/L) operating under ambient thermodynamic conditions and exhibiting fast hydrogen sorption kinetics are of practical importance. It is clear that the storage material should consist of light elements such as Li, B, and C etc. Hydrides of these elements are too strongly bound to be easily desorbed. Attempts were made to deposit light weight transition metals on carbon surfaces such as fullerenes, nanotubes etc., however, they tend to cluster together reducing hydrogen uptake dramatically. One way to achieve high storage is to functionalize simple organic molecules such as $C_4H_4$, $C_5H_5$ etc. with light weight metals such as Sc and Ti. In this presentation, we will discuss based on DFT computations, the dependence of hydrogen uptake on the nature of substrate, the desportion energies, and the nature of bonding.

**N16 7 Ab initio simulation of hydrogen storage in BN systems** * STEPHEN SHEVLIN, *Queen Mary, University of London* ZHENGXIAO GUO, *Queen Mary, University of London* We model via first principles simulation hydrogen storage in boron nitride systems, such as h-BN sheets, the paradigm BN molecule borazine ($B_3N_3H_6$) and ammonia-borane ($BNH_6$). We found $H_2$ preferentially adsorbs on the perfect h-BN surface but strongly bound atomic hydrogen prefers to adsorb on vacancies, with consequences for hydrogen storage. The addition of TM (transition metal) atoms to boron nitride, to act as adsorbents for hydrogen, was investigated using borazine as a prototype system for h-BN. The binding of TM atoms (Sc, Ti, V etc.) to borazine was determined, with the variation in bonding intimately related to the electronic structure. The dopants were found to promote the binding of both hydrogen atoms and molecules to borazine, increasing binding energy by $\sim$ 300% and 1500%, respectively. Initially TM dihydrides form but as hydrogen concentration increases molecular hydrogen becomes preferred. Bound hydrogen is stable at room temperature and the maximum hydrogen capacity and kinematics of this prototype system will be presented. In addition, the dissociation of $BNH_6$ itin vacuo, on the surface of $MgH_2$, and in the presence of TM catalysts is modeled.

**N16 8 Atomic and Molecular Hydrogen Interaction with Ti-Doped Al (100): Hydrogen Dissociation and Surface Alane Formation** ERIK MULLER, PETER SUTTER, PERCY ZAHL, *Center for Functional Nanomaterials, Brookhaven National Laboratory* SANTANU CHAUDHURI, JAMES MUCKERMAN, *Department of Chemistry, Brookhaven National Laboratory* A comprehensive research effort on the atomistic mechanisms underlying hydrogen storage in Ti-doped $NaAlH_4$ is aimed at deriving a knowledge base for the rational optimization of this and other related complex hydride materials. Our investigation focuses on the role of the Ti dopants in promoting reversible hydrogenation, a key requirement for any practical hydrogen storage material. The re-hydrogenation reaction proceeds from the crucial initial step of dissociative adsorption of molecular hydrogen on Al or NaH. A specific Al:Ti complex was recently predicted as an active site for $H_2$ dissociation on extended Al(100) surfaces [1]. Combining high-resolution surface imaging experiments (scanning tunneling microscopy, low-energy electron microscopy) with density functional theory, we are investigating the dissociative adsorption of $H_2$ on Ti-doped Al(100) prepared in ultrahigh vacuum. We will discuss our progress toward identifying catalytically active sites for H2 dissociation on this surface, as well as pathways toward the formation of mobile Al-species. [1] S. Chaudhuri and J.T. Muckerman, J. Phys. Chem. B 109, 6952 (2005).

**N16 9 Theoretical Study of Hydrogen Dissociation on the $TiAl_3$ Surface*** YAN WANG, M. Y. CHOU, *School of Physics, Georgia Institute of Technology* In order to better understand the catalytic role played by Ti in enhancing the reaction kinetics of sodium alanate, we present a first-principles investigation of hydrogen dissociation and adsorption on the pure Al surface as well as on the Ti doped surface with a local alloy composition of $TiAl_3$. The most energetically favorable location for Ti near the surface is identified. It is found that the presence of Ti promotes H adsorption on the surface with the H atom sitting on top of an Al atom. The binding between Ti and Al modifies the surface charge distribution near the adsorption site and facilitates the adsorption process. The potential energy surface for $H_2$ dissociation over both pure Al and the alloy surfaces are also discussed.

**N16 10 Phase Stability of Mixed-Alkali Alanates** ZHU MA, *School of Physics, Georgia Institute of TeZhuchnology, Atlanta, GA 30332* MEI-YIN CHOU, *School of Physics, Georgia Institute of Technology, Atlanta, GA 30332* To date sodium alanate $NaAlH_4$ is the only reversible complex hydride that satisfies the international density targets for hydrogen storage materials of 5 wt.% and 70 kg/m$^3$. The reversible hydrogenation process takes place at reasonable conditions. Therefore, it is desirable to increase the H wt.partially replacing Na with a lighter alkali metal such as Li. To study the stability of these mixed-alkali alantes, we perform first-principles calculations for the alloy systems $Na_{1-x}Li_xAl\ H_4$ and $Na_{3(1-x)}Li_{3x}AlH_6$ within the framework of density functional theory and pseudopotentials. For the compositions we have considered for the tetrahydrides, the mixing energies are all positive, indicating that the sodium and lithium alanates prefer being phase separated. For the hexahydrides, one stable intermediate compound is found. The binding characteristics of these mixed-alkali alanates will be discussed.

**N17 1 Terahertz Semiconductor Detectors: Designs to Applications.**
UNIL PERERA, *Georgia State University*

The work describes terahertz photon detectors based on semiconductor micro- and nano-structures using homojunctions, and heterojunctions. A Homojunction or HEterojunction Interfacial Workfunction Internal Photoemission (HIWIP or HEIWIP) infrared detector, formed by a doped emitter layer, and an intrinsic layer acting as the barrier followed by another highly doped contact layer, can detect Terahertz photons due to intraband transitions. The threshold can be tailored by adjusting the band offset between the emitter and the barrier. This principle can be used with any semiconductor material combination. HIWIPs have the same material (doped and undoped) in the emitters and barriers, while HEIWIPs have different band gap material in the two layers. The detection mechanism involves free carrier absorption in the emitter, followed by the internal photoemission of photoexcited carriers across the junction barrier, and then the collection of carriers by the applied electric field at the contacts. Utilization of nanoplasmonic resonances to enhance the terahertz absorption using engineered and self-assembled metal nanostructures on HEIWIP detectors will also be discussed. The metal nanostructures will act as enhanced frequency couplers, which will allow more efficient absorption of terahertz radiation as it is converted into surface plasmons. The near field of SPs will affect the electron gas in the photodetectors the same way as the far-field does. Thus the local field enhancement known for other phenomena and devices could be achieved. Work supported in part by US NSF and US Airforce.

**N17 2 III-V Semiconductor Diodes and the Terahertz Technology Gap** THOMAS CROWE, *Virginia Diodes, Inc.* The terahertz frequency band, spanning from roughly 100 GHz through 10 THz, is often sited as the most scientifically rich, yet unexplored region of the electromagnetic spectrum. Scientific applications include radio astronomy, chemical spectroscopy, plasma diagnostics, compact range radar, atmospheric remote sensing and electron paramagnetic resonance studies of organic molecules. Recently, many groups have developed rudimentary imaging systems for this frequency band, either for basic scientific investigations or defense and security scanners. However, the inherent difficulty of creating sources of terahertz power that are sufficiently powerful, tunable, reliable and robust is a primary difficulty. Researchers in the field generally speak of the terahertz technology gap, which spans the transition from classical electronics to quantum photonics. This talk will consider the nature of the terahertz technology gap and the technological transition from electronics to photonics. Efforts to develop useful sources and receivers of terahertz energy based on III-V semiconductor diodes will be discussed. Also, important recent results, including the development of all-solid-state sources and receivers for the 0.1 – 3 THz frequency range will be presented. Finally, the fundamental limitations of this technology will be considered.

**N17 3 Spontaneous emission from accelerated Bloch electrons – Bloch oscillation radiation*** VALERIY SOKOLOV, GERALD IAFRATE, *Dept. of Electrical and Computer Engineering, NCSU, Raleigh, NC 27695-8617* JOSEPH KRIEGER, *Dept. of Physics, Brooklyn College, CUNY, Brooklyn, NY 11210* A theory of spontaneous emission of radiation for a Bloch electron traversing a single band in an external electric field is presented. The radiation field is described by a free space quantized electromagnetic field in the Coulomb gauge. It is shown that the spontaneous emission occurs with frequencies equal to integral multiples of the Bloch frequency without any itad hoc assumptions concerning the existence of Wannier-Stark levels. An explicit expression for the transition probability is derived in first-order perturbation theory relative to the radiation field. Although the output frequency of the radiation can be operationally tuned from the gigahertz to terahertz spectral range by varying the constant electric field, it is estimated that a spontaneous emission power output of only about 0.1 of a microwatt is available using GaAs-based superlattices. In this regard, it is noted that the atomic spontaneous emission probability and related transition rates can be enhanced by properly tailoring the surrounding electromagnetic environment. Therefore, considering Bloch oscillations in a resonant microcavity to enhance the spontaneous emission is a noteworthy alternative for exploring tunable gigahertz to terahertz radiation sources.

**N17 4 Developing a voltage tunable two-color corrugated QWIP focal plane array** KWONG-KIT CHOI, CARLOS MONROY, *U. S. Army Research Laboratory* THEODOR TAMIR, MING LEUNG, *Polytechnic University* JINJIN LI, DANIEL TSUI, *Princeton University* Single color quantum well infrared photodetector focal plane array (QWIP FPA) has been fully developed. The trend is toward FPAs with spectral analysis and target discrimination capabilities. The challenges of achieving a two-color QWIP FPA are the identification of an effective coupling scheme for both wavelengths and a voltage tunable QWIP material. The former is needed to ensure high sensitivity in both wavelengths and the latter is needed in high resolution FPAs

where only one external connection per pixel may be permissible. In this talk, we will discuss the detector parameters needed for high performance infrared imaging, the corrugated light coupling scheme, and the voltage tunable two-color QWIP materials based on superlattices (SLs). In the coupling design, one approach is to use Fabry-Perot oscillations in the triangular cavities to enhance both incident intensities. In the material design, the focus is on the electron energy relaxation rate in the energy relaxation layers (ERL) lying between the active SL periods. By computing the hot-electron distribution after traversing through the ERL layer, one can determine the doping required to eliminate cross-talk between the two colors.

**N17 5 Study of a broadband high-gain InGaAs/InGaAsP quantum-well infrared photodetector** J. LI, *Princeton University* K.K. CHOI, *US Army Research Laboratory* J.F. KLEM, J.L. RENO, *Sandia National Laboratories* D.C. TSUI, *Princeton University* PRINCETON UNIVERSITY TEAM, US ARMY RESEARCH LABORATORY COLLABORATION, SANDIA NATIONAL LABORATORIES COLLABORATION, Lattice-matched InGaAs/InP quantum well infrared photodetectors (QWIPs) exhibit high photoconductive gain but nonadjustable detection wavelength because of their fixed barrier height. The use of $In_xGa_{1-x}As_yP_{1-y}$ (InGaAsP) as the barrier material is superior to that of InP with regard to flexibility of the operating wavelength. In this work we investigate the use of InGaAsP barriers in QWIPs for long-wavelength infrared detection applications. We studied a broadband quantum well InGaAs/InGaAsP detector covering 8-14 $\mu$m and found excellent agreement between observed and calculated responsivity spectra. This result shows the validity of our design model. To determine the usefulness of InGaAsP in long-wavelength detection, we also designed a GaAs/AlGaAs quantum well detector with a similar spectrum and compared its performance with that of the InGaAs/InGaAsP detector. Dark current noise measurement indicates that the gain of InGaAsP is 4.6 times larger than that of AlGaAs, showing that InGaAsP is a good candidate for long-wavelength high-speed infrared detection.

**N17 6 Interfaces as tools in the design of short period type-II InAs/GaSb superlattices for mid-IR detection** FRANK SZMULOWICZ,*HEATHER HAUGAN,†GAIL BROWN, K. MAHALINGAM,‡ *Air Force Research Laboratory* B. ULRICH, *Bowling Green State University* S. MUNSHI, *Air Force Research Laboratory* The effect of interface anisotropy on the electronic structure of InAs/GaSb type-II superlattices is exploited in the design of thin-layer superlattices for mid-IR detection threshold. The design is based on a theoretical envelope function model that incorporates the change of anion and cation species across InAs/GaSb interfaces, in particular, across the preferred InSb interface. The model predicts that a given threshold can be reached for a range of superlattice periods with InAs and GaSb layers as thin as a few monolayers. A number of superlattices with periods ranging from 50.6 to 21.2 angstroms for the 4 micron detection threshold were grown by molecular beam epitaxy based on the model design. Low temperature photoluminescence and photoresponse spectra confirmed that the superlattice band gaps remained constant at 330 meV although the period changed by the factor of 2.5.

**N17 7 Quantum Hall Devices as efficient and fast THz photodetectors** NIKOLAI G. KALUGIN, *Dept. of Physics, Texas A&M University* CHRISTIAN STELLMACH, *Inst. of Applied Physics, TU Braunschweig, Germany* YURI B. VASILYEV, *Ioffe Physicotechnical Inst., St. Petersburg, Russia* RENE BONK, ALEXANDER HIRSCH, *Inst. of Applied Physics, TU Braunschweig, Germany* GÜNTER HEIN, *Physikalisch-Technische Bundesanstalt, Germany* GEORG NACHTWEI, *Inst. of Applied Physics, TU Braunschweig, Germany* Efficient THz photodetectors on the basis of quantum Hall (QH) system have been developed during the recent years. Engineering of the device shape and selection of the parameters of operation allow to implement QH detectors with response times ranging from 10 ns to milliseconds. The spectral resolution of QH detectors, ranging between 1-2 meV at energies of 8-12 meV of the incoming radiation, is a function of the electron mobility and of the bias voltage. QH photodetectors are tunable by the magnetic field and a gate voltage. The combination of these properties together with the high sensitivity of QH THz detectors serves as a basis for an implementation of reliable spectrometer-on-chip devices for THz spectroscopy and imaging.

**N17 8 Type-II Strained Layer InAs-GaSb Superlattice Photodiodes For Long Wave IR Detection** MARK FIELD, GERARD SULLIVAN, AMAL IKHLASSI, BERINDAR BRAR, *Rockwell Scientific* MICHAEL FLATTE, *University of Iowa* CHRISTOPHER GREIN, *University of Illinois* MICHAEL WEIMAR, *Texas A&M University* We have fabricated and tested p-i-n photodiodes in InAs-GaSb superlattice material with measured cutoff wavelengths from 8.5 – 10 $\mu$m, and compared their performance with mercury cadmium telluride (MCT) detectors of the same cutoff wavelengths. Impedance area (R0A) products approaching the MCT devices have been demonstrated with quantum efficiencies of over 14 % per micron depth of the intrinsic layer. Progress towards designs with longer cutoff wavelengths, up to 16 $\mu$m, will be discussed along with issues and latest results on fabrication of a focal plane array using this material.

**10:00**

**N17 9 Electro-optically tunable compact terahertz source** DONG WU, *Naval Research Laboratory* The promise of terahertz technology for surveillance and reconnaissance applications is huge. Despite the technical advantages, the major challenge today in terahertz technology is the development of a portable high-power terahertz source. Of the several available terahertz source technologies those based on the difference frequency technique are very promising, as they can produce a relatively high power terahertz beam over the frequency from 100 GHz to 3.5 THz, which is tunable. However, earlier this technique suffered from a high loss of terahertz signal, and produced a weak terahertz beam, in part due to a large impedance mismatching. Also its frequency tuning was cumbersome and its tuning range was limited since it was typically performed by rotating a nonlinear optical crystal against the pumping beam. In our recent experiments we modified the technique to improve the impedance matching and to replace the mechanical tuning with an electro-optical tuning. With this

new technique we demonstrated a terahertz beam output power exceeding 10 mW (occasionally ~ 100 mW) at frequencies around 1 THz. Our new technique the frequency tuning is very convenient and not limited by the geometry of the experimental set up. Detailed experiments and experimental results will be discussed

**10:12**
**N17 10 Terahertz time domain spectroscopy of hollow polycarbonated metal waveguides** APARAJITA BANDYOPADHYAY, AMARTYA SENGUPTA, JOHN FEDERICI, *New Jersey Institute of Technology* VALENCIA JOHNSON, JAMES HARRINGTON, *Rutgers-The State University of New Jersey* Recently, the terahertz region of the electromagnetic spectrum has gained critical significance in various technical applications and fundamental research problems, involving nondestructive evaluation of material parameters, bio-medical imaging, remote sensing and security screening. However, for applications in which THz radiation needs to be transmitted over a long distance without atmospheric absorption, a flexible waveguide could have potential applications simplifying the propagation of THz radiation in remote locations. Different structures like rigid hollow metallic waveguides, solid wires, or short lengths of solid-core transparent dielectrics such as sapphire and plastic have already been explored for THz guiding purposes. Recently, it has been reported that Cu coated flexible, hollow polycarbonate waveguide has a low loss of less than 4 dB/m in single mode operation, at 1.89 THz. In the present study, using a broadband THz source of photoconductive antennae, we characterize the loss and dispersion profile of Cu coated flexible, hollow polycarbonate waveguide having an inner diameter of 2mm. Insertion loss and the attenuation coefficient were calculated using waveguides of lengths between 40mm and 70mm.

**N17 11 Single Crystal Si Passive Optical Components for itmm-Astronomy** ARI BROWN, *Goddard Space Flight Center* JAMES CHERVENAK, DAVID CHUSS, EDWARD WOLLACK, ROSS HENRY, S. HARVEY MOSELEY, Construction of ultrasensitive, cryogenic-focal-planes for itmm-radiation detection requires simultaneous maximization of detector quantum efficiency and minimization of stray light effects, e.g., optical ''ghosting.'' To achieve this task in the focal plane detector arrays of the Atacama Cosmology Telescope, integration of two technologies are envisioned; (1) an antireflective (AR) coating for reducing ghosting from the reflected component and increasing absorption at the focal plane, and (2) a backside absorber for suppressing reflections of the transmitted component. We propose a novel approach, involving single crystal Si components, to fabricate AR coatings and backside absorbers. AR coatings are made from Si dielectric honeycombs, in which their dielectric constant may be tuned via honeycomb dimension and wall thickness. Backside absorbers consist of AR Si honeycomb coated-resistors, and the resistors consist of P-implanted Si wafers. This approach enables us to circumvent the mechanical complexities arising from thermal expansion effects, because the detector array, back-short, and AR coating are fabricated out of the same material. We also extend the functionality of single crystal Si in the field of itmm-radiation detection by fabricating curved, low-loss, broadband waveguides. These waveguides may enable compact structures for applications requiring variable pathlength, e.g., interferometric spectroscopy.

**N18 1 Quantum Interference in Multiwall Carbon Nanotubes.**
CHRISTOPH STRUNK, *University of Regensburg, Germany*

Recent low temperature conductance measurements on multiwall carbon nanotubes in perpendicular and parallel magnetic field are reported. An efficient gating technique allows for a considerable tuning of the nanotube doping level. This enables us to study extensively the signature of nanotube bandstructure in electron quantum interference effects like weak localization, universal conductance fluctuations and the Aharonov-Bohm effect. We show that the weak localization is strongly suppressed at peaks at certain gate voltages which can be linked with the bottoms of one-dimensional electronic subbands. This assignment allows a detailed comparison of theoretical calculations with the experimental data. In agreement with the theory, we find clear indications for a pronounced energy dependence of the elastic mean free with a strong enhancement close to the charge neutrality point. In large parallel magnetic field, we observe a superposition of h/2e-periodic Altshuler-Aronov-Spivak oscillations and an additional h/e-periodic contribution. The latter contribution shows a diamond-like pattern in the B/$V_{gate}$-plane, which reflects the magnetic field dependence of the density of states of the outermost shell of the nanotube.

**N18 2 Three-dimensional images of contact geometry between carbon nanotubes and metal contacts using electron tomography** JUDY CHA, MATTHEW WEYLAND, *School of Applied and Engineering Physics, Cornell University* JAMES SETHNA, *Physics Department, Cornell University* DAVID MULLER, *School of Applied and Engineering Physics, Cornell University* A significant barrier to the widespread application of carbon nanotube transistors is the variability in contact resistance between

metallic leads and nanotubes. Varying by orders of magnitude, the contact resistance has recently been reported to depend on the size of the nanotube. To understand why, we study the three-dimensional contact geometry between metal contacts and nanotubes using electron tomography. Spatially resolved core-level electron energy-loss spectroscopy reveals a change in the local electronic structure of the nanotube in contact with gold-palladium We report successful three-dimensional reconstructions of the metal-nanotube interface for gold, gold-palladium and titanium contacts that explain the change in the electronic structure of the nanotube.

**8:48**

**N18 3 Electrically Tunable Magnetic Properties of Defective Metallic Carbon Nanotubes*** YOUNG-WOO SON, MARVIN L. COHEN, STEVEN G. LOUIE, *Department of Physics, University of California at Berkeley and Materials Sciences Divisions, LBNL* We present a first-principles study of the magnetic properties of metallic carbon nanotubes with various defects under a homogeneous transverse electric field. Single carbon adatoms, hydrogen passivated single carbon adatoms, and the various vacancies in (10,10) nanotubes are shown to play the role of magnetic impurities. The relative energy levels of quazi-localized states of such magnetic impurities with respect to the Fermi level are changeable with the application of a transverse electric field so that the corresponding magnetic ground states are shown to be tunable. Our results suggest that a pure organic nanomagnet could be realizable and their magnetic properties are controllable by electric fields.

**N18 4 Band structure modulation in carbon nanotube-metal junction** VADIM PULLER, SLAVA V. ROTKIN, *Lehigh University, Physics Dept, 16 Memorial E Dr, Bethlehem, PA 18015* In transport experiments carbon nanotubes (NTs) are embedded in metallic contacts. Distortion of NT shape within the NT-metal junction region may result in the change of NT electronic structure: the deformation can open a band gap in otherwise metallic nanotube, and reduce or completely close the gap in a semiconducting one. Local band structure modulation has non-negligible effect on the electron transmission through NT-metal interface, e.g. the Shottky barrier transparency is changing exponentially with the gap width. To analyze the deformation-induced change of the NT band structure in the contact region, we develop a comprehensive theory of the inhomogeneous deformations in NT, which combines the tight-binding approach with continuous description of the deformation field, and is applicable for NT of any chirality. We calculate the band gap variation in the contact region, and discuss the effect of the deformation on the NT-metal contact resistance.

**N18 5 Ab initio Calculation of Contact Effects on Transport Properties of Carbon Nanotubes Connected to Metallic Electrodes** NOBUHIKO KOBAYASHI, *Nanotech Res Inst, AIST, JAPAN* TAISUKE OZAKI, *Res Inst Comp Sci, AIST, JAPAN* KENJI HIROSE, *Fund Env Res Lab, NEC, JAPAN* Recently, a number of studies have been performed to make carbon nanotube devices. One of the important issues in the developments of the carbon nanotube devices is the control of contact effects of the electrodes. To detect electric signals through nanotubes, electrodes must be connected to the nanotubes. Contact with the electrodes sensitively influences the transport properties. Therefore, it is important to discuss the transport properties on the basis of the detailed electronic state calculation that includes the effect of contact with the electrodes. We have developed a first-principles method of analyzing quantum transport in nanometer-scale systems between electrodes. The electronic states are calculated using a numerical atomic orbital basis set in the framework of the density functional theory, and the conductance is calculated using the Green's function method. We apply the method to calculating transmission spectra of carbon nanotubes connected to metallic electrodes, and discuss the contact effect of the electrodes on the transport properties in the finite size of metallic and semiconducting nanotubes.

**9:24**

**N18 6 Electronic Structure of Metal-covered Semiconducting Carbon Nanotubes** WENGUANG ZHU, *Harvard University* EFTHIMIOS KAXIRAS, *Harvard University* Carbon nanotube field-effect transistor (CNFET) are regarded as potential building blocks for future nanoelectronics. The interaction between a carbon nanotube and metal contacts and the resulting electronic structure effects are crucial for device properties. In this talk, we present recent results on the properties of semiconducting single wall carbon nanotubes in contact with Pd, in a fully covered geometry that resembles experimental setups. We use first-principles calculations to determine the electronic structure, charge transfer effects, electrostatic potential and Fermi level alignment at the interfaces between the metal contact and various semiconducting single-wall carbon nanotubes.

**9:36**

**N18 7 Atomic-Scale Theory and Modeling of Electronic and Molecular Transport through Carbon Nanotubes** YONG-QIANG XUE, *SUNY-Albany* In this talk, we investigate the application of carbon nanotubes as novel transport channels for electrons and molecules using atomistic simulation. (1) Electronic transport: In this talk, we present a Green's function based self-consistent tight-binding study of electron transport through SWNT junction devices, which takes fully into account the 3D atomistic nature of the electronic processes. We discuss insights obtained from such atomistic study on the contact/diameter dependence of junction conductance and self-consistent study of current transport through metal-SWNT-metal junctions. (2) Molecular transport: Carbon nanotube could also be used to build assemblies for controlled transport of biomolecules for nanofluidic devices. Water confinement inside such nanoscale cylindrical core plays a significant role in determining the insertion and flow of biomolecules through the nanotube channel, which can be strongly affected by surface functionalization. Molecular dynamics simulations have been carried out to study the structure and thermodynamics of water in carbon nanotube and its effect on the spontaneous insertion of DNA molecules inside the nanotube channel. The simulations can provide valuable insights into the transport of molecules through nanoscale pore or channel structures.

**N18 8 Signatures of Chemical Defects in Carbon Nanotube Electronic Devices** BRETT R. GOLDSMITH, A. KANE, PHILIP G. COLLINS, *Department of Physics and Astronomy, University of California Irvine, Irvine, CA 92697-4576* The study of chemical defects in carbon nanotubes has important implications for their operation as electronic devices, and many synthesis and fabrication techniques for such devices result in non-zero defect densities. Scanned probe microscopy techniques are particularly useful for identifying these sites and then examining their electronic properties. We have examined a number of electronic devices in which single defects play important roles in determining the two- and three-terminal device behavior. Using conducting-tip atomic force microscopy to measure local electronic properties, we distinguish one type of defect from another and correlate this with the device characteristics. Furthermore, we can chemically modify and reinvestigate the same defect site. Ultimately, the goal is to use the device characteristics as a kind of signature to reliably infer the presence of particular chemical defects. This work is partly supported by NSF grant DMR-0239842.

**N18 9 Gated Spin Transport through an Individual Single Wall Carbon Nanotube*** BHASKAR NAGABHIRAVA, TANESH BANSAL, *Department of Electrical and Computer Engineering, University of Louisville, Louisville* GAMINI SUMANASEKERA, *Department of Physics, University of Louisville, Louisville* LEI LIU, *Department of Physics, McGill University, Montreal* BRUCE ALPHENAAR,† *Department of Electrical and Computer Engineering, University of Louisville* We report on the fabrication and characterization of ferromagnetically contacted ''short channel'' SWNT devices that show clear hysteretic switching in the magnetoresistance, and provide strong evidence for SWNT spin transport. The main difference between our work and previous studies is that we have greatly reduced the transport length separating the ferromagnetic contacts to distances on the order of 10 nm. Preliminary measurements demonstrate this reduction to be extremely beneficial. We have observed clear hysteretic switching in the magnetoresistance in 75% of our devices, and are able to modify the magnetoresistance between +15% and -10% as a function of gate voltage. The gate mediated change in magnitude itand sign of the magnetoresistance switching allows us to discount other non-spin related sources for the observed signal and provides the basis for the first SWNT spin transistor. We note that the short channel contacting scheme is generally applicable to non-ferromagnetic contacts as well, and provides a straightforward technique for fabricating SWNT quantum dot devices.

**N18 10 Spin transport studies in mesoscopic graphite** BARBAROS OEZYILMAZ, PHILIP KIM, *Department of Physics, Columbia University, New York, NY 10027* We present experimental studies on spin transport in mesoscopic graphite. Two dimensional graphite sheets have been fabricated by means of micromechanical exfoliation. Spin injection has been achieved by employing ferromagnetic Co electrodes. We use the shape anisotropy of the electrodes to uniquely define the magnetic state of the device. Typical two terminal resistances are in the order of 1 $k\Omega$. We will discuss the switching behavior of the device magnetoresistance as a function of temperature, the gate bias voltage and of the source drain bias.

**10:24**

**N18 11 Ballistic conductance in narrow graphene strips*** D. ARESHKIN, *GWU* J.W. MINTMIRE, *OSU* C.T. WHITE, *NRL* With structures making them suitable for in-plane device processing, high aspect ratio graphene strips with widths down to tens of nanometers or smaller could ultimately provide important components in carbon-based quantum electronics. However, in comparison to corresponding single-wall carbon nanotubes, such strips will likely have a higher degree of imperfection due to variations in their widths and interactions with the substrate which will degrade their conductance. Also, unlike nanotubes, they can exhibit highly localized edge states which are degenerate with their more extended states at or near the Fermi level. On the other hand, their more extended states near the Fermi level have properties similar to those exhibited by related states in nanotubes, which should suppress the effects of back scattering both due to short and long-range disorder. Stimulated by these observations and recent experiments on graphene sheets, simulations were performed to assess the effects of various types of disorder on the conductance of narrow graphene strips. The results indicate that these strips can exhibit ballistic conductance over large distances in the presence of reasonable disorder making them excellent synthetic targets for carbon-based device applications.

**N18 12 Probing Biological Processes on Supported Lipid Bilayers with Single-Walled Carbon Nanotube Field-Effect Transistors** XINJIAN ZHOU, *LASSP, Cornell University* JOSE MANUEL MORAN-MIRABAL, *School of Applied and Engineering Physics, Cornell University* HAROLD CRAIGHEAD, *School of Applied and Engineering Physics, Cornell University* PAUL MCEUEN, *LASSP, Cornell University* We have formed supported lipid bilayers (SLBs) by small unilamellar vesicle fusion on substrates containing single-walled carbon nanotube field-effect transistors (SWNT-FETs). We are able to detect the self-assembly of SLBs electrically with SWNT-FETs since their threshold voltages are shifted by this event. The SLB fully covers the NT surface and lipid molecules can diffuse freely in the bilayer surface across the NT. To study the interactions of important biological entities with receptors imbedded within the membrane, we have also integrated a membrane protein, GT1b ganglioside, in the bilayer. While bare gangliosides can diffuse freely across the NT, interestingly the NT acts as a diffusion barrier for the gangliosides when they are bound with tetanus toxin. This experiment opens the possibility of using SWNT-FETs as biosensors for label-free detection.

**10:48**

**N18 13 First Principles Properties of Polymeric Photovoltaic Materials** T. JAYASEKERA, J. W. MINTMIRE, *Department of Physics, Oklahoma State University* Recent reports suggest that the acceptor-donor junction for bulk heterojunction photovoltaic devices can be achieved using single wall carbon nanotubes (SWNT) and polymers such as poly-3-octothiophenes (P3OT). Optical excitation is believed to occur in the organic polymer which acts as a good hole conductor, with electron transfer to the SWNT which acts as a good electron conductor. An appropriate theoretical understanding of the photovoltaic effect requires knowledge of the electronic states near the Fermi level in these materials. We calculate the electronic structure of infinitely long quasi one-dimensional nanostructures such as carbon nanotubes or electroactive chain polymers, such as polythiophenes using a first

principles, all electron, self consistent local density functional (LDF) approach. We present and compare electronic structure calculations for SWNTs and poly-3-alkyl-thiophenes. Further we discuss the variation of effective mass of charge carriers in polymers and SWNTs in the vicinity of Fermi level. This work was supported by the US Office of Naval Research and the DoD HPCMO CHSSI program through the Naval Research Laboratory.

**N19 1 High field magnetoresistance in *p*-(In,Mn)As/*n*-InAs heterojunctions** BRUCE WESSELS, STEVEN MAY, *Materials Science and Engineering, Northwestern University* The high field magnetoresistive properties of a *p*-$In_{0.96}Mn_{0.04}As$/*n*-InAs junction have been measured. The heterojunctions were formed by epitaxially depositing an InMnAs thin film on an InAs substrate using metal-organic vapor phase epitaxy. Under forward bias, a large, nonsaturating magnetoresistance is observed at temperatures from 25 to 295 K in fields up to 9 T. At room temperature, the magnetoresistance increases linearly with magnetic field from 1.5 to 9 T and is greater than 700 % at 9 T. The magnetoresistance can be simulated using a modified diode equation, including a field-dependent series magnetoresistance.

**N19 2 Room Temperature Tunnel Magnetoresistance and Spin Polarized Tunneling Studies with Organic Semiconductor Barrier** T. S. SANTOS, P. MIGDAL, I. C. LEKSHMI, J. S. MOODERA, *Francis Bitter Magnet Lab, MIT, Cambridge, MA* J. S. LEE, *Nano-device Research Center, KIST, Seoul, Korea* Organic semiconductors, $\pi$-conjugated, with a weak spin-orbit interaction, show promise for spin-conserved transport applications.[1,2] An organic spin-valve utilizing the molecular organic semiconductor tris (8-hydroxyquinolinato)aluminum ($Alq_3$), demonstrated giant magnetoresistance at LHe temperatures.[1] The $Alq_3$ films in this spin-valve were $>$ 130nm, and the spin diffusion length was 45nm. Our current study demonstrates spin polarized tunneling through an ultra-thin layer of $Alq_3$ in a magnetic tunnel junction. Significant tunnel magnetoresistance was measured in a MTJ structure at room temperature, which increased when cooled to low temperatures. Tunneling characteristics, such as the I-V behavior and temperature and bias dependence of the TMR, show good quality of the organic tunnel barrier. Spin polarization of the tunnel current from Co, Fe and NiFe electrodes through the $Alq_3$ layer was directly measured using a superconducting Al electrode as the spin detector. This demonstration of spin-conserved transport through an organic semiconductor at room temperature shows the potential of this material for further study. Supported by KIST-MIT Program and NSF. 1) Z. H. Xiong, et al, Nature **427**, 821 (2004). 2) V. Dediu, et al, Solid State Commun. **122**, 181 (2002).

**N19 3 Diluted Magnetic Double Barrier Resonant Tunneling Structures for Novel Magnetically-Defined Quantum Dot and Nano Structures*** ZAILI FANG, A.M. CHANG, *Department of Physics, Duke University, Durham, NC 27708* X.Y. LIU, J.K. FURDYNA, *Department of Physics, University of Notre Dame, Notre Dame, IN 46556* The further development of Spintronics requires the direct control of the spin degree of freedom. A milestone on the path towards this accomplishment has been recently achieved by the demonstration of the successful operation of a magnetic resonant tunneling diode[1]. We will report our results on manganese doped double barrier tunneling structures (II-IV group) with varying doping, confining potential and well width. These structures, in which both the barrier and well are doped with manganese, show a Zeeman splitting tendency in the vertical transport through the barrier in magnetic field. This tendency can be exploited as spin filter for spintronic applications. Based on this spin voltage transport property of diluted magnetic semiconductor heterostructures and the interaction of superconductors and semiconductors, we propose a novel spin aligned vertical quantum dot device. Progress on the fabrication of this device will also be reported.

*Research supported in part by NSF DMR-02105191.

**N19 5 Magnetic Resonances in the circular polarization of light emitted by Fe/InAs QD spin LEDs** M. YASAR, S. DELIKANLI, R. MALLORY, A. PETROU, *SUNY Buffalo* G. KIOSEOGLOU, A.T. HANBICKI, C.H. LI, B.T. JONKER, *Naval Research Laboratory* The circular polarization $P_{circ}$ of the light emitted from InAs QD LEDs was studied as function of applied magnetic field $B$ in the 5-75 K temperature range. The quantum dots are incorporated at the center of a GaAs quantum well of width $L_W$. At$T$ = 5 K we observed two distinct resonances in the $P_{circ}$ versus $B$ plot. For $L_W$ = 430 Å the resonances occur at $B$ = 4.6 T (strong) and $B$ = 2.3 T (weak). The strength of the resonances depends critically on bias voltage $V$ (very pronounced at low $V$values) The resonances become weaker with increasing temperature and disappear completely by $T$ = 60 K. No resonances were observed in LEDs in which the QDs were not incorporated in a quantum well. We propose a model that takes into account the confinement conduction subbands of the GaAs quantum well and the dependence of their energies on magnetic field. Acknowledgements: This work is supported by the DARPA SpinS Project, ONR, and NSF.

**N19 6 Tailoring magnetic anisotropy in ferromagnetic metal / semiconductor contacts for spin injection*** C. H. LI, G. KIOSEOGLOU, A. T. HANBICKI, T. J. ZEGA, R. M. STROUD, B. T. JONKER, *Naval Research Lab, Washington, DC* Robust spin injection across an Fe/AlGaAs interface has recently been demonstrated, producing an electron spin polarization $>$ 32% in a GaAs QW. In an effort to incorporate a spin injecting metal contact with perpendicular remanence and to explore interface effects on spin

injection, we have grown MnGa thin films epitaxially on GaAs(001) LED structures by MBE. Streaky RHEED patterns indicate single crystalline films. Although lattice matched to GaAs, TEM shows that while MnGa crystallizes nicely away from the interface, defects exist at the interface. The insertion of a thin ( $\sim$ 5ML) Fe seed layer between MnGa and AlGaAs promotes the initial nucleation of MnGa and provides a means to control the structure of the spin-injecting interface, while the magnetic behavior is determined by the MnGa. Samples are processed to form surface emitting LEDs, and the EL is dominated by QW excitonic emission. A 0.5% remanent circular polarization is observed, which tracks the MnGa magnetization obtained by independent SQUID measurements. Comparison between MnGa spin-LEDs with and without the Fe seed layer (including interface properties), and magneto absorption effects in these heterostructures, will be discussed.

*Supported by DARPA and ONR.

**9:12**

**N19 7 Quasi-one-dimensional spin polarized states in T-shaped nanostructures** PAWEL REDLINSKI, BOLDIZSAR JANKO, *University of Notre Dame* We present results of theoretical and numerical investigations of T-shaped semiconductor nano-wire structures. Such structures have been synthesized in Molecular Beam Epitaxy laboratories by using traditional (GaAs) and magnetic (GaMnAs) semiconductors. The wire is formed in a three-stage MBE process and in its final form, the structure looks as if one quantum well (QW) called Stem well grew perpendicularly into the second QW, the so-called Arm well. The quasi 1D states are formed at the intersection of the two QWs. Typically in the T-shaped structures the thickness of the wire is of order of few nm. For such thickness there is only one conduction channel and the energy states of quasi-particles are indexed by a single quantum number, the 1D linear momentum $k$, and by its spin. There are two distinctive features present in this type of systems: strong spin-orbit coupling, and the lack of square symmetry of the wire cross section. These features have profound implications and make this system very important from theoretical point of view. Results, obtained within the **kbullet p** formalism, show that at $k \neq 0$ the valence band states are non-degenerate with respect to the spin degree of freedom. Both dispersions of spin up and spin down states are well modeled as parabolic bands but with different effective masses. It opens possible to manipulate the spin degrees of freedom in a T-shaped quantum structure.

**9:24**

**N19 8 Atomistic spin-orbit effects on the electronic structure of T-shaped quantum wires** JAVIER AIZPURUA, *Donostia Intl Physics Center, Donostia, Spain* GARNETT W. BRYANT, *NIST, Gaithersburg, MD* The electronic structure and optical properties of GaAs/AlGaAs T-shaped quantum wires are studied by use of an empirical tight-binding method (ETB). This model allows us to study atomistic effects on the electronic structure of wires that have a complicated geometrical cross section. We find that the electronic structure for electrons is similar to that described by effective mass models whereas the electronic structure for holes shows important modifications when spin-orbit coupling is included in the atomistic model. The binding energies of the holes in a T-wire agree with previous effective mass model calculations. However, we find that asymmetries in the spatial distribution of these hole states are induced by atomistic spin-orbit effects. Moreover, the atomistic tight-binding model predicts complex band crossings for hole states that are not predicted by simpler effective mass theories. Consequences for the optical response of T-wires and for excitonic and electron-hole plasma phases in T-wires are discussed.

**N19 9 Quasi-one-dimensional spin field-effect transistors** JAESEUNG JEONG, HYUN-WOO LEE, *Pohang University of Science and Technology* We study a spin field effect-transistor(SFET) with multiple transport modes. Energy dispersion relations and spin profiles of eigen-transport modes are examined numerically and analytically for weak and strong Rashba spin-orbit coupling parameters. Electron transport properties of the multiple-mode SFET are investigated including the Fabry-Perot-type interference due to multiple reflections and the peak splitting by external magnetic fields. Impurity scattering effects are also addressed.

**9:48**

**N19 10 Lateral diffusive spin transport in layered structures*** HANAN DERY, LUKASZ CYWINSKI, LU J. SHAM, *Department of Physics, University of California San Diego* A one dimensional theory of lateral spin-polarized transport is derived from the two dimensional flow in the vertical cross section of a stack of ferromagnetic and paramagnetic layers. This takes into account the influence of the lead on the lateral current underneath, in contrast to the conventional 1D modeling by the collinear configuration of lead/channel/lead. Our theory is convenient and appropriate for the current in plane configuration of an all-metallic spintronics structure as well as for the planar structure of a semiconductor with ferromagnetic contacts. For both systems we predict the optimal contact width for maximal magnetoresistance and propose an electrical measurement of the spin diffusion length for a wide range of materials. This work was supported by NSF DMR-0325599.

**N19 12 Controlling spin in an electronic interferometer with spin-active interfaces** CHRISTOPH BRUDER, *Dept. of Physics and Astronomy, University of Basel, CH-4056 Basel, Switzerland* AUDREY COTTET, *Laboratoire de Physique des Solides, Université Paris Sud, F-91405 Orsay Cedex, France* TAKIS KONTOS, *Laboratoire Pierre Aigrain, Département de Physique, ENS, 24, rue Lhomond, F-75231 Paris Cedex 05, France* WOLFGANG BELZIG, *University of Konstanz, Theoretical Solid State Physics, Department of Physics, M703, D-78457 Konstanz, Germany* CHRISTIAN SCHÖNENBERGER, *Dept. of Physics and Astronomy, University of Basel, Klingelbergstr. 82, CH-4056*

*Basel, Switzerland* We consider electronic current transport through a ballistic one-dimensional quantum wire connected to two ferromagnetic leads. We study the effects of the spin-dependence of interfacial phase shifts (SDIPS) acquired by electrons upon scattering at the boundaries of the wire. The SDIPS produces a spin splitting of the wire resonant energies which is tunable with the gate voltage and the angle between the ferromagnetic polarizations. This property could be used for manipulating spins. In particular, it leads to a giant magnetoresistance effect with a sign tunable with the gate voltage and the magnetic field applied to the wire.

**10:24**

**N19 13 Interferometric detection of spin-polarized transport** G. SALIS, S. F. ALVARADO, *IBM Research, Zurich Research Laboratory, 8803 Rüschlikon, Switzerland* It is shown that in addition to its sensitivity to spin polarization, the magneto-optic Kerr effect strongly depends on the spatial distribution of spin-polarized charge carriers. Using time-resolved Kerr rotation, the dynamics of spin- polarized electrons can thus be monitored on the nanometer length scale. This is demonstrated experimentally for optically- excited electron spins in the depletion layer of *n*-doped GaAs close to a metallic electrode. The Kerr rotation exhibits fast oscillations that originate from an interference of the light reflected at the electrode with that reflected at the front of the electron distribution moving into the semiconductor. From these oscillations, the dynamics of the electron front is obtained, which is strongly screened by the space-charge field of the excited electron-hole pairs and can be controlled by an electric bias across the Schottky barrier. In addition, the dynamics provides information on the Schottky-barrier height, the depletion-layer thickness and the doping concentration.

**10:36**

**N19 14 Spin Resolved Current Focusing in InSb Heterostructures*** ARUNA DEDIGAMA, DAVID DEEN, SHEENA MURPHY, NITI GOEL, JOEL KEAY, MICHAEL SANTOS, *University of Oklahoma* KYOICHI SUZUKI, SEN MIYASHITA, YOSHIRO HIRAYAMA, *NTT Basic Research Laboratories* Spin-resolved current focusing has been observed in InSb/AlInSb structures. While InSb has the most significant Rashba and Dresselhaus effects of any of the III-V semiconductors, Dresselhaus effects are expected to dominate in the symmetrically doped structures used here. The double quantum point contact devices were designed with typical dimensions of 0.5 micron which preserve ballistic transport up to 185K as measured in previous experiments. Focusing peaks were observed near the expected values of perpendicular magnetic field; however the first focusing peak was a doublet. With application of a parallel magnetic field the doublet evolved into a singlet as expected for spin resolved focusing.

**N19 15 Spintronic Ratchet** SAYEEF SALAHUDDIN, SUPRIYO DATTA, *School of Electrical and Computer Engineering, Purdue University, West Lafayette, IN-47907* Carefully designed ratchets are of great interest, practically and conceptually, as means to convert fluctuations into useful work. We argue that a recently proposed ''Spin-Capacitor'' [Appl. Phys. Lett. **87**, 013115 (2005)] exhibits characteristics that have close resemblance to ratchets. It shows unidirectional current-voltage (I-V) characteristics that depend on the spin excitation spectrum of a neighboring array [http://arxiv.org/abs/cond-mat/0511566]. More interestingly, if the spins in the array are out of equilibrium, useful work can be extracted at the expense of energy/entropy. This is manifested as a **non-zero current at zero bias** and we argue that a recent experiment in an integer quantum hall system [http://link.aps.org/abstract/PRL/v95/e056802] shows evidence for this general principle.

## SESSION N20: FOCUS SESSION: COMLEX OXIDE THIN FILMS SURFACES AND INTERFACESS III: NEW MATERIALS, NEW TECHNIQUES, AND EFFECTS OF STRAIN

**Wednesday Morning, 15 March 2006**
**317, Baltimore Convention Center at 8:00**
**Anand Bhattacharya, Argonne National Laboratory, presiding**

**8:00**

**N20 1 Growth and Properties of a New Correlated Electron Perovskite Thin Film – $PbVO_3$.** LANE W. MARTIN, QIAN ZHAN, WENKAN JIANG, *Materials Science and Engineering, University of California, Berkeley* MIAOFANG CHI, NIGEL BROWNING, *Chemical Engineering and Materials Science, University of California, Davis and National Center for Electron Microscopy, Lawrence Berkeley Nat. Lab.* YURI SUZUKI, R. RAMESH, *Materials Science and Engineering, University of California, Berkeley* We report the growth of single phase, fully epitaxial thin films of a relatively new perovskite material, lead vanadate ($PbVO_3$), using pulsed laser deposition. This growth realizes the first production of $PbVO_3$ outside of high-temperature and high-pressure techniques through growth of epitaxial thin films on various substrates. Structural analysis of the $PbVO_3$ thin films using transmission electron microscopy, x-ray diffraction, and Rutherford backscattering spectroscopy reveals films that are single phase, highly crystalline, and have a tetragonally distorted perovskite structure, with $a = 3.79$Å and $c = 5.02$Å (c/a = 1.32). Electron energy loss spectroscopy and x-ray absorption spectroscopy were used to show the stabilization of vanadium in the $V^{4+}$ state, thereby proving the creation of a new $d^1$ system for intensive physical study. Films exhibit semiconducting behavior in plane of the film with thermally activated behavior and distinctly different properties from other $d^1$ $AVO_3$ thin films. Studies of the magnetic and ferroelastic/ferroelectric nature of $PbVO_3$ are also underway.

**8:12**

**N20 2 Phase Transitions of $SrFeO_3$ Studied Using a Single-Crystalline Film** NAOAKI HAYASHI, SHIGETOSHI MURANAKA, *Graduate School of Human and Environmental Studies, Kyoto University* TAKAHITO TERASHIMA, *Research Center for Low temperature and Materials Sciences, Kyoto University* MIKIO TAKANO, *Institute for Chemical Research, Kyoto University* To study the electronic nature of $SrFeO_3$ (SFO), which is a cubic perovskite containing $Fe^{4+}$ equipped with deep *d* levels and is, therefore, dominated by *p*-hole character, a single crystalline film was grown and the resistivity (it$\rho$), Hall effect, magnetoresistance (itMR) and susceptibility were measured. It is known

that this oxide in bulk form becomes antiferromagnetically ordered in a screw spin structure. The $T_N$ of the film has been found to be at 120~ 125 K from the susceptibility measurement, while the transport properties showed well-defined anomalies at 105 K, rather than at the $T_N$. The metallic film (it$\rho$ = 9× $10^{-4}\Omega$cm at 300 K) exhibited a hysteretic, inflectional drop in the it$\rho$ -*T*curve at 105 K after showing a very small anomaly at 125 K; the Hall coefficient was positive and temperature-independent above 110 K but increased quickly below ~ 100 K; the itMR changed its sign from negative to positive quite steeply at 105 K. Considering these results together with what is known about bulk samples, we conclude that SFO undergoes its antiferromagnetic transition in two stages, passing an incompletely coherent stage before entering the final coherent state.

**8:24**

**N20 3 Magnetic Properties of PLD Grown Expitaxial Double Perovskite Thin Films*** D.E. BROWN, S. TOTAPALLY, Y. YOO, S. KOLESNIK, J. MAIS, O. CHMAISSEM, J. CHURILLA, B. DABROWSKI, C. KIMBALL, *Physics Dept., Northern Illinois University* M. HAJI-SHEIK, *Electrical Engineering Dept.,Northern Illinois University* Transition metal oxides with a double perovskite structure $A_2FeMoO_6$ and (A = Ca, Ba, Sr) has attracted a great deal of attention owing to their high magnetic transition temperatures and spin dependent transport properties. Electronic structure calculations and experimental results show that these materials are half-metallic ferrimagnets with localized up-spin electrons on the Fe ions and itinerant down-spin electrons shared between Fe and Mo. The Fe and Mo atoms are ordered on alternating, corner-shared octahedral sites, however, the ordered array can have imperfections that are dependent upon synthesis conditions. We have grown, using a pulsed laser deposition device, epitaxial double perovskite thin films. These films have been characterized by SQUID, resistivity, and x-ray crystallography measurements. The measurements show that double perovskite thin films can be grown with a high degree of order between the Fe and Mo atoms. Thus these materials can be attractive candidates for spin electronic devices.

*Work at NIU is supported by the Department of Education.

**8:36**

**N20 4 Exotic Single Crystal Thin Films Made From Cobalt Ferrite.** H. CORCORAN, *Morgan State University* A. COLEMAN, *Morgan State University* A. LISFI, *Morgan State University* C. M. WILLIAMS, *Morgan State University* W. MORGAN, *Morgan State University* A. KUMAR, *Morgan State University* The search for new magnetic materials is driven by technological demands such as increasing the magnetic recording density. Materials possessing a large magnetic anisotropy are suitable media to meet such requirements since a stable magnetization can be promoted in nano-structures. Hard ferrites such as the hexagonal ($BaFe_{12}O_{19}$) and the cubic ($CoFe_2O_4$) are attractive for such kind of applications due to their large magnetocrystalline anisotropy and high chemical stability. In this talk we report on exotic properties of films made from $CoFe_2O_4$. Epitaxial $CoFe_2O_4$ thin films have been grown by pulsed laser deposition (PLD) on (100) MgO substrate. Two types of spin-reorientation have been observed in such films upon annealing or increasing the film-thickness. In the as-deposited layers and at low thickness the easy axis of the magnetization is confined to the normal to the film plane whereas at large thickness the film plane becomes the preferential direction of the magnetization. On the other hand annealing induces a reorientation of magnetic anisotropy, which switches from the normal to the film plane in the as-deposited film to be in-plane aligned in the annealed state. The origin of both reorientations is explained in term of competition between stress and magnetocrystalline anisotropies.

**8:48**

**N20 5 Magnetic Anisotropy of Cr-Substituted Magnetostrictive Cobalt Ferrite** YEVGEN MELIKHOV, JOHN SNYDER, CHESTER LO, PAUL MATLAGE, SANG-HOON SONG, KEVIN DENNIS, *Iowa State University, Ames, IA 50011, USA* DAVID JILES, *Cardiff University, Cardiff CF243AA, UK* In order to tailor the magnetomechanical response of substituted cobalt ferrite for strain sensing and actuating applications, more needs to be known about the variation of the basic magnetoelastic and magnetic properties with temperature and composition. In this study, the variation of magnetic anisotropy with temperature and composition for a series of Cr-substituted cobalt ferrites, $CoCr_xFe_{2-x}O_4$, ($0 \leq x \leq 0.8$) was investigated. In order to determine the cubic anisotropy constant $K_1$,the ''high field'' regime (from 1 T to 5 T) of the major magnetic hysteresis loops, which were measured at temperatures over the range 10-400 K using a SQUID magnetometer, was fitted using the law of approach approximation $M(T) = M_S(1\text{-}8/105K_1^2/(\mu_0 H M_S)^2)$ plus a forced magnetization term linear in applied field *H*. It was found that anisotropy increases with decreasing temperature, with the steepest increase coming at progressively lower temperatures for increasing Cr content. For fixed temperatures, anisotropy decreases with increasing Cr content. For the pure cobalt ferrite and x=0.2 Cr samples it appears that for temperatures less than 150 K, 5 Tesla is not enough to saturate the samples, so anisotropy cannot be computed correctly by this method. This research was supported by NSF, Grant No.DMR-0402716, and by NASA, Award No.NAG-1-02098.

**9:00**

**N20 6 Influence of substrate strain on $(La_{1-x}Pr_x)_{1-y}Ca_yMnO_3$ phase transition*** DANE GILLASPIE, J.X. MA, *Univ. of Tenn Physics Dept. and ORNL* H-Y. ZHAI, *ORNL* Z. WARD, E.W. PLUMMER, *Univ. of Tenn Physics Dept. and ORNL* H. CHRISTEN, *ORNL* J. SHEN, *Univ. of Tenn Physics Dept. and ORNL* The large-scale phase separation between ferromagnetic metallic (FMM) and charge-ordered insulating (COI) domains observed in $(La_{1-x}Pr_x)_{1-y}Ca_yMnO_3$ (LPCMO) crystals has attracted a lot of attention. This coexistence of phases is very sensitive to structural and magnetic changes, and is responsible for the enhanced magnetoresistance in LPCMO compared to its parent compounds. The energy balance of the FMM and COI phases is still not well understood. We can change the energy balance by changing the substrate, and therefore the strain on the thin film, and thereby improve our understanding of the phase transition. We have grown and characterized several different thicknesses of LPCMO on $LaAlO_3$, $SrLaGaO_4$, $NdGaO_3$ and $SrTiO_3$ substrates. We have observed that the compressive strain from the $LaAlO_3$ substrate suppresses the long-range charge ordering in the sample, and enhances magnetoresistance and magnetic hysteresis. The charge ordering is also suppressed in the films on $SrLaGaO_4$, even though the strain is negligible. Conversely, the tensile strain from the $NdGaO_3$ and $SrTiO_3$ substrates enhances the long-range charge ordering and reduces the magnetoresistance and magnetic hysteresis.

**9:12**

**N20 7 The role of strain in the magnetic properties of $La_{0.7}Sr_{0.3}MnO_3$ films studied by magnetic force microscopy** RAVI KUMMAMURU, YEONG-AH SOH, *Dept. of Physics and Astronomy, Dartmouth College, Hanover, NH 03755.* NEIL MATHUR, LUIS HUESO, *Department of Materials Science, University of Cambridge, Cambridge CB2 3QZ, UK* CONDENSED MATTER, DEPARTMENT OF PHYSICS AND ASTRONOMY, DARTMOUTH COLLEGE TEAM, DEVICE MATERIALS GROUP, DEPARTMENT OF MATERIALS SCIENCE, UNIVERSITY OF CAMBRIDGE COLLABORATION, In order to elucidate the role of strain in the magnetic properties of manganite films, we studied the behavior of the magnetic domains in $La_{0.7}Sr_{0.3}MnO_3$ (LSMO) films grown on $SrTiO_3$ (STO) and $NdGaO_3$ (NGO) substrates, which are differently strained. Our previous studies on the magnetic properties of $La_{0.7}Sr_{0.3}MnO_3$ films grown on STO substrates using magnetic force microscopy showed a distinct magnetic texture within magnetic domains, and spin reorientation and enhancement of $T_C$ near grain boundaries. These results were attributed to the strain in the film caused by the lattice mismatch with the substrate and the strain relaxation at the grain boundaries. Our new studies on $La_{0.7}Sr_{0.3}MnO_3$ films grown on NGO substrates, which have very low strain due to a close lattice match between the film and substrate, show no presence of magnetic texture and a very sharp transition from the paramagnetic to ferromagnetic phase.

**9:24**

**N20 8 Strain Induced Crystal Superstructure in Manganite Films** YEONG-AH SOH, *Dartmouth College* ZAHIRUL ISLAM, JONATHAN LANG, GEORGE SRAJER, *Argonne National Laboratory* NEIL MATHUR, MARK BLAMIRE, *University of Cambridge* Using xray diffraction we studied in detail the crystal structure of a 100 nm thick $La_{0.7}$ $Sr_{0.3}MnO_3$ film grown on a $SrTiO_3$ substrate. Satellite peaks are observed at $(H \pm \delta h, K, L)$ for nonzero $K$ and $(H, K \pm \delta k, L)$ for nonzero $H$. No satellite peaks are observed around $(0\ 0\ L)$ reflections. Our measurements show that the modulation wave vectors and polarization vectors representing the atomic displacements are perpendicular to each other and point in the direction parallel to the plane of the film. $L$ scans around the main Bragg peaks and around the satellite peaks exhibit strong Laue oscillations indicating that the superstructure is coherent throughout the whole thickness of the film. We will discuss the results of the xray measurements in connection with the scanning probe microscopy measurements done on the same film.

**9:36**

**N20 9 Electronic properties of structural twin and antiphase boundaries in materials with strong electron-lattice couplings*** K. H. AHN, *Advanced Photon Source, Argonne National Laboratory, Argonne, IL 60439* T. LOOKMAN, A. SAXENA, A. R. BISHOP, *Theoretical Division, Los Alamos National Laboratory, Los Alamos, NM 87545* Using a symmetry-based atomic scale theory of lattice distortions, we show that in functional materials with strong electron lattice coupling, the electronic properties are distinctly modified near elastic textures such as twin boundaries (TBs) and antiphase boundaries (APBs), which can be directly measured by STM. The results also show that the heterogeneities of electron local DOS are not confined within TBs and APBs, but can propagate into domains in the form of Friedel oscillations for TBs and with the wave vector related to short wave length lattice distortions for APBs. The results are discussed in relation with perovskite manganites and other functional electronic materials. Reference: Ahn, Lookman, Saxena, and Bishop, Phys. Rev. B 71, 212102 (2005).

**N20 10 Ultra-thin Perovskite Manganite films on $SrTiO_3$ and $SrTiO_3$/Si heterostructures** A. PRADHAN, *Norfolk State University* D. HUNTER, K. ZHANG, B. LASLEY, K. LORD, T.M. WILLIAMS, R.R. RAKHIMOV, *Center for Materials Research, Norfolk State University* We report on the growth and characterization of high-quality ultra-thin $La_{0.7}Ba_{0.3}MnO_3$ and $La_{0.7}Sr_{0.3}MnO_3$ epitaxial films on $SrTiO_3$ and $SrTiO_3$-buffered Si (100) and Si (111) substrates by pulsed-laser deposition. The films demonstrate remarkable magnetic and electrical properties associated with the colossal magnetoresistance behavior at and above room temperature. The enhanced transition temperature of manganite films on buffered Si substrates is discussed in terms of the strain relaxation at the interface between the manganite film and the $SrTiO_3$ buffer layer which is caused by the smaller grain size. We also report the doping of Ru (x=0.3 to 0.4) into Mn sites in LSMO films grown both on STO and STO buffered Si. The films display remarkable hardening of $H_c$ due to the charge-transfer-enhanced exchange coupling. We have optimized doping for the compensation of hole doping by the valence effect of Ru, This effect has been explained in terms of the charge transfer between the $Mn^{4+}$ and $Ru^{4+}$ species and ferromagnetic interaction between the resultant $Mn^{3+}$ and $Ru^{5+/4+}$. The electrons in $Ru^{4+}$ partially occupy the degenerated $t_{2g}$ orbitals due to the fact that Ru is a heavy metal, we expect a single-ion anisotropy of Ru spins through a spin-orbit channel. This structure is highly applicable for fabrication of the magnetic tunnel junctions.

**N20 11 Variation of magnetic domain structure correlated to low-field magnetoresistance hysteresis in $La_{0.66}Ca_{0.34}MnO_3$ film as observed by magnetic force microscopy.*** CHANGBAE HYUN, CASEY ISRAEL, WEIDA WU, ALEX DE LOZANNE, *Department of Physics, University of Texas at Austin* ALAKA P. VALANJU, RODGER M. WALSER, *Electrical and Computer Engineering, University of Texas at Austin, Austin, TX 78712* M.E. GOMEZ, J. G. RAMIREZ, *Thin Films Group. Universidad del Valle, A.A. 25360 Cali, Colombia* G.A. MENDOZA, *Magnetic Materials and Nanostructures Group. Universidad del Quindío, Armenia, Colombia* The ferromagnetic domain structure of a 150-nm-thick $La_{0.66}Ca_{0.34}MnO_3$ film was imaged by magnetic force microscopy (MFM) as a function of in-plane applied field at 240K, just below $T_C$. The film was grown by sputtering on a (001) $SrTiO_3$ substrate. The variation of the domain structure is correlated with the hysteresis in both magnetization and magnetoresistance. The resistance peak in the magnetoresistance coincides with the coercivity of the film and sweeping changes in the MFM images. We show the effect of applying the in-plane magnetic field along both in-plane crystalline axes.

*This work is supported by NSF DMR-0308575.

**10:12**

**N20 12 Anisotropic magnetoresistance in colossal magnetoresistive $La_{1-x}Sr_xMnO_3$ thin films** JENG-BANG YAU, *Yale University* X. HONG, *Yale University* C. H. AHN, Y. BASON, *Bar Ilan University* L. KLEIN, *Bar Ilan University* We report on magnetic field and temperature dependent measurements of the anisotropic magnetoresistance (AMR) in epitaxial $La_{1-x}Sr_xMnO_3$ (LSMO) thin films. While in 3*d* ferromagnetic alloys increasing the magnetization, either by reducing the temperature or increasing the magnetic field, increases the AMR, in LSMO films the AMR dependence on magnetization displays non-monotonic behavior which becomes particularly pronounced in lightly doped compounds. This could imply that these samples may be electronically inhomogeneous, in which increased magnetization yields enhanced uniformity which suppresses spin-dependent scattering and hence reduces the AMR.

**10:24**

**N20 13 Size effect in percolative phase separation of colossal magnetoresistive (La,Pr,Ca)$MnO_3$ films.** HONG-YING ZHAI, *Oak Ridge National Laboratory* JIANXING MA, DANE GILLASPIE, THOMAS WARD, *Oak Ridge National Laboratory and University of Tennessee* ANTHONY HMELO, *Vanderbilt University* LEONARD FELDMAN, *Vanderbilt University* JIAN SHEN, *Oak Ridge National Laboratory and University of Tennessee* $La_{1-x-y}Pr_yCa_xMnO_3$(LPCMO) (where x=3/8) is electronically phase-separated into a sub-micrometre-scale mixture of ferromagnetic metallic (FMM) and charge-ordered insulating (COI) domains. Transport through the ferromagnetic network depends sensitively on the domain structure, which can be controlled by magnetic field, light, and strain, etc. Enhanced CMR effect can be achieved in the vicinity of the percolative threshold. Using optical lithography, e-beam lithography, and focused ion beam techniques, we can fabricate series micron and sub-micron structures on LPCMO films grown on $LaAlO_3$ and $SrTiO_3$ using pulsed laser deposition. Size dependant transport properties will be addressed in detail. Research sponsored by the U.S. Department of Energy under contract DE-AC05-00OR22725 with Oak Ridge National Laboratory.

**10:36**

**N20 14 Combinatorial Hall Effect System for Oxide Films*** JEFFREY CLAYHOLD, *Physics Department, Miami University, Oxford, OH 45056* BRYAN KERNS, DAVID RENCH, MICHAEL SCHROER, IVAN BOZOVIC, *Brookhaven National Laboratory* Combinatorial film growth techniques have made it possible to produce large numbers of high-quality oxide films at one time. Characterizing the samples by traditional methods would be far too slow. Certain measurements, such as the the Hall effect, require careful temperature control and lock-in amplifiers to resolve the small signal. We have built special-purpose, multichannel resistance bridges to measure the Hall effect simultaneously in 32 samples. The voltage resolution is less than 2 nV for signals on the order of 1 $\mu$V, for a signal-to-noise ratio of 500. We will discuss Hall effect data from samples of $La_{2-x}Sr_xCuO_4$.

*Supported by Brookhaven National Laboratory and the Department of Energy.

**10:48**

**N20 15 B-site substitution in $LaTiO_3$ thin films: influence on the titanium oxidation state.** A. GUILLER, C. MARCHIORI, M. SOUSA, R. GERMANN, J. P. LOCQUET, J. FOMPEYRINE, *IBM Research GmbH* J. W. SEO, *IPMC, Ecole Polytechnique Federale de Lausanne* $LaTiO_3$ (LTO) is a Mott insulator, antiferromagnetic at RT, and exhibits a Metal Insulator Transition (MIT) at the Neel temperature. Despite its complex chemistry, it is an interesting candidate to fabricate field-effect devices. A full device requires the deposition of a dielectric in contact with the LTO thin film such as $HfO_2$. This choice will be discussed, and we will present issues related to a possible interdiffusion. Adding Hf in the LTO layer leads to a clear change of the resistivity measured as a function of temperature, and strongly influences the MIT temperature. Starting from a semiconducting LTO, 20% Hf substitution on the perovskite B-site makes the layer become metallic from RT down to 4.2K. The average valence of Ti is increasing from $Ti^{3+}$ towards $Ti^{4+}$ with the substitution of Hf, as shown by XPS. Several explanations can be proposed beyond a real incorporation of Hf into the LTO matrix. Besides a pure electronic effect, structural and catalytic effects have been then investigated in details by means of XRD, XPS and HRTEM. Multilayers as well as single-phase thin films have been fabricated to disentangle these different effects. Our results will be discussed taking also into account a possible material loss in the structure. We will in particular explore the behavior of La-deficient structure to qualitatively explain our data.

## SESSION N21: MICROFLUIDIC PHYSICS II
**Wednesday Morning, 15 March 2006**
**318, Baltimore Convention Center at 8:00**
**Patrick Tabeling, Ecole Sup, presiding**

**8:00**

**N21 1 Microfluidics with Gel Emulsions** CRAIG PRIEST, ENKHTUUL SURENJAV, STEPHAN HERMINGHAUS, RALF SEEMANN, *Max-Planck-Institute for Dynamics and Self-Organization* Microfluidic processing is usually achieved using single phase liquids. Instead, we use monodisperse emulsions to compartment liquids within microchannel geometries. At low continuous phase volume fractions, droplets self-organize to form well-defined arrangements, analogous to foam. While it is well-known that confined geometries can induce rearrangement of foam compartments at the millimeter-scale, similar dynamics are also expected for gel emulsions. We have studied online generation, organization and manipulation of gel emulsions using a variety of microchannel geometries. ''Passive'' reorganization, based on fixed channel geometries, can be supplemented by ''active'' manipulation by incorporating a ferrofluid phase. A ferromagnetic phase facilitates reorganization of liquid compartments on demand using an electromagnetic trigger. Moreover, coalescence between adjacent compartments within a gel emulsion can be induced using electrical potential. Microfluidics using gel emulsions will be well-suited for combinatorial chemistry, DNA sequencing, drug screening and protein crystallizations.

**8:12**

**N21 2 In-situ Generation of Focal Conic Defects in Flow of Smectic-A Liquid Crystals in Microchannels*** SHAHAB SHOJAEI-ZADEH, SHELLEY ANNA,† *Carnegie Mellon University* The response of ordered phases of layered liquids such as smectic-A liquid crystals to flow is often dominated not by the direct coupling of flow to molecular degrees of freedom, but by the driven motion of defects in these systems. This is because flow generates instabilities in these systems that lead to the formation of defects. Most attention to date focuses on the global viscoelastic behavior and shear alignment of layered liquids, while little work has been done to understand defect motion and defect/flow interaction in these systems. Here we introduce a new approach, which enables simultaneous generation and observation of focal conic defects in pressure-driven flow of smectic-A liquid crystals. We observe that introducing a sudden change in the cross-sectional area of a microchannel via a small obstacle leads to the formation of a steady stream of defects. Generated defects move along the microchannel and interact with each other and with the flow itself. We measure the pressure drop and defect velocity and relate these to observed defect size and microchannel geometry. These results provide a novel way of probing nonlinear behavior of layered fluids under flow.

**8:24**

**N21 3 Folding and swirling of viscous threads in microfluidics** THOMAS CUBAUD, THOMAS G. MASON, *UCLA, Chemistry and Biochemistry Dept.* We study miscible multiphase flows with large viscosity contrast in microchannels. We investigate the folding instability of a viscous thread surrounded by a less viscous liquid that flow into a diverging microchannel. In this situation, extensional viscous stresses cause the thread to bend and fold rather than dilating in order to minimize dissipation. We show that diffusive mixing at the boundary of the thread can significantly modify the folding flow morphologies. We relate the folding frequency to the characteristic shear rate. We also examine the hydrodynamic coupling between multiple threads and the threads' rupturing into arrays of viscous swirls, reminiscent of the Kelvin-Helmholtz instability.

**8:36**

**N21 4 Observations of Tipstreaming and Thread Formation in a Microfluidic Flow Focusing Device** SHELLEY ANNA, *Carnegie Mellon University* HANS MAYER, *Department of Mechanical Engineering, Carnegie Mellon University* We present a novel method of generating sub-micron scale droplets in a microfluidic device. In particular we utilize the interaction of fluid motion and surfactant transport during the tipstreaming mode of droplet formation, which is achieved using a flow focusing microfluidic design. Tipstreaming is a mode of drop breakup in which daughter droplets, usually orders of magnitude smaller than the parent drops, are ejected from the pointed tips of parent droplets or bubbles. An attractive characteristic of tipstreaming is that droplets produced are not limited by the device feature size. In this work we observe that tipstreaming occurs within a specific range of capillary number (Ca $\sim$ 0.1 to 1, consistent with literature values for tipstreaming), flow rate ratio, and surfactant concentration, and that tipstreaming is preceded by the formation of thin threads that follow the pinchoff of larger droplets. We measure the thread diameter and length as a function of dimensionless parameters and discuss our results with respect to surfactant diffusion and kinetic timescales relative to flow timescales.

**8:48**

**N21 5 Drops and Jets in two Phase Coaxial Flows** ANDREW UTADA, ALBERTO FERNANDEZ-NIEVES, DAVID WEITZ, *Harvard University* We discuss the transition from dripping to jetting from a nozzle in a coaxially flowing fluid. The fact that the outer fluid is viscous and moving affects the transition from dripping to jetting as well jet shape and drop formation mechanism. We relate the physics of drop formation to a recently reported microcapillary device (1,2) that generates monodisperse double emulsions. (1) A. S. Utada, E. Lorenceau, D. R. Link, P. Kaplan, H. A. Stone, D. A. Weitz, Science 308, 537 (2005) (2) E. Lorenceau, A. S. Utada, D. R. Link, G. Cristobal, M. Joanicot, D. A. Weitz, Langmuir in press, (2005).

**9:00**

**N21 6 Geometrically controlled jet-like instabilities in microfluidic two-phase flows** KATHERINE HUMPHRY, *Department of Physics, Harvard University, Cambridge MA 02138, USA* ARMAND AJDARI, *Laboratoire de Physico-Chimie Theorique, ESPCI, Paris, F-75005, France* HOWARD STONE, ALBERTO FERNANDEZ-NIEVES, *Division of Engineering and Applied Sciences, Harvard University, Cambridge MA 02138, USA* DAVID WEITZ, *Department of Physics and Division of Engineering and Applied Sciences, Harvard University, Cambridge MA 02138, USA* We demonstrate effects of confinement in microfluidic devices with a two phase co-flowing system. When the flow rate of the inner fluid is small compared to the flow rate of the outer fluid, and the resulting width of the inner fluid is smaller than the height of the channel, the inner fluid breaks into droplets, as expected for a three-dimensional system. On the other hand, when the width of the second phase becomes comparable to the height of the microfluidic device, Rayleigh capillary instabilities are suppressed, and the inner fluid forms a jet that does not break, as might be expected for a purely two-dimensional system. We show that by changing the dimensions of the microfluidic channel we can transition from a stable co-flow to drop break-up. The experimental results are compared with of model of this two-phase flow.

**9:12**

**N21 7 Playing with Microfluidic Droplets and Actuators** PATRICK TABELING, *ESPCI-CNRS* VALESSA BARBIER, *Univ Paris XIII* HERVÉ WILLAIME, *ESPCI-CNRS* MMN TEAM, In the lab-on a chips of the future, flows will be handled at the microscale through mazes of microchannels using actuators. Here we concentrate on PDMS based microfluidic systems and we use actuators to introduce localized perturbations on a chip, close to where droplets are formed, i.e. near the intersection of a main and a side channel along which oil and water flows are driven. We observe Arnold tongues and devil staircases leading to the formation of regular or quasiperiodic-like droplets. These behaviors are well accounted for by modelling the system as a non linear oscillator driven by an external forcing. The characteristics of the regimes that are observed depend on the flow-rate conditions. In some range of flow-rates, we show that the droplet sizes can be varied by one order of magnitude by changing the actuation frequency, without modifying the flow-rates.These findings are used to understand the complex behavior of droplet emittors placed in parallel.

**9:24**

**N21 8 Droplet Traffic Control at a simple T junction** PASCAL PANIZZA, WILFRIED ENGL, ANNIE COLIN, *LOF/CNRS* ARMAND AJDARI, *ESPCI* A basic yet essential element of every traffic flow control is the effect of a junction where the flow is separated into several streams. How do pedestrians, vehicles or blood cells divide when they reach a junction? How does the outcome depend on their density? Similar fundamental questions hold for much simpler systems: in this paper, we have studied the behaviour of periodic trains of water droplets flowing in oil through a channel as they reach a simple, locally symmetric, T junction. Depending on their dilution, we observe that the droplets are either alternately partitioned between both outlets or sorted exclusively into the shortest one. We show that this surprising behaviour results from the hydrodynamic feed-back of drops in the two outlets on the selection process occurring at the junction. Our results offer a first guide for the design and modelling of droplet traffic in complex branched networks, a necessary step towards parallelized droplet-based ''lab-on-chip'' devices.

**9:36**

**N21 9 Manipulation and stretching of bacteria and liposomes by Microfluidics** EYAL ZUSSMAN, WAEL SALALHA, *Faculty of Mechanical Eng., Technion, Israel* Microfluidic technology can be useful in lab-on-a-chip applications of biological assays, environmental monitoring, detection of toxic materials, as well as for assembly of nano- and micro-scale objects into more complex systems. In this work we focused on the orientation of rod-shaped bacteria (Bacillus) by employing shear flow and a high rate elongation flow, and stretching of giant liposomes with diameter size of tens of microns, which can be used as a simplified model for cell behavior. This was achieved by flows of dilute rod-like bacteria and liposome suspensions within a micro-channel by means of a capillary-driven motion. Fluidic alignment situations were tested, firstly by Venturi-like flow which produces a sufficiently converging and diverging flow, and secondly by sink-like flow in a converging microchannel. In the first method we found that the converging part of the flow aligns rod-like bacteria, whereas the diverging part disaligns them, while in the second method the rod-like bacteria can perfectly align along the streamlines. In addition we used the same technology to test liposome deformation while they are flowing through a Venturi-like microchannel. The microfluidics devices were fabricated from poly(dimethylsiloxane) (PDMS) by soft lithographic techniques.

**N21 10 Continuous separation of serum from human whole blood within a microfluidic device** JOHN DAVIS, *Princeton University* DAVID INGLIS, *Princeton University* JAMES STURM, *Princeton University* ROBERT AUSTIN, *Princeton University* We were able to demonstrate separation of red and white blood cells from their native blood plasma, using a technique known as deterministic lateral displacement. The device takes advantage of asymmetric bifurcation of laminar flow around obstacles. This asymmetry creates a size dependent deterministic path through the device. All components of a given size follow equivalent migration paths, leading to high resolution. A subsequent version of the device will focus on the removal of platelets from whole blood. Samples will be extracted from the microfluidic device and analyzed by conventional flow cytometry.

**10:00**

**N21 11 Reversible Dialysis in a Microfluidic Formulator.** SEILA SELIMOVIC, JUNG-UK SHIM, SETH FRADEN, *Brandeis University* In order to facilitate the screening of conditions for protein crystallization, we have been using the Microfluidic Formulator chip (Stephen Quake, PNAS Vol. 101, 40). This PDMS device allows us to mix up to 40 different reagents and protein solutions. We use this combinatorial approach along with a ''drop-on-demand'' method whereby we employ on-chip positive displacement pumps to form aqueous droplets containing protein and separate them by plugs of oil. Subsequently, the aqueous drops containing protein are guided by surface tension forces into storage chambers. To control the chemical potential of these sub-nanoliter protein samples, we fabricate reservoirs underneath the storage compartments. A thin PDMS membrane that is permeable to water, but not to protein or salt, separates the reservoirs from the storage chambers. Water can permeate into or out of the stored samples until the chemical potentials of the reservoir and the protein solution are equal leading to protein crystallization in some chambers.

**10:12**

**N21 12 A noble microfluidic device for protein crystallizations.** JUNG-UK SHIM, SETH FRADEN, *Brandeis University* A high throughput, low volume microfluidic device has been constructed out of poly(dimethylsiloxane) elastomer. We have demonstrated that sub-nanoliter water-in-oil drops of protein solutions of different composition can be rapidly stored in individual wells, which allows screening of 1000 conditions while consuming a total of only 1 microgram protein on a 20 $cm^2$ chip. This reduction in protein needed for crystal screens allows high-throughput crystallization of mammalian proteins expressed in tissue culture. A significant advance over current microfluidic devices is that each pot is in contact with a reservoir through a dialysis membrane which only water and other low molecular weight organic solvents can pass, but not salt, polymer or amphiphile. This enables the concentration of all solutes in a solution to be reversibly, rapidly, and precisely varied in contrast to current microfluidic methods, which are irreversible. This microfluidic dialysis technology solves a major problem in protein crystallization, the decoupling of nucleation from growth. The device will also be useful for general studies of the phase behavior of protein solutions.

**N21 13 Shear induced particle migration in binary colloidal suspensions*** DENIS SEMWOGERERE, ERIC R. WEEKS, *Emory University* JEFFREY F. MORRIS, *City College of New York* We present experimental investigations of the spatial and temporal evolution of particle migration in pressure driven flows of Brownian particle suspensions. Binary suspensions of 1 $\mu$m- and 3 $\mu$m-diameter colloidal particles at a variety of concentration ratios and volume fractions are pumped through a 50 $\mu$m x 500 $\mu$m rectangular-cross-section capillary tube. Shear rate gradients caused by the resulting parabolic velocity profile drive particles away from the walls towards the center of the channel where the shear rate is lowest. Size segregation is observed. We measure the development of the size segregation by tracking the evolution of the particle concentration down the center of the tube of the small and large sized particles. The flows are directly imaged using high-speed confocal microscopy (up to 300 images/second).

*Supported by NSF (DMR-0239109).

**N21 14 Using permeable microcapsules to deliver nanoparticles on substrates** ROLF VERBERG, ALEXANDER ALEXEEV, ANNA BALAZS, *University of Pittsburgh* We present a novel algorithm to simulate nanoparticles in the presence of a substrate, microcapsules and an externally driven flow. Here, the microcapsules consist of an elastic shell that encloses a fluid with either a dissolved chemical component or a suspension of nanoparticles that are small enough to be treated as so-called tracer particles (mutually non-interacting particles without excluded volume). The model couples a lattice-Boltzmann model for the fluid flow, a lattice-spring model for the elastic shell, and a Brownian dynamics model to simulate tracer trajectories. We then apply the model to simulate the release of nanoparticles from a microcapsule as it rolls along a substrate, as well as the subsequent particle adsorption on the wall. We study the effect of flow conditions, reaction kinetics, capsule elasticity, and capsules-substrate interaction on the rate of deposition and the size of the area of deposition at the substrate. The results provide guidelines for designing effective micro-scale delivery systems.

**N22 1 Field Dependence of Magnetic Vortex Dynamics** R.L. COMPTON, J.P. PARK, P.A. CROWELL, *University of Minnesota* We have used time-resolved Kerr microscopy (TRKM) to investigate the dynamical behavior of micron diameter disks patterned from sputtered Permalloy (Py) films. Different growth conditions yielded grain diameters of $\sim$ 35 nm and $\sim$ 80 nm while average roughness (Ra) remained less than 1 nm for 50 nm thick films. The magnetization of the disks relaxes into a vortex ground state, in which broadband spin dynamics include a low frequency vortex translational mode (vortex mode) that is expected to be nearly independent of field, based on simulations and analytical theory. We measured the field dependence of the vortex dynamics of individual disks using 5 Oe field steps from 0 Oe through the vortex annihilation field ($H_a$). For a 1 $\mu$m diameter disk the vortex mode has a mean frequency of $\sim$ 300 MHz, but the frequency fluctuates throughout the entire field range ($H_a \sim$ 350 Oe) with a magnitude $\Delta f \sim$ 200 MHz and a characteristic period $\sim$ 30 Oe. The fluctuations are not symmetric about zero field and look different in detail for different disks, but are highly repeatable for the same disk. We have also observed non-linear effects including the presence of up to 3 higher harmonics of the vortex mode, with a higher harmonic occasionally dominating the spectrum. A consistent interpretation is that the vortex core samples a distribution of pinning potentials, some of which are anharmonic, as it traverses the disk under the influence of the static applied field. Supported by NSF DMR 04-06029.

**N22 2 Fractional vortices and composite domain walls in flat nanomagnets*** OLEG TCHERNYSHYOV, GIA-WEI CHERN, *Johns Hopkins University* We provide a simple explanation of complex magnetic patterns observed in ferromagnetic nanostructures. To this end we identify elementary topological defects in the field of magnetization: ordinary vortices in the bulk and vortices with *fractional* winding numbers ( $\pm$ 1/2) confined to the edge [1]. Domain walls found in experiments and numerical simulations in strips and rings are composite objects containing two or more of the elementary defects. Allowed compositions of a domain wall in a strip or ring are constrained by simple selection rules of topological origin: (i) An edge contains an odd number of edge defects. (ii) The net winding number of all edge and bulk defects is zero. The walls observed most frequently in experiments and simulations contain a halfvortex and an antihalfvortex (transverse walls in thin and narrow strips) or two antihalfvortices and a vortex (vortex walls in thicker and wider strips). [1] O. Tchernyshyov and G.-W. Chern, Phys. Rev. Lett. **95,** 197204 (2005).

**N22 3 Magnetic domains in ferromagnetic particles with perpendicular anisotropy** STAVROS KOMINEAS, CHRISTOFOROS MOUTAFIS, TONY BLAND, *University of Cambridge* We derive a Derrick-like virial theorem for static states in a disc-shaped ferromagnetic particle with an axially symmetric magnetic configuration. This is applied to elementary magnetic states such as a single domain and a vortex. We calculate the vortex state in a disc-shaped particle with no anisotropy and study the very thin and very thick limits. In the very thin limit the virial relation effectively gives the vortex core radius. We also consider a particle with significant perpendicular anisotropy and show that a vortex is a static state for sufficiently thin particles. For thicker particles the vortex core expands to become comparable to the particle lateral size while the magnetization at the periphery of the particle tilts out of plane opposite to the vortex core region. In sufficiently thick particles, the magnetic state takes the form of a magnetic ''bubble'' (well-known in films) viewed here as a bidomain state. The signature of a bubble is its magnetostatic field which consists of two concentric regions of opposite sign above the particle top surface. Higher order states of multiple concentric domains of opposite magnetization are found in larger particles. We finally study the effect of an external field on magnetic bubble states.

**8:36**
**N22 4 Composite domain walls in flat nanomagnets: the dipolar limit*** GIA-WEI CHERN, HYUN YOUK, KATHLEEN MERIT, OLEG TCHERNYSHYOV, *Johns Hopkins University* Topological defects play an important role in nanoscale ferromagnets. We have previously demonstrated that domain walls in thin strips and rings are composite objects made of bulk vortices (winding numbers $n = \pm 1$) and edge defects (fractional winding numbers $n = \pm 1/2$) and given analytical solutions in the exchange limit [1]. Experimentally accessible systems are in the opposite regime where the dipolar interaction dominate. In this limit the vortex solution remains unchanged, the antivortex and antihalfvortex are deformed but survive, whereas the halfvortex acquires a high magnetostatic energy and becomes unstable. Accordingly, domain walls in this limit consist of two antihalfvortices and a vortex between them. We present a model of the domain wall in the magnetostatic limit in which the location of the vortex

core is a variational parameter. As the width and thickness of a strip change, the global and local minima of the total magnetic energy yield the familiar transverse and vortex walls, as well as more exotic configurations such as the ''diagonal wall'' with a vortex hanging close to an edge. [1] O. Tchernyshyov and G.-W. Chern, Phys. Rev. Lett. **95**, 197204 (2005).

**N22 5 Single vortex dynamics in patterned ferromagnetic ellipses*** KRISTEN BUCHANAN, *Argonne National Laboratory* PIERRE ROY, *Angstrom Laboratory, Sweden* MARCOS GRIMSDITCH, FRANK FRADIN, KONSTANTIN GUSLIENKO, SAM BADER, VAL NOVOSAD, *Argonne National Laboratory, USA* ARGONNE NATIONAL LABORATORY, USA TEAM, ANGSTROM LABORATORY, SWEDEN TEAM, Measurements of low frequency dynamics of single magnetic vortices confined in elliptic ferromagnetic dots made of Permalloy with dimensions 2x1 $\mu m^2$ and 3x1.5 $\mu m^2$, 40-nm thick, have been performed using a microwave reflection method. Resonances were recorded in the sub-GHz range that can be attributed to the vortex translational mode where the vortex core follows an elliptic trajectory around its equilibrium position. The existence of single vortex states in the samples was confirmed by magnetic force microscopy. The frequency of this translational mode varies little under the influence of an in-plane static field H along the easy axis, however, it increases by more than a factor of two when H is applied along the hard axis. Micromagnetic simulations are used to explore the origin of the observed field dependence.

**N22 6 The relationship between the sign of exchange bias and the magnetization depth profile of Co/$FeF_2$** MICHAEL FITZSIMMONS, BRIAN KIRBY, *Los Alamos National Laboratory, Los Alamos NM 87545* SUJOY ROY, ZHI-PAN LI, IGOV V. ROSHCHIN, R. MORALES, S.K. SINHA, IVAN K. SCHULLER, *Department of Physics, University of California at San Diego, La Jolla CA 92093* We have used the unique spatial sensitivity of polarized neutron beams in reflection geometry to measure the depth dependence of magnetization across the interface between a ferromagnet (Co) and an antiferromagnet ($FeF_2$). Our Co/$FeF_2$ bilayer sample is one that exhibits either positive or negative exchange bias depending upon the magnitude of the cooling field. For positive exchange bias, pinned magnetization at the Co/$FeF_2$ interface is directed opposite to the cooling field, while in the $FeF_2$ bulk, the net pinned magnetization is parallel to the cooling field. For negative exchange bias, the net pinned magnetization near the Co/$FeF_2$ interface is parallel to the direction of the cooling field. We propose a model that explains the cooling field dependence of the sign of exchange bias. Work at LANL and UCSD was funded by the U.S. Department of Energy, BES-DMS, and by a University of California Campus-Laboratory Collaboration grant.

**N22 7 Vortex State in Sub-100 nm Magnetic Nanodots.**

IGOR V. ROSHCHIN, *Physics Department, UCSD, La Jolla, CA*

Magnetism of nanostructured magnets, which size is comparable to or smaller than ferromagnetic domain size, offers a great potential for new physics. Detailed knowledge of magnetization reversal and possible magnetic configurations in magnetic nanostructures is essential for high-density magnetic memory. Many theoretical and experimental studies are focused on a magnetic vortex which in addition to a circular in-plane configuration of spins has a core, - the region with out-of-plane magnetization. We present a quantitative study of the magnetic vortex state and the vortex core in sub-100 nm magnetic dots. Arrays of single-layer and bilayer nanodots covering over 1 $cm^2$ are fabricated using self-assembled nanopores in anodized alumina. This method allows good control over the dot size and periodicity. Magnetization measurements performed using SQUID, VSM, and MOKE indicate a transition from a vortex to a single domain state for the Fe dots. This transition is studied as a function of the magnetic field and dots size. Micromagnetic and Monte Carlo simulations confirm the experimental observations. Thermal activation and exchange bias strongly affect the vortex nucleation field and have a much weaker effect on the vortex annihilation field. Direct imaging of magnetic moments in sub-100 nm dots is extremely difficult and has not been reported yet. Polarized grazing incidence small angle neutron scattering measurements allow dot imaging in reciprocal space. Quantitative analysis of such measurements performed on 65 nm Fe dots yields the vortex core size of $\sim$ 15 nm, in good agreement with the 14 nm obtained from the simulations. This work is done in collaboration with Chang-Peng Li, Zhi-Pan Li, S. Roy, S. K. Sinha, (UCSD), Xavier Batlle (U. Barcelona), R. K. Dumas, Kai Liu, (UC Davis), S. Park, R. Pynn, M. R. Fitzsimmons (LANL), J. Mejia Lopez (Pontificia U. Catolica de Chile), D. Altbir, (U. de Santiago de Chile), A. H. Romero (Cinvestav-Unidad Queretaro), and Ivan K. Schuller (UCSD) and supported by AFOSR, US DOE, NSF, UC-CLE, Spanish MECD, Catalan DURSI, FONDECYT, Millennium Initiative, and Conacyt Mexico.

**N22 8 Using multiple antiferromagnet/ferromagnet interfaces as a probe of grain size dependent exchange bias in polycrystalline Co/$Fe_{50}Mn_{50}$*** B. BOLON, M.A. HAUGEN, A. ABINFUENTES, J. DENEEN, C.B. CARTER, C. LEIGHTON, *Dept. of Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, MN 55455* We have used ferromagnet/antiferromagnet/ferromagnet trilayers and ferromagnet/antiferromagnet multilayers to probe the grain size dependence of exchange bias in polycrystalline Co/FeMn. X-ray diffraction and transmission electron microscopy characterization show that the FeMn grain size increases with increasing FeMn thickness in the Co (30 Å) / FeMn system. Hence, in Co (30 Å) / FeMn / Co (30 Å) trilayers the two Co layers ''sample'' different FeMn grain sizes at the two antiferromagnet/ferromagnet interfaces. For FeMn thicknesses above $\sim$ 100 Å, where simple bilayers have a thickness independent exchange bias, we are therefore able to deduce the influence of grain size on the exchange bias and coercivity (and their temperature dependence) by measuring trilayer and multilayer samples with varying FeMn thickness. Increasing the average grain size results in a large decrease in exchange bias energy. We interpret the results as being due to a decrease in uncompensated spin density with increasing grain size, further evidence for the importance of defect generated uncompensated spins.

**N22 9 Interplay between reversal asymmetry, training, and anisotropy, in epitaxial NiMn/Ni exchange biased bilayers** M.S. LUND, C. LEIGHTON, *University of Minnesota* We have employed electron and x-ray diffraction, x-ray reflectivity, conventional magnetometry, and polarized neutron reflectivity to probe epitaxial NiMn/Ni bilayers. Binary alloys such as NiMn often require an annealing procedure to induce AF ordering which leads to interdiffusion at the AF/ F interface and a subsequent, and poorly understood, reduction in exchange bias. Our previous work with neutron reflectivity revealed a 35 Å interdiffused region that contains competing AF and F interactions resulting in a very unusual temperature dependant magnetic interface location (M.S. Lund, M.R. Fitzsimmons, S. Park, and C. Leighton, APL 2004). In this work we find that at low temperatures there is a rapid divergence of the exchange bias field, coincident with the onset of strong training, an obvious reversal asymmetry, and the appearance of higher order induced anisotropies. We show in a simple way that the rapid increase in bias field, strong training, and reversal asymmetry are all consequences of the induced anisotropies. In addition, we are able to demonstrate in a single sample that uniaxial anisotropy favors low training, while biaxial anisotropy results in large training, confirming a recent theoretical prediction (A. Hoffmann, PRL 2004). Research was supported by NSF MRSEC.

**N22 10 Effect of Hard Layer Demagnetization on the Magnetization Reversal of Epitaxial Fe/SmCo Spring Magnets*** KAI LIU, J.E. DAVIES, *UC - Davis* E.E. FULLERTON, *Hitachi Global Storage Tech* J.S. JIANG, S.D. BADER, *Argonne National Lab* In epitaxial Fe/SmCo, a classical spring magnet, irreversible magnetization reversal is observed once the SmCo hard layer starts switching [1,2]. To distinguish the soft and hard layer reversibility separately, we studied the effect of partial SmCo layer demagnetization on the reversal behavior of the entire bilayer using the first and second order reversal curve methods (FORC and SORC, respectively). The FORC distribution [2,3] shows two distinct features during the hard layer reversal: a negative/positive pair of features and a single positive peak. The negative/positive pair is from the soft Fe layer reversal and is a manifestation of the interlayer exchange coupling. The single positive peak occurs at larger applied fields and corresponds to the reversal of the hard SmCo layer. A SORC measurements were done at several reversal fields to determine the reversibility along different FORCs. We observe that the Fe layer remains mostly reversible. The partially demagnetized SmCo layer is the main source of irreversibility, particularly when the applied field approaches the hard layer nucleation/saturation field. **N22 11 Electrically controlled exchange bias for spintronic applications*** XI HE, SRINIVAS POLISETTY, CHRISTIAN BINEK, *University of Nebraska-Lincoln* Electrically controlled exchange bias (EB) is proposed for novel spintronic applications [1]. Basic effects of electrically controlled EB and its magnetoelectric (ME) switching are studied in a $Cr_2O_3(111)/(Co/Pt)_3$ heterostructure. Exchange coupling between the ME antiferromagnet $Cr_2O_3$ and a ferromagnetic CoPt multilayer exhibits perpendicular EB. The latter is controlled by applied axial electric fields inducing excess magnetization at the interface. The enhancement of this hitherto weak tuning effect is explored when replacing ME bulk pinning systems by epitaxal thin films. Recently, the sign of the EB field has been tuned via field cooling the system in either parallel or antiparallel axial magnetic and electric fields [2]. Here, the crossover from bulk to thin film ME pinning systems is studied and spintronic applications are suggested based on the electrically controlled EB. Pure voltage control of magnetic configurations of tunneling magneto resistance spin valves is proposed as an alternative to current−induced magnetization switching. In addition we suggest an XOR operation realized in a ME ally pinned giant magneto resistance structure. [1] Ch. Binek, B. Doudin, J. Phys. Condens. Matter **17**, L39 (2005). [2] P. Borisovetal, Phys. Rev. Lett. **94**, 117203 (2005).

**N22 12 Exchange bias training effect in coupled all ferromagnetic bilayer structures*** SRINIVAS POLISETTY, XI HE, CHRISTIAN BINEK, *University of Nebraska-Lincoln* ANDREAS BERGER, *Hitachi Global Storage Technologies* We study exchange coupled bilayers of soft and hard ferromagnetic (FM) thin films by means of Alternating Gradient Force Magnetometry. A CoCr thin film realizes the magnetically soft layer (SL) which is exchange coupled via a Ru-interlayer with a hard CoPt-CrB pinning layer (HL). This new class of all FM bilayers shows remarkable analogies to conventional antiferromagnetic (AF)/FM exchange bias (EB) heterostructures. Not only do these all FM bilayers exhibit a tunable EB effect, they also show a distinct training behavior upon cycling the SL through consecutive hysteresis loops. Training resembles the cycle dependent evolution of the bias field and is to a large extend analogous to the gradual

degradation of the EB field observed upon cycling the FM top layer of a AF/FM EB heterostructure through consecutive hysteresis loops. However, in contrast to these conventional EB systems, our all FM bilayer structures allow the observation of training induced changes in the bias-setting HL by means of simple magnetometry. Our experiments show unambiguously that the training effect is driven by deviations from equilibrium in the pinning layer. A comparison of the experimental data with predictions from a theory based upon triggered relaxation phenomena shows excellent agreement.

**N22 13 Alignment-Sensitive Reversal Mechanisms of Epitaxial-$FeF_2$/Polycrystalline-Ni Exchange Biased Thin Films*** JUSTIN OLAMIT, KAI LIU, *UC Davis Physics Department* ZHI-PAN LI, IVAN K. SCHULLER, *UC San Diego Physics Department* Magnetization reversal mechanisms of epitaxial-$FeF_2$/polycrystalline-Ni exchange biased thin films were investigated with vector magnetometry and a First Order Reversal Curve (FORC) technique [1]. The FORCs were measured **without** remounting the sample after the vector magnetometry measurements, ensuring consistency between the two methods. Samples were exchange biased by field cooling along the $FeF_2$ spin axis. When the applied field is aligned with the spin axis, the transverse hysteresis loop is flat and FORC analysis shows that the magnetization switching is highly irreversible ( $\sim$ 80%), indicating that domain nucleation and motion is the reversal mechanism. With a misalignment of 5[r], the transverse hysteresis loop shows that the reversal is predominantly by rotation [2] and FORC analysis shows that the majority of the magnetic switching is by a reversible mechanism (only $\sim$ 40% irreversible). These results demonstrate that the magnetization reversal mechanisms are **itextremely sensitive** to the alignment of the applied field with the antiferromagnet spin axis and the exchange bias direction [3]. 1. **N23 1 Antiferromagnetic Heisenberg Spin Layers coupled with Dipolar Interaction – a Monte Carlo study of $Rb_2MnF_4$*** CHENGGANG ZHOU, THOMAS C. SCHULTHESS, *Computer Science and Mathematics Division, Oak Ridge National Laboratory, P.O. Box 2008, Oak Ridge, TN 37831-6164* DAVID P. LANDAU, *Center for Simulational Physics, University of Georgia, Athens GA, 30602* $Rb_2MnF_4$ is a quasi-2D antiferromagnetic (AF) system, in which $Mn^{2+}$ ions carrying spin-5/2 occupy square lattices perpendicular to the c-axis of the tetragonal unit cell. These spins interact via mostly nearest neighbor isotropic AF exchanges, while the dipolar interaction contributes to the effective anisotropy that stabilizes the AF phase at low temperatures. In a magnetic field parallel to the c-axis, the AF phase is terminated along a spin-flop line, and a transverse (XY) phase appears. We perform large scale extensive Monte Carlo simulations to map out the phase diagram and investigate the critical behavior along the phase boundaries. A novel reweighting technique is used to efficiently handle the dipolar interaction. Our results suggest that both the AF phase and the XY phase experience continuous transitions across the spin-flop line, which is consistent with a bicritical point at zero temperature. We also found that the effect of the weak inter-planar coupling is not completely negligible for the spin-flop transition and the properties of the XY phase.

**N23 3 Dynamical correlations of the Quantum Dimer Model on the triangular lattice** ARNAUD RALKO, *ITP, Ecole Polytechnique Fédérale de Lausanne, Switzerland* MICHEL FERRERO, FEDERICO BECCA, *INFM-Democritos, SISSA, Trieste, Italy* DMITRI IVANOV, FRÉDÉRIC MILA, *ITP, Ecole Polytechnique Fédérale de Lausanne, Switzerland* Using Green's function Monte Carlo simulations, we have studied the zero-temperature properties of the quantum dimer model (QDM) on the triangular lattice [1] on clusters with up to 588 sites. A detailed comparison of the static properties in different topological sectors as a function of the cluster size and for different cluster shapes has allowed us to identify different phases, and to to show explicitly the presence of topological degeneracy in a phase close to the Rokhsar-Kivelson point, in agreement with an earlier suggestion [2]. We have also extended the Green's function Monte Carlo algorithm to calculate dynamical correlation functions. Preliminary results on the dimer-dimer correlations confirm the extension of the RVB phase and bring new insight on the nature of the transition to the $\sqrt{12} \times \sqrt{12}$ phase and on the type of long-range order realized in that phase. **N23 4 Towards material-specific simulations of high-temperature superconducting cuprates.***
THOMAS SCHULTHESS, *Oak Ridge National Laboratory*

Simulations of high-temperature superconducting (HTSC) cuprates have typically fallen into two categories: (1) studies of generic models such as the two-dimensional (2D) Hubbard model, that are believed to capture the essential physics necessary to describe the superconducting state, and, (2) first principles electronic structure calculations that are based on the local density approximation (LDA) to density functional theory (DFT) and lead to materials specific models. With advent of massibely parallel vector supercomputers, such as the Cray X1E at ORNL, and cluster algorithms such as the Dynamical Cluster Approximation (DCA), it is now possible to systematically solve the 2D Hubbard model with Quantum Monte Carol (QMC) simulations and to establish that the model indeed describes *d*-wave superconductivity [1]. Furthermore, studies of a multi-band model with input parameters generated from LDA calculations demonstrate that the existence of a superconducting transition is very sensitive to the underlying band structure [2]. Application of the LDA to transition metal oxides is, however, hampered by spurious self-interactions that particularly affects localized orbitals. Here we apply the self-interaction corrected local spin-density method (SIC-LSD) to describe the electronic structure of the cuprates. It was recently applied with success to generate input parameters for simple models of Mn doped III-V semiconductors [3] and is known to properly describe the antiferromagnetic insulating ground state of the parent compounds of the HTSC cuprates. We will discus the models for HTSC cuprates derived from the SIC-LSD study and how the differences to the well-known LDA results impact the QMC-DCA simulations of the magnetic and superconducting properties. **N23 5 Mechanism of Noncollinearity and Magnetoelectric Coupling in Incommensurate Multiferroics** IVAN SERGIENKO, ELBIO DAGOTTO, *Oak Ridge National Laboratory* Using extensive Monte-Carlo simulations of a modified orbitally degenerate double-exchange model applied to the multiferroic perovskites $R\mathrm{MnO}_3$ ($R$ = Gd, Tb, Dy), we show that the spiral magnetic phase results from the interplay between the double exchange coupling, superexchange, Jahn-Teller and Dzyaloshinskii-Moriya (DM) interactions. The DM interaction also induces a small ferroelectric moment and provides the mechanism of the strong coupling between the unusual magnetism and ferroelectricity. We also discuss the magnetoelectric effects in the applied magnetic fields.

**N23 6 Numerical Study of Magnetism in the Periodic Anderson Model*** YONG-QIANG WANG, HAI-QING LIN, *Institute of Theoretical Physics and Department of Physics, The Chinese University of Hong Kong, Hong Kong SAR, China* JAMES GUBERNATIS, *Los Alamos National Laboratory, USA* The periodic Anderson model is believed as a candidate of the minimal lattice models for itinerant ferromagnetism. Several numerical methods, including exactly diagonalization, constrained-path Monte Carlo method and mean field method, are employed to investigate the magnetic properties of the model in one dimension and two dimensions. By changing the band-filling, chemical potential of the impurity band and the hybridyzation between conduction band and impurity band, we found that in some parameter regions, different magnetic ordering exist. Some of results confirm the previous works and some are new.

**N23 7 Bond-diluted Heisenberg spin systems on coupled ladders** DAOXIN YAO, ANDERS W. SANDVIK, A.H. CASTRO NETO, DAVID K. CAMPBELL, *Department of Physics, Boston University, MA 02215* We study spin-1/2 Heisenberg spin systems with bond dilution on coupled ladders or striped phases. The diluted bond configurations can be static or dynamic. The dynamic case with motion of the bonds is described by pseudo-spins and modeled by anisotropic Heisenberg spin chains in an external field. The systems are studied using the stochastic series expansion quantum Monte Carlo method. We find the quantum critical point for real spins from the ordered phase to the disordered phase is sensitive to the bond configuration. A study of the ground state energy shows strong differences for different bond configurations, which may be related to phase separation. Under certain conditions, real spin systems with bond-dilution can be described by a coupling-weakened fully coupled spin systems. For the pseudo-spins, an effective field induced by the real spins is observed.

**N23 8 Thin Ising films with both competing surface fields and a magnetic field gradient: A Monte Carlo study*** LIJUN PANG, D.P. LANDAU, *Center for Simulational Physics, University of Georgia, Athens, GA30602* K. BINDER, *Institute of Physics, University of Mainz, Germany* Extensive Monte Carlo simulations are used to study the interesting effects resulting from a linearly varying magnetic field on a thin Ising film (equivalent to applying gravity to the corresponding lattice-gas model). Besides

competing surface fields acting on two LxL free surfaces a distance D apart from each other, we also apply a magnetic field g that varies linearly between the surfaces and which competes with the surface fields. To determine the phase diagram, we look for bulk two-phase conexistence at different values of g and temperature T. In situations with only competing surface fields applied, the interface unbinding transition[1] happens at temperature $T_c(D)$. The addition of the g field produces a phase diagram in which, as g increases, the temperature bounding bulk two-phase coexistence first goes up from $T_c(D)$, and then decreases. For small g, we find a second order transition, whereas for large g, the transition appears to be first order. We will compare our simulation results with theoretical predictions[2].

**N23 9 Electronic structure and excitation spectra of transition metal monoxides investigated via orbital-dependent functionals*** J. ASHLEY ALFORD, OSCAR D. RESTREPO, ADOLFO G. EGUILUZ, *Oak Ridge National Laboratory/Univ. of Tennessee* THOMAS C. SCHULTHESS, *Oak Ridge National Laboratory* We are investigating the electronic structure of strongly correlated 3d transition metal monoxides with two orbital dependent functionals, the self-interaction corrected local spin-density method (SIC-LSD) as well as the LDA+U method. Both functionals are known to reproduce the antiferromagnetic insulating ground state of, for example, CoO and NiO. We perform a detailed comparison of magnetic moments, exchange, and electronic structure calculated with the two methods. In addition, we study the interplay between the electronic structure and the electron-hole excitations in both the insulating and the metallic phases. Our results are compared with available experimental data.

**N23 10 Ab initio calculations on the frustrated magnet $ZnCr_2O_4$** KEVIN T. CHAN, JAY D. SAU, MARVIN L. COHEN, *UC Berkeley and Lawrence Berkeley National Laboratory* PEIHONG ZHANG, *University at Buffalo* The complex oxide $ZnCr_2O_4$ is a good realization of the Heisenberg antiferromagnet on a pyrochlore lattice and is a strongly frustrated magnetic system. Recent experiments have shown that $ZnCr_2O_4$ undergoes a lattice distortion and a transition from paramagnetic to antiferromagnetic order at $T_c = 12.5K$. Infrared spectroscopy has shown a large splitting of a phonon mode involving magnetic ions. We perform ab initio total energy calculations of the exchange coupling constant and phonon modes using the plane-wave pseudopotential formalism with the LSDA+U method, and we compare the results to experiment. This work was supported by National Science Foundation Grant No. DMR04-39768 and by the Director, Office of Science, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering, U.S. Department of Energy under Contract No. DE-AC03-76SF00098. **N23 11 Anisotropic magnetic phases** JULIO F. FERNANDEZ, *ICMA, CSIC, Zaragoza, Spain* JUAN J. ALONSO, *Universidad de Malaga, Spain* We study how magnetic phases vary with uniaxial and fourfold anisotropy constants, C and D. We do this for classical magnetic dipoles on cubic lattices with dipolar and nearest neighbor exchange interactions. By mean field and by Monte Carlo calculations, results are obtained for bulk and n-layer film systems under no applied external field. We pay special attention to the spin reorientation (SR) transition. We find (1) a reentrant SR transition for a narrow range of C/D values, and (2) that the ratio of the ordering temperature to the SR temperature varies with C/D but depends rather weakly on the exchange constant.

**10:36**
**N23 12 Alternative methods to characterize phase transitions in Ising systems*** EUGENIO E. VOGEL, BERNARDO FIERRO, FERNANDO BACHMANN, *Universidad de La Frontera, Temuco, Chile* The Binder cumulant (BC) is defined in terms of average values of second and fourth momenta of an order parameter q. Simulations for Ising systems show that the curves for BCs they all cross at the same temperature regardless of the size of the system. We present here two alternative and different methods to obtain the critical temperature after finding the time evolution of any order parameter q(t), after equilibration. First, we consider the time autocorrelation functions for the absolute value of a site order parameter, $|q|$, for different system sizes, showing that they also cross at the same temperature where BCs cross. Second, we show that the ''weight'' in bites of the compressed file containing vector q(t) maximizes at a temperature close to the critical temperature; a scaling analysis takes us back to the temperature of previous crossing. The main advantage of the new methods is its easy physical interpretation.

**N24 1 Unique refractive index and thickness values for polymer films via ellipsometry** ALAN R. ESKER, UFUK KARABIYIK, MIN MAO, *Virginia Tech, Department of Chemistry (0212), Blacksburg, VA 24061* SUSHIL K. SATIJA, *Center for Neutron Research, National Institute of Standards and Technology, Gaithersburg, MD 20899* In this study, elliposometry using multiple ambient media at Brewster's angle is used to determine unique values of refractive index and film thickness for polymer thin films. Measurements were made for polymer thin films on HF etched silicon wafers against air and water. Results obtained for poly(t-butyl acrylate), polystyrene, and trimethylsilyl cellulose

confirm that the refractive indices agree well with the literature values and that the film thicknesses agree with values obtained from X-ray reflectivity. This technique provides a rapid unambiguous method for determining a film's thickness and refractive index for polymers.

**N24 2 Watching How Molecules Orient in a Surface Forces Apparatus, Using Confocal Raman Spectroscopy** SHAN JIANG, *UIUC, Materials Science and Engineering Department* MINSU KIM, *UIUC, Physics Department* SUNG CHUL BAE, STEVE GRANICK, *UIUC, Materials Science and Engineering Department* Much is known about surface forces, less about where they come from. This laboratory is engaged in direct vibrational spectroscopic measurements of how molecules orient in confined geometries. Regarding force measurements, PDMS (polydimethylsiloxane) was a model system for many years. In this study, we describe direct experiments using a novel version of confocal Raman spectroscopy. This experiment allows direct measurement of how the PDMS molecules orient under confinment as well as under subsequent shear. When the thickness of the fluid film is less than the unperturbed radius of gyration of the polymer, we obtain two novel findings: (a) linewidth analysis of peaks reveals that vibrational relaxation times are perturbed in this confined geometry; (b) orientation of the chain backbone is not everywhere the same within the molecularly-thin film; domains of various orientation are observed instead.

**N24 3 Polymer dynamics at local scales: origin of ripples formation** ROBERT SZOSZKIEWICZ, *School of Physics, Georgia Institute of Technology, Atlanta, GA 30332* TAKASHI OKADA, *School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA 30332* ENRICO GNECCO, *Institute of Physics, University of Basel, Switzerland* WILLIAM KING, *School of Mechanical Engineering, Georgia Institute of Technology, Atlanta, GA 30332* SETH MARDER, *School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA 30332* ELISA RIEDO, *School of Physics, Georgia Institute of Technology, Atlanta, GA 30332* A plethora of nanowear patterns in polymers has been obtained by heating the polymers and scanning their surfaces with an atomic force microscope (AFM) tip (1, 2). These morphologies represent the nanoscale realization of aeolian ripples in sandy deserts and are similar to patterns obtained during evolution of surfaces during ion sputtering (3). By means of locally heated AFM probes we studied ripples on various polymer films. While the theory of aeolian ripples formation is very complicated (3), we show that the key morphological features in our results can be explained in terms of the elastic and diffusive properties of the polymer. From measurements of the ripple spacing we study the local dynamics of polymers in the vicinity to the glass transition. (1) B. Gotsmann and U. Durig, Langmuir 20, 1495 (2004) (2) R. H. Schmidt, G. **N24 4 Probing surface relaxation of polystyrene films using gold nano-particles** ZAHRA FAKHRAAI, *Physics Department, University of Waterloo, Waterloo, ON, N2L 3G1 Canada* JAMES A FORREST, *Physics Department, University of Waterloo, Waterloo, ON, N2L 3G1 Canada* Polymer thin films are usually used to probe the confinement effects on the dynamics of glass former materials. Many studies show that the glass transition temperature of thin polymer films is decreased below bulk Tg for very thin films. There is evidence that this Tg reduction is due to the existence of a more mobile region near the surface of the film. However, it is very hard to directly measure the existence of this layer, let alone more quantitative aspects such as thickness or viscoelastic properties. In this work we probe the near surface behaviour of thin polystyrene films using a nanorheological technique. To do this, we uniformly distribute gold nanoparticles on the surface. A particle's motion on the surface is then driven by surface capillary waves. The motion of nanoparticles is detected by dynamic light scattering. Since the particles only interact with the surface region (determined independently using AFM), these experiments tell us about the viscoelastic properties of the near surface region.

**N24 5 Grazing-incidence x-ray scattering studies on surface melting in ultrathin polymer films*** TADANORI KOGA, Y. WANG, M. RAFAILOVICH, J. SOKOLOV, *Stony Brook University* A. TIKHONOV, D. SCHULTZ, M. LEE, *University of Chicago* M. TOLAN, *Dortmund University* The aim of this study is to investigate surface crystal structures formed in ultrathin (thickness below 100 nm) polymer films by using surface-sensitive x-ray scattering techniques. This study was motivated by our current experimental finding that showed a drastic suppression (the decrease of $\sim$ 50[r]C) in the surface melting temperature ($T_m$) of ultrathin polymer films, which was determined as the onset of surface softening by using the shear modulation force microscopy (SMFM) method[1]. In order to clarify the relationship between the melting behavior and surface crystal structures, we integrated a variety of grazing-angle x-ray scattering techniques including reflectivity, diffuse scattering, grazing-incidence diffraction, and grazing-incidence small-angle scattering. As a result, we found that diffuse scattering, which is sensitive to surface roughness, drastically changed at $T_m$ determined from SMFM, while the surface crystallinity decreased with increasing temperature, but remained up to the bulk melting temperature. A model to explain the mechanism of the surface melting will be discussed. [1] Wang, Y. et al. Macromolecules, **37**, 3319 (2004).

**N24 6 The Tg-Nanoconfinement Effect and the Relaxation of Residual Stresses in Spin-Coated Films of Polystyrene and Styrene-Containing Copolymers: Characterization by Intrinsic Fluorescence.** MANISH K. MUNDRA, CHRISTOPHER J. ELLISON, ROSS BEHLING, JOHN M. TORKELSON, *Northwestern University, Evanston, IL 60208* The glass transition temperatures (Tgs) of films of polystyrene (PS) and styrene (S)-methyl methacrylate (MMA) copolymers have been determined using intrinsic fluorescence from styrene units. The Tgs are measured by a break in the temperature dependence of fluorescence intensity measured upon cooling from the equilibrium liquid state. As the film thickness decreases below 50 nm, there is a substantial deviation in Tg from bulk Tg, with PS and high S-content copolymers exhibiting a reduction in Tg and high MMA-content copolymers exhibiting an increase in Tg. This is explained by a competition of free surface effects and the effects of attractive polymer-substrate interactions. As the intrinsic fluorescence is a combination of monomer and excimer fluorescence, it reflects the local conformational population. This is used to determine the conditions at which residual stresses induced by spin coating are relaxed away, leading to a steady-state conformational population

and fluorescence signal independent of annealing time. Films must be heated to temperatures well above Tg (Tg + 30 K) for several minutes to achieve constant fluorescence independent of further annealing. Annealing for short times close to Tg is insufficient to achieve an equilibrium conformational population.

**N24 7 Dynamics of very thin polymer films on supported surface** CHUNHUA LI, *State University of New York at Stony Brook* HYUNJUNG KIM, *Sogang University, Korea* JUN JIANG, CLIVE LI, TADANORI KOGA, *State University of New York at Stony Brook* LAURENCE LURIO, *Northern Illinois University* SUNIL SINHA, *University of California San Diego* JONATHAN SOKOLOV, MIRIAM RAFAILOVICH, *State University of New York at Stony Brook* STATE UNIVERSITY OF NEW YORK AT STONY BROOK TEAM, SOGANG UNIVERSITY, KOREA COLLABORATION, NORTHERN ILLINOIS UNIVERSITY COLLABORATION, UNIVERSITY OF CALIFORNIA SAN DIEGO COLLABORATION, In this work, we study the effect of solid substrate surface on the viscosity of polymer thin films. We found that the viscosity of polymer thin film increased about two orders of magnitude near the solid substrate. Measurements performed on split layer substrates indicated that this layer was responsible for trapping the subsequent layers, and propagating the effect of the surface interactions to the chains without direct contacts to the surface. If this layer was applied prior to the rest of the film, it in fact screened the surface interactions and even caused auto-dewetting of the other layers in the film. These results will be discussed in terms of the ''two fluid'' hypothesis. This surface interaction was also found to induce the ''melt fracture'' of the polymer thin film during the dewetting process where we see the cracks in the less viscous bottom layer.

**9:24**

**N24 8 The Distribution of Tgs in Thin and Ultrathin Methacrylate-Based Polymer Films: Percolation of Free Surface and Interface Effects over Tens and Hundreds of Nanometers.** RODNEY D. PRIESTLEY, MANISH K. MUNDRA, PERLA RITTIGSTEIN, LINDA J. BROADBELT, JOHN M. TORKELSON, *Northwestern University, Evanston, IL 60208* A multilayer/fluorescence method is used to measure the distribution of Tgs in poly(methyl methacrylate) (PMMA) films. The average Tg increases with decreasing total film thickness (h) below 90 nm. In bulk, bilayer films, the free surface layer exhibits a reduced Tg at a thickness of 30 nm or less. The Tg reduction at the free surface is a fraction of that in polystyrene (PS) films; a 14-nm-thick free surface layer exhibits a Tg reduction of $\sim$ 6 K in PMMA and $\sim$ 32 K in PS. The Tg increase observed in the substrate layer of a PMMA bilayer, bulk film exceeds the Tg reduction observed at the free surface and occurs over longer length scales. An amazing effect of confinement of the total multilayer film on the free surface layer Tg of PMMA has been observed. When h $<$ 250 nm, a 12-nm-thick free surface layer exhibits an increase in Tg with decreasing h, and the free surface layer Tg exceeds that of bulk Tg when h $<$ 90 nm. This is the first demonstration that a free surface layer can exhibit Tg $>$ bulk Tg and means that the perturbation of Tg dynamics at the substrate can percolate over hundreds of nanometers in PMMA films. These results will be contrasted with those of poly(isobutyl methacrylate) films which exhibit no average Tg-confinement effect.

**9:36**

**N24 9 Dynamics of Polymer Thin Film Mixtures** BRIAN M. BESANCON, *Department of Chemical Engineering, University of Texas at Austin* PETER F. GREEN, *Department of Materials Science and Engineering, University of Michigan* CHRISTOPHER L. SOLES, *NIST Polymers Division* We examined the influence of film thickness and composition on the glass transition temperature ($T_g$) and mean square atomic displacements (MSD) of thin film mixtures of deuterated polystyrene (dPS) and tetramethyl bisphenol-A polycarbonate (TMPC) on Si/$SiO_x$ substrates using incoherent elastic neutron scattering (ICNS). The onset of dissipative motions, such as those associated with the glass transition and sub-Tg relaxations, are manifested as ''kinks'' in the curve of elastic intensity (or MSD) versus temperature. From the relevant kinks, the $T_g$ was determined as a function of composition and of film thickness. The dependence of the $T_g$ on film thickness exhibited qualitatively similar trends, at a given composition, as determined by the ICNS and ellipsometry measurements. However, with increasing PS content, the values of $T_g$ measured by INS were consistently larger then those measured by ellipsometry. These results are examined in light of existing models on the thin film glass transition and component blend dynamics.

**9:48**

**N24 10 Dynamics of Block copolymer films*** HYUNJUNG KIM, *Dept. of Physics and Interdiscplinary Program of Integrated Biotechnology, Sogang University, Korea* HEEJU LEE, YOUNG JOO LEE, *Dept. of Physics, Sogang University, Korea* ZHANG JIANG, SUNIL SINHA, *Dept. of Physics, UC San Diego and LANSCE* XUESONG JIAO, *Northern Illinois University* ADRIAN RUEHM, *Max Planck Institute for Metal Research, Germany* S. G. J. MOCHRIE, *Yale Univ.* We have investigated the dynamics of thin block copolymer films of ploy(styrene)-b-poly(dimethylsiloxane) using X-ray Photon Correlation Spectroscopy (XPCS). The films were supported on Si substrates and measured at melt. The results are compared with the theory of overdamped thermal capillary waves on thin films. The lateral length scales examined were between 600 and 6000 nm. We selectively measured the dynamics from the surface and from the micelles by changing incident angles and found the different behaviors between them.

**N24 11 Conformational Anisotropy and the Glass Transition in Polymer Thin Films** FOLUSHO OYEROKUN, *UCSB* ANNA CAVALLO, *Uni-Mainz* MARCUS MUELLER, *Uni-Gottingen* KENNETH SCHWEIZER, *UIUC* A segmental level theory of the ideal kinetic glass transition, or dynamic crossover, temperature ($T_c$) in confined polymer films has been developed. The theory is based on an anisotropic generalization of a coarse grained polymer mode coupling theory which utilizes conformational and thermodynamic information from anisotropic PRISM theory and computer simulations. Confinement is found to enhance the bulk compressibility and induce anisotropic segmental dynamics. For noncapped films (free standing or supported films on neutral substrates) the theory predicts suppression of $T_c$, with confinement. The underlying mechanism is reduction of the degree of coil interpenetration and intermolecular repulsive contacts due to segmental scale alignment and deformation. The predicted suppres-

sion of $T_c$ is nonuniversal and follows an inverse power law dependence on film thickness in reasonable agreement with experiments. For capped films simulations find a weak variation of the dimensionless compressibility with confinement suggesting little or no shift of $T_g$.

**10:12**
**N24 12 Radial Thickness Profiles of Spincoated Thickness Gradient Films** MONIKA MICHALEK, BERNIE NICKEL, JOHN DUTCHER, *University of Guelph* By dropping a polymer solution onto a spinning substrate at a position displaced from the axis of rotation, one can produce a film in which the thickness increases with increasing radial distance (thickness gradient film). Since each film contains a continuous range of thickness values, one can track subtle changes in the physical properties with film thickness by using a local probe of the film properties. We have used two such local probes, focused ellipsometry and atomic force microscopy, to measure the radial thickness profiles. We have also developed a simple, fluid flow model that describes the dependence of the polymer film thickness on radial distance from the axis of rotation. A detailed comparison between the measured and calculated radial thickness profiles will be discussed.

**10:24**
**N24 13 Internal Phase Separation Induces Dewetting in Multicomponent Polymer Films** HYUN-JOONG CHUNG, RUSSELL J. COMPOSTO, *MSE and LRSM, U. of Pennsylvania* KOHJI OHNO, TAKESHI FUKUDA, *ICR, Kyoto U.* Thin liquid films that dewet from their substrate are ubiquitous as demonstrated by the beading of paint on oily surface. Although most coatings contain more than one component, the dewetting mechanisms in multicomponent films are not understood. Using dPMMA:SAN (50:50) films (550 nm) with or without nanoparticles (NP), we demonstrate, for the first time, that the Laplace pressure induced by internal phase-separated structure is the driving force for roughening and rupture in polymer blend films. Three NP were investigated, namely $NP_A$, $NP_B$, and $NP_C$ which either partition into dPMMA or weakly and strongly segregate to the dPMMA/SAN interface, respectively. $NP_B$ are more effective than $NP_A$ at stabilizing the film, whereas $NP_C$ are able to prevent film rupture. Upon annealing, roughened films display a periodic, lacey structure, resembling patterns from spinodal dewetting. The fluctuation periodicity scales with roughness evolution as $it\lambda_s \propto R_q^{1/4}$ for neat blends and blends with $NP_A$, whereas the scaling breaks down for blends containing $NP_B$ and $NP_C$. These studies show that phase separation is responsible for film roughening.

**10:36**
**N24 14 Dewetting Morphology and Dynamics of Ordered Symmetric Block Copolymer Films: Stability of Nanoscopic Liquid Bilayers** MATTHEW J. FARRAR, ANDREW B. CROLL, KARI DALNOKI-VERESS, *Physics and Astronomy, McMaster University* Symmetric diblock copolymers, which form lamella upon micro-phase separation, can have unique dewetting properties. In this experimental study we explore the effects of the microphase separation on the dewetting of three different systems. We begin with the dewetting of disordered thin poly(styrene)-b-poly(methyl methacrylate) films on poly(dymethyl siloxane) coated Silicon. In this case, the film is not allowed to relax to its lamellar state before dewetting begins. The complex interplay between dewetting and microphase separation leads to hole growth that appears dendritic and deviates dramatically from the conventional circular hole growth. In a second experiment, the thin films are arrange into their lamellar equilibrium before being transferred onto an unfavourable substrate, which initiates dewetting. On an unfavourable substrate, these films show remarkable stability. Holes that do form are cylindrical but grow at a much-reduced rate when compared to a homopolymer system. Finally, hole growth in free-standing ordered lamellar films is explored. Here we again see significant stability and extremely slow dynamics – an ordered free-standing film is stable, or nearly stable, even though the liquid film is well above the glass transition temperature and only of order 1 lamella ( $\sim$ 30nm) thick!

**10:48**
**N24 15 Interfacial segregation and micellization of hydrogen bonding copolymers** MICHELLE LEFEBVRE, MURAT GUVENDIREN, MONICA OLVERA DE LA CRUZ, KENNETH SHULL, *Department of Materials Science and Engineering, Northwestern University* An AB diblock copolymer in which A and B have unfavorable interactions will segregate to an interface between A and B homopolymers. The driving force for segregation is increased if the B homopolymer is replaced by a C homopolymer and B and C have favorable interactions. When copolymer accumulates at the interface, the preferred interfacial curvature changes as a function of the copolymer composition. This change in curvature leads to a variety of possible morphologies, including micelles, swollen micelles, or inverted micelles. To examine this effect we use a model system where A is polystyrene (PS), B is poly(4-hydroxystyrene) (PHS), and C is poly(2-vinylpyridine) (PVP), and the PHS and PVP can undergo hydrogen bonding. We measure the interfacial segregation of PS- PHS copolymers at an interface between PS and PVP using dynamic secondary ion mass spectrometry.

**N25 1 Organic photovoltaics - towards high performance low bandgap polyfluorene/fullerene bulk heterojunction devices.**
OLLE INGANÄS, *Linköping University*

We use alternating copolymers of polyfluorene (APFOs) in polymer/fullerene blends as used in plastic solar cells. APFO-3/PCBM devices typically give power conversion efficiencies up to 3.4 % (AM1.5, 100 mW/cm$^2$). The APFO's are stable, have high mobility and may be fashioned for liquid crystalline phases, as well as for broad optical absorption.

By chemical design it is possible to move the optical absorption edge out to 1000 nm, and also to extract this absorption in photocurrent generation out to 1000 nm. As polymer bandgap is reduced, LUMO and HOMO orbitals shift. This requires the use of modified fullerene acceptors, with shifted orbitals, necessary to give the conditions for photoinduced charge transfer with the low bandgap polymers. The APFO polymers therefore give the necessary variability to catch a larger fraction of the solar spectrum. We have developed full optical and electrical model, predicting device performance for multilayer cells and for tandem cells, and using as input empirical determination of optical and electronic transport properties. We find the hole mobility to be a limiting parameter for device function.

**N25 2 High Performance Organic Light-Emitting Diodes Based on Intramolecular Charge Transfer Emission from Donor-Acceptor Molecules** ABHISHEK KULKARNI, XIANGXING KONG, SAMSON JENEKHE, *Departments of Chemical Engineering and of Chemistry, University of Washington, Seattle WA, 98195* A clear understanding of the key factors governing the electroluminescence (EL) efficiency of emissive donor-acceptor (D-A) molecules in OLEDs is currently lacking, but is essential to a rational molecular design of future emissive materials. In this study, OLEDs based on intramolecular charge transfer emission from 3,7-[bis(4-phenyl-2-quinolyl)]-10-methylphenothiazine (BPQ-MPT) and 3,6-[bis(4-phenyl-2-quinolyl)]-9-methylcarbazole (BPQ-MCZ) had device performances that differ by orders of magnitude. High performance (44360 cd/m$^2$, 21.9 cd/A, 5.78% external quantum efficiency (EQE) at 1140 cd/m$^2$) green OLEDs were achieved from BPQ-MPT which has a HOMO level at 5.09 eV and a non-planar geometry. In contrast, diodes with far lower performance (2290 cd/m$^2$, 1.4 cd/A, 1.7% EQE) were obtained from BPQ-MCZ which has a HOMO level of 5.75 eV and a planar geometry. These results highlight the pronounced influence of the electron donor strength and molecular geometry on the EL efficiency of D-A molecules.

**N25 3 Reversible Persistence and Effects of Oxygen on the Photoconductivity of Porphyrin Nanorods** E. A. MULLER, V. H. JOINES, W. F. SMITH, *Haverford College* A. D. SCHWAB, *Appalachian State U.* J. C. DE PAULA, *Lewis and Clark College* D. E. JOHNSTON, A. T. JOHNSON, *U. of Pennsylvania* Tetrakis(4-sulfonatophenyl) porphine ($TPPS_4$) self assembles[1] into well-defined nanorods with intriguing photoelectronic properties.[2] New experiments show that illumination under Ar for several hours induces a change to persistent behavior, i.e. conductivity decays slowly when light is removed, rather than dropping to zero. After resting 24 hours, the sample recovers non-persistent behavior. The dark conductivity of $TPPS_4$ aggregates formed by a different technique is sensitive to $O_2$ .[3] We find that the conductivity under illumination of nanorod aggregates decreases when 0.2% $O_2$ is added, but this change is reversible. By contrast, if the sample is exposed to 21% $O_2$ shortly after light is removed, the photoconductivity is permanently lowered. These effects may be due to a combination of $O_2$-mediated quenching of excited state porphyrin and oxidation.

**N25 4 Photoinduced Charge Transport Spectra for Porphyrin and Naphthalene Derivative-based Dendrimers** J.H. PARK, Y. WU, J.R. PARQUETTE, A.J. EPSTEIN, *The Ohio State University, Columbus OH 43210* Dendrimers are important chemical structures for harvesting charge. We prepared model dendrimers using two porphyrin derivatives and a naphthalene derivative. Films of these porphyrin derivatives have a strong Soret band ( $\sim$ 430nm) and four significant Q-bands; the naphthalene derivative has strong absorption at 365 and 383nm. Two kinds of photovoltaic cell structures [ITO/BaytronP/(thick or thin) dendrimer/Al] are constructed to investigate the optical response spectra of dendrimers under electric potential($V$) on the cell (range from -1V to 2V). To obtain pure optical responses, incident light is modulated with an optical chopper and a lock-in amplifier is used to measure current ($I_{AC}$) and phase ($\theta$). For the excitation of the Soret band, $I_{AC}$ and $\theta$ do not change substantially with change of sign and amplitude of $V$. For Q-bands and naphthalene absorption bands, $\theta$ nearly follows the polarity of V on the cells and $I_{AC}$ is linear with $V$. Hence, $I_{AC}$ is nearly ohmic for Q- band although there are shifts due to built-in-potential. $I_{AC}$ for Soret band is almost same for thick and thin active layer cells. In contrast, $I_{AC}$ increases with thickness increase for Q bands. Mechanisms of photogeneration and charge transport will be discussed.

**N25 5 Carbon nanotube sheets as transparent charge injectors in organic light-emitting diodes** CHRISTOPHER WILLIAMS, MEI ZHANG, RAQUEL OVALLE, KRUTARTH TRIVEDI, ALEXANDER KUZNETSOV, SERGEY LEE, RAY BAUGHMAN, ANVAR ZAKHIDOV, *The University of Texas at Dallas* Carbon nanotubes (CNTs) have been recognized for their potential in many applications ranging from high strength materials and fibers to true nanoscale electronics. Recently a method for making strong and transparent CNT sheets has been developed, producing free-standing multiwall nanotube sheets which are easy to process [1]. Their mechanical and electrical properties allow them to meet the needs of a wide range of applications, particularly in optoelectronics. We show here the potential for using these thin, flexible CNT sheets in the development of flexible organic light-emitting diode (OLED) displays. The high transparency of the sheets, the high degree of orientation of tubes and the high work function of the material make them suitable hole injectors for typical hole transport materials used in OLEDs and polymeric LEDs (PLEDs). We show that CNT sheets can be used as anodes for both PLEDs and molecular OLEDs. We also introduce a method for producing inverted OLEDs on existing drive electronics for active matrix displays and a design for a transparent display using CNT sheets as both the electron and hole injector. **N25 6 Dissociation Processes of Singlet and Triplet Excitons in Organic Photovoltaic Cells** ZHIHUA XU, YUE WU, BIN HU, *University of Tennessee* The dissociation processes of singlet and triplet excitons were studied based on single-layer photovoltaic cells using: fluorescent Aluminum (III) 8-hydroxyquinoline ($Alq_3$) and phosphorescent itfactris (2-phenylpyridine) iridium ($Ir(ppy)_3$) molecules. We found that triplet exciton dissociation leads to a more efficient photovoltaic response as compared to singlet excitons. The short-circuit photocurrent action spectra suggest that the triplet excitons dissociate mainly at the metallic electrode interface while the singlet excitons exhibit bulk dissociation. This interface dissociation of triplet excitons forms a mechanism for phosphorescent organic materials to show efficient photovoltaic responses. Therefore, control of singlet-to-triplet exciton ratio presents a new pathway to enhance photovoltaic response from organic materials.

**N25 7 Multilayer polymer devices: light emitting diode and vertical hot carrier transistor** HSIN-FEI MENG, *National Chiao Tung University* SHENG-FU HORNG, CHAIN-SHU HSU, SHIN-RON TZENG, YU-CHIANG CHAO, SYUAN-LIN YANG, Two new devices based on polymer multilayers are presented:charged-balanced LED and hot carrier transistor. 1. An intermediate liquid buffer layer is introduced to overcome the dissolution problem of solution-processed multilayer polymer light-emitting diodes. This method can be applied to arbitrary combinations of polymers with no restriction on solvents. As an example, a hole-blocking layer is successfully spin-coated on the emissive polymer layer. Three typical p-type polymers, The electron-hole balance is improved by the addition of hole-blockinglayer. The electroluminescence efficiency can be increased up to 5 times, while the luminance up to 7 times. Electron-blocking layer is applied to blue polyfluorene copolymer and the brightness is as high as 30,000 $cd/m^2$ while the yield is 4 cd/A. 2. Metal-base hot-carrier transistor with conjugated polymer emitter and collector is demonstrated. The device is fabricated by multiple spin-coating with the metal base sandwiched between two polymers. A thin insulating layer of LiF is inserted between emitter and base to enhance the hot carrier kinetic energy and reduce the mutual dissolution. Using poly(9-vinylcarbazole) as the emitter, Al as base, and poly(3-hexylthiophene) as the collector, common-emitter current gain of 26 is obtained with operation voltage as low as 5V.

**9:48**

**N25 8 Single-crystal films of a combination of materials (co-crystal) involving DAST and IR-125 for electro-optic applications** A. NARAYANAN, J. TITUS, H. RAJAGOPALAN, P. VIPPA, M. THAKUR, *Photonic Materials Research Laboratory, Auburn University, AL* Single-crystal film of DAST (4'-dimethylamino-N-methyl-4-stilbazolium tosylate) has been shown [1] to have exceptionally large electro-optic coefficients ($r_{11} \sim$ 770 pm/V at 633 nm). In this report, single crystal film of a combination of materials (co-crystal) involving DAST and a dye molecule IR-125 will be discussed. Modified shear method was used to prepare the co-crystal films. The film has been characterized using polarized optical microscopy, optical absorption spectroscopy and x-ray diffraction. The optical absorption spectrum has two major bands: one at about 350–600 nm corresponding to DAST and the other at about 600-900 nm corresponding to IR-125. The x-ray diffraction results show peaks involving the presence of DAST and IR-125 within the co-crystal film. Since the co-crystal has strong absorption at longer wavelengths it is expected to show higher electro-optic coefficients at longer wavelengths. Preliminary measurements at 1.55 $\mu$m indicate a high electro-optic coefficient of the co-crystal film. [1] Swamy, Kutty, Titus, Khatavkar, Thakur, Appl. Phys. Lett. **85**, 4025 (2004); Kutty, Thakur, Appl. Phys. Lett. **87**, 191111 (2005).

**N25 9 Highly efficient third-order optical nonlinearities and their frequency dependence in donor-substituted cyanoethynylethene molecules.** JOSHUA C. MAY, IVAN BIAGGIO, *Department of Physics and Center for Optical Technologies, Lehigh University* TSUYOSHI MICHINOBU, FRANÇOIS DIEDERICH, *Laboratorium für Organische Chemie, ETH-Hönggerberg* We report on a new class of organic molecules with record efficiency for application in third-order nonlinear optics (NLO). The third-order polarizability, $\gamma$, of several donor-substituted cyanoethynylethene molecules was determined at the off-resonant wavelength of 1.5 microns using four-wave mixing. The nonlinearities were found to be extraordinarily large relative to the small molecular masses and were found to be within 50 times Kuzyk's fundamental limit,[1] with $53 \times 10^{-48}$ $m^5V^{-2}$ as the highest $\gamma$ value. Select molecules were further investigated at wavelengths on and surrounding their two-photon (TP) absorption peaks, revealing large TP cross sections and the resonant influence on the real and imaginary parts of $\gamma$. Several members of this molecular family can be vapor-deposited and are likely candidates for third-order NLO devices. When considering their small mass, the *specific* $\gamma$ ($\gamma$ per molecular mass) for this family (off resonance, at 1.5$\mu$m) is up to $6.5 \times 10^{-23}$ $m^5V^{-2}Kg^{-1}$, approximately one order of magnitude larger than previously known large $\gamma$ molecules.[2]

**N25 10 A Time-Dependent Density Functional Theory Study of One-and Two-Photon Absorption: Donor-Acceptor Chromophores.** RUTH PACHTER, PAUL N. DAY, KIET A. NGUYEN, *Air Force Research Laboratory, Materials & Manufacturing Directorate, Wright-Patterson Air Force Base, Ohio 45433-7702* We report time-dependent density functional theory (TDDFT) calculations of one-photon, and two-photon absorption spectra, for a series of compounds, in which electron donating and accepting groups are attached to a core having a delocalized pi-electron structure, such as stilbene or fluorene. We find that the calculated excitation energies are in better agreement with experimental data upon the application of (x-c) functionals that take into account long-range interactions, and also by the inclusion of solvent effects. Furthermore, two-photon absorption cross-section predictions are improved with the application of quadratic response TDDFT, in comparison to experiment.

**10:24**

**N25 11 Two Photon Absorption in a Novel Nano-optical Material Based on the Nonconjugated Conductive Polymer, Poly(beta-pinene)** JITTO TITUS, MRINAL THAKUR, *Photonic Materials Research Laboratory, Auburn University, AL* As recently reported, the electrical conductivity of the nonconjugated polymer, poly(beta-pinene) increases by more than ten orders of magnitude upon doping with iodine [1]. The FTIR, optical absorption and EPR measurements have shown that radical cations are formed upon doping and charge-transfer involving the isolated

double-bond in poly(beta-pinene). In this report, exceptionally large two-photon absorption in iodine-doped poly(beta-pinene) will be discussed. The linear absorption spectrum of medium-doped poly(beta-pinene) have peaks at about 4 eV and 3.1 eV. The first peak is due to the radical cation and the second due to the charge-transfer between the double bond and the dopant. The two-photon absorption of the medium-doped polymer has been measured at 730-860 nm using open-aperture z-scan with 150 femtosecond pulses from a Ti:Sapphire laser. A two-photon peak at about 1.5 eV with a magnitude of more than 1 cm/MW has been observed. The large magnitude of the two-photon absorption coefficient which is proportional to the imaginary part of the third order susceptibility has been attributed to the special structure of the radical cation and the confinement within a sub-nanometer dimension. [1] Vippa, Rajagopalan and Thakur, J. Poly. Sci. Part B: Poly. Phys., 43, 3695 (2005).

**N25 12 Temperature dependent electrical and optical characterization of polyfluorene based organic light-emitting-diodes*** MOHAMMAD ARIF, S. GUHA, *Department of Physics, Univ. of Missouri-Columbia* M.S. YUN, S. GANGOPADHYAY, *Department of Electrical Engineering,Univ. of Missouri-Columbia* Polyfluorene (PF) conjugated polymers have received widespread attention due to their strong blue emission, high charge mobility and excellent chemical and thermal stability which creates great prospect for optoelectronic device applications. Efficient and well balanced injection of charge carriers and transport capabilities are of paramount importance for high luminescence efficiency of organic light emitting diodes (OLEDs). The maximum current flowing through metal/semiconductor is limited by available space and trapped charges, barrier heights, applied electric field and mobility of the carriers. In this work we present detailed current- voltage (I-V) measurements as a function of temperature from 2- ethylhexyl substituted PF (PF2/6) based OLEDs. PF2/6 is characterized by Tg of 80 $^{o}$C and a nematic liquid crystalline phase above 150 $^{o}$C. Barrier heights for current injection were calculated as a function of thermal cycling. The characteristic I-V measurements were fitted with ideal space charge limited conduction (SCLC) with traps to calculate carrier mobilities and trap concentration. Preliminary studies of Raman scattering from these working devices will be discussed.

**N25 13 Pi-Conjugated Dendrimers for Organic Photovoltaics** SEAN SHAHEEN, WILLIAM MITCHELL, NIKOS KOPIDAKIS, JOSEPH BOZELL, GARRY RUMBLES, *National Renewable Energy Lab* Polymer-based organic photovoltaic (OPV) devices are promising candidates for low-cost solar cell fabrication. The operation of such devices is known to be strongly dependent upon the morphology and carrier mobility of the polymer. Here we discuss the use of pi-conjugated dendrimers in OPV devices. Dendrimers have a precisely defined molecular weight, in contrast to pi-conjugated polymers, which leads to a well-defined morphology. This morphology can be highly ordered owing to strong pi-electron interactions between dendrimers. We have synthesized a family of phenyl-cored thiophene dendrimers with a variable number of arms and and variable number of thiophenes in each arm. The optical band gaps of these materials in thin film form range from 2.3 to 2.6 eV. Time-resolved microwave conductivity measurements of the dendrimers showed a power-law dependence of lifetimes extending into the millisecond regime, indicative of a very pure material. Preliminary OPV devices fabricated by blending the dendrimers with a soluble fullerene yielded maximum open-circuit-voltages of 900 mV and external quantum efficiencies of 22%. A reduced band gap dendrimer was also synthesized by adding strong electron withdrawing groups onto the phenyl core, resulting in an optical band gap of 1.82 eV. This material show good molecular ordering as evidenced by x-ray diffraction.

## SESSION N26: FOCUS SESSION: DNA AND PROTEIN ANALYSIS WITH MICRO AND NANO FLUIDICS

**N26 1 Formation of bi-nanopores in silicon chips*** SANG RYUL PARK, HONGBO PENG, X. S. LING, *Brown University* Solid-state nanopores are holes with diameter and length on the order of 20 nm or smaller embedded in an insulating solid membrane. These nanopores have been shown to allow linear translocation of DNA molecules in buffer conditions and can be used as an electronic device for detecting and characterizing nucleic acids and proteins. Here we report a novel method of fabricating bi-nanopores in silicon chips using feedback electrochemical etching. The simplicity and low-cost of our approach, taking advantage of the well-known anisotropic etching behavior of silicon in alkaline solutions, bring solid-state nanopores closer to industrial-scale applications.

*This work was supported by the NSF-NIRT program.

**8:12**
**N26 2 Fabrication of nanopores in wax using laser-induced shrinking*** SHANSHAN WU, SANG RYUL PARK, X. S. LING, *Brown University* We developed a simple laser heating induced shrinking technique for making plastic nanopore bio-sensing devices. Our technique is capable of shrinking thermoplastic pores of diameters up to several hundred micrometers to a few nanometers. We have made nanopore devices by applying this technique to Apiezon W wax (thermoplastics) micropores. Our DNA translocation experiments with 48 kilo base pairs (kbp) double-stranded λ DNA (λ dsDNA) have yielded convincing results of the functionality of these devices as biomolecular nanosensors.

*This work is supported by an NSF-NIRT (Nanoscale Interdisciplinary Research Team) grant.

**N26 3 Ion Valence and Solution Temperature Effects on DNA Translocations in Solid-State Nanopores** JAMES UPLINGER, *Physics Department, University of Arkansas* DANIEL FOLOGEA, *Physics Department, University of Arkansas* JIALI LI, *Physics Department, University of Arkansas* Solid-state nanopore device provides a sensitive and robust environment for single DNA analysis. When a nanopore is the only partition between two reservoirs filled with an ionic solution and electrical conduction is established any DNA molecule translocation through the nanopore will partially block the open pore current. The current blockage and dwell time depends on both the external parameters, such as applied voltage, ionic strength and on characteristics of the DNA molecule itself, such as the charge and geometry. The properties of the molecule can be modulated by interactions with the ionic solution, and these will produce modifications of the current blockage and translocation time. Here we report on how the DNA translocation signature is modified when: (1) salts of varied valences are used and concentration of the surrounding solution changes; (2) the temperature of ionic solution changes. The mobility and diffusion coefficient of DNA molecule at above conditions are estimated.

**N26 4 DNA in nanofluidic devices.**
ROBERT RIEHN, *Princeton University*

Nanochannels with a channel cross-section of around 100 nm x 100 nm or less are emerging as a powerful new technique for single-molecule DNA analysis. In these nanochannels, DNA is linearized to a constant fraction of its contour length, and thus spatial locations measured by fluorescence microscopy can be directly related to genomic locations. Because the stretching in nanochannels is caused by lateral confinement, molecules are free to undergo longitudinal fluctuations. Hence, time-averaging over a single molecule is meaningful, and a high resolution can be achieved even using few molecules. We will present how DNA imaging in nanochannels can be applied to common tasks in molecular biology that go beyond simple sizing. In particular, we will discuss the genomic identification of human DNA fragments using fluorescent markers, and how to perform enzymatic reactions, such as restriction mapping using endonucleases, in nanochannels. We will also present our recent progress in the development of ''nanoplumbing,'' that is devices that contain junctions of nanochannels. We will show how device dimensions influence the transport of DNA at those nanochannel junctions, and how those properties can be utilized in the design of devices and exotic materials.

**N26 5 Nanoscale electrical detection of DNA** CHIH-KUAN TUNG, *Department of Physics, Princeton University* ROBERT REIHN, *Department of Physics, Princeton University* LUKAS URBAN, *Department of Physics, Unversity of Illinois, Urbana-Champaign* ALI YAZDANI, *Department of Physics, Princeton University* ROBERT AUSTIN, *Department of Physics, Princeton University* We try to detect DNA electrically by different nano-devices, including single-walled carbon nanotubes and platinum nano- wires. We will demonstrate the responses of carbon nanotubes conductance to the exposure to DNA, and ac lock-in measurements across metal nano-wires based on the biochemical properties of the DNA bases. The effects of different bases are also studied, which may provide us a real opportunity to sequence DNA electrically.

**9:24**
**N26 6 DNA Translocation Dependence on Ionic Solution Concentration in a Solid-State Nanopore Device** BRIAN THOMAS, *Physics Department University of Arkansas Fayetteville Arkansas 72701* DANIEL FOLOGEA, *Physics Department University of Arkansas Fayetteville Arkansas 72701* JIALI LI, *Physics Department University of Arkansas Fayetteville, Arkansas 72701* Our work describes dsDNA translocations through a silicon nitride nanopore subjected to an applied electric field in solutions of different ionic strengths. We demonstrate how the ion concentration affects DNA shielding and, consequently, its effective negative charge. These modifications alter key parameters of the translocation process, such as the dwell time and current drop of the event. In this way, the DNA/salt interaction process can be explored by translocation experiments.

**9:36**
**N26 7 DNA size and conformations analysis using a synthetic nanopore** DANIEL FOLOGEA, *University of Arkansas, Physics Department, Fayetteville, AR72701* JAMES UPLINGER, *University of Arkansas, Physics Department, Fayetteville, AR72701* BRIAN THOMAS, *University of Arkansas, Physics Department, Fayetteville, AR72701* BRADLEY LEDDEN, *University of Arkansas, Physics Department, Fayetteville, AR72701* ERIC BRANDIN, *Harvard University, Department of Molecular and Cellular Biology, Cambridge, MA02138* DANIEL BRANTON, *Harvard University, Department of Molecular and Cellular Biology, Cambridge, MA02138* JIALI LI, *University of Arkansas, Physics Department, Fayetteville, AR72701* Our work reveals the ability of a synthetic nanopore made in a silicon nitride membrane to discriminate between different conformations and lengths of DNA molecules and presents a comparative analysis with the electrophoretic behavior of the same DNA. Double stranded linear, supercoiled and relaxed form of the same DNA, linear restriction fragments, as well as single stranded DNA, are passed through a synthetic nanopore filled with a buffered ionic solution, and a subsequent analysis in terms of current blockage, translocation time and integrated events area shows the analytical ability of such a device. Also, we prove that an intercalating agent increases the temporal resolution by increasing the translocation time up to a factor of two.

*Invited Papers*

**N26 8 Microfluidic Protein Crystallography.**
CARL HANSEN, *University of British Columbia*

Due to their impressive economies of scale and unique mass transport properties microfluidic devices have become viable technologies for nano-volume protein crystallization screening and growth. In particular, soft microfluidic devices based on multilayer soft lithography (MSL) have been successfully applied to systematic protein solubility studies and efficient nanoliter volume screening by free interface diffusion. While these systems have proven highly effective in identifying crystallization conditions for a large number challenging crystallization targets, realizing the full potential of microscale crystallization requires complementary technologies for crystal optimization and harvesting. In this talk I will briefly review previous studies of protein phase space mapping and crystallization screening, and will present recent work on a microfluidic device which provides a link between chip-based nanoliter volume crystallization screening and structure analysis through ''kinetic optimization'' of crystallization reactions and direct in situ structure determination. Using this device we demonstrate control over crystal quality, reliable scale-up from nanoliter volume reactions, facile harvesting and cryo-protectant screening, and protein structure determination at atomic resolution from data collected in-chip.

**N26 9 Statics and Dynamics of Single DNA Molecules Confined in Nanoslits** PO-KENG LIN, *Department of Physics, National Taiwan University, Taipei, Taiwan* CHI-CHENG FU, *Institute of Atomic and Molecular Science, Academia Sinica, Taipei, Taiwan* Y.R. CHEN, *Graduate Institute of Electronics Engineering and Department of Electrical Engineering, National Taiwan University, Taipei, Taiwan* WUNSHAIN FANN, *Institute of Atomic and Molecular Science, Academia Sinica,Taipei, Taiwan* C.H. KUAN, *Graduate Institute of Electronics Engineering and Department of Electrical Engineering, National Taiwan University, Taipei, Taiwan* de Gennes provided the scaling predictions for the linear polymer chain trapped in slit with dimension close to the Kuhn length decades ago; however, it has yet to be compared with experiments. We have fabricated nano-slits with vertical dimension similar to the Kuhn length of ds-DNA, $\sim$ 100nm, using standard photolithography. Single DNA molecules with length range from 2 to75 micrometers were successfully inject into the slits and the Brownian motions were imaged by fluorescence microscopy. The distributions of the radius of gyration and the two-dimensional asphericity were measured and it is found that the DNA exhibit highly anisotropic shape distribution. The scaling exponents for the chain extension and the center-of-mass diffusion coefficient will also be discussed.

**10:36**
**N26 10 Slowing down DNA translocation using magnetic and optical tweezers*** HONGBO PENG, SHANSHAN WU, SANG RYUL PARK, ANDREW POTTER, X. S. LING, *Brown University* Electric-field driven DNA translocation through nanopores can be exploited for DNA sequencing and other applications. However, the DNA translocation under normal patch-clamp-type measurement is too fast to allow detailed measurements of individual or few nucleotides. We propose a concept to slow down the DNA translocation through the nanopore by using magnetic (or optical) tweezers. The 3' end of a single-strand DNA can be attached to a streptavidin-coated magnetic bead through a single biotin molecule. During DNA translocation, the 5' end of DNA will be electrophoretically drawn through the nanopore to the itrans side while the 3' end of DNA stays in the itcis side with the magnetic bead. A set of permanent magnets or electric coils can be used to generate a magnetic field gradient large enough to pull the bead, hence the DNA out of the nanopore. The net force on the magnetic bead will determine this back-translocation speed. By carefully tuning the magnetic field gradient and the voltage bias on the nanopore, one can make the back-translocation much slower than the conventional forward-translocation in which case the DNA is driven only by the electric force. We will report our experimental design as well as the preliminary results.

**N26 11 Patterned Periodic Nanofilter Array for Continuous-Flow Bimolecular Separation** JIANPING FU, *Department of Mechanical Engineering, MIT* JONGYOON HAN, *Department of Electrical Engineering and Computer Science, Division of Biological Engineering, MIT* We present an experimental study on sieving process of small biomolecules (i.e., proteins and small DNAs) in one- and two-dimensional periodic arrays of nanofilter. The nanofilters served as artificial sieves with precise pore size characterization and showed exceptional size selectivity and separation efficiency from the periodicity of the environment. A kinetic model is developed to explain the electrophoretic drift of charged molecules across periodically modulated free energy landscapes. Further experimental evidence shows the crossover from Ogston-like sieving to entropic trapping mechanism depending on nanofilter thickness and on electric field strength. We also demonstrate continuous-flow biomolecule separation with a device containing of two-dimensional periodic nanofilter arrays. The interaction between migrating molecules and the two-dimensional physical landscapes cause molecules of different sizes to follow radically different paths leading to separation. Continuous-flow fractionations of small DNA molecules (50bp-766bp) as well as SDS-protein complexes (11kDa-200kDa) were achieved in about 5 minutes with a resolution of 10%. By virtue of its gel-free and continuous-flow operation, this device suggests himself a key component to an integrated biomolecule sample preparation and analysis microsystem.

**N27 1 Tight binding calculations of vibrational and thermal properties of amorphous silicon** MICHAEL MEHL, *Naval Research Laboratory* JOSEPH FELDMAN, DIMITRIS PAPACONSTANTOPOULOS, *Naval Research Laboratory and George Mason University* NOAM BERNSTEIN, *Naval Research Laboratory* By displacing atoms by different amounts and computing atomic forces within the NRL tight binding method we obtain all second order (harmonic) and some third order (anharmonic) coupling constants of a 1000 atom TB-relaxed Wooten CRN model of amorphous silicon. The harmonic force constant results allow us to study various properties including vibrational density of states, dynamic structure factors, specific heat and thermal conductivity within Kubo theory. We shall present results of these applications and compare to experiment and previous work based on the Stillinger Weber potential.

**8:12**
**N27 2 Manifestation of Negative Compressibility in Low-Density Electron Liquids: Anomaly in the Ion-Pair Distribution Function in Supercritical Fluid Rb** YASUTAMI TAKADA, *ISSP, Univ. of Tokyo* It is a well-known fact that the electronic compressibility $\kappa$ diverges in the 3D electron gas as the density parameter $r_s$ approaches 5.25. A recent investigation clarifies that this divergence is due to the excitonic effect in the electron-hole pair excitation, in particular, to its zero-energy excitation [1]. For $r_s > 5.25$, $\kappa$ becomes negative, leading to the negative static dielectric function $\varepsilon(q,0)$ for at least small $q$ owing to the compressibility sum rule. Then we can expect that two positive test charges do not repel but attract to each other in such a system. Keeping this situation in mind, we have calculated the ion-pair distribution function g(R) in the expanded Rb liquid metal by using the Monte Carlo method and found interesting features in g(R) characteristic to the negative $\varepsilon(q,0)$ [2]. Such features have been observed by the recent measurement of g(R) in the supercritical fluid Rb metal with continuously increasing $r_s$ from 5.25 [3]. This confirms the situation of $\kappa < 0$ in the low-density 3D electron gas for the first time. [1] YT, J. Superconductivity **18**, No.3 (2005). [2] H. Maebashi and YT, to be submitted. [3] K. Matsuda and K. Tamura, private communication.

**8:24**
**N27 3 Finite temperature quasiparticle self-consistent GW approximation** SERGEY FALEEV, *Sandia National Laboratories* MARK VAN SCHILFGAARDE, TAKAO KOTANI, *Arizona State University* FRANCOIS LEONARD, MICHAEL DESJARLAIS, *Sandia National Laboratories* We present a new ab initio method for electronic structure calculations of materials at finite temperature (FT) based on the all-electron quasiparticle self-consistent GW (QPscGW) approximation and Keldysh time-loop Green's function approach. We apply the method to Si, Ge, GaAs, InSb, and diamond and show that the band gaps of these materials universally decrease with temperature in contrast with the local density approximation (LDA) of density functional theory (DFT) where the band gaps universally increase. At temperatures of a few eV the difference between quasiparticle energies obtained in FT-QPscGW and FT-LDA approaches significantly reduces. This result suggests that existing simulations of very high temperature materials based on the FT-LDA are more justified then it might appear from well-known LDA band gap errors at zero-temperature.

**8:36**
**N27 4 Iterative minimization by Kohn–Sham inversion and potential mixing** ROOPE ASTALA, MALCOLM STOTT, *Department of Physics, Queen's University, Kingston, Ontario, Canada* Applications of Hohenberg–Kohn–Sham density functional theory to problems in materials physics are critically dependent on algorithms for iterating the Kohn–Sham equations to self-consistency. We present an approach for obtaining the self-consistent solution, which explores a connection between iterative minimization and Kohn–Sham inversion, iti.e. finding a self-consistent potential for a given density. The central idea is to perform the Kohn–Sham inversion using a position-dependent Lagrange multiplier and to construct a new trial potential from the result. The method is variational, in contrast to commonly-used density mixing approaches, and has excellent convergence. We demonstrate the method using a real-space pseudopotential implementation with applications to small molecules.

**8:48**
**N27 5 Atomic Forces and Geometry Optimisation with the ONETEP Linear-Scaling DFT Method** ARASH MOSTOFI, *Massachusetts Institute of Technology, USA* PETER HAYNES, *Cavendish Laboratory, University of Cambridge, UK* CHRISKRITON SKYLARIS, *Physical and Theoretical Chemistry Laboratory, University of Oxford, UK* MIKE PAYNE, *Cavendish Laboratory, University of Cambridge, UK* ONETEP[1] (Order-*N* Electronic Total Energy Package), is a density functional method, based on plane-waves, whose computational cost scales only linearly with the number of atoms. ONETEP uses a localised yet orthogonal basis of periodic cardinal sine (psinc) functions[2], also known as Dirichlet or Fourier Lagrange-mesh functions, which are formed from a discrete sum of plane-waves. The localised non-orthogonal generalised Wannier functions (NGWFs) which span the occupied subspace are represented in terms of these psinc functions and are optimised during the calculation. This choice of basis and optimisation of the NGWFs results in smooth potential energy surfaces and enables the use of the Hellmann-Feynman theorem for the calculation of atomic forces. These have been implemented within a quasi-Newton geometry optimisation scheme and preliminary results are presented. [1] J. Chem. Phys. **122**, 084119 (2005). [2] J. Chem. Phys. **119**, 8842 (2003).

**N27 7 Effect of Ti and metal vacancies on the dehydrogenation of $Na_3AlH_6$*** SA LI, PURU JENA, *Virginia Commonwealth University* RAJEEV AHUJA, *Uppsala University* VIRGINIA COMMONWEALTH UNIVERSITY TEAM, UPPSALA UNIVERSITY COLLABORATION, Electronic and structural properties of sodium-aluminum hexahydride ($Na_3AlH_6$) formed during the decomposition reaction of sodium alanate ($NaAlH_4$) are calculated using density functional theory and generalized gradient approximation for exchange and correlation potential. The roles of Ti substitution at the Na and Al sites as well as that of Na and Al vacancies on the desorption of hydrogen have also been investigated. We show that the improvement in dehydrogenation of $Na_3AlH_6$is due to the addition of Ti much the same way as that in $NaAlH_4$, namely through the weakening of the metal-hydrogen bond. However, as in the case of $NaAlH_4$, vacancies are found to be more effective in desorbing hydrogen at lower temperatures than Ti substitution at the Na or Al sites.

**N27 8 Excitation Energies from Time-Dependent Density Functional Theory within Modified Linear Response: Inclusion of the Electron-Hole Hartree-Fock Interaction** CHUNPING HU, OSAMU SUGINO, *Institute for Solid State Physics, University of Tokyo, and also CREST, Japan Science and Technology Agency* YOSHIYUKI MIYAMOTO, *Fundamental and Environmental Res. Labs, NEC, Japan* Time-dependent density functional theory (TD-DFT) within linear response (LR) has gained enormous popularity in the calculation of electronic excitations, whereas it is known to give considerably underestimated excitation energies for Rydberg and charge-transfer excitations. Although the incorrect long-range behavior of exchange-correlation (XC) potentials has been blamed for this problem, a different point of view on the LR scheme without any correction of XC potentials is presented here. Analyzing approximate excitation energies from LR within adiabatic local density approximation (ALDA) and the exact exchange (EXX) scheme, we propose a modified LR theory to strictly include the electron-hole Hartree-Fock interaction kernel, and to make excitation energy expression in ALDA explicitly similar to the EXX one. TD-LDA calculations within modified LR on typical diatomic molecules show that excitation energies of both Rydberg and charge-transfer excitations can be greatly improved to the EXX-level accuracy.

**N27 9 Quasiparticle Corrections to the Electronic Properties of Point Defects*** ARNO SCHINDLMAYR, *Forschungszentrum Jülich and Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany* MAGNUS HEDSTRÖM, PHILIPP EGGERT, MATTHIAS SCHEFFLER, *Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany* We present a quantitative ab initio method for calculating defect states and charge-transition levels of point defects in semiconductors. It relies on a separation into lattice and electronic energy contributions, which are treated within density-functional theory and many-body perturbation theory, respectively. We use the $GW$ approximation for the self-energy to determine the quasiparticle corrections to defect states in the band gap. As an example, we consider anion vacancies on the (110) surfaces of III-V semiconductors. The calculated charge-transition levels, in particular, show a clear improvement over the local-density approximation and are in close agreement with the available experimental data. As the surface is simulated by a slab within the supercell approximation, we place special emphasis on a convergence analysis of the quasiparticle properties in this approach. The dynamic polarization between the periodic images can be understood within a simple model, which also allows an a posteriori correction.

**N27 10 Probing the Ab-initio Fermi Surface Efficiently using Wannier Interpolation** JONATHAN YATES, IVO SOUZA, *LBNL and University of California, Berkeley* XINJIE WANG, DAVID VANDERBILT, *Rutgers University* Modern *ab-initio* techniques are able to provide an accurate description of the electronic structure for a wide range of materials. However, evaluation of the transport properties of metals requires an extremely detailed, and hence computationally expensive, sampling of the Fermi surface. We show that the electron group velocity and effective mass can be obtained directly from the Wannier representation of a system. This leads to an efficient and precise method for the calculation of transport properties using Wannier interpolation. We will present calculations of the ordinary Hall coefficient and thermoelectric power for a variety of materials.

**N27 11 Nonlinear Optical Response of Polar Semiconductors in the Terahertz Range** ERIC ROMAN, JONATHAN YATES, *University of California, Berkeley* MAREK VEITHEN, *Université de Liège* DAVID VANDERBILT, *Rutgers University* IVO SOUZA, *University of California, Berkeley* Using the Berry-phase finite-field method, we compute from first-principles the recently measured[1] infrared (IR) dispersion of the nonlinear susceptibility $\chi^{(2)}$ in III-V zincblende semiconductors. At far-IR (terahertz) frequencies, in addition to the purely electronic response $\chi_\infty^{(2)}$, the total $\chi^{(2)}$ depends on three other parameters, $C_1$, $C_2$, and $C_3$, describing the contributions from ionic motion. They relate to the TO Raman polarizability and the second-order displacement-induced dielectric polarization and forces, respectively. Contrary to a widely-accepted model,[2] but in agreement with the recent experiments on GaAs,[1] we find that the contribution from mechanical anharmonicity dominates over electrical anharmonicity. By using Richardson extrapolation to evaluate the Berry's phase in $k$-space by finite differences, we are able to improve the

convergence of the nonlinear susceptibility from the usual[3] $\mathcal{O}[(\Delta k)^2]$ to $\mathcal{O}[(\Delta k)^4]$, dramatically reducing the computational cost.

**N27 12 Breathing oscillations accompanying Bloch oscillations of wavepackets in periodic potentials*** MIGUEL PRUNEDA, *UC Berkeley* IVO SOUZA, *UC Berkeley* Using a 1D tight-binding model, we study the evolution of a well-localized wavepacket of Bloch states under an applied electric field. We apply a novel algorithm[1] for solving numerically the equations of motion which does not rely on the single-band approximation and can thus be used to explore interband Zener tunneling effects. In addition to the well-known Bloch oscillations of the center of the packet, we show that as the waveform moves in k-space, its real-space width varies in response to the change in the local quantum metric,[2] $g(k)$, of the underlying Bloch states. A generalized uncertainty relation is obtained between the spread in position and in *crystal* momentum of a wavepacket. It differs from the usual position/momentum uncertainty relation because of the interband matrix elements of the position operator in the crystal-momentum representation, which introduce a correction in terms of $g(k)$.

**N27 13 Nonadiabatic Transition in the Quantum Hall Effect** MANABU MACHIDA, NAOMICHI HATANO, *IIS, University of Tokyo* JUN GORYO, *Aoyama Gakuin University* We analyze the nonadiabatic transition in a 2D electron system with a periodic potential in the quantum Hall regime. We obtain corrections to the Chern-number term of the Hall conductance and a non-vanishing diagonal conductance. We treat the electric field as a time-dependent vector potential in the Hamiltonian. We calculate the time evolution of the density operator taking account of the first order of the electric field, and thereby study the electric conduction when the system evolves nonadiabatically. We thus obtain analytical expressions of the diagonal and off-diagonal conductances and calculate them numerically.

**N28 1 PEG Surface Modification by Thermoreversible Ligand Cleavage in Nanoparticle Composites.** RICK BEYER, PHILIP COSTANZO, *Army Research Laboratory* The control of surface chemistry is an increasingly important area of research in the polymer science community; a simple example of a need for controlled surface properties can be found in the need for surfaces that are resistant to bacterial growth for medical applications. In this study, we have successfully modified the surface properties of solvent cast poly(ethylene glycol) (PEG) films, triggered by exposure to an elevated environmental temperature. PEG matrices of varying molecular weights have modified with gold nanoparticles functionalized with thiol terminated, poly(styrene)-PEG block copolymer (P(S-*b*-PEG)) ligands. Gold nanoparticles approximately 15 nm in diameter were first synthesized via reduction of $HAuCl_4$ with oleyl amine. Diels-Alder chemistry was then used to create P(S-*b*-EG) ligands that, with increasing temperature, dissociate into simple thiol-terminated PS ligands and PEG oligomers. The ligand-modified gold particles were characterized via small-angle X-ray scattering and TEM. After dissociation occurs, around 90 [r]C, the gold particles are suddenly functionalized with only a PS ligand and thus immiscible in the surrounding PEG matrix. The gold nanoparticles are then driven to the surface of the films, measurably denoted by a change in contact angle. After cooling below 60 [r]C, the Diels-Alders linkages reform, stabilizing the film surfaces with the new morphology trapped both chemically and kinetically.

**8:12**
**N28 2 Smart Polymeric Surfaces: Responsiveness and Reconstruction** JULIE CROWE, JAN GENZER, *N.C. State University* The ultimate responsive surface is one that instantaneously responds to its environment with a measurable property change. In our research we utilize model poly(vinylmethyl)siloxane elastomer (SE) networks modified with thiol alkanes to provide hydrophobic or hydrophilic surface properties. The cooperative effects of polymer mobility, arising from the high flexibility of the siloxane backbone, and the enthalpic interactions between the outside medium and the SE functionalized surface control the degree of responsiveness as measured by dynamic and static contact angle. The initial parameters screened were alkane chain length, medium temperature, and end-group functionality. Real-time wetting force measurements have been obtained with dynamic contact angle, where the surface reconstruction is measured continuously providing a means to determine the kinetics of reconstruction and reversibility. Our examples show that not only are SE networks excellent stimuli-responsive substrates, but that the magnitude of change and repeated reversibility are unparallel to most polymeric surfaces.

**8:24**
**N28 3 Conformations of Amphiphilic Comb Copolymer Chains Confined to Two Dimensions Through Self-Organization at the Polymer/Water Interface** WILLIAM KUHLMAN, ELSA A. OLIVETTI, LINDA G. GRIFFITH, ANNE M. MAYES, *Massachusetts Institute of Technology* Amphiphilic comb copolymers composed of a hydrophobic poly(methyl methacrylate) (PMMA) backbone and short, hydrophilic PEO side chains (PMMA $-$ *g* $-$ PEO) are known to self-organize at the polymer/water interface, resulting in the effective confinement of the backbone to two dimensions for chains at the surface of a PMMA-*g*-PEO film. Conformations of polymers thus confined were studied through selective nanoparticle labeling of PEO side chains of polymer molecules at the film surface. Transmission electron microscopy was used trace the backbone trajectory of nanoparticle labeled chains. The distribution of observed chain lengths is found in good agreement with the distribution determined by gel permeation chromatography. The 2D radius of gyration ($R_g$) calculated from the observed conformations was found

to scale with number of backbone segments ($N$) as $R_g \sim N^{0.69\pm0.02}$. This value agrees with Monte Carlo simulations for a system of similar polydispersity, which yield a scaling exponent between that for 2D isolated chains and monodisperse polymer melts ($R_g \sim N^{0.64\pm0.03}$).

**8:36**

**N28 4 Temperature-responsive polymers and brushes with tunable onset of response** THERESA FOLEY, *Penn State University* KIRIL EFIMENKO, *North Carolina State University* JAN GENZER, *North Carolina State University* EVANGELOS MANIAS, *Materials Science and Engineering, Penn State University* Temperature-responsive polymers are of high interest in the scientific field of stimuli responsive materials, in particular water soluble polymers with a response at $\sim 36.5^{o}$C. However, difficulties in tailoring this T-response, as illustrated for example from studies of PNIPAM in numerous functionalized and copolymer forms, has hampered their proliferation. Here we present a systematic series of temperature-responsive polymers, which were designed, synthesized, and studied, and we show that we can tailor with high sensitivity their onset of T-response via the design of their monomer. Specifically, we demonstrate lower critical solution temperature (LCST) in water finely tuned between 5 and $70^{o}$C, by controlling the hydrophilic/hydrophobic balance in the monomer (closely following predictions of phase behavior theories). In addition, we will also show that these polymers maintain their T-responsive characteristics when end-tethered to solid surfaces, over a wide range of grafting densities in combinatorial brushes. This approach allows for controlling contact angle, adhesion and tackiness as a function of temperature.

**8:48**

**N28 5 Single Molecule Experiments with Adsorbed Polyelectrolytes*** SERGIY MINKO, YURI ROITER, We report on the AFM study of single polyelectrolyte (positively charged) molecules (PE) adsorbed on mica surfaces at different conditions (we vary pH and salt concentration). The study was carried out under aqueous solutions in a liquid cell. We observed behavior of PE in real time. The AFM experiments were experiments when possible effects of the AFM tip on PE conformations were minimized. A series of experiments were carried out when PE was adsorbed between two electrodes at applied electrical potential. The AFM images were processed to extract contour length, end-to-end distance, and radii of center of mass. The experiments revealed several interesting facts about adsorption of PE. The chain statistics was found to be consistent with the 2D random walk model. A decrease of charge density resulted in the coil-to-globule transition. The globules appear as a strongly deformed swollen polymer globule. In saline solutions the globules resemble necklace-like globules. PE chains were mobile if an electrical field was applied. The motion of PE chains can be describes as a caterpillar-like motion.

**N28 6 Quantifying How Polymer Interfacial Diffusion Differs from Bulk** LIANG HONG, *Materials Science and Engineering Department, University of Illinois at Urbana-Champaign* STEVE GRANICK, *Department of Materials Science and Engineering, Chemistry, Physics, Chemical Engineering, University of Illinois at Urbana-Champaign* Whereas polymer adsorption-desorption kinetics are reasonably well explored, in-plane diffusion is not. This talk will describe the molecular weight (M) and surface coverage dependence of two polymers, polystyrene (PS) and polydimethylsiloxane (PDMS) adsorbed to quartz from organic solvent. The M scaling of surface diffusion is quantified, and a surprising dependence on surface coverage is described. Time permitting, additional studies will be described in which, for the first time, polymer self-diffusion has been studied within a surface forces apparatus designed for fluorescence spectroscopy. Using FRAP (fluorescence recovery after photobleaching) to study slow diffusion and FCS (fluorescence correlation spectroscopy) to study rapid diffusion, we quantify how the self-diffusion coefficient of PDMS oligomer melts slows with diminishing surface separation, when PDMS is confined between mica surfaces.

**9:12**

**N28 7 Balancing size exclusion and adsorption of polymers in nanopores** WON KIM, CHANG Y. RYU, *Rensselaer Polytechnic Institute, Department of Chemistry and Chemical Biology* The liquid chromatography at critical condition (LCCC) presents the condition, at which the size exclusion and adsorption of polymer chains are balanced upon interactions with nanoporous substrates. In this study, we investigate how the polymer interactions with nanopores are affected by the solvent quality and nanopore size. Specifically, we measure the retention times of monodisperse polystyrenes in C18-bonded nanoporous silica column as a function of molecular weight, when a mixed solvent of methylene chloride and acetonitrile are used as elutent. C18-bonded silica particles with 70, 100, and 250 A pore size are used as a stationary phase to study how the transition from SEC-like to IC-like retention behavior depends on the condition of temperature and solvent composition. To locate the LCCC at various nanopore sizes, the temperature and solvent composition have been varied from 0 to 60 C and from 51 to 62 v/v% of methylene chloride, respectively.

**9:24**

**N28 8 Polymer brushes dynamics by evanescent wave dynamic light scattering** BENOIT LOPPINET, VASSILIKI MICHAILIDOU, GEORGE FYTAS, *IESL-FORTH* JUERGEN RUEHE, *IMTEK Freiburg Germany* Dynamics of swollen brush is experimentally measured by dynamic light scattering in the total internal reflection geometry. Dense thick polymer polystyrene brushes with varying grafting densities are obtained through grafting from synthesis. When highly swollen in good solvent, concentration fluctuations are found to decay through a fast diffusive mechanism, attributed to the expected cooperative diffusion, akin to semi-dilute polymer solutions. Its hydrodynamic size is found to be comparable to the estimated distance between grafting chains. De-swelling of the brush by lowering solvent quality (using cyclohexane at different temperatures) leads to qualitative different dynamics. An extra slower relaxation with a broad distribution of relaxation times is observed, which strongly depends on solvent quality, with an extensive slow down of it characteristic time and an increase of scattered intensity upon cooling. This complex dynamics is discussed in relation to the dynamics in entangled semi-dilute solution in theta solvent. Finally, the brownian dynamics of colloidal particles (radius from 17nm to 100nm) in contact with the brushes are reported. The particles are found to marginally penetrate the brush, but to nonetheless exhibit dynamics reflecting their interactions with the outer part of the brush.

**9:36**

**N28 9 Electromechanical Recognition of Molecules Adsorbed on Microcantilevers** SANGMIN JEON, DONGKYU LEE, *POSTECH* THOMAS THUNDAT, *ORNL* An alternating current was applied to gold-coated silicon microcantilevers in sodium chloride solution. The cantilever is coated on one side with a thin layer of gold. Since the applied electric field through the cantilever attracts oppositely charged ions onto the gold layer, the variation of surface charges induces the oscillation of the cantilever. The larger the applied voltage is, the more the cantilever oscillates. When the experiment was repeated with self-assembled monolayer coated cantilever, the amplitude of the oscillation is decreased because the monolayer hinders the ions from approaching to the cantilever. In-situ measurements of the adsorption of mercaptohexanol molecules under the electric field clearly showed that the decrease of the oscillation resulted from the formation of the layer. When a square electric field was applied to 1-mercaptoethanol, 1-mercaptopropanol, and 1-mercaptohexanol coated cantilever, the bending profile of the cantilever depended on the kinds of the monolayer. This method can be used to study the diffusion of small ions through thin films as well as the structure of self-assembled monolayer.

**N28 10 Dependence of surface diffusivity on the molecular conformation of single hydrophobic polyelectrolytes molecules*** JIANG ZHAO, SHENGQIN WANG, *Institute of Chemistry, Chinese Academy of Sciences, Beijing 100080, China* Hydrophobic polyelectrolytes are found to have their conformation change from an extended chain to globule via neck- lace structures. In this work, surface diffusion of single poly (2-vinylpryridine) (P2VP) molecule was studied under different chemical environment (pH value and ionic strength). Via hydrophobic interaction, P2VP molecules adsorbed to a hydrophobic surface. By fluorescence correlation spectroscopy, fluorescence labeled P2VP molecules were found to raise their surface diffusivity moderately but monotonously when the pH value was tuned from 2.0 to 6.5. The physical mechanism of the diffusivity dependence on molecular conformation is discussed.

*Supported by Natural Science Foundation of China (NSFC) and Chinese Academy of Sciences (CAS).

**10:00**

**N28 11 Adsorption of polymers onto selective mixed brushes.** A.I CHERVANYOV, G. HEINRICH, *Leibniz-Institut fur Polymerforschung Dresden, Hohe Str. 6, 01069 Dresden, Germany* Reversible adsorption of polymers onto selective mixed brushes is studied theoretically. Mixed brushes are recently developed self-adoptive materials that reversibly change their morphology in response to altering external factors (e.g. quality of the solvent). The above changes in the morphology result in the formation of different patterns on the outer surface of the brush. It is shown that thus achieved patterning of the adsorbing surface of the mixed brush drastically enhances the adsorption of polymers, as compared to the adsorption onto the homogeneous brush surface. The density profiles and absorbances of the selected homo- and copolymers are calculated for the three different morphologies ('ripple', 'dimple' and random) of the binary brush. The interplay between conformational entropy and binding energy of the adsorbed polymer leads to the reach adsorption-desorption behavior that is described by the developed theory. The calculated isotherms are compared with the experimental data and Monte-Carlo simulation results. In addition, the developed theory is applied to the study of the polymer adsorption onto the non-uniform binary brush in the presence of the gradient of chemical composition.

**10:12**

**N28 12 Nano-meter structured three-phase contact line and its surface-guided alignment effect*** GANG LIU, JIANG ZHAO, *Institute of Chemistry, Chinese Academy of Sciences, Beijing 100080, China* We report our studies on the air-liquid-solid three-phase contact line on the periodically patterned surface made of polystyrene-b-polymethylmethacrylate (PS-b-PMMA). The difference of the contact angle of the liquid (water and polymer solution) on PS and PMMA generates the contact line with periodic structures of 40 nm length scale. Such a structured contact line was found to produce surface guided alignment effect for single DNA molecules by the molecular combing process and to generate surface-guided morphology of the polymer films through a combination of de-pinning and de- wetting process.

*Supported by Natural Science Foundation of China (NSFC) and Chinese Academy of Sciences (CAS).

**10:24**

**N28 13 Surface diffusion of adsorbed polymers studied by molecular dynamics simulation** WONKI ROH, ERIK LUIJTEN, *University of Illinois at Urbana-Champaign* We study the diffusion of adsorbed polymers near a flat surface by means of molecular dynamics simulations, as a function of chain length $N$, adsorption energy, and surface coverage $\phi$. We find that the two-dimensional diffusion coefficient scales as $D \sim N^{-1.017\pm0.011}$, in agreement with other experimental and simulation results. The relation between lateral diffusion coefficient and surface coverage shows an exponential decay. We also investigate the conformation of the adsorbed chains. The number of ''trains,'' ''loops,'' and ''tails'' per chain, as well as the number of monomers in tails and loops increase as surface density increases and adsorption energy decreases, whereas the number of monomers in trains decreases. The parallel radius of gyration increases as a power law of the chain length, $\langle R_{g\|}^2 \rangle \sim N^{2\nu}$, with a power that is in good agreement with the Flory exponent $\nu = 3/4$ for two-dimensional chains. $\langle R_{g\|}^2 \rangle$ decreases with increasing surface density and decreasing adsorption energy, whereas $\langle R_{g\perp}^2 \rangle$ remains almost constant with increasing surface density and increases with decreasing surface energy.

**10:36**

**N28 14 Solvent and salt effects on the adsorption of polymers to charged surfaces** GOVARDHAN REDDY, ARUN YETHIRAJ, *Univeristy of Wisconsin - Madison* The effect of solvent quality and salt concentration on the adsorption of charged polymers to a planar uniformly charged surface is studied using molecular dynamics simulation. The polyion chains are modeled as chains of charged spheres, the counter ions to the polyions and the surface are modeled as charged spheres, and the solvent molecules are modeled as uncharged spheres. The polyion adsorption is studied as a function of monomer and salt concentration, solvent quality and surface charge density of the surface. The amount of polyion adsorbed on the surface increases with the decrease in solvent quality as the system approaches a bulk phase transition. There are some surprising and counter-intuitive results in this re-

gime. For example, incoprporating a short-ranged attraction between the polymers and the surfaces decreases the number of adsorbed polymers, and the amount of polyion adsorbed decreases as the salt concentration increases.

**10:48**

**N28 15 Mean-field theory of planar absorption of RNA molecules*** TOAN NGUYEN, *Dept. of Physics and Astronomy, University of California, Los Angeles* ROBIJN BRUINSMA, *Dept. of Physics and Astronomy, University of California, Los Angeles* WILLIAM GELBART, *Dept. of Chemistry and Biochemistry, University of California, Los Angeles* Interaction between the viral RNA and the protective protein capsid plays a very important role in the cell infection and self-assembly process of a virus. To better understand this interaction, we study a similar problem of absorption of RNA on an attractive wall. It is known that the secondary structure of a folded RNA molecules without pseudo-knots has the same topology as that of a branched polymer. We use a mean-field theory for branched polymers to analytically calculate the RNA concentration profile. The results are compared to known exact scaling calculations and computer simulations.

## SESSION N29: FOCUS SESSION: PHYSICAL MODELS OF ION CHANNEL FUNCTION

**Wednesday Morning, 15 March 2006**
**326, Baltimore Convention Center at 8:00**
**Bob Eisenberg, Rush University, presiding**

***Contributed Papers***

**8:00**

**N29 1 The metabolic energy cost of action potential velocity** PATRICK CROTTY, *University of Virginia Health System* THOMAS SANGREY, *Emory University* WILLIAM LEVY, *University of Virginia Health System* Voltage changes in neurons and other active cells are caused by the passage of ions across the cell membrane. These ionic currents depend on the transmembrane ion concentration gradients, which in unmyelinated axons are maintained during rest and restored after electrical activity by an ATPase sodium-potassium exchanger in the membrane. The amount of ATP consumed by this exchanger can be taken as the metabolic energy cost of any electrical activity in the axon. We use this measure, along with biophysical models of voltage-gated sodium and potassium ion channels, to quantify the energy cost of action potentials propagating in squid giant axons. We find that the energy of an action potential can be naturally divided into three separate components associated with different aspects of the action potential. We calculate these energy components as functions of the ion channel densities and axon diameters and find that the component associated with the rising phase and velocity of the action potential achieves a minimum near the biological values of these parameters. This result, which is robust with respect to other parameters such as temperature, suggests that evolution has optimized the axon for the energy of the action potential wavefront.

**8:12**

**N29 2 The Dependence of Ionic Conduction on the Dielectric Properties of Ion Channels** MARCO SARANITI, DAVID MARREIRO, *Illinois Institute of Technology* SHELA ABOUD, *Worcester Polytechnic Institute* The ion channel OmpF porin is a water filled trimer found in the outer membrane of itEscherichia coli. Each monomer is a hollow barrel structure with a physical constriction near the center that reduces the width of the pore to approximately 6 Å. Highly charged residues line the inside of the pore constriction, generating an intense electric field that facilitates the dynamics of ions through the channel. The cost of simulating these systems for long times is an oversimplification of key physical features of the ion channel system, most notably, the polarization effects related to the solvent (water) and the protein are poorly represented by a stepwise constant dielectric constant. While the use of this model for the aqueous solution inside the permeation pore is arguably suitable because the ionic hydration shell remains intact (at least away from the central constriction), its validity is questionable when used to describe the polarization response of the protein. In this work, a previously validated $P^3M$ force-field scheme, self-consistently coupled to a Brownian Dynamics kernel, is used to investigate the influence of the protein dielectric constant on permeation in OmpF porin. The computed channel conductivity is in agreement with experimental measurements. Increased cation selectivity at low ionic concentrations is also observed in the simulations and appears to be dependent on the rings of aspartic acid residues around the mouths of the porin.

**8:24**

**N29 3 Rocking and Flashing Ratchet Mechanisms of Ion Current Rectification in Asymmetric Nanopores in the Presence of Calcium** ZUZANNA SIWY, MATTHEW POWELL, ERIC KALMAN, *Univ. of California, Irvine* BOB EISENBERG, *Rush University Medical Center, Chicago* We have investigated an engineered system of a single nanopore in a plastic membrane that shows rectification depending on the chemical composition of the surrounding solutions. No lipid bilayer is involved so the system is simple and robust with $>$ 10 gigohm leak resistance. The single nanopores are tapered cones with openings of diameter $\sim$ 600 nm and $\sim$ 5 nm. The single nanopores were prepared by the track-etching technique. The walls of the pores have carboxylate groups with surface density $\approx$ 1.5 ($\mathbf{e}/[\mathrm{nm}]^2$). Transport properties of these nanopores were studied by recording current-voltage curves in a variety of solutions. In KCl solutions these single asymmetric nanopores are cation selective and rectify with a ratio of limiting conductances $\approx$ 4-10. The K ions flow with lower resistance from the smaller to larger opening. Adding millimolar Ca to both sides reverses the direction of rectification and produces a negative incremental resistance; i.e., larger magnitudes of voltage produce smaller magnitudes of ion current. The rectifying properties of these asymmetric nanopores are described by rocking and flashing ratchet models of directional motion. It will be interesting to compare permeation, selectivity, and gating properties of the polymer nanopores and biological voltage-gated calcium channels.

**8:36**
**N29 4 Ion selectivity in the ryanodine receptor and other calcium channels.**
DIRK GILLESPIE, *Rush University Medical Center*

Biological ion channels passively conduct ions across cell membranes, some with great specificity. Calcium channels are selective channels that range in their $Ca^{2+}$ affinity depending on the channel's physiological role. For example, the L-type calcium channel has micromolar affinity while the ryanodine receptor (RyR) has millimolar affinity. On the other hand, both of these channels have the chemically-similar EEEE and DDDD amino acid motifs in their selectivity filters. An electrodiffusion model of RyR that reproduces and predicts $>$ 50 data curves will be presented. In this model, ions are charged, hard spheres and the chemical potential is computed using density functional theory of fluids. Ion selectivity arises from a competition between the need for cations to screen the negative charges of the channel and the crowding of ions in the tiny space of the channel. Charge/space competition implies that selectivity increases as the channel volume decreases (thereby increasing the protein charge density), something that has recently been experimentally confirmed in mutant channels. Dielectric properties can also increase selectivity. In Monte Carlo simulations, $Ca^{2+}$ affinity is much higher when the channel protein has a low dielectric constant. This counterintuitive result occurs because calcium channel selectivity filters are lined with negatively-charged (acidic) amino acids (EEEE or DDDD). These permanent negative charges induce negative polarization charge at the protein/lumen interface. The total negative charge of the protein (polarization plus permanent) is increased, resulting in increased ion densities, increased charge/space competition, and there in increased $Ca^{2+}$ affinity. If no negative protein charges were present, cations would induce enough positive polarization charge to prevent flux.

**9:12**
**N29 5 Modeling Activity: Ions to Hydrophobics in Crowded Biological Solutions** MONTGOMERY PETTITT, *University of Houston* Nonideal solutions play a role in many aspects of chemistry. As concentrations increase, concentration itself becomes a less useful quantity to understand equilibria. Industrial and medicinal chemistry often fail due to the difference between concentration and activity. An understanding of the impact of the crowded conditions in the cytoplasm on its biomolecules is of clear importance to biochemical, medical and pharmaceutical science. Work on the use of small biochemical compounds to crowd protein solutions indicates that a quantitative description of their non-ideal behavior is possible and straightforward. Here, we will show what the structural origin of this non-ideal solution behavior is from expression derived from a semi grand ensemble approach. We discuss the consequences of these findings regarding protein folding stability and solvation in crowded solutions through a structural analysis of the m-value or the change in free energy difference of a macromolecule in solution with respect to the concentration of a third component.

**N29 6 Entropy driven insulator-metal crossover in ion channels and water filled nanopores** JINGSHAN ZHANG, ALEX KAMENEV, BORIS SHKLOVSKII, ANATONY LARKIN,* *University of Minnesota* We consider ion transport of an ion channel in a lipid membrane or a water filled nanopore in silicon films [1]. It is known that due to the large ratio of dielectric constants of water (80) and lipid (2), the electric lines of an ion in the channel are squeezed. This should lead to a large electrostatic self-energy barrier for Ohmic resistance [2]. Nevertheless biological channels are well transparent at least for some selected ions. To address this paradox, we study reduction of the electrostatic barrier by a finite concentration of salt in water and/or by immobile charges on the internal channel walls. We show that both types of charges reduce the barrier, leading to insulator-metal crossover resembling metal-insulator transition in excited gas or in doped semiconductors. But here entropy plays the role of quantum mechanics. Evolution of ion channels took into account biological concentration of monovalent salt, and more importantly, made some channels charged from inside to reduce electrostatic barrier for a given sign of ions (cation/anion selectivity). We also show that in the channel with negative wall charges fractionalization of divalent Ca ions into monovalent excitations leads to good Ca-Vs.-Na selectivity of Ca channels. [1] A. Kamenev, J. Zhang, A. I. Larkin, B. I. Shklovskii, Physica A 359, 129 (2006); J. Zhang, A. Kamenev, B. I. Shklovskii, Phys. Rev. Lett. 95, 148101 (2005); cond-mat/0510327. [2] A. **N29 7 Measurement of gating forces of mechanosensitive channels of large conductance in Escherichia coli** ELVIS PANDZIC, PAUL WISEMAN, MARIA KILFOIL, *Physics McGill* J. L. NADEAU TEAM,*J. A. MAURER COLLABORATION,† In order to sense and respond to external mechanical stimuli, cells have evolved schemes to incorporate mechanosensors within their plasma membranes. Mechanosensitive channels of large conductance (MscL) are used by bacterial cells to respond quickly and effectively to hypo-osmotic shock: the opening of this channel permits cells to quickly release large amounts of osmolytes in order to quickly equalize unbalanced osmotic pressure across a membrane. In this study, we are investigating the physical mechanism of the MscL gating within the native environment of the itEscherichia coli cells. We are using the green fluorescent protein (GFP) and derivative proteins (CFP, BFP) to label the C-termini of MscL subunits in order to observe the channels in live bacteria by fluorescence microscopy. Moreover, we label the opposite termini with a different chromophore system that constitutes an excellent fluorescence resonance energy transfer (FRET) pair with CFP. Channels are activated within the bacterial membrane by osmotic stress and interactions between differently labeled subunits are measured by fluorescence microscopy.

**N29 8 Calculating Ion Permeation through Biological Channel Proteins.***
ROB COALSON, *University of Pittsburgh*

We have developed methodology to simulate the current of ions (Na+, Cl-, etc.) through a general three-dimensional ion channel structure embedded in a lipid bilayer when an electric potential is applied across the membrane. These calculations are done at the level of Brownian dynamics, i.e., ions are treated as particles and their motion is computed using a stochastic algorithm which simulates Brownian motion. Water solvent is treated as a dielectric continuum, which both supplies the thermal agitation underlying the motion of the ions and influences the electrostatic forces on these ions by virtue of its dielectric constant (which differs substantially from that of the protein-membrane complex). Application is made to the Glycine Receptor channel, emphasizing physico-chemical influences on ion current, e.g., charges of critical pore-lining amino acids, channel geometry, etc.

**N29 9 Morphometric approach to selectivity and gating of ion channels** ROLAND ROTH, *MPI fuer Metallforschung, Heisenbergstrasse 3, 70569 Stuttgart, Germany* A physical understanding of selectivity and gating of ion channels requires the free energy of the fluid confined in the channel pore. The free energy depends not only on fluid properties like its density, but also on the interaction between fluid particles and the confining protein, which gives rise to a potentially complicated dependence of the free energy on the conformation of the protein. Here we propose a simple thermodynamic approach that employs the idea that the free energy can be separated into geometrical measures and corresponding thermodynamic coefficients. Our approach enables us to calculate the change in the free energy caused by a change of the pore conformation such as that underlying the gating of an ion channel. We study the connection between the geometrical change of a hydrophobic pore and capillary evaporation, i.e. the effect that water is expelled from the permeation pathway and ion flow is thereby stopped although the pore remains wider than the water or ion diameters. We estimate the energy it takes to remove the water from the pore. Within the same thermodynamic framework, we can also study effects of pore conformation on the equilibrium absorption of ions and thus on ionic selectivity of the channel.

**10:36**
**N29 10 Voltage Sensor in Voltage-gated ion channels** FRANCISCO BEZANILLA, *Institute for Molecular Pediatric Science. University of Chicago* Voltage-gated ion channels are intrinsic membrane proteins that play a fundamental role in the generation and propagation of the nerve impulse. Their salient characteristic is that the probability of the ion channel of being open depends steeply on the voltage across the membrane where those channels are inserted. Thus, in a membrane containing many channels, the ionic conductance is controlled by the membrane potential. The voltage exerts its control on the channel by reorienting intrinsic charges in the protein, generally arginine or lysine residues located in the 4th transmembrane segment of the channel protein, a region that has been called the voltage sensor. Upon changing the membrane potential, the charged groups reorient in the field generating a transient current (gating current). The properties of the gating current may be studied with a small number of channels to infer the operation of the sensor at the single molecule level by noise analysis or with a large number of channels to infer the details of the energy landscape the sensor traverses in opening the pore. This information is global in nature and cannot pinpoint the exact origin of the charge movement that generates the gating current. The movement of physical charges in the protein has been inferred with site-directed mutagenesis of the charged residues to histidine that allows the study of proton accessibility. The actual movement has been studied with fluorescence spectroscopy, fluorescence resonance energy transfer. The combined information of site-directed mutagenesis, gating currents, fluorescence studies and emerging crystal structures have started to delineate a physical representation of the conformational changes responsible for voltage sensing that lead to the opening of the conduction pore in voltage-gated ion channels.

## SESSION N30: BLOCK COPOLYMER PHASE BEHAVIOR
**Wednesday Morning, 15 March 2006**
**327, Baltimore Convention Center at 8:00**
**Thomas Epps, National Institute of Standards and Technology, presiding**

**8:00**
**N30 1 Equilibrium Phase Diagram of a Model Rod-Coil Block Copolymer** B.D. OLSEN, R.A. SEGALMAN, *University of California Berkeley and Lawrence Berkeley National Lab* Rod-coil block copolymers can be used to form important self-assembled structures containing functional blocks such as helical polypeptides or conducting polymers. The thermodynamics of these materials is distinct from classical block copolymers due to the conformational asymmetry of the polymer chain and the effect of liquid crystallinity on the microphase structure. We have recently developed a weakly segregated model system, poly(alkoxyphenylene vinylene-b-isoprene) (PPV-b-PI), in which rod-rod and rod-coil interactions are modulated by the presence of short side chains on the rod. We present the phase diagram for rod-coil block copolymers in the weak segregation limit, demonstrating equilibrium lamellar, nematic, and isotropic phases. As molecular weight is increased, subtle order-order transitions in the lamellar phase become obvious. In particular, we will discuss the relative stabilities of smectic phases based on scattering data. Finally, we will discuss the non-lamellar hexagonal phases that are observed as the relative rod-fraction of the block copolymer is decreased.

**8:12**

**N30 2 Phase behavior of linear ABC triblock copolymer** JOON CHATTERJEE, FRANK S. BATES, *Department of Chemical Engineering and Material Science, University of Minnesota* We report the study of melt phase behavior of poly(isoprene-*b*-styrene-*b*-ethylene oxide) as our model ABC triblock copolymer. Previous investigations on this system have discovered a network phase with $O^{70}$ space group symmetry in an orthorhombic lattice adjacent to network phases with cubic lattice symmetries, namely, alternating gyroid and core-shell gyroid. The present study investigates and expands the phase diagram with varying monomer compositions and temperature. Nearly monodisperse triblock copolymers with controlled molecular weights and block compositions are synthesized by anionic polymerization techniques. Blending of homopolymers with the triblock copolymer is used to refine the phase boundaries. Dynamic mechanical spectroscopy, small angle x-ray scattering, TEM and optical experiments are used to characterize the equilibrium morphologies. Other new phases such as hexagonal cylinders and bcc spheres have been observed. We observe that the phase diagram is not symmetric across the $f_A = f_C$ isopleth.

**8:24**

**N30 3 Electron tomography of a novel non-cubic network phase in ABC copolymers** GERD E. SCHROEDER, STEPHEN T. HYDE, *Applied Maths, RSPhysSE, Australian National University, 0200 ACT, Australia* HERMIS IATROU, NIKOS HADJICHRISTIDIS, *Chemistry Dept, Univ of Athens, Panepistimiopolis, Zografou 15771, Athens, Greece* SATOSHI AKASAKA, HIROKAZU HASEGAWA, *Dept of Polymer Chemistry, Grad School of Engineering, Kyoto Univ, Katsura, Nishikyo-ku, Kyoto 615-8510, Japan* We report the discovery of a novel bicontinuous tetragonal phase in the linear ABC triblock terpolymer system polystyrene (PS), polyisoprene (PI) and polydimethylsilocane (PDMS). The data is consistent with spacegroup Fddd and is distinctly non-cubic. The channel topology is distinct from the better-known cubic bicontinuous mesophases (diamond and gyroid types, with channels). It consists in 2 identical intertwined labyrinths with 3- and 4-connected nodes. Our mesophase differs from an earlier report of a copolymer phase (also in a linear terpolymer system) with the same spacegroup by Epps *et al* (Macromolecules **37**, 8325-41, 2004), who deduced a single channel morphology, based on TEM and SAXS data. Our proposal is based on 3D $e^-$-tomography data. The channel geometry is identified via a medial surface (MS) algorithm. For a labyrinth, the MS is a generalised channel graph consisting in surface patches. In contrast to line graphs, the MS is a complete descriptor of both topology and geometry. It provides robust shape characteristics, and is a useful tool for visualisation of complicated hyperbolic mazes.

**8:36**

**N30 4 Phase behavior of poly(pentafluorostyrene-b-methyl methacrylate) block copolymers** TRACY BUCHOLZ, YUEHLIN LOO, *University of Texas at Austin* Fluorine-containing polymers have garnered interest for properties such as chemical inertness, high thermal stability, and low dielectric constants. Previously, the controlled synthesis of fluoropolymers has been difficult due to the electron-withdrawing nature of fluorinated monomers. This issue, however, has been addressed with the development of atom transfer radical polymerization. Using this technique, we have been able to synthesize diblock copolymers containing polypentafluorostyrene (PPfS) and poly(methyl methacrylate), PMMA. The resulting diblock copolymers exhibit narrow molecular weight distributions ( $\leqslant$ 1.1) and undergo microphase separation to form highly-ordered nanostructures at moderate molecular weights. Comparisons of order-disorder transition temperatures with anionically synthesized poly(styrene-b-isoprene), PS/PI, diblocks of comparable molecular weights and compositions suggest that the segregation strength of PPfS/PMMA is within a factor of two of that of PS/PI. This observation is surprising given the chemical uniqueness of PPfS and PMMA but is in fact in agreement with the theoretical segregation strength relative to PS/PI predicted by differences in their solubility parameters.

**N30 5 Perforated layer structures in liquid crystalline block copolymers** KISHORE TENNETI, *Drexel University* XIAOFANG CHEN, *Peking University* CHRISTOPHER LI, *Drexel University* YINGFENG TU, XINHUA WAN, QI-FENG ZHOU, *Peking University* IGORS SICS, BENJAMIN HSIAO, *University of Stony Brook* DREXEL UNIVERSITY TEAM, PEKING UNIVERSITY COLLABORATION, UNIVERSITY OF STONY BROOK COLLABORATION, Phase structures of a series of poly(styrene-block-(2,5-bis-(4- methoxyphenyl)oxycarbonyl)styrene) (PS-b-PMPCS) liquid crystalline rod-coil block copolymers (LCBCPs) were investigated using thermal analysis, X-ray analysis and transmission electron microscopy. In the low molecular weight asymmetric BCP system, perforated layer structures were observed where the excessive PS molecules punctured the PMPCS domains and these perforations uniquely possess tetragonal in-plane symmetry. In the high molecular weight system, these perforated layer structures were observed in symmetric samples. Randomly initiated perforations became more regular and uniform upon blending with PS homopolymer in symmetric BCPs. These regular perforations also possess tetragonal in-plane symmetry.

**9:00**

**N30 6 Self-assembly of polydisperse acrylic block copolymers** ANNE-VALERIE RUZETTE, LUDWIK LEIBLER, *Laboratoire Matiére Molle et Chimie, UMR 7167 ESPCI-CNRS, Paris, France* FLORENCE CHAUVIN,*DENIS BERTIN, *Chimie, Biologie et Radicaux Libres, UMR 6517, Marseille, France* PIERRE GERARD, *ARKEMA, Lacq, France* Self-assembled block copolymers present great interest since they combine at the nanometer scale intrinsic properties of different homopolymers. Over the past decade, remarkable progress in synthetic chemistry has unveiled new opportunities to prepare tailored block copolymers of judiciously chosen monomer type and architecture at reasonable cost. In particular, controlled radical polymerizations (CRP) are suitable to all kinds of vinyl monomers in common mass, suspension or even emulsion processes. Most synthetic efforts in this field have focused on developing a ''living'' character of free radical chain-ends and control polydispersity in length and composition. Here, we discuss a different, though quite common, situation where only one of the copolymer blocks is controlled. Overall composition and molecular weight polydispersities are thus large. Self-assembly and mesoscopic order in these ''asymmetrically polydisperse'' block copolymers and their blends is discussed.

**9:12**

**N30 7 Electrospun poly(styrene-b-isoprene) fibers that exhibit internal structure** SERGIO MENDEZ, VIBHA KARLA, PRASHANT KAKAD, MARLEEN KAMPERMAN, YONG JOO, *Cornell University* We have used the elelctrospinning process to fabricate fibers from THF / poly(styrene-b-isoprene) (PS-PI) diblock copolymer solutions. We spun fibers with copolymers that had various volume fractions of PI. These fibers had diameters ranging from 200 nm to 5 microns depending on the processing conditions such as solution concentration, needle size, electric field, etc. The goal of this investigation was to observe the formation of self-assembled microstructures within the fibers. SAXS data indicates that the copolymer microphase separates and that there is some degree of globally ordered domains; however, TEM images indicate that this order is more local which might be due to the short residence time in the electrospinning process. By comparison, SAXS and TEM data of PS-PI films exhibits unambiguous global ordering. In an attempt to improve the long range order within the fibers, we performed various annealing treatments, and found that heating at temperatures below the glass transition temperature only had a small effect.

**9:24**

**N30 8 Confinement induced novel morphologies of block copolymers** AN-CHANG SHI, *McMaster University* BIN YU, BAOHUI LI, *Nankai University* Self-assembly of block copolymers confined in cylindrical nanopores is studied systematically using a simulated annealing method. For diblock copolymers which form two-dimensional hexagonally-packed cylinders with period $L_0$ in the bulk, novel structures such as helices and stacked toroids spontaneously form inside the cylindrical pores. These confinement induced morphologies have no counterpart in the bulk system and they depend on the pore diameter ($D$) and the surface-polymer interactions, reflecting the importance of structural frustration and interfacial interactions. On tightening the degree of confinement, transitions from helices to toroids to spheres are observed. Mechanisms of the morphological transitions can be understood based on the degree of structural frustration parametrized by the ratio $D/L_0$.

**9:36**

**N30 9 Self-assembly of three-dimensional morphologies in a diblock copolymer melt confined in a cylindrical nanopore*** WEIHUA LI, ROBERT A. WICKHAM, *Department of Physics, STFX, Antigonish, NS* The microdomain morphologies of an AB diblock copolymer melt confined in a cylindrical nanopore are investigated using three- dimensional real-space self-consistent mean-field theory. We find that many structures self-assemble in the pore, including cylinders, helices, toroids, disks, and spheres. We compute the relative stability of these structures and locate transitions between phases as the diameter of the pore is varied. We focus on narrow pores for simplicity since it appears that the number and complexity of the structures formed increases as the pore size increases. For each of our morphologies, we measure the inter-domain distance, the degree of chain stretching, the area of A/B interface, and the A/B interfacial curvature. We identify which of these factors are driving the structural transitions. Our results will be compared with recent experiments and simulations.

**N30 10 Effects of confinement on the order-disorder transitionin diblock copolymer melts and crystallization** DADONG YAN, BING MIAO, CHARLES C. HAN, *PPCL, Joint Laboratory of Polymer Science and Materials, Institute of Chemistry, Chinese Academy of Sciences, Beijing 100080, China* AN-CHANG SHI, *Department of Physics and Astronomy, McMaster University, Hamilton, Ontario L8S 4M1, Canada* The effects of confinement, in terms of size and geometry, on the order-disorder transition (ODT) in diblock copolymer melts are studied theoretically. Confinements are applied by restricting diblock copolymers in given geometries of slab, cylinder and sphere, respectively. Within the frame of self- consistent field theory, the second-order fluctuation of free energy functional is studied, and its minimum determines the spinodal point of the homogeneous phase. For the slabs and cylindrical cases the spinodal point $(\chi N)_s$ of the homogeneous phase is independent of the confinement, while in spherical case $(\chi N)_s$ is increased except some suitable radius of the sphere. In addition, using the idea that before nucleation there are fluctuations of the orientation of polymer chains, the puzzling direction of lamellae in the crystallization under confinement can be explained.

**10:00**

**N30 11 Effect of Cross-linking on the Structure and Thermodynamics of Lamellar Block Copolymers** ENRIQUE GOMEZ, NITASH BALSARA, *University of California, Berkeley* JAYAJIT DAS, ARUP CHAKRABORTY, *Massachusetts Institute of Technology* The effect of cross-linking on the structure and thermodynamics of a lamellar poly(styrene-itblock-isoprene) copolymer was studied using small angle X-ray scattering (SAXS), depolarized light scattering (DPLS) and transmission electron microscopy (TEM). The selective cross-linking of the polyisoprene block took place either in the disordered state, in an isotropic ordered state, or in a shear-aligned ordered state. Using DPLS and TEM, the grain structure as a function of cross-linking density was studied. The order-disorder transition temperature for various block copolymer networks was determined as function of cross-linking density, and comparisons are made to a mean-field theory.

**10:12**

**N30 12 Influence of Conformational Asymmetry on the Phase Behavior of Ternary Homopolymer/Block Copolymer Blends around the Bicontinuous Microemulsion Channel** NING ZHOU, TIMOTHY LODGE, FRANK BATES, *University of Minnesota* We have developed a new ternary polymeric system, poly(ethylene-alt-propylene) (PEP) / poly(butylene oxide) (PBO) / PEP-PBO, to study the complex phase behavior near the bicontinuous microemulsion phase channel. The molecular weights of the PEP and PBO homopolymers are 2600 and 3050 g/mol, respectively, and copolymer is 23.4 kg/mol with volume fraction composition fPBO = 0.49. A combination of small-angle neutron scattering, small-angle X-ray scattering, rheology, optical microscopy and visual oil bath measurements was employed to map out the phase diagrams at five fixed homopolymer PBO/PEP ratios, ranging from 40/60 to 60/40 by volume, with copolymer concentrations ranging from 0 to 100%. It was found that the bicontinuous microemulsion channel is consistently cut off at low temperature by a hexagonal phase. We attribute this phenomenon to the effect of the conformational asymmetry between the PEP and PBO

species, whereby the more flexible PBO component induces a spontaneous curvature toward the PBO domains. These findings complement previous descriptions of the isopleth phase diagrams for the A/B/A-B systems, and identify a new design variable for preparing bicontinuous phases.

**10:24**
**N30 13 Swelling and Shrinkage of Lamellar Domain of Conformationally Restricted Block Copolymers by Metal Chloride*** DONG HYUN LEE, JIN KON KIM, *Department of Chemical Engineering, Pohang University of Science and Technology* JUNE HUH, *School of Materials Science and Engineering, Seoul National University* DU YEOL RYU, *Department of Chemical Engineering, Yonsei University* The lamellar domain spacing (D) of symmetric polystyrene-block- poly(2-vinyl pyridine) copolymer (PS-P2VP) and PS-block-poly(4- vinyl pyridine) copolymer (PS-P4VP) with cadmium chloride (CdCl2) were studied by using rheometry, small angle X-ray scattering and transmission electron microscopy. With increasing amount of CdCl2, D of PS-P2VP increased greatly, but it decreased for PS-P4VP. This is due to different types of the coordination between CdCl2 and nitrogen atoms in the 2-position of pyridine ring (intra-chain coordination), compared with nitrogen atoms in the 4-position (inter-chain coordination).

*This work was supported by the Creative Research Initiative Program (KOSEF).

**10:36**
**N30 14 Azimuthal Orientational Correlations due to Excluded Volume Epitaxy in Growing Anisotropic Grains** ASHOUTOSH PANDAY, SAMUEL GIDO, *University of Massachusetts, Amherst, MA 01003* The understanding of the microstructure of anisotropically shaped grains can have a strong influence on a range of material properties, including transport, mechanical and electro-optical properties. A grain-structure related phenomenon, called Excluded Volume Epitaxy (EVE) is reported in this study. EVE is a local, inter-grain orientational correlations effect, which results from a combination of sporadic nucleation of anisotropic grains and impingement of growing grains. Due to EVE, the anisotropically shaped grains have a tendency to be similarly aligned in a local neighborhood, despite the fact that there is no global orientation in the sample. This effect has been verified by transmission electron microscope (TEM) images of lamellar block copolymers and optical micrographs of small molecule crystals. Additionally, to quantify the effect of EVE, a modeling and simulation study involving random nucleation and subsequent growth of anisotropic grains was performed. The simulation study revealed a tendency for azimuthal, inter-grain orientational correlation and re-confirmed the experimental observation of EVE.

**SESSION N31: CARBON NANOTUBES: THEORY**
**Wednesday Morning, 15 March 2006**
**328, Baltimore Convention Center at 8:00**
**Dimitrios Papaconstantopoulos, Naval Research Laboratory, presiding**

**8:00**
**N31 1 Cyanide Nanotubes** YINA MO, EFTHIMIOS KAXIRAS, *Harvard University* The discovery of carbon nanotubes (CNTs) has given birth to an entire field devoted to the study of these one-dimensional (1D) nano-scale structures with extraordinary properties and tremendous promise for applications. To mention but a few, single wall carbon nanotubes are reported to exhibit Luttinger liquid behavior and proximity-induced superconductivity, and can be efficient hydrogen storage systems. The electronic properties of a carbon nanotube are fully determined by its helicity and range from metallic to semiconducting. However, when growing nanotubes, it is not possible to control the helicity; thus, carbon nanotube properties are not a result of design but luck. To overcome this limitation, Cohen and coworkers predicted the existence of insulating boron-nitride nanotubes (BNTs) and Zettl produced such tubes experimentally; these tubes are semiconducting and their properties vary less with helicity. Here we propose another type of structurally simple and energetically stable nanotubes consisting of transition metals and cyanide units. which are semiconductors with large band gaps ( $\sim 2 - 3$ eV). Using first-principles calculations, we study the properties of these nanotubes and find that their helicity does not significantly affect the electronic band gap. The nature of bonding in these systems singles out a particular helicity as energetically more stable, suggesting that only one type of tube will be predominantly formed with well defined electronic properties.

**8:12**
**N31 2 Electronic Structure of Core-Shell Semiconductor Nanowires** LI YANG, MEI-YIN CHOU, *Georgia Institute of Technology* We investigate the electronic structure of silicon/germanium core-shell nanowires with first-principles calculations using the local density approximation (LDA) with pseudopotentials and plane waves. The atomic configurations of the core-shell nanowires are fully relaxed. By examining the wave functions in real space, the electronic states at the band edge are found to be localized in either the core or the shell part of the nanowire. The band offsets are calculated for different core-shell structures. Given the cylindrical band offsets and the associated confined electronic states, a novel doping mechanism in nanowires is proposed for the manufacturing of high-speed nano-devices.

**8:24**
**N31 3 Dielectric properties of carbon nanotubes from first principles*** BORIS KOZINSKY, NICOLA MARZARI, *Massachusetts Institute of Technology* We characterize the response of single- (SWNT) and multi-wall (MWNT) carbon nanotubes to static electric fields using first-principles calculations and density-functional theory. The longitudinal polarizability of SWNTs scales as the inverse square of the band gap, while in MWNTs it is given by the sum of the polarizabilities of the constituent tubes. The transverse polarizability of SWNTs is insensitive to band gaps and chiralities and is proportional to the square of the effective radius; in MWNTs the outer few layers dominate the response. The transverse response is intermediate between metallic and insulating, and a simple electrostatic model based on a scale-invariance relation captures accurately the first-principles results. Dielectric response in both directions remains linear up to very high values of the applied field.

*Supported by NSF/NIRT.

**8:36**
**N31 4 Atomic-scale and electronic structure of double-walled carbon nanotubes.** KYLE RITTER, NOUREDDINE TAYEBI, JOSEPH LYDING, *Beckman Institute for Advanced Technology, University of Illinois, Urbana-Champaign* Ultra-high vacuum scanning tunneling microscopy (STM) and spectroscopy have been used to elucidate the electronic and atomic-scale structure of double-walled carbon nanotubes[1] (DWNTs) on the Si(100) 2x1:H

surface. Atomically clean DWNT-surface interfaces were facilitated by an itin situ deposition method[2] which enables simultaneous resolution of the DWNT chirality and surface atomic structure. A key result includes the observation of periodic 2.7 nm spatial modulation superimposed on the nanotube chirality at both positive and negative scanning biases for a 2 nm diameter semiconducting DWNT. The periodic modulation of the DWNT topography suggests the lattices of the inner and outer nanotubes produce an interference pattern depending on the relative alignment of the constituent carbon atoms. Experimental data (diameter, chiral angle, and local density of state measurements) will be supplemented with simulated STM images which illustrate subtle changes in the outer nanotube topography depending on the inner nanotube chirality. 1. DWNTs synthesized by Nanocyl (www.nanocyl.com) 2. P.M. Albrecht and J.W. Lyding. Appl. Phys. Lett. 83, 5029 (2003).

**8:48**

**N31 5 All-electron electronic properties of carbon nanotubes through multiresolution analysis** IVAN P. DAYKOV, TOMÁS A. ARIAS, *Department of Physics, Cornell University, Ithaca, NY, 14853* Utilizing our latest developments of density functional calculations using multiresolution wavelet-like basis we compute the electronic properties of carbon nanotubes by including all electrons.

**9:00**

**N31 6 Molecular Dynamics Simulations of DNA-Functionalized Carbon Nanotube Chemical Sensors** ROBERT JOHNSON, MICHAEL KLEIN, ALAN JOHNSON, *University of Pennsylvania* We have conducted all-atom classical molecular dynamics simulations onDNA-functionalized carbon nanotube chemical sensors, including the presence of water. Our simulations verify that single stranded DNA (ssDNA) binds to a single-wall carbon nanotube (swCN) via a pi-pi stacking interaction. Preliminary simulations of a partially hydrated system also suggest that the ssDNA conformation about a swCN exhibits nanoscale pockets that can result in additional binding sites for analytes. Molecular dynamics simulations have also been performed to determine binding orientations of analytes adsorbed to the swCN-ssDNA system. To determine possible chemical gating effects of analytes on the swCN, we numerically calculate changes in the electric potential at the surface of the swCN due to the introduction of ssDNA and analytes. Results of further simulations of a fully hydrated system will also be presented.

**9:12**

**N31 7 Fluxional handles for direct control of conductance in functionalized carbon nanotubes** YOUNG-SU LEE, NICOLA MARZARI, *Department of Materials Science and Engineering, Massachusetts Institute of Technology* A class of covalent functionalizations for single-wall carbon nanotubes is identified — from extensive first-principles calculations — that preserves the conduction channels of metallic nanotubes. Cycloaddition of carbenes or nitrenes can induce bond cleaving between two adjacent sidewall carbons, restoring their original $sp^2$ hybridization and recovering in the process a transparent $\pi$ manifold, radically at variance with the strong scattering permanently induced by other common covalent functionalizations. The chirality and curvature of the nanotube and the chemistry of the addends can force or inhibit this bond cleavage, that in turn controls very distinctly the transport properties of the functionalized conductor. A well-defined range of diameters can be found for which certain addends —such as dicyanocarbene—exhibit a bistable switchable state, where the opening or closing of the sidewall bonds, and the accompanying on/off switch in the conductance, can be directed with chemical, electrochemical or optical means.

**9:24**

**N31 8 Silicon-carbon nano-structures to nano-tubes.*** M.N. HUDA, LEONARD KLEINMAN, *University of Texas at Austin, Austin, Texas 78712* A.K. RAY, *University of Texas at Arlington, Arlington, Texas-76019* There have been continuing efforts to stabilize silicon cage-type nano-structures or nano-tubes which can be used in similar ways as the carbon-based fullerene structures. This is due to the fact that the current semiconductor industries are based on silicon. Silicon carbide is the focus of scientific research due to its potential use even in extreme conditions, such as extreme high-temperature, high-power capabilities and high radiation conditions. In the present study, a set of novel silicon carbon nanosructures ($Si_{2n}C_n$) in tubular form have been studied which can be extended to form silicon carbide nano-tubes. Generalized gradient approximation to density functional theory has been used with an all electron basis set to study the stability of these structures. A frequency analysis has been performed to ensure that all the frequencies are real. A slight structural shift has been predicted between the hydrogen saturated and –unsaturated nano-tubes.

**N31 9 *Ab initio* study of semiconducting carbon nanotubes adsorbed on the Si(100) surface: diameter- and registration-dependent atomic configurations and electronic properties*** SALVADOR BARRAZA-LOPEZ, PETER M. ALBRECHT, NICHOLS A. ROMERO,[†] KARL HESS, *University of Illinois* We present a theoretical study within density functional theory in the local density approximation of semiconducting carbon nanotubes adsorbed on the unpassivated Si(100) surface. We find that the interaction between the nanotube and silicon surface results in significant atomic re-arrangment of the surface atoms. Since the spatial configuration of the surface dimers determines to a great extent the electronic properties of the surface, our first-principles calculations indicate a tendency towards metallicity for the semiconducting tube-Si(100) surface system. We confirm this for nanotubes of different diameters and chiral angles, and find the effect to be independent of the orientation of the nanotubes on the surface. **N31 10 A plasmon absorption model for a super-lattice of single-walled carbon nanotubes** M. E. MARKES, *University of Nebraska-Kearney* P. F. WILLIAMS, *University of Nebraska-Lincoln* Several years ago one of us (P. F. Williams*) developed a self-consistent dielectric response model for one-dimensional metals at high frequency using a tight-binding approximation. At the time this model was found useful in a study of the single-particle excitations and plasmon dispersion curves of tetrathiofulvalene-tetracyano-quinodimethane (TTF-TCNQ). This paper is a report of

work in progress to extend this model to arrays of single-walled carbon nanotubes. First the quasi one-dimensional model is extended to represent free electrons confined to the surfaces of cylindrical shells arranged in a 2-D square array. The collective electronic excitations of this system are characterized by a frequency and wavelength dependent complex dielectric constant obtained using the method of self-consistent fields in the random phase approximation. Progress in extending the model to arrays of shells with surface structure will also be discussed.

**N31 11 Numerical Results for SU(4) and SU(2) Kondo Effect in Carbon Nanotubes** GEORGE MARTINS, *Department of Physics, Oakland University, Rochester, MI 48309* CARLOS BUSSER, *Condensed Matter Sciences Division, Oak Ridge National Laboratory, Oak Ridge, Tenessee, 37831* New numerical results are presented for the Kondo effect in Carbon Nanotube (CNT) quantum dots (QDs). As recently reported by P. Jarillo-Herrero *et al.* (Nature **434**, 484 (2005)), the Kondo effect in CNTs presents an SU(4) symmetry, which arises from the entanglement of orbital and spin degrees of freedom. As the number of cotunneling processes increases, thanks to the extra (orbital) degree of freedom, the Kondo temperature reaches a high value of $T_K = 7.7K$. Interesting considerations can be drawn regarding the change from SU(4) to SU(2) symmetries depending on the hopping matrix elements between the leads and the CNT QD. Our results will analyze the transition between the SU(4) and the so-called two-level SU(2) (2LSU(2)) Kondo regimes induced by the variation of the coupling of the QD to the leads. The effect of an external magnetic field along the tube direction will also be analyzed. Our results will be compared with available Numerical Renormalization Group (NRG) results by M-S Choi *et al.* (Phys. Rev. Lett. **95**, 067204 (2005)). A comparison with the experimental results will be made to gauge the adequacy of the model and approximations made.

**N31 12 Deep levels in the band gap of the carbon nanotube with vacancy-related defects*** GUNN KIM, *N.C. State University, USA* BYOUNG WOOK JEONG, JISOON IHM, *Seoul National University, Korea* We study the modification in the electronic structure of the carbon nanotube induced by vacancy-related defects using the first-principles calculation. Three defect configurations which are likely to occur in semiconducting carbon nanotubes are considered. A vacancy-adatom complex is found to bring about a pair of localized states deep inside the energy gap. A pentagon- octagon-pentagon topological defect produced by the divacancy is structurally stable and gives rise to an unoccupied localized state in the gap. We also discuss the character of partially- occupied localized state produced by a substitutional impurity plus a monovacancy.

**N31 13 Transport Properties in Carbon Nanotubes films for Hydrogen Sensor Applications*** JIANWEI ZHANG, YAO HE, CHAO CAO, LEX KEMPER, HAI-PING CHENG, *Department of Physics and Quantum Theory Project, University of Florida* Thin single-walled carbon nanotue (CNT) films doped with palladium (Pd) on surface are shown to be promising in hydrogen(H2) sensor applications. We study electronic transport properties of CNT/Pd/H2 system by combining first-principles band structure calculations with Boltzmann transport theory. The coupling between Pd atoms and carbon nanotues is described by the Kondo model. An effective scattering potential, which creates the major resistance in nanotubes, is calculated by fitting potential parameters to the calculated band structures. In addition, intersection resistance between the nanotubes is also included in our simulations. We will present the band structure of the CNT/Pd system with and without the hydrogen atoms or hydrogen molecules. The conductance change of the whole nanotube films in the presence of hydrogen gas will be shown.

**N31 14 Theoretical Study of Iron Filled Carbon Nanotubes** MARIANA WEISSMANN, *C.N.E.A., Buenos Aires, Argentina* GRISELDA GARCIA, MIGUEL KIWI, RICARDO RAMIREZ, *Facultad de Fisica, PUC, Chile* CHU-CHUN FU, *CEA, Saclay, France* We have investigated, using ab-initio methods, the geometry and magnetic structure of free standing and encapsulated iron nanowires, both in perfect and defective single wall carbon nanotubes. The geometries adopted consist of two layers of iron atoms per unit cell, arranged in hcp(0001) and bcc(011) structures, repeated periodically along the wire axis, When the ratio of the nanowire to nanotube diameter is small there is an attractive interaction among them and the density of states at the Fermi energy corresponds to a single spin orientation, as for the free standing nanowires. These systems are therefore potentially interesting for spintronics. When the same ratio is close to one the systems are less stable and a tendency towards antiferromagnetic ordering is observed due to the confinement.

**N32 1 The Solid-State Fabrication, Structure, and Multifunctional Applications of Strong Carbon Nanotube Yarns and Transparent Sheets .***
R.H. BAUGHMAN, *University of Texas at Dallas*

We describe novel methods for producing polymer-free carbon nanotube yarns and transparent sheets (self-assembled textiles), and describe their application as multifunctional materials. These fabrication methods are conducted at room

temperature in the solid state for multi-walled carbon nanotubes, which are much cheaper to produce that our previously used single-walled carbon nanotube fibers. The yarns have a maximum failure strength of above 460 MPa (850 MPa after polymer infiltration), they are highly resistant to creep and to knot or abrasion-induced failure, and they provide a giant Poisson's ratio for stretch in the fiber direction. The nanotube textiles have higher gravimetric strength than the strongest steel sheet or the polymers used for ultralight air vehicles and proposed for solar sails. Applications evaluations are described for artificial muscles, thermal and light harvesting, energy storage, field-emission electron sources, electrically conducting appliques, three types of lamps and displays, and sensors.

**N32 2 Mechanical Reinforcement of Functionalized Carbon Nanotube-Polyethylene Polymer Composites** MERLYN PULIKKATHARA, VALERY KHABASHESKU, *Rice Quantum Institute, Rice University* Carbon nanotube-polymer composites are promising materials for a variety of applications including space exploration and the aerospace industry. In this work, we functionalized and fabricated a series of single walled carbon nanotube (SWNT) composite samples using medium density polyethylene (MDPE). The composites were made by shear mixing melt processing of MDPE with up to 1 wt.% added pristine and functionalized SWNTs including fluoro (F), undecyl and urea SWNT-derivatives. The former two were prepared as described earlier, while the synthesis of the latter is a novel method that has been developed utilizing a solvent free reaction of fluoro-SWNT with molten urea. FTIR, Raman, and AFM data confirm that urea bonds covalently to the SWNT surface and displaces most of the fluorine. Initial tensile strength (TS) of the MDPE composites loaded with urea-F-SWNT reinforced 48% and undecyl-functionalized SWNTs show unprecedented reinforcement up to 185% compared to neat MDPE. These preliminary results show that these functionalized SWNT increased the mechanical strength in of MDPE composites. The FTIR, Raman, AFM, SEM, TEM, XPS, TGA, and TS data of studied materials will be presented.

**8:48**

**N32 3 Adhesion and Reinforcement in Carbon Nanotube Polymer Composite** CHENYU WEI, *NASA Ames Research Center* The temperature dependent adhesion behavior and reinforcement in carbon nanotube(CNT)-polymer (polyethylene) composite is studied through molecular dynamics (MD) simulations. The interfacial shear stress through van der Waals interactions is found to increase linearly with applied tensile strains along the nanotube axis direction, until the non-covalent bonds between CNTs and molecules break successively. A lower bound value about 46 MPa is found for the shear strength at low temperatures. Direct stress-strain calculations show significant reinforcements in the composite in a wide temperature range, with $\sim$ 200% increase in the Young's modulus when adding 6.5% volume ratio of short CNTs, and comparisons with the Halpin-Tsai formula are discussed.

**N32 4 Multi-scale Real-Space Characterization of Carbon Nanofiber Composites** BENJI MARUYAMA, *Air Force Research Laboratory, Materials & Manufacturing Directorate* SIRINA PUTTHANARAT, *University of Dayton Research Institute* LAWRENCE DRUMMY, RICHARD VAIA, JONATHAN SPOWART, *AFRL, Materials & Manufacturing Directorate* CARLA LEER, FERRIE VAN HATTUM, *University of Minho, Portugal* Good dispersion of the reinforcement phase in nanocomposites is recognized as critical to achieving material property goals. Hierarchical nanocomposite morphologies can be quantified by a combination of 1) Reciprocal space methods such as scattering, 2) Real space imaging such as AFM and TEM, and/or 3) Inference from established structure-property models. However, none of these techniques alone has proven satisfactory to quantitatively characterize nanocomposite morphologies across multiple length scales and link them to properties. Nor have they been adequate to define quality control metrics for dispersion. The current effort is devoted to characterizing dispersion in carbon nanofiber composites from the nano- to meso-scales (i.e., 10 nm - 10 mm) using the Multi-Scale Analysis of Area Fractions (MSAAF) technique of Spowart et al. This technique uses a fractal analysis of real space images to generate a homogeneous length scale (scale at which the statistical variability in concentration is at some threshold), and a fractal dimension characteristic of the dispersion over a wide range of length scales. This work is part of a larger effort to determine structure/property relations of complex materials systems.

**9:12**

**N32 5 Radial Elasticity of Nanotubes** ISMAEL PALACI, STEPHAN FEDRIGO, HARALD BRUNE, *Swiss Federal Institute of Technology (EPFL), Institute of the Physics of Nanostructures, Lausanne, Switzerland* CHRISTIAN KLINKE, *IBM Watson Research Center, Nanoscale Science Department, New York, USA* ELISA RIEDO, *Georgia Institute of Technology, School of Physics, Atlanta, USA* The last decade has lead to the discovery of many nanostructures like nanotubes, nanowires or nanobelts. Industrial applications of these nanostructures need practical tools to characterize their optical, electrical or mechanical properties. Here we propose to use state of the art atomic force microscopy to characterize the radial elasticity of nanotubes of different diameters. The nanostructures were elastically strained in the radial direction by applying small indentation amplitudes. In the case of multiwalled carbon nanotubes, this method enables to extract the radial Young modulus from compliance measurements. We find 600 GPa for our smallest tubes with a radius $R = 2.2$ nm. The values strongly decrease with increasing radii until they reach an asymptotic value of $30 \pm 10$ GPa at $R \geqslant 4$ nm. The normal force vs. indentation curves are in qualitative agreement with molecular dynamics simulations.

**9:24**

**N32 6 Dissipation in suspended carbon nanotube oscillators*** P. ALEX GREANEY, JEFFREY C. GROSSMAN, *University of California, Berkeley* The vibrational properties of doubly clamped suspended single walled carbon nanotubes are studied numerically using continuum, and atomistic methods. Of interest is the dissipation of energy in athermally excited modes. Simple continuum arguments may be used to bound the limits of energy dissipation that arise due to the scale of the nanotubes; however, more detailed atomistic descriptions are required to capture the dissipation due to coupling between phonon modes. This work has implication for the use of carbon nanotubes as high frequency resonators in nanomechanical systems.

*This material is based upon work supported by the National Science Foundation under Grant No.EEC- 0425914.

**N32 7 Structure and Mechanical Properties of Model Nanotube Composites** ANDREW B. SCHOCH, KENNETH R. SHULL, L. CATHERINE BRINSON, WESLEY R. BURGHARDT, THOMAS O. MASON, NEIL J. KIDNER, SUPAPORN WANSOM, LETA Y. WOO, *Northwestern University* Thermoreversible gels based on solutions of acrylic triblock copolymers have been infused with multi-walled carbon nanotubes at various loadings. The fast transition between liquid and solid states allows for the nanotubes to be frozen into their positions. These composite materials exhibit distinct mechanical and electrical properties from the bulk gel. The storage modulus of the filled gels persists at temperatures well above the gel transition and signifies elasticity that comes solely from the nanotube inclusions. The magnitude of this additional elasticity at high temperatures increases dramatically with increasing nanotube volume fraction above a ''percolation'' threshold that is extremely low. Sensitivity to nanotube interactions is enhanced by the low background levels of gel elasticity above the gel transition temperature. Complementary alternating current impedance spectroscopy measurements were performed to asses the onset of electrical percolation in these systems.

**N32 8 In vivo MRI of single-wall carbon nanohorns through magnetite nanoparticle attachment** JIN MIYAWAKI, *JST/SORST* MASAKO YUDASAKA, *JST/SORST and NEC* HIDETO IMAI, *NEC* HIDEKI YORIMITSU, HIROYUKI ISOBE, EIICHI NAKAMURA, *The University of Tokyo* SUMIO IIJIMA, *JST/SORST and NEC* Superparamagnetic magnetite (SPM) is used as a contrast agent in magnetic resonance imaging (MRI). Thus, the SPM-attachment to carbon nanotubes (CNTs) will enable to visualize motional behaviors of CNTs in the living body through MRI. We found that the strong attachment of the SPM nanoparticles (ca. 6 nm size) to one type of CNTs, single-wall carbon nanohorns (SWNHs), could be achieved through a deposition of iron acetate clusters on SWNHs in ethanol at room temperature, followed by heat-treatment in Ar. In vivo MRI visualized that the SWNHs attached with the SPM nanoparticles accumulated in several organs of mice when injected into mice via tail veins. This simple method for the SPM-attaching on CNTs would facilitate the toxicity assessment of CNTs and the applications of CNTs in bioscience and biotechnology.

**N32 9 Sensor applications and spin-transport measurements in carbon nanotube nanocomposites** J. SANDERS, J. GASS, H. SRIKANTH, *Functional Materials Lab, Dept. of Physics, University of South Florida-Tampa, 33620, USA* F.K. PERKINS, E.S. SNOW, *Nanotechnology Section, U.S. Naval Research Lab, Washington, D. C* Vertical and horizontal carbon nanotubes have been grown at USF using CVD and PECVD techniques with Ni and Fe nanoparticle catalysts. At NRL we have used CVD to produce carbon nanotube networks on $SiO_2/Si^{++}$ substrates to build sensors for chemical and bio agents by measuring capacitance and conductance. Various chemical vapors are able to be sensed with a fast response and recovery as well as a high degree of selectivity. A microfluidic flow system has been developed to extend the sensing applications to biological analytes. It is also known that carbon nanotubes are excellent transmission channels for charge and spin transport. In addition to the biosensors, we will also report on our experiments probing charge and spin transport through nanotube networks using point contact Andreev reflection (PCAR) based on superconducting and ferromagnetic junctions. Work at USF supported by DARPA/ARO through grant # W911NF-05-1-0354.

**N32 10 Characterisation of a Hydroxyapatite and Carbon Nanotube Bioceramic Composite** C. KEALLEY, B. BENNISSAN, *University of Technology, Sydney, Australia* A. VAN RIESSEN, *Curtin University of Technology, Australia* M. ELCOMBE, *Australian Nuclear Science and Technology Organisation, Australia* A biocompatible composite for bone replacement applications was investigated. The effects that the microstructure may have on the mechanical properties of the bioceramic have been assessed. Hydroxyapatite was prepared as reported previously[1] with 2, 5 and 10 wt% of carbon nanotubes (CNTs) being incorporated during the production before hot isostatic pressing. Microstructural analysis of the composite has been undertaken by SEM/EDS, TEM/EDS, XRD and ND. The effects of concentration of the CNTs on the mechanical properties of the composite material have been determined. At 2 wt% excellent densification has been achieved, and there is a significant improvement in Vickers Hardness and Young's Modulus. However, as expected fracture toughness is reduced. **10:24**

**N32 11 The physical properties and possible applications of metal coated carbon nanotubes** ENGIN DURGUN, *Bilkent University* SEFA DAG, *ORNL* SALIM CIRACI, *Bilkent University* We show that Ti atoms can form a continuous coating of carbon nanotubes at various amounts of coverage. The circular cross section of the tubes changes to a square-like form, and the semiconducting tube becomes a ferromagnetic metal with high quantum ballistic conductance. Metallicity is induced not only by the metal-metal coupling, but also by the band gap closing of SWNT at the corners of the square. The magnetic properties of Ti coated tubes depend strongly on the geometry, amount of Ti coverage and also on the elastic deformation of the tube. While the magnetic moment can be pronounced significantly by the positive axial strain, it can decrease dramatically upon the adsorption of additional Ti atoms to the monolayer coting of the nanotube. Besides, electronic structure and spin- polarization near the Fermi level can also be modified by radial strain. On the other hand, it is found that Ti and V

decorated carbon nanotubes of various radii and chirality can adsorb large amounts of hydrogen molecules and can be possible candidates for hydrogen storage applications. The other transtions metals like Fe, Co, Cr, and Mn cannot cover nanotube surface uniformly but can only be adsorbed in clustered forms. Depending on the geometry and amount of adsorption these systems can posses high polarization near Fermi level with variable magnetic moments which can be useful in spintronic devices.

**10:36**
**N32 12 Field Emission from Carbon Nanotubes: From Isolated Nanotubes to Matrix Cathodes.** DAVID CAREY, RICHARD SMITH, RAVI SILVA, *University of Surrey* The high aspect ratio and current carrying ability of carbon nanotubes (CNTs) make them an attractive material for electron sources. Field screening effects are known to occur at high nanotube densities and most large area field emission characteristics (FECs) reflect ensemble averages of the sites with the lowest effective potential barriers. We have studied the FECs and enhancement factor from isolated nanotubes mounted on high resolution manipulators within a scanning electron microscope. We have further developed an in-situ three terminal characterisation facility allowing estimates of the screening factor of the gate electrode and gate transparency. Measurements of the FEC of carbon nanotube – polymer spin cast composites cathodes have also been made. A range of samples with arc discharge nanotube mass fractions up to 7 % was prepared. Electron emission at low applied electric fields is observed. The transport and emission mechanism of the electrons is discussed in terms of a polymer coating that surrounds the nanotube and acts as a tunnel barrier. This gives rise to fluctuation induced tunnelling between the nanotubes which affects the field emission. The effects of the disordered percolation control network on the field emission along with prospects for applications are discussed.

**10:48**
**N32 13 Thermal Field Emission from a Single Carbon Nanotube** GONGPU ZHAO, JIAN ZHANG, QI ZHANG, HAN ZHANG, *Department of Physics and Astronomy, University of North Carolina at Chapel Hill, Chapel Hill, NC 27599-3255* TIE TANG, *National Institute for Materials Science, Tsukuba 305-0047, Japan* OTTO ZHOU, LU-CHANG QIN, *Department of Physics and Astronomy, University of North Carolina at Chapel Hill, Chapel Hill, NC 27599-3255* Carbon nanotubes (CNTs) exhibit excellent characteristics in field-induced electron emission with high brightness, stable emission current, long service time and narrow energy distribution. But it is still not clear how carbon nanotubes behave under high electric field and high temperature. We have characterized the thermal field emission properties of an individual multiwalled carbon nanotube fabricated by a two step process. The characterization was conducted in the transition zone between thermionic emission and field emission. An approximation has been made to the Murphy-Good equation so that the temperature at the CNT apex can be extracted. The boundary of transition zone was determined experimentally by activating thermal field emission at various temperatures. We also show that higher temperature will improve the emission stability and remove disruptions in the emission current.

**N33 1 Nonlinear dynamics and flow transitions in viscoelastic shear flows.***
R. SURESHKUMAR, *Washington University, St. Louis, MO 63130*

Dynamical explorations of viscoelastic flows are of fundamental and practical interest. Elastic forces cause flow instability even in the absence of inertia (creeping flow) and greatly modify the onset and ensuing sequence of flow transitions in flows with finite inertia. While past research has yielded much progress, literature on several intriguing nonlinear phenomena has been only slowly emerging. These include: (i) nonlinear transitions in itlinearly itstable, parallel shear flows, (ii) influence of elastic instability on itpressure-flow rate relationship under creeping flow conditions, (iii) effect of elasticity on itpattern formation in itcurved shear flows and (iv) novel instabilities caused by thermal effects induced by itviscous heating. The recent advances and challenges in the abovementioned areas will be discussed.

**N33 2 Low-dimensional models for coherent states in viscoelastic turbulent shear flows** ANSHUMAN ROY, *University of Michigan, Ann Arbor* ALEXANDER MOROZOV, WIM VAN SAARLOOS, *Leiden University* RONALD LARSON, *University of Michigan, Ann Arbor* We present low-dimensional models for the sustenance of turbulence in shear flows of viscoelastic liquids. We develop these models by systematically investigating the effect of incremental amounts of elasticity on the self-sustaining process maintaining turbulence in shear flows. The recently proposed (Waleffe, 1997) self-sustaining process for shear flows consists of streamwise rolls leading to redistribution of the mean shear into spanwise streaks. A Kelvin-Helmholtz instability of the spanwise streaky flow then results in the regeneration of the streamwise rolls via nonlinear interactions. With the help of our low-dimensional model, we are able to identify which part of the cycle is interrupted or enhanced by the presence of elasticity. Additionally, we explore the effect of fluid rheology on the flow kinematics, particularly the role played by the first and second normal

stress differences. For Newtonian liquids, such low-dimensional models have demonstrated their utility by helping to understand the features of full numerical solutions of turbulent flows. We believe that our low dimensional model for viscoelastic turbulent flow will help interpret experiments and direct numerical simulations of turbulent drag reduction by polymers.

**N33 3 Instabilities in the oscillatory flow of a complex fluid** JORDI ORTIN, MIREIA TORRALBA, *Dept. ECM, Universitat de Barcelona, Spain* ALFONSO A. CASTREJON-PITA, GABRIELA HERNANDEZ, GUADALUPE HUELSZ, JOSE ANTONIO DEL RIO, *Centro de Investigacion en Energia, UNAM, Mexico* The dynamics of both a Newtonian and a viscoelastic shear- thinning fluid, subjected to an oscillatory pressure gradient in a vertical tube, is studied experimentally. PIV is used to determine the 2d velocity fields in the vertical plane of the tube axis, for driving amplitudes from 0.8 to 2.5 mm and driving frequencies from 2.0 to 11.5 Hz. The Newtonian fluid exhibits always a laminar flow regime, independent of the axial position. For the complex fluid, instead, the parallel shear flow regime exhibited at low amplitudes [Torralba et al., Phys. Rev. E **72**, 016308 (2005)] becomes unstable at higher drivings against the formation of symmetric vortices, equally spaced along the tube. At even higher drivings the vortex structure itself becomes unstable, and complex nonsymmetric structures develop. The system studied represents an interesting example of the development of shear-induced instabilities in nonlinear complex fluids in purely parallel shear flow.

**9:00**

**N33 4 Instability of a Sheared Fluid-Gel Interface** SATISH KUMAR, *University of Minnesota* SHENG LIN-GIBSON, ERIK K. HOBBIE, *NIST* The planar interface between a viscous fluid and an elastic gel is known to be unstable to simple steady shear flow [V. Kumaran and R. Muralikrishnan, Phys. Rev. Lett. **84**, 3310 (2000)]. By embedding a small number of micron-sized Latex particles at the planar interface between a Newtonian fluid and a soft viscoelastic gel, we use stroboscopic particle tracking to study the onset of this instability in the limit of large gel-to-fluid thickness ratios. The mean-square displacement of the interface and the power spectrum of displacement fluctuations are measured as a function of applied shear rate and gel modulus. Long-wavelength fluctuations with a periodic component are observed in the plane of flow and vorticity, with limited motion normal to the plane of the interface. By relating the power spectrum of fluctuations to the viscoelasticity of the gel, we discuss potential applications in the area of non-Brownian microrheology, where one exploits this instability to optically infer the rheological properties of an otherwise inaccessible soft phase.

**9:12**

**N33 5 DNS of Viscoelastic Turbulent Channel Flow at High Drag Reduction** ANTONY BERIS, *University of Delaware* KOSTAS HOUSIADAS, *Aegian University, Greece* LUO WANG, *University of Delaware* A new method has been developed to enable Direct Numerical Simulations (DNS) of viscoelastic turbulent channel flow with high accuracy spectral methods at high values of drag reduction (HDR), when the polymer molecules undergo high extensional deformation. To faithfully represent that we have expressed the conformation tensor, c, as the exponential of another tensor a, c=exp(a) and we solve for a instead of c. Thus, by construction, the positive definite property of c is always preserved. In addition, a stabilizing artificial diffusion has been added to the viscoelastic constitutive model and efficiently implemented numerically using a multigrid method. The Finite-Elasticity Non-Linear Elastic Dumbbell model with the Peterlin approximation (FENE-P) is then used to represent the effect of polymer molecules in solution. To achieve HDR we used high values of the key model parameters: (a) the maximum extensional viscosity, which for the FENE-P constitutive model is proportional to the quantity (1-$\beta$)*L[2], where $\beta$ is the solvent viscosity ratio and L is the maximum extensibility parameter and (b) the friction Weissenberg number, We$\tau$.

**9:24**

**N33 6 Time Dependent Drag Reduction by Long Chain Polymers in Taylor-Couette Flow** DANIEL D. LANTERMAN, *IREAP, Dept. of Physics, University of Maryland, College Park 20740* MATHEW FERGUSON, *IREAP, Dept. of Physics, University of Maryland, College Park 20740, National Institute of Health, Bethesda Maryland 20892* DANIEL P. LATHROP, *IREAP, Dept. of Physics, University of Maryland, College Park 20740* The addition of small amounts of long chain polymers has been shown to dramatically reduce the drag in some aqueous turbulent flows. We examined this effect in flow between concentric rotating cylinders (Taylor-Couette flow). The apparatus is instrumented to measure torque on the inner cylinder and can achieve Reynolds numbers up to $Re = 1.4 \cdot 10^6$. Reductions in drag of up to 47% are seen immediately after the addition of the polymer (typical concentrations 10-20 ppm), but this value decays over a time scale of tens of minutes. While the scission of individual polymer molecules may also be important, light scattering measurements, performed on liquid samples, suggest the formation of entangled aggregates of polymer molecules. The polymers used are polyacrylamide with mean molecular weights of 5.5 and 18 MDaltons. Tested concentrations range from 0.5 to 100 parts per million by mass. We examine the dependence on concentration and shear rate (Reynolds number).

**9:36**

**N33 7 Nonlinear traveling waves as a framework for understanding turbulent drag reduction** WEI LI, LI XI, MICHAEL GRAHAM, *Univ. of Wisconsin-Madison* Nonlinear traveling waves that are precursors to laminar-turbulent transition and capture the main structures of the turbulent buffer layer have recently been found in all the canonical parallel flow geometries. We study the effect of polymer additives on these ''exact coherent states'' (ECS), in the plane Poiseuille geometry. Many key aspects of the turbulent drag reduction phenomenon are found, including: delay in transition to turbulence; drag reduction onset threshold; diameter and concentration effects. The examination of the ECS existence region leads to a distinct prediction, consistent with experiments, regarding the nature of the maximum drag reduction regime. Specifically, viscoelasticity is found to completely suppress the normal (i.e. streamwise-vortex-dominated) dynamics of the near wall region, indicating that the maximum drag reduction regime is dominated by a distinct, and perhaps intrinsically elastic, flow structure.

**9:48**

**N33 8 Complex dynamics in simple models of shear banding** SUZANNE FIELDING, *School of Mathematics, University of Manchester* HELEN WILSON, *Department of Mathematics, University College London* PETER OLMSTED, *School of Physics and Astronomy, University of Leeds* Complex fluids commonly undergo flow instabilities and flow-induced transitions that result in spatially heterogeneous ''shear banded'' states. Often, these

banded states display oscillatory or chaotic dynamics, measured in the bulk rheological signals and in the motion of the interface between the bands. Until recently, however, theory predicted a steady state comprising stationary bands separated by a flat interface. We discuss recent theoretical progress in capturing complex dynamics of the banded state: first in a model in which the interface (or interfaces) remains flat but moves in a chaotic way; second in a model that explicitly allows for undulations along the interface.

**10:00**
**N33 9 Elastic Instabilities of Polymer Solutions in Extensional Flows*** PAULO ARRATIA, *University of Pennsylvania* JERRY GOLLUB, *Haverford College & University of Pennsylvania* When flexible polymer molecules (in dilute solution) pass near the hyperbolic point of a microchannel cross flow, they are strongly stretched. As the strain rate is varied at low Reynolds number $< 0.01$, tracer and particle-tracking experiments show that molecular stretching produces two flow instabilities, one in which the velocity field becomes strongly asymmetric, and a second in which it fluctuates non- periodically in time. The flow is strongly perturbed even far from the region of instability, and this phenomenon can be used to produce mixing. Bulk flow instabilities are not observed in dilute solutions of rigid polymers or Newtonian fluids under similar conditions.

*Work supported primarily by NSF DMR-0405187, with additional support by NSF DMR05-20020.

**10:12**
**N33 10 Delay of Disorder by Diluted Polymers** CHRISTIAN WAGNER, *Universitaet des Saarlandes* ANDRIY KITYK, *Technical University of Czestochowa* We study the effect of diluted flexible polymers on a disordered capillary wave state. The waves are generated at an interface of a dyed water sugar solution and a low viscous silicon oil. This allows for a quantitative measurement of the spatio-temporal Fourier spectrum. The primary pattern after the first bifurcation from the flat interface consists of squares. With increasing driving strength we observe a melting of the square pattern. It is replaced by a weak turbulent cascade. The addition of a small amount of polymers to the water layer does not affect the critical acceleration but shifts the disorder transition to higher driving strengths and the short wave length - high frequency fluctuations are suppressed.

**10:24**
**N33 11 Shear thickening, shear localization and elastic turbulence.** DANIEL BONN, *LPS/ENS and WZI Amsterdam* The vast majority of complex fluids is shear thinning. The mechanisms of shear thinning are relatively well understood, and the phenomenon is widely used to tailor the rheology of complex fluids. Shear thickening is the exception to this rule, is incompletely understood and hardly ever used to tailor fluid properties. We study shear thickening in granular pastes (cornstarch), and show that shear localization (banding) is an essential ingredient for shear thickening. For high flow rates, the shear banding is followed by elastic turbulence. Our measurements provide us with the mechanism of both shear thickening and the flow instabilities that result from it.

**10:36**
**N33 12 A Transitional Pathway to Turbulence in Elastic Fluids** BRUCE SCHIAMBERG, LAURA SHEREDA, HUA HU, RONALD LARSON, *University of Michigan* Multiple scenarios have been discovered by which laminar flow transitions to turbulence, where transitions are caused by inertia or temperature, in Newtonian fluids. Here we show in non-Newtonian fluids a transition sequence that is due to elasticity from polymers, with negligible inertia. Multiple states are found linking the stable base flow to ''elastic turbulence'' in the flow between a rotating and stationary disk, including circular and spiral rolls, and stationary and time-dependent modes. Also, a surprising progression from apparently ''chaotic'' flow to periodic flow and then to ''elastic turbulence'' is found. In these experiments, either shear stress or shear rate is incrementally increased and then held at fixed values. The modes we discover have distinct rheological signatures, and we also image the accompanying secondary-flow field kinematic structures. Finally, we have explored how polymer concentration and gap-to-radius ratio affect (and possibly limit) the transitional pathway. The most concentrated solution tested appears to stabilize an additional, time-periodic mode. In conclusion, we have studied an unexplored route, which we hope, in time, will make it possible to compare experimentally and theoretically the routes to purely elastic turbulence with those for inertial turbulence, leading to a richer understanding of both.

**N35 1 Structural properties of Complex networks.**
JOSÉ MENDES, *University of Aveiro*

The k-core decomposition was recently applied to a number of real-world networks (the Internet, the WWW, cellular networks, etc and was turned out to be an important tool for visualization of complex networks and interpretation of cooperative processes in them. Rich k-core architectures of real networks were revealed. The k-core is the largest subgraph where vertices have at least k interconnections. We find the structure of k-cores, their sizes, and their birth points — the bootstrap percolation thresholds. I will show a derivation of exact equations describing the k-core organization of a randomly damaged uncorrelated network with an arbitrary degree distribution. This allows us to obtain the sizes and other structural characteristics of k-cores in a variety of damaged and undamaged random networks and find the nature of the k-core percolation in complex networks. These general results will be applied to the classical random graphs and to scale-free networks, in particular, to empirical router-level Internet maps. We find that not only the giant connected components in infinite networks with slowly decreasing degree distributions are resilient against random damage, as was known, but their entire k-core architectures are robust.

**N35 2 Skeleton and fractal scaling in complex networks** KWANG-IL GOH,*GIOVANNI SALVI, BYUNGNAM KAHNG, DOOCHUL KIM, *Seoul National University* We find that the fractal scaling in a class of scale-free networks originates from the underlying tree structure called skeleton, a special type of spanning tree based on the edge betweenness centrality. The fractal skeleton has the property of the critical branching tree. The original fractal networks are viewed as a fractal skeleton dressed with local shortcuts. An in- silico model with both the fractal scaling and the scale- invariance properties is also constructed. The framework of fractal networks is useful in understanding the utility and the redundancy in networked systems.

**N35 3 Analysis of structure of small-world networks** TAO JIA, RAHUL KULKARNI, EIVIND ALMAAS, *Lawrence Livermore National Labs* We study the distribution function for minimal paths in small-world networks. We express this distribution in a convex combination form, and use numerical studies to obtain a functional fit for the convex coefficient in the limit of large system sizes and small disorder. Finally, we find analytic expressions for minimal paths distribution based on the functional fit for the convex coefficient. Our analysis can also be considered from the perspective of 1D random walks, our work thus provides a mapping between the structure of small-world networks and the exit problem for a class of 1D random walks.

**N35 4 Inverted Berezinskii-Kosterlitz-Thouless Behavior on Scale-Free Hierarchical-Lattice Small-World Net** MICHAEL HINCZEWSKI, *F. Gürsey Res. Cent. and MIT* A. NIHAT BERKER, *Koç U. and MIT* We have obtained exact results for a hierarchical lattice incorporating three key features of real-world networks: a scale-free degree distribution, a high clustering coefficient, and the small-world effect. By varying the probability $p$ of long-distance bonds, the entire spectrum from an unclustered non-small-world network to a highly-clustered small-world system is studied. Expressions for the degree distribution $P(k)$ and clustering coefficient $C$ are obtained for all $p$, as well as for the average path length $\ell$ for $p = 0,1$. The Ising model on this network is studied by exact renormalization-group transformation of the quenched bond probability distribution, using up to 562,500 renormalized probability bins for the distribution. For $p < 0.494$, we find power-law critical behavior of the magnetization and susceptibility, with exponents continuously varying with $p$, and exponential decay of correlations away from $T_c$. For $p \geq 0.494$, where the network exhibits a small-world character, the critical behavior radically changes: We find an inverted Berezinskii-Kosterlitz-Thouless singularity, between a low-temperature phase with nonzero magnetization and finite correlation length and a high-temperature phase with zero magnetization and infinite correlation length, with power-law decay of correlations. Approaching $T_c$ from below, the magnetization and the susceptibility respectively exhibit $\exp(-C/\sqrt{T_c - T})$ and $\exp(D/\sqrt{T_c - T})$ singularities.

**N35 5 Origin of Fractality in the Growth of Complex Networks** CHAOMING SONG, *Levich Institute and Physics Department, City College of New York* SHLOMO HAVLIN, *Minerva Center and Department of Physics, Bar-Ilan University* HERNAN MAKSE, *Levich Institute and Physics Department, City College of New York* The emergence of self-similarity and modularity in complex networks raises the fun- damental question of the growth process according to which these structures evolve. The possibility of a unique growth mechanism for biological networks, WWW and the Internet is of interest to the specialist and the laymen alike,

as it promises to uncover the universal origins of collective behavior. Here, we present the concept of renormalization from critical phenomena as a mechanism for the growth of fractal and non-fractal modular networks. We show that the key principle that gives rise to the fractal architecture of networks is a strong effective ''repulsion'' between the most connected nodes (hubs) on all length scales, rendering them very dispersed.

**9:24**

**N35 6 A rescaling procedure for complex networks** FRANCESCO RAO, *Centro Studi e Ricerche Enrico Fermi, Rome Italy* GUIDO CALDARELLI, *CNR-INFM Istituto dei Sistemi Complessi, Rome Italy* PAOLO DE LOS RIOS, *Ecole Polytechnique Federale de Lausanne, Switzerland* CENTRO FERMI ROME ITALY TEAM, ISTITUTO DEI SISTEMI COMPLESSI ROME, ITALY TEAM, ECOLE POLYTECHNIQUE FEDERALE DE LAUSANNE TEAM, We present here a renormalization scheme for graphs. We introduce a decimation procedure by weighting the different nodes through their centrality. In such a way we obtain rescaled graphs with the same statistical properties of the one at the finest scale. We present the results of such method for some numerical simulations of various models. We also apply this procedure to the real graph composed by Internet Autonomous System. We believe that this procedure can help in detecting the scale free-properties of such structures and can be fruitfully applied whenever the size of a system is that large that it is impossible to be visualized as well as described as a whole.

**9:36**

**N35 7 Statistical Properties of Sampled Networks** SANG HOON LEE, PAN-JUN KIM, HAWOONG JEONG, *Department of Physics, KAIST* We study the statistical properties of the sampled scale-free networks, deeply related to the proper identification of various real-world networks. We exploit three methods of sampling, and investigate the topological properties such as degree and betweenness centrality distribution, average path length, assortativity, and clustering coefficient of sampled networks compared with those of original networks. It is found that the quantities related to those properties in sampled networks appear to be estimated quite differently for each sampling method. We explain why such a biased estimation of quantities would emerge from the sampling procedure, and give appropriate criteria for each sampling method to prevent the quantities from being overestimated or underestimated.

**9:48**

**N35 8 Routing and Congestion in Power Law Graphs** SAMEET SREENIVASAN, *Boston University* EDUARDO LOPEZ, ZOLTAN TOROCZKAI, *Center for Non Linear Studies, Los Alamos National Laboratory* We investigate a simple model of packet routing on a power law (scale free) graph where packets arrive at each node at a given rate and are routed to a randomly chosen destination along the shortest path between the source and destination. This mimics the Shortest Path Routing protocol used in the internet. It was previously found that there is a critical rate of packet arrival beyond which there is an onset of congestion and packets start accumulating on the network. This critical rate depends on the maximum betweenness incurred on the network when shortest path routing is used. We analytically find a bound on the maximal betweenness incurred in shortest path routing and compare it to the optimal (least possible) maximal betweenness that can be acheived using an arbitrary routing protocol. This provides an effective quantitative measure of the optimality of Shortest Path Routing.

**N35 9 Connectivity and Cost Trade-offs in Multihop Wireless Networks*** MAY LIM, *New England Complex Systems Institute and Brandeis University* DAN BRAHA, *New England Complex Systems Institute and University of Massachusetts Dartmouth* SANITH WIJESINGHE, *New England Complex Systems Institute* STEPHENSON TUCKER, *Sandia National Laboratory* YANEER BAR-YAM, *New England Complex Systems Institute* Ad-hoc wireless networks are of increasing importance in communication and are frequently constrained by energy use. Here we propose a distributed, non-hierarchical adaptive method using preferential detachment for adjusting node transmission power to reduce overall power consumption without violating network load limitations. We derive a cost and path length trade-off diagram that establishes the bounds of effectiveness of the adaptive strategy and compare it with uniform node transmission strategy for several node topologies. We achieve cost savings as high as 90% for specific topologies.

**N35 10 Locating overlapping dense subgraphs in gene (protein) association networks and predicting novel protein functional groups among these subgraphs** GERGELY PALLA, *(a) Biological Physics Research Group of HAS and (b) Department of Biological Physics, Eotvos University* IMRE DERENYI, *(b)* ILLES J. FARKAS, *(a,b)* TAMAS VICSEK, *(a,b)* Most tasks in a cell are performed not by individual proteins, but by functional groups of proteins (either physically interacting with each other or associated in other ways). In gene (protein) association networks these groups show up as sets of densely connected nodes. In the yeast, Saccharomyces cerevisiae, known physically interacting groups of proteins (called protein complexes) strongly overlap: the total number of proteins contained by these complexes by far underestimates the sum of their sizes (2750 vs. 8932). Thus, most functional groups of proteins, both physically interacting and other, are likely to share many of their members with other groups. However, current algorithms searching for dense groups of nodes in networks usually exclude overlaps. With the aim to discover both novel functions of individual proteins and novel protein functional groups we combine in protein association networks (i) a search for overlapping dense subgraphs based on the Clique Percolation Method (CPM) (Palla, G., et.al. Nature 435, 814-818 (2005), http://angel.elte.hu/clustering), which explicitly allows for overlaps among the groups, and (ii) a verification and characterization of the identified groups of nodes (proteins) with the help of standard annotation databases listing known functions.

**N35 11 Scaling Properties of Topological Neural Nets*** ALFRED HUBLER, *Department of Physics, University of Illinois at Urbana-Champaign* JOSEPH JUN, *Department of Physics, Penn State University* We study the agglomeration of metallic particles in an electric field. Earlier it has been shown that this system is a hardware implementation of a neural net [1]. In this paper we study the growth and topological properties of the emerging net-

works. In contrast to other networks the conductivity of the connections has a fixed value, but the completeness and number of connections depends on the training patterns. We find that the patterns grow in three stages: growth of shooters, ramification, and expansion [2]. The emerging patterns are hierarchical. For the limiting patterns certain properties are highly reproducible, such as the number of end points and the number of branching points, while other properties are not well reproducible, such as the number of tree structures. Further there are power law relations between the mass and the number of branching points and the number of end points. [1] M. Sperl, A. Chang, N. Weber, and A. **N36 1 Symmetry considerations for semiconductor nanocrystals** GUSTAVO M. DALPIAN, *University of Texas* MURILO L. TIAGO, MARIE LOPEZ DEL PUERTO, *University of Minnesota* JAMES R. CHELIKOWSKY, *University of Texas* Semiconductor nanocrystals or quantum dots show a wide range of physical properties with respect to their size or shape. In this paper we show that symmetry is also an important characteristic that can lead to different electronic and optical properties, mainly for small nanocrystals. This means that two spherical nanocrystals with similar sizes but different symmetries have different optical and electronic signatures, which should be accessible experimentally. We use pseudopotential density- functional theory, on a real space approach, to address the differences between spherical nanocrystals with similar sizes but different symmetries. We will report differences in the energy gap, the crystal field splitting and the absorption spectra for CdSe nanocrystals. The symmetry of the nanocrystal is also important when studying doping of nanocrystals.

**8:12**
**N36 2 Optical transitions and the nature of Stokes shift in spherical CdS quantum dots*** DENIS DEMCHENKO, LIN-WANG WANG, *Lawrence Berkeley National Laboratory, Berkeley, California 94720* Resonant Stokes shift observed in CdS quantum dots (QDs) has been previously studied theoretically using $\mathbf{k} \cdot \mathbf{p}$ approach. The large values of measured Stokes shift along with the structure of the excitonic levels obtained by the $\mathbf{k} \cdot \mathbf{p}$ calculations have suggested an optically forbidden *P* envelope valence state, thus forming a spatial symmetry induced ''dark exciton'' in CdS QDs, in contrast with the spin-forbidden exchange interaction induced ''dark exciton'' found in CdSe QDs. Since the $\mathbf{k} \cdot \mathbf{p}$ method has been known to incorrectly predict the energy levels in other QDs, here we apply *ab initio* accuracy methods to study this problem. Using the LDA-based charge patching method to generate the Hamiltonian, combined with the folded spectrum method to solve the single particle states of thousand-atom nanostructures, we find that the top of the valence band state is *S*-like, thus optically bright, in contrast with all the previous $\mathbf{k} \cdot \mathbf{p}$ calculations. Our results also indicate the range of applicability of the $\mathbf{k} \cdot \mathbf{p}$ method. The calculated electron-hole exchange splitting suggests that the spin-forbidden valence state may explain the nature of the ''dark exciton'' in CdS quantum dots.

**N36 3 Bright Exciton Fine Structure Observed in Single CdSe Nanocrystal Quantum Dots** S.A. CROOKER, M. FURIS, *National High Magnetic Field Laboratory, Los Alamos, NM* H. HTOON, M.A. PETRUSKA, V.I. KLIMOV, *Chemistry Division, Los Alamos National Laboratory, Los Alamos, NM* The fine structure splitting of bright excitons in epitaxial quantum dots provides a basis for many quantum computation and entanglement schemes. We demonstrate the existence of a similar splitting in single colloidal CdSe nanocrystals through high- resolution, polarization-resolved, low-temperature photoluminescence (PL) experiments. At 4K, single-dot spectra reveal emission from two distinct, linearly- (and orthogonally- ) polarized bright exciton states. This splitting of the nominally degenerate spin $\pm$ 1 bright excitons ranges from 1 to 2 meV, depending on nanocrystal size. These values agree well with the splitting recently inferred from spin-polarized resonant PL of nanocrystal ensembles measured in high magnetic fields to 33 Tesla [1]. Similarly to epitaxially-grown quantum dots, the observed fine structure likely results from shape anisotropy of the nanocrystal (i.e. a reduction of axial symmetry), leading to a long-range, anisotropic electron-hole exchange. [1] M. Furis et al., cond-mat/0511567.

**8:36**
**N36 4 The Peculiar electronic structure of PbSe quantum dots*** JOONHEE AN, ALBERTO FRANCESCHETTI, S. DUDIY, ALEX ZUNGER, *National Renewable Energy Laboratory, Golden, Colorado 80401* PbSe quantum dots have recently emerged as promising systems that may realize direct carrier multiplication (DCM) for solar cell applications. We have calculated the underlying electronic/optical structure of PbSe nanocrystals with an atomistic pseudopotential method, finding that the electronic structure is more subtle than k · p or tight-binding calculations have previously suggested. The following two effects emerge from our calculations: (i) The bulk-degenerate L states forming the VBM and CBM are split due to (1) valley-valley coupling, (2) valence-conduction interband coupling, and (3) the strong anisotropy of the bulk L valleys. Optical absorption is dictated by transitions among anisotropic dot states characteristic of transverse and longitudinal effective masses. Our calculated optical absorption spectrum is in good agreement with experiment. In particular, our calculation reproduces the measured second obsorption peak that had previously been attributed to forbidden transitions $1S_h \rightarrow 1P_e$ or $1P_h \rightarrow 1S_e$ on the basis of k · p and tight-binding

calculations. (ii) Using our calculated single-particle states, we evaluate DCM mechanism, showing that the rate of X-to-XX (exciton to biexciton) transitions far exceeds the reverse, XX-to-X rate, thus opening the way to efficient DCM.

**N36 5 Study of colloidal quantum dot surfaces using an innovative thin-film positron 2D-ACAR method** B. BARBIELLINI, A. BANSIL, *Northeastern U.* S. W. H. EIJT, H. SCHUT, *Delft University of Technology* P. E. MIJNARENDS, *Northeastern U. and Delft University of Technology* A. B. DENISON, *Lawrence Livermore National Laboratory* Despite a wealth of information, many fundamental questions regarding the nature of the surface of nanosized inorganic particles and its relationship with the electronic structure remain unsolved. We have investigated the electron momentum density (EMD) of colloidal CdSe quantum-dots via depth-resolved positron 2D angular correlation of annihilation (2D-ACAR) spectroscopy at the Delft intense variable-energy positron beam. This method, in combination with first-principles calculations of the EMD, shows that implanted positrons are trapped at the surface of CdSe nanocrystals. They annihilate mostly with the Se electrons and monitor changes in composition and structure of the surface while hardly sensing the ligand molecules. We thus unambiguously confirm [1] the strong surface relaxation predicted by first-principles calculations [2]. Work supported by the USDOE. [1] S.W.H. Eijt et al., Nature Materials (in press). **N36 6 Fluorescence blinking statistics from single CdSe nanorods*** SIYING WANG, *University of Pennsylvania* NATHAN LANDY, *Swarthmore College* TARA FINLEY, *Swarthmore College* HUGO ROMERO, *University of Pennsylvania* MARIJA DRNDIC, *University of Pennsylvania* CATHERINE CROUCH, *Swarthmore College* We report that room temperature fluorescence from single colloidally synthesized CdSe nanorods exhibits intermittency (blinking) with truncated power-law off-time and on-time statistics. The nanorods have cross-sectional diameter 5 nm and length 20 nm and are deposited on mica substrates. The aggregated off-time statistics from 67 single nanorods follow a power law: $P(t_{off}) \sim t_{off}^{-\alpha}$, with $\alpha \approx 1.1$. Power-law behavior extends to off-times of roughly 10 s; longer-time probabilities fall below the best-fit power law. Individual nanorods also show power-law off-time statistics with $1 \leqslant \alpha \leqslant 1.3$. On-time probabilities drop below a power law after only $\sim$ 0.6 s; no on-times longer than $\sim$ 3 s are observed. These results differ somewhat from those observed with spherical CdSe or CdSe/ZnS core-shell nanocrystals, for which power-law statistics persist to much longer on- and off-times.

**N36 7 Time-resolved photoluminescence of individual CdS nanowires** L.V. TITOVA, THANG B. HOANG, H.E. JACKSON, L.M. SMITH, *Dept. of Phys., Univ. of Cincinnati, Cincinnati, OH 45221* J.M. YARRISON-RICE, *Dept. of Phys., Miami Univ., Oxford, OH 45056* J.L. LENSCH, L.J. LAUHON, *Dept. of Mat. Sci. and Eng., Northwestern Univ., Evanston, IL 60208* We study photoluminescence (PL) dynamics of single VLS-prepared CdS nanowires. AFM imaging reveals that while some nanowires are straight and uniform, the others show significant morphological irregularities. Low temperature PL of uniform nanowires displays a single near band edge (NBE) peak. Spectra of the irregular nanowires exhibit a broad PL band with a high energy shoulder in the same energy range as the NBE peak of the uniform nanowires, as well as an array of narrow peaks at the lower energy. Spatially-resolved PL images indicate that the narrow lines originate at specific locations along the nanowire. Time-resolved PL (TRPL) measurements show that NBE emission in all nanowires is short-lived (lifetime $<$ 50 ps), indicating the presence of non-radiative recombination channels. On the other hand, TRPL of the localized states exhibit are significantly longer (400 ps to 1 ns) and vary from line to line. At room temperature, the PL spectra of all nanowires, regardless of the morphology, consist of the single short-lived NBE emission peak. We acknowledge the support of ACS through the PRF, and NSF through grants 0071797, 0216374, and a graduate fellowship (JLL).

**9:24**

**N36 8 Morphology and temperature dependence of single CdS nanowire photoluminescence** THANG B. HOANG, L.V. TITOVA, H.E. JACKSON, L.M. SMITH, *Univ. of Cincinnati, Cincinnati, OH* J.M. YARRISON-RICE, *Miami Univ., Oxford, OH* J.L. LENSCH, L.J. LAUHON, *Northwestern Univ., Evanston, IL* We study the optical properties of single CdS nanowires (grown by VLS method using 50 nm catalysts) using the technique of micro-PL. We studied ten wires, several that were straight and uniform, and others with morphological irregularities. At room temperature, the PL spectra of all wires are alike and consist of a single line around 2.41 eV. At low temperature (5 K), the PL properties of these two groups of wires differ significantly: the spectra of the uniform wires display a single peak near the band edge, and the spectra of the irregularly shaped wires exhibit a series of sharp lines at lower energies. Detailed PL imaging reveals that the sharp lines are emitted only from particular positions along the wires. Moreover, most of the photons emitted at low temperatures occur at energies below the band edge PL of bulk CdS. This suggests that the sharp lines result from defects or surface states which rapidly trap carriers from the bulk of the wires. As the temperature increases, the sharp lines begin to weaken at about 30 K and completely disappear at 85 K, while a peak which emerges from the high energy shoulder of the low-T emission band becomes dominant and survives up to room temperature. We acknowledge the support of ACS through PRF, and NSF through grants 0071797, 0216374, and a graduate fellowship (JLL).

**9:36**

**N36 9 Probing the Electronic and Vibronic Structure of Single and Ensemble CdS Nanowires using Resonant Raman Scattering.** A. ABDI, L.V. TITOVA, L.M. SMITH, H.E. JACKSON, *Dept. of Physics, Univ. of Cincinnati, Cincinnati, OH 45221* J.M. YARRISON-RICE, *Dept. of Physics, Miami Univ., Oxford, OH 45056* J.L. LENSCH, L.J. LAUHON, *Dept. of Materials Science and Engineering, Northwestern Univ., Evanston, IL 60208* Semiconductor nanostructure electronic and vibrational states can be sensitively probed using resonant Raman scattering (RRS) even when such states are not accessible through photoluminescence or transport techniques. We present an investigation of the electronic and vibrational states in both a single CdS nanowire and in an ensemble of CdS nanowires using RRS at room temperature. The CdS nanowire samples were grown using a chemical vapor deposition and gold-catalyzed vapor liquid solid growth technique. We

observe strong 1-LO and 2-LO Raman resonances within the broader photoluminescence emission. The energy separation between the peaks of the 1-LO and 2-LO resonance of an ensemble of CdS nanowires was found to be 34 meV. Raman scattering from a single nanowire exhibits similar behavior but with a narrower resonance. These results demonstrate that RRS is a powerful tool for probing the electronic and vibrational properties of semiconductor nanostructures. We acknowledge the support of ACS through PRF, and NSF through grants 0071797, 0216374, and a graduate fellowship (JLL).

**N36 11 Exciton-polariton emission and absorption in inorganic-organic hybrid crystals $ZnTe(en)_{0.5}$*** YONG ZHANG, G. M. DALPIAN, B. FLUEGEL, SU-HUAI WEI, A. MASCARENHAS, *National Renewable Energy Laboratory* XIAOYING HUANG, JING LI, *Rutgers University* LINWANG WANG, *Lawrence Berkeley National Laboratory* The ultimate accuracy and quality test of nanotechnologies based on either MBE or MOCVD growth is perhaps to make an ultra-short-period superlattice with one monolayer thick alternating components. However, neither artificially nor spontaneously ordered monolayer superlattices (e.g., GaAs/AlAs or GaP/InP) that have been grown by either MBE or MOCVD have been shown to have the desired perfection [1,2]. Recently, we have successfully synthesized a group of II-VI based inorganic-organic crystalline hybrid superlattices with single atomic-layer thick inorganic slabs and single molecular-length organic spacers [3]. We will report experimental and/or theoretical studies on the exciton-polariton emission and absorption, exciton binding energies, and dielectric properties for a prototype hybrid superlattice $ZnTe(en)_{0.5}$ [4,5]. **N37 1 Single electron transistors without tunnel junctions tailored by local oxidation of metallic ultra thin films** VINCENT BOUCHIAT, *CNRS* MARC FAUCHER, CÉCILE DELACOUR, THIERRY FOURNIER, BERNARD PANNETEIR, *CNRS/CRTBT* We present the fabrication and low temperature electric properties of nanoscale metallic constrictions made by local oxidation with an Atomic Force Microscope of weakly localized niobium ultra-thin (3nm) strip lines. These constrictions implements nanoscale resistors with resistance of the order of the resistance quantum. Both laterally constrained and variable thickness junctions are made with a lateral gate coupled to the interjunction electrode. Circuits following both geometries exhibits reproducible low contrast gate oscillations at 4K which phase inverts with drain source voltage. The gate modulation of the current is in strong disagreement with the orthodox theory that involves tunnelling. Transport is interpreted as single or multiple islands in series for which Coulomb blockade is induced by the highly resistive sheet resistance.

**N37 2 Single-Walled Carbon Nanotubes as Shadow Masks for Nanogap Junction Fabrication*** ETIENNE DE POORTERE, LIMIN HUANG, MINGYUAN HUANG, SHALOM WIND, JAMES HONE, STEPHEN O'BRIEN, HORST STORMER, COLUMBIA NANOSCALE SCIENCE AND ENGINEERING CENTER COLLABORATION, We report a technique for fabricating nanometer-scale gaps in Pt wires on insulating substrates, using individualit single-walled carbon nanotubes as shadow masks during metal deposition. 83% of the devices display current-voltage dependencies characteristic of direct electron tunneling. Fits to the current-voltage data yield gap widths in the 0.8 - 2.3 nm range for these devices, dimensions that are well suited for single-molecule transport measurements.

**N37 3 Self-Assembly for Large Scale Fabrication of Integrated Electronic Devices Based on 1-D Nanostructures.*** JUNTAE KOH, MINBAEK LEE, JIWOON IM, SUNG MYUNG, SEUNGHUN HONG, *School of Physics, Seoul National University, Seoul, Korea* Recently, electronic devices based on 1-dimensional (1-D) nanostructures (e.g. carbon nanotubes (CNTs) and nanowires) have been drawing much attention as next-generation device architecture. However, the shortage of reliable nanomanufacturing methods for such circuits has hindered their practical applications. One promising nanomanufacturing method can be 'surface-programmed assembly' process, where functional molecular monolayer on the substrate guides the 'selective assembly' and

'alignment' of nanowires and nanotubes on the substrate without relying on any external forces. Using this method, we successfully assembled and aligned carbon nanotubes and vanadium oxide nanowires on various substrates including Au, silicon oxide, Si, Al, and polymer. Furthermore, by additional microfabrication process, we demonstrated large-scale fabrication of various device structures such as junctions and top-gate transistors based on CNTs and vanadium oxide nanowires. Significantly, since this process does not require any high-temperature processing steps, it can be applied to virtually general substrates and may remove current difficulty in manufacturing of electronic devices based on 1-D nanostructures.

**N37 5 Nanoscale devices on thin films by ultra-high-resolution lithography*** MICHAEL FISCHBEIN, *University of Pennsylvania* MARIJA DRNDIC, *University of Pennsylvania* It is possible to achieve exceptionally high resolution with lithographic techniques that use scanning and transmission electron beams by using a thin film as a substrate. With this approach, numerous structures such as nanowires, nanorings, nanogaps and quantum dots can be made with dimensions under ten nanometers and in some cases even less than one nanometer. The flexibility of this fabrication approach also allows these extremely small structures to be easily contacted by large electrodes and therefore integrated into full electronic devices that exhibit effects due to carrier confinement. Furthermore, because these devices are on thin films, they are compatible with imaging by transmission electron microscopy (TEM). Basic devices made with this approach will be introduced. Extensions to devices with more complicated geometries and those which also include non-lithographically prepared nanostructures will be discussed as well.

**N37 6 Correlated electrostatic force microscopy and transmission electron microscopy study of nanostructures on silicon nitride membranes** ZONGHAI HU, MICHAEL FISCHBEIN, MARIJA DRNDIC, *University Of Pennsylvania* Silicon nitride membrane windows allow correlated electrostatic force microscopy and transmission electron microscopy (EFM/TEM) study of electrical and structural properties of the same nanoscale electronic devices fabricated on top of them. Under EFM, nanoscale charge transport patterns are distinguished and correlated with structural details as imaged by high resolution TEM. Examples of nanostructures studied include lithographically fabricated devices and self-organized nanocrystal arrays. Implications of the results on the transport mechanisms of these nanostructures will also be discussed. This work is supported by ONR Young Investigator Award N000140410489, ACS PRF Grant 41256-G10, NSF Career Grant DMR-0449553, and NSF NSEC Grant DMR-0425780.

**N37 7 Local Photocurrent Mapping of Nanowire Photodetectors with Ohmic and Schottky Contacts** YI GU, JOHN P. ROMANKIEWICZ, JESSICA L. LENSCH, TERI W. ODOM, LINCOLN J. LAUHON, *Northwestern University* Near-field scanning photocurrent microscopy (NSPM) was used to determine the mechanisms of carrier transport and collection in CdS nanowire photodetectors. NSPM employs an apertured NSOM probe as a local ( $<$ 100 nm) illumination source to map the local photocurrent as a function of the tip position along the device, i.e., from one metal contact to the other. Striking differences between Schottky and ohmically contacted devices have been observed in maps of the local photocurrent. In the Schottky devices, the photoinduced current is localized to the reverse biased diode, whereas in ohmic devices, the peak photoresponse position shifts continuously with applied bias. Modeling of the photocurrent profiles in ohmically contact devices gives the mobility-lifetime product for electrons and for holes. When independent carrier lifetime measurements are considered, one can extract electron and hole mobilities. As expected for CdS, the electron mobility exceeds the hole mobility, producing the observed shift of the photocurrent peak towards the hole collector. The effects of surface passivation and trap filling on carrier transport have also been explored.

**9:48**
**N37 8 Negative Differential Resistance in CdSe Nanorod Devices.*** HUGO ROMERO, DONG TRAN, GREGORY CALUSINE, MARIJA DRNDIC, *Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, Pennsylvania 19104* Semiconductor quantum rods are expected to exhibit interesting novel behaviors because of their well-defined shape with the long axis preferably grown along the unique c axis. They would also allow for efficient quasi-1D electrical transport. Thus, when organized into arrays of aligned quantum rods separated by insulating barriers, improved and unconventional electronic transport could be achieved compared to that of ''spherical'' nanocrystal arrays. Here, we report on the observation of interesting charging properties in electronic devices consisting of CdSe quantum rod thick films as the active components. The low bias regime of the current-voltage characteristics of such devices displays mul-

tiple negative differential resistance behavior and step-like structures at room temperature. This effect may be related to the alignment of localized trap levels in the insulating barriers with the carrier levels in the quantum rods.

**N37 9 Electron transport of nanoscale P-donor wires in silicon*** T.-C. SHEN, *Utah State University* S. J. ROBINSON, J. R. TUCKER, *University of Illinois at Urbana-Champaign* Three dimensional carrier transport in doped semiconductors has been extensively investigated. However, transport in low-dimensions is much less clear because of the difficulty to confine dopant distribution in a crystal. In the past few years we have created 2D embedded dopant sheets by exposing Si(100) surfaces to phosphine molecules in ultrahigh vacuum followed by growing epitaxial silicon over-layers at room temperature. Electron density in these delta layers can be as high as $\sim 1.5 \times 10^{14}$ cm$^{-2}$. We find that surface roughness dictates the carrier mobility and activation, even though all surfaces are atomically clean and locally ordered. Furthermore, applying STM e-beam lithography on a single-layer H-resist enables us to define P-donor wires at widths from 200 nm to 5 nm in 2-terminal device templates. The As-implanted electrodes in the device templates provide ohmic contact with P-donor wires. In this presentation we will discuss our electrical and magneto-resistance measurement of various P-donor nanostructures at cryogenic temperatures. The goal of this research is to apply 2D P-donor patterns as building blocks for nanoscale integrated circuits.

**N37 10 Confined Doping for Control of Transport Properties in Nanowires and Nanofilms*** JIANXIN ZHONG, G. MALCOLM STOCKS, *Oak Ridge National Laboratory* Doping, an essential element for manipulation of electronic transport in traditional semiconductor industry, is widely expected to play important role as well in control of transport properties in nanostructures. However, traditional theory of electronic disorder predicts that doping in one-dimensional and two-dimensional systems leads to carrier localization, limiting practical applications due to poor carrier mobility. Here, a novel concept is proposed that offers the possibility to significantly increase carrier mobility by confining the distribution of dopants within a particular region [1]. Thus, the doped nanostructure becomes a coupled system comprising a doped subsystem and a perfect crystalline subsystem. We showed that carrier mobility in such a dopped nanowire or a nanofilm exhibits counterintuitive behavior in the regime of heavy doping. In particular, the larger the dopant concentration the higher the carrier mobility; we trace this transition to the existence of quasi-mobility-edges in the nanowires and mobility edges in nanofilms. J.X. Zhong and G.M. Stocks, Nano Lett., in press, (2005).

**N37 11 Field emission characteristics of GaN nanorods on self-implanted (111) Si*** H.W. SEO, X.M. WANG, Q.Y. CHEN, *Dept. of Physics & Texas Center for Superconductivity, University of Houston, Texas, USA.* L.W. TU, Y.J. TU, C.L. HSIAO, M. CHEN, *Dept.of Physics & Center for Nanoscience and Nanotechnology, National Sun Yat-Sen University, Taiwan, Republic of China.* O. LOZANO, D.H. KIM, P.V. WADEKAR, WEI-KAN CHU, *Dept. of Physics & Texas Center for Superconductivity, University of Houston, Texas, USA.* Periodic arrays of GaN nanostructures have been fabricated by MBE growth on self-implanted (111) Si substrates. Nano-capillary condensation was found to be an effective catalytic process fostering the formation of epitaxially aligned GaN nanorods supported by a thin film matrix. Changes of Si substrate surface morphology as a result of ion bombardments prior to the thin-film deposition are responsible for the enhanced nanorod growth. The density of nanorods in relation to implanted ion dosages was studied. Field emission measurement was performed to understand the physical characteristics of functional devices based on such nanostructures. Experimental details and their implications for the future development of nanostructure and nano-device fabrications will be presented.

**N37 12 Conductance measurement of GaN nanorods*** O. LOZANO, H.W. SEO, Q.Y. CHEN, *Dept. of Physics & Texas Center for Superconductivity, University of Houston, Texas, USA.* L.W. TU, Y.J. TU, C.L. HSIAO, M. CHEN, *Dept.of Physics & Center for Nanoscience and Nanotechnology, National Sun Yat-Sen University, Taiwan, Republic of China.* D.H. KIM, P.V. WADEKAR, WEI-KAN CHU, *Dept. of Physics & Texas Center for Superconductivity, University of Houston, Texas, USA.* GaN nanorods have been grown by molecular beam epitaxy over a thin-film GaN matrix on Si substrate. We have studied the conductance behaviors of a single nanorod and clusters nanorods. Transport measurement of internal emission of electrons from nanorod-clusters was carried out with metallic contacts over the nanostructure. Vacuum tunneling of externally emitted electrons from individual nanorod was measured using a scanning tunneling microscope-first in constant voltage mode to locate the more conductive nanorods, which was then followed by measurements at various applied voltage. Observations are made to distinguish thin film matrix from the nanorods by their efficiencies of electron emission. The characteristics of I-V curves will be reported and the applications of these nanorods to electron-emission devices will be discussed.

*Supported by NSF grant DMR-0404542, DOE grant DE-FG02-05ER46208, the Welch Foundation and the State of Texas.

**N37 13 Structural and Electronic Properties of GaN and InN Nanowires grown using Hot-Wall CVD** ELENA CIMPOIASU, ERIC STERN, GUOSHENG CHENG, RYAN MUNDEN, ARIC SANDERS, MARK A. REED, *Departments of Electrical Engineering, Applied Physics, and Physics, Yale University, New Haven, CT* We study the electron-mobility dependence on the free carrier concentration itn exhibited by hot-wall chemical-vapor deposition-grown gallium nitride (GaN) and indium nitride (InN) nanowires. The growth involves flow of ammonia over solid sources of gallium or indium and the substrate, which is covered

with metal catalyst (in case of GaN) or is catalyst-free (in case of InN). The nanowires are subsequently deposited on oxidized silicon wafers and fabricated in field-effect transistors using optical lithography. In this way, more than 1000 devices were characterized at room temperature. Both types of nanowires show high carrier concentration ($10^{19} - 10^{20}$ $cm^{-3}$ for GaN and $10^{20} - 10^{21}$ $cm^{-3}$ for InN), with mobility decreasing with increasing free carrier concentration, consistent with ionized impurity scattering. Mobility levels range between below 1 to 100 $cm^2/Vs$. Estimations of the ionized impurity mobility indicate that GaN wires grow heavily compensated, and subsequent anneals in ammonia result in even higher compensation levels. We were also successful in doping GaN nanowires with magnesium, for p-type doping. Similar chemical, structural, and electronic analysis will be presented. This work was partially supported by DARPA through AFOSR, ARO, AFOSR, NASA, by the Department of Homeland Security, and by NSF.

**N38 1 Anomalous dimensional crossover in critical microwave-conductivity fluctuations of superconducting $La_{2-x}Sr_xCuO_4$ thin films** HARUHISA KITANO, TAKEYOSHI OHASHI, ATSUTAKA MAEDA, *Department of Basic Science, University of Tokyo* ICHIRO TSUKADA, *Central Research Institute of Electrical Power Industry* We demonstrate that there are two dimensional crossover lines separating the phase diagram of $La_{2-x}Sr_xCuO_4$ (LSCO) into three regions with different universality classes, by using a dynamic scaling analysis of the microwave complex conductivity. For underdoped LSCO from x=0.07 to x=0.14, we show clear evidence for the 2D-itXY universality class (the BKT transition in the nearly decoupled $CuO_2$ planes), while the 3D-itXY universality class is observed for nearly optimally doped region (x=0.15, 0.16). Surprisingly, for overdoped LSCO with x> 0.17, we found that the critical behavior strongly suggested the 2D universality class, in contrast to the reduction of anisotropic properties with hole-doping. We discuss the implication of these results in terms of the effect of the quantum critical fluctuations.

**N38 2 Finite Size Effects in YBCO Films in Zero and Non-Zero Field*** SU LI, *Center for Superconductivity Research, Department of Physics, University of Maryland, College Park* HUA XU, *Center for Superconductivity Research, Department of Physics, University of Maryland, College Park* M. C. SULLIVAN, *Department of Physics, Ithaca College* STEVEN M. ANLAGE, *Center for Superconductivity Research, Department of Physics, University of Maryland, College Park* C. J. LOBB, *Center for Superconductivity Research, Department of Physics, University of Maryland, College Park* The phase transition in high Tc superconductors in a magnetic field has been intensely studied. However, only a few papers have discussed finite-size effects (Phys. Rev. B **69**, 214524 (2004)). Neglecting finite size effects can cause misinterpretation of the experimental data leading to incorrect critical exponents. We will report results of DC transport measurements on YBa2Cu3O6.95 films in zero field (less than 50 nT) as well as in fields up to 6 T. The results will be analyzed in terms of field-induced finite size effects and thickness-induced finite size effects.

**N38 3 Fluctuations at the superconductor/normal phase transition of YBCO thin films** HUA XU, SU LI, CHRISTOPHER LOBB, STEVEN ANLAGE, *Center for Superconductivity, Department of Physics, University of Maryland, College Park, MD 20742* The zero-field phase transition of high $T_c$ superconductors has been studied by a number of techniques, such as penetration depth, magnetic susceptibility, specific heat and thermal expansion, which reveal information about the static, properties of fluctuations. Transport properties (such as the conductivity) which probe the dynamics near $T_c$ are less explored, and a wide range of critical exponents were reported experimentally. We investigated fluctuation effects of $YBa_2Cu_3O_{7-d}$ (YBCO) around $T_c$ by doing frequency-dependent microwave conductivity measurements and dc current-voltage characteristics on the same film. For each experiment the scaling behavior of the data was investigated. The critical exponents $\nu$ and z from the two different experiments will be extracted and compared. We also investigated YBCO frequency-dependent conductivity fluctuation effects for different powers or currents and for different film thickness. The finite size effects in both the microwave and DC voltage current experiments will also be discussed. (This work was supported by NSF grant number DMR-0302596).

**N38 4 Transport and Noise Properties of High Temperature Superconductor Nanostructures** D.S. CAPLAN, X. ZHAI, J.N. ECKSTEIN, D.J. VAN HARLINGEN, *University of Illinois at Urbana-Champaign* The study of transport and noise properties of high-$T_c$ superconductor nanostructures provides a sensitive probe of their local electronic structure and may give insight into the proposed mechanisms for the superconductivity and the nature of the anomalous normal phases. We discuss a novel technique for fabricating nanostructures based on the growth of cuprate films on substrates pre-patterned by Focused Ion Beam etching. We report measurements in underdoped YBCO and BSCCO nanostructures fabricated by this technique that are designed to understand anomalous switching noise observed in the pseudogap phase above $T_c$. Our goal is to test if these signal show the existence of dynamical domains characterized by inhomogeneous conductivity or by anisotropic charge stripes.

**8:48**
**N38 5 Thermoelectric power as evidence for a Quantum Phase Transition in electron-doped cuprates $Pr_{2-x}Ce_xCuO_{4-y}$.*** PENGCHENG LI, R.L. GREENE, *Center for Superconductivity Research and Department of Physics, University of Maryland, College Park, MD, 20742* K. BEHNIA, *Laboratoire de Physique Quantique (CNRS), ESPCI, 10 Rue Vauquelin, 75005 Paris,*

*France* We report magnetic field driven normal state thermoelectric power (S) measurement in electron-doped cuprate system $Pr_{2-x}Ce_xCuO_{4-y}$ as a function of doping (x from 0.11 to 0.19) down to 2K. Consistent with the normal state Hall effect[a], S in the underdoped region (0.11-0.15) is negative. S changes sign at certain temperatures in overdoped samples (0.16-0.18), which supports the picture of a spin density wave rearrangement of the Fermi surface[b]. More significantly, both S and S/T at 2K (at 9T) increase dramatically from x=0.11 to 0.16, and then saturate in the overdoped region. This kink around x=0.16 is similar to the previous Hall effect result[a] in $Pr_{2-x}Ce_xCuO_{4-y}$. Our results are further evidence for antiferromagnetism to paramagnetism quantum phase transition in electron-doped cuprates. a. Y. Dagan et al, Physical Review Letters, 92 (16) 167001, 2004 b. A. Zimmers et al, Europhysics Letters 70 (2) 225, 2005.

**N38 6 Anomalous Nernst Effect in High-$T_c$ Superconductors by Layer Decoupling** JOSE P. RODRIGUEZ, *California State University at Los Angeles* The extended vortex-liquid phase found in high-$T_c$ superconductors at temperatures and magnetic fields that lie above the vortex-lattice melting line can be attributed to weak inter-layer coupling. We compute the diamagnetic contribution to the equilibrium magnetization there, $M$, using the corresponding uniformly frustrated $XY$ model, given in terms of the phase of the superconducting order parameter[1]. A high-temperature expansion that is valid in the vicinity of the mean-field phase transition yields (i) that $-M$ increases monotonically with the external magnetic field, and (ii) that it vanishes as the mean-field phase transition is approached from below. Further, we show (iii) that the assumption of a direct dependence between $M$ and the Peltier transport coefficient results in an anomalous Nernst signal inside of the vortex-liquid phase. These results are compared to recent experimental determinations of the equilibrium magnetization and of the Nernst effect in the vortex-liquid phase of high-$T_c$ superconductors[2]. [1] J.P. Rodriguez, PRB **66**, 214506 (2002); **69**, 069901(E) (2004). [2] Y. Wang, et al., PRL, in press (arXiv: cond-mat/0503190).

**9:12**

**N38 7 Thermoelectric transport near the pair breaking quantum phase transition out of a *d*-wave superconductor** DANIEL PODOLSKY, ASHVIN VISHWANATH, JOEL MOORE, *University of California at Berkeley* SUBIR SACHDEV, *Harvard University* We study electric, thermal, and thermoelectric conductivities in the vicinity of a $z = 2$ superconductor-diffusive metal transition in two dimensions, both in the high and low frequency limits. We find violation of the Wiedemann-Franz law, with a Lorentz ratio *below* the Sommerfeld value (more charge than heat transport). In addition, the dc thermoelectric conductivity $\alpha$ does not vanish at low temperatures, in contrast to Fermi liquids. We introduce a Langevin equation formalism to study critical dynamics over a broad region surrounding the quantum critical point.

**9:24**

**N38 8 Competing orders in LSCO probed by heat transport** SHIYAN LI, *University of Sherbrooke, Canada* D. G. HAWTHORN, *University of Toronto, Canada* LOUIS TAILLEFER, *University of Sherbrooke, Canada and Canadian Institute for Advanced Research* K. YAMADA, *Tohoku University, Japan* We elucidate the nature of the thermal metal-to-insulator transition in $La_{2-x}Sr_xCuO_4$ (LSCO) [1] through measurements of the thermal conductivity $\kappa$ performed very close to the transition, down to temperatures as low as 50 mK and in magnetic fields $H$ up to 17 T. For a single crystal with x = 0.15, a monotonic increase in the residual linear term $\kappa_0/T$ is observed up to 17 T, as expected for a d-wave superconductor. For a crystal with x = 0.144, however, we observe an initial increase in $\kappa_0/T$ at low field, followed by a decrease when $H$ exceeds a critical field $H^*$. This result is consistent with recent neutron scattering measurements on a similar sample [2], which show that static spin-density-wave (SDW) order is not present in zero field, but sets in at a critical magnetic field $H^*$, and then co-exists/competes with superconductivity (SC) for $H > H^*$. Taken together, these two measurements reveal that the SC phase gives way to a phase which is both magnetic and insulating, whether by increasing magnetic field or by decreasing doping. Using low-energy quasiparticle transport, we map out the $T = 0$ field-doping ($H - x$) phase diagram of LSCO. [1] D.G. Hawthorn et al., Phys. Rev. Lett. 90, 197004 (2003); X.F. Sun et al., Phys. Rev. Lett. 90, 117004 (2003). [2] B. Khaykovich et al., Phys. Rev. B 71, 220508(R) (2005).

**N38 9 Existence of a boson mode in underdoped YBCO** NICOLAS DOIRON-LEYRAUD, S.Y. LI, *Université de Sherbrooke* M. SUTHERLAND,* *University of Toronto* L. TAILLEFER, *Université de Sherbrooke and CIAR* R. LIANG, D.A. BONN, W.N. HARDY, *University of British Columbia and CIAR* We have examined the underdoped region of the cuprate phase diagram via a study of heat transport at temperatures down to 50 mK in samples of YBCO with a hole concentration in the vicinity of 5%. The measured thermal conductivity was found to be well described by a sum of three terms, $\kappa(T) = aT + bT^{\alpha} + cT^3$, which we associate with, respectively, fermionic quasiparticles, phonons, and a new bosonic mode. By comparing data taken at different doping levels on the same sample it was possible to track the evolution of the $T^3$ term. Its coefficient was found to increase with decreased doping, i.e., with proximity to magnetism. We speculate that this term may be associated with the transport of heat by magnons, as observed recently by Li et al. [1] in the undoped cuprate material $Nd_2CuO_4$. This would suggest that long range magnetic order in YBCO appears at a doping level very close to that at which superconductivity ends. [1] S.Y. Li et al., Phys. Rev. Lett. **95**, 156603 (2005).

**N38 10 Low-Temperature Normal State Hall Effect in High-$T_c$ $La_{2-x}Sr_xCuO_4$*** FEDOR BALAKIREV, *Los Alamos National Laboratory, Los Alamos, NM 87545, USA* JONATHAN BETTS, *Los Alamos National Laboratory, Los Alamos, NM 87545, USA* ALBERT MIGLIORI, *Los Alamos National Laboratory, Los Alamos, NM 87545, USA* ICHIRO TSUKADA, *Central Research Institute of Electric Power Industry, Komae, Tokyo 201-8511, Japan* YOICHI ANDO, *Central Research Institute of Electric Power Industry, Komae, Tokyo 201-8511, Japan* GREGORY BOEBINGER, *National High Magnetic Field Laboratory, Tallahassee, FL 32310, USA* We report Hall effect measurements in the normal state of the high-$T_c$ superconductor $La_{2-x}Sr_xCuO_4$. The Hall resistivity was measured by suppressing superconductivity in 60T magnetic field, thus revealing the normal-state behavior in the low

temperature limit. The carrier concentration is varied from overdoped to underdoped regimes by partially substituting La with Sr in a set of thin film samples. We find a discontinuity in the doping dependence of the Hall coefficient suggestive of a phase transition near optimal doping.

**10:00**

**N38 11 Effect of Disorder Outside the $CuO_2$ Planes on $T_c$ of Copper Oxide Superconductors.** KAZUHIRO FUJITA, *Department of Advanced Materials Science, University of Tokyo, L.A.S.S.P. Department of Physics, Cornell University* KENJI KOJIMA, *Department of Physics, University of Tokyo* HIROSHI EISAKI, *Nanoelectronics Research Institute, National Institute for Advanced Industrial Science and Technology (AIST)* SHIN-ICHI UCHIDA, *Department of Physics, University of Tokyo, Department of Advanced Materials Science, University of Tokyo* The effect of disorder on the superconducting transition temperature $T_c$ of cuprate superconductors is examined. Disorder is introduced into the cation sites in the plane adjacent to the $CuO_2$ planes of single-layer systems, $Bi_2Sr_{1.6}Ln_{0.4}CuO_{6+y}$. Disorder is controlled by changing rare earth (Ln) ions with a different ionic radius with the doped carrier density kept constant. We show that this type of disorder works as weak scatterers in contrast to the in-plane disorder produced by Zn, but remarkably reduces $T_c$, suggesting novel effects of disorder on high-$T_c$ superconductivity.

**N38 12 Mixed State $c-$ axis Resistivity of $Y_{0.54}Pr_{0.46}Ba_2Cu_3O_{7-\delta}$ Single Crystals*** T. KATUWAL, V. SANDU, C.C. ALMASAN, *Kent State University* B.J. TAYLOR, M.B. MAPLE, *University of California at San Diego* We report temperature $T$, magnetic field $H$, and angle $\theta$ dependent out-of-plane resistivity $\rho_c$ measurements on $Y_{0.54}Pr_{0.46}Ba_2Cu_3O_{7-\delta}$ single crystals. We performed these measurements in order to investigate the origin of the large $\rho_c$ of layered superconductors like cuprates and of its T, H, and $\theta$ dependence. The $\rho_c(T,H,\theta)$ data are very well fitted by the Ambegaokar $-$ Halperin expression [V. Ambegaokar and B. I. Halperin, Phys. Rev. Lett. 22, 1364 (1969)] for temperatures up to the critical temperature $T_c$ and applied magnetic field up to 14 T. This implies that in the underdoped cuprates the layered structure can be depicted as stacks of Josephson junctions. We calculated the value of the critical current density $J_c$ at different temperatures by using the above model and the values of the fitting parameters. Both the magnitude and $T$ dependence of $J_c$ are consistent with previous reports. This result supports the applicability of the model and indicates that the mixed state $c-$ axis dissipation is mainly due to the Josephson effect.

**N38 13 C-axis Resistivity and Magnetoresistance of the Electron-doped Cuprate $Pr_{1.85}Ce_{0.15}CuO_4$** WEIQIANG YU, B. LIANG, R. L. GREENE, *Center for Superconductivity Research, Department of Physics, University of Maryland, College Park, MD 20742* C-axis resistivity and magnetoresistance have been studied extensively in the hole-doped high temperature superconductors. Observations, such as a resistivity upturn and associated negative magnetoresistance (n-MR), were attributed to the pseudogap. Recently similar phenomena were reported in the electron-doped superconductor $Sm_{1.85}Ce_{0.15}CuO_4$ (SCCO), and a universal Zeeman splitting of a spin gap (pseudogap) state was proposed [1]. Here we report transport properties of $Pr_{1.85}Ce_{0.15}CuO_4$ (PCCO) ($T_C \approx 25K$) single crystals for comparison. Our c-axis n- MR can be explained by superconducting fluctuations due to the Aslamazov-Larkin (AL) process and the fluctuating electronic density of states (FDOS) above $H_{C2}$. We find that PCCO does not follow the Zeeman scaling behavior as reported for SCCO. This work is supported by NSF (Grant DMR 0352735).

**N38 14 Resistivity and Hall effect measurements in $Pr_{2-x}Ce_xCuO_{4-y}$ up to 60 T*** R.L. GREENE, PENGCHENG LI, *Center for Superconductivity Research and Department of Physics, University of Maryland, College Park, MD, 20742* F. BALAKIREV, *National High Magnetic Field Lab in Los Alamos National Lab, Los Alamos, NM, 87545* We report resistivity and Hall effect measurements in the electron$-$doped cuprate system $Pr_{2-x}Ce_xCuO_{4-y}$ in magnetic field up to 60 T. We found negative magneto resistance (MR) in the under doped region for all magnetic field values, similar to the low field data reported previously a. The MR becomes positive at high field in the optimal doped (x=0.15) sample at low temperature. Most surprisingly, we observed a substantial magnetic field dependence of the Hall coefficient at high field (above $\sim$ 40 T) in optimal dopedand over doped samples (from x=0.15 to 0.19) in a certain temperature range. As pin density wave induced Fermi surface reconstruction model can be used to explain this phenomenon. We also report for the first time the parallel upper critical field (H//abplane) for $Pr_{2-x}Ce_xCuO_{4-y}$. (A.Y. Daganetal, Physical Review Letters **94**(5), 11 2005).

**N38 15 Role of Disorder and Oxygen Reduction on Transport Properties in $Pr_{1.83}Ce_{0.17}CuO_{4\pm\delta}$*** J. S. HIGGINS, Y. DAGAN,† M. C. BARR, R. L. GREENE, *Center for Superconductivity Research, Physics Department, University of Maryland, College Park, Maryland, USA 20742* B. D. WEAVER, *Naval Research Laboratory, Code 6818, Washington, DC, USA 20375* We present a study on the effects of changing the oxygen content in the electron-doped superconducting cuprate $Pr_{2-x}Ce_xCuO_{4\pm\delta}$ (PCCO). Epitaxial, c-axis oriented, overdoped (x = 0.17) thin films were grown using a pulsed laser deposition technique, and the oxygen content was adjusted during a post-growth annealing

process. In addition to the transition temperature ($T_c$), measurements of the Hall effect and resistivity were performed at low temperatures ($T < T_c$, $H > H_{C2}$) in several films of different oxygen content. We compare the disorder observed in these oxygenated samples with disorder induced by proton irradiation in an optimally annealed ($x = 0.17$) film. An analysis of the data demonstrates that a change in the oxygen content of PCCO has two separable effects: 1) a disorder effect, and 2) a doping effect similar to that of cerium.

**N39 1 Clean and Dirty $MgB_2$ Thin Films by Hybrid Physical-Chemical Vapor Deposition.***
XIAOXING XI, *Penn State University*

The interband and intraband scattering in $MgB_2$ have significant influences on various properties of this two-band superconductor. In order to explore new physical phenomena and realize the potential for applications in $MgB_2$, it is desirable to control the interband and intraband scattering arbitrarily and independently. Hybrid physical-chemical vapor deposition (HPCVD) is a promising technique towards this goal. It has produced very clean $MgB_2$ films with a residual resistivity ratio of 60. The tensile strain in the films due to crystallite coalescence results in a softening of the $E_{2g}$ phonon and higher-than-bulk $T_c$ values. The long mean free path of the films, which are the cleanest $MgB_2$ materials reported, allow magnetoresistance measurements that reveal rich features of the two-band Fermi surfaces. The HPCVD technique also allows doping of the clean films in a controlled manner, which modifies the interband and intraband scattering and results in record-high upper critical field $H_{c2}$ of over 60 T. The demonstrations of HPCVD for high quality polycrystalline coatings on coated conductor fibers, high deposition speed and thick films, and on various polycrystalline substrates make it a promising technology for high field applications of $MgB_2$.

**N39 2 Hybrid Physical-Chemical Vapor Deposition of $MgB_2$ Film on Flexible Dielectric and Metallic Substrates** ERIC MAERTZ, A. V. POGREBNYAKOV, J. M. REDWING, X. X. XI, *The Pennsylvania State University* The need for flexible dielectric and metallic substrates arises when considering making wires or tapes for high field applications. To accomplish this, Cu wire and foil with a buffer layer, flexible yttrium stabilized zirconium (YSZ), as well as Nb, Ta, and stainless steel foil were used as substrates for polycrystalline $MgB_2$ film growth. The foil substrates used range from 1 to 3 mil thickness. The buffer layers deposited on Cu were Ni plating (on 28 BSG wire) as well as $TiB_2$ and Nb deposited by sputtering. These served as a barrier to prevent the chemical reaction between Cu and Mg that occurs during deposition of $MbB_2$. The resistance vs. temperature (R-T) dependences were recorded for the films successfully grown on these substrates. For the films on YSZ, R-T was recorded initially and then after bending of the film on the substrate over a diameter of 20mm. The $T_C$ of $MgB_2$ on stainless steel was 38K; on YSZ and Nb it was 38.5K. This is lower than epitaxial films on SiC substrate with $T_c$ up to 41.5K. The R-T curve for $MgB_2$ on YSZ remained almost completely unchanged after bending. These films hold promise for electromagnetic field generation applications. This work is supported by NSF and ONR.

**N39 3 Planar $MgB_2$ superconductor-normal metal-superconductor Josephson junctions** KE CHEN, Y. CUI, QI LI, *Department of Physics, The Pennsylvania State University, University Park* X. X. XI, *Department of Physics and Department of Materials Sciene and Engineering, The Pennsylvania State University, University Park* SHANE A. CYBART, *Department of Physics, University of California, San Diego* R. C. DYNES, *Department of Physics, University of California, Berkeley* X. WEN, J. M. REDWING, *Department of Materials Sciene and Engineering, The Pennsylvania State University, University Park* We have fabricated planar superconductor-normal metal-superconductor (SNS) $MgB_2$ Josephson junctions using $MgB_2$ films grown by hybrid physical chemical vapor deposition (HPCVD). The junctions exhibit resistively-shunted-junction-like (RSJ-like) current-voltage characteristics up to 31 K. Ac Josephson effect was observed and the behavior of the Shapiro steps are in good agreement with theoretical predictions. The magnetic field modulation of the critical current also agrees with the thin film planar junction be-

havior. The junction's behavior can be described by Likharev's proximity effect model with rigid boundary at dirty limit. A dc SQUID with modulation depth of 45 $\mu$V at 29 K has been demonstrated. This work is supported by ONR, NSF, and AFOSR.

**9:00**

**N39 4 Fabrication and characterization of $MgB_2$/ thermal oxide barrier /Pb Josephson tunnel junctions** YI CUI, KE CHEN, QI LI, XIAOXING XI, *Department of Physics, The Pennsylvania State University* JOHN M. ROWELL, *Arizona State University* Cross-bridge Josephson tunnel junctions were fabricated, using $MgB_2$ films grown by hybrid physical-chemical vapor deposition (HPCVD) and barriers made by thermal oxidation at different temperatures. The junctions showed clear Josephson tunneling characteristics with high supercurrents, high $I_cR_N$ products ($I_cR_N$ products $\sim$ 1.8 mV at 4.2 K), and small subgap current leakage. The external DC magnetic field dependence was also measured and showed clear Fraunhofer pattern. The properties of the thermal oxide barrier depend sensitively on the oxidation temperature. The potential height and barrier thickness of 0.7 eV and 1.8 nm, respectively, were inferred from conductance measurements at high bias voltage. Two superconducting gaps of 2.0 meV and 7.5 meV for $MgB_2$ were observed from these sandwich-type tunnel junctions. These results suggest the potential of using $MgB_2$ thermal oxide layers as a barrier for practical Josephson tunnel junction fabrication. This work is supported by ONR and NSF.

**9:12**

**N39 5 MgB2 Tunnel Junctions with Native or Thermal Oxide Barriers** RAKESH SINGH, *Arizona State University* RAGHURAM GANDIKOTA, JIHHON KIM, NATHAN NEWMAN, JOHN ROWELL, $MgB_2$ tunnel junctions ($MgB_2$/barrier/$MgB_2$) were fabricated using an oxide (or a mixture of oxides) grown on the first $MgB_2$ film as the tunnel barrier, by exposure to air at 20$^o$C (native oxide) or 160$^o$C (thermal oxide). Such barriers therefore survived the deposition of the second electrode at 300$^o$C, even over junction areas of $\sim$ 1mm$^2$. The sum of the superconducting gaps of the top and bottom electrodes, from conductance-voltage data, was as high as 4.3 mV and this sum gap remained non-zero for temperatures above 30 K. Conductance vs. voltage dependencies of all-$MgB_2$ junctions and those of the type $MgB_2$/Native or Thermal Oxide/Metal (Pb, Au, or Ag) were used to characterize the height and width of the barriers formed. Such barriers have surprisingly low barrier heights, with typical values for barrier height and width being 0.2 V and 4.5 nm respectively. These values are very different from those reported in the literature. These results show that tunnel barriers grown on $MgB_2$ can have different properties (barrier height and width), depending on the film growth, surface composition and oxidation conditions.

**9:24**

**N39 6 All $MgB_2$ tunnel junction with $Al_2O_3$ tunnel barrier*** HEEJAE SHIM, JAGADEESH S. MOODERA, *Francis Bitter Magnet Laboratory, MIT, Cambridge, MA* $MgB_2$ tunnel junctions are attractive not only from superconducting electronics application part of view but also from the fundamental physics to understand multi-gap superconductors. All $MgB_2$ planar junctions with $Al_2O_3$ tunnel barrier were fabricated in situ in an MBE system by coevaporation of Mg and B for $MgB_2$ and plasma oxidized Al for tunnel barrier on Si (111) substrate. The junctions exhibit the current-voltage characteristic for quasiparticle and Josephson tunneling including microwave induced Shapiro steps. From conductance spectrum at 1 K, we clearly observe features that correspond to different $\pi$ and $\sigma$ superconducting energy gaps for the two $MgB_2$ electrodes. The observed multi-gap structure will be discussed with the difference of crystallographic orientation of $MgB_2$ at the interface between tunnel barrier and both superconducting layers.

**N39 7 Scanning tunneling spectroscopy and high-frequency response of MgB2 films** M.S. RZCHOWSKI, D.M. KIM, J. GIENCKE, C.B. EOM, *University of Wisconsin-Madison* T.W. HEITMANN, *Syracuse University* The critical issues governing thin-film MgB2 applications can be traced to factors both microscopic, arising from the two-gap structure and scattering mechanisms, as well as mesoscopic, determined by connectivity and grain boundary characteristics. These are intertwined to the extent that substitutional doping to control gap characteristics and band scattering can strongly affect connectivity through grain boundary segregation and growth of second phases. These issues can be addressed with a combined approach of gap characterization by low-temperature scanning tunneling spectroscopy, and temperature-dependent microwave conductivity measurements. We discuss preliminary results characterizing gap properties with low-temperature superconducting-tip scanning tunneling microscopy, and 10 GHz cavity-based microwave conductivity measurements.

**9:48**

**N39 8 Thickness dependence of the properties of $MgB_2$ films grown by hybrid physical-chemical vapor deposition** ALEXEJ POGREBNYAKOV, *Department of Physics and Department of Materials Science and Engineering, The Pennsylvania State University* ARSEN SOUKIASSIAN, JOAN REDWING, *Department of Materials Science and Engineering, The Pennsylvania State University* XIAOXING XI, *Department of Physics and Department of Materials Science and Engineering, The Pennsylvania State University* Properties of pure $MgB_2$ films of different thicknesses (up to $\sim$ 1 $\mu$m) grown by hybrid-physical-chemical vapor deposition on sapphire substrates were studied. In accordance with the previous results for the films with thicknesses up to about 400 nm, $T_c$ of the films on $Al_2O_3$ levels off at a value of 40.0 - 40.5 K at thicknesses larger than 200 nm. The residual resistivity, $\rho_0$, monotonically decreases with thickness, which is caused by a reduction of the surface and interface scattering (size effect on resistivity). For films with thickness over $\sim$ 800 nm, $\rho_0$ is below 0.15 $\mu\Omega$.cm and $RRR >$ 60. X-ray studies of the films did not reveal any other phases besides $MgB_2$. In this talk, $MgB_2$ films of even larger thickness and the thickness dependence of critical current density will also be reported.

**N39 9 Far-infrared Studies of the Two-Gap Behavior in Epitaxial $MgB_2$ Films*** JIUFENG TU, *The City College of New York* G.L. CARR, *BNL* R.P.S.M. LOBO, *ESPCI* P. ORGIANI, X.X. XI, *Penn State* Far-infrared transmission and reflectivity measurements have been carried out for a series of pure and carbon-doped epitaxial $MgB_2$ films. While the carbon-doped film exhibits the typical characteristics for a dirty BCS superconductor in the $T_S$ /$T_N$ and $R_S$ /$R_N$ ratios, the pure $MgB_2$ films can only be understood knowing the multi-gap nature of the superconducting

state in $MgB_2$. As a function of increasing $T_c$, the fraction of the Cooper pairs having the larger gap increases. Both gaps appear to follow the BCS temperature dependence. However, the two gaps exhibit different behavior when a magnetic field is applied along c-axis. While the smaller gap can be suppressed by a relatively small field, the larger gap can persist up to 10 T. These infrared measurements indicate that the two superfluids coexist quite independently in the superconducting state of $MgB_2$.

**N39 10 Penetration Depth Anisotropy in $MgB_2$ measured by Small-Angle Neutron Scattering** D. PAL, L. DEBEER-SCHMITT, T. BERA, M.R. ESKILDSEN, *Department of Physics, University of Notre Dame, Notre Dame, IN 46556* C.D. DEWHURST, R. CUBITT, *Institut Laue-Langevin, 6 Rue Jules Horowitz, F-38042 Grenoble, France* J. JUN, N.D. ZHIGALDO, J. KARPINSKI, *Laboratory for Solid State Physics, ETH, CH-8093 Zurich, Switzerland* V.G. KOGAN, *Ames Laboratory and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011* Traditionally the anisotropy of a type-II superconductor is described either by $\gamma_\lambda = \lambda_c/\lambda_{ab}$ or $\gamma_H = H_{ab}/H_c = \xi_{ab}/\xi_c$. with the two considered to be identical. However, in materials with anisotropic gaps this is generally not the case. $MgB_2$ represents an extreme case in which $\gamma_\lambda \neq \gamma_H$. While there is consensus on the value of $\gamma_H(T)$, measurements of $\gamma_\lambda$ are still contradictory. Here we demonstrate a novel use of small-angle neutron scattering to determine $\gamma_\lambda$ in $MgB_2$, by measuring the misalignment between the applied field and the direction of the flux-line lattice as the field is rotated between the *c* axis and the basal plane. Using a two-band/two-gap model we can fit the angular dependence of the misalignment, yielding $\gamma_\lambda = 1.1 \pm 0.2$ at 4.9 K and 0.4 T.

**N41 1 Oxygen-deficient defects and hydrogen in irradiated Si/SiO2 systems** RENEE VAN GINHOVEN, *Sandia National Labs* HAROLD HJALMARSON, *Sandia National Labs* Performance of Si/SiO2 devices is degraded by ionizing radiation through the production of interface traps and buildup of trapped charge in the oxide. This process is connected to the presence of hydrogen in the oxide. Exposure to ionizing radiation stimulates release of mobile hydrogen, which can migrate through the oxide to the Si/SiO2 interface and depassivate H-terminated Si-dangling bonds. The resulting interface trap states act as charge recombination centers. Our calculations focus on the interaction of hydrogen with oxygen deficient centers in the oxide. In the bulk oxide, these defects can release hydrogen from Si-H groups, or crack H2 molecules. These active sites may also act as border trap recombination centers when near the interface. Our presentation will describe molecular scale mechanisms for radiation-induced generation of free hydrogen using density functional theory applied to fully periodic models. The oxide is represented by both crystalline and amorphous configurations. Sandia is a multiprogram laboratory operated by the Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy under contract DE-AC04-94AL85000.

**N41 2 Photo-catalytic studies of transition metal doped titanium dioxide thin films processed by metalorganic decomposition (MOD) method** P. TALAGALA, X. MARKO, K.R. PADMANABHAN, R. NAIK, *Wayne State University, Detroit MI* D. RODAK, Y.T. CHENG, *General Motors R&D Center, Warren MI* We have synthesized pure and transition element (Fe, Co and V) doped Titanium oxide thin films of thickness $\sim$ 350 nm on sapphire, Si, and stainless steel substrates by Metalorganic Decomposition (MOD) method. The films were subsequently annealed at appropriate temperatures ( 500-750C) to obtain either anatase or the rutile phase of $TiO_2$. Analysis of the composition of the films were performed by energy dispersive X-ray(EDAX) and Rutherford backscattering spectrometry(RBS). Ion channeling was used to identify possible epitaxial growth of the films on sapphire. Both XRD and Raman spectra of the films exhibit that the films annealed at 550C are of anatase phase, while those annealed at 700C seem to prefer a rutile structure. The water contact angle measurements of the films before and after photoactivation, demonstrate a significant reduction in the contact angle for the anatase phase. However, the variation in contact angle was observed for films exposed to UV ( $< 10^o$-$30^o$) and dark ($25^o$-$50^o$). Films doped with Fe show a trend towards lower contact angle than those doped with Co. Results with films doped with V will also be included.

**N41 3 Proton Conduction and Microstructure of Lanthanum Phosphates*** GABRIEL HARLEY, LINDSEY KARPOWICH, LUTGARD DE JONGHE,† *University of California, Berkeley, 94720* Lanthanum phosphate (LaPO4) has been recently studied as a potential proton conducting ceramic electrolyte for fuel cells. The complexity of the La2O3 - P2O5 system, particularly in the 1000 - 1600K range, leads to the difficulty in forming phase pure LaPO4 by traditional synthesis methods. Complex microstructures involving amorphous and crystalline phases at grain boundaries have been detected by high resolution transmission electron microscopy, and have been shown to affect proton conductivity by several orders of magnitude. A simple model is used to predict conductivity of the material based on grain size and grain-boundary phases, and experimental results match up well with the model. Conductivities as high as 3.6E-5 S/cm at 773 K were found for undoped LaPO4.

**N41 4 Comparison of the electronic structures of four crystalline phases of $FePO_4$*** PING TANG, N. A. W. HOLZWARTH, *Wake Forest University* $LiFePO_4$ in the olivine structure is a promising cathode material for Li-ion batteries. During normal battery operation, an olivine form of $FePO_4$ is formed. Experimen-

tal evidence suggests that the olivine phase is meta-stable relative to a quartz-like trigonal phase. In addition, several other meta-stable phases have been reported[1] including a monoclinic and a high pressure $CrVO_4$ structure. We have carried first-principles electronic structure calculations on all of these phases in order to investigate their relative stability and other properties using both LAPW and PWPAW methods.[2] We find that the LSDA approximation systematically underestimates the lattice constants and the calculated stability ordering of the phases is inconsistent with experiment. In contrast the GGA approximation models the phase stability in closer agreement with experiment, although the lattice constants are systematically over-estimated.

*Supported by NSF Grant No. DMR-0405456.

**N41 5 First-principles study of phase stability and phase transition in $Ga_2O_3$*** JIANJUN DONG, BIN XU, *Department of Physics, Auburn University* Gallium oxide ($Ga_2O_3$) is a promising opto- and/or electronic wide-band-gap semiconductor. For example, it has been considered as a gate dielectric oxide for MOS device based on GaN or GaAs. In addition to the ground-state monoclinic $\beta$-phase, a rhombohedral $\alpha$-phase metastably exists at ambient conditions. The conditions of stability of either phase are not well understood. In this talk, we will present our recent itab initio calculation results of thermodynamic properties of the $\alpha$ and $\beta$ phase. We have computed Gibbs free energies of the two phases based on the total energy density functional theory (DFT) and the statistical quasi-harmonic approximation (QHA), calculated the thermal equations of states, and estimated the equilibrium phase boundary. We have further calculated the pressure dependence of Raman and IR frequencies in the two phases. Our results will be compared with some recent experimental data.

*This work is partially funded by DOE (DE-FG02-03ER46060).

**N41 6 Phase transition of Ta-modified $Pb(Sc_{0.5}Nb_{0.5})O_3$ nanoceramics** MARGARITA CORREA, RAM CHOUDHARY, RAM KATIYAR, *Department of Physics, University of Puerto Rico, San Juan PR00931-3343* Ferroelectric relaxors are promising candidates for multilayer ceramic capacitors. We have synthesized nanocrystalline $Pb(Sc_{0.5}Nb_{(1-x)/2}Ta_{x/2})O_3$, $(0.1< x < 0.9)$ by a high-energy ball milling technique. Analysis of as prepared powders using an X-ray technique shows the formation of materials in the tetragonal phase. TEM micrographs reveal that the particle size decreases to $\sim$ 20nm from $\sim$ 200nm on increasing the milling time These particles are nanocrystalline as evident by the diffraction rings of the selected area diffraction patterns of the activated powders. Studies of dielectric properties as a function of temperature (200-600K) and frequency (1 kHz – 1 MHz) of the sintered samples at different temperatures have shown that the materials have relaxor ferroelectric behavior and diffuse phase transition for $x \leqslant 0.5$. However, for $x \geqslant 0.6$ a diffuse phase transition without the frequency dispersion has been observed. The dielectric/relaxor properties of the compounds are dependent upon the sintering temperature, time, and composition. Detailed results will be presented.

**N41 7 Substrate-induced strain effects on the transport properties of pulsed laser deposited Nb doped $SrTiO_3$ films.*** WEGDAN RAMADAN, SATISH OGALE, SANKAR DHAR, SHIXIONG ZHANG, DARSHAN KUNDALIYA, ISSEI SATOH, THIRUMALAI VENKATESAN, *Center for Superconductivity Research, Department of Physics, University of Maryland, College Park, MD 20742-4111* Thin films of Nb doped $SrTiO_3$(NSTO) are grown via pulsed laser deposition (PLD) on $LaAlO_3$ (LAO, 001), $MgAl_2O_4$ (MAO, 001), $SrTiO_3$ (STO, 001), and Y-stabilized $ZrO_2$(YSZ, 001) substrates. The film growth is examined under various growth conditions. The dependence of film properties on the film-substrate lattice mismatch, film thickness, and substrate temperature is investigated. The electrical transport in NSTO films is shown to exhibit a strong sensitivity to strain, which is suggested to arise from the dependence of carrier mobility on bond distortions/stretching and related changes in phonon modes.

**N41 8 Blue-light emission at room temperature from $Ar^+$-irradiated $SrTiO_3$** DAISUKE KAN, *Institute for Chemical Research, Kyoto University* TAKAHITO TERASHIMA, *Research Center for Low Temperature and Materials Sciences, Kyoto University* RYOKO KANDA, ATSUNOBU MASUNO, *Institute for Chemical Research, Kyoto University* ATSUSHI ISHIZUMI, *Graduate School of Material Science, Nara Institute of Science and Technology* YOSHIHIKO KANEMITSU, YUICHI SHIMAKAWA, MIKIO TAKANO, *Institute for Chemical Research, Kyoto University* $SrTiO_3$ is a key material for fabricating oxide-based electronic devices. We found that $Ar^+$-irradiated, metallic $SrTiO_3$ crystals emit 430-nm blue-light at room temperature. Oxygen-deficient metallic $SrTiO_3$ thin films also show the blue-light emission. Reciprocal mapping using synchrotron x-ray radiation at SPring-8 reveals a slight elongation of the lattice parameter along the out-of-plane direction both for these samples. We, therefore, suggest that the $Ar^+$-irradiation introduces oxygen deficiency in the crystal surface, and that the deficiencies generate conduction carriers which wait ready for the recombination with photo-exited holes, and play an important role in the emission. It is emphasized that the emitting region could be patterned into any size and shape by combining conventional photolithography and $Ar^+$-milling. These new features of $SrTiO_3$ will open up new possibilities for the oxide-based electronic devices.

**N41 9 Measurement of the Electric Field Gradient at $^{181}$Ta in $ZrSiO_4$and $HfSiO_4$ using Perturbed Angular Correlation Spectroscopy** HERBERT JAEGER, *Miami University* SEAN McBRIDE, *University of Nebraska-Lincoln* Perturbed angular correlation spectroscopy (PAC) is a nuclear technique often used to probe the hyperfine interaction of a nuclear moment with extra-nuclear fields. For example the electric field gradient (EFG) at a $^{181}$Ta probe nucleus in zircon ($ZrSiO_4$) depends on the arrange-

ment of the Zr, Si, and O-atoms and is very sensitive to structural rearrangements. Our PAC experiments with zircon show that a very subtle rearrangement of Si-atoms within the unit cell leads to a change in the temperature dependence of the EFG. We are currently performing a series of PAC experiments on the isostructural hafnon ($HfSiO_4$). Preliminary results show no evidence of a similar structural rearrangement. In addition to the EFG, we also measure the anisotropy of the $\gamma\gamma$-cascade emitted during the decay of a $^{181}$Ta nucleus. The measured anisotropy depends somewhat on the geometry of the sample and detector arrangement. However, with a given nucleus and a fixed geometry one would not expect a substantial change in the anisotropy during a series of measurements, say as a function of temperature. Yet our PAC spectra of zircon show a consistent decrease of the anisotropy in the temperature range between 650 and 800°C. Preliminary PAC spectra of hafnon show no change of the anisotropy. Reasons for this apparent loss in anisotropy will be discussed.

**9:48**

**N41 10 Structure, Energetics, and Clustering Interactions for Cu on $TiO_2$ (110) at Various Coverages** SCOTT J. THOMPSON, STEVEN P. LEWIS, *University of Georgia* $TiO_2$ (110) is one of the prototypical metal-oxide surface systems, studied extensively and under a variety of different conditions by experimentalists and theorists alike. Recent experiments have enhanced our understanding of the structure of the stochiometric surface, and our Density Functional Theory calculations show excellent quantitative agreement with these latest results. In addition, strong interactions between metal catalysts and their supporting oxide substrates give rise to enhanced catalytic properties, and we are exploring this phenomenon for the prototypical system of Cu on the (110) surface of rutile $TiO_2$. In this talk, we will present our theoretical results for the surface structure and elaborate on the agreement with the latest experimental findings as well as the differences from previous theoretical work on this important system. We will also discuss predictions of the structure and energetics for Cu on $TiO_2$ (110) at various coverages and on both stoichiometric and reduced surfaces, where specific focus will be upon clustering interactions and the formation of Cu islands, which has been observed experimentally.

**10:00**

**N41 11 *Ab initio* molecular dynamics of a proton in amorphous $SiO_2$ illustrating the hopping mechanism** JULIEN GODET, ALFREDO PASQUARELLO, *Ecole Polytechnique Fédérale de Lausanne, Institute of Theoretical Physics, CH-1015 Lausanne* The scaling of metal-oxide-semiconductor devices to smaller dimensions is a major issue in current silicon technology. In order to understand the role of hydrogen at silicon-oxide interfaces, we here investigate charged states of hydrogen in amorphous $SiO_2$ ($a$-$SiO_2$) using first-principles calculations (DFT-GGA). We first show that the formation energies of $H^0$, $H^+$ and $H^-$ in $a$-$SiO_2$ are essentially equivalent to those in $\alpha$-quartz. In particular, the $H^+$ and $H^-$ species are always more stable than their neutral counterpart. Then, we focus on the basic diffusion mechanism of the proton in $a$-$SiO_2$. Our molecular dynamics simulations show that the proton hops between O atoms. The hopping does not occur between first O neighbors connected through the network, but takes place across rings when the O–O distance is about 2.3 Å. The hopping process is favored by the thermal vibrations of the O atoms.

**N41 12 Unusual compressibility in the negative-thermal-expansion material $ZrW_2O_8$*** ALBERT MIGLIORI, C. PANTEA, H. LEDBETTER, Y. ZHAO, T. KIMURA, *LANL* PETER B. LITTLEWOOD, *Cavendish Lab., Univ. of Cambridge* J. VAN DUIJN, *Dept. of Physics and Astronomy, Johns Hopkins Univ.* G.R. KOWACH, *Dept. of Chemistry, The City College of NY* The negative thermal expansion (NTE) compound $ZrW_2O_8$ has been well-studied because it remains cubic with a nearly constant, isotropic NTE coefficient over a broad temperature range. However, its elastic constants seem just as strange as its volume because NTE makes temperature acts as itpositive pressure, decreasing volume on warming and, unlike most materials, the thermally-compressed solid it softens. Does $ZrW_2O_8$ also soften when pressure alone is applied? Using pulse−echo ultrasound in a hydrostatic SiC anvil cell, we determine the elastic tensor of monocrystalline ZrW2O8 near 300 K as a function of pressure. We indeed find an unusual decrease in bulk modulus with pressure. Our results are inconsistent with conventional lattice dynamics, but do show that the thermodynamically−complete constrained−lattice model can relate NTE to elastic softening as increases in either temperature or pressure reduce volume, establishing the predictive power of the model, and making it an important concept in condensed−matter physics.

**N41 13 Oxide films imaged on a nanometer-scale by single-electron tunneling force microscopy*** CLAYTON C. WILLIAMS, EZRA BUSSMANN, NING ZHENG, *University of Utah* Recently, we reported a scanning probe technique to manipulate a single electron to and from states in a nonconducting surface by electron tunneling. Each electron is detected by electrostatic force as it tunnels between a scanning probe and the surface. Electrons are manipulated by tuning the probe Fermi level with respect to the states by a dc voltage. This manipulation serves as the mechanism for imaging and for performing electronic spectroscopy of states in dielectric films. The energy distribution of the states is measured by counting the electrons tunneling to the surface at incrementally varied voltages. The spatial distribution of states is imaged on a nanometer-scale by counting each electron tunneling on a 2-D grid. We present spectroscopic and imaging results from silicon dioxide and hafnium oxide. The density and spatial distribution of states is compared for various growth parameters. The measurements reveal evidence for energy relaxation and charge movement in the states. This new nanometer-scale approach provides the means to locate and identify electronic states in nonconducting surfaces, opening for exploration a whole class of materials not accessible to the STM. **N41 14 A novel approach to the growth of polycrystalline hydroxyapatite thin films*** ZHENDONG HONG, LAN LUAN, SEBUM PAIK, BIN DENG, DONALD ELLIS, JOHN KETTERSON, *Department of Physics and Astronomy, Northwestern University* ALEXANDRE MELLO, ALEXANDRE ROSSI, JOICE TERRA, *Centro Brasileiro de Pesquisas Fisicas, Brasil* NORTHWESTERN UNIVERSITY COLLABORATION, CBPF COLLABORATION, Hydroxyapatite (HA) thin films on metals have been extensively studied in connection with bioimplants. Conventional sputtering techniques have shown some advantages

over the commercially utilized plasma spray method; however, the as-sputtered films are usually amorphous which can cause serious adhesion problems when post-deposition heat treatment is necessitated. We present a novel opposing RF magnetron sputtering approach for the room temperature preparation of HA thin films on various substrates at low power levels. The as-sputtered films are found to be polycrystalline and the preferred orientations of the films vary with the substrate material and orientation. The effects of different sputtering parameters on the physical, chemical and structural properties was also studied. Finally, patterned films fabricated both before and after deposition have been prepared for further in vitro cell culture experiments.

**N41 15 Finite temperature properties of $(Ba,Sr)TiO_3$ disordered alloys and $BaTiO_3/SrTiO_3$ superlattices from first-principles*** SERGEY LISENKOV, LAURA WALIZER, LAURENT BELLAICHE, *University of Arkansas* We develop and use a first-principles-based scheme to predict properties of $(Ba,Sr)TiO_3$-based systems at finite temperature. This scheme yields a composition-versus-temperature phase diagram of disordered $(Ba_{1-x}Sr_x r)TiO_3$ solid solutions that is in rather good agreement with experimental data. We further use this scheme to reveal and understand the strain-versus-temperature phase diagram of several $BaTiO_3/SrTiO_3$ superlattices. A wide variety of dipole patterns, including homogeneous ferroelectric phase and periodic stripe patterns, are predicted to occur depending on the interplay between temperature, strain and superlattice periods.

**N42 1 Shock-Induced Chemical Reactions of Polycyclic Aromatic Hydrocarbons** MARK ELERT, *U. S. Naval Academy* SERGEY ZYBIN, *California Institute of Technology* SHANNON REVELL, *U. S. Naval Academy* CARTER WHITE, *Naval Research Laboratory* Polycyclic aromatic hydrocarbons (PAHs) have been found in the atmospheres of Jupiter and Titan, and also in meteorites, interplanetary dust, and circumstellar graphite grains. The ubiquity of these complex organic structures and their stability under extreme conditions make them a significant factor in discussions of brebiotic chemistry in the solar system. To study the shock-induced chemistry of PAHs under conditions appropriate for astrophysical impacts, molecular dynamics simulations have been carried out for solid naphthalene and anthracene using a reactive empirical potential. The major reaction channels for these two closely related compounds were found to be substantially different. Product distributions were also found to depend strongly on the orientation of the PAH crystal relative to the shock propagation direction.

**8:12**

**N42 2 Interatomic bond-order potentials for atomistic simulations of materials at extreme conditions** YONGXUE YU, IVAN OLEYNIK, *Univ. of South Florida* Molecular dynamics simulations provide an excellent opportunity to address fundamental physics and chemistry of materials at extreme conditions. However, the results of MD modeling can only be as reliable as the ability of the interatomic potentials to properly describe a variety of chemical effects including bond-breaking and bond-making. Our recent MD simulations of shock compression of covalently bonded materials such as diamond and silicon using REBO interatomic potential for diamond and EDIP potential for Si showed that the properties of C and Si systems at large pressures and temperatures are not well described in spite of the fact that the near equilibrium properties of both diamond and silicon are well reproduced. We present new results on development of analytic bond-order potentials (BOPs) for covalently bonded materials at extreme conditions. These BOPs are derived using the powerful concepts of moments of density of states, Green's function and Lanczos recursion, applied within the two-center, orthogonal tight-binding bond representation of electronic structure. Importantly, they include explicit analytic expressions for both the $\sigma$ and $\pi$ bonds. We will describe details of BOP construction including devising a first-principle database of fundamental materials properties, its fitting by the tight-binding (TB) model, and devising the analytic BOPs using the direct link between TB and analytic BOPs via the bond orders. Validation of analytic BOPs by comparison with first-principles high-pressure data will also be discussed.

**N42 3 First-principles modeling of energetic materials** MIKE CONROY, *University of South Florida* IVAN OLEYNIK, *University of South Florida* CARTER WHITE, *Naval Research Laboratory* The prediction of properties of energetic materials using atomic-scale simulation techniques is one of the promising areas of energetic materials (EM) research. One of the challenges is to understand the initial response of EM to shock loading based on fundamental atomic-scale properties of EM crystals. We report the results of first-principles density-functional calculations of static and thermodynamic properties of PETN, HMX and RDX molecular crystals including properties of different crystalline phases and their equations of states (EOS). The EOS are extended beyond simple isotropic constitutive relationships to include materials response upon uniaxial compressions and high pressures up to 100 GPa. The predictions of the theory are compared with recent experimental results.

**N42 4 Direct Simulation of Detonations: Applications to the $H_2$-$Cl_2$ System*** PATRICK D. O'CONNOR, *Pennsylvania State University* LYLE N. LONG, *Pennsylvania State University* JAMES B. ANDERSON, *Pennsylvania State University* Earlier simulations in our laboratory showed that ultrafast detonations having steady-state velocities greater than predicted by the Chapman-Jouguet (CJ) and the Zeldovich-von Neumann-Döring (ZND) theories could be produced by very fast model reactions. In

this paper we will report matching studies incorporating a realistic treatment of the reaction $H_2 + Cl_2 \rightarrow 2\ HCl$ reacting by the Nernst chain reaction mechanism with ignition, propagation and termination steps along with the inclusion of rotational and vibrational degrees of freedom for diatomic species and the realistic treatment of energy exchanges among all species. The $H_2$-$Cl_2$ system is the prototypical system for studying detonations both experimentally and theoretically, and is an ideal candidate for investigation. Our simulations are made using Bird's direct simulation Monte Carlo method which produces the full details of the coupled gas-dynamic and reaction effects as well as temperature, velocity, density, pressure, and species profiles for the detonation waves. By comparing predictions with available experimental measurements for the system, we will be able to predict the likelihood that ultrafast detonations can be observed for the $H_2$-$Cl_2$ reaction.

**8:48**

**N42 5 Molecular Dynamics Simulations of Thermal Induced Chemistry in TATB*** JASON QUENNEVILLE, TIMOTHY GERMANN, *Los Alamos National Laboratory* Equilibrium molecular dynamics (MD) simulation of high explosives can provide important information on their thermal decomposition by helping to characterize processes with timescales that are much longer than those attainable with non-equilibrium MD shock studies. A reactive force field is used with MD to probe the chemisty induced by intense heating ('cook-off') of 1,3,5-triamino-2,4,6-trinitrobenzene (TATB). The force field (ReaxFF) was developed by van Duin, Goddard and coworkers† at CalTech and has already shown promise in predicting the chemistry in small samples of RDX under either shock compression or intense heat. Large-system simulations are desired for TATB because of the high degree of carbon clustering expected in this material. We will show results of 100,000-particle simulations at several temperatures, carried out with the massively parallel GRASP MD software developed at Sandia National Lab. Finally, we will compare the reactions and reaction timescales with those of RDX and HMX. † A. C. T. Van Duin, itet al, itJ. Phys. Chem. A, **1005**, 9396 (2001).

**N42 6 Decomposition of Energetic Materials at Extreme Conditions** RIAD MANAA, LAURENCE FRIED, *Lawrence Livermore National Laboratory* Detailed description of chemical reaction mechanisms of solid energetic materials at high-density and temperatures is essential for understanding events that occur at the reactive front of these materials, and for the subsequent development of predictive models of materials properties. In this talk, we will report the results of our ongoing ab initio based molecular dynamic simulation of the chemistry of TATB, at density of 2.9 g/cm$^3$ and temperature of 1500K, and at density of 2.87 g/cm$^3$ and temperature of 2500 K. These conditions are similar to those experienced at the CJ and von Neumann spike Following the dynamics for a time scale of up to forty picoseconds allows the construction of approximate rate laws for typical products such as $H_2O$, $N_2$, CO, and $CO_2$. The approximate reaction rates obtained for these products at the CJ state will be compared to those obtained recently for HMX at similar conditions. This work was performed under the auspices of the U.S. Department of Energy by the Lawrence Livermore National Laboratory under contract number W-7405-Eng-48.

**9:12**

**N42 7 Transitions between strong shock and elastic-plastic shock regimes in tin and Lennard-Jonesium.** J.M.D. LANE, MICHAEL MARDER, *Center for Nonlinear Dynamics/Dept. of Physics* SHOCK TEAM, We have recently developed the Continuous Hugoniot Method as an efficient numerical approach to study the front dynamics of steady shocks. This method produces a continuous set of shock states as a function of the shock strength driving parameter. We use our method to investigate the shock states at and near the transition between the strong shock and elastic-plastic shock regimes in both single-crystal tin and Lennard-Jonesium along the $\langle 100 \rangle$ directions.

**9:24**

**N42 8 Multi-scale molecular dynamics simulations of steady shock waves in Lennard-Jones and nitromethane** EVAN REED, *Lawrence Livermore National Laboratory* LAURENCE FRIED, M. MANAA, WILLIAM HENSHAW, CRAIG TARVER, *Lawrence Livermore National Laboratory* We compare spatial profiles of steady shock waves using our multi-scale simulation technique (Phys. Rev. Lett. 90, 235503 (2003)) and direct simulation techniques and find good agreement. Multi-scale simulations of shocked amorphous Lennard-Jones are in good agreement with NEMD simulations and multi-scale simulations of shock waves in analytical equations of state of explosives are in good agreement with hydrodynamic simulations. In both cases, agreement improves with distance behind the shock front. We have applied the multi-scale technique to the study of chemically reactive shock waves in condensed nitromethane (CH3NO2) using the density-functional tight-binding (DFTB) method. We study shock waves with speeds ranging from 5.5 km/s to 8 km/s for durations up to 0.5 ns behind the shock front. We believe these are the longest duration tight-binding simulations of shocked matter ever performed.

**9:36**

**N42 9 First-principles approach to reactivity in the presence of shockwave** CHRISTOPHER MUNDY, *LLNL* I.-F. WILL KUO, *LLNL* ALESSANDRO CURIONI, *IBM* EVAN REED, *LLNL* LARRY FRIED, *LLNL* Gaining insight into the mechanisms leading to detonation in energetic materials within a planar shock geometry had been thought to be computationally prohibitive. The use of the Multiscale Shock Method (MSSM) of Reed et. al has opened the possibilities to study the chemistry of complex molecular systems undergoing uniaxial shock compression using Kohn-Sham density functional theory (KS-DFT). Here, we present results of nitromethane under various levels of shock loading and reveal the chemical mechanisms underlying the detonation process. We will also discuss an alternative non-Hamiltonian formulation of the MSSM. The aforementioned formulation is present in both CPMD and CP2K software packages. We also will compare and contrast different formulations of KS-DFT (both plane- wave and hybrid schemes) and discuss future of scaling the MSSM method to tera- scale platforms such as Blue Gene/L.

**N42 10 Finding the structure of phosphorus in phase IV by the first-principles calculation** TAKAHIRO ISHIKAWA, HITOSE NAGARA, KOICHI KUSAKABE, NAOSHI SUZUKI, *Osaka University* Phosphorus in phase IV (P-IV) had been unclear since first experimental report. Using the metadynamics combined with the first-principles calculation, we obtained a new structure. The structure is a monoclinic of sc: a=c=4.22Å, b=4.15Å, $\beta$=97.76° and a modulation is observed along the b-axis. We noted this modulated pattern and, for modulated structures having other wave-lengths, compared the x-ray diffraction patterns of these structures with experimental one. As a result, limited to the case of commensurate patterns because of the periodic boundary condition for the calculations, the structure whose period is 4 times as long as that of the non-modulated structure is the most compatible for the experimental result. For this pattern, calculating the enthalpy for pressure, it is lower than both sc and sh in the range from 118 GPa to 128 GPa. Recently Akahama et al. have determined the structure of P-IV, which is rather close to our structure. Our calculation shows the transition from sc to P-IV was the first order phase transition.

**N42 11 First Principles Phonon and Elasticity Computations for Iron under extreme conditions*** XIANWEI SHA, R.E. COHEN, *Carnegie Institutiion of Washington* We performed linear-response Linear-Muffin-Tin-Orbital (LMTO) and particle-in-cell (PIC) model calculations to understand and predict the lattice dynamical, thermal equation of state and elastic properties of bcc, fcc, and hcp iron as functions of pressure and temperature. The phonon dispersion and phonon density of states have been calculated at different volumes and show good agreement with experiment. We derived the Helmholtz free energy based on both the linear response LMTO and PIC calculations, and found that the calculated geometric mean phonon frequencies and free energies from these two different methods agree well under pressure, in contradiction to an earlier calculation. We performed detailed investigations on the behavior of elastic constants and various thermal equation of state parameters, including the bulk modulus, the thermal expansion coefficient, the Grüneisen ratio, and the heat capacity as functions of temperature and pressure. We made detailed comparison with experiment and earlier theoretical calculations. We do not find the large change in c/a axial change with T. Sound velocities at extreme conditions have also been examined. These first-principles data provide important information to understand shock dynamics and other interesting phenomena under extreme conditions.

**N42 12 Ab initio studies of magnetism at extreme volume and shape deformation** MOJMIR SOB, *Masaryk University, Brno* MARTIN FRIAK, *Institute of Physics of Materials, Academy of Sciences of the Czech Republic, Brno* DOMINIK LEGUT, *Institute of Physics of Materials, Academy of Sciences of the Czech Republic, Brno* MIROSLAV CAK, *Faculty of Mechanical Engineering, Brno University of Technology* MARTIN ZELENY, *Faculty of Chemistry, Brno University of Technology* Magnetic solids constitute a basis of many technologically important materials, however, very little is known how their magnetic behavior changes when a high-strain deformation is applied (as it is, for example, in heavily deformed regions of extended defects, such as grain boundaries, dislocation cores, crack tips etc.). In the present talk, we report on magnetic behavior of iron, nickel, FeCo, $Ni_3Al$ and $Fe_3Al$ at the extreme volume as well as tetragonal and trigonal deformation. The total energies are calculated by spin-polarized full-potential LAPW method and are displayed in contour plots as functions of tetragonal or trigonal distortion $c/a$ and volume; borderlines between various magnetic phases are shown. Stability of tetragonal magnetic phases of $\gamma$-Fe is discussed. In case of Fe, Ni and FeCo, the calculated phase boundaries are used to predict the lattice parameters and magnetic states of overlayers from these materials on various (001) substrates. Whereas magnetism does not play an important role in stabilization of the $L1_2$ structure in $Ni_3Al$, the magnetic effects in Fe and $Fe_3Al$ are vital.

**N42 13 Electronic Structure of Actinides under Pressure.**
BORJE JOHANSSON, *Department of Physics, Uppsala University*

The series of heavy radioactive elements known as the actinides all have similar elemental properties. However, when the volume per atom in the condensed phase is illustrated as a function of atomic number, perhaps the most dramatic anomaly in the periodic table becomes apparent. The atomic volume of americium is almost 50% larger than it is for the preceding element plutonium. For the element after americium, curium, the atomic volume is very close to that of americium. The same holds also for the next elements berkelium and californium. Accordingly from americium and onwards the actinides behave very similar to the corresponding rare-earth elements - a second lanthanide series of metallic elements can be identified. This view is strongly supported by the fact that all these elements adopt the dhcp structure, a structure typical for the lanthanides. The reason for this behavior is found in the behavior of the 5f electrons. For the earlier actinides, up to and including plutonium, the 5f electrons form metallic states and contribute most significantly to the bonding. In Np and Pu they even dominate the bonding, while all of a sudden they become localized in Am, very much like the 4f electrons in the lanthanide series, and contribute no longer to the cohesion. This withdrawal of 5f bonding gives rise to the large volume expansion between plutonium and americium. This difference between the light and heavy actinide suggests that it would be most worthwhile to strongly compress the transplutonium elements, thereby forcing the individual 5f electron wave functions into strong contact with each other (overlap). Recently high pressure experiments have been performed for americium and curium and dramatic crystal structure changes have been observed. These results and other high pressure data will be discussed in relation to the basic electronic structure of these elements.

**8:12**
**N43 2 Electromagnetically induced transparency and precision measurement of atomic transitions in a laser-cooled sample of cesium atoms*** CHIN-CHUN TSAI, MING-DA TSAI, MEI-JU LU, RAY-YUAN CHANG, *Center for Quantum Information Science and Department of Physics, National Cheng-Kung University* Electromagnetically induced transparency (EIT) has observed in a cascade system of laser-cooled Cs atoms and the atomic energy levels have been measured to an accuracy of 0.0003 $cm^{-1}$. In our experiment, Cs atoms are loaded into the magneto-optical trap (MOT) from a background vapor that has a pressure of $10^{-9}$ torr. The number of Cs atoms is estimated using a CCD camera to be $10^7$ occupying a roughly spherical volume having a radius of 2 mm and the temperature of the atom cloud is measured using a time of flight technique to be about 100 $\mu$K. A diode laser excites the Cs atoms from $|6\,^2S_{1/2}, F = 4\rangle$ state to $|6\,^2P_{3/2}, F = 5\rangle$ state, then a dye laser couples the 6 $P_{3/2}$ state to the higher excited, $|9\,^2D_{3/2}\rangle$, $|9\,^2D_{5/2}\rangle$, $|10\,^2D_{3/2}\rangle$, $|10\,^2D_{5/2}\rangle$, and $|11\,^2S_{1/2}\rangle$ atates. The signal is monitored by detecting the trap loss while changing the pump or coupling laser frequency. The effect on the EIT signals by changing the pump laser detuning and the coupling laser power is also discussed. The line positions are measured by comparing the saturation absorption spectrum of molecular iodine (accuracy $<$ 3 MHz).

*We greatly acknowledge the support of the National Science Council, Taiwan.

**N43 3 Femtosecond Coherent Raman Spectroscopy in Biomolecules** ZOE-ELIZABETH SARIYANNI, YURI ROSTOVTSEV, *Dept. of Physics and Inst. for Quantum Studies, Texas A&M University, College Station, TX 77843* TORSTEN SIEBERT, WOLFGANG KIEFER, *Institut für Physikalische Chemie, Universität Würzburg, 97074 Würzburg, Germany* GUY BEADIE, JOHN REINTJES, *US Naval Research Lab, Code 5614, 4555 Overlook Ave., Washington, DC 20375* MARLAN SCULLY, *Dept. of Physics, Electrical and Chemical Engineering and Inst. for Quantum Studies, Texas A&M University, College Station, TX 77843* We present a scheme for identification of biomolecules in real time by using Coherent Anti-Stokes Raman Spectroscopy (CARS) with femtosecond pulses. The nonlinear interaction of the pulses with the molecules is calculated analytically as well as numerically and comparison is made with the experimental results. We show that the commonly used rotating wave approximation needs to be waved for our fast dephasing molecules. Propagation effects are simulated, in addition to the nonlinear interaction, and it is shown how one needs to balance the electronic resonance enhancement and the losses due to absorption, in order to maximize the signal at the output of the optically dense medium. In the transient regime, we present and analyze the generation of polarization beats. These beats are generated due to the very broad bandwidth of the femtosecond pulses, which allows for the coupling of more that one vibrational modes at a time.

**8:36**
**N43 4 Dephasing of excitons in single ZnSe quantum wells using 30 fs pulses** PRADEEP BAJRACHARYA, HANS-PETER WAGNER, SUVRANTA K. TRIPATHY, HANS-PETER TRANITZ, *Department of Physics, University of Cincinnati, Cincinnati, Oh, 45221* The dephasing of excitons in homogenously broadened 10nm wide ZnMgSe/ZnSe single quantum wells is investigated using ultra short ( $<$ 30fs) light pulses in two beam and three beam four wave mixing (FWM) configuration. The observed FWM traces show marked quantum beats due to excitation of higher exciton transitions within the 80 meV spectrally broad pulses. For pulse delay times shorter than 500 fs, non-Markovian signal decay is observed. For longer delay times the exciton dephasing becomes single exponential indicating the transition from quantum kinetics to classical Boltzmann kinetics. Intensity and polarization dependent FWM measurements give further information on the physical nature and scattering processes that take place in both time regimes. This work is supported by the National Science Foundation (DMR-0305076).

**8:48**
**N43 5 Dynamics of high amplitude coherent phonons in photoexcited bismuth*** DAVID REIS, *FOCUS Center and Department of Physics, University of Michigan* DAVID FRITZ, *FOCUS Center and Department of Physics, University of Michigan* EAMMON MURRAY, *Department of Physics and Tyndall National Institute, University College, Cork, Ireland* STEPHEN FAHY, *Department of Physics and Tyndall National Institute, University College, Cork, Ireland* JARED WAHLSTRAND, *JILA/University of Colorado* We report on studies of high amplitude coherent phonons in photoexcited bismuth. All optical experiments, in which two pump pulses are used to coherently control the amplitude $A_{1g}$ phonon at a fixed carrier density, allow us to separate the effects of carrier dynamics from anharmonicity. The results show that the the time dependent frequency of the phonon is dominated by electronic softening of the interatomic potential. Seperate first-principals theoretical calculations confirm these results for photoexcited carrier densities up to approximately 2% of the valence electrons. We comment on the possibility of x-ray diffraction and diffuse scattering as a means of measuring the detailed dynamics.

**N43 6 Optimization and Rate-Equation Model for Second-Harmonic Generation in Mid-Infrared Quantum Cascade La-**

**sers** JING BAI, DAVID CITRIN, *Georgia Institute of Technology* We present the rate-equation simulation of a mid-infrared quantum cascade laser with optimized second-harmonic generation. The simulation is performed by optimization of the structure design followed by self-consistently solving the rate equations for the carriers in the various levels. The optimized structure was obtained by supersymmetric quantum mechanics with both position-depended mass and band nonparabolicity included. In the rate-equation model, the second harmonic generation process is described by sequentially two single photon absorption and one second-harmonic photon generation. Nonunity pumping efficiency is accounted by all relevant electron-electron and electron-LO phonon scatterings between injector/collector and active region are included. The modal gain, linear power and second-harmonic power can then be calculated based on the steady-state populations in the active region. Results show that the optimized structure has higher modal gain and linear to nonlinear conversion efficiency.

**9:12**

**N43 7 Observation of a coherent exciton-LO phonon resonance in a ZnSe single quantum well** SUVRANTA K. TRIPATHY, HANS-PETER WAGNER, PRADEEP BAJRACHARYA, *Department of Physics, University of Cincinnati, Cincinnati, Oh, 45221* A. UETA, D. HOMMEL, *Institut für Festkörperphysik, Universität Bremen, D-28334 Bremen,Germany* A new coherent signal has been observed while performing two- beam degenerate four-wave mixing (FWM) experiments on a 3nm ZnMgSSe/ZnSe single quantum well (SQW) using 30fs laser pulses. In this SQW structure the exciton binding energy exceeds the LO-phonon energy (31.6 meV). The observed spectral feature is blue shifted with respect to the heavy-hole bound exciton transition by $\sim$ 32 meV and indicates the formation of a coherent exciton-LO phonon resonance with a dephasing time of $\sim$ 500 fs. This tentative assignment is further supported by photoluminescence excitation (PLE) and by reflection measurements. This work is supported by the National Science Foundation (DMR-0305076).

**N43 8 Vibrational Lifetimes and Frequency-Gap Law of Hydrogen Bending Modes in Semiconductors** BAOZHOU SUN, GUNTER LUEPKE, *Department of Applied Science, the College of William and Mary* GANG SHI, MICHAEL STAVOLA, *Department of Physics, Lehigh University* NAGESWARA SUNKARANAM, SRIRAM DIXIT, NORMAN TOLK, FELDMAN LEONARD, *Department of Physics and Astronomy, Vanderbilt University* Vibrational lifetimes of hydrogen and deuterium related bending modes in semiconductors are measured by transient bleaching spectroscopy and high-resolution infrared absorption spectroscopy. We find that the vibrational lifetimes follow a universal frequency-gap law, i.e., the decay time increases exponentially with increasing decay order, with values ranging from 1 ps for a one-phonon process to 265 ps for a four-phonon process. The temperature dependence of the lifetime shows that the bending mode decays by lowest-order multi-phonon process. Our results provide new insights into vibrational decay and the giant isotope effect of hydrogen in semiconductor systems.

**9:36**

**N43 9 High field gradient for electron acceleration and ultrashort electron pulse formation** ALEXANDER POKROVSKY, ALEXANDER KAPLAN, *Johns Hopkins University* We explore a possibility of strongly inelastic scattering and large energy exchange between the tightly focused laser and electron beams in the ''transverse'' geometry, whereby the beams propagate normally to each other. In the most basic configuration of the laser standing wave we demonstrate that multi-MeV electron acceleration per pass is attainable, if the field has large spatial gradient along the direction of electron motion. The electron motion in this case is relativistic, and the energy gain or loss can be retained by an electron with very high efficiency. The proposed scheme may provide enormous $\sim$ 0.1 TeV/cm acceleration gradient. We also show that the transverse electron and laser beam configuration can cause strong temporal electron focusing resulting in formation of ultra-short electron bunches. Such a system has a potential to operate as a full-switch laser gate for electrons, a new base element of a free-electron laser and laser electron accelerators.

**9:48**

**N43 10 Relativistic effect of ponderomotive force direction reversal in a standing laser wave** ALEXANDER KAPLAN, ALEXANDER POKROVSKY, *ECE Department, Johns Hopkins University* In our research, we theoretically discovered a relativistic effect of the direction reversal of the field-gradient (ponderomotive) force (PF) in a standing laser wave. This reversal makes the high-field areas attractive for electrons, in contrast to the regular PF, and it represents the only effect known so far that pins down a distinct borderline between relativistic and nonrelativistic motion. We demonstrated that the collinear configuration, in which the laser wave is linearly polarized with electric field, $\vec{E}$ parallel to the initial electron momentum, $\vec{p}_0$, is the optimal configuration for the relativistic reversal. In that case, the transverse PF reverses its direction when the incident momentum is $p_0 = mc$. The reversal effect vanishes in the cases of circular and linear with $\vec{E} \perp \vec{p}_0$ polarizations. We have discovered, however, that the counter-rotating circularly polarized standing waves develop attraction and repulsion areas along the axis of laser, in the laser field whose intensity is homogeneous in that axis, i.e. has no field gradient.

**N43 11 Spatial and pulse shape dependence of K$\alpha$ source from high contrast fs laser plasmas in regime of Relativistic Engineering** LIMING CHEN, *Advanced Photon Resaerch Center, Japan Atomic Energy Agency* Interaction of intense Ti: Sapphire laser with Cu foil targets has been studied by measuring hard X-ray generation. Hard x-ray spectroscopy and K$\alpha$ X-ray conversion efficiency ($\eta_K$) from Cu plasma have been studied as a function of laser intensity via pulse duration scan (60 fs $\sim$ 600 fs), laser pulse energy scan (60 mJ $\sim$ 600 mJ) and target displacement scan from best focus. For intensity I $>$ 1x10$^{17}$ W/cm$^2$, the Cu $\eta_K$ keep on increasing to reach a maximum value of $1x10^{-4}$ at an intensity $I = 1x10^{18}$ W/cm$^2$. The focusing was varied widely to give a range of intensities from $10^{15}$W/cm$^2$ $\sim$ $10^{18}$ W/cm$^2$. Two individual emission peaks are obtained, one is at best focal spot and the other is at larger target offset corresponding to $\sim$ $10^{15}$ W/cm$^2$. Each peak is corresponding to different energy absorption mechanism. In addition, when we introduce slightly detuning of compressor gratings at the best focal condition, it shows $\eta_K$ generated by negatively skewed 100 fs pulse width laser irradiation reach $5x10^{-4}$ and almost 7 times greater than the case of positively skewed pulse. Vacuum Heating is greatly stimulated in this case and preciously control of preplasma is the key factor in tuning control of X-ray emission in relativistic itfs regime.

**10:12**
**N43 12 Guiding of 100 TW Relativistic Laser Pulses by 10 mm Plasma Channels** LIMING CHEN, *Advanced Photon Resaerch Center, Japan Atomic Energy Agency* First experiments for laser-gas plasma interaction about electron acceleration have been performed with 30 fs, 100 TW relativistic Ti:Sapphier laser pulse interaction with long slit (1.2 x 10 $mm^2$) gas plasmas. The world record it10 mm length plasma channel formed that was longer than 20 times the Rayleigh length. Plasma density was the key factor for this long channel stimulation under 100 TW laser pulse irradiation that was much higher than critical power for relativistic self-focusing. For the first time, channel characteristics such as laser bending, hosing and cavity formation were demonstrated experimentally. In case of long channel guiding, accelerated electron bunch was tightly collimated with low emmitance it$<$ 0.8 $\pi$ mm mrad and quasi-monoenergetic electron bunch (it$\sim$ 70 MeV) was obtained as well. Accelerated electron charge current with electron energy $>$ 1 MeV was $\sim$ 10 nC/shot which was highest value in laser accelerator, to our knowledge, and ascribed to the contribution of long plasma channel.

**SESSION N44: QUANTUM CRITICALITY AND NEMATIC ORDERING**
**Wednesday Morning, 15 March 2006**
**347, Baltimore Convention Center at 8:00**
**Q. Si, Rice University, presiding**

**8:00**
**N44 1 The Effect of the Berry Phase on the Quantum Critical Properties of the Bose-Fermi Kondo model** STEFAN KIRCHNER, *Rice University* QIMIAO SI, *Rice University* The theory of the quantum critical point of a $T = 0$ transition is traditionally formulated in terms of a quantum-to-classical mapping, leading to a theory of its classical counterpart in elevated dimensions. Recently, it has been shown that this mapping breaks down in an SU(N)$\times$ SU(N/2) Bose-Fermi Kondo model (BFKM) [1], a BFKM with Ising anisotropy [2] and the spin-boson model [3]. Here we report the Quantum Monte Carlo results for the scaling properties of the quantum critical point of the BFKM with Ising anisotropy. In addition, using the Lagrangian formulation of the BFKM, we study the critical properties in the presence and absence of the spin Berry phase term. The results of the two cases are compared with the numerical results. [1] L. Zhu, S. Kirchner, Q. Si, and A. Georges, Phys. Rev. Lett. 93,267201 (2004). [2] M. Glossop and K. Ingersent, Phys. Rev. Lett. 95, 067202 (2005). [3] M. Vojta, N-H Tong, and R. Bulla, Phys. Rev. Lett. 94, 070604 (2005).

**8:12**
**N44 2 Quantum Critical Behaviour Near the Kondo Breakdown Fixed Point*** INDRANIL PAUL, *SPhT, CEA Saclay, L'Orme des Merisiers, 91191 Gif-sur-Yvette, France and Materials Science Division, Argonne National Lab, Argonne, IL-60439* CATHERINE PÉPIN, *SPhT, CEA Saclay* MIKE R. NORMAN, *Materials Science Division, Argonne National Lab* We study the Kondo-Heisenberg model using a fermionic representation for the localized spins. In this model, the mean field Kondo hybridization at $T = 0$ can be continuously tuned to zero as a function of the exchange interactions. We calculate the fluctuations of the hybridization and its associated gauge potential at the one loop level, and their contribution to the specific heat and spin susceptibility, near the quantum critical point.

*Work supported by the U. S. Dept of Energy, Office of Science, under contract No. W-31-109-ENG-38.

**8:24**
**N44 3 Kondo Screening and Fermi Surface in the Antiferromagnetic Metal Phase** SEIJI YAMAMOTO, *Rice University* QIMIAO SI, *Rice University* We address the Kondo effect deep inside the antiferromagnetic metal phase of a Kondo lattice Hamiltonian with SU(2) invariance. The local- moment component is described in terms of a non-linear sigma model. The Fermi surface of the conduction electron component is taken to be sufficiently small, so that it is not spanned by the antiferromagnetic wavevector. The effective low energy form of the Kondo coupling simplifies drastically, corresponding to the uniform component of the magnetization that forward-scatters the conduction electrons on their own Fermi surface. We use a combined bosonic and fermionic (Shankar) renormalization group procedure to analyze this effective theory and study the Kondo screening and Fermi surface in the antiferromagnetic phase. The implications for the global magnetic phase diagram, as well as quantum critical points, of heavy fermion metals are discussed.

**8:36**
**N44 4 Sign change of the Grüneisen parameter and magnetocaloric effect near quantum critical points** MARKUS GARST, *Theoretical Physics Institute, University of Minnesota, USA* ACHIM ROSCH, *Institute for Theoretical Physics, University of Cologne, Germany* Strong fluctuations near a quantum critical point lead to a singular entropy distribution in the phase diagram. This results in strong signatures of the Grüneisen parameter and the magnetocaloric effect. In particular, a sign change of the Grüneisen parameter coincides with the accumulation point of entropy in the phase diagram. If the quantum critical point is the endpoint of a line of finite temperature phase transitions the sign change generically occurs in the Ginzburg regime of the classical transition as observed in several heavy fermion compounds. In addition, we predict a sharp peak in the Grüneisen parameter at the critical temperature due to the contribution of classical critical fluctuations. For magnetic field tuning these signatures are also reflected in the magnetocaloric effect. Moreover, we discuss the case of metamagnetic quantum criticality where the sign change is located at the critical magnetic field.

**8:48**
**N44 5 Towards a unification of local moment magnetism and the Kondo lattice** JEROME RECH, *Rutgers University, CEA Saclay* PIERS COLEMAN, *Rutgers University* GERGELY ZARAND, *Budapest University of Technology and Economics* OLIVIER PARCOLLET, *SPhT CEA Saclay* We apply the Schwinger boson scheme to the fully screened Kondo model and generalize the method to include antiferromagnetic interactions between ions. Our approach unifies the Kondo impurity approach of Parcollet and Georges with the Schwinger boson description of antiferromagnetism of Arovas and Auerbach, enabling the formalism to describe magnetically correlated and magnetically ordered heavy electron phases. For the single impurity, our approach captures the Kondo crossover from local moment behavior to a Fermi liquid with a non-trivial Wilson ratio. When applied to the two

impurity model, the mean-field theory describes the ''Varma Jones'' quantum phase transition between a valence bond state and a heavy Fermi liquid. We will extend the method to the Kondo lattice, and explore the nature of the phase diagram connecting the heavy electron phase, the magnetic phase and the spin-liquid phase.

**9:00**

**N44 6 Quasi-particle linewidth close to a quantum critical point: Crossover from non-Fermi liquid to Fermi liquid behavior*** PEDRO SCHLOTTMANN, *Florida State University* Heavy fermion systems frequently display non-Fermi liquid behavior due to a nearby quantum critical point. A nested Fermi surface together with the remaining interaction between the carriers after the heavy particles are formed may give rise to itinerant antiferromagnetism. The order can gradually be suppressed by mismatching the nesting and a quantum critical point is obtained as $T_N \rightarrow 0$. The quasi-particle linewidth is calculated in the paramagnetic phase following an approach outlined by Virosztek and Ruvalds (Phys. Rev. B **42**, 4064 (1990)). The linewidth shows a crossover from non-Fermi liquid ( $\sim T$) to Fermi liquid ( $\sim T^2$) behavior with increasing nesting mismatch and decreasing temperature. The quasi-particle linewidth is a quantity relevant to the electrical resistivity and the width of the inelastic neutron scattering quasi-elastic peak.

**N44 7 Curie law, entropy excess, and superconductivity in heavy fermion metals and other strongly interacting Fermi liquids** V.A. KHODEL, M.V. ZVEREV, *Russian Research Centre Kurchatov Institute* VICTOR YAKOVENKO, *Department of Physics, University of Maryland* Low-temperature thermodynamic properties of strongly interacting, itinerant Fermi liquids with fermion condensate are investigated. We demonstrate that the spin susceptibility of these systems exhibits the Curie-Weiss law, and the entropy contains a temperature-independent term. The excessive entropy is released at the superconducting transition, enhancing the specific heat jump $\Delta C$ and rendering it proportional to the effective Curie constant. The theoretical results are favorably compared with the experimental data on the heavy fermion metal $CeCoIn_5$, as well as $^3$He films. Reference: cond-mat/0508275, Phys. Rev. Lett. (December 2005).

**9:24**

**N44 8 Super-frustration for strongly-correlated fermions in two dimensions** PAUL FENDLEY, *University of Virginia* KARELJAN SCHOUTENS, *University of Amsterdam* We prove that there exists an exotic ''super-frustrated'' state of strongly-correlated spinless fermions hopping on a two-dimensional lattice. This state is characterized by an extensive ground-state entropy, and very possibly is at a non-Fermi-liquid quantum critical point. We give explicit Hamiltonians which exhibit this behavior. Exploring various lattices and limits, we show how the ground states can be frustrated, quantum critical, or combine frustration with a Wigner crystal.

**9:36**

**N44 9 Domain formation in electronic nematic phase coupled to lattice deformation** HYEONJIN DOH, YONG BAEK KIM, *Dept. of Physics, Univ. of Toronto, Canada* KEUN HYUK AHN, *Advanced Photon Source, Argonne National Laboratory* Motivated by the experiments on $Sr_3Ru_2O_7$, we have investigated the possibility of domain formation in electronic nematic phase coupled to lattice deformations. It has been suggested that the formation of the nematic order may explain the two consecutive metamagnetic transitions observed in $Sr_3Ru_2O_7$. Our study may serve as the explanation of the high residual resistivity observed in a range of magnetic fields.

**9:48**

**N44 10 Non-Fermi Liquid Behavior of Nematic Fermi Fluids** MICHAEL LAWLER, EDUARDO FRADKIN, *University of Illinois at Urbana-Champaign* Following the initial study of Ref. 1, we explore the behavior of physically relevant quantities in the vicinity of the quantum critical point between a nematic Fermi fluid and a Fermi liquid. As shown in Ref. 1, this strong coupling fixed point is completely accessible within the method of high dimensional bosonization and we continue the analysis presented therein focusing on quasiparticle properties, such as the fermion residue and the fermion spectral function. We show in particular, that the fermion residue vanishes according to the essential singularity $\exp(-1/\sqrt{\delta})$ where $\delta$ is the dimensionless coupling constant measuring the distance to the critical point. Also, at low temperatures, we verify explicitly that the heat capacity obey's the non-Fermi liquid powerlaw of $T^{2/3}$. We conclude with a discussion of the signatures of the nematic phase that would appear in light scattering and angle resolved photo emission spectroscopy experiments. [1] Lawler, Barci, Fernandez, Fradkin and Oxman, unpublished; cond-mat/0508747.

**10:00**

**N44 11 Phase and amplitude fluctuations for the $l = 2$ Pomeranchuk instability in two dimensions.** JORGE QUINTANILLA, *ISIS facility, Rutherford Lab. (U. K.)* MASUDUL HAQUE, *Utrecht University, the Netherlands* For a two-dimensional fermionic system, we analyze models that produce shape-distortion instabilities of the Fermi surface in the $l = 2$ channel, leading to a non-Fermi liquid with nematic order. The finite-temperature phase diagram contains a transition of the Kosterlitz-Thouless type and a crossover at higher temperatures, corresponding respectively to the disordering of phase and amplitude degrees of freedom.

**10:12**

**N44 12 Interplay between parallel and diagonal electronic nematic phases in interacting systems** HAE-YOUNG KEE, HYEONJIN DOH, NIR FRIEDMAN, *Dept. of Physics, Univ. of Toronto, Canada* An electronic nematic phase is a spontaneous broken state of a discrete rotational symmetry of a given crystal. There exist two distinct electronic nematic phases in a square lattice. One is the parallel nematic order which breaks the symmetry in $x$- and $y$-direction, and the other is the diagonal nematic order which breaks the diagonal $(x + y)$ and the anti-diagonal $(x - y)$ symmetry. We investigate the different features and the mutual interaction between these two nematic orders. We also discuss the possible implication of our results in the context of neutron scattering and Raman spectroscopy measurements in high $T_C$ superconductors.

**10:24**

**N44 13 Interacting fermions in two dimensions: singularities in the perturbation theory and the role of collective modes.** SUHAS GANGADHARAIAH, *University of Utah* DMITRII GUTMAN, *University of Florida* DMITRII MASLOV, *University of Florida* We consider a system of interacting fermions in two dimensions. It is shown that even for an infinitesimally weak interaction a straight-forward perturbation theory is ill defined near the mass shell. Starting from the second order, the perturbative expansion for the self-energy is singular at the mass shell. We show that this singularity is a manifestation of a non- perturbative effect: the interaction of fermions with the collective mode. The singularities in the perturbation series for the self-energy is treated by resumming the most divergent diagrams. A threshold for emission of zero-sound waves leads to a non-monotonic variation of the self-energy. Consequently, the spectral function acquires a non-Lorentzian kink-like feature. This feature is reminiscent to spin-charge separation in 1D, as the kink is absent in a spin-polarized system. We examine the possibility of detecting the kink in momentum-conserving tunneling between two parallel layers of a 2D electron gas.

**10:36**

**N44 14 Ferromagnetic quantum phase transition in an itinerant three-dimensional system** RONOJOY SAHA, DMITRII MASLOV, *Dept. of Physics, University of Florida, Gainesville, FL 32611-8440, USA* ANDREY CHUBUKOV, *Dept. of Physics, University of Wisconsin-Madison, 1150 University Avenue, Madison, WI 53706-1390, USA* The non-analytic behavior of the spin susceptibility both away and near the quantum critical point signals the breakdown of the Hertz-Millis scenario for a ferromagnetic quantum phase transition in itinerant systems. It is believed that in both 2D and 3D $\chi_s$ increases as a function of the magnetic field ($H$) or momentum ($q$), which indicates a tendency to either first order transition or ordering at finite $q$. We show that the 3D case is different from the 2D one. Away from the 3D critical point, the non-analytic part of $\chi_s$ can be of either sign, depending on microscopic parameters. The non-analyticity in 3D arises from two physically distinct processes: excitations of a single and three particle-hole pairs. Both processes contribute a max $\{H^2,q^2\}\ln\max\{H^2,q^2\}$ term to $\chi_s$, but the signs of these contributions are opposite. The single-pair process leads to an increase of $\chi_s$ with $H,q$ whereas the three pair one corresponds to a decrease. In the paramagnon model, the three pair contribution always wins sufficiently close to the Stoner instability. We also discuss the behavior of $\chi_s$ in the immediate vicinity of the quantum critical point within the spin-fermion model.

**10:48**

**N44 15 Metallic phase in a two-dimensional disordered Fermi system with singular interactions** VICTOR GALITSKI, *Physics Department, University of Virginia* We consider a two-dimensional disordered system of gapless fermions interacting with a singular transverse gauge-field. We study quantum corrections to fermion conductivity and show that they are very different from those in a usual Fermi liquid. In particular, the weak-localization effect is suppressed by magnetic field fluctuations. We argue that these fluctuations can be considered static at time scales of fermionic diffusion. By inducing fluxes through diffusive loops that contribute to weak localization, they dephase via the Aharonov-Bohm effect. It is shown that while the flux-flux correlator due to thermal fluctuations of magnetic field is proportional to the area enclosed by the loop, the correlator due to quantum fluctuations is proportional to the perimeter of the loop. The possibility of dephasing due to these quasistatic configurations is discussed. We also study interaction induced effects and show that perturbation theory contains infrared divergent terms originating from unscreened magnetic interactions. We show that due to singular small-angle scattering, the corresponding contributions to the density of states and conductivity are very large and positive indicating that the fermion-gauge system remains metallic at low temperatures.

## SESSION N45: EXOTIC PHASES IN STRONGLY CORRELATED SYSTEMS

**Wednesday Morning, 15 March 2006**
**348, Baltimore Convention Center at 8:00**
**A. Sandvik, Boston University, presiding**

**8:00**

**N45 1 Fractionalization in a strongly correlated exciton system*** SUNG-SIK LEE, PATRICK LEE, *Massachusetts Institute of Technology* We show that fractionalized phases arise out of a strongly coupled exciton bose condensate in a multi-band insulator. Based on a world line picture of exciton, we demonstrate that the deconfinement phases can occur in a gauge theory of the exciton model despite an infinite bare gauge coupling. A world sheet of electric flux line in the emergent gauge theory is identified as a web of exciton world lines. It is shown that a deconfined U(1) gauge theory with ''photon'' and either fractionalized boson or fermion can emerge out of a single model depending on the coupling constants. The statistics and spin of the fractionalized particles are shown to be determined uniquely by the dynamics of the model. The exciton model can be numerically simulated without sign problem and some of our results will be shown.

*This work was supported by the NSF grant DMR-0517222.

**8:12**

**N45 2 Criticality in correlated quantum matter*** ANGELA KOPP, SUDIP CHAKRAVARTY, *UCLA* At quantum critical points (QCPs) quantum fluctuations occur on all length scales, from microscopic to macroscopic, which, remarkably, can be observed at finite temperatures, the regime to which all experiments are necessarily confined. But how high in temperature can the effects of quantum criticality persist? That is, can physical observables be described in terms of universal scaling functions originating from the QCPs? We answer these questions by examining exact solutions of models of systems with strong electronic correlations and find that QCPs can influence physical properties at surprisingly high temperatures. As a powerful illustration of quantum criticality, we predict that the zero temperature superfluid density, $\rho_s(0)$, and the transition temperature, $T_c$, of the copper-oxide superconductors are related by $T_c \propto \rho_s(0)^y$, where the exponent $y$ is different at the two edges of the superconducting dome, signifying the presence of the respective QCPs. This relationship can be tested in high quality crystals.

*supported by the NSF under grant DMR-0411931

**8:24**

**N45 3 Deconfined quantum-criticality in a 2D $S = 1/2$ Heisenberg model*** ANDERS SANDVIK, *Boston University* The two-dimensional $S = 1/2$ Heisenberg model including a four-spin interaction is studied using a ground state projector quantum Monte Carlo (QMC) method in the valence bond basis. The model is sign-problematic in standard QMC methods formulated in the $S^z$ basis, but not in the valence bond basis. The ground state is studied on lattices with up to $40 \times 40$ spins. The four-spin interaction is shown to suppress the antiferromagnetic order, leading to a phase transition into a valence-bond-solid (VBS) state. The finite-size scaling of the singlet-triplet gap (which can be calculated with the valence bond projector using an improved estimator) scales as $1/L$ at the transition point, indicating a quantum phase transition with dynamic exponent $z = 1$. This, and a large spin-spin correlation exponent, $\eta \approx 0.4$, suggests that the transition is a *deconfined quantum-critical point*. This would then be the first example of a model Hamiltonian for which this exotic Néel–VBS quantum-criticality has been observed.

*Supported by NSF grant No. DMR-0513930

**8:36**

**N45 4 Bilayer antiferromagnet with four-spin interaction*** THOMAS C. LANG, *Boston University, TU Graz, Austria* ANDERS W. SANDVIK, *Boston University* We investigate a spin-1/2 Heisenberg antiferromagnet with four-spin interaction on bilayer square and honeycomb lattices. In addition to the standard Neel and quantum disordered phases, these models can be expected to have a valence-bond-solid (VBS) phase [1]. Our aim is to locate the VBS phase and to investigate, in particular, a transition from quantum disorder to VBS. This is potentially a deconfined quantum critical point [1]. We use a recently introduced ground state projection Monte Carlo method which allows us to study these models without negative-sign problems [2]. [1] A. Vishwanath et al, Phys. Rev. B **69**, 224416 (2004). [2] A. W. Sandvik, Phys. Rev. Lett. **95**, 207203 (2005).

*Supported by NSF grant No. DMR-0513930

**8:48**

**N45 5 Simulations of Quantum Spin Models on 2D Frustrated Lattices** ROGER MELKO, *Oak Ridge National Laboratory* Algorithmic advances in quantum Monte Carlo techniques have opened up the possibility of studying models in the general class of the S=1/2 XXZ model (equivalent to hard-core bosons) on frustrated lattices. With an antiferromagnetic diagonal interaction (Jz), these models can be solved exactly with QMC, albeit with some effort required to retain ergodicity in the near-degenerate manifold of states that exists for large Jz. The application of the quantum (ferromagnetic off-diagonal) interaction to this classically degenerate manifold produces a variety of intriguing physics, including an order-by-disorder supersolid phase, novel insulating states, and possible exotic quantum critical phenomena. We discuss numerical results for the triangular and kagome lattices with nearest and next-nearest neighbor exchange interactions, and focus on the relevance of the simulations to related areas of physics, such as experiments of cold trapped atomic gasses and the recent theory of deconfined quantum criticality.

**9:00**

**N45 6 Quantum phase transition from a valence bond crystal to an antiferromagnet*** KENNETH GRAHAM, *University of Michigan, Dept. of Physics* SAMUEL MOUKOURI, *University of Michigan, Dept. of Physics and Michigan Center for Theoretical Physics* We use the recently proposed two-step density-matrix renormalization group to study a ground state phase transition from a dimerized phase to a Néel phase in a frustrated spatially anisotropic Heisenberg and $t - J$ models. We compute critical exponents for the gap and correlation functions.

*We thank the NSF for support via grant no. DMR-0426775.

**9:12**

**N45 7 Calculations of Domain Wall and $Z_4$ Vortex Energies in the Dimerized Phase of J1-J2 Heisenberg Model** TYLER BRYANT, RAJIV R.P. SINGH, *UC Davis* We develop a series expansion method to calculate the Domain Wall Energy per unit length and the $Z_4$ vortex energies in the dimerized phase of the J1-J2 Heisenberg Model. The energy difference between the state with and without domain walls is calculated by series expansions around two different dimer configurations. The calculations are used to study the transition away from the dimerized phase. These calculations are compared with other studies of the phase boundaries in this system.

**9:24**

**N45 8 The nature of quantum phase transition in quantum compass model** HAN-DONG CHEN, *Department of Applied Physics, Stanford University and Department of Physics, UIUC* CHEN FANG, *Department of Physics, Purdue University* JIANGPING HU, *Department of Physics, Purdue University* HONG YAO, *Departmenf of Physics, Stanford University* In this work, we show that the quantum compass model in two dimension can be mapped to a fermionic model with local density interaction and the quantum phase transition point at the symmetric point Jx=Jz marks a first order phase transition.

**9:36**

**N45 9 Quantum Nematic Phase in the Emery Model** KAI SUN, EDUARDO FRADKIN, *UIUC* STEVEN KIVELSON, *Stanford University* We investigate one strong coupling regime of the Emery model of a CuO plane in the strong coupling limit first discussed in Ref. [1]. In this regime the on-site repulsion energies are much larger than the inter site Coulomb repulsions and the hopping terms. By integrating out the copper sites, we mapped this model into an interacting fermionic model on an effective two-dimensional crossed-chains lattice. We will discuss the simpler case of spinless fermions on this effective lattice in the regime in which the residual interactions are weak. Using a mean-field approach, we discuss the isotropic-nematic phase transition in this system. We show that the nematic phase may exist even for infinitesimally weak interactions. We investigate this phase transition for a range of dopings, temperatures and interactions. For certain choice of parameters, the effective electronic states behave like those of a 2D square lattice model, but for some other choices, its properties are reminiscent of a quasi-one-dimensional system. [1] Steven A. Kivelson, Eduardo Fradkin, and Ted Geballe, PRB 69, 144505 (2004)

**9:48**

**N45 10 No sliding in time** KIRILL SHTENGEL, *UC Riverside* CHETAN NAYAK, *Microsoft* WAHEB BISHARA, *Caltech* CLAUDIO CHAMON, *Boston University* We analyse the following apparent paradox: As has been recently proved by Hastings, under a general set of conditions, if a *local* Hamiltonian has a spectral gap above its (unique) ground state, all connected equal-time correlation functions of local operators decay exponentially with distance. On the other hand, statistical mechanics provides us with examples of 3D models displaying so-called sliding phases which are characterised by the algebraic decay of correlations within 2D layers and exponential decay in the third direction. Interpreting this third direction as time would imply a gap in the corresponding (2+1)D quantum Hamiltonian which would seemingly contradict Hastings' theorem. The resolution of this paradox lies in the non-locality of such a quantum Hamiltonian.

**10:00**

**N45 11 Quantum dimer model on a two dimensional pyramid lattice.** HONG YAO, *Department of Physics, Stanford University, CA 94305* HANDONG CHEN, *Department of Physics, Uiversity of Illinois, Urbana-Champaign, IL 61801* CONGJUN WU, *Kavli Institute for Theoretical Physics, University of California, Santa Barbara, CA 93106* We study the Rokhsar-Kivelson (RK) quantum dimer model on a two dimensional corner-sharing pyramid lattice. Contrast to other lattices such as square and triangular lattice, on the RK line (V=t, V' arbitrary), the dimer-dimer correlation is exact zero as long as dimers are a few lattice constants away from each other. More interestingly, a deconfined dimer liquid phase (or RVB phase) is found to the left of the RK line in the phase diagram. There are two kinds of confined valence bond crystal (VBC) states to the very left of the RVB phase. And there is a VBC state to the right of the RK line. Surprisingly, the spinor excitations are deconfined within the model even though the underlining state breaks the translational symmetry and rotational symmetry.

**10:12**

**N45 12 A doped interacting quantum dimer model on the square lattice** STEFANOS PAPANIKOLAOU, ERIK LUIJTEN, EDUARDO FRADKIN, *University of Illinois at Urbana-Champaign* We introduce a generalized quantum dimer model [1] for interacting dimers on the square lattice [2] which can be mapped to generic 2D classical partition functions. More specifically, we show that the amplitudes of the exact ground state wavefunction are given by the Gibbs weights of a 2D classical doped interacting dimer model. We use this mapping to determine the phase diagram in the interaction - hole density plane. Analytically, we exploit a direct microscopic mapping of the classical dimer model on the square lattice to a special 8-vertex model and generalized Coulomb gases. Numerically, we use a novel rejection-free geometrical cluster algorithm [3] for classical interacting dimers on the square lattice, in the canonical ensemble. We also use simulations to study the system in the grand canonical ensemble. We discuss the structure of the phase diagram and its critical behavior. 1. D.S. Rokhsar and S.A. Kivelson, PRL 61, 2376 (1988), 2. F. Alet et al. PRL 94, 235702 (2005), 3. J. Liu and E. Luijten, PRL 92, 035504 (2004).

**10:24**

**N45 13 Possible New Physics at Quantum Critical Points: Skyrmions as Elementary Excitations of 2 + 1 D Antiferromagnets** ZAIRA NAZARIO, DAVID I. SANTIAGO, *Stanford University* It has recently been proposed that there are degrees of freedom intrinsic to quantum critical points that can contribute to quantum critical physics. We point out that intrinsic critical degrees of freedom exist quite generally below the upper critical dimension. We show that in 2 + 1 D antiferromagnets skyrmion excitations are stable at criticality and identify them as the critical excitations.

**10:36**

**N45 14 Possible New Physics at Quantum Critical Points: Skyrmions as critical Spin 1/2 Excitations of 2+1 D Antiferromagnets** DAVID SANTIAGO, *Stanford University* ZAIRA NAZARIO, *Stanford University* We show that despite the absence of a Hopf term and zero Berry phase terms, the Nèel ordered phase of 2 + 1 D quantum antiferromagnets have spin 1/2 excitations, i.e. *spinons*. The spinons are skyrmion excitations of a topological nature. Since skyrmion gap is proportional to the spin stiffness, quantum criticality corresponds to skyrmion gap collapse. We speculate that skyrmions are relevant at criticality and are, perhaps, related to recent suggestions of critical fractionalization.

**10:48**

**N45 15 Quartet condensation of fermions** ASEEM TALUKDAR, *University of Cincinnati* We investigate quartet condensation in fermion systems with four internal states. Physical examples include spin-3/2 fermionic atoms, transition metal oxides with orbital degeneracy, bi-layered systems with electrons and holes and quadra-layer spin-polarized electron hole systems. We consider a simple SU(4) symmetric model in which the fermions interact among themselves with point attractive interactions. The effective free energy functional of the Cooper Pairs (CP) is found to contain attractive interactions among certain types of CP's. This will allow the CP's to form bound states or quartets. Using a variational calculation based on the Bogoliubov inequality, we find that the system may undergo quartet condensation which will suppress the CP instability. By tuning the interaction away from the SU(4) limit, a phase transition from quartet to CP condensation can occur.

## SESSION N46: SEMICONDUCTOR DEVICES/ SEMICONDUCTORS GENERAL

**Wednesday Morning, 15 March 2006**
**349, Baltimore Convention Center at 8:00**
**Andrei Sergeev, University at Buffalo, presiding**

**8:00**

**N46 1 Dielectric and Photovoltaic Physics in Thin-Film Crystalline Sulfides*** RODNEY McKEE, *Oak Ridge National Laboratory* FRED WALKER, *Oak Ridge National Laboratory* Solar energy utilization has been the hope and sought-for solution to local energy needs at least since the late 1800's. In today's terms, solar energy is one of the few renewable energy sources with the potential to have a major impact on domestic energy independence. There is a rich, but incomplete scientific literature on the underpinning photovoltaic physics of solar cell development. This literature does however, clearly identify a pervasive, unsolved physics problem – itdeep level electronic states in wide band gap

semiconductors quench the electro-optic behavior of solar cells: either p-type or n-type doping is inhibited both of which are required for the basic function of a semiconducting p-n junction solar cell. We will report on our approach towards solving this problem via layer-sequenced stabilization of thin-film photovoltaics that enable symmetric p or n-type doping. We will bring interface phase physics to the synthesis process for sulfur-based chalcogenides to show that the valence and conduction band energy levels as well as defect formation energies in these systems can be systematically modified in wide bandgap photovolatics.

**N46 2 Metal-semiconductor-metal junctions with silver sulphide barrier layers*** I. CHAITANYA LEKSHMI, YASMIN AFSAR, JAGADEESH S. MOODERA, *Francis Bitter Magnet Lab, MIT, Cambridge, MA* Atomic level electrical switching requires innovative methods of charge transport, wherein the device can be switched between ''on'' and ''off'' states at ambient temperatures by applying reasonably small voltages. Recently, the mixed conducting property of silver sulphide was utilized in making a quantized conductance atomic switch[1] which satisfies these requirements. We present the fabrication of metal-semiconductor-metal junctions where a $Ag_2S$ layer is sandwiched between two metal electrodes. Current-voltage measurement shows diode characteristics for these junctions at large thickness (100 Å) of $Ag_2S$. At lower thicknesses, the nature of transport changes over to a nonlinear tunnel junction like behaviour up to an applied external voltage of 1.5 V. The growth, morphology and transport properties of $Ag_2S$ layers depend critically on the deposition conditions. Using the tunnel junction, we investigate the effects of parameters such as growth and thickness of semiconducting layers, choice of metal electrodes and the metal-semiconductor interface on the charge transport across the junction. **N46 3 Characterization of hydrogenation processes for c-Si photovoltaics** S. KLEEKAJAI, M. STAVOLA, F. JIANG, *Lehigh University* A commonly used method to introduce H into Si solar cells to passivate bulk defects is by the post-deposition annealing of an H-rich $SiN_x$ surface layer that also acts as an antireflection coating.[1] It previously had been impossible to characterize the small concentration of H that is introduced by this method. Our work on the properties of the transition-metal-H complexes in Si has led us to develop a novel method to characterize the introduction of H into Si.[2] We have used IR spectroscopy coupled with transition-metal impurities introduced into Si-test samples to act as traps for H. The transition-metal-H complexes can then be detected with high sensitivity to determine the concentration and penetration depth of H in the samples. This model system has been used to obtain insight into what solar-cell processing strategies lead to the best passivation of defects in the Si bulk. We thank V. Yelundur and A. Rohatgi for an enjoyable and fruitful collaboration. This work is supported by NSF Grant DMR 0403641 and NREL grant AAT-1-31605-04. 1. A. G. Aberle, Sol. Energy Mater. Sol. **8:36**

**N46 4 Optical switching and structural properties of Ge2Sb2Te5 and Ge2Sb2Te7 films*** T. W. HERRING, *University of Utah* P. C. TAYLOR, *Colorado School of Mines* C. E. INGLEFIELD, M. J. NELSON, *Weber State University* D. A. BAKER, M. A. PAESLER, *North Carolina State University* Ge2Sb2Te5 and Ge2Sb2Te7 are materials important in phase change memory applications, but the structures of both the amorphous and crystalline phases are not well known. Large areas of optically switched material are needed in order to probe the structure. Films of amorphous Ge2Sb2Te5 varying in thickness between 20 nm and 100 nm were crystallized by exposure to a focused beam of 532 nm laser light with a power density of approximately 50 $kW/cm^2$. Rastering of the crystallized spots produces areas of several square millimeters suitable for experiments to probe the structure of the films. The switching causes little change in surface topography as measured by atomic force microscopy. Ablation of the films occurs if the power density is too high. The structure of optically crystallized films studied by EXAFS will be discussed. Films of Ge2Sb2Te7 will also be discussed.

**N46 5 Interface Dielectric Function in ZnO/Ag Structures for Applications as Back-Reflectors in Thin Film Solar Cells** DEEPAK SAINJU, NIKOLAS PODRAZA, JIAN LI, ROBERT COLLINS, *University of Toledo, Ohio* MAARIJ SYED, *Rose-Hulman Institute of Technology* Sequential deposition of optically-opaque Ag followed by the transparent conductor ZnO, both by magnetron sputtering on substrates such as stainless steel, is a key process for efficient optical back-reflectors (BRs) of thin film solar cells. The roughness scale investigated in our work is an order of magnitude smaller than that studied previously. We have first analyzed Ag deposition by real time spectroscopic ellipsometry (RTSE) over the energy range from 1.0 eV to 6.5 eV in order to establish the final roughness thickness on the Ag just prior to itin situ deposition of ZnO. Values from 10 to 50 Å are obtained, for a relatively narrow range of substrate temperature (20-90°C). We employ the same RTSE probe to analyze the interface and bulk optical properties of ZnO and thus deduce a complete optical model of the BR. Our model for the dielectric function of the interface layer helps explain the losses in the BR structure. It includes contributions from free electrons associated with the Ag component, and bound electrons associated with a metal particle plasmon resonance near 2.7 eV and with interband transitions from Ag and ZnO. The effect of the interface layer on reflectance of BR structures is evaluated.

**N46 6 High-performance ZnO/ZnMgO FET using a hetero-MIS stricture** SHIGEHIKO SASA, *Osaka Institute of Technology* MASASHI OZAKI, KAZUTO KOIKE, MITSUAKI YANO, MASATAKA INOUE, We propose a new structure of ZnO/ZnMgO field-effect transistors (FETs) for simplifying the fabrication process as well as for the improvement of the FET characteristics. Recently, we developed a ZnO/ZnMgO heterostructure FET (HFET) by utilizing a two-dimensional electron gas channel layer

formed in the selectively-doped single quantum well structure.[1)] In the HFET fabrication process, the ohmic contact formation is crucial because of the difficulty in removing the top ZnMgO barrier layer with the underlying ZnO channel remained. The use of a very thin (1-2 nm) ZnMgO top barrier layer enables the formations of both good ohmic contacts without the ZnMgO etching and the gate electrodeD We used metal-insulator semiconductor (MIS) gate structure with the use of a 50-nm-thick $Al_2O_3$ gate insulator. The thin ZnMgO barrier acts as a setback layer for the channel electrons from the ZnMgO/$Al_2O_3$ interface. The 1-$\mu$m-gate device showed a complete FET operation with a transconductance of as high as 28 mS/mm and the effective mobility of 62 $cm^2$/Vs. 1) K. Koike et al., Appl. Phys. Lett. **87**, 112106 (2005).

**N46 7 First-principles calculations of mobilities in novel MOSFETs** MATTHEW EVANS, *Vanderbilt University* SOKRATES PANTELIDES, *Vanderbilt University* Nanoscale metal-oxide-semiconductor field-effect transistors (MOSFETs) incorporating novel materials demonstrate unusual electron transport behavior. Straining the silicon lattice results in significant increases in electron and hole mobility. However, mobility calculations using standard approximations have difficulty explaining this increase. MOSFETs using novel gate dielectrics (e.g. hafnium oxide) have mobilities that are much lower than MOSFETs using silicon dioxide as the dielectric. ''Interface quality'' has been invoked as a likely cause of this difference, but few attempts have been made to tie the mobility decrease to scattering mechanisms associated with the novel dielectric structure. In this talk, we report results of mobility calculations in MOSFETs with a strained-Si channel and with alternate gate dielectrics. The calculations employed a recently developed first-principles method based on atomic-scale interface models.[1] Changes in the local environment of atomic-scale interface roughness defects are shown to potentially account for the increase in mobility under strain. Interstitial Hf defects near the silicon-oxide interface can act as traps and are shown to impact the mobility in MOSFETs with hafnium oxide gate dielectrics. [1] M. H. Evans, X.-G. Zhang, J. D. Joannopoulos, and S. T. Pantelides, Phys. Rev. Lett., v. 95, p. 106802 (2005).

**N46 8 Negative Bias Temperature Instability (NBTI) recovers fully with bake at 325 C or above and the device is equivalent to new.** ANASTASIOS KATSETOS, *IBM* Negative Bias Temperature Instability (NBTI) is one of the major degradation mechanisms of PMOSFET devices. When the p-channel Field Effect Transistor (PFET) gate is biased negatively with respect to the channel, as in CMOS inverter, at elevated temperature the threshold voltage (Vt) decreases (absolute value increases for application temperatures) and the drive current (Ion) decreases. This degrades the device performance and may lead to circuit failure. NBTI is process dependent and has strong dependence on temperature, gate voltage, time, and gate oxide thickness. It also depends on device area and or geometry. NBTI models used in industry are empirical. I have observed, on different technologies, in the last several years that NBTI recovers with bake. The recovery amount depends on the bake temperature, which can be the stress temperature, and happens very fast at any temperature. Full recovery is achieved at temperatures above 325 degrees C. After full bake recovery the device behaves like new with NBTI equal to the NBTI of the original stress.

**N46 9 Calculation of the Phonon Lifetime of Photoexcited Bismuth*** EAMONN MURRAY, *Department of Physics and Tyndall National Institute, University College, Cork, Ireland* DAVID PRENDERGAST,† TADASHI OGITSU, *Lawrence Livermore National Laboratory* STEPHEN FAHY, *Department of Physics and Tyndall National Institute, University College, Cork, Ireland* Phonon lifetimes of the zone-center longitudinal optical phonon in bismuth are calculated with respect to the fraction of valence band electrons excited into the conduction bands. Second order density-functional perturbation theory (DFPT), combined with the frozen phonon technique, is used to calculate the third-order anharmonic couplings between phonons. Calculations on the photoexcited system are performed by constraining the occupations of the valence and conduction bands, giving a certain excited electron-hole plasma density. It is found that the calculated decrease in the phonon lifetime with excitation is due both to the reduction of the phonon frequency and an increase in the coupling to other phonons.

**N46 10 Defect levels in semiconductors - is the band gap problem truly a problem?*** PETER A. SCHULTZ, *Sandia National Laboratories, Albuquerque, NM* Quantitative predictions of defect properties in semiconductors using density functional theory (DFT) have been crippled by standard supercell methods, which have incorrect boundary conditions for an isolated defect, and the band gap problem, where DFT drastically underestimates the band gap. I present a generalized supercell method with boundary conditions appropriate to point defects, to fix the electrostatic boundary conditions, remove ambiguity in charge reservoir, include bulk polarization effects, and specifically account for defect level dispersion. I compute formation energies for an extensive set of defects in silicon. The resulting defect level spectrum in silicon exhibits no band gap problem. The results agree remarkably well with experiment for those values that are experimentally known, and predict heretofore unobserved electronic transitions important for the electrical response of irradiated semiconductor devices.

**N46 11 Structural, optical, and electrochromic properties of $V_2O_5$ thin films by Metalorganic Decomposition** M.B. SAHANA, G. LAWES, K. R. PADMANABHAN, R. NAIK, *Wayne State University, Detroit,* V.M NAIK, *University of Michigan, Dearborn* $V_2O_5$ a n-type semiconductor has been widely used in variety of technological applications such as solid state battery cathodes, solar cell windows, and electrochromic devices as it

allows easy intercalation/deintercalation of different ions due its open layered structure. Recently the attention has been focused on the development of thin films of $V_2O_5$ as a cathode material in microbatteries owing to the miniaturization of electronic devices. We report the preparation of $V_2O_5$ thin films by cost effective easy method of metalorganic decomposition technique using vanadium naphthenate oxide precursor. The solution is spin coated on glass and ITO coated glass substrates. The resulting films on annealing at 450°C are comprised of $V_2O_5$ nanoparticles as evidenced from X-ray diffraction and Raman spectra. UV-VIS studies indicate band gap of $\approx$ 2.4 eV. The dependence of electrochromic properties of these films, heat treated at various temperatures, on microstructure and crystallinity will be presented.

**N46 12 Structure of III-Sb(001) Surfaces Under Extreme Sb-rich Conditions** JEFFERY HOUZE, SUNGHO KIM, SEONG-GON KIM, *Mississippi State University* STEVEN C. ERWIN, *Naval Research Laboratory* We use density functional theory to study the structure of III-Sb(001) (III = Al or Ga) growth surfaces. Various reconstruction models are considered to construct the surface stability diagram under different III-Sb growth conditions. We found that AlSb surface stability diagram identifies experimentally observed surface reconstructions quite well. For GaSb, however, all $(n \times 5)$-like reconstructions proposed to date have too high surface formation energies compared to the ones with wrong periodicities and thus cannot adequately model the structures observed experimentally under extreme Sb-rich growth conditions. Our results indicate that the existing reconstruction models for GaSb(001) surface require revisiting and demonstrate the need for a better reconstruction model.

**10:24**

**N46 13 A density functional study of the effect of pressure on GeTe** LEONARD KLEINMAN, B.R. SAHU, ADRIAN CIUCIVARA, *University of Texas at Austin* We compare local density approximation (LDA) and generalized gradient approximation (GGA) calculations of GeTe as a function of applied pressure. The LDA yields a poor result for the zero pressure trigonal angle but good to excellent results for the zero pressure lattice constants, energy gap, and relative positions of the two sublattices. More importantly, it yields results within the wide range of experimental values for the critical pressure at which the ferroelectric trigonal to rock-salt transition takes place. We also calculate the zero pressure polarization.

**10:36**

**N46 14 Pressure-Raman study of optical phonon anharmonicity and metastable phase in $^{68}Zn^{76}Se$*** R.E. TALLMAN, B.A. WEINSTEIN, *Physics Department, SUNY at Buffalo, NY* R. LAUCK, M. CARDONA, *Max Plank Institut fur Festkorperforschung, Germany* The effects of hydrostatic pressure on the one- and two-phonon Raman spectra of isotopic purity $^{68}Zn^{76}Se$ are studied to 15GPa at 300K. With increasing pressure the TO-TA(X,K) difference-mode shifts rapidly to higher energy, moving above the 2TA overtone band at 5.8GPa with no significant 4-phonon mixing. Above 10GPa, the one-phonon TO($\Gamma$) peak broadens rapidly, reaching $\sim$ 60cm$^{-1}$ FWHM and overlapping both TO-TA(X,K) and LO($\Gamma$). After the sample undergoes the forward and reverse high-pressure transitions, the sphalerite-structure Raman features return (including the strongly broadened TO($\Gamma$) peak) and a new sharp line attributed to a metastable ZnSe phase appears. The TO($\Gamma$) broadening in ZnSe is much stronger than that due to pressure-tuning of the anharmonic decay TO($\Gamma$) $=>$ TA+LA(X,W,K) in GaP and ZnS.[1] Our results suggest that the resonant anharmonic interactions in ZnSe may be strongly enhanced by spatial confinement and disorder in the domains of nucleating phases. **10:48**

**N46 15 Raman scattering in $Zn_{1-x}Fe_xTe$, a van Vleck diluted magnetic semiconductor*** X. LU, S. TSOI, I. MIOTKOWSKI, S. RODRIGUEZ, A.K. RAMDAS, *Purdue University* H. ALAWADHI, *Sharjah University, UAE* T.M. PEKAREK, *University of North Florida* $Zn_{1-x}Fe_xTe$, a zinc blende II-VI diluted magnetic semiconductor(DMSs), exhibits van Vleck paramagnetism, thanks to the electronic level structure of $Fe^{2+}$ with $T_d$ site symmetry, Subjected to crystal field and spin-orbit coupling, the lowest level of its ground state multiplet has a $\Gamma_1$ non-magnetic level, with a $\Gamma_4$ magnetic level just above it. This level ordering leads to its van Vleck paramagnetism. The Raman spectra of this DMS display the $\Gamma_1 \rightarrow \Gamma_4$electronic transition($\Gamma^*$) whose Zeeman splittings are interpreted in terms of symmetry considerations and numerical calculations. The magnetic field and the temperature dependence of the spin-flip Raman line of the donor-bound electron in $Zn_{1-x}Fe_xTe$ exhibit characteristics typical of van Vleck paramagnetism and, in combination with magnetization measurements, yield the s-d exchange constant $\alpha N_0 = 236.9 \pm 9$ meV. The Raman spectra also show $\Gamma^*$ in combination with LO phonons which exhibit an intermediate mode behavior.

**11:15**
**P1 1 Electrochemical gate-controlled conductance of single molecules.**
N.J. TAO, *Arizona State University*

The ability to measure and control current through a single molecule is a basic requirement towards the ultimate goal of building an electronic device using single molecules. This ability also provides one with a rather unique opportunity to study charge transport, a phenomenon that plays vital roles in many chemical, electrochemical and biological processes, on a single molecule basis. To reliably measure the current, one must: 1) provide a reproducible contact between the molecule and two probing electrodes; 2) find a signature to identify that the measured conductance is due to not only the sample molecules but also a itsingle sample molecule; 3) provide a third gate electrode to control the current. The method that we have used to create individual molecular junctions is to bring two electrodes into and out of contact with each other in the presence of sample molecules terminated proper linkers that can bind covalently to the electrodes. The individually created molecular junctions vary in the atomic scale details of the contact configurations, and statistical analysis is used to extract the conductance of the molecular junction with the most probable configuration. When several configurations occur with comparable probabilities, the method may result in multiple conductance values. In order to control the current through a molecule, we use an electrochemical gate in which the molecular junction is immersed in an electrolyte and biased with respect to a reference. We have studied three types of molecules: electrochemically inactive molecules, electroactive molecules that undergo irreversible redox reactions, and electroactive molecules that undergo reversible redox reactions. These molecular systems exhibit rather different electrochemical gating behaviors.

**11:51**
**P1 2 Electron Transport in Molecular Transistors.**
ZHEN YAO, *Department of Physics, The University of Texas at Austin, Austin, TX 78712*

We have fabricated molecular transistors by depositing molecules between nanometer-spaced electrodes created via electromigration. Electron transport in these devices is dominated by the single-electron tunneling effect. Several examples will be discussed including (1) excitations of intramolecule vibrations in single trimetal-molecule transistors, (2) room-temperature single-electron tunneling transistors using alkanedithiols here the transport occurs through ultrasmall Au nanoparticles spontaneously formed during thiol assembly, and (3) Kondo resonance and co-tunneling behavior in metal-porphyrin and expanded-porphyrin molecule transistors.

**12:27**
**P1 3 Electron-vibron coupling in single molecule transistors.**
KARSTEN FLENSBERG, *Niels Bohr Institute*

I discuss coupling between electron transport and vibrational degrees of freedom in single-molecule and nanotube systems. The coupling gives rise several effects such as sidebands in the differential conductance, rectification due to polaron formation,and interesting interplay with the Kondo resonance.

**13:03**
**P1 4 Field Regulation of Single Molecule Conductivity by a Charged Atom.**
ROBERT WOLKOW, *National Institute for Nanotechnology*

A new concept for a single molecule transistor is demonstrated [1]. A single chargeable atom adjacent to a molecule shifts molecular energy levels into alignment with electrode levels, thereby gating current through the molecule. Seemingly paradoxically, the silicon substrate to which the molecule is covalently attached provides 2, not 1, effective contacts to the molecule. This is achieved because the single charged silicon atom is at a substantially different potential than the remainder of the substrate. Charge localization at one dangling bond is ensured by covalently capping all other surface atoms. Dopant level control and local Fermi level control can change the charge state of that atom. The same configuration is shown to be an effective transducer to an electrical signal of a single molecule detection event. Because the charged atom induced shifting results in conductivity changes of substantial magnitude, these effects are easily observed at room temperature. [1] Paul G. Piva1,Gino A. DiLabio, Jason L. Pitters, Janik Zikovsky, Moh'd Rezeq, Stanislav Dogel, Werner A. Hofer & Robert A. Wolkow, Field regulation of single-molecule conductivity by a charged surface atom, NATURE **435**, 658-661 (2005).

**11:15**
**P2 1 The origin of anomalous transport in a high temperature superconductor.**
NIGEL HUSSEY, *University of Bristol*

The metallic state of high-temperature superconductors is anomalous in that the Hall coefficient is strongly temperature dependent while the resistivity varies linearly in temperature over a wide temperature range. Although this *T*-linear resistivity gradually weakens with doping, crucially it survives until superconductivity is destroyed. Both the superconducting pairing interaction and the origin of this anomalous transport have yet to be determined, though most theoretical approaches consider them to be intrinsically linked. Through novel analysis of polar angular magnetoresistance oscillations, we have succeeded to determine the full temperature and momentum dependence of the mean free path of the charge carriers in highly doped $Tl_2Ba_2CuO_{6+\delta}$ ($T_c$ = 15K) up to 60K. From this, we have been able to identify the origin of the *T*-linear resistivity itand the temperature dependence of the Hall coefficient for this particular compound. Given the correlation between the appearance of the *T*-linear resistivity and the onset of superconductivity, this additional scattering is also a prime candidate for the pairing mechanism for high temperature superconductivity itself**.**

**11:51**
**P2 2 Nodal-antinodal quasiparticle anisotropy reversal in the overdoped high-$T_c$ cuprates.***
ANDREA DAMASCELLI, *University of British Columbia*

The cuprate superconductors can be tuned through a remarkable progression of states of matter by doping charge carriers into $CuO_2$ planes. The most generic feature of this tuning is a sequence from a Mott antiferromagnetic insulator, to the d-wave superconductor at intermediate doping, and eventually to an overdoped metal which is widely believed to be described by Fermi liquid theory. Of these three, the testing of Fermi liquid theory in the overdoped regime has been particularly hampered by a lack of compounds suitable for a wide range of experimental techniques. Important breakthroughs could come from the study of $Tl_2Ba_2CuO_{6+\delta}$ (Tl2201), a clean and structurally simple system with a very high $T_c$, whose natural doping range extends from optimal to extreme overdoping as one varies the oxygen content. Recent success in high-purity single crystal growth [1] gave us the opportunity of performing the first extensive ARPES study of the low-energy electronic structure of heavily overdoped Tl2201, which reveals a novel phenomenology: contrary to the case of under and optimally-doped cuprates, quasiparticles are sharp near ($\pi$,0), i.e. the antinodal region where the gap is maximum, and broad at ($\pi$/2, $\pi$/2), i.e. the nodal region where the gap vanishes [1,2]. This reversal of the nodal-antinodal quasiparticle anisotropy across optimal doping and its relevance to scattering, many-body, and quantum-critical phenomena in the high-Tc cuprate superconductors, is discussed. **P2 3 Scanning tunneling spectroscopy studies of $Bi_2Sr_2CaCu_2O_{8+x}$ from the strongly underdoped to strongly overdoped regime.**
JAMES SLEZAK, *Department of Physics, Cornell University*

Using atomically resolved scanning tunneling microscopy (STS), we investigate the electronic structure $Bi_2Sr_2CaCu_2O_{8+x}$ across a range of doping levels from x $\sim$ 0.1 up to as high as $\sim$ 0.23, with significant changes in electronic structure observed above p$\sim$ 0.21. New sample preparation processes [1] were used to produce heavily overdoped crystals suitable for the imaging of various forms of electronic heterogeneity. The evolution of the gap map $\Delta$(r), coherence peak height map A(r), the inelastic tunneling signatures $\omega$(r), and the quasiparticle interference LDOS modulations, as well as their interrelations across this range of doping levels, will be presented. **P2 4 Evolution of superconducting gap and metallic ground state in cuprates from transport.**
LOUIS TAILLEFER, *University of Sherbrooke & Canadian Institute for Advanced Research*

We report on fundamental characteristics of the ground state of cuprates in the limit of T=0, for both normal and superconducting states, obtained from transport measurements on high-quality single crystals of YBCO and Tl-2201, as a function of hole concentration. The superconducting gap is extracted from thermal conductivity; it is found to scale with the superconducting transition temperature throughout the overdoped regime, with a gap-to-Tc ratio of 5 [1]. The normal state is accessed by suppressing superconductivity with magnetic fields up to 60 T and is characterized by the limiting behavior of its electrical resistivity; while carrier localization is observed in YBCO at low temperature for carrier concentrations p below 0.1 hole/planar Cu, at p=0.1 and above the material remains highly metallic down to T=0 [2]. This shows that the non-superconducting state of underdoped cuprates, deep in the pseudogap phase, is remarkably similar to that of strongly overdoped cuprates, e.g. at p=0.3. We compare these results with similar measurements on other cuprates and discuss their implication for our understanding of the cuprate phase diagram. [1] In collaboration with: D.G. Hawthorn, S.Y. **P2 5 Optical properties of Cuprates in the Normal and superconducting state.***
DIRK VAN DER MAREL, *University of Geneva*

For superconducting materials it is interesting and important to determine the kinetic energy of the conduction electrons, $< <H> >_T$, because its behavior as a function of temperature dependence, in particular at the superconducting phase transition, provides a direct and profound insight in the mechanisms by which the superconducting phase is stabilized. The intra-band optical spectral weight, W(T), is, apart from a minus sign, closely related to the kinetic energy[1]. With modern optical techniques it is possible to measure W(T) very accurately as a function of temperature. Over the past few years several teams have reported that by the superconducting phase transition affects the optical conductivity over an energy range of several electron Volts[2-8]. Some of these results were accurate enough to determine the effect of superconductivity on W(T). Here we present new optical data for a large number of underdoped and optimally doped samples of various compositions. In order to clearly distinguish the effect of the superconducting phase transition from other temperature dependencies, we use a dense sampling of temperatures (1 spectrum every Kelvin) over a broad range of temperatures and frequencies. All our data support that the change at Tc of W(T) parallel to the CuO2-planes is opposite to the trend expected from the BCS prediction. For strongly overdoped samples the observed behavior of W(T) in the normal state and in the superconducting state is qualitatively different compared to underdoped and optimally doped superconductors. ## SESSION P3: PHYSICS TEACHER PREPARATION AT A CRISIS: INNOVATIVE PROGRAMS ADDRESSING A NATIONAL NEED

**Wednesday Morning, 15 March 2006; Ballroom I, Baltimore Convention Center at 11:15**
**Ramon Lopez, Florida Institute of Technology, presiding**

**11:15**
**P3 1 Improving the preparation of K-12 teachers: Contributions from physics education research.***
PAULA HERON, *University of Washington*

Physics education research can contribute to efforts by college and university faculty to improve the preparation of K-12 teachers to teach physics and physical science. Examples are used to demonstrate the need to help teachers deepen their

understanding of basic topics and to illustrate how a research-based curriculum can assist in this process. Evidence is presented of the impact on student learning in K-12 classrooms.

*Supported in part by the National Science Foundation.

**11:51**
**P3 2 UTeach: Secondary Teacher Preparation in Science and Mathematics at the University of Texas at Austin.**
MICHAEL MARDER, *The University of Texas at Austin*

The UTeach Program is a joint effort of the College of Natural Sciences, the College of Education and the Austin Independent School District to recruit, prepare and support math and science teachers for the State of Texas. UTeach uses early and on-going field experiences to capture the imagination of preservice teachers and provide a foundation for more advanced pedagogical courses. With over 400 students enrolled and over 80 graduates per year, UTeach is one of the largest programs producing secondary science, mathematics, and computer science teachers in the nation. Most UTeach students are undergraduates, but around 10% are people of many ages with strong backgrounds in mathematics or science who have decided to enter teaching. Hallmarks include: Four-year degree plans that enable undergraduates to obtain certification at no cost in time or money. Active recruitment and support including tuition reimbursement, paid internships, personal advising, and guidance by master teachers. Emphasis on preparing teachers who will be knowledgeable of their discipline, experienced with involving students in scientific inquiry, and practiced in employing new technologies to enhance student learning. A revised, streamlined professional education sequence drawing on research on learning, standards-based curricula, multiple forms of assessment, and proven strategies for achieving equity and integrating technology into math and science education. Program flexibility with multiple entry points (from freshman to post baccalaureate), integrated degree plans, and proficiency-based assessment, including the development of individual teaching portfolios. For more information on UTeach, see tthttp://uteach.utexas.edu.

**12:27**
**P3 3 Better prepared future teachers = better physics department!***
GAY STEWART, *University of Arkansas*

A more scientifically literate society benefits physics as a profession. It is best realized by better serving all undergraduate physics students. Arguably, the most important are future K-12 teachers. In better-serving all students, the department also benefits. University of Arkansas, Fayetteville has seen a drastic change in number of majors, the number of students active in research and the number of graduates pursuing graduate work while also increasing the number of majors who decide to teach. What works to build these numbers and strengthen these resources at Arkansas will be discussed, with additional examples from other members of the growing Coalition of institutions that are seeking to improve and promote physics and physical science teacher education within physics departments. This group, the Physics Teacher Education Coalition (www.PTEC.org), is bringing together innovative ideas and practices throughout the country to help meet the critical shortage of well prepared and actively supported teachers. The program will be described and information provided for those interested in taking advantage of these efforts.

*PhysTEC is supported in part by the National Science Foundation.

**13:03**
**P3 4 Sustainable and Scalable Reforms in Physics Education: Research studies from Colorado PhysTEC.**
NOAH FINKELSTEIN, *University of Colorado at Boulder**

While many practices developed within the physics education research community have been demonstrated as successful, they respond to calls and employ practices that echo efforts from the early part of the 20th Century. Are we bound to the same limited success as these precursors? We examine what it means to replicate proven reforms and to develop models for sustainable implementation of these reforms. As part of the Colorado Physics Teacher Education Coalition, we have implemented the Tutorials in Introductory Physics, which were developed by researchers at the University of Washington. We present research on the successful implementation of these reforms at the University of Colorado and begin to answer the questions: What does it mean to replicate an educational program? and How might these educational transformations be sustained? We present empirical data on the success of reforms and the fidelity of implementation as well as theoretical frames for analyzing these data. We also present a model (the Learning Assistant program) designed for sustaining these reforms and for increasing student interest and retention in teaching.

*In collaboration with Steven Pollock, University of Colorado at Boulder.

**13:39**
**P3 5 The AAPT/PTRA Program: Professional Development for Pre-College Physics Teachers Hosted by College and University Physics Departments.**
WARREN HEIN, *American Association of Physics Teachers*

The American Association of Physics Teacher's Physics Teaching Resource Agents (AAPT/PTRA) program has a twenty year history of providing professional development for in-service pre-college physics and physical science teachers. More than 500 teachers have been prepared through NSF-funded summer institutes to provide professional development for their peers in a wide variety of venues ranging from urban, inner-city classrooms to classrooms in low population rural areas. A wide variety of inquiry-based, active engagement workshops have been developed that can assist in-service teachers at all experience and preparation levels, from new and crossover teachers to those who have taught for many years. AAPT/PTRA presenters are typically active physics teachers who share lessons learned in their classrooms on how to adopt research-based practices. College and university physics and astronomy departments interested in providing in-service professional development for pre-college teachers in their geographic areas can enter into agreement with the AAPT/PTRA program to utilize the services of these trained professional development providers. United States Department of Education Math and Science Partnership funds that are allocated to each state are an excellent source of funds that physics and astronomy departments can use to support this type of professional development for physics and physical science teachers. An example of a funded program currently in place in Texas will be presented. AAPT/PTRA program is currently funded by NSF grant # ESI-0138617.

## SESSION P4: KEITHLEY AWARD SESSION
**Wednesday Morning, 15 March 2006; 308, Baltimore Convention Center at 11:15**

**11:15**
**P4 1 Nanocalorimetry: Using Si-micromachined Devices for Thermodynamic Measurements of Thin Films and Tiny Crystals.***
FRANCES HELLMAN, *Physics Dept., University of California, Berkeley, and Materials Sciences Division, Lawrence Berkeley Lab*

We have used Si micromachining to fabricate membrane-based calorimeters for measuring thermodynamic properties of microgram-quantity samples over a temperature range from 1.7 to 550K in magnetic fields to 8T. Prototype scaled down devices have been made which allow precise measurements of nanogram quantities. Different types of thermometers are used for different purposes and in different temperature ranges. Current development efforts are extending the temperature range to 0.3 - 800K, and we are collaborating with the national high magnetic field lab to extend the field range to 65T in pulsed magnets. These devices are particularly useful for specific heat measurements of thin film samples (100-400 nm thick) deposited directly onto the membrane through a Si micromachined evaporation mask. They have also been used for small bulk samples attached by conducting paint or In, and for powder samples dissolved in a solvent and dropped onto devices. The measurement technique used (relaxation method) is particularly suited to high fields because thermal conductance is measured in zero field and is field independent, while the relaxation time constant does not depend on thermometer calibration. The devices have been used with little modification for thermal conductivity and thermopower measurements, and are well suited to measurements of calorimetric signals such as those occurring at phase transitions or under irreversible thermal behavior. I will discuss device fabrication and thermal analysis which allow us to precisely identify heat flow in the devices and consequent limits on the absolute accuracy, as well as possible future directions for device development. I will also briefly discuss examples of measurements on several materials of current interest: 1) amorphous Si and its alloys, 2) high precision critical temperature studies of $La_{1-x}Sr_xMnO_3$ and $La_{1-x}Ca_xMnO_3$, 3) antiferromagnetic CoO nanoparticles and thin layers, 4) Fe/Cr giant magnetoresistance multilayers.

*I would like to thank the DOE and NSF for support.

**11:51**
**P4 2 High-Resolution Microcalorimeter Detectors for X-ray Spectroscopy.**
TERRENCE JACH, *National Institute of Standards and Technology, Gaithersburg, MD*

For many decades, standard wavelength- and energy-dispersive x-ray detectors have dominated experimental physics. Recently, microcalorimeter detectors of various types that count individual photons have started to make an appearance on the experimental scene. I shall describe the development of Transition Edge Sensor (TES) detectors at NIST, with particular emphasis on their use in high-resolution x-ray spectrometry. These detectors combine the broad energy range of a SiLi or Ge detector with energy resolution approaching that of diffraction-related methods. The technologies for producing ultra-cold temperatures and for fabricating superconducting electronics have made these detectors practical to

use on a daily basis. By means of careful matching of absorber and energy, detectors can be built to cover energy ranges from 1 keV to 100 keV. By extrapolating from single-pixel detectors to arrays, the possibility of large detection areas, high count rates, and even imaging is starting to look realistic. While embodying some challenging technical constraints, microcalorimeter x-ray detectors will provide attractive advantages and opportunities for physicists in a number of fields.

**12:27**
**P4 3 Angle-Resolved High Field Low Temperature Calorimetric Measurements of Low Dimensional Materials.**
NATHANAEL FORTUNE, *Smith College*

Quasi-two-dimensional materials exhibit a rich variety of magnetic-field-induced superconducting and magnetic states. These states are highly anisotropic with respect to magnetic field orientation; in some cases, the very existence of the state is field angle dependent. To establish the phase boundaries of these high-field, low temperature, angle-dependent states, we have fabricated miniature rotatable calorimeters for measurements of specific heat and the magnetocaloric effect at temperatures ranging from 0.1K to 20K in magnetic fields up to 20, 35 or 45 tesla. The sample orientation relative to the applied field can be continuously varied at low temperature along a single axis (with a resolution of 0.02 degrees) and at room temperature along a second axis (with a resolution of 2 degrees). The sample temperature can be programatically set and regulated to better than 0.1 percent over the entire field and temperature range, allowing field sweeps at constant temperature in addition to temperature sweeps at fixed fields. In this talk, I will discuss the design, performance, and evolution of our calorimeter and recently obtained results, including the calorimetric observation of an angle-dependent magnetically enhanced FFLO superconducting state in a heavy fermion superconductor and an angle-dependent quantum fluctuation induced ''plateau state'' at 1/3 of the saturation magnetization in a quasi 2D S = 1/2 Heisenberg antiferromagnet.

**13:03**
**P4 4 Some non-traditional approaches to thermal and thermodynamic measurements.***
ALBERT MIGLIORI, *Los Alamos National Laboratory*

Three non-traditional measurement methods for measurement of thermal and thermodynamic quantities are explored. Each method is not commonly used, has some astonishing advantages, and produces outstanding accuracy with little chance for error for several reasons. One reason in common is that for each method, only one quantity is measured. The methods include noise spectroscopy for the measurement of the elastic tensor of solids (and maybe other states of matter), third-harmonic measurements of thermal conductivity and specific heat, and impulse methods for obtaining the difficult-to-acquire ''ZT'' for thermoelectrics.

**SESSION P5: SHEDDING LIGHT ON THE ENIGMA OF THE TRANSITION TO TURBULENCE IN PIPES AND OTHER SHEAR FLOWS**
**Wednesday Morning, 15 March 2006; 309, Baltimore Convention Center at 11:15**
**Tom Mullin, DFD; R.R. Kerswell, Bristol University, presiding**

**11:15**
**P5 1 The Transition to and from Turbulence in a pipe.***
TOM MULLIN, *DFD*

A discussion of experimental investigations of the stability of flow along a pipe will be given. The transition to turbulence is catastrophic when a well–defined amplitude of injected perturbations is exceeded. The stability threshold scales inversely proportional to the Reynolds number, $Re$, with a sharp cut off at low $Re$ values. On the other hand, the decay from the turbulent state exhibits systematic exponential behavior with diverging timescales which are indicative of critical behavior. The long transients contain spatio-temporal coherence which suggest connections with recent theoretical developments.

*Support from EPSRC 'Senior Fellowship'. Joint work with J. Peixhino.

**11:45**
**P5 2 Transient growth and subcritical transition in shear flows.**
DAN HENNINGSON, *KTH Mechanics*

The possibility for disturbance growth in shear flows which are linearly stable is discussed, and it is shown that a necessary condition is that the underlying linear operator is non-normal, i.e. that it is associated with non-orthogonal eigenfunctions. Since the non-linear terms are conservative it is only by utilizing linear growth mechanisms associated with the non-normal linearized operator that energy growth is possible also for subcritical finite amplitude disturbances. The non-normal effects are manifested in the possibility for large transient growth of the disturbance energy, large response to forcing and large sensitivity of the eigenvalues. The optimal transient growth and response to forcing are calculated as the norm of the matrix exponential and resolvent, respectively. The optimal disturbances are streamwise vortices and the optimal responses are streaks of high and low velocity in the streamwise direction. These flow structures are prevalent in all subcritical transitional shear flows, including pipes and channels. It is shown by direct numerical simulations that transition scenarios initiated by the optimal disturbances have low transition thresholds. The dependence of the thresholds on the Reynolds number is also presented. Finally, extensions of the transient growth concept to more complex flows are discussed and examples of its use given.

**12:15**
**P5 3 Self-Sustaining Process and Exact Coherent Structures in Shear Flows.**
FABIAN WALEFFE, *Depts. of Mathematics and Engineering Physics, University of Wisconsin-Madison*

The Self-Sustaining Process (SSP) is a weakly nonlinear theory of a fundamental three-dimensional nonlinear process in shear flows. It is the basic mechanism that enables enhanced momentum transport and the redistribution of the mean shear energy into smaller scales and, ultimately, turbulent motions. I will briefly review the 40 years of observations of streaks and coherent structures in the near wall region of turbulent shear flows that led to the formulation of the SSP theory. A primary impact of the SSP, besides providing some level of mechanistic understanding, has been to provide a method to calculate unstable traveling wave solutions of the Navier-Stokes equations. This approach has now been successfully carried out in all canonical wall-bounded shear flows with stress as well as velocity boundary conditions. The traveling waves thus obtained show striking similarity with the observed near-wall coherent structures, earning them the name of 'exact coherent structures'. Furthermore, those unstable waves have been shown to capture basic statistics of turbulent flows remarkably well, thereby providing hope for a quantitative theory of turbulence over smooth walls. The traveling waves come in many kinds: small scales, large scales and multi-scales. The asymptotics of the large scale traveling waves as the Reynolds number goes to infinity is remarkably simple and confirms the asymptotic validity of the SSP. These large scale coherent states may yield a new promising target for the control of turbulence in shear flows.

**12:45**
**P5 4 Travelling waves in pipe flow and their relevance for transition to turbulence.**
RICH KERSWELL, *Bristol University*

The problem of understanding the nature of pressure-driven fluid flow through a circular straight pipe remains one of the oldest problems in fluid mechanics. The steady, unidirectional parabolic (laminar) flow solution named after Hagen (1839) and Poiseuille (1840) is linearly stable yet temporally and spatially disordered 3-dimensional (turbulent) solutions can easily be triggered at sufficiently large flow rates (Reynolds 1883). In contrast with Rayleigh-Benard convection where transition to turbulence proceeds along an orderly sequence of bifurcations at well-defined values of the thermal driving, the transition in a pipe is abrupt, dependent on the level of ambient disturbances in the system and, at least close to the threshold flow rate, transient. The recent discovery of travelling wave solutions (which represent saddle points in phase space) in this system has at last provided a theoretical stepping stone towards rationalizing the transition process. We will discuss the structure of these waves as well as evidence of their relevance during the transition process.

**13:15**
**P5 5 Two scenarios for dynamics of perturbations in pipe Poiseuille flow.**
ANATOLI TUMIN,* *The University of Arizona*

Two experiments on perturbations in circular pipe flows and their possible theoretical interpretations are discussed to illustrate complexity of the problem. The experimental data by A. Kaskel (1961) are discussed within the framework of spatial transient growth theory, and we argue that the phenomenon of transient growth was observed in the pipe-flow experiments. Another experiment (Eliahou et al, 1998) illustrates how weak streamwise vortices provide instability of the secondary disturbances which, in turn, amplify the steady vertical structures. The latter is consistent with the self-sustaining process scenario. These examples, and more recent DNS and experimental studies represent typical controversies that arise in the study of complex systems.

*In collaboration with Prof. Eli Reshotko, CWRU.

**13:45**
**P5 6 Edge of chaos in the transition to turbulence.**
BRUNO ECKHARDT, *Philipps Universität Marburg*

We study the boundary of the laminar region near the onset of turbulence. Approaching the boundary from the laminar side, the lifetime of perturbations increases, diverges when the boundary is reached, and varies chaotically for larger amplitudes. In the chaotic region, lifetimes vary sensitively with amplitude, consistent with the strange saddle picture of the turbulence proposed earlier. The trajectory on the edge between the laminar and chaotic regions is asymptotic to a single well defined state, essentially independent of the type of perturbation. The edge then becomes the stable manifold of this structure. In the case of a model shear flow, the edge states are simple or period doubled or chaotic trajectories. The case of pipe flow shows less variability and the edge state seems to remain close to a state with simple vortical structure. This is joint work with T.M. Schneider (U Marburg), J.D. Skufca (Clarkson U) and J. Yorke (U Maryland).

## SESSION P6: QUANTUM SPIN DYNAMICS IN MOLECULAR NANOMAGNETS
**Wednesday Morning, 15 March 2006; 310, Baltimore Convention Center at 11:15**
**Andrew Kent, New York University, presiding**

**11:15**
**P6 1 Quantum Dynamics of the Neel Vector of Antiferromagnetic Nanomagnets.**
OLIVER WALDMANN, *University of Bern*

This abstract was not received electronically.

**11:51**
**P6 2 Universal Mechanism of Spin Relaxation in Solids.**
EUGENE CHUDNOVSKY, *Lehman College, CUNY*

Conventional elastic theory ignores internal local twists and torques. Meantime, spin-lattice relaxation is inherently coupled with local elastic twists through conservation of the total angular momentum (spin + lattice). This coupling gives universal lower bound (free of fitting parameters) on the relaxation of the atomic or molecular spin in a solid [1] and on the relaxation of the electron spin in a quantum dot [2]. [1] E. M. Chudnovsky, D. A. Garanin, and R. Schilling, Phys. Rev. B **72**, 094426 (2005). [2] C. Calero, E. M. Chudnovsky, and D. A. Garanin, Phys. Rev. Lett. **95**, 166603 (2005).

**12:27**
**P6 3 Organization of Single Molecule Magnets on Surfaces.***
ROBERTA SESSOLI, *Department of Chemistry, University of Florence, Italy*

The field of magnetic molecular clusters showing slow relaxation of the magnetization has attracted a great interest for the spectacular quantum effects in the dynamics of the magnetization that range from resonant quantum tunneling to topological interferences. Recently these systems, known as Single Molecule Magnets (SMMs), have also been proposed as model systems for the investigation of flame propagation in flammable substances. A renewed interest in SMMs also comes from the possibility to exploit their rich and complex magnetic behavior in nano-spintronics. However, at the crystalline state these molecular materials are substantially insulating. They can however exhibit significant transport properties if the conduction occurs through one molecule connected to two metal electrodes, or through a tunneling mechanism when the SMM is grafted on a conducting surface, as occurs in scanning tunnel microscopy experiments. Molecular compounds can be organized on surfaces thanks to the self assembly technique that exploits the strong affinity of some groups for the surface, e.g. thiols for gold surfaces. However the deposition of large molecules mainly comprising relatively weak coordinative bonds is far from trivial. Several different approaches have started to be investigated. We will briefly review here the strategies developed in a collaboration between the Universities of Florence and Modena. Well isolated molecules on Au(111) surfaces have been obtained with sub-monolayer coverage and different spacers. Organization on a large scale of micrometric structures has been obtained thanks to micro-contact printing. The magnetic properties of the grafted molecules have been investigated through magneto-optical techniques and the results show a significant change in the magnetization dynamics whose origin is still object of investigations.

*Matteo Mannini of the University of Florence and Andrea Cornia of the University of Modena & Reggio Emilia (Italy) are gratefully acknowledged.

**13:03**
**P6 4 First Principles Calculations and Spin Models.***
BRUCE HARMON, *Ames Laboratory*

Single magnetic molecules are fascinating entities. The individual transition metal ions have well defined spin states associated with localized d-orbitals bonded to ligands, which mediate the effective exchange or magnetic coupling among spins. At low temperatures and magnetic fields the internal complexity of the molecule can often (but not always) be ignored, with only the total collective spin determining the ground state and first few excited states. Using $Mn_{12}$ and $V_{15}$ as prototypes, this talk will describe a more reductionist approach and describe first principles electronic structure calculations used to gain insight into the electronic and magnetic structure of the individual transition metal ions and their interactions. Various spin coupling schemes and phenomenological Hamiltonians will be presented and compared to a variety of experimental results. Many colleagues and students from a number of institutions have contributed to this work and will be acknowledged during the talk.

*Supported by DOE Office of Science/BES under Contract No. W-7405-Eng-82.

**13:39**
**P6 5 Density-Functional Theory of Molecular Magnets.***
KYUNGWHA PARK, *Virginia Tech*

Molecular magnets are large (a few nanometers in diameter), well-defined, discrete molecules consisting of several transition metal ions interacting through organic and/or inorganic ligands. Among thousands of synthesized molecular magnets, there is a class of molecular magnets known as single-molecule magnets (SMMs) which have large effective magnetic moments and behave as single-domain magnetic nanoparticles in an external magnetic field. They are particularly interesting because of observed quantum tunneling of magnetization and their possible applications in magnetic recording and molecular electronics. In this talk, I will demonstrate how quantum mechanics can be used to study the properties of SMMs from a first-principles vantage point. In particular, I will present density-functional calculations of the electronic, vibrational, and magnetic properties of selected SMMs, such as the total magnetic moment, electronic energy gaps, Raman scattering spectra, exchange constants, spin excitation energetics, and magnetic anisotropy barriers. I will also discuss what types of molecular environmental changes can significantly influence the exchange interaction, magnetic anisotropy, and observed quantum tunneling in the SMMs.

*Supported by the ONR, the DoD HPC CHSSI program, and the W.M. Keck Foundation.

## SESSION P7: FOCUS SESSION: PHYSICS OF TRANSCRIPTIONAL REGULATORY NETWORKS
**Wednesday Morning, 15 March 2006; 307, Baltimore Convention Center at 11:15**
**Joshua Socolar, Duke University, presiding**

**11:15**
**P7 1 Programming bacterial dynamics by synthetic killer circuits.**
LINCHONG YOU, *Duke University*

This abstract was not received electronically.

**11:51**
**P7 2 Molecules, nonlinearity, and function in regulatory networks.**
NICOLAS BUCHLER, *Rockefeller University*

Biological regulatory networks are capable of sophisticated functions, such as integrating chemical signals, storing memories of previous molecular events, and keeping time. These networks often contain feedback loops, which can promote bistability and oscillation. However, feedback alone is not enough. Strong nonlinearities in the network dynamic are also needed. It is known that many regulatory proteins form higher-order complexes and multimers. I will discuss two important sources of nonlinearity in multimerization. First, ample experimental evidence suggests that protein subunits itin vivo can degrade less rapidly when associated in complexes. For homodimers, this effect leads to a concentration dependence in the protein degradation rate. Theoretical analysis of two model gene circuits in bacteria, i.e. switch and oscillator, demonstrates that this effect can substantially enhance the function of these circuits. Second, active proteins can often be sequestered into inactive complexes. This molecular titration can lead to sharp nonlinearities, and suggests a scenario for the rapid evolution of bistable or oscillatory circuits in nature.

**12:27**
**P7 3 Combinatorial Regulation in Yeast Transcription Networks.**
HAO LI, *University of California, San Francisco*

Yeast has evolved a complex network to regulate its transcriptional program in response to changes in environment. It is quite common that in response to an external stimulus, several transcription factors will be activated and they work in combinations to control different subsets of genes in the genome. We are interested in how the promoters of genes are designed to integrate signals from multiple transcription factors and what are the functional and evolutionary constraints. To answer how, we have developed a number of computational algorithms to systematically map the binding sites and target genes of transcription factors using sequence and gene expression data. To analyze the functional constraints, we have employed mechanistic models to study the dynamic behavior of genes regulated by multiple factors. We have also developed methods to trace the evolution of transcriptional networks via comparative analysis of multiple species.

**13:03**
**P7 4 Gene expression dynamics during cell differentiation: Cell fates as attractors and cell fate decisions as bifurcations.***
SUI HUANG, *Harvard Medical School*

During development of multicellular organisms, multipotent stem and progenitor cells undergo a series of hierarchically organized ''somatic speciation'' processes consisting of binary branching events to achieve the diversity of discretely distinct differentiated cell types in the body. Current paradigms of genetic regulation of development do not explain this discreteness, nor the time-irreversibility of differentiation. Each cell contains the same genome with the same $N(\sim 25{,}000)$ genes and each cell type $k$ is characterized by a distinct stable gene activation pattern, expressed as the cell state vector $S_k(t) = \{x_{k1}(t),.\, x_{ki}(t),.\, x_{kN}(t)\}$, where $x_{ki}$ is the activation state of gene $i$ in cell type $k$. Because genes are engaged in a network of mutual regulatory interactions, the movement of $S_k(t)$ in the $N$-dimensional state space is highly constrained and the organism can only realize a tiny fraction of all possible configurations $S_k$. Then, the trajectories of $S_k$ reflect the diversifying developmental paths and the mature cell types are high-dimensional attractor states. Experimental results based on gene expression profile measurements during blood cell differentiation using DNA microarrays are presented that support the old idea that cell types are attractors. This basic notion is extended to treat binary fate decisions as bifurcations in the dynamics of networks circuits. Specifically, during cell fate decision, the metastable progenitor attractor is destabilized, poising the cell on a 'watershed state' so that it can stochastically or in response to deterministic perturbations enter either one of two alternative fates. Overall, the model and supporting experimental data provide an overarching conceptual framework that helps explain how the specifics of gene network architecture produces discreteness and robustness of cell types, allows for both stochastic and deterministic cell fate decision and ensures directionality of organismal development.

**13:39**
**P7 5 Network theory and prediction of regulatory switches.**
ALEXEI VAZQUEZ, *University of Notre Dame*

While the influence of the high intracellular concentration of macromolecules on cell physiology is increasingly appreciated, its impact on the function of intracellular molecular interaction networks remains poorly understood. To test the effect of molecular crowding on the function of metabolic networks, we introduce a modified form of flux balance analysis that takes into account the constraint imposed by the limit on the attainable concentration of enzymes in the crowded cytoplasm. We demonstrate and experimentally confirm that the method can successfully predict the existence of regulatory points that allow switching from high to low biomass yield pathways when changing cellular growth rate. These results demonstrate that molecular crowding represents a bound on the achievable functional states of metabolic networks, and provide a systematic approach to uncover potential regulatory points in cellular metabolism.

**11:15**
**P8 1 The secret of splashing: interplay of air and roughness.**
LEI XU, *University of Chicago*

We studied splashing on both smooth and rough dry surfaces using high speed photography. For smooth substrates, a striking phenomenon is observed: splashing can be completely suppressed by decreasing the pressure of the surrounding gas. The threshold pressure where a splash first occurs is measured as a function of the impact velocity and found to depend on the molecular weight of the gas and the viscosity of the liquid. Both experimental scaling relations support a model in which the compressibility of the gas is responsible for creating the splash[1]. For the case of rough substrates, we systematically varied both the surface roughness and the pressure of the surrounding gas and found two distinct contributions to a splash. One is caused by air and has the same characteristics as the ''coronal'' splash observed on smooth substrates. A second, ''prompt'' splash, contribution is caused by surface roughness. We have also measured the size distribution of the droplets emitted from a splash. For a smooth surface, a broad distribution of droplet sizes is found at high gas pressures. As the gas pressure is lowered towards the splash/no-splash transition the distribution gets more and more peaked at a characteristic size. For a rough surface, the distribution is strongly correlated with the surface roughness.

**P8 2 Statistical Mechanics of a Geophysical Jet*** EMILY CONOVER, J.B. MARSTON, *Brown University* We investigate the equal-time statistics of an equatorial jet in a two-dimensional quasi-geostrophic model of a planetary atmosphere on a rotating sphere[1]. Potential vorticity is advected by the barotropic flow and at the same time relaxes towards the zonal shear flow of an underlying equatorial jet. A transition to turbulence occurs at sufficiently slow relaxation rates. Statistics accumulated by direct numerical simulation[2] are compared to those obtained by a simple cumulant expansion. We study rigorous upper bounds on the instability size[3] and discuss the limitations of the cumulant expansion.

**P8 3 High-Speed X-ray Investigation of Granular Jets*** JOHN ROYER, ERIC CORWIN, ANDREW FLIOR, BRYAN CONYERS, MARIA-LUISA CORDERO, MARK RIVERS, PETER ENG, HEINRICH JAEGER, *James Franck Institute, The University of Chicago* When a heavy sphere is dropped onto a bed of loose, fine sand, a large, focused jet of sand shoots upward.[12] Experiments at reduced air pressure reveal that the jet in fact consists of two components: a wispy, thin jet that varies little with pressure followed by a thick air-pressure-driven jet[3]. To observe the initial stages of jet formation inside the granular bed, we employed x-ray radiography using the high-intensity beams available at the Advanced Photon Source. This technique allowed us to image the motion of the sphere and the evolution of the void left behind it at frame rates up to 6600 frames per second. The x-ray movies reveal that gravity-driven collapse produces the initial, thin jet, while the compression of an air pocket trapped below the surface drives up the thick jet. We also find that the interstitial air alters the compressibility of the sand bed. In vacuum a visible compaction front precedes the ball, while at atmospheric pressure the sand flows out of the way of the ball, behaving more like an incompressible fluid.

**P8 4 Measurement of Stopping Force in Low Velocity Impact Cratering** JOSEPH AMATO, MICHAEL NITZBERG, *Colgate University* The time dependent stopping force on a ball dropped into a granular medium has been measured using an accelerometer embedded within the ball. The velocity dependence of the force shows two distinct behaviors: (1) for impacts with large (200 $\mu$m) irregularly shaped sand particles, $F(v) \propto v^{1/2}$; for impacts with 100 $\mu$m spherical glass beads, $F(v) \propto (v - v_0)$. The accelerator apparatus yields reproducible, low noise data that reveals peculiar features such as a downward acceleration pulse just before the ball comes to rest.

**P8 5 Giant bubble-pinchoff.***
DETLEF LOHSE, *University of Twente*

Self-similarity has been the paradigmatic picture for the pinch-off of a drop. Here we will show through high-speed imaging and boundary integral simulations that the inverse problem, the pinch-off of an air bubble in water, does not obey self-similarity (of the first kind): A disk is quickly pulled through a water surface, leading to a giant, cylindrical void, which at collapse creates an upward and a downward jet. The neck radius h(tau) of the void does NOT scale with the inertial power law exponent 1/2 (i.e., does not obey ''Rayleigh-scaling''). This is due to a second length-scale, the inverse curvature of the void,which follows a power-law scaling with a different exponent. Only for infinite Froude numbers the scaling exponent 1/2 is recovered. In all cases we find the void-profile to be symmetric around the minimal void radius up to the time the airflow in the neck deforms the interface.

**P8 6 Nano-liquid bridges in ambient conditions** WEI KANG, UZI LANDMAN, *School of Physics, Georgia Institute of Technology, Atlanta, GA 30332* The dynamics of nano-liquid bridges in an ambient gaseous environment is studied using molecular dynamics simulations. Under these conditions new behavior close to break-up is found, compared to the behavior in vacuum. The probability for appearance of a long-thread structure close to pinch-off, versus the appearance of a double-cone profile in vacuum, depends on the density of the ambient gas. The stochastic lubrication equation that has been introduced by Moseler and Landman [1] for the case of break-up in vacuum is modified to include an additional term representing the effect of the ambient gas. Numerical integration of the modified stochastic lubrication equation shows good agreement with the molecular dynamics simulations. [1] M. Moseler and U. Landman, Science 289, 1165(2000).

**P8 8 Levitation of Falling Spheres in Stratified Fluids*** RICHARD McLAUGHLIN, ROBERTO CAMASSA, BYRON HUFF, RICHARD PARKER, *University of North Carolina* UNC RTG FLUIDS GROUP COLLABORATION, The motion of sphere's falling under the influence of gravity is a classical problem dating back to Galileo and earlier. How a falling body additionally interacts with its environment is an equally challenging problem and involves strong coupling between the body and fluid via hydrodynamic drag. We present new phenomena[2] concerning the motion of a sphere falling through a sharply stratified (two layer) fluid in which the falling heavy body stops and reverses its direction (bounces) before ultimately returning to descent. Shadowgraph imaging shows the physics responsible for this surprising motion is a coupling between the body and the ambient boundary layer fluid, which is endowed with a negative potential energy as it is drawn into the lower layer, forming a rising turbulent plume. The hydrodynamic coupling between the sphere and this plume temporarily arrests the motion, even causing the bead to rise back through the transition layer. We present measurements of this trapping phenomena, and report the long residence times in which the sphere is trapped within the transition layer as a function of the bottom layer fluid density field for an array of different sized spheres. [2] N. Abaid, D. Adalsteinsson, Akua Agyapong, and R. M. McLaughlin, ''An Internal Splash: Falling Spheres in Stratified Fluids,'' Physics of Fluids, 16, no. 5, 1567-1580, 2004.

**P8 9 Sodium luminescence from laser-induced bubbles in salt water*** SONNY VO, TIM HSIEH, HAN-CHING CHU, GARY WILLIAMS, *UCLA* Luminescence from collapsing laser-induced bubbles in salt water (up to 1M NaCl) has been studied. We find a new emission pulse from the 589 nm sodium line that arrives about 50 ns prior to the main blackbody luminescence pulse. This may be related to the dynamics of the compressional heating process in the bubble. We have also noticed in the salt water that the time duration of the blackbody pulse is reduced by up to 30% from the duration in pure water, and this has been observed in several other alkali salt solutions.

**P8 10 The dynamics of a flexible loop in a high-speed flow** SUNGHWAN JUNG, *AML, Courant Inst., New York Univ.* KATHLEEN MARECK, *AML, Courant Inst., New York Univ.* MICHAEL SHELLEY, *AML, Courant Inst., New York Univ.* JUN ZHANG, *AML, Courant Inst., New York Univ.* We study the behavior of an elastic loop in a fast-flowing soap film. The loop is wetted into the film and is held fixed at a single point against the oncoming flow. We interpret this system as a 2D closed flexible body moving in a quasi-2D flow. The loop is deformed by the flow, and this coupled fluid-structure system shows bi-stability: stationary and oscillatory. In its stationary state, the loop essentially remains motionless and its wake is a von Kármán vortex street. In its oscillatory state, the loop sheds two vortex dipoles within each oscillation period. The frequency of oscillation of the loop is linearly proportional to the flow velocity.

**14:03**
**P8 11 Superfluid-like shock waves in nonlinear optics** WENJIE WAN, JASON W. FLEISCHER, *Princeton University* It is well-known, but often underappreciated, that condensate dynamics has analogies with nonlinear light propagation in optics. In both cases, a single, macroscopic wavefunction describes the coherent wave behavior of interest. Here, we take advantage of this correspondence and examine superfluid-like spatial shock waves by propagating coherent light through a nonlinear crystal. We report the observation of both 1D and 2D shock waves, their nonlinear behavior as a function of intensity, and double-shock wave collisions. Analytical calculations and numerical simulations show excellent agreement with the experimental results. The fine structures and features observed here match similar observations in previous shock studies using superfluids and BEC, obtained in this case in a table-top apparatus, without the need for vacuum isolation, ultracold temperatures, etc. Moreover, the inherent optical advantages of easy control of the wavefunction input and direct imaging of the output make us optimistic that the nonlinear photonic systems described here will lay the foundation for a whole series of condensate-inspired experiments, many of which would be difficult (if not impossible) to perform in the corresponding condensed matter environments.

**P10 1 First Principles Dynamics Beyond the Born-Oppenheimer Approximation.***
TODD MARTINEZ, *UIUC*

The dynamics of molecules in excited electronic states almost invariably involves breakdown of the Born-Oppenheimer approximation, necessitating treatment of quantum mechanical effects for both electrons and nuclei. The ab initio multiple spawning (AIMS) method has been developed in order to model molecular dynamics in excited states from first principles, solving both the electronic and nuclear Schrödinger equations ''on the fly.'' We discuss some recent developments in the AIMS methodology and applications to photodamage in DNA bases. Theoretical results are compared directly to femtosecond spectroscopy experiments. Recent attempts to couple the AIMS approach with optimization algorithms to redesign fluorescent proteins will also be discussed, if time allows.

**P10 2 First principles studies of CO adsorption and oxidation on the $Cu_2O$(100) surface*** SERGEY STOLBOV, DUY LE, TALAT S. RAHMAN, *Physics Department, Kansas State University* This work is motivated by the experimental results [1] indicating that the rate of CO oxidation on $Cu_2O$ surface is much higher than that on Cu and CuO surfaces. To gain insight into the nature of this effect we study from first principles the energetics of adsorption and oxidation of CO on $Cu_2O$(100). Applying the itab initio thermodynamics approach [2] to the surface in contact with gaseous $O_2$, we find that the O-termination of $Cu_2O$(100) is preferred for all reasonable range of temperature and the $O_2$ pressure. We find that CO adsorbed on surface O associates with it to form $CO_2$ without any activation barrier. On the other hand, CO adsorbing on a surface Cu atom, it is found to slide first towards the neighboring O atom to form $CO_2$ as in the previous case. We analyze the local densities of electronic states and valence charge densities of the systems to rationalize the obtained results.

**P10 3 Electronic structure and bonding properties of K and $K^+$ on graphite under external electric field*** ALEJANDRO TAPIA, ROMEO DE COSS, *Department of Applied Physics, CINVESTAV-Merida, Mexico.* GABRIEL CANTO, *CCMC-UNAM, Ensenada, Mexico.* The effect of an external electric field on the adsorption of K and $K^+$ on the graphite (0001) surface, are studied by means of first- principles total-energy calculations. The results were obtained with the pseudopotentials LCAO method (SIESTA code) and the Generalized Gradient Approximation (GGA) for the exchange-correlation potential. The structural parameters, bonding properties, and electronic structure of the K and $K^+$-graphite system are studied in the triangular (2x2) overlayer phase as a function of the external electric field magnitude. We find an important change in the K and $K^+$-graphite bonding as a consequence of the charge transfer from the adatom towards the substrate induced by the electric field. However, we find that none of the investigated systems show diffusion of K or $K^+$ into graphite even with a strong electric field. The results are discussed in the light of the experimental observed diffusion of K into graphite, presumably induced by external electric fields.

**P10 4 Carbon-based nanostructured materials for enhanced $H_2$ production** M.K. KOSTOV, E.E. SANTISO, A.M. GEORGE, K.E. GUBBINS, M.B. NARDELLI, *North Carolina State University* A key fundamental limit of the thermal splitting of bulk water is the fact that the ground state of oxygen is paramagnetic, whereas the ground state of water is diamagnetic. Here, we propose to explore a new paradigm in $H_2$ production: a process in which the system remains on the spin singlet potential surface throughout the reaction, by exploiting the catalytic role of defective carbon substrates. Using first principles modeling techniques, we found evidence that mono-vacancy defects in graphite and carbon nanotubes give rise to a rich chemistry, yielding many possible water dissociation pathways, some of which have activation barriers lower than half the value for the dissociation of bulk water. This reduction is caused by spin selection rules that allow the system to remain on the same spin surface throughout the reaction. These novel reactions enhance the hydrogen yield and the reaction rate. In the presence of water only, this reaction is self-limiting: when all of the defects are oxidized, the reaction is complete, and no further $H_2$ is produced. There are several possibilities to achieve regeneration of the active surface sites, such as photo-excitation, vibrational excitations or further reaction with other molecules. We will discuss this exploration in the context of a complete cycle of energy storage and release through the production of $H_2$.

**12:27**

**P10 5 Quantum dynamics with wavepackets and density matrices: A novel computational tool with applications to biological enzymes.*** SRINIVASAN IYENGAR, *Indiana University* A recently developed computational approach for simultaneous dynamics of electrons and nuclei is discussed. The approach is based on a synergy between quantum wavepacket dynamics and ab initio molecular dynamics. The quantum dynamics is performed using an efficient banded, sparse and Toeplitz representation for the discretized free propagator that is formally exact. Ab initio molecular dynamics is achieved by using (a) an extended Lagrangian formalism, known as atom-centered density matrix propagation, that effects an adjustment of time-scales of the electronic motion, (b) Born-Oppenheimer dynamics. The quantum dynamics and ab initio dynamics schemes are coupled through a time-dependent self consistent field-like procedure. Higher order coupling between the subsystems is inherent when the Born-Oppenheimer procedure is used as opposed to atom-centered density-matrix propagation. A fundamental computational bottleneck associated with the computation of the interaction potential between the ab initio and quantum dynamical subsystem are overcome through a novel importance sampling approach and this aspect is also discussed. Further generalization for periodic quantum dynamical treatment in extended systems is outlined.

**P10 6 First-Principles pH Theory*** YONG-HYUN KIM, S. B. ZHANG, *National Renewable Energy Laboratory* Despite being one of the most important macroscopic measures and a long history even before the quantum mechanics, the concept of pH has rarely been mentioned in microscopic theories, nor being incorporated computationally into first-principles theory of aqueous solutions. Here, we formulate a theory for the pH dependence of solution formation energy by introducing the proton chemical potential as the microscopic counterpart of pH in atomistic solution models. Within the theory, the general acid-base chemistry can be cast in a simple pictorial representation. We adopt density-functional molecular dynamics to demonstrate the usefulness of the method by studying a number of solution systems including water, small solute molecules such as $NH_3$ and HCOOH, and more complex amino acids with several functional groups. For pure water, we calculated the auto- ionization constant to be 13.2 with a 95 % accuracy. For other solutes, the calculated dissociation constants, i.e., the so- called $pK_a$, are also in reasonable agreement with experiments. Our first-principles pH theory can be readily applied to broad solution chemistry problems such as redox reactions.

**P10 7 Efficiency and accuracy in transition-metal chemistry: a self-consistent GGA+U approach** HEATHER KULIK, MATTEO COCOCCIONI, NICOLA MARZARI, *DMSE, Massachusetts Institute of Technology* Transition-metal centers are the active sites for a broad variety of biological and inorganic chemical reactions. Notwithstanding this central importance, density-functional theory calculations based on local-density or generalized gradient approximations often fail qualitatively and quantitatively in describing energetics, multiplet structures, reaction barriers, and geometries around the active sites. We suggest here an alternative approach, mutuated from the Hubbard U correction to solid-state problems, that provides an excellent agreement with accurate, correlated-electron quantum chemistry calculations in paradigmatic test cases that range from the ground state of the $Fe_2$ dimer to the potential energy surfaces for the addition-elimination of molecular hydrogen on $FeO^+$. The Hubbard U is determined with a novel self-consistent procedure based on a linear-response approach.

**P10 8 First principles calculation of the x-ray absorption spectra of ice and liquid water*** DAVID PRENDERGAST,[†] GIULIA GALLI,[‡] *Lawrence Livermore National Laboratory* Recent interpretations of x-ray absorption spectra (XAS) of ice and liquid water propose that the standard, tetrahedral model of the liquid should be replaced with a model where each water molecule possesses two stronger and two weaker hydrogen bonds to nearest neighbor molecules. We have investigated this issue and find no conclusive evidence to discount the standard model. Using density functional theory (DFT) calculations we find an excellent agreement with experiment for the XAS of ice I. We perform TIP4P classical molecular dynamics simulations of the liquid at 300K. Using 10 statistically uncorrelated snapshots of 32 molecules in our DFT calculations, we compute the XAS of this standard liquid model and also find a reasonable agreement with experiment. The

spectral differences between liquid and solid arise from both structural disorder and the presence of dangling hydrogen bonds.

**P10 9 Exploiting unitary invariance in ab initio molecular dynamics: Applications to spectral decomposition and surface reactions*** MARK TUCKERMAN, *New York University* The methodology of ab initio molecular dynamics, wherein finite-temperature dynamical trajectories are generated using forces computed ''on the fly'' from electronic structure calculations, has benefited significantly from its combination with maximally localized electronic orbitals. The latter exploit the unitary invariance of the total energy to generate orbitals with maximum spatial locality. These orbitals resemble the classic textbook picture of molecular orbitals and, hence, are useful tools for analyzing electronic structure. In addition, maximally localized orbitals, expanded in localized basis sets, are a key component in linear scaling methods. In this talk, it will be shown how techniques from quantum field theory can be used to reformulate ab initio molecular dynamics in such a way that maximally localized orbitals are generated automatically and dynamically as the calculation proceeds. As an application of the technique, it will be shown how IR spectra can be decomposed to reveal particular structures in aqueous solutions. A second application will focus on the addition of organic molecules to the Si(100)-2x1 surface.

**P10 10 Engineering protein structure and function with computational protein design** JEFFERY SAVEN, *University of Pennsylvania* Understanding molecular folding has important applications to understanding biology and to developing new therapeutics and new materials. Protein design also opens new ways to probe the determinants of folding and to facilitate the study of proteins. Such design is complicated, however, by the conformational complexity of proteins and by the large numbers of possible sequences. Recent computational methods for identifying the properties of amino acid sequences likely to fold to a given three-dimensional structure will be presented. Several examples of structures so designed, which have been experimentally synthesized and characterized, will be presented.

**13:39**

**P10 11 First-Principles Calculations of van't Hoff Plots for Novel Hydrogen-Storage Materials*** NIKOLAI ZARKEVICH, D.D. JOHNSON, *Department of Materials Science and Engineering, and Materials Computation Center, University of Illinois at Urbana-Champaign* A van't Hoff plot, log(P) vs. 1/T, provides information on the free-energy change in a reaction and is widely used to characterize hydrogen-storage materials. Recently, a new reaction of $LiBH_4$ destabilized by $MgH_2$ (yielding over 11 wt.% of $H_2$) was proposed.[1] Here we investigate this reaction and its products by first-principles calculations and construct the van't Hoff plot for a direct comparison to experiment. Although it is often assumed that there is a constant slope in the van't Hoff plot for ease of interpretation, we find an important non-linearity arising from temperature-dependent vibrational entropy difference, etc. This non-linearity can be critical for an accurate comparison to experimental data, and between various reactions to determine optimal hydrogen-storage systems. Including these effects, we find agreement with recent measurements.

**P10 12 Application of Generalized Sturmians to the Bound States of Two-Electron Atoms and Molecules** EDDIE RED, ALBERT WYNN III, CHARLES WEATHERFORD, *Florida A&M University* A variation on the method of Generalized Sturmians [J. Avery, Hyperspherical Harmonics and Generalized Sturmians, Kluwer, 2000], is applied to the calculation of the ground and excited states of two-electron atoms and molecules (etc. He, $H_2$). In the present implementation of this method, each determinant formed from a set of primitive one-electron Sturmians, is required to separately solve the Schödinger equation. In the process, the screening constant of each one- electron Sturmian orbital is non-iteratively uniquely determined. The resultant generalized eigenvalue problem however has a non-positive- definite overlap matrix. The method of ''corresponding orbitals'' [H.F. King et. al. J. Chem. Phys. 47, 1936 (1967)] is used to produce a positive-definite overlap matrix. A CI calculation is then performed whereby the Hartree-Fock calculation is avoided. Results will be presented and compared with Hartree-Fock based CI calculations.

**14:03**

**P10 13 Characterizing the potential energy landscape by its geodesic paths** CHENGJU WANG, RICHARD M. STRATT, *Department of Chemistry, Brown University, Providence, RI 02912* We suggest that the time evolution of a condensed-matter system is related to a unique exploration path in its multidimensional potential energy surface. We show that sampling from what we call the potential energy landscape filling ensemble, we can study the potential energy landscape of a monatomic Lennard-Jones system without the complications of barrier hopping processes. The ensemble defined to include all the configurations with potential energy less than a specified value, allows us to sample the geodesic path between two randomly selected configurations. The geodesics were tentatively related to the dynamics of the system under the assumption that the geodesic path corresponds to the most efficient exploration route on its potential energy surface. The derived dynamic parameters were compared with those obtained from a molecular dynamics simulation. The agreement we found offers us a new method for relating the dynamics of a system to the topology of its static potential energy surface.

**P11 1 High resolution infrared and microwave spectra of OCS solvated in helium clusters.** WOLFGANG JAEGER, *University of Alberta* ROBERT MCKELLAR, *National Research Council of Canada* YUNJIE XU, *University of Alberta* In recent years, exciting progress has been made in determining the onset and following the evolution of a bulk phase property, namely superfluidity, in the microscopic size regime. Our previous microwave and infrared studies of small $He_N$-OCS and $He_N$-$N_2O$ clusters extended up to N=8 and N=19, respectively, and the infrared spectra with CO or $CO_2$ as probe reached almost up to N=20. We have now been able to extend the studies on $He_N$-OCS to much larger N-values in both the infrared and microwave regions. The B rotational constants that were extracted from the spectra show unexpected, non-classical behavior as a function of N, the number of helium atoms. We will present the experimental techniques used and an interpretation of the observed trends in spectroscopic observables.

**11:27**
**P11 2 Recurrences in rotational dynamics and superfluid response in doped He-HCCCN and He-$N_2O$ clusters** NIKOLAY BLINOV, *Department of Chemistry, University of Alberta* PIERRE-NICHOLAS ROY, *Department of Chemistry, University of Alberta* WOLFGANG JÄGER, *Department of Chemistry, University of Alberta* Recent experiments on He-$N_2O$ complexes revealed the oscillatory behavior of the rotational constant in the range of cluster sizes corresponding to the completion of the first solvation shell. We use the path-integral Monte Carlo approach to show that this phenomenon can be associated with a non-monotonic size evolution of the non-classical rotational inertia and superfluidity, the origin of which can be traced back to combined solvent layering and bosonic exchange effects. Using the dopant molecule as an experimental microscopic probe of superfluidity, we show that in small doped helium clusters superfluidity builds up in stages correlated with the filling and completion of solvation shells.

**11:39**
**P11 3 Infrared spectra and intensities of $H_2O$-$N_2$, $H_2O$-$O_2$ and $H_2O$-Ar complexes in superfluid He droplets.** SUSUMU KUMA, *Kyoto University* MIKHAIL N. SLIPCHENKO, *University of Southern California* KIRILL KUYANOV, *University of Southern California* TAKAMASA MOMOSE, *University of British Columbia* ANDREY F. VILESOV, *University of Southern California* The infrared spectra of $H_2O$-$N_2$, $H_2O$-$O_2$ and $H_2O$-Ar complexes in superfluid He droplets were measured in the range of the stretching vibrational bands of water molecules. The infrared intensities of anti-symmetric stretching band of these complexes showed no significant increase with respect to that of a single $H_2O$ molecule as opposed to the predicted intensities in previous theoretical calculations. From the analysis of the observed spectra, it was found that $H_2O$ in $H_2O$-$O_2$ and $H_2O$-Ar rotates nearly freely inside the complexes, while that in $H_2O$-$N_2$ does not. The conformation of these complexes were estimated from the rotational constants obtained from the analysis.

**P11 4 Spectroscopic Properties of Aerosols and their Microscopic Origin.**
RUTH SIGNORELL, *University of British Columbia*

Large molecular aggregates with sizes ranging from less than nanometers up to microns play an important role in atmospheric processes, as components of the interstellar medium, and as drug delivery systems in medicine. The vibrational dynamics of these particles can be strongly influenced by intrinsic particle properties such as size, shape, or surface area. These phenomena are discussed here for several pure and composite ice particles which consist of $CO_2$, $N_2O$, $NH_3$, $SO_2$, their isotopomers, and different carbohydrates. The aerosol are generated in collisional cooling cells, by supersonic expansions, and by rapid expansion of supercritical solutions [1]. The vibrational dynamics is studied in situ with a rapid scan Fourier transform infrared spectrometer. We demonstrate that only the combination of experiments with microscopic models leads to a comprehensive understanding of the various features observed in the infrared spectra. The corresponding molecular model (exciton model [1,2]) allows us not only to calculate spectra for large molecular aggregates, but also to derive propensity rules for the occurrence of characteristic effects in infrared spectra of particles. **P11 5 Kinetics and Products of Radical-Initiated Oxidation of Organic Particles Using Aerosol CIMS** GEOFFREY SMITH, JOHN HEARN, *University of Georgia* Ambient aerosol can contain a significant fraction of organic material which may react with trace gases in the atmosphere. Recently, it has been proposed that reactions with radical species, such as OH and Cl, may constitute a substantial loss mechanism for organic particles. In particular, the radical-initiated oxidation could lead to the creation of smaller, more volatile species which remove mass from the particles. An accurate assessment of the importance of these radical reactions requires measurements of their rates of reaction as well as identification of the subsequent products. We are exploring OH- and Cl-initiated reactions using Aerosol CIMS (chemical ionization mass spectrometry) to monitor changes in the compositions of the aerosol as well as the gas phase. This technique is well-suited to the study of organic species since the mass spectra contain very little fragmentation. These experiments provide insight into the oxidative processing which may potentially alter many critical properties of organic aerosol, including hygroscopicity and their ability to act as cloud condensation nuclei.

**12:39**

**P11 6 Gas-phase infrared spectroscopy of ionic uranyl coordination complexes*** DAVID MOORE, *UC Berkeley* ANITA GIANOTTO, *Idaho National Lab* NICK POLFER, *FOM Institute for Plasma Physics* JOS OOMENS, *FOM Institute for Plasma Physics* MIKE VAN STIPDONK, *Wichita State University* GARY GROENEWOLD, *Idaho National Lab* The uranyl dication ($UO_2^{2+}$) is the primary carrier of uranium in environmental and biological systems, yet relatively little is known about its chemical properties. Mass spectrometric studies have confirmed that the properties, and in particular the reactivity of the uranyl center is rather dependent on its coordination environment. The current study uses IRMPD spectroscopy of ionic uranyl complexes, recorded using a free-electron laser coupled to an FTICR mass spectrometer, to investigate the effects of cluster size and composition on the infrared spectra. The central observation from the current study is that the asymmetric uranyl stretch is quite sensitive to the coordination environment, showing clear, reproducible, incremental redshifts as the number and electron donating ability of the ligands is increased. These spectral trends are accurately reproduced by computed frequencies from DFT calculations. Results from complexes containing anionic ligands are also presented, and are consistent with the presence of a significant barrier to electron transfer within the complexes.

**P11 7 Stable highly symmetric dopant encapsulated binary clusters*** PETER LIEVENS, SVEN NEUKERMANS, EWALD JANSSENS, *Laboratory of Solid State Physics and Magnetism, K.U.Leuven, Celestijnenlaan 200D, B-3001 Leuven, Belgium* While clusters composed of rare gas atoms exhibit enhanced stabilities for high symmetry geometries, magic numbers in simple metal clusters are determined by the number of delocalized valence electrons. Altering the composition of binary clusters allows to tailor independently the cluster geometry (number of atoms) and electronic properties (number of delocalized electrons). We produce beams of binary clusters with a dual-target dual-laser vaporization source. Size and composition dependent stability fluctuations are investigated with photofragmentation and mass spectrometry, and ionization energies with threshold laser ionization spectroscopy. We recently studied clusters of noble metals doped with transition metal atoms, and of group IVa elements doped with di- and trivalent metal atoms. Evidence is presented for the existence of combined closures of shells of atoms and shells of electrons for specific binary species. Phenomenological interpretations of new electronic shell closures are compared with DFT calculations of their geometry and electronic structure.

**P11 8 Factors Controlling Polymorph Formation in Nonphotochemical Laser-Induced Nucleation (NPLIN) of Aqueous Glycine Solutions** XIAOYING SUN, BRUCE A. GARETZ, *Polytechnic University, Brooklyn, NY 11201* The supersaturation and polarization dependence of nonphotochemical laser-induced nucleation (NPLIN) was studied in aqueous glycine solutions at wavelengths of 532 and 1064 nm, using linearly, circularly and elliptically polarized light. We observed a narrow supersaturation window (SS=1.45-1.54) for ''polarization switching,'' i.e. different polarizations producing different polymorphs. We also observed that, within this window, a small range of ellipticities near unity could induce the nucleation of the alpha polymorph, and that this range depended on supersaturation. Similar ''polarization switching'' behavior was observed at wavelengths of 1064 and 532 nm, although the supersaturation window became narrower at lower laser intensities at both wavelengths. Order-parameter ellipsoids and triangles based on optical Kerr alignment are presented to aid the interpretation of the experimental results.

**P11 9 Density Functional Studies of Magic Metal-$(C_{60})_2$ Clusters** EVA ZUREK, *Max Planck Institute for Solid State Research* JOCHEN AUTSCHBACH, *Department of Chemistry, University at Buffalo* Previous experimental studies of $C_{60}$-metal clusters revealed that clusters with composition $C_{60}Ba_{32}$ and $(C_{60}K_6)_nK^+$ appeared as magic peaks in the Time-of-Flight mass spectra due to geometric and electronic stability, respectively. Recent experiments using a new heating technique have revealed a different set of magic peaks, which cannot be explained by either one of the aforementioned mechanisms. We present theoretical studies addressing the stability and bonding of these newly observed magic clusters. Molecular density functional calculations have been performed to determine the most energetically stable geometrical configurations for $M_n(C_{60})_2$ clusters, with $M$ = K, Ba and $1 \leq n \leq 6$. The bonding mechanisms have been analyzed in some detail. The results indicate that for barium containing clusters, ionic bonding (transfer of the valence $6s$ electrons to the $C_{60} - \pi^*$ orbitals) and covalent bonding (between the barium $5d$ and $C_{60} - \pi^*$ orbitals) are the dominant mechanisms. Moreover, a metal cluster is formed between the two fullerenes (Ba-Ba bonding). For the potassium containing clusters, only ionic bonding was found. Calculations of the Gibbs free energies indicate that $Ba_3(C_{60})_2$ and $K_4(C_{60})_2$ are the most stable structures, in agreement with experimental results. The role of the entropy is found to be very important in determining which clusters are magic.

**13:27**
**P11 10 Photoelectron spectroscopy as a structural probe of intermediate size clusters** LEEOR KRONIK, OLGA GULIAMOV, *Weizmann Institute of Science* KOBLAR A. JACKSON, *Central Michigan University* We examine the utility of photoelectron spectroscopy (PES) as a structural probe of $Si_n^-$ in the n = 20 – 26 size range by determining isomers and associated photoelectron spectra from first principles calculations. Across the entire size range, we consistently obtain good agreement between theory and experiment [Hoffmann et al., itEur. Phys. J. D **16**, 9 (2001)]. We find that PES can almost invariably distinguish between structurally distinct isomers at a given cluster size, but that structurally similar isomers usually cannot be reliably distinguished by PES. For many, but not all, sizes the isomer giving the best match to experiment is the lowest-energy one found theoretically. Thus, combining theory with PES experiments emerges as a useful source of structural information even for intermediate size clusters.

**P11 11 Nearly Free Electron Gas in a Silicon Cage** J. ULISES REVELES, SHIV KHANNA, *Department of Physics, Virginia Commonwealth University, Richmond Va. 23284* Theoretical investigations of the ground state geometries, electronic structure, spin magnetic moment and the stability of the metal encapsulated $MSi_{12}$ ( M= Sc, Ti, V, Cr, Mn, Fe, Co, Ni) clusters have been carried out within a gradient corrected density functional formalism. The ground state of most $MSi_{12}$ clusters are shown to have the lowest spin multiplicity as opposed to the high spin multiplicity of free transition metal atoms. Consequently, a proper inclusion of the spin conservation rules is needed to understand the variation of the binding energy of M to $Si_{12}$ clusters. Using such rules, $CrSi_{12}$ and $FeSi_{12}$ are found to exhibit the highest binding energy across the neutral while $VSi_{12}^-$ has the highest binding energy across the anionic $MSi_{12}^-$series. It is shown that the variations in binding energy, electron affinity and ionization potential can be rationalized within an 18-electron sum rule commonly used to understand the stability of chemical complexes and shell filling in a confined free electron gas.

**13:51**
**P11 12 Single and Multiple Rings, and Cages in $SiO_x$ Clusters** PENEE CLAYBORNE, ARTHUR REBER, J. ULISES REVELES, SHIV KHANNA, *Department of Physics, Virginia Commonwealth University, Richmond Va, 23284* A. WELFORD CASTLEMAN, *Department of Chemistry and Physics, The Penn State University, University Park, Pa 16802* ASHRAF ALI, *Laboratory for Extraterrestrial Physics, Code 691 NASA Goddard Space Flight Center, Greenbelt Md, 20771* Theoretical studies on the geometry, electronic structure and stability of $Si_nO_m$ clusters have been carried out within a gradient corrected density functional formalism. It is shown that the ground states of small $Si_nO_n$ clusters containing upto 4 units are single rings. The first Si-Si bond appears at $Si_5O_5$, and starting at this size, the elementary rings begin to assemble into multiple rings that eventually lead to cages. The ground state structures at larger sizes have a central core of pure Si atoms decorated by outer shell of SiO units. An analysis of the fragmentation patterns shows that $Si_7O_7$ and $Si_{10}O_{10}$ are particularly stable species. The results of our investigations on the $Si_nO_{n-1}$ and $Si_nO_{n+1}$ species will also be presented. In particular, we will examine possible reaction mechanisms that could lead to the formation of $SiO_2$ from SiO molecules in interstellar space.

**P12 1 The crossover from collective motion to periphery diffusion for small adatom-islands on Cu(111) and Ag(111)*** ALTAF KARIM, *Kansas State University* ABDELKADER KARA, *Kansas State University* AHLAM AL-RAWI, *Kansas State University* OLEG TRUSHIN, *Academy of Science, Russia* TALAT RAHMAN, *Kansas State University* The diffusion of two dimensional adatom islands (containing 2-100 atoms) on Cu(111) and Ag(111) has been studied, using the newly developed self-learning Kinetic Monte Carlo (SLKMC) method [Phys. Rev. B 72, 115401, 2005]. A variety of multiple and single atom processes are revealed in the simulations and the size dependence of the diffusion coefficients and effective diffusion barriers are calculated. From the tabulated frequencies of events found in the simulation, we show a crossover from diffusion due to the collective motion of the island to a regime in which the island diffuses through the periphery dominated mass transport. This crossover occurs for island sizes of 8 to 11 atoms. For islands containing 19 to 100 atoms the scaling exponent is 1.5, which is in good agreement with previous work. The diffusion of islands containing 2 to 10 atoms can be explained primarily on the basis of a linear increase of the barrier for the collective motion with the size of the island.

**P12 2 Excitation of frustrated translation and nonadiabatic adatom hopping induced by inelastic tunneling*** KAI LIU, *Institute of Physics, Chinese Academy of Science* SHIWU GAO, *Institute of Physics, Chinese Academy of Sciences, and Department of Physics, Goteborg University* The dynamics of lateral manipulation for cobalt/Cu(111) has been investigated combining the model of vibrational heating and first-principles density functional calculations [1]. The frustrated translational mode responsible for lateral excitation is identified as a vibrational resonance involving a concerted motion between the adatom and surface phonons. The calculated frequency shows good agreement with the onset energy for adatom hopping induced by inelastic tunneling. Simulation of the power law, compared with experiment, suggests that the atom hopping overcomes a nonadiabatic barrier due to the nonequilibrium local heating of the translational mode. **P12 3 Metal Island Coalescence Stress for Varying Surface Traction** STEVEN SEEL, EDMUND WEBB III, JONATHAN ZIMMERMAN, *Sandia National Laboratories* During Volmer-Weber thin film growth, discrete metal islands grow on a substrate. When the separation between their adjacent free surfaces becomes small enough, islands coalesce and trade surface energy for elastic strain energy. While it is understood that traction between island and substrate directly influences coalescence stress, questions re-

main. For instance, wafer curvature measurements during growth of low traction systems indicate zero stress in the growing film. This results from a lack of mechanical coupling between film and substrate so island stress cannot be accurately determined from experimental data. We examine, via atomistic simulations, coalescence between two metal islands as a function of island size and island-substrate traction. We reveal the stress state in the coalesced structure for low traction where entire islands are able to slide along the substrate. This is compared to higher traction where islands can only slide near the point of coalescence resulting in local tensile strain. We conclude by examining the dependence upon island size of the traction above which only local sliding is observed. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy's National Nuclear Security Administration under Contract DE-AC04-94AL85000.

**P12 4 Effects of Strain on Island Morphology and Size Distribution in Submonolayer Island Growth*** G. NANDIPATI, J.G. AMAR, *University of Toledo* We have carried out kinetic Monte Carlo simulations of submonolayer heteroepitaxial growth using a model in which the strain energy is approximated by a long-range $1/r^3$ interaction. For the case of irreversible growth with rapid island relaxation due to edge-diffusion we find that the island-shape changes from square to rectangular in the presence of sufficient strain. However, in this case fluctuations play an important role and the scaled island-size distribution is only weakly affected by strain. General scaling forms for the island-width and island-length distributions are also derived. Simulation results for a reversible model of Cu/Ni(001) growth, for which an interesting shape transition has been experimentally observed, are also presented and compared with experiments.

**P12 5 Incidence-angle dependence of optical reflectivity difference from an ultrathin film on a solid surface*** J. P. LANDRY, J. GRAY, M. K. O'TOOLE, X. D. ZHU, *Dept. of Physics, Univ. of California at Davis* The oblique-incidence reflectivity difference (OI-RD) technique is a special form of polarization-modulated nulling ellipsometry that has been judiciously used in studies of ultrathin films and other surface-bound changes on a solid or even liquid substrate. We have recently studied the incidence angle dependence of the optical reflectivity difference signals in response to ultrathin films on transparent and opaque substrates. We find that the classical three-layer model reproduces the experimentally obtained angular dependence for a monolayer of xenon on Nb(110) and for a monolayer of protein molecules on functionalized glass. We report the findings of this recent experimental investigation and explore the enhancement of the optical response near the Brewster angle (or its equivalent for opaque substrates) in thin film detection.

**P12 6 Time Resolved Study of Ordering Between Quantum Well Islands by Wide-Area k-Space Mapping** HAWOONG HONG, L. BASILE, P. CZOSCHKE, A. GRAY, T.-C. CHIANG, *Fredrick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign* The growth of Pb quantum well islands on Si(111) was investigated in time resolved manners. The wide-area momentum space mapped in our x-ray diffraction techniques allows simultaneous observation of the lateral ordering and height distributions of Stranski-Krastanov (S-K) islands during deposition, annealing, and cycling between deposition and annealing. These islands are formed not by strain relaxation but through quantum phase separation. The ordering of these islands exhibits unusual behaviors not well described by existing strained island theories. The population of islands always decreases monotonically during all three processes. However, the island ordering was stable without coarsening with time, at least within the experimental condition. This study suggests that quantum well effect may provide a new mechanism for uniform self-assembled nanostructures.

**P12 7 Sublimation of Atomic Layers from a Chromium Surface** WACEK SWIECH, SHU-JUNG TANG, SUNEEL KODAMBAKA, IVAN PETROV, PETER FLYNN, TAI-CHANG CHIANG, *University of Illinois at Urbana-Champaign* We employ low-energy electron microscopy to study the kinetics of thermal etching, or sublimation, of Cr(001) at $\sim$ 1100 K. Atomic layers are removed from the surface by spontaneous nucleation and growth of two-dimensional vacancy islands, by rotation of spiral steps, and by island decay. The growth rates of vacancy islands and the rotation frequencies of double spirals are measured as a function of temperature, and the results are correlated with activation barriers of surface processes. Mass transport between the surface and bulk is shown to be unimportant.

**P12 8 Iso-coverage diffusion zones observed with LEEM during annealing of Ag on Si(001)*** KELLY ROOS, *Department of Physics, Bradley University* KIMBERLY ROOS, *Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign* FRANK MEYER ZU HERINGDORF, MICHAEL HORN-VON HOEGEN, *Institute for Experimetnal Physics, University of Duisburg-Essen* JOACHIM KRUG, *Institute for Theoretical Physics, University of Cologne* During high temperature annealing of 3D Ag islands grown on Si(001) PEEM images reveal the emergence of a bright zone surrounding the decaying islands. Microdiffraction patterns from these bright areas display a (2x3) Ag reconstruction. The decaying Ag islands act as sources of Ag adatoms which then diffuse on the surface. The (2x3) reconstruction spreads away from the island to a distance determined by the interplay of diffusion and desorption, and by the local coverage of Ag: the outer boundary of the imaged diffusion zones constitutes an ''iso-coverage boundary.'' We describe the time and temperature behavior of these iso-coverage zones, and present a simple continuum model that describes the iso-zone size as a function of the diffusion and desorption rates.

**P12 9 Imprinting Chirality into inorganic CuO Thin Films** ROLAND WIDMER, ROMAN FASEL, OLIVER GROENING, FRANZ-JOSEF HAUG, PIERANGELO GROENING, EMPA MATERIALS SCIENCE AND TECHNOLOGY, FEUERWERKERSTRASSE 39, CH-3602 THUN TEAM, Switzer et al. [1] have shown, that thick ( $>$ 300nm) films of CuO grown electrochemically in the presence of chiral tartaric acid (TA) acquires a chiral orientation with respect to the growth surface. We have investigated this growth on Au(100) in the presence of chiral TA for low film thicknesses by X-ray Photoelectrons Spectroscopy and X-ray Photoelectron Diffraction (XPD). The resulting XPD patterns were analyzed by single scattering cluster calculations. XPD revealed that using chiral L(+)- or D(-)-TA in the deposition process results in a chiral CuO surface which exhibits mirror-symmetric, non-superimposable patterns with the corresponding chirality imprinted already for film thicknesses below 3nm. Whereas the XPD patterns of the CuO films deposited with the racemic DL-TA and the ''achiral'' meso-TA are completely symmetric. The selectivity of enantiomeric CuO films was demonstrated by subsequent deposition of CuO from a solution containing DL-TA onto a CuO film grown with only one of the enantiomeric forms. Additionally, films with alternating chirality were produced. [1] J. A. Switzer, H. M. Kothari, P. Poizot, S. Nakanishi, E. W. Bohannan, Nature, 2003, 425, 490

**P12 10 Geometry and Electronic Structure of Alumina Supported Ag Clusters** ELIZABETH A. SOKOL, SARA E. MASON, *University of Pennsylvania* VALENTINO R. COOPER, *Rutgers, The State Univ. of N.J.* ANDREW M. RAPPE, *University of Pennsylvania* We use DFT/GGA to model silver clusters supported on Al-terminated alpha-alumina. A variety of cluster sizes and geometry are considered. We find that the adsorption of the Ag clusters causes dramatic surface relaxations and polarization of the Ag clusters as some Ag atoms of the clusters bond with O, while others bond with Al. For comparison, we also model adsorption of a single Ag atom, which bonds at a hollow site (relative to surface oxygen). We use the electronic structure of the adsorbed clusters to interpret the bonding interaction between the Ag atoms and surface O and Al atoms. The differences in Ag-surface bonds within the cluster give rise to different electronic environments at each Ag atoms. This effect has implications of this result to reactivity.

**13:15**

**P12 11 Adsorptive and chemical properties of supported silver clusters** SARA E. MASON, ELIZABETH A. SOKOL, *University of Pennsylvania* VALENTINO R. COOPER, *Rutgers, The State Univ. of N.J.* ANDREW M. RAPPE, *University of Pennsylvania* Unlike bulk metal slabs, clusters of transition metals on nonmetallic supports have a finite electron reservoir. Additionally, the interaction of clusters with the support can lead to polarization in the cluster. These effects give rise to adsorption properties quite different from those of bulk metal. We characterize the adsorption of different atomic and molecular species on silver clusters supported by Al-terminated alpha-alumina using DFT/GGA calculations. A range of cluster sizes and cluster geometries is onsidered and the adsorption energetics and geometries are compared with those of bulk silver metal.

**13:27**

**P12 12 Alkali ion scattering from sputter-induced Au nanoclusters** P. KARMAKAR, G.F. LIU, *Department of Physics, University of California, Riverside, California 92521* Z. SROUBEK, *Institute of Radio Engineering and Electronics, Czech Academy of Science, Chaberska 57, 182 51, Prague 8, Czech Republic* J.A. YARMOFF, *Department of Physics, University of California, Riverside, California 92521* The neutralization of scattered 3 keV $^{23}Na^{+}$ ions is used to probe the confined states of sputter induced Au nanoclusters on a $TiO_2(110)$ substrate. The neutral fraction of Na scattered from Au nanoclusters deposited on $TiO_2(110)$ is high compared to bulk Au, as described earlier (G.F. Liu, Z. Sroubek, J.A. Yarmoff, Phys. Rev. Lett. **92**, 216801 (2004)). Here, normal incidence 0.5 keV $Ar^{+}$ ion bombardment of a thin Au film is employed as an alternative method for the self-organized formation of Au nanoclusters. The interplay between curvature dependent sputtering and surface diffusion during $Ar^{+}$ bombardment works to develop the Au nanoclusters. The neutral fraction of the scattered Na gradually increases from 5% to 50% as the cluster dimensions decrease due to the $Ar^{+}$ sputtering. XPS is used to quantify the reduction of Au coverage with sputtering time. STM revels a decrease of both the rms roughness and the correlation length of Au nanoclusters with $Ar^{+}$ fluence.

**13:39**

**P12 13 CO oxidation reaction on Au clusters supported on the $TiO_2(110)$ surface** DAVIDE RICCI, ANGELO BONGIORNO, UZI LANDMAN, *Georgia Institute of Technology, School of Physics* ANKE WOERZ, MATTHIAS ARENZ, UELI HEIZ, *Technical University of Munich, Lehrstuhl fuer Phyzsikalische Chemie* We have studied by means of density functional theory (DFT) plane waves calculations, the CO oxidation reaction on $Au_8$ clusters adsorbed on both the stoichiometric and reduced rutile $TiO_2(110)$ surfaces. $O_2$ molecules bind at the interface between the $TiO_2(110)$ surface and the gold particle, where they become partially charged through the population of the anti-bonding molecular orbital, resulting in the extension of the O-O bond length to values of peroxo-like states. When CO is co-adsorbed on the gold-particles, the Langmuir-Hinshelwood and the Elay-Rideal mechanisms are possible for the oxidation reaction. Both the catalytic cycles have been considered and the theoretical results have been compared with experimental findings obtained on size-selected $Au_8$ clusters deposited on thin, oxidized and reduced $TiO_2$ films.

**P13 1 Quantum Control with Nonclassical Light.**
YARON SILBERBERG, *Weizmann Institute*

Most of the experimental advances in coherent quantum control in recent years have involved ultrashort pulses and pulse shaping techniques. These pulses have been an excellent source of coherent light with precise phase relationship between the various frequency components. In several recent works we have investigated the possibility of using broadband nonclassical light, generated by down-conversion of narrow-band lasers, for coherent control. Such light, for most purposes, exhibit the properties of a broadband thermal noise, but also unique quantum correlations between spectral mode pairs at the signal and idler frequencies that are required for quantum control. We have investigated both the single-photon limit, when the light was composed of individual entangled photon-pairs, and the large signal limit, when the light is not weak but does exhibit nonclassical phase correlations. In the high-intensity limit, we have shown that coherent control of two-photon absorption can be performed with incoherent non-classical light. We showed that the signal-idler phase correlations cause the spectral quantum interference to be completely constructive for two-photon interactions that have a final state energy equal to the pump laser frequency. Consequently, even though the broadband down converted light is neither coherent nor pulsed, it induces two-photon absorption just like a coherent ultrashort pulse, and may likewise be coherently controlled by pulse-shaping techniques. We also demonstrated that pulse shaping techniques can be used in the single-photon limit, where we shape the two-photon correlation function. We demonstrate control of the quantum interference of photons at a beam-splitter, and the generation of Bell-states using polarization pulse-shaping techniques. We believe that the combination of quantum control techniques with quantum optics could add an important ingredient to the toolbox of quantum information and computing.

**P13 2 Bell state generation in the presence of complicated entangling interactions*** KENJI MISHIMA, *JST-CREST* KOICHI YAMASHITA, *The University of Tokyo, JST-CREST* We present theoretical investigations on the entanglement generation of bipartite two- and three-level systems interacting with complicated entangling interactions and external electromagnetic fields. The theoretical method employed is based on rotating wave approximation (RWA). By using the partitioning of the complicated entangling interaction matrix, we propose a method of creating the Bell state from the initial separable state in bipartite two-level systems. In addition, by using the bipartite three-level model systems, we show how to create decoherence-free subspace when the Bell state is to be generated. The present work will be useful for realization of entanglement manipulation in the presence of complicated entangling interactions in molecular systems.

*The authors wish to thank CREST, JST for funding.

**12:03**
**P13 3 High-Precision Coherent Control of Molecular Wave Packets** HIROYUKI KATSUKI, *Institute for Molecular Science, National Institutes of Natural Sciences, Japan* KOUICHI HOSAKA, HISASHI CHIBA, KENJI OHMORI, INSTITUTE FOR MOLECULAR SCIENCE, NATIONAL INSTITUTES OF NATURAL SCIENCES, JAPAN TEAM, CREST, JAPAN SCIENCE AND TECHNOLOGY AGENCY, JAPAN COLLABORATION, THE GRADUATE UNIVERSITY FOR ADVANCED STUDIES (SOKENDAI), JAPAN COLLABORATION, The quantum interference of two vibrational wave packets has been

precisely controlled in the electronically excited state of a diatomic molecule by using a pair of fs laser pulses whose relative phase $\phi$ is locked within the attosecond time scale, and the real time evolution of that interference has been observed by another fs probe pulse. The real-time evolution shows a clear dependence on $\phi$. We have also measured a population code, which is a population ratio among the vibrational eigenstates within a WP. The population code also shows a clear dependence on $\phi$. The ordinary frequency domain interpretation based on the spectral interference of locked pulses may be useful to elucidate $\phi$ dependence of population codes, but is no longer suitable for the present real-time observation. The combination of a population code and real-time evolution is useful to obtain both phase and amplitude information stored in a WP.

**12:15**

**P13 4 Nanolocalized Nonlinear Electron Photoemission under Coherent Control*** MARK STOCKMAN, *Department of Physics and Astronomy, Georgia State University* We theoretically show that two-photon coherent control yields electron photoemission from metal nanostructures that is localized in nano-size hot spots whose positions are controllable on a nanometer scale, in agreement with recent experiments. We propose to use silver V-shapes as taylored nanoantennas for which the position of the coherently controllable photoelectron-emission hot spot can be deterministically predicted. We predict that the low-frequency, high-intensity (quasistationary) excitation of the photoemission leads to an exponentially high contrast of the coherent control. REFERENCES M. I. Stockman and P. Hewageegana, ''Nanolocalized Nonlinear Electron Photoemission under Coherent Control,'' Nano Lett. 5(11), 2325-2329 (2005)

**P13 5 Monitoring Molecular Dynamics using Coherent Electrons from High-Harmonic Generation** NICK WAGNER, ANDREA WÜEST, IVAN CHRISTOV, TENIO POPMINTCHEV, XIBIN ZHOU, MARGARET MURNANE, HENRY KAPTEYN, *University of Colorado and National Institute of Standards and Technology* In this talk, we will discuss the first observation of intramolecular vibrational dynamics using electrons rescattered during the process of high-order harmonic generation. We excite coherent vibrations in $SF_6$ using impulsive Raman scattering with a short laser pulse. A second, more-intense laser pulse generates high-order harmonics of the fundamental laser, at wavelengths of $\sim$ 20-50 nm. The high-order harmonic yield is observed to oscillate, at frequencies corresponding to all the Raman-active modes of $SF_6$, with an asymmetric mode most visible. This is in contrast to conventional impulsive stimulated Raman spectroscopy where only the symmetric breathing mode of the molecule is easily observed. The data also show evidence of relaxation dynamics following impulsive excitation of the molecule. Our results indicate that high harmonic generation is a sensitive probe of vibrational dynamics and may yield more information simultaneously than conventional ultrafast spectroscopic techniques. Since the de Broglie wavelength of the recolliding electron is on the order of interatomic distances, i.e. $\sim$ 1.5 Å, small changes in the shape of the molecule lead to large changes in the high harmonic yield. This work therefore demonstrates a new spectroscopic technique for probing ultrafast internal dynamics in molecules that uniquely combines ultrafast time resolution with atomic-scale structural information.

**P13 6 Observation and control of ultrafast quantum interferences in atoms and molecules.**
BERTRAND GIRARD, *Lab. Collisions, Agrégats, Réactivité, IRSAMC, Univ. P. Sabatier - Toulouse 3*

I will present several examples of ultrafast interferences in atoms and molecules, at the femtosecond and picosecond time scale. In a two level atom, real-time quantum state holography is performed through interferences between quantum states created by a reference pulse and a chirped pulse resulting in coherent transients. A sequence of several measurements allows one to measure the real and imaginary parts of the excited state wave function. These measurements are performed during the interaction with the ultrashort laser pulse. The extreme sensitivity of this method to the pulse shape provides a tool for electric field measurement. In a molecule, the transient interferences between two oscillating wave-packets have been observed and controlled. In a first experiment, a vibrational wave packet is created in the iodine B state. Due to anharmonicity, the wave-packet spreads and recombines in one single wave packet (revival time) or two wave-packets (half revival time). When these two wave packets cross, they transiently create a stationary wave which is observed. In a second experiment, the same situation is created by launching two wave packets in the same potential well with an ultrastable relative phase. The delay, set to 1.5 vibrational periods, is stabilized with sub 100 attosecond precision. The same transient interference pattern is observed. Moreover, the relative phase between the counterpropagating wave packets can now be controlled by scanning the interpulse delay on an optical period.

**P13 7 Final resolution of the step-wise versus concerted mechanism controversy for excited-state double proton transfer in the 7-azaindole dimer in the gas phase** HIROSHI SEKIYA, KENJI SAKOTA, *Department of Chemistry, Faculty of Science, Kyushu University* CHIE OKABE, NOBUYUKI NISHI, *Institute for Molecular Science* The excited-state double-proton transfer (ESDPT) reaction in the 7-azaindole dimer has been extensively studied by spectroscopic methods in the gas phase and in solution. Two ESDPT mechanisms, stepwise and concerted mechanisms, have been proposed so far. However, a definite conclusion has not been provided due to a lack of clear evidence. We provide final resolution of the stepwise versus concerted mechanism controversy for the ESDPT reaction in the 7-azaindole dimer by electronic spectroscopy and picosecond-time resolved spectroscopy in the gas phase (K. Sakota, C. Okabe, N. Nishi, H. Sekiya, J. Phys. Chem. A, 109, 5245 (2005)). The ESDPT reaction in the 7-azaindole dimer proceeds via the concerted mechanism. We propose a dynamic cooperative effect, where the motions of the two transferring protons couple with each other through the electronic reorganization (K. Sakota ,H. Sekiya, J. Phys. Chem. A, 109, 2718 (2005); 109,2722 (2005)).

**P13 8 On the Control of Product Yields in the Photofragmentation of Deuteriumchlorid Ions ($DCl^+$) – Cl + $D^+$ < - - $DCl^+$ - - > $Cl^+$ + D.*** KARL-MICHAEL WEITZEL, GEORG BREUNIG, ALEXANDRA LAUER, *Philipps Universitaet Marburg, FB Chemie, Germany* MIKHAIL KOROLKOV, *Academy of Science, Minsk, Belarus* We have investigated the prospect of controlling the photofragmentation of deuterium chloride ions ($DCl^+$) via ultra short IR laser pulses both by experiments and by numerical solution of coupled Schrödinger equations. The calculations provide evidence that the ratio of product ion yields $Cl^+$ versus $D^+$ can be manipulated by appropriate choice of laser pulse parameters, in particular central laser wavelength, pulse duration, intensity and chirp [1]. The analysis of time dependent populations reveals phase sensitive competition between intra- and inter-electronic state excitation. Complementary, we have performed one- and two-color fs experiments looking at the dissociation of $DCl^+$ ions at 800 nm [2] and in the range from 3.5$\mu$m to 7.5$\mu$m (2857$cm^{-1}$ to 1333$cm^{-1}$) [3]. In particular we show, that the ratio of product yields $D^+/Cl^+$ can be controlled via the chirp of the laser pulse at 4.5$\mu$m. References [1] M.V. Korolkov, K.-M. Weitzel, J. Chem. **P13 9 Femtosecond pulse shaping in the mid infrared region using a Dazzler** TAKAMASA MOMOSE, *The University of British Columbia, Tokyo Institute of Technology, CREST, JST* MASAAKI TSUBOUCHI, *The University of British Columbia, CREST, JST* YUKI MIYAMOTO, *Kyoto University* We present a method to produce programmable phase- and amplitude-modulated femtosecond laser pulses in the mid infrared region (MIR: 3 – 10 $\mu$m) by difference-frequency generation (DFG). The signal output (NIR: 1.1 – 1.5 $\mu$m) of an optical parametric amplifier was shaped with an acousto-optic programmable dispersive filter (Dazzler), and mixed in a $AgGaS_2$ crystal with the idler pulse temporary stretched by passing a dispersion block to generate MIR pulses. A Dazzler provides convenient and precise way of shaping femtosecond pulses in NIR region. It is, however, not well understood how the phase and amplitude modulations are transferred from a NIR pulse to a MIR pulse via DFG process. We will discuss the analysis of the shaped NIR and MIR pulses using a frequency-resolved optical gating (FROG) and an FT-IR

**P13 10 Fast Transient Electron Magnetic Resonance at 240 GHz*** JOHAN VAN TOL, *National High Magnetic Field Lab* The zero-field splitting of the excited triplet states of organic molecules often is of the order of 1 GHz or less, and transient EPR at X-band is generally sufficient for the determination of the zero-field splitting and kinetic parameters in these type of molecules. However, information on the g-factor and g-anisotropy cannot be obtained at conventional EPR frequencies, and interpretations of the data in terms of electronic structure are mostly limited to symmetry considerations. On the other hand information of the g-anisotropy provides additional clues with respect to electronic structure, while a direct comparison with radical-ion forms of the molecules becomes possible. Experimental data of transient EPR at 240 GHz will be presented for a variety of system (fullerene-based and porphyrin-based). EPR at these very high frequencies can accurately determine the g-anisotropy and in some cases the orientation of the g-tensor with respect to the ZFS tensor. Also at these high frequencies sub nanosecond processes can be measured. Examples will be given.

**P13 11 Response of Dipicolinic Acid ($C_5H_5N(COOH)_2$) to Ultrafast Laser Pulses*** PETRA SAUER, ROLAND ALLEN, *Texas A&M University* Dipicolinic acid (DPA) and its salts are common constituents of bacterial spores, including those of anthrax. It has been proposed that such spores can be detected via spectroscopic techniques which employ ultrashort laser pulses. The development of these techniques should be enhanced by a detailed understanding of the microscopic processes that transpire when a molecule is subjected to femtosecond-scale pulses of various intensities, durations, and polarizations. We have recently developed a model that can be used to perform realistic simulations of the electronic and nuclear dynamics of biological molecules (containing carbon, hydrogen, oxygen and nitrogen) when they are subjected to such pulses. The bond lengths and vibrational frequencies for a variety of test molecules are in reasonable agreement with those obtained in experiment and itab initio calculations. Here we report results of simulations for DPA responding to femtosecond-scale laser pulses, with an analysis of the vibrational modes and electronic states which are most relevant for various choices of the laser pulse parameters.

**P16 1 Molecular sensing using point contact conductivity modulation** ADAM DICKIE, ROBERT WOLKOW, *University of Alberta* The electrical properties of semiconductors are sensitive to external influences, such as the adsorption of gaseous molecules. For single crystal Si surfaces, the change in conductivity induced by molecular adsorption is a very small fraction of the bulk conductivity, precluding their use as efficient sensors. Here we show that point contacts on Si surfaces in UHV environments can overcome this fundamental limitation, through the use of minority-carrier-induced conductivity modulation. Point contacts made to clean, low-doped $n-$ Si(100) produce significant surface inversion layers. The inversion layer minority-carrier population is exponentially dependent upon surface charge. Slight increases in the surface charge density, from gas molecule adsorption, are detected as large increases in sample conductivity, as electrons flow in to balance the positive hole space charge. The sensitivity of this simple device structure is so high that physisorption of inert gas molecules such as He, $N_2$, and Ar can be detected as conductivity increases of 2 – 100%; the specific response is proportional to the molecular ionization potential. Decreasing the point contact size, from micro- to nano- to atomic-scale, increases device sensitivity because of increased minority-carrier injection ratios.

**P16 2 Humidity dependence of molecular tunnel junctions with an AlOx/COOH- interface** XIAOHANG ZHANG, STEPHEN MCGILL, PENG XIONG, *Physics Department & MARTECH, Florida State University, Tallahassee, FL* We have studied the electron transport in planar tunneling junctions with aluminum oxide and an organic self-assembled monolayer (SAM) as the tunnel barrier. The structure of the junctions is Al/AlOx/SAM/(Au, Pb) with a junction area of $\sim$ 0.4mm$^2$. The organic molecules investigated include mercaptohexadecanoic acid (MHA), hexadecanoic acid (HDA), and octadecyltrichlorosilane (OTS); all of which form ordered SAMs on top of aluminum oxide. The use of a superconducting electrode (Al) enables us to determine unambiguously that these are high-quality tunnel junctions. For junctions incorporating MHA, the transport behavior is found to be strongly humidity dependent. The resistance of these junctions drops more than 50% when placed in dry nitrogen and recovers when returned into the ambient. The same drop also occurs when the sample is placed into a vacuum, and backfilling the vacuum with either dry N2 or O2 has negligible effect on the resistance. For comparison, junctions with HDA show the same humidity dependence, while OTS samples do not. Since both MHA and HDA have carboxylic groups and OTS does not, the results suggest that water molecules at the AlOx/COOH- interface play the central role in the observed behavior. Inelastic tunneling spectroscopy (IETS) has also been performed to understand the role of water. This work was supported by a FSU Research Foundation PEG grant.

**P16 3 Signatures of magnetism in an individual Mn12O12 molecule probed by single-electron tunneling.** MOON-HO JO, *Dept of Materials Science and Engineering, POSTECH* JACOB E. GROSE, DANIEL C. RALPH, *Dept of Physics, Cornell Univ* KANHAYALAL BAHETI, JEFFREY R. LONG, *Dept of Chemistry. UC Berkeley* WENJIE LIANG, MANDAR M. DESHMUKH, HONGKUN PARK, *Department of Chemistry & Chemical Biology and Department of Physics* We report low-temperature electron transport through individual molecular clusters, Mn12O12(O2C-R)16(H2O)4, [Mn12O12], where R is -CH3 and -CHCl2. Energy level spectroscopy with single-electron tunneling probes the ground state spin of the individual Mn12O12 molecules, and exhibits signatures of their magnetism. In particular the absence of the spin degeneracy is manifested as an energy splitting between low-lying energy manifolds of the ground state spin at zero-magnetic field, and it signifies the magnetic anisotropy of an individual Mn12O12 molecule. We also discuss the influence of this anisotropy to the electron tunneling spectrum in the presence of a magnetic field.

**P16 5 Exploring electron transport through organic monolayers using conductive tip AFM techniques** DENIS SCAINI, *Synchrotron Trieste, Trieste, Italy; Department of Physics, University of Trieste, Trieste, Italy* MATTEO CASTRONOVO, *Department of Physics, University of Trieste, Trieste, Italy* MARTINA

DELL'ANGELA, *Synchrotron Trieste, Trieste, Italy;* ROBERT HUDEJ, *Synchrotron Trieste, Trieste, Italy; International School for Advanced Studies (ISAS), Trieste, Italy* LOREDANA CASALIS, *Synchrotron Trieste, Trieste, Italy* GIACINTO SCOLES, *Synchrotron Trieste, Trieste, Italy; International School for Advanced Studies (ISAS), Trieste, Italy; Princeton University, Princeton, NJ* We follow an alternative approach to the study of Metal-molecule-Metal junctions that uses a combination of two atomic force microscopy (AFM) techniques. We use Nanografting to build a nanopatch of the molecules of interest and a second made of a reference molecule into a hosting self assembled monolayer (SAM) typically made of alkanethiols. After the tip is changed to a conductive one CT-AFM is used to characterized the whole system recording, at the same time, the system topography. Some of the advantages of this approach are the possibility to build and study a wide range of different M-m-M junctions and the in-situ control of the quality of the monolayers and patches. Results will be presented on saturated and unsaturated thiols self-assembled and nanografted on Au(111) surfaces. The results will be compared with those obtained by Liang and Scoles at Princeton using similar techniques.

**P16 7 Electronic Conduction in Metal/Molecule/Semiconductor Devices.**
DAVID JANES, *School of Electrical and Computer Engineering, Purdue University*

In the field of molecular electronics, the contacts to the molecular elements are critical interfaces. The use of semiconductor contacts allows direct covalent bonding, provides an additional degree of freedom due to the semiconductor states, and, in certain circumstances, can minimize the effects of electrical shorting due to direct metal/substrate contacts. This talk will describe the development and electrical characterization of metal/molecule/semiconductor device structures on GaAs and Si active layers. In order to observe the conductance of the molecular species, rather than that of the semiconductor barrier, the semiconductor layers used in this study are generally highly doped. In these structures, the electronic conduction between the metal and semiconductor can be modulated by choice of molecular species. Several alkyl thiol and aromatic thiol molecules have been employed in order to determine the effects of molecular length, conjugation and intrinsic dipole moment. In certain molecules, conductance peaks or memory/switching effects have been observed. The current-voltage characteristics and conductance versus temperature both indicate that the molecular layers change the transport mechanism, generally involving a lower effective barrier height than that of a metal/semiconductor Schottky barrier. Studies on both n- and p- type substrates, including those with nanometer scale cap layers, allow the effects of the molecular and semiconductor barriers to be isolated. A basic conduction model has been developed, based on the electrostatics of the structure and thermionic-field-emission analysis of the semiconductor portion of the barrier.

**P18 1 Electrically-Induced Infrared Emission from Carbon Nanotube Devices.**
JIA CHEN,* *IBM T. J. Watson*

The optical properties of carbon nanotubes (CNTs) are currently the focus of intense study. CNTs are direct band gap materials and their optical spectra have long been attributed to transitions between free particle bands. We show that studies of electrically-excited infrared (IR) emission from single nanotube molecules provide new insights into the electron-hole interactions in quasi-1D systems. We demonstrate strongly-enhanced electroluminescence from a partially suspended CNTFET operated under unipolar transport conditions [1]. In our devices, carriers are generated locally, when a single type of carrier is accelerated under high local electric fields at intra-molecular junctions to energies sufficient to create strongly correlated e-h pairs (excitons). This excitation mechanism contrasts with emission from radiative recombination of carriers (electrons and holes) injected from the opposite ends (source and drain) of a CNTFET operated under ambipolar transport conditions. The new excitation mechanism is about 1000 times more efficient than recombination of independently injected electrons and holes, and it results from weak electron-phonon scattering and strong electron-hole binding caused by one-dimensional confinement. We show that the light emission intensity increases exponentially with the drive current in partially suspended CNTFETs, while in 3D materials light emission is usually proportional to the product of the electron and the hole currents. The strong Coulomb interaction between electrons and holes in a 1D CNT creates bound excitons whose binding energies are more than an order of magnitude larger that those in 3D materials, preventing them from dissociating under electrical fields thus contributing little to drive current compared with that in 3D. Finally, the much higher exciton density achieved in our devices than that in typical photoluminescence experiments allows us to detect emission from higher excitation states in CNTs. [1] J. Chen, V. Perebeinos, M. Freitag, J. Tsang, Q. Fu, J. Liu, Ph. Avouris, Science 310, 1171 (2005).

**P18 2 Exciton Formation and Electroluminescence Quenching during 1D Impact Excitation of Carbon Nanotubes Field-Effect Transistors** LAËTITIA MARTY, *Regroupement Québécois sur les Matériaux de Pointe (RQMP) and Chemistry Department, University of Montreal* ELYSE ADAM, DAVID MÉNARD, *RQMP and Physical Engineering Department, Ecole Polytechnique of Montreal* RICHARD MARTEL, *RQMP and Chemistry Department, University of Montreal* There are few studies addressing the influence of excitonic effects on the electro-optical response of carbon nanotube (CNT) devices. We present here near infra-red electroluminescence (EL) from unipolar single-wall carbon nanotube field effect transistors (CNFETs) at high drain-source voltages. The conditions for emission at high field reveal that a single carrier type induces EL in CNFETs through a mechanism involving 1D impact excitation. Well-resolved spectra show that the emission is assigned to the radiative recombination of the $E_{1,1}$ exciton. An emission quenching is also observed at high field and attributed to an exciton-exciton annihilation process and free carrier generation. Excitons binding energy in the order of 270 meV for 1.4 nm CNTs is inferred from the spectral features.

**12:03**
**P18 3 Uni- and Ambipolar Light Emission From Inhomogeneous Carbon Nanotube FET's** JAMES TSANG, MARCUS FREITAG, JIA CHEN, PHAEDON AVOURIS, *IBM T. J. Watson Research Center* Heterogeneities in the environment of CNTFETs can produce stationary, unipolar, electroluminescence, in addition to the normal ambipolar emission. We compare the unipolar emission with the ambipolar emission in the same device to characterize the unipolar emission process and show how the heterogeneities modify the electronic properties of the CNT. If a CNTFET is partially covered by a PMMA overlayer, changes in the IV characteristics are observed which correlate with discontinuities in the motion of the ambipolar emission at the PMMA boundary, and the generation of unipolar emission at the boundary. These PMMA induced changes show there is a step in the potential along the CNT at the boundary. Similarly, localized effects in both the ambi- and unipolar emission are observed in CNTFETs containing closed loops. The unipolar emission requires the junction between the portions of the single carbon nanotube that form the base of a loop must support the voltage drop needed to generate the light. Direct comparison of the ambipolar and unipolar emission in the same device demonstrates the efficiency of the unipolar processes.

**12:15**
**P18 4 Carbon Nanotube p-n Junction Diodes** JI UNG LEE, *GE Global Research* We describe the formation of p-n junctions along individual single-walled carbon nanotubes (SWNTs) using electrostatic doping techniques. The electrostatic doping preserves the pristine nature of CVD grown SWNTs, and when suspended, these diodes can be described by the ideal diode equation. The low background leakage currents coupled with a built-in electric field region to transport the quasi particles also makes these diodes ideal for studying the optical responses of SWNTs. We will describe several characteristics of SWNT diodes such as the quantum efficiency, origin of the quasi-particles (electrons and holes) currents, and effects due to excitons.

**12:27**

**P18 5 Electronic Transport in Individual Carbon Nanotube P-N Junction Diodes** NATHANIEL GABOR, *Laboratory of Solid State Physics, Cornell University* KEN BOSNICK, *National Institute for Nanotechnology, National Research Council of Canada* PAUL MCEUEN, *Laboratory of Solid State Physics, Cornell University* We have investigated electronic transport in single-walled carbon nanotube p-n junction diodes formed using gates to electrostatically dope the tube. Previous measurements [1] have shown that such diodes demonstrate nearly ideal turn-on behavior at room temperature and low biases, consistent with thermal activation over the junction barrier. We have performed measurements over a broad temperature range and have verified that the transport is by thermal activation. From the temperature dependence of the current-voltage characteristics, we can extract the nanotube band gap and the transmission coefficient through the p-n junction region. [1] J.U. Lee et al, App. Phys. Lett. **85**, 145 (2004)

**12:39**

**P18 6 Negative differential conductance in suspended semiconducting carbon nanotubes** HAIBING PENG, ALEX ZETTL, *Center of Integrated Nanomechanical Systems and Department of Physics, University of California at Berkeley, Berkeley, CA 94720* Suspended single-wall carbon nanotubes (SWCNTs) have been grown directly on metal electrodes with electrical contact by chemical vapor deposition. Extraordinary negative differential conductance was observed for the first time in suspended semiconducting SWCNTs. The current-voltage characteristics show an abrupt drop of conductance as the source-drain voltage is increased, followed by a constant differential conductance at higher voltage. The effect is qualitatively different from the recently reported negative differential conductance in metallic SWCNTs (it-Phys. Rev. Lett. **95** 155505, 2005). We suggest that the observed negative differential conductance in semiconducting SWCNTs may be attributable to Schottky barriers between the as-grown suspended SWCNTs and the electrodes, instead of optical phonon scattering invoked in explaining the negative differential conductance in metallic SWCNTs. Our observations not only have potential applications for novel electronic devices, but also shed light on better understanding and manipulating SWCNTs transistors.

**P18 7 Nanotube Film Electrodes in Electro-Optic Devices*** ZHUANGCHUN WU, *[1]* JEREMIAH K. MWAURA, *[2]* MARIA NIKOLOU, *[1]* TIMOTHY STECKLER, *[2]* DAVID B. TANNER, *[1]* JOHN R. REYNOLDS, *[2]* ANDREW G. RINZLER, *[1] 1. Dept. of Physics, 2. Dept. of Chemistry, University of Florida, Gainesville, FL* The interface between conjugated polymers and conducting electrodes is crucial for the operation of organic electronic devices such as light emitting diodes (LEDs), electrochromics and photovoltaics. Transparent electrodes in these devices have been based mostly on indium tin oxide (ITO). There have been efforts to develop conducting polymer electrodes, and some success has been realized with films based on poly(3,4-ethylene-dioxythiophene)-poly(styrene sulfonate) (PEDOT-PSS).[1] In most cases however, the polymer conductivity is too low for such applications. Pure nanotube thin films, demonstrated to have much higher conductivities while exhibiting good transparency in the visible and near to mid IR, provide attractive alternatives.[2] Here we describe fabrication and performance of two devices: (1) an MEH-PPV polymer LED using a carbon nanotube film as the hole injecting electrode and (2) an infrared transmissive/absorptive electrochromic cell that makes use of the superior IR transmittance of the nanotube films. 1. **P18 8 Measurements of exciton binding energies in single wall nanotubes using field dependent photocurrent spectroscopy** A.D. MOHITE, J.-T. LIN, G.U. SUMANASEKERA, B.W. ALPHENAAR, *Dept of Electrical & Comp. Engr., Univ. of Louisville* We have used electric field dependent photocurrent measurements to distinguish between band-to-band and excitonic transitions in the excitation spectrum of a single wall nanotube capacitor. The zero field photocurrent spectrum is limited to carriers excited into continuum states that can freely diffuse from the nanotubes and into the metal contact. Application of an applied field allows for the separation of the bound exciton states via field ionization. Near the $E_{11}$ resonance, both excitonic and band-to-band transitions are resolvable with a binding energy of 109 meV. This is in reasonable agreement with recent theory for 1.3 nm diameter nanotubes[1]. Near the $E_{22}$resonance, we observe only a single field independent peak in the photocurrent spectrum indicating a fast decay of the exciton into the lower energy continuum states. Surprisingly, we are also able to resolve an exciton resonance associated with metallic nanotubes. Theory shows that in metallic nanotubes, optical transitions between the overlapping states at the Fermi energy are disallowed, giving rise to a symmetry gap[2]. We measure the binding energy of the metallic exciton to be 49 meV for 1.3 nm diameter tubes. **References** (1) Perebeinos, V.; Tersoff, J.; Avouris, Ph., Phys. Rev. Lett. **2004**, 92, 257402. **P18 9 Optical Properties of Aligned Carbon Nanotube Mats for Photonic Applications** G.L. ZHAO, *Southern University and A&M College; Visiting Fellow, Princeton University* D. BAGAYOKO, *Southern University and A&M College* L. YANG, *NASA Ames Research Center* We studied the optical properties of the aligned carbon nanotube (16, 0), (10, 0) and (8, 4) mats for photonic device applications. We employed the ab-initio density functional calculations in the linear combination of atomic orbital formalism. We calculated the electronic structure of the carbon nanotube mats and the real and imaginary parts of the dielectric functions as functions of photon energy. The calculated dielectric functions of the aligned carbon nanotube mats show a strong anisotropy when the electric field of light is parallel or perpendicular to the tube axes. Especially, there are strong peaks in the imaginary part of the dielectric function near the absorption edges, when the electric field of light is parallel to the carbon nanotube axes. The unusual optical properties of the semiconducting carbon nanotube mats present a new opportunity for applications in new electro-optical devices in the infrared energy region. Acknowledgments: this work was funded in part by NSF (Award No. 0508245), NASA (Award No. NCC 2-1344), and ONR (Grant No: N00014-05-1-0009).

**P18 10 Theory of Auger Recombination of Excitons in One-Dimensional Nanostructures*** FENG WANG, YANG WU, MARK S. HYBERTSEN, TONY F. HEINZ, *Columbia University* The effective Coulomb interaction is greatly enhanced in one-dimensional (1D) systems. As has been recently demonstrated for single-walled carbon nanotubes [1], this strong Coulomb interaction causes the formation of tightly bound exciton states upon optical excitation of semiconducting materials. The strength of the Coulomb interaction in 1D systems leads to a second consequence: Auger recombination of excitons, also known as exciton-exciton annihilation, can be very efficient. Here we investigate the 1D Auger process using a point-contact model for the Coulomb interaction. We show that the Auger process is essentially temperature independent, in contrast to the behavior of weakly bound excitons and free carriers in bulk semiconductors. We apply the explicit expression that we have derived to single-walled carbon nanotubes. We obtain an Auger rate of $\sim 0.6\,\mathrm{ps}^{-1}\,\mu\mathrm{m}$, comparable to the reported experimental value [2]. [1] F. Wang et al., Science **308**, 838 (2005); [2] F. Wang et al., Phys. Rev. B **70**, 241403 (2004).

**P18 11 Measurement of Optical Stark Effect in Semiconducting Single-Walled Carbon Nanotubes** DAOHUA SONG, FENG WANG, GORDANA DUKOVIC, LOUIS E. BRUS, TONY F. HEINZ, *Columbia University, New York, NY 10027* M. ZHENG, G.B. ONOA, E.D. SEMKE, *DuPont Central Research and Development, Wilmington, DE 19880* The optical Stark effect in quantum-confined systems, such as quantum wells, has been the subject of active interest for many years. In this paper we present the first measurement of the optical Stark effect in carbon nanotubes. In our experiment we used two-color femtosecond spectroscopy to probe the $E_{11}$ transition in the nanotubes while applying a strong optical pump beam at significantly lower photon energy (the large detuning limit). The sample was an aqueous suspension of (6,5)-enriched single-walled carbon nanotubes. An instantaneous shift in the absorption line by up to 1 meV was observed; the magnitude of the shift scaled linearly with the pump intensity. The nature of the optical Stark effect in the carbon nanotube system, with its strong excitonic transitions, will be discussed.

**P18 12 Bandgap Modulation by Transverse Electric Fields in Single Wall Carbon Nanotubes** J. M. KINDER, *University of Pennsylvania* E. J. MELE, *University of Pennsylvania* We study the variation of the electronic bandgap of semiconducting carbon nanotubes in a static electric field perpendicular to the nanotube axis. We consider three models for the transverse field profile and find that the spectrum is sensitive to the spatial variation of the transverse field. For a uniform transverse field, we show the bandgap is fixed until the field strength exceeds a critical value, in agreement with previous theoretical work. In contrast, we find no critical behavior when the applied field is localized to a region of the nanotube much smaller than its length. An arbitrarily weak field produces bound states inside the unperturbed bandgap whose binding energy vanishes as the fourth power of the applied field strength. The field strengths required to reduce the gap by a few percent are the same order of magnitude as those commonly used in scanning tunneling microscopy.

**P19 1 Direct observation of the Aharonov-Casher phase*** M. KÖNIG, *Physikalisches Institut(EP3) der Universitaet Wuerzburg, Am Hubland, D-97074 Wuerzburg, Germany* E. M. HANKIEWICZ, *Texas A&M University, College Station, TX 77843-4242 and University of Missouri-Columbia, Columbia, MO 65211* JAIRO SINOVA, *Texas A&M University, College Station, TX 77843-4242* A. TSCHETSCHETKIN, V. HOCK, V. DAUMER, M. SCHÄFER, C. R. BECKER, H. BUHMANN, L. W. MOLENKAMP, *Physikalisches Institut(EP3) der Universitaet Wuerzburg, Am Hubland, D-97074 Wuerzburg, Germany* We report the direct observation of Aharonov-Casher effect, which can occur when electrons propagate in a ring structure in the presence of spin-orbit interactions and external magnetic field perpendicular to the ring plane. The transport measurements have been conducted on the series of ring structures fabricated from HgTe/HgCdTe quantum wells. We study Aharonov-Bohm type conductance oscillations as a function of Rashba spin-orbit splitting strength. We observe non-monotonic phase changes indicating that an additional phase factor modifies the electron wave function. We associate these observations with the Aharonov-Casher effect and confirm it by numerical calculations of the magnetoconductance for a multichannel ring within the Landauer-Büttiker formalism.

**P19 2 Spin Interference Effect in a Square Loop Array including the Rashba and Dresselhaus Terms*** T. KOGA[2], H. OKUTANI, *GSIST, Hokkaido University and* [2]*CREST, JST* Y. SEKINE, [3]*NTT Basic Research Laboratories, NTT Corporation* J. NITTA[2,3], *GSEng., Tohoku University* The effect of electron wave interference to the electric conductivity ($\sigma$), including the effect of spin degree of freedom, is investigated through nanolithographically defined square (and other) loop array structures fabricated on $In_{0.52}Al_{0.48}As/In_{0.53}Ga_{0.47}As/In_{0.52}Al_{0.48}As$ quantum wells (QW). In this experiment, we measure $\sigma$'s of QWs as a function of magnetic field $B$ ($\mathbf{B}\perp$ QW plane). These samples had a gate electrode covering the entire loop array structures, where a gate voltage $V_g$ was applied between the metal gate electrode and the QW. We note that $V_g$ controls both the carrier density and the Rashba and Dresselhaus spin-orbit terms within the QWs. It turned out that the magnetoconductance $\sigma(B)$ oscillates as a function of $B$ with a period corresponding to $h/2e$, which is denoted as the

AAS oscillation. We found that the amplitude of the AAS oscillation in this system also oscillated as a function of $V_g$, which is called as a ''spin interference'' effect. We investigated this effect, which is also in close relation to the ''Aharonov-Casher'' effect (electric control of the phase of the electronic wave function), in detail including both the Rashba and Dresselhaus spin-orbit terms quantitatively.

**11:39**

**P19 3 Numrical simulation of a spin interferometer based on a single square loop with Rashba interaction** ZHENYUE ZHU, QING-FENG SUN, BIN CHEN, XIN-CHENG XIE, *Oklahoma State University* We numerically calculate the transverse conductance as a function of magnetic field in two models. One is an exact 1D model and the other is a quasi 1D square loop system which is similar to the experimental setup by Koga et. al. From the conductance curves, we employ FFT (Fast Fourier transform) and IFFT (inverse Fast Fourier transform) to extract separately the oscillatory part of conductance whose period correspond to the magnetic flux quanta (AB oscillation) and half quanta (AAS oscillation). We show that the spin precession angle $\theta$ is modulated by the Rashba interaction strength. From the curves about the amplitude of AB or AAS oscillations at B=0 versus $\theta$, we find that the node positions of $\theta$ in the exact 1D model fits well with previous theoretical calculations, but there are some deviations for the quasi 1D model.

**11:51**

**P19 4 Ahronov-Bohm oscillations in a GaAs 2D hole system** BABUR HABIB, EMANUEL TUTUC, MANSOUR SHAYEGAN, *Princeton University* We have grown shallow 2D hole samples in GaAs for implementing mesoscopic structures via local anodic oxidation using an AFM. In this talk we present our results of a ring device which shows clear Ahronov-Bohm oscillations. The amplitude of the resistance oscillations are about 10% of the ring resistance, the strongest seen in a 2D hole system to date.

**12:03**

**P19 5 Zero-field spin-splitting in $Al_xGa_{1-x}N$/GaN heterostructures** IKAI LO, M.H. GAU, W.T. WANG, J.K. TSAI, S.F. TSAY, J.C. CHIANG, *Department of Physics, Center for Nanoscience and Nanotechnology, National Sun Yat-Sen University, Kaohsiung, Taiwan, Republic of China.* DEPARTMENT OF PHYSICS, CENTER FOR NANOSCIENCE AND NANOTECHNOLOGY, NATIONAL SUN YAT-SEN UNIVERSITY, COLLABORATION, We have observed the beating Shubnikov-de Haas oscillations with respect to the zero-field spin splitting of 2DEG in $Al_xGa_{1-x}N$/GaN heterostructures. The spin-splitting energy was obtained about 9 meV from the beating SdH frequency derived by the non-linear curve fitting. A new mechanism ($\Delta_{C1} - \Delta_{C3}$ coupling) was proposed to describe the large spin splitting in wurtzite GaN, which is originated from the band folding effect and intrinsic wurtzite structure inversion asymmetry. The band-folding effect generates two conduction bands ($\Delta_{C1}$ and $\Delta_{C3}$), in which $p$-wave probability has tremendous change when $k_z$ approaches anti-crossing zone. The $\Delta_{C1} - \Delta_{C3}$ coupling can produce a spin-splitting energy much larger than traditional Rashba or Dresselhaus effects. This project is supported in parts by National Science Council, Core Facilities Laboratory in Kaohsiung-Pintung area, Taiwan (ROC).

**12:15**

**P19 6 Exact Landau Levels in Two-Dimensional Electron Systems with Rashba and Dresselhaus Spin-Orbit Interactions in a Perpendicular Magnetic Field** DEGANG ZHANG, C.S. TING, *Texas Center for Superconductivity, University of Houston, Houston, TX 77204* C.-R. HU, *Department of Physics, Texas A&M University, College Station, TX 77843* We study a two-dimensional electron system in the presence of both Rashba and Dresselhaus spin-orbit interactions in a perpendicular magnetic field. Defining a suitable boson operator and using the unitary transformations we are able to obtain the exact Landau levels in the range of all the parameters. When the strengths of the Rashba and Dresselhaus spin-orbit interactions are equal, the Zeeman and spin-orbit splittings are independent of the Landau level index $n$. Due to the Zeeman energy, new crossing between the eigenstates $|n,k,s = 1,\sigma>$ and $|n+1,k,s' = -1,\sigma'>$ is produced at certain magnetic field for larger Rashba spin-orbit coupling. This degeneracy leads to a resonant spin Hall conductance if it happens at the Fermi level.

**P19 7 Spatial imaging of the spin Hall effect and current-induced polarization in two-dimensional electron gases.*** VANESSA SIH,† *Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106*

Spin-orbit coupling in semiconductors relates the spin of an electron to its momentum, and provides a pathway for electrically initializing and manipulating electron spins in zero magnetic field for applications in spintronics and spin-based quantum information processing. This coupling can be regulated with strain in bulk semiconductors and quantum confinement in semiconductor heterostructures. Using Faraday and Kerr rotation spectroscopies with temporal and spatial resolution, current-induced spin polarization[1] and the spin Hall effect[2] have been observed in bulk semiconductors. More recently, we have investigated the spin Hall effect and current-induced spin polarization in a two-dimensional electron gas confined in (110) AlGaAs quantum wells using Kerr rotation microscopy[3]. In contrast to previous measurements, the

spin Hall profile shows complex structure and the current-induced spin polarization is out-of-plane. The experiments map the strong dependence of the current-induced spin polarization to the crystal axis along which the electric field is applied, reflecting the anisotropy of the spin-orbit interaction. These results reveal opportunities for tuning a spin source using quantum confinement, strain and device engineering in non-magnetic materials.

**P19 8 Spin Hall effect, spin-accumulation, and spin-currents in mesoscopic structures** MARIO BORUNDA, *Texas A&M University* KENTARO NOMURA, *University of Texas* JAIRO SINOVA, *Texas A&M University* Spin dependent transport effects in strongly spin-orbit coupled paramagnetic systems, such as the spin Hall Effect, have been studied extensively over the last few years. We explore how spin accumulation in a mesoscopic device could be used to observe the effect through electrical and optical means. We report calculations of spin flow in finite size samples with strong spin-orbit coupling using the non-equilibrium Green's function formalism in both the linear and the non-linear regimes. We explore different geometries and spin-orbit coupling mechanism to understand how spin relaxes near the interfaces. We will also report on the progress made in understanding the spin Hall Effect in the bulk regime and how it connects to the closely related effect of the anomalous Hall effect in ferromagnetic materials.

**13:15**
**P19 9 The finite spin Hall effect in semicondutors** NAOYUKI SUGIMOTO, *Department of Applied Physics, University of Tokyo* SHIGEKI ONODA, *Spin Superstructure Project, ERATO, Japan Science and Technology Agency* SHUICHI MURAKAMI, NAOTO NAGAOSA, *Department of Applied Physics, University of Tokyo* We formulate the theory of the spin Hall effect taking into account the impurity scattering effect as general as possible with the focus on the definition of the spin current. The conserved spin current (Zhang *et, al*. [cond- mat/0503505]) satisfying the continuity equation of spin in the bulk is considered in addition to the conventional one defined by the anti-symmetric product of the spin and velocity operators. The condition for the non-zero spin Hall current is clarified from a generic viewpoint and the following new results for explicit models are obtained: (i) spin Hall current in Rashba model is non-zero on the non-delta impurity scattering potential, and (ii) spin Hall current vanishes in cubic Rashba model on the delta impurity scattering potential.

**13:27**
**P19 10 What is intrinsic and what is extrinsic in the spin Hall effect?*** EWELINA HANKIEWICZ, GIOVANNI VIGNALE, *Univ. of Missouri-Columbia* MICHAEL FLATTÉ, *University of Iowa* Two different forms of the spin Hall effect, intrinsic and extrinsic, have been recently proposed and observed in experiments. The intrinsic effect is caused by spin-orbit coupling in the band structure of the semiconductor and survives in the limit of zero disorder, whereas the extrinsic effect is caused by spin-orbit coupling between Bloch electrons and impurities. We treat both effects on equal footing within the framework of the exact Kubo linear response formalism. We show that the ''side-jump'' term, which is usually considered part of the extrinsic spin Hall effect, is really intrinsic, because it is independent of disorder. Furthermore, it is the only non-zero *intrinsic* contribution to the spin-Hall effect for the linear Rashba (or Dresselhaus) spin-orbit coupling model. On the other hand, the skew scattering term is the only *extrinsic* contribution to the spin-Hall effect within this model. The proof based on gauge invariance holds at all orders in disorder and electron-electron interactions and to first order in spin-orbit coupling, but does not apply to more complex spin-orbit coupled bands (e.g the Luttinger model). We also study many-body effects and predict that the spin Coulomb drag will reduce the spin Hall conductivity.

**P19 11 Spin Hall Effect in Doped Semiconductor Structures*** WANG-KONG TSE, SANKAR DAS SARMA, *University of Maryland* We present a microscopic theory of the extrinsic spin Hall effect based on the diagrammatic perturbation theory. Side-jump (SJ) and skew-scattering (SS) contributions are explicitly taken into account to calculate the spin Hall conductivity, and we show their effects scale as $\sigma_{xy}^{SJ}/\sigma_{xy}^{SS} \sim (\hbar/\tau)/\varepsilon_F$, where $\tau$ being the transport relaxation time. Motivated by recent experimental work we apply our theory to n-doped and p-doped 3D and 2D GaAs structures, obtaining analytical formulas for the SJ and SS contributions. Moreover, the ratio of the spin Hall conductivity to longitudinal conductivity is found as $\sigma_s/\sigma_c \sim 10^{-3} - 10^{-4}$, in reasonable agreement with the recent experimental results of Kato et al. [Science 306, 1910 (2004)] in n-doped 3D GaAs system.

**13:51**
**P19 12 Intrinsic spin Hall conductivity*** PAVEL KROTKOV, *University of Maryland* SANKAR DAS SARMA, *University of Maryland* In an isotropic 2D gas with general dispersion and linear-in-k spin-orbital interaction of the Rashba or Dresselhaus type in the presence of impurities we find that an intrinsic spin-Hall conductivity is finite and is of the order of the spin-orbit term squared. It vanishes only in the well-studied particular case of a quadratic dispersion.

*Supported by NSF, US-ONR, and LPS-NSA.

**14:03**

**P19 13 Imaging Stationary Flow of Spin Hall Effect-Induced Spin Densities in Mesoscopic Nanostructures** LIVIU ZÂRBO, *University of Delaware* SATOFUMI SOUMA, *Tokyo University of Science* BRANISLAV NIKOLIĆ, *University of Delaware* The spin Hall effect has recently attracted a lot of attention in semiconductor spintronics since it offers a novel way of all-electrical generation and manipulation of pure spin currents by employing spin-orbit (SO) couplings. To describe spin Hall transport on a scale of a few nanometers we introduce the concept of bond spin current and corresponding local flowing spin densities between the sites of the lattice model of a multiterminal SO coupled semiconductor nanostructure, and express them in terms of the nonequilibrium (Keldysh) Green functions. Our predictions for the out-of-plane polarized steady state spin densities flowing into the transverse interaction-free electrodes due to the longitudinal charge current injected into high-mobility two-dimensional electron gas (2DEG) with Rashba SO coupling crucially depend on the size of 2DEG in the units of spin precession length. In the presence of disorder, the flowing spin Hall densities remain non-zero in the bulk of the 2DEG. Moreover, we also find in-plane polarized spin densities flowing into the longitudinal leads due to the magneto-electric effect. These theoretically predicted images of mesoscopic spin Hall flow could be tested via recently advanced Kerr rotation microscopy.

**P20 1 Intrinsic nanoscale electronic phase separation and simple percolation in $La_{1-x}Sr_xCoO_3$*** J. WU, *Materials Science, Univ. of Minnesota* J. PARKER, *Physics, Univ. of Minnesota* C. PERREY, B. CARTER, *Materials Science, Univ. of Minnesota* J. LYNN, *Nist Center for Neutron Research, NIST* H. ZHENG, J. MITCHELL, *Materials Science Division, Argonne National Lab* C. LEIGHTON, *Materials Science, Univ. of Minnesota* The doped pervoskite cobaltite $La_{1-x}Sr_xCoO_3$ has been advanced as a model system for studying magnetoelectronic phase separation. We present here a combination of chemically sensitive high-resolution TEM, SANS, and transport data that reveal interesting new features of this phase separation. The TEM data show that the material is chemically homogenous down to nm length scales, proving that the phase separation is truly intrinsic electronic phase separation. The SANS data, which were performed at several compositions below $x = 0.18$ (where long-range ferromagnetism (FM) sets in), reveal that the FM clusters have a maximum size of about 2-3 nm, itindependent itof doping. This demonstrates that the percolation transition that occurs at $x = 0.18$ is due to an increasing density of clusters with increasing x, itnot an expansion of cluster size. These observations naturally explain the simple percolation observed in single crystal transport, i.e. conductivity exponents close to predicted values and a critical composition ($x = 0.18$) close to the expected value for the 3-D percolation limit.

**P20 2 Short-range magentic correlations and dynamic orbital ordering in the thermally activated spin state of $LaCoO_3$** S. ROSENKRANZ, *Argonne National Laboratory* D. PHELAN, D. LOUCA, S.H. LEE, *University of Virginia* P.J. CHUPAS, R. OSBORN, H. ZHENG, J.F. MITCHELL, *Argonne National Laboratory* The cobalt perovskites $La_{1-x}Sr_xCoO_3$ show intriguing spin, lattice, and orbital properties similar to the ones observed in colossal magnetoresistive manganites. The $x=0$ parent compound is a non-magnetic insulator at low temperatures, but shows evidence of a spin-state transition of the cobalt ions above 50K from a low-spin to an intermediate or high-spin configuration. Using high resolution, inelastic neutron scattering, we observe a distinct low energy excitation at 0.6meV coincident with the thermally induced spin state transition observed in susceptibility measurements. The thermal activation of this excited spin state also leads to short-range, dynamic ferro- and antiferromagnetic correlations. These observations are consistent with the activation of a zero-field split intermediate spin state as well as the presence of dynamic orbital ordering of these excited states. Work supported by US DOE BES-DMS W-31-109-ENG-38 and NSF DMR-0454672

**11:39**

**P20 3 Emergence of Magnetism in $La_{1-x}Sr_xCoO_3$** D. PHELAN, DESPINA LOUCA, S.-H. LEE, *University of Virginia, Dept. of Physics* S. ROSENKRANZ, J.F. MITCHELL, *Materials Science Division, Argonne National Laboratory* Orbital, spin, and charge degrees of freedom play a central role in the physics of CMR-type transition metal perovskite oxides. $La_{1-x}Sr_xCoO_3$ is a system in which a ferromagnetic, metallic state emerges when holes are doped into the parent compound, a non-magnetic, Mott insulator in the ground state. We have studied this system using elastic and inelastic neutron scattering techniques on single crystals with $0 \leqslant x \leqslant 0.2$. With hole doping the ferromagnetic correlations between Co spins become static and isotropically distributed due to the formation of ferromagnetic droplets. The correlation length and condensation temperature of these droplets increase rapidly with metallicity due to the double exchange mechanism. Diffuse spin dynamics appear as the correlation length increases. The dynamics are broad in energy indicative of a spin wave continuum.

**11:51**

**P20 4 Local Matrix-Cluster Interactions In $La_{1-x}$ $Sr_xCoO_3$.** SEAN GIBLIN, *CCLRC-Rutherford Appelton Lab, UK* IAN TERRY, *Durham University, UK* ANDREW BOOTHROYD, DHARMALINGIAM PRABHAKARAN, *University of Oxford, UK* JING WU, CHRIS LEIGHTON, *CEMS, University of Minnesota, USA* Magneto-electronic phase separation plays an integral part in many recent advances in the understanding of correlated electron systems. We have studied the magnetically phase separated material $La_{1-x}$ $Sr_xCoO_3$ and the parent compound $LaCoO_3$, using muon spectroscopy and magnetic susceptibility measurements. The muon as a local magnetic probe is sensitive to the magnetic field distribution in $LaCoO_3$ in the LS state, which is a direct consequence of magnetic excitons. We believe that these excitons are interacting with the Co ions undergoing the known thermally induced spin transition. By directly comparing the results of the parent compound with $La_{1-x}$ $Sr_xCoO_3$we can observe

the hole-rich ferromagnetic clusters interacting with the neighboring hole poor matrix for low x. This mechanism, detected here for the first time, may play an important role in the rich electrical and magnetic properties of $La_{1-x}$ $Sr_xCoO_3$.

**12:03**

**P20 5 Anisotropy-driven magnetic anomalies in $Pr_{1-x}Sr_xCoO_3$*** CHRIS LEIGHTON, DOUG STAUFFER, JING WU, *University of Minnesota* QING HUANG, JEFF LYNN, BRIAN TOBY, *NIST* JOHN MITCHELL, *Argonne National Lab* Interest in the perovskite cobaltites has been growing steadily due to the intriguing phenomena they exhibit. It is well known that the availability of various Co ion spin states in the cobaltites provides an additional degree of freedom in comparison to the manganites. In this work we demonstrate that the cobaltites also possess another factor of considerable importance not present in the manganites – large magnetocrystalline anisotropy. As previously reported [Mahendiran et al PRB 68 024427 (2003)] at $x > 0.30$ $Pr_{1-x}Sr_xCoO_3$ displays an additional anomaly below the Curie temperature, where the magnetization can dramatically increase or decrease depending on applied field. We demonstrate here, using magnetometry, transport, heat capacity, and neutron diffraction, that this results from a structural phase transition from a low symmetry to higher symmetry (tetragonal) phase on reducing T. Although the Co moment is unaffected, a sharp change in the magnetocrystalline anisotropy takes place and is reflected in the hysteresis loop shape, coercivity, and remnance. The complex and puzzling behavior of the field dependence of the magnetization vs. T curves is then simply explained by the T dependent variations in hysteresis loop shape.

**12:15**

**P20 6 Magnetic properties and phase separation in $Pr_{1-x}Sr_xCoO_3$, using $^{59}$Co NMR** R. SMITH, P.L. KUHNS, M.J.R. HOCH, W.G. MOULTON, *National High Magnetic Field Laboratory* D. STAUFFER, J. WU, C. LEIGHTON, *University of Minnesota* Doped transition metal oxides including manganites and cobaltites have revealed a rich variety of properties that may be technologically important. The mixed valence cobaltite $Pr_{1-x}Sr_xCoO_3$(PSCO) has a phase diagram reminiscent of $La_{1-x}Sr_xCoO_3$(LSCO) but with a number of significant differences. For x=0.5 the system is ferromagnetic (FM) below $T_C$= 240 K but anomalous magnetization behavior is found close to 120 K with an associated crystal structure change from low symmetry to tetragonal with decreasing *T*. For $x < 0.3$ no change in magnetic properties or crystal structure is found below $T_C$. Zero-field $^{59}$Co NMR spectra show that differences in FM character between x=0.5 and x=0.3 samples are negligibly small at temperatures in the range 3-30 K No FM line was observed for x=0.2; a narrow paramagnetic- like signal only slightly shifted from the diamagnetic $^{59}$Co spectrum is observed in high- field NMR for all three x values, providing evidence of some form of phase separation where a paramagnetic phase coexists with the FM phase. The results will be compared with the very different phase separation data previously obtained for LSCO.

**12:27**

**P20 7 Structural and Magnetic Properties of the Kagomé Antiferromagnet $YbBaCo_4O_7$** JOHN MITCHELL, *Materials Science Division, Argonne National Laboratory* ASHFIA HUQ, *IPNS, Argonne National Laboratory* LAURENT CHAPON, PAOLO RADAELLI, KEVIN KNIGHT, *ISIS, Rutherford Laboratory* PETER STEPHENS, *SUNY Stonybrook* HONG ZHENG, *Materials Science Division, Argonne National Laboratory* The mixed-valent compound $YbBaCo_4O_7$ is built up of Kagomé sheets of $CoO_4$ tetrahedra, linked in the third dimension by a triangular layer of $CoO_4$ tetrahedra in an analogous fashion to that found in the known geometrically frustrated magnets such as pyrochlores and $SrCr_{9x}Ga_{12-9x}O_{19}$ (SCGO). We have undertaken a study of the structural and magnetic properties of this compound using combined high resolution powder neutron and synchrotron X-ray diffraction. $YbBaCo_4O_7$ undergoes a first order trigonal to orthorhombic phase transition at 175 K that breaks the trigonal symmetry of the structure. We show that this transition occurs as a response to a markedly underbonded $Ba^{2+}$ site in the high-temperature phase and does not appear to involve charge-ordering of $Co^{2+}/Co^{3+}$ ions in the tetrahedra. The symmetry-lowering relieves the geometric frustration of the structure, and a long-range ordered 3-D antiferromagnetic state develops below 80 K.

**12:39**

**P20 8 Crystal Structure and Magnetic Properties of an oxygen deficient n = 2 Ruddlesden-Popper phase $Sr_3Co_2O_{5.67}$** JULIENNE M. HILL, JOHN F. MITCHELL, *Materials Science Division, Argonne National Laboratory, Argonne, IL 60439* BOGDAN DABROWSKI, *Department of Physics, Northern Illinois University, DeKalb, IL 60115* Interest in charge, orbital, and spin state phenomena in perovskite and related cobalt oxides is a growing area of transition metal oxide physics. Recently, J. Matsuno et al.[1] have found that epitaxial films of the n = 1 Ruddlesden-Popper (R-P) phase $Sr_2CoO_4$ are metallic ferromagnets with relatively high $T_C \sim$ 250 K. This is particularly interesting in light of the formal oxidation state of Co, $Co^{4+}$, offering no clear source of carriers. To extend the materials chemistry and physics of the R-P series of cobaltites, we have synthesized the n = 2 R-P phase $Sr_3Co_2O_{7-\delta}$ in bulk form. The crystal structure [from neutron powder diffraction (NPD) data] of our most oxygen-deficient sample, $Sr_3Co_2O_{5.67}$ is orthorhombic itImmm with a = 3.94025(9) Å, b = 3.67479(9) Å and c = 20.6642(5) Å. The magnetization versus temperature data show two antiferromagnetic transitions at approximately 170 K and 220 K. To further elucidate the magnetic properties of this material, we have conducted a temperature-dependent NPD study. The low temperature magnetic structure is surprisingly complex and suggestive of an incommensurate ordering wave vector. Full details and results of the NPD study will be given.

[1]J. Matsuno et al., PRL **93**, 167202 (2004).

**12:51**

**P20 9 Complex magnetic structure of YBaCo4O7** LAURENT C. CHAPON, *ISIS Facility, Rutherford Appleton Laboratory, UK* JOHN F. MITCHELL, *Materials Science Division, Argonne National LAboratory, USA* PAOLO G. RADAELLI, *ISIS Facility, Rutherford Appleton Laboratory, UK* The new series of mixed-valent oxides RBaCo4O7 (R=Yb,Tb,Y) show complex structural and magnetic behavior. We have recently revealed, for the Yb analog, that a stuctural phase transition occurs in response to an extremely underbounded Ba2+ site. The symmetry lowering from orthorhombic to tetragonal, releases the frustration and allows the

system to order magnetically below 80K. Here we present our neutron diffraction study of the analog compound YBaCo4O7, that shows the same structural phase transition at high temperature and a magnetic transition at around 110K, where the system orders antiferromagnetically with propagation vector k=0. The magnetic structure, solved by global optimization algorithms, shows a non colinear Co-spins arrangement that results from the unique topology of the Co interactions. The magnetic structure is found to be strongly temperature dependent between 1.6K and 110K, which provide crucial information about the relative strengths of competing interactions.

**13:03**

**P20 10 The effect of transition metal ions distribution on magnetic properties of $Li_x(Ni_yMn_yCo_{1-2y})O_2$.** NATASHA A. CHERNOVA, MIAOMIAO MA, JIE XIAO, M. STANLEY WHITTINGHAM, *Institute for Materials Research, SUNY at Binghamton, Binghamton NY 13902-6000* PETER Y. ZAVALIJ, *Department of Chemistry and Biochemistry, University of Maryland, College Park, MD 20742-4454* $Li_x(Ni_yMn_yCo_{1-2y})O_2$ compounds have layered O(3) structure with an occupancy disorder as Ni ions migrate to the lithium layer. Ni ions provide strong antiferromagnetic (AF) exchange between the transition metal (TM) layers; therefore the degree of disorder has a pronounced effect on the magnetic properties. Ni migration is reduced when the amount of Co or Li is increased. In this work we study temperature and magnetic field dependences of magnetization and the ac susceptibility of $Li_x(Ni_yMn_yCo_{1-2y})O_2$ with various Li and Co contents. We have shown that in $LiNi_{0.5}Mn_{0.5}O_2$ compound large amount of Ni on Li sites facilitates AF order within the TM layer, while interlayer Ni ions contribute to the net magnetic moment. This is consistent with the ''flower'' order of the TMs proposed from the Monte-Carlo simulations. With increasing Co content, the ''flower'' structure is destroyed and a spin glass state is observed in Co-containing compounds. This work is financially supported by the US Department of Energy, Office of FreedomCAR and Vehicle Technologies, through the BATT program at LBNL.

**P20 11 Observation of Magnetic Memory Effect and Photo-induced Magnetism in $Y_{0.33}Sr_{0.67}CoO_{3-\delta}$** M. IZUMI, Y.F. ZHANG, S. SASAKI, *Tokyo University of Marine Science and Technology* O. YANAGISAWA, *Yuge National College of Maritime Technology* We prepared the $Y_{0.33}Sr_{0.67}CoO_{3-\delta}$by the conventional solid state method which sintered under the $O_2$ flow. The sample was finally annealed under the oxygen and nitrogen atmosphere. A DC magnetization jump was found about 200 K with a large thermal hysteresis at 0.01 T indicating a kind of magnetic memory effect. The magnetization jump comes from the inter-spin state transition on $Co^{3+}$ ion from low to intermediate spin state. The magnetic memory effect gradually disappears with the magnetic field increase and the jump temperature ($T_J$) shifts to low temperature. Annealed samples indicate high $T_J$, $T_C$ and the magnetization coming from the oxygen content difference. Under the irradiation of a pulsed near-infrared laser ($\lambda$ = 1050 nm), the $T_J$ shifts to low temperature and the magnetization below $T_J$ decreases. Photo-induced effect is weakened with the magnetic field. Laser irradiation may suppress spin-state transition of the part $Co^{3+}$ ions.

**P20 12 Local Electronic and Spin Structure of GdBaCo2O5.5 from X-ray Absorption Spectroscopy** KYLE SHEN, DAVID HAWTHORN, DARREN PEETS, ILYA ELFIMOV, GEORGE SAWATZKY, *University of British Columbia* ALEXEY TASKIN, YOICHI ANDO, *CRIEPI, Japan* The family of $RBaCo_2O_{5+\delta}$ cobaltates is known to exhibit a rich variety of magnetic behavior as a function of oxygen content and temperature. We present x-ray absorption measurements on detwinned single crystals of $GdBaCo_2O_{5.5}$, where the structure is comprised of alternating rows of $CoO_6$ octahedra and $CoO_5$ pyramids. $GdBaCo_2O_{5.5}$ exhibits successive paramagnetic, ferromagnetic, and antiferromagnetic phases, and also exhibits a ''spin blockade'' effect upon doping. These unusual behaviors are believed to stem from the nearly degenerate spin states of the $Co^{3+}$ ions which can potentially vary from low (S=0), intermediate (S=1), to high (S=2) spin states. Our recent x-ray absorption measurements provide the first measurements of the local electronic and spin states. Measurements of the temperature and polarization dependence of the x-ray absorption at the oxygen K edge clearly indicate an abrupt change in the orbital populations at the metal-insulator transition at T $\sim$ 360 K. We combine our spectroscopic measurements with atomic multiplet and LSDA+U calculations to provide a first insight into the true nature of the spin state transitions which govern the unusually rich magnetic properties of the $RBaCo_2O_{5+\delta}$ cobaltates.

**P20 13 High Pressure and High Resolution Magnetization of $GdBaCo_2O_{5.5}$** R. P. GUERTIN, *Tufts Univ., Medford, MA 02155* E. S. CHOI, P. SCHLOTTMANN, *NHMFL/Florida State Univ., Tallahassee, FL 32310* Z. X. ZHOU, *ORNL, Oak Ridge, TN 37830* We present the results of two rather diverse experiments designed to reveal new features of the complex magnetic properties of $GdBaCo_2O_{5.5}$ and, in particular, lanthanide/transition metal coupling in oxide materials. First, high resolution magnetization, M (H,T), measurements on an untwinned single crystal show a small but non-zero coupling between the 3d-shell Co-based magnetic order and the 4f shell Gd paramagnetism. Second, high pressure magnetization measurements on a polycrystalline sample suggest a weakening of the ferromagnetic interplane coupling at the expense of a strengthening of the antiferromagnetic interplane coupling. In the measured pressure range, however, no unambiguous pressure-induced spin transition was observed. Finally, low temperature isothermal magnetization measurements under pressure indicate a slight weakening of the effective Co-generated molecular field, affecting the Gd paramagnetism. The totality of data contained in this work suggests that there is a small but definitive molecular field effect at the Gd sites, which is a function of the strength of transition metal magnetism ordering at higher temperatures.

**P20 14 Electron-phonon coupling and low-temperature structure of $NaV_2O_5$** JUERGEN SPITALER, *Institute for Atomistic Modelling and Design of Materials,University Leoben* E. YA. SHERMAN, *Department of Physics, University of Toronto* H.G. EVERTZ, *Institute for Theoretical Physics, Graz Technical University* CLAUDIA AMBROSCH-DRAXL, *Institute for Atomistic Modelling and Design of Materials,University Leoben* INSTITUTE FOR ATOMISTIC MODELLING AND DESIGN OF MATERIALS,UNIVERSITY LEOBEN TEAM, INSTITUTE FOR THEORETICAL PHYSICS, GRAZ TECHNICAL UNIVERSITY

COLLABORATION, $NaV_2O_5$ is an extraordinary example of a structure where charge, spin and lattice degrees of freedom strongly interact. This low-dimensional compound is characterized by V atoms arranged in the form of ladders. At ambient conditions it is found to be quarter-filled with one electron distributed over one rung of the ladder. Going below $T_c = 34K$, $NaV_2O_5$ undergoes a phase transition involving a reordering of the V charges, a lattice deformation and a spin pairing. In order to investigate the mechanisms driving the phase transition, parameters of electron-phonon and spin-phonon for the $\Gamma$ point phonons are determined from ab initio calculations within density functional theory. They are compared to the corresponding parameters of the isostructural $CaV_2O_5$, where no phase transition occurs. Moreover, ab initio results of several candidates for the low-temperature supercell of $NaV_2O_5$ are presented and analyzed in terms of total energies and electric field gradients.

**14:03**

**P20 15 Quasi-one-dimensional electronic structure of $\beta'$-$Cu_xV_2O_5$ ($x$=0.33$\sim$ 0.65) studied by photoemission*** S.-K. MO, F. WANG, J. W. ALLEN, *Univ. of Michigan* J. HE, *Univ. of Tennessee* R. JIN, D. MANDRUS, *Oak Ridge National Lab* H. HÖCHST, *Synchrotron Radiation Center* $\beta'$-$Cu_xV_2O_5$ is a quasi-one-dimensional (quasi-1D) oxide that undergoes a metal to insulator transition (MIT) when $x$ decreases from 0.65 to below 0.60. It becomes a superconductor below 6K under pressure around 3GPa. In the metallic phase, the electrical resistivity along the chain direction is 30 times larger than that across the chain direction, making this material suitable for studies of quasi-1D electronic structures. We present the first photoemission spectra of $\beta'$-$Cu_xV_2O_5$ in both metallic (x=0.60, 0.65) and insulating (x =0.33, 0.55) phases. Angle-integrated spectra show a clear indication of the MIT. Nonetheless the intensity near the Fermi energy ($E_F$) is heavily suppressed in the metallic phase, just as in the spectra of $Li_{0.9}Mo_6O_{17}$ and certain other low dimensional oxides [1]. We observe a single band crossing $E_F$ along the chain direction, around the $\Gamma$-point of the Brillouin zone, only in the metallic phase angle-resolved spectrum. Fermi surface intensity maps have clear 1D character and the Fermi wavevector changes according to the concentration of the dopant. [1] G.-H. Gweon, J.W. Allen, and J.D. Denlinger, Phys. Rev. B **68**, 195117 (2003).

**P21 1 Multi-Point Holographic Micro-Velocimetry** ROBERTO DI LEONARDO, *INFM-CNR Dipartimento di Fisica, Universita' di Roma ''La Sapienza,'' Roma, Italy* JONATHAN LEACH, *Department of Physics and Astronomy, University of Glasgow, Glasgow, Scotland* HASAN MUSHFIQUE, *Department of Electrical Engineering, University of Glasgow, Glasgow, Scotland* JOHN COOPER, *Department of Electrical Engineering, University of Glasgow, Glasgow, Scotland* GIANCARLO RUOCCO, *INFM-CNR Dipartimento di Fisica, Universita' di Roma ''La Sapienza,'' Roma, Italy* MILES PADGETT, *Department of Physics and Astronomy, University of Glasgow, Glasgow, Scotland* We show how holographic optical trapping can be used for the multi-point measurement of fluid flow in microscopic geometries. An array of microprobes can be simultaneously trapped and used to map out the fluid flow in a microfluidic device. The optical traps are alternately turned on and off such that the probe particles are displaced by the flow of the surrounding fluid and then re-trapped. The particles' displacements are monitored by digital video microscopy and directly converted into velocity field values. The validity of the technique is demonstrated for the case of the flow around a spinning sphere and the flow at the outlet of a micro-channel.

**P21 2 A Hybrid Microwave Source and Irradiator for Biological Lab On a Chip Applications.** DAVID ISSADORE, *Harvard University, Department of Engineering and Applied Sciences* TOM HUNT, KRISTI ADAMSON, *Harvard University, Physics* ROBERT WESTERVELT, *Harvard University, Department of Engineering and Applied Sciences* RICK ROGERS, *Harvard Medical School* Using a standard lithographic process, we have built a hybrid microwave irradiator for use in microwave enhanced chemistry and localized, rapid heating. The device combines a 100mW microwave source with a near field antenna to produce an entirely on-chip system for delivering microwave energy into a thin( $< 100\mu$m) layer above a substrate. The antenna utilizes a serpentine wire pattern to produce a thin layer of intense microwave electromagnetic field intensity that falls off exponentially in distance away from the substrate. The device, including RF electronics, was built on a standard 1'' by 3'' glass slide, and several antenna pixel sizes are tested for Biological Lab On a Chip Applications. This work is made possible by the NSEC NSF grant PHY-0117795.

**P21 3 Simulations of Contact Line Motion in Partially Miscible Fluids** SHENGFENG CHENG, *Dept of Physics and Astronomy, The Johns Hopkins University, Baltimore, MD 21218, USA* COLIN DENNISTON, *Dept of Applied Mathematics, The University of Western Ontario, London, Ontario, Canada N6A 5B8* MARK ROBBINS, *Dept of Physics and Astronomy, The Johns Hopkins University, Baltimore, MD 21218, USA* We report on extensive molecular-dynamics simulations of contact line motion in partially miscible fluids confined between two solid walls and sheared in a Couette geometry. Our results show that diffusion alone cannot remove the stress singularities at the contact line or lead to no-slip boundary conditions on the fluid velocity. Computed velocity fields show that there is a substantial drop of the fluid velocity near the contact line, which is associated with the gradient of the fluid-solid interfacial tension in the same region. However, the fluid velocity does not fall to zero at the contact line, in contrast to the case where fluids are immiscible. The nonzero velocity leads to a net advective flux across the fluid-fluid interface, which is balanced by the diffusive flux induced by the concentration gradient. The advective and diffusive fluxes across the interface are only significant in the very first layer of fluid atoms.

**P21 4 Macromolecular Liquids Slip Over Solid Surfaces: Experimental Studies of the Slip Length*** KARIN JACOBS, RENATE FETZER, *Saarland University, Dept. of Experimental Physics, 66041 Saarbruecken, Germany* We present a novel method to asses the slip length and viscosity of thin films of highly viscous Newtonian liquids. We quantitatively analyze dewetting fronts of low molecular weight polystyrene melts on Octadecyl- (OTS) and Dodecyltrichlorosilane (DTS) polymer brushes [1]. Using a thin film (lubrication) model derived in the limit of large slip lengths, we can extract slip length and viscosity of films with thicknesses between 50 nm and 230 nm and temperatures above the glass transition. We find slip lengths from 100 nm up to 1 micron on OTS and between 300 nm and 10 microns on DTS covered silicon wafers. The slip length decreases with temperature. The obtained values for the viscosity are consistent with independent measurements [2]. [1] R. Fetzer, K. Jacobs, A. Muench, B. Wagner, T.P. Witelski, Phys. Rev. Lett. 95, 127801 (2005) [2] R. **P21 5 Source of Shear Dependent Slip at Liquid/Solid Interfaces** NIKOLAI PRIEZJEV,* *Michigan State University* SANDRA TROIAN,† *Princeton University* Slippage at liquid/solid interfaces can strongly influence transport behavior in micro- and nanoscale systems. Previous molecular dynamics (MD) studies of simple and polymeric fluids subject to planar shear at small Reynolds number have shown that the slip length increases as a power law in the shear rate for moderate to high values. The corresponding boundary condition provides a new generalization of the Navier slip law. In this talk, we examine what physical mechanism is responsible for the shear rate exponent by focusing on the collision events between the fluid particles in the first layer and the adjacent wall particles comprising a crystalline surface. By examining the interfacial frictional force as a function of the fluid sliding velocity, we recover similar behavior as inherent in the generalized slip condition and determine that the dominant frictional response stems from the repulsive part of the Lennard-Jones interaction potential. A reduced kinetic model describing the scattering of a single molecule with a given slip velocity along a crystalline surface helps explain the saturation in the frictional force at large sliding velocities. These results elucidate how different is the slip behavior at liquid/solid interfaces from that observed in rarefied gases.

**P21 6 Apparent Slip at Hydrophilic Surface: Flow Profile within 1 nm from the Surface** SUNG CHUL BAE, STEPHEN ANTHONY, STEVE GRANICK, *Departments of Materials Science and Engineering, of Chemistry, of Physcis, University of Illinois* Fluid dynamics within small channels draws great interest due to the development of microfluidic devices, yet details about flow immediately at a solid surface remain too vague. Here, by using fluorescence energy transfer (FRET and fluorescence quenching) approaches, we measured the flow rate of fluorescence quencher molecules within 1 nm from the quartz surface within a specially-designed microfluidic device. In parallel, we have simulated the flow dynamics at the surface, in order to separate cleanly the actual near-surface velocity from the confounding effects of near-surface diffusion.

**12:27**

**P21 7 Slip versus Friction : Modifying the Navier condition** EVANGELOS KOTSALIS, *ETHZ* JENS WALTHER, *ETHZ & TU Denmark* PETROS KOUMOUTSAKOS, *ETHZ* The modeling of fluid-solid interfaces remains one of the key challenges in fluid mechanics. The prevailing model, attributed to Navier, defines the fluid ''slip'' velocity as proportional to the wall shear and a parameter defined as the slip length. Several works have in turn proposed models for this slip length but no universal model for the slip velocity has been accepted. We present results from large scale molecular dynamics simulations of canonical flow problems, indicating, that the inadequacy of this classic model, stems from not properly accounting for the pressure field. We propose and validate a new model, based on the fundamental observation that the finite ''slip'' velocity is a result of an imbalance between fluid and solid intermolecular forces. An excess force on the fluid elements will lead to their acceleration which in turn may result in a slip velocity at the interface. We formulate the slip velocity in terms of fluid-solid friction $F_f$ and propose a generalized boundary condition: $F_f = F_s + F_p = \lambda_u u_s + \lambda_p p$ where p denotes the pressure, and $\lambda_u$and $\lambda_p$ the viscous and static friction coefficients, for which universal constants are presented. We demonstrate that the present model can overcome difficulties encountered by the classical slip model in canonical flow configurations.

**P21 8 Slip and Air-Entrainment at Water-Solid Interfaces** YINGXI ELAINE ZHU, PRASAD SARANGAPANI, *Department of Chemical and Biomolecular Engineering, Univerisity of Notre Dame* ASHIS MUKHOPADHYAY, *Wayne State University* A number of recent studies performed with water flow past hydrophobic microchannels have reported the existence of 'slip' at wall and suggested the existence of the interfacial gas layer as the underlying mechanism for the slip motion, yet the details are much disputed. We combine microscopy and advanced laser spectroscopy to directly and non-invasively detect the interfacial gas layer in flowing water past micro/nano-channels whose surface chemistry and gap spacing are varied. We observe that the dimension of the gas layer strongly depends on surface hydrophobicity and flow rates. Surprisingly, we have also observed the slip motion of water over hydrophilic surfaces with a strong dependence on liquid-loading conditions. We propose a mechanistic theory about air-entrainment that can account for our observations to elucidate the origin of the gas formation at water-solid interface and its consequence on slip motion.

**P21 9 Rheology of sub-nanometer thick water films** TAI-DE LI, ROBERT SZOSZKIEWICZ, ELISA RIEDO, SCHOOL OF PHYSICS, GEORGIA INSTITUTE OF TECHNOLOGY TEAM, Knowing the behavior of water in small volumes is essential for the understanding of many processes in biology, tribology, and geophysics. Water under nano-confinement plays a crucial role in biological and technological systems. Here, we report an experiment in which an atomic force microscope tip approaches a flat solid surface in purified water, while small lateral oscillations are applied to the tip. The normal and lateral forces acting on the tip

are measured directly and simultaneously as a function of water thickness. We find that, for hydrophilic surfaces, oscillatory solvation forces are present in the last four adjacent water layers where the dynamic viscosity is measured to grow up orders of magnitude in respect to bulk water. The same effects are present for atomically smooth surfaces and slightly rough surfaces. Oscillatory solvation forces have been detected also when the confining flat surface was hydrophobic.

**P21 10 Wetting morphologies on surfaces nanopatterned with chemical stripes*** ANTONIO CHECCO, OLEG GANG, BENJAMIN M. OCKO, *Condensed Matter Physics and Materials Science Dept. Brookhaven Natl. Laboratory* SOFT MATTER GROUP TEAM, Here we investigate the wetting of simple, volatile liquids on model chemical nanopatterns created using Local Oxidation Nanolithography. This technique makes use of a biased, metallic AFM tip to locally oxidize the methyl-terminations of a self-assembled monolayer (octadecylthrichlorosilane) into carboxylic acid termination[1]. With this method we have realized parallel, 50 to 500 nm wide, wettable stripes (carboxylic) embedded into a non-wettable (methyl) surface. Several organic (polar, non-polar), volatile liquids have been condensed onto the nanopatterned surface and the resulting wetting morphologies have been studied in-situ by using an environmental AFM. Initially the liquid only condenses on the wettable stripes to form a thin liquid film. Close to saturation the liquid morphology becomes drop-like. Eventually, when more and more liquid is condensed on the stripes, the liquid drops may ''spill over'' into the non-wettable spacer so that neighboring lines merge and undergo a ''morphological wetting transition.'' For all of these regimes we show that long-range forces are relevant to nanoliquid ''shape.'' Results will be compared with those of Density Functional Theory.[1] R. Maoz, S. Cohen, and J. Sagiv, Adv. Mater. **11**, 55 (1999)

**P21 11 Self-propelled film-boiling liquids** HEINER LINKE, MICHAEL TAORMINA, BENJAMIN ALEMAN, LAURA MELLING, COREY DOW-HYGELUND, RICHARD TAYLOR, *University of Oregon* MATTHEW FRANCIS, *University of Sydney* We report that liquids perform self-propelled motion when they are placed in contact with hot surfaces with asymmetric (ratchet-like) topology. Millimeter-sized droplets or slugs accelerate at rates up to 0.1 g and reach terminal velocities of several cm/s, sustained over distances up to a meter. The pumping effect is observed when the liquid is in the film-boiling regime, for many liquids and over a wide temperature range. We propose that liquid motion is driven by a viscous force exerted by vapor flow between the solid and the liquid. This heat-driven pumping mechanism may be of interest in cooling applications, eliminating the need for an additional power source.

**13:27**

**P21 12 Ratcheting motion of capsules on tailored substrates** ANNA C. BALAZS, KURT A. SMITH, ALEXANDER ALEXEEV, ROLF VERBERG, *University of Pittsburgh* We study the motion of microcapsules on attractive surfaces. The capsules, modeled as fluid-filled elastic shells, represent polymeric microcapsules or biological cells. Certain periodic surface patterns give rise to directed capsule motion for a symmetric energy input, such as an oscillatory shear flow. We use a numerical model which integrates a lattice spring representation of the capsule shell and the substrate with a lattice Boltzmann representation for the fluid regions. We consider, as a surface pattern, a series of asymmetric ramps. The minimum shear necessary to drive a capsule ''forward'' over one ramp is less than that needed to drive the capsule ''backward'' over a ramp. We show under what conditions it is possible to move the capsule forward, in a ratcheting motion, via an imposed oscillatory flow. These patterned surfaces could be used to control capsule motion precisely, based on flow and surface properties. They coud also be used to efficiently sort capsules based on their size or material properties.

**P21 13 Electrowetting for Digital Microfluidics** TOM HUNT, KRISTI ADAMSON, *Harvard Physics* DAVID ISSADORE, ROBERT WESTERVELT, *Harvard Division of Engineering and Applied Science* Droplet based chemistry promises to greatly impact biomedical research, providing new avenues for high throughput, low volume assays such as drug screening. Electrowetting on Dielectric (EWOD) is an excellent technique for manipulating microscopic drops of liquid. EWOD uses buried electrodes to locally change the surface energy between a droplet and a substrate. We present microfabricated devices for moving droplets with EWOD. One example of such a device consists of a series of 16 interdigitated electrodes, decreasing in size from 1mm to 20 microns. Each electrode is addressable by an independent, computer controlled, high voltage supply. This work made possible by a gift from Phillip Morris and the NSEC NSF grant PHY-0117795.

**13:51**

**P21 14 Surface mediated liquid transport on nanotube** MIN-FENG YU, *Univ. of Illinois at Urbana-Champaign* KYUNGSUK YUM, The surface mediated liquid transport on nanotubes was studied using a nanotube-based liquid transport system. Micros-cale liquid droplets were formed and transferred to nanotubes using the liquid transport system integrated with a nano-manipulator. If the spreading parameter $S$ is larger than a threshold value $S_c$, the liquid spontaneously flows out of the liquid droplet through a thin precursor film formed along the nanotube surface. The liquid transport on nanotube surfaces was studied itin situ by measuring the volume flow rate which was obtained from a direct observation of the droplet. The flow rate dependence on the size of nanotubes and surface energy were also investigated. The surface mediated liquid transport phenomenon can be exploited for the development of nanoscale liquid transport system for nanofabrication and nanoscale devices for biological and chemical applications. **P22 1 Disorder, itinerant ferromagnetism and the anomalous Hall effect in two dimensions** PARTHA MITRA, ARTHUR HEBARD, *Department of Physics University of Florida* This talk will describe research motivated by the lack of consensus on what happens in a band ferromagnet such as iron when the itinerancy of the electrons, which carry spin information, is compromised by disorder. We address this challenging problem by performing itin situ studies of magnetotransport in a series of films having sheet resistances varying from 50 to 1,000,000 Ohms. In the weakly disordered regime of this two-dimensional system, where the quantum corrections to the conductivity have logarithmic temperature dependence, we find a surprising scaling of the longitudinal and anomalous Hall (transverse) resistances. For higher disorder the scaling breaks down and the anomalous Hall resistance $R_{xy}$ saturates at a constant value near 100 Ohms. These results imply the presence of an itanomalous Hall insulating state where the longitudinal $L_{xx}$ and transverse $L_{xy}$ conductivities approach zero with a ratio $R_{xy} = L_{xy}/L_{xx}^2$ that remains constant.

**11:27**
**P22 2 Theory of Anomalous Hall Effect in Ferromagnets** SHIGEKI ONODA, *Spin Superstructure Project, ERATO, Japan Science and Technology Agency* NAOYUKI SUGIMOTO, NAOTO NAGAOSA, *Department of Applied Physics, University of Tokyo* Mechanism of the anomalous Hall effect (AHE) in ferromagnetic metals has been controversial over many decades. Karplus-Luttinger initiated the discussion by focusing on the intrinsic thermodynamic Hall current produced by the band structure with a spin-orbit interaction. Later, it was argued that instead, scattering by impurity or disorder together with the spin-orbit interaction distorts the electron motion as the skew scattering or the side jump and these extrinsic contributions dominate over the Hall current. Here, we reexamine this issue by fully taking account of both the impurity scattering and the anomalous velocity in terms of the quantum transport theory. We demonstrate that apart from the conventional nonequilibrium transport current, an equilibrium Hall current flows even in the presence of dissipation in metals. This equilibrium Hall current contains the intrinsic one which has a topological non-perturbative nature associated with degeneracy of the band dispersions in the momentum space. We also show that there appears a crossover from the extrinsic regime to the intrinsic as the electron damping rate becomes comparable to or larger than the energy scale of the spin-orbit coupling. This resolves the long standing puzzle on the mechanism and reveals a new small energy scale governing the quantum transport in multiband systems.

**11:39**
**P22 3 Quantum correction to the anomalous Hall conductivity of ferromagnetic metallic films** KHANDKER MUTTALIB, *University of Florida* PETER WOELFLE, *University of Karlsruhe, Germany* Motivated by new anomalous Hall effect (AHE) data on polycrystalline Fe films we calculate the interaction correction to the AHE for both the skew scattering and the side jump mechanisms. The correction to the longitudinal conductivity is also considered. We use a model of randomly located short range impurity potentials of arbitrary scattering strength, inducing spin-orbit scattering, and an isotropic band ferromagnet. The quantum correction is found to depend sensitively on the strengths of the scattering potential and the spin-orbit interaction. In the limit of weak scattering, known results are recovered.

**11:51**
**P22 4 Spin Hall effects in diffusive normal metals.** ROMAN SHCHELUSHKIN, ARNE BRATAAS, We study transport in normal metals in an external magnetic field. We employ the Keldysh formalism to find transport equations in the presence of the spin-orbit interaction, interaction with magnetic impurities, and nonmagnetic impurity scattering. This system exhibits an interplay between a transverse spin imbalance (spin Hall effect) caused by the spin-orbit interaction, a Hall effect via the Lorentz force, and spin precession due to the Zeeman effect. The spin and charge accumulations are computed numerically in experimentally relevant thin film geometries. The out-of-plane spin Hall potential is suppressed when the Larmor frequency is larger than the spin-flip scattering rate. The in-plane spin Hall potential vanishes at a zero magnetic field and attains its maximum at a finite magnetic field before spin precession starts to dominate. Spin injection via ferromagnetic contacts creates a transverse charge Hall effect that decays in a finite magnetic field due to spin precession.

**P22 5 Resistance and Scattering Anisotropy of Al Interfaces with Co, Fe, and Co(91)Fe(9).*** NIKOLETA THEODOROPOULOU, THIBAULT HAILLARD, AMIT SHARMA, REZA LOLOEE, WILLIAM PRATT JR., JACK BASS, *Dept. of Physics and Astronomy, Michigan State University* The properties of normal/ferromagnetic metal interfaces, described by the interface specific resistance, AR* (A = area, R = resistance) and spin scattering anisotropy, $\gamma$, are of both fundamental interest and practical interest for optimizing current-perpendicular-to-plane (CPP) magnetoresistance (MR) and current-induced magnetization-switching (CIMS) in nanopillars. From measurements of the CPP resistances and MRs of sputtered [Al/F]x$N$ (F= Fe, Co, Co(91)Fe(9)) multilayers with $N$-bilayers, and Al/F-based exchange-biased spin-valves, we are able to estimate 2AR* and $\gamma$ for each metal pair at 4.2K. In each case, 2AR* is large and $\gamma$ is small, comparable to values of 2AR* $\sim$ 9 f$\Omega$m$^2$ and $\gamma \sim 0.03$ for Permalloy (Py)/Al interfaces [1], and each differing by an order of magnitude from the parameters for well-studied Co/Cu and Py/Cu interfaces (2AR* $\sim$ 1 f$\Omega$m$^2$, $\gamma \sim 0.8$). The values of AR* with Al are too large to be explained by the resistivities of alloyed Al/F interfaces. The similarity of results for Py, Fe, Co, and Co(91)Fe(9) strongly suggests that spin dependent scattering at Al/F interfaces is determined mainly by the properties of Al. [1] N. Theodoropoulou et al., J. Appl. Phys. (In Press, 2006).

**12:15**

**P22 6 Current-Perpendicular-to-Plane (CPP) Resistance of Cu/Al Interfaces*** AMIT SHARMA, NIKOLETA THEODOROPOULOU, REZA LOLOEE, WILLIAM PRATT JR., JACK BASS, *Department of Physics, Michigan State University, East Lansing, MI 48824* . The recent discovery [1] that the current-perpendicular-to-plane (CPP) interface specific resistance (area A times resistance R) of Py/Al (Py = Permalloy = Ni(84)Fe(16)) is almost 10 times larger than that of Py/Cu, led us to examine also the resistances and magnetoresistances of Py/Cu/Al/Cu/Py exchange-biased spin-valves (EBSV) and [Cu/Al]x*N* multilayers with *N* repeats. Using two different techniques, we estimate the interface specific resistance of sputtered Al/Cu interfaces as $2AR(Al/Cu) \sim 2$ f-ohm-$m^2$ at 4.2K. However, some of the data from these two techniques, as well as from the Cu/Al/Cu EBSV studies, show unusual behaviors that suggest that the Cu and Al atoms might not always stay where they are deposited. We will describe our CPP-resistance results, and plan to supplement them with x-ray and cross-sectional TEM studies. [1] N. Theodoropoulou et al., J. Appl. Phys. (In Press, 2006).

**P22 7 Spin transport and spin-flip scattering in magnetic multilayer structures.***
SAMIR GARZON, *University of South Carolina Nanocenter*

The existence of spin-flip scattering at the interface between ferromagnetic (F) and nonmagnetic (N) layers of magnetoresistive F/N/F structures can significantly reduce the size of the magnetoresistance, limiting the sensitivity and increasing the power consumption of F/N/F devices such as GMR magnetic field sensors, magnetic read heads, and MRAM's [1]. Detecting and measuring the degree of spin flip scattering in F/N/F structures can allow further optimization in such devices as well as increase the understanding of interfacial spin transport. Our nonlocal spin injection and detection experiments on mesoscopic Co-$Al_2O_3$-Cu-$Al_2O_3$-Co spin valves provide evidence for the existence of interfacial spin-flip scattering in magnetoresistive devices [2]. By extending the conventional picture of spin-dependent interfacial resistances ($R_\uparrow$, $R_\downarrow$) to include two additional spin-flip scattering channels ($R_{\uparrow\downarrow}$,$R_{\downarrow\uparrow}$) [3] we have shown that the nonlocal resistance contains information about both the degree of spin polarization and the degree of spin-flip scattering at the F/N interface. The magnitudes of $R_{\uparrow\downarrow}$ and $R_{\downarrow\uparrow}$ depend on the relative orientation of the detector magnetization and the nonequilibrium magnetization in the normal metal. We have observed that the difference in spin-flip scattering between up and down channels vanishes at low temperatures, but for T$>$ 100K it increases nonlinearly with temperature. Further evidence for the presence of interfacial spin-flip scattering can be obtained from noise measurements, which are extremely sensitive to the microscopic transport details. **P22 8 Measurement of spin-diffusion length in sputtered Ni films*** CHARLES MOREAU, *Albion College* WILLIAM PRATT, *Michigan State University* NORMAN BIRGE, *Michigan State University* The spin-diffusion length of the electron represents a fundamental transport parameter and plays a central role in the development of spintronic devices. While several measurements of the spin-diffusion length in normal metals and in ferromagnetic alloys exist, measurements in elemental ferromagnets (Ni, Fe, Co) have been scarce. We present a novel sample geometry using giant magnetoresistance (GMR) for the measurement of the spin-diffusion length in elemental ferromagnets with weak scattering asymmetry. We report the first measurement of the spin-diffusion length of Ni using an exchanged-biased Permalloy-based spin-valve, Py/Ni/Cu/Py, where the Ni layer acts as a GMR spoiler layer when its thickness becomes greater than the spin-diffusion length in Ni.

**P22 9 Magneto-transport in $Fe_3O_4$/Nb:$SrTiO_3$ schottky junction diode** DARSHAN KUNDALIYA, S.B. OGALE, J. HIGGINS, T. VENKATESAN, *Center for Superconductivity Research, University of Maryland, College Park, MD-20742* L.F. FU, N.D. BROWNING, *LBNL, NCEM, One Cyclotron Road, Berkeley, CA-94720* Among the half metallic ferromagnets, $Fe_3O_4$ is of particular interest because of its half metallicity, high curie temperature and a charge ordering transition at 120K (popularly known as Verwey transition ($T_V$)). These materials are also expected to show 100% spin polarization. In view of these fascinating properties, we studied temperature dependent transport, magnetic, structural and interface characteristics of epitaxial schottky junctions between $Fe_3O_4$ and Nb:$SrTiO_3$ (with different Nb concentrations). Epitaxial thin films of $Fe_3O_4$ were grown on Nb:$SrTiO_3$ substrates by PLD technique. The films show epitaxial growth along (100)-axis direction. We also performed HR-TEM and EELS study to ensure a better quality interface. In the temperature range above $T_V$, 300K-130K, the I-V characteristic shifts towards higher forward bias voltage upon lowering temperature. On further decreasing temperature (below $T_V$), the trend is reversed. Junction parameters such as the Schottky barrier height (it $\phi_B$) and ideality factor (it $\eta$) are extracted using thermionic emis-

sion theory at all temperatures. These parameters show interesting and systematic trends above and below $T_V$. From the magnetic field dependence of non linear I-V characteristics data, a spin polarization of $\sim$ 80% is estimated for the magnetite electrode at $T_V$.

**P22 10 Spin filtering of hot electrons in ferromagnetic layers** DRISS LAMINE, *Laboratoire de Physique de la matière condensée, UMR 7643-CNRS, Ecole Polytechnique. 91128 Palaiseau Cedex, France* NICOLAS ROUGEMAILLE, *Lawrence Berkeley National Laboratory, 1 Cyclotron Road MS/72, Berkeley, CA 94720, USA* GEORGES LAMPEL, YVES LASSAILLY, JACQUES PERETTI, *Laboratoire de Physique de la matière condensée, UMR 7643-CNRS, Ecole Polytechnique. 91128 Palaiseau Cedex, France* We present a spin dependent transport experiment where spin polarized electrons, injected from vacuum, are spin-filtered when entering into a thin ferromagnetic layer. The role of the interface between this spin-filter layer and the ''current collector'' is analysed. In a first geometry, the ''current collector'' is a semiconductor and the transmitted current is measured through a Fe/Oxide/GaAs diode. In that case, the measured electrons are selected at the interface, at an energy higher than the Schottky barrier. In a second geometry, the spin filter is a self standing thin layer Au/Co/Au and the ''current collector'' is a faraday cup. In that case, only electrons that overcome the vacuum energy level of the gold are measured. In both cases, the spin dependent part of the collected current is measured when the ferromagnetic layer is reversed. We have found an energy domain where both the collected current and its spin dependence increase over orders of magnitude. The role of the interface in the spin-dependent transport is discussed and a spin dependent transport model is presented.

**P22 11 Mesoscopic Conductance Fluctuations in Cobalt Nanoparticles** YAGUANG WEI, XIYA LIU, LIYUAN ZHANG, DRAGOMIR DAVIDOVIC, *Georgia Institute of technology* SCHOOL OF PHYSICS, GEORGIA INSTITUTE OF TECHNOLOGY TEAM, We present measurements of mesoscopic conductance fluctuations in Cobalt particles of diameter 200nm. Samples are made by e-beam lithography and shadow metal deposition. Co particles are not single domain; domain walls are nucleated at the contacts between Co and Cu-reservoirs. We obtain the dependence of peaks in differential resistance with the applied voltage and the magnetic field during the magnetization reversal process at 0.03K temperature. The conductance fluctuations with the magnetic field are caused by a mechanism different from the usual Aharonov-ohm effect. In particular, domain walls are found to generate significant mesoscopic fluctuations. We obtain that electron transfer across the domain wall is associated with a phase change of about $5\pi$. We explain how this phase-shift arises from a not perfectly parallel spin-transport across domain walls. The dephasing time is very short, $\tau_\phi \sim ps$. Fast dephasing is correlated with the strong magnetocrystalline anisotropy in Co. This work was performed in part at the Georgia-Tech electron microscopy facility. We thank P. Brouwer for valuable discussions. This research is supported by the David and Lucile Packard Foundation grant 2000-13874 and Nanoscience/Nanoengineering Research Program at Georgia-Tech.

**P22 12 Spin transport through atomic scale chromium Coulomb islands*** MARC VAN VEENHUIZEN, JAGADEESH MOODERA, *Massachusetts Institute of Technology* Electrical current through metallic islands coupled via tunnel barriers to external leads is governed by the Coulomb repulsion and can be brought down to single electron transport. The spin-degeneracy of the electrons can be lifted by choosing both the leads and the islands to be magnetic. The combination of spin-splitting and Coulomb blockade creates a device geometry capable of resonant tunneling of a single spin-direction only. Maximum effect can be obtained by minimization of the size of the Coulomb islands in order to suppress spin-relaxation. We report on our efforts to make a spin-resonant tunneling device using atomic size clusters of chromium atoms, submerged in an alumina-barrier in a conventional magnetic tunnel junction set-up. The $300x300\ \mu m^2$ size magnetic tunnel junction consists of a cobalt bottom electrode, an aluminum-oxide tunnel barrier, a delta-doping layer of chromium in the range of $1 - 6$ Å, an alumina tunnel barrier, and a permalloy top-electrode. Transport measurements reveal Coulomb blockade behavior.

**P22 13 Orbital nature of spin magnetic moment** CHIH-PIAO CHUU, *University of Texas* MING-CHE CHANG, *University of Texas* QIAN NIU, *University of Texas* In view of the application of spintronics, it is important to understand the physical observable of the spin, i.e. its magnetic moment. We show by constructing a wave-packet in the upper bands of the Dirac equation that the spin magnetic moment (Bohr magneton) is a direct result of the self-rotation in the wave-packet. In this sense, an non-relativistic electron is really a rotating charged object, confirming the original speculation on the physical nature of the electron spin. In a Bloch band of a crystal, a wave-packet can acquire additional self-rotating orbital angular momentum, giving rise to a change of the spin magnetic moment and causing a modification of the g-factor from 2.

**P23 1 Thermal transport of dimerized and frustrated spin-1/2 chains*** FABIAN HEIDRICH-MEISNER, *Department of Physics and Astronomy, The University of Tennessee, Knoxville, and Condensed Matter Sciences Division, Oak Ridge National Laboratory* ANDREAS HONECKER, WOLFRAM BRENIG, *Institut für Theoretische Physik, Technische Universität Carolo-Wilhelmina zu Braunschweig, Germany* We present a numerical study of thermal transport in dimerized and frustrated spin-1/2 chains at finite temperatures. Since these models are nonintegrable, the thermal Drude weight scales to zero in the thermodynamic limit. The conductivity at finite frequencies, however, is non-zero and we discuss the scaling with system size as well as the extrapolation to the zero-frequency limit. Results for three cases are presented. First,

the dimerized chain is studied in the limit of weakly coupled dimers. In this case, interactions of the elementary triplet excitations are weak, which should allow for an analytical description based on a bond-boson operator representation. Second, we compare the thermal conductivity of the frustrated chain in the massless and the massive regime of this model. Finally, we extract the zero-frequency thermal conductivity of the isotropic two-leg spin ladder and discuss implications for the interpretation of recent experiments for $La_5Ca_9Cu_{24}O_{41}$.

**P23 2 A systematic method for constructing a spin-singlet basis for quantum antiferromagnets*** VLADIMIR GRITSEV, *Department of Physics, Harvard University* JULIEN SUDAN, DIONYS BAERISWYL, *Department of Physics, University of Fribourg, Switzerland* We present a new method for constructing a complete orthonormal basis for the singlet states of quantum spin-1/2 lattice systems. Our approach can be used for any dimension and an arbitrary lattice symmetry. In this talk the main group- and graph-theoretical steps are explained. The general theory is then applied to the one-dimensional quantum antiferromagnet. Exploiting the symmetries of closed rings, we can drastically reduce the number of basis states for the different eigenstates of the Hamiltonian (in the singlet sector). The method allows to calculate in an efficient way expectation values of any operator.

**P23 4 Comparison of Magnetic Field-Modified Electronic Excitations in Ni(II) Compounds** VIRGINIA LONG, E.C. SCHUNDLER, P.O. MAKUMBE, *Colby College, Waterville ME* X. WEI, *NHMFL, Tallahassee, FL* B.R. LANDRY, K.R. MAXCY, M.M. TURNBULL, C.P. LANDEE, *Clark University, Worcester MA* NTDN ($Ni[tn]_2[NO_2]_2$) can be considered a paramagnetic analog material to the Haldane compounds NENP and NENB ($Ni[en]_2NO_2ClO_4$ and $Ni[en]_2NO_2BF_4$; where en = $C_2N_2H_8$ and tn = $C_2N_3H_10$). Except for the different bonding of one $NO_2$ group and the absence or presence of spin chains, NTDN and the Haldane compounds have nearly identical electronic coordination around the $Ni^{2+}$ ions. Here, we report and compare the magnetic field ($H$)-dependent polarized optical transmittance of the three materials in the range 9,000 to 22,000 $cm^{-1}$. The $H$ dependence is manifest in the varying intensities of certain electronic absorptions with applied field. Although all three materials possess similar $H$- sensitive excitations, the details of the $H$ dependence differ with the magnetic ground states. In NTDN, the intensity changes commence at $H = 0$ and saturate at $\approx$ 10 T, whereas in the Haldane compounds, the onset of changes is at the gap- closing critical field, $H_C$, above which the intensity is linearly modified with field. The mechanism of the $H$- dependence is yet to be clarified and probably depends on the nature of the electronic excitation. Intensity variations with applied field are observed in both $Ni^{2+}$-to-$NO_2^-$ charge transfer transitions and $Ni^{2+}$ $d - d$ spin forbidden excitations.

**P23 5 Magnetic Chains Assembled with Atomic Precision** CYRUS F. HIRJIBEHEDIN, CHRISTOPHER P. LUTZ, ANDREAS J. HEINRICH, *IBM Research Division, Almaden Research Center* We report the first study of small magnetic chains constructed and studied itin-situ with atomic precision. By positioning Mn atoms one at a time with an STM, we are able to follow the low energy excitation spectrum of the chain as it changes dramatically with length. The low energy spectra of chains built from an odd number of atoms display a spin-flip excitation similar to that of a single Mn atom. In even-length chains the spin flip excitation is absent and is replaced by an excitation at higher energies that splits into three distinct modes in a magnetic field. We interpret these results as direct evidence of the antiferromagnetic coupling of the individual atomic spins. Quantitative comparison of our results with the Heisenberg model allows us to directly obtain the coupling strength J$\sim$ 6meV between atomic spins and suggests that the total spin of the individual Mn atoms on the surface is 5/2.

**12:15**

**P23 6 Resonant Quantum Tunneling of spin chains in 3D-magnetically ordered CoTAC** CARLEY PAULSEN, *CRTBT-CNRS Grenoble, France* ELSA LHOTEL, *CRTBT-CNRS Grenoble, France* EUGENE KHAYSKO, *National Academy of Sciences of Ukraine* CoTAC is a well know molecular spin chain system which orders in an antiferromagnetic canted state at $4.15K$. We show that, below $300mK$, the dynamics of the magnetization in the $c$-direction are governed by resonant quantum tunneling of the magnetization. This conclusion is based on a number of experimental observations: the temperature independence of the relaxation of the magnetization, speeding up of the relaxation at a well defined magnetic field value ($1025Oe$) and the increase of the magnetization each time this field is crossed during a succession of minor loops. The key to understanding this behavior could be the absence of resonance in zero field. We propose a mechanism to describe this behavior using a simple model of domain wall nucleation which explains many of the unusual experimental observations.

**P23 7 Extended Valence-Bond Solid Picture for Quasi-One-Dimensional Quantum Magnets** MUNEHISA MATSUMOTO, Ground-state gapped phases of quasi-one-dimensional quantum magnets are given an comprehensive interpretation based on an extended valence-bond solid (VBS) picture. We introduce composite spins with the enlarged spin magnitude in the ground state and regard the system as an effective single spin chain that consists of composite spins. The relevance of the composite spins in the ground state is revealed by the effects of dimerization in the spin-spin couplings. In order to characterize the gapped phases, we inspect the configuration of valence bonds by calculating the appropriate order parameters by the quantum Monte Carlo method

with the continuous-time loop algorithm. The so-called short-range resonating-valence bond solid state is identified to be an extended VBS state. Dimensional crossover to the two-dimensional systems is also discussed.

**12:39**

**P23 8 Luttinger sum rules in the 2-channel spin 1 Kondo chain** IAN McCULLOCH, *Institut fur Theoretische Physik C, RWTH-Aachen* We present numerical results, using the DMRG method, for the zero-temperature phase diagram of the one-dimensional 2-channel Kondo lattice model, coupled to $S = 1$ localized spins. Unlike the previously studied 1-channel $S = 1/2$ case, the $S = 1$ localized spins in the 2-channel model permit a gapped Haldane state, which stabilizes the weak-coupling (''small'' Fermi surface) paramagnetic phase. We focus on the paramagnetic region approaching half-filling, where the interesting possibility has been recently raised of a non-trivial crossover region where the Fermi wavenumber varies continuously.

**12:51**

**P23 9 Coupling of Spin and Charge Degrees of Freedom in a Hydrodynamic Two-Fluid Approach** FABIO FRANCHINI, *Stony Brook University* ALEXANDER ABANOV, *Stony Brook University* We use a hydrodynamic approach to study correlated quantum one- dimensional systems. One can derive an effective hydrodynamics in the limit of smooth densities and slow velocities. In the limit when gradients of density and velocity can be neglected, one obtains an integrable system. We discuss the origin of this integrability and, as an application, we calculate some non trivial correlation functions. The Hydrodynamic description is a useful tool to study the dynamics of a system. We introduce a two-fluid hydrodynamic description of one-dimensional spin 1/2 fermions with contact interactions. It is known that linearized hydrodynamics (bosonization) exhibits spin-charge separation. In the full *non-linear* theory, the spin and charge degrees of freedom are coupled to each other, therefore spin waves carry charge as well. We discuss the dynamics of such system.

**13:03**

**P23 10 Coupled one-dimensional magnetic systems: the truncated conformal spectrum approach*** YURY ADAMOV, ROBERT KONIK, ALEXEI TSVELIK, *Brookhaven National Laboratory* We develop a combined analytical/numerical technique in order to understand coupled, possibly strongly, one dimensional magnetic systems. The approach trades on exact knowledge of the underlying one dimensional subsystem and the concomitant ability to compute exactly matrix elements of operators coupling the subsystems together. With these matrix elements in hand, the fully coupled system is first truncated and then diagonalized numerically. In this way we obtain both the spectrum and correlation functions of the system. The truncation can be improved upon through a renormalization group procedure. As a test case we consider coupled quantum Ising chains.

**13:15**

**P23 11 Random antiferromagnetic spin chains with enlarged symmetry** JOSÉ A. HOYOS, EDUARDO MIRANDA, *IFGW, Unicamp, Campinas, SP, Brazil* We present the asympotically exact solution of some random antiferromagnetic spin chains with enlarged symmetry groups. Using a generalization of the strong disorder real space renormalization group method, we considered both the isotropic SU(N) and the anisotropic SU(4) chains with totally antisymmetric irreducible representations. In the first case, the system is governed by a universal infinite-randomness fixed point (IRFP), with activated dynamical scaling between energy ($\Omega$) and length ($L$) scales $\Omega \sim \exp(-L^{\psi})$ (with the tunneling exponent $\psi = 1/N$), and average correlation function decaying as a power law with exponent $\eta = 4/N$. All thermodynamic quantities are universal with exponents depending only on $N$. In the second case, relevant for systems with $SU(2)_{spin} \otimes SU(2)_{orbital}$ symmetry, we determined the full phase diagram as a function of the mean anistropy and its variance. All stable fixed points are of the IRFP variety with activated dynamical scaling. The tunneling exponents span a wide range of values and can even be larger than the SU(2) value, $\psi = 1/2$.

**13:27**

**P23 12 Thermodynamics and magnetization process of the frustrated ferromagnetic spin-1/2 chain** FABIAN HEIDRICH-MEISNER, *Department of Physics and Astronomy, The University of Tennessee and Condensed Matter Sciences Division, Oak Ridge National Laboratory* DANIEL C. CABRA, TEMO VEKUA, *Laboratoire de Physique Théorique, Université Louis Pasteur Strasbourg, France* ANDREAS HONECKER, *Institut für Theoretische Physik, Technische Universität Carolo-Wilhelmina zu Braunschweig, Germany* We report a study of the thermodynamics and magnetization curve of a $J_1$–$J_2$ spin-1/2 chain with a ferromagnetic nearest neighbor coupling $J_1$ and an antiferromagnetic next-nearest neighbor interaction $J_2$. This model has recently been suggested to describe the properties of different compounds such as $LiCuVO_4$ and $Rb_2Cu_2Mo_3O_{12}$. We present results for both the specific heat and the magnetic susceptibility for the whole parameter range of $J_2/4 <| J_1| < 0$ obtained by exact diagonalization of up to $N = 24$ sites. The specific heat exhibits a two-peak structure for $J_1 < 0$, originating from, first, the proximity to a ferromagnetic ground state and, second, antiferromagnetic fluctuations at higher energies. Furthermore, the magnetization process at zero temperature is analyzed by means of the density matrix renormalization group technique. Particular emphasis is given to the presence (or rather absence) of magnetization plateaus and a comparison with other theoretical results for the ground-state phase diagram.

**13:39**

**P23 13 The Magnetic phase diagram of the spin-chain system $Ca_{2+x}Y_{2-x}Cu_5O_{10-\delta}$: Oxygen hole-doping** KEESEONG PARK, *Department of Physics, The University of Texas at Austin* JOHN MARKERT, *Department of Physics, The University of Texas at Austin* Recently, K. Kudo et al.[1] studied the magnetic ground state in the edge-sharing $CuO_2$ chains in the spin- chain system $Ca_{2+x}Y_{2-x}Cu_5O_{10-\delta}$. In that study, the antiferromagnetic transition temperature decreases with increasing $x$ and disappears around $x=1.4$ followed by the appearance of a spin-glass phase at $x=1.5$. We propose that the oxygen content should be included in the hole doping effect by $p = 1/5(x - 2\delta)$ in the spin-chain system. We present x-ray diffraction, magnetic susceptibility, specific heat and iodometric titration measurements[2] which indicate that an oxygen deficiency shifts the magnetic features toward higher $x$. For example, for $x = 1$ samples, the single crystals of Ref.1 are equivalent to our oxygen deficient polycrystalline sample with $\delta \approx 0.5$. Such a composition has an only slightly suppressed Néel temperature, while for nearly fully oxygenated

$x = 1$ samples, the antiferromagnetic transition is completely suppressed.[3]

**P23 14 Low temperature magnetization and the excitation spectrum of antiferromagnetic quantum Heisenberg rings** LARRY ENGELHARDT, MARSHALL LUBAN, *Ames Laboratory and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011* We have performed quantum Monte Carlo calculations to obtain the low temperature magnetization and differential susceptibility for finite, antiferromagnetic Heisenberg rings of intrinsic spins $s = 1/2,1,3/2,2,5/2,3,7/2$. From these data we have determined the level-crossing fields as well as the dependence of the minimal excitation energies on the total spin quantum number $S$. For large intrinsic spins ($s \geq 3/2$) we find that the data exhibit scaling behavior, approaching the classical limit proportional to $s^{-1.05}$. Since this limit is approached so slowly, even $s = 7/2$ spins are distinctly non-classical. We have also found for large $s$ that as the number of spins $N$ increases, the energy gap between the ground state and the first excited state approaches zero proportional to $1/N^{\alpha}$, where $\alpha \approx 0.76$ for $s = 3/2$ and $\alpha \approx 0.84$ for $s = 5/2$. Finally, we demonstrate the usefulness of our results by examining the $Fe_{12}$ molecular ring, leading to a new, more accurate estimate of the exchange constant for this system than has been obtained heretofore.

**14:03**
**P23 15 Magnetic Properties of a Coordination Polymer [$Mn_3$ [$(OH)_2Na_2(3\text{-}cnba)_6$]n** TAN YUEN, CHYAN LONG LIN, *Physics Dept., Temple University* PRINCY VARUGHESE, JING LI, *Dept. of Chemistry & Chemical Biology, Rutgers University* JING-TANG LI, JUN TAO, RONG-BIN HUANG, LAN-SUN ZHENG, *Dept. of Chemistry and State Key Laboratory for Physical Chemistry of Solid Surface, Xiamen University, Xiamen 361005, China* Magnetic properties of [Mn3($OH$)2$Na$2(3 − $cnba$)6]n(3−Hcnba=3−cyanobenzoic acid), a newly discovered three-dimensional coordination polymer, were investigated using magnetic susceptibility M(T)/H and isothermal magnetization M(H). The crystal structure of [Mn3($OH$)2$Na$2(3 − $cnba$)6]n is triclinic with a space group P−1. The lattice parameters area= 6.663Å,b= 12.971Å,c= 14.161Å,$\alpha$ = 70.13[$r$], $\beta$=88.43[r], and $\gamma$=76.47[r]. The results ofM(T) /Hon powder samples show that the effective moment $\mu$ effof Mn2+ is 5.88$\mu$Bat temperatures above 100K, close to the expected value for a free Mn2+ ion. Below 3K, [Mn3($OH$)2$Na$2 (3 − $cnba$)6]n orders antiferromagneticly. A sudden slope change in M(H)measured at is observed at a very small critical field of Hc≈20G, suggesting a metamagnetic transition. Above 20kG, M(H) starts to saturate, reaching a value equivalent to 1.7 $\mu$B per Mn2+ ion. The magnetic behavior of the complex is interpreted in terms of an effective ferrimagnetic Mn(II) chains in which spin moments are linked by interactions in an AF−F−AF(F= ferromagnetic and AF= antiferromagnetic) sequence in the triangular magnetic repeating unit.

**P26 1 NMR Studies of Enzyme Structure and Mechanism.**
ALBERT MILDVAN, *Johns Hopkins U. School of Medicine*

At least three NMR methodologies pioneered by Al Redfield, have greatly benefited enzymology: (1) the suppression of strong water signals without pre-saturation; (2) sequence specific NH/ND exchange; and (3) dynamic studies of mobile loops of proteins. Water suppression has enabled us to identify unusually short, strong H-bonds at the active sites of five enzymes (three isomerases and two esterases), and to measure their lengths from both the chemical shifts and D/H fractionation factors of the deshielded protons involved (J. Mol. Struct. 615, 163 (2002)). Backbone NH exchange studies were used to detect regions of an NTP pyrophosphohydrolase in which NH groups became selectively protected against exchange on Mg(2+) binding, and further protected on product (NMP) binding, thus locating binding sites as well as conformationally linked remote sites (Biochemistry 42, 10140 (2003)). Dynamic studies were used to elucidate the frequency of motion of a flexible loop of GDP-mannose hydrolase (66,000/sec) containing the catalytic base His-124, from exchange broadening of the side chain NH signals of His-124 in the free enzyme. The binding of Mg(2+) and GDP-mannose lock His-124 in position to deprotonate the entering water and complete the reaction.

**11:27**
**P26 2 Interference between relaxation and parameters for protein structure determination.***
EVA DE ALBA, *National Institutes of Health*

The effect of cross-correlated relaxation on scalar and dipolar coupling measurements is analyzed. We compare one-bond proton-carbon scalar and dipolar couplings of protein methine and methylene sites obtained by monitoring proton and

carbon magnetization. Apparent J-coupling constants of the same pair of nuclei vary depending on the type of magnetization involved. The discrepancies are of different magnitude for methine and methylene moieties. Dynamic frequency shifts are partially responsible for the observed differences. More importantly, the largest observed variations can be explained by processes of magnetization transfer originated by cross-correlated relaxation. These later effects are not cancelled when obtaining residual dipolar couplings.

*In collaboration with Nico Tjandra, National Institutes of Health.

**11:39**
**P26 3 Multiple Quantum Relaxation Probes of Protein Dynamics on Multiple Timescales** RANAJEET GHOSE, *City College of New York* Several effects may lead to significant differences between the relaxation rates of zero-quantum coherences (ZQC) and double-quantum coherences (DQC) (collectively known as multiple-quantum coherences) generated between a pair of spin 1/2 nuclei in solution. These include the interference between the anisotropic chemical shifts of the two nuclei participating in formation of the ZQC or DQC, the individual dipolar interactions of each of the two nuclei with the same proton, and the slow modulation of the isotropic chemical shifts of the two nuclei due to conformational exchange. Motional events that occur on a timescale much faster than the rotational correlation time (picosecond-nanosecond) influence the first two effects, while the third results from processes that occur on a far slower timescale (microsecond-millisecond). An analysis of the differential relaxation of ZQC and DQC is thus informative about dynamics on the fast as well as the slow timescales. We present here a set of NMR experiments that measure the differential relaxation of ZQC and DQC involving several backbone and sidechain nuclei in proteins. These measurements provide significant insight into the complex dynamic modes that exist in the protein backbone and sidechains. A detailed understanding of these dynamic modes may provide clues into the role of dynamics in modulating protein function.

**P26 4 A Plastic Explosive-Degrading Enzyme.***
ANNE-FRANCES MILLER, *University of Kentucky*

The enzyme nitroreductase catalyzes reduction of high explosives such as TNT and RDX. Although a well-resolved $^{1}H^{15}N$-HSQC is obtained at 37 °C, the HSQC at 4 °C is concentrated between 7.5 and 8.5 ppm and is comprised of sharp overlapped peaks. Thus, it appears that the protein denatures upon cooling. However, the non-covalently-bound FMN cofactor is not released at the lower temperature. Similarly, ultra-violet CD spectroscopy shows that the protein retains essentially full secondary structural content at 4 °C. Thus, it appears that nitroreductase exists as an ensemble of rapidly interconverting loose structures at lower temperature, only adopting a single long-lived structure above 20 °C. Both saturation transfer from water and solvent proton exchange measurements, demonstrate that resonances of the poorly-dispersed spectrum represent protons closer to water, and in faster exchange with it. Thus we propose that the single well-defined structure is favored entropically, by release of water molecules that solvate the protein at 4 °C. We propose that the loosely structured state plays a role in accommodating binding of diverse substrates.

**P26 5 Protein-Protein Interactions during Bacterial Chemotaxis using Methyl TROSY Nuclear Magnetic Resonance.** DAMON HAMEL, FREDERICK DAHLQUIST, *University of California Santa Barbara* During bacterial chemotaxis, the histidine autokinase CheA interacts with the chemotaxis receptors with the help of the coupling protein CheW. The CheA-CheW interaction is typical of many macromolecular complexes where protein-protein interactions play an important role. In this case a relatively small protein, CheW (18 kDalton), becomes part of a much larger complex. Here we describe a new method to map the residues at a protein-protein interface for macromolecular complexes of molecular weight greater than 100 kDalton. The method exploits the C13 methyl TROSY methodology developed in Lewis Kay's laboratory. The essence of the Kay approach is that a portion of the intensity of HMQC spectra of individual -(13)CH3 resonances in an otherwise deuterated macromolecule have much reduced dipole-dipole relaxation and remain sharp and relatively easy to detect, even in macromolecules of molecular mass 100 kD or greater. The reduction in dipolar interactions is lost if a given methyl group comes in close contact with other protons such as those supplied by the interface of a protonated interaction partner. Comparing the -(13)CH3 resonances of a protein of interest in the presence of a protonated versus deuterated interaction partner allows the methyls at the interface can be identified. The application of the approach for establishing points of contact between CheA and CheW will be discussed.

**P26 6 Structural Basis for Specific Membrane Targeting by the HIV-1 Gag Protein.***
MICHAEL F. SUMMERS, *University of Maryland Baltimore County*

In HIV-1 infected cells, newly synthesized retroviral Gag polyproteins are directed to specific cellular membranes where they assemble and bud to form immature virions. Membrane binding is mediated by Gag's matrix (MA) domain, a 132-residue polypeptide containing an N-terminal myristyl group that can adopt sequestered and exposed conformations. Membane specificity was recently shown to be regulated by phosphatidylinositol-(4,5)-bisphosphate (PI(4,5)P2), a cellular factor abundant in the inner leaflet of the plasma membrane (PM). We now show that phosphoinositides, including soluble analogs of PI(4,5)P2 with truncated lipids, bind HIV-1 MA and trigger myristate exposure. The phosphoinositol moiety and one of the fatty acid tails binds to a cleft on the surface of the protein. The other fatty acid chain of PI(4,5)P2 and the exposed myristyl group of MA bracket a conserved basic surface patch implicated in membrane binding. Our findings indicate that PI(4,5)P2 acts as both a trigger of the myristyl switch and as a membrane anchor, and suggest a structure-based mechanism for the specific targeting HIV-1 Gag to PI(4,5)P2-enriched membranes.

**P26 7 Vinculin Tail Dimerization and Paxillin Binding.**
SHARON CAMPBELL, *University of North Carolina*

Vinculin is a highly conserved cytoskeletal protein that is essential for regulation of cell morphology and migration, and is a critical component of both cell-cell and cell-matrix complexes. The tail domain of vinculin (Vt) was crystallized as a homodimer and is believed to bind F-actin as a dimer. We have characterized Vt dimerization by Nuclear Magnetic Resonance (NMR) Spectroscopy and identified the dimer interface in solution by chemical shift perturbation. The Vt dimer interface in solution is similar to the crystallographic dimer interface. Interestingly, the Vt dimer interface determined by NMR partially overlaps the paxillin binding region previously defined coarsely by deletion mutagenesis and gel-blot assays. To further characterize the paxillin binding site in Vt and probe relationship between paxillin binding and dimerization, we conducted chemical shift perturbations experiments using a paxillin derived peptide, LD2. Our NMR experiments have confirmed that the paxillin binding site and the Vt dimerization site partially overlap, and we have further characterized both of these two binding interfaces. Information derived from these studies was used to identify mutations in Vt that selectively perturb paxillin binding and Vt self-association. These mutants are currently being characterized for their utility in structural and biological analyses to elucidate the role of paxillin binding and Vt dimerization in vinculin function.

**P26 8 Protein dynamics and allostery** BABIS KALODIMOS, *Rutgers University, Chemistry Department, Newark NJ 07102* Cooperativity and allostery are phenomena of universal importance in biological systems. According to the classical ''mechanical'' view allosteric interactions are mediated by a series of discrete changes in bonding interactions that alter the protein conformation. Nevertheless, proteins may have adopted additional mechanisms for energetically linking distant sites, thereby allowing a signal to be propagated over long distances. We have identified a cooperative biological system wherein allosteric interactions appear to be mediated exclusively by transmitted changes in protein motions. Changes in the structure, fast and slow protein motions and the redistribution of the native-state ensemble along the cooperative reaction coordinate have been characterized.

**P26 9 Protein Dynamics in an RNA Binding Protein.***
KATHLEEN HALL, *Washington University School of Medicine*

Using $^{15}N$ NMR relaxation measurements, analyzed with the Lipari-Szabo formalism, we have found that the human U1A RNA binding protein has ps-ns motions in those loops that make contact with RNA. Specific mutations can alter the extent and pattern of motions, and those proteins inevitably lose RNA binding affinity. Proteins with enhanced mobility of loops and termini presumably lose affinity due to increased conformational sampling by those parts of the protein that interact directly with RNA. There is an entropic penalty associated with locking down those elements upon RNA binding, in addition to a loss of binding efficiency caused by the increased number of conformations adopted by the protein. However, in addition to local conformational heterogeneity, analysis of molecular dynamics trajectories by

Reorientational Eigenmode Dynamics reveals that loops of the wild type protein undergo correlated motions that link distal sites across the binding surface. Mutations that disrupt correlated motions result in weaker RNA binding, implying that there is a network of interactions across the surface of the protein. (KBH was a Postdoctoral Fellow with Al Redfield from 1985-1990). This work was supported by the NIH (to KBH) and NSF (SAS).

**P26 10 Axial Rotation of Lipids in Membranes.**
RICHARD PASTOR, *Food and Drug Administration*

This study was motivated by Mary Roberts and Al Redfield, who proposed that the observed 10 ns decay time in their phosphorous NMR measurements of DPPC in bilayers originated from axial rotation of the lipid. Analyses of correlation functions and average first passage times from 50 ns molecular dynamics of DPPC bilayers strongly support their interpretation. The rotational anisotropy of a lipid in a bilayer is close to 1.0, in contrast to the 2.5 expected for a hydrodynamic cylinder with lipid dimensions. This implies that axial rotation is dominated by headgroup, not tail, interactions.

**P26 11 High Resolution Field Cycling NMR in Biopolymers in Solution: Current and Potential Applications.**
ALFRED REDFIELD, *Brandeis University*

I have been exploring the feasibility and utility of performing high resolution relaxation and cross-relaxation (NOE) in an unmodified shared commercial NMR instrument (PNAS 101:17066-17071) in collaboration with Mary Roberts of Boston College and Elan Eisenmesser of Brandeis. We can move a sample from 11.7 T to low (fringe) field 40- 80 cm above the commercial probe, and back, in 0.3 to 0.5 sec. I am making the system move the sample more gently, to avoid protein denaturation, using a stepping-motor timing-belt linear-motor. I willreview our initial papers on a DNA octamer, and phospholipidvesicles using phosphorus NMR. We emphasize phosphorus,in part, because relaxation studies over a wide range can make behavior of this biologically important species more readily interpretable than at high field alone. Then I will discuss a range of biochemical experiments, not yet done, using the full capability of our commercial instrument for multidimensional preparation and detection before and after field-cycling, and utilizing other nuclear species (H, C, and N). These involve especially use of electron-paramagnetic species and/or studies of small molecules in fast binding exchange with larger ones, and/or increased hetero-NOE effects at low field, to get new information on dynamics and structural preferences. Predictably we have found that, once we start to work on a specific biopolymer problem, we think of more things to do than we expected at first.

**P27 1 Analytic structure of Bloch functions for linear molecular chains*** EMIL PRODAN, *PRISM, Princeton University* In this talk I will discuss Hamiltonians of the form $H = -\nabla^2 + v(x,y,z)$, with $v(x,y,z)$ periodic along the $z$ direction, $v(x,y,z+b) = v(x,y,z)$. The wavefunctions of $H$ are the well known Bloch functions $\psi_{n,\lambda}(x,y,z)$, with the fundamental property $\psi_{n,\lambda}(x,y,z+b) = \lambda\psi_{n,\lambda}(x,y,z)$ and $\partial_z\psi_{n,\lambda}(x,y,z+b) = \lambda\partial_z\psi_{n,\lambda}(x,y,z)$. I will give the generic analytic structure (i.e. the Riemann surface) of $\psi_{n,\lambda}(x,y,z)$ and their corresponding energy, $E_n(\lambda)$, as functions of $\lambda$. I will also discuss several applications, like a compact expression of the Green's function or the asymptotic behavior of the density matrix and other correlation functions for insulating molecular chains.

**P27 2 First-principles calculation of Hubbard parameter: Constrained local density functional approach with Maximally localized Wannier function** KAZUMA NAKAMURA, *Department of Physics, University of Tokyo, Japan* RYOTARO ARITA, *Department of Physics, University of Tokyo, Japan* YOSHIHIDE YOSHIMOTO, *Institute for Solid State Physics, University of Tokyo, Japan* SHINJI TSUNEYUKI, *Department of Physics, University of Tokyo, Japan* We present a new ab initio method for calculating effective onsite Coulomb interactions of itinerant and strongly correlated electron systems. The method is based on constrained local density functional theory formulated in terms of maximally localized Wannier functions. This scheme can be implemented with any basis, and thus allows us to perform the constrained calculation with plane-wave-based electronic-structure codes. We apply the developed method to the evaluation of the onsite interaction of 3d transition-metal series. The results are discussed using a heuristic formula for screened Coulomb interactions. This work was supported by NAREGI Nanoscience Project, Ministry of Education, Culture, Sports, Science and Technology, Japan.

**P27 3 Electronic structure of $Cu_{2-x}S$ and related compounds** PAVEL LUKASHEV, WALTER R. L. LAMBRECHT, *Case Western Reserve Univ.* TAKAO KOTANI, MARK VAN SCHILFGAARDE, *Arizona State Univ.* Chalcosite $Cu_2S$ and digenite $Cu_{1.8}S$ are possibly interesting semiconductors for photovoltaic applications. Their electronic structure is poorly understood because their crystal structure is complex. If consists of a close-

packed lattice of S with mobile Cu occupying various types of interstitial sites with a statistical distribution depending on temperature. As a starting point for understanding these materials, we investigated the simpler antifluorite structure. Both local density approximation (LDA) and self-consistent quasiparticle GW calculations with the full-potential linearized muffin-tin orbital method give a semimetallic band structure with the Fermi level pinned at a degenerate Cu-d band state at $\Gamma$. A random distortion of the Cu atoms from the perfect antifluorite positions inside each S cage is found to break the degeneracy of the *d* state at $\Gamma$ and thus opens up a small gap of about 0.1 eV in LDA. The experimental evidence for a semiconducting gap of about 1 eV is critically examined. To gain further insight into the Cu d and s-band shifts beyond LDA, we considered other Cu compounds such as $Cu_2O$ and CuBr. We compare their LDA and GW band structures and determined the effective masses and Kohn-Luttinger Hamiltonian parameters for CuBr.

**P27 4 The Applicability of Different Quantum Mechanical Methods to Transition Metal Oxides** ORKID COSKUNER, EMILY JARVIS, THOMAS ALLISON, CARLOS GONZALEZ, ANNE CHAKA, *National Institute of Standards and Technology, Physical and Chemical Properties, Gaithersburg, MD 20889* NIST, COMPUTATIONAL CHEMISTRY GROUP TEAM, Numerous quantum mechanical methods and basis sets have been applied extensively to organic molecules. However, the performance of these is not well understood for transition metal oxides. We employed different methods along with several basis sets for optimizing the geometries in the gas phase and calculating the IR spectra as well as thermodynamic properties including Gibbs free energy and enthalpy of linear, trigonal and tetrahedral metal oxides. The MCSCF and DFT methods generally give the most accurate results for organic and inorganic molecules. Surprisingly, our studies showed that the results obtained for iron(III) oxides at the GVB and MP2 levels gave more accurate results than the MCSCF and hybrid methods. Similarly, for aluminum and chromium oxides, the calculations with MP2 and PBE yielded thermodynamic properties, which are closer to experimental values.

**P27 5 Zeroth-moment dielectric sum rule applied to electron damping*** ERIC L. SHIRLEY, *NIST* J.A. SOININEN, *U. Helsinki* J.J. REHR, *U. Washington, Seattle* The first and inverse-first frequency moments of the dielectric function, epsilon(q,omega), are given by the f-sum rule and Kramers-Kronig transformation of the static dielectric function. Model expressions for these quantities are plentiful. The square of the zeroth moment must be less than the product of the above two, by Cauchy-Schwartz. (It equals that product in single-plasmon-pole models). In this work, we present simple ways to estimate the zeroth moment as a function of q. This facilitates an improved model for epsilon(q,omega) that requires minimal computation and exhibits realistic behavior without use of a pole model. We apply this to calculating the electron self-energy, particularly lifetime damping effects in insulators near the band gap.

**P27 7 Prediction of Born-Oppenheimer Interatomic Forces Using Orbital-Free Density Functional Theory with Approximate Kinetic Energy Functionals*** S.B. TRICKEY, V.V. KARASIEV, FRANK E. HARRIS,† *Quantum Theory Project and Department of Physics, U. of Florida* Rapid calculation of Born-Oppenheimer forces is essential for driving the so called quantum region of a multi-scale molecular dynamics (MD) simulation. The orbital-free (OF) DFT approach is appealing but has proven difficult to implement because of the challenge of constructing reliable orbital-free approximations to the kinetic energy functional. To be maximally useful for multi-scale simulations, an OF-KE functional must be local (i.e. one-point). In the face of these difficulties, we demonstrate that there is a way forward. By requiring only that the approximate functional deliver high-quality forces, by exploiting the ''conjointness'' hypothesis of Lee, Lee, and Parr, by enforcing a basic positivity constraint, and by parameterizing to a carefully selected, small set of molecules we are able to generate a OF-KE functional that does a good job of describing various $H_qSi_mO_n$ clusters as well as CO and $H_2O$ (providing encouraging evidence of transferability).

**P27 8 Fitting of Molecular Densities by Compact, Atom-Centered Expansion*** V.V. KARASIEV, S.B. TRICKEY, FRANK E. HARRIS,† *Quantum Theory Project and Dept. of Physics, U. of Florida* Use of an orbital-free (OF) version of DFT requires both a suitable approximate Kohn-Sham kinetic energy functional and a systematic but simple model of the system density. We report useful approximations to the KS density via a very compact expansion in atom-centered functions. Spherically averaged, isolated-atom densities are used as basis functions to expand spherically symmetric atom-centered contributions. A simplified expansion in real spherical harmonics is then added to the spherically symmetric contributions. Although drastically simplified, such representations of the density nevertheless result in impressively small mean square deviations relative to the target KS density. The fitted density can then be combined with an approximate

OF-KE functional we have developed[1] to generate energy surfaces. These energy surfaces have shapes similar to those arising from true KS densities, and are therefore suitable for calculation of forces to drive molecular dynamics simulations.

**P27 9 Magnetic Field Effects upon Exchange-Correlation in the Hooke's Atom*** WUMING ZHU, SAMUEL TRICKEY, *Quantum Theory Project and Department of Physics, University of Florida, Gainesville, FL 32611* Extending Density Functional Theory (DFT) to coulombic systems in a non-vanishing magnetic field in a computationally feasible way is highly desirable. Even though the current DFT (CDFT) formalism is long-established, there still are no generally applicable, reliable $E_{xc}, \mathbf{A}_{xc}$ functionals analogous with the LDA. Progress can be made by comparison study on a solvable correlated system. Hooke's atom is well-known in ordinary DFT because its Schrödinger equation can be solved exactly for some coupling strengths and numerically with high accuracy for the rest. Hence exact Kohn-Sham quantities are readily available. Using our extensions (exact and numerical) to non-zero B-field, we examined the effects on exchange- correlation holes and energies and considered possible ways to include the essential ones in $E_{xc}, \mathbf{A}_{xc}$. In our tests, the CDFT vorticity variable, $\nu$, turns out to be a computationally difficult quantity which may not be appropriate in practice to describe external B field effects on $E_{xc}, \mathbf{A}_{xc}$.

**P27 10 The problems in the density functional theory with the total spin and space symmetry and the invariant properties of the electron density.** I.G. KAPLAN, *Instituto de Investigaciones en Materiales, UNAM, Apdo. Postal 70-360, 04510 México D.F. México* The problems in the density functional theory (DFT) arising when it is applied to the spin and space multiplets are discussed. It is rigorously proved that the electron density of an arbitrary *N*-electron system does not depend upon the value of the total spin *S* of the state and preserves the same analytical form for all states with the definite *S*. It is also proved that the diagonal element of the full density matrix is invariant respecting all operation of the group symmetry of the state, i.e, it is a group invariant. From these results follows that the problems in DFT with the total spin and degenerated states cannot be solved within the framework of density matrix formalism.

**13:15**
**P27 11 Dehydrogenation in catalyst activated $MgH_2$*** SA LI, PURU JENA, RAJEEV AHUJA, *Virginia Commonwealth University* VIRGINIA COMMONWEALTH UNIVERSITY TEAM, UPPSALA UNIVERSITY COLLABORATION, Dehydrogenation in catalyst activated magnesium hydride ($MgH_2$) has been investigated using itab initio Molecular Dynamics (MD) simulation and Nudged Elastic Band (NEB) method. Our calculation explains why small amount of $Nb_2O_5$ catalyst can substantially improve the thermodynamics and kinetics of $MgH_2$. We show that $Nb_2O_5$ promotes the creation of Mg vacancies and that the hydrogen desorption from the vicinity of Mg vacancies occurs in molecular form and is exothermic. The activation energy barrier for $H_2$ desorption in vacancy containing magnesium hydride (1.02 eV) is much lower than that in the pure magnesium hydride (3.30 eV). Therefore, the effective catalyst for dehydrogenation in $MgH_2$ will be one that can easily facilitate MgO formation.

**P27 12 A method for biased surface electronic structure: a planewave non-repeated slab approach** MINORU OTANI, OSAMU SUGINO, *Institute for Solid State Physics, Tokyo University* We have developed a new formalism for calculating electronic structures in a symmetric/asymmetric slab model [1]. The method can treat not only surfaces exposed to vacuum but also biased surfaces. To solve the Kohn-Sham equation, we adopt a conventional Kohn-Sham solver in a repeated slab model. On the other hand, for the Poisson equation, we solve it in a whole space along surface normal direction. Owing to this treatment we can easily obtain work functions of the surface and we can calculate polarized surfaces without dipole correction. By introducing an effective screening medium and imposing appropriate boundary conditions to the Poisson equation, we can calculate a surface that is placed in front of electrode. In this model it is possible to apply a bias voltage to the surface by changing the Fermi energy of the surface. Thus we can calculate electronic and geometric structures of the biased surface. This model corresponds to the experimental setup for the scanning tunneling microscopy or back-gate field effect transistor. The important advantage of the method is that we can easily implement it in a conventional first-principles calculation method. References: [1] M. Otani and O. Sugino, submitted to PRB.

**P29 2 Observation of membrane fusion between individual virus particles and supported lipid bilayers** LAURA WESSELS, KEITH WENINGER, *North Carolina State University* A portion of the host cell membrane is incorporated into newly produced, enveloped virus particles during an active infection. Fusion of that viral membrane with the membrane of targeted host cells is generally accepted to be a key step for the infection of normal cells as a virus spreads among a normal cell population. For the best studied enveloped viruses, viral proteins catalyze the membrane fusion reaction during a low pH step along the cellular endocytotic pathway. To gain a better understanding of the molecular mechanisms underlying viral membrane fusion, we have constructed an itin vitro fluorescence assay to allow high resolution, real time measurements of Sindbis viral fusion to supported lipid bilayers. Single particle tracking is used to observe individual virus particles. The mixing of a fluorescent dye incorporated into the viral membrane with the supported bilayer reports fusion. We present results regarding the effects of different lipid blends as well as different buffer conditions on membrane fusion for Sindbis virus. We compare the fusion of virus produced in mammalian cells to that from insect cells.

**11:39**

**P29 3 Simulating Domain Formation and Fusion in Lipid Bilayers** MARK STEVENS, *Sandia National Laboratories* The lipid dynamics is the source of the variety of membrane structures and dynamics found in celss. Many of the interesting phenomena of biomembranes involve time scales of at least microseconds, which have been beyond simulations until recently. Coarse-grained models of lipid molecules have been developed to reach these long time scales and maintain the essential physical character of the molecules. Using these models in molecular dynamics simulations, time scales in the $\mu$s to ms range are treatable. As examples, simulations of domain formation and membrane fusion will be presented. In mixed lipid systems, the formation of domains is now understood to be an active component in biological processes. Our simulations reveal the dynamics of the lipid molecules that form domains in binary systems. In particular, the correlation between the two monolayers of the bilayer is dependent on the molecular structure of the lipid molecules. Membrane fusion is a fundamental process of cellular transport and infection processes. Understanding the basic principles governing membrane fusion has many important consequences. The coarse-grained molecular dynamics simulations show how lipid molecular structure influences the fusion process.

**11:51**

**P29 4 Lipid Coupling in Asymmetric Supported Lipid Bilayers Revealed by Fluorescence Correlation Spectroscopy** YAN YU, *Dept. of Materials Science & Engineering, UIUC* LIANGFANG ZHANG, *Dept. of Chemical & Biomolecular Engineering, UIUC* STEVE GRANICK, *Dept. of Materials Science & Engineering, of Physics, of Chemistry, and of Chemical & Biomolecular Engineering, UIUC* In biological systems, phospholipids asymmetry in two leaflets is a key feature of cell membranes for membrane biogenesis, intracellular fusion and signal transduction. Detailed information of the interactions and dynamics of the asymmetric membranes is paramount for design of applications. Here we use fluorescence correlation spectroscopy (FCS) to measure the coupling between 1, 2-dilauroyl-itsn-glycero-3-phosphocholine (DLPC) and 1, 2-dipalmitoyl-itsn-glycero-3-phosphocholine (DPPC) in asymmetric planar-supported bilayers (PSLBs), at temperatures where DLPC is in the fluid phase but DPPC is in the gel phase. Asymmetric PSLBs were prepared by placing dilute fluorescent-labeled 1, 2-dimeristoyl-itsn-glycero-3-phosphoethanolamine (DMPE) in DLPC leaflet as the probe for measuring lateral diffusion within the host leaflet environment. By constructing asymmetric bilayers where DLPC is alternatively in the top and in the bottom leaflet, we compare lipid coupling between the two leaflets with frictional interaction between the leaflets and the nanometer-thick water layer that separates the bottom leaflet from the solid support.

**12:03**

**P29 5 Dissipative Particle Dynamics Simulation of Structure Properties of Lipid Micelles** JINSUO ZHANG, YI JIANG, *MSK-575, Los Alamos National Lab* We chose dissipative particle dynamics (DPD) simulation to study the micelle structure properties. The self-assembly lipid is modeled by a flexible chain with head and tail particles. By changing interaction parameters between the solution particles and the lipid particles, three types of solution are considered: water, oil and water-oil mixture. It is found that the tail/head chains forming the micelle core have a very disorder distribution. The relation between the core radius with the aggregation number as well as the number of oil particles inside is obtained based on the simulation results and the molecular packing parameter. The mean density of particles in the core is higher than that in the simulation box. For micelles without oils inside, the density depends on the number of head particles in a lipid molecule, and the dependence becomes weaker as more oil particles are captured. At the core surface, head particles form clusters with water particles incorporated between the clusters. Comparisons with results from other simulation method such as MD show that DPD achieves high performance in simulating micelle formation and structure properties.

**12:15**

**P29 6 Anomalously Slow Domain Growth in Membranes with Asymmetric Transbilayer Lipid Distribution** MOHAMED LARADJI, *Physics Department, University of Memphis, Memphis, TN 38152* P.B. SUNIL KUMAR,* *Center for Biomembrane Physics, University of Southern Denmark, Campusvej 55, DK-5230,*

*Odense-M, Denmark* The effect of asymmetry in transbilayer lipid distribution on the phase separation of self-assembled multicomponent fluid vesicles is investigated numerically via dissipative particle dynamics. We show that this asymmetry induces a spontaneous curvature wich alters significantly the morphology and dynamics of the lipid mixture. In particular, at intermediate tension, domain growth is found to be anomalously slow dynamics. In contrast, in the limiting cases of low and high tensions, the dynamics proceed toward full phase separation.

**P29 8 Stabilization of Model Membrane Systems by Disaccharides. Quasielastic Neutron Scattering Experiments and Atomistic Simulations** EMMANOUIL DOXASTAKIS, *Dept. of Chem. & Biol. Engr., Univ. of Wisconsin* VICTORIA GARCIA SAKAI, *NIST Center for Neutron Research and Univ. of Maryland* SATOSHI OHTAKE, *Dept. of Chem. & Biol. Engr., Univ. of Wisconsin* JANNA K. MARANAS, *Dept. of Chem. Engr., Penn. State University* JUAN J. DE PABLO, *Dept. of Chem. & Biol. Engr., Univ. of Wisconsin* Trehalose, a disaccharide of glucose, is often used for the stabilization of cell membranes in the absence of water. This work studies the effects of trehalose on model membrane systems as they undergo a melting transition using a combination of experimental methods and atomistic molecular simulations. Quasielastic neutron scattering experiments on selectively deuterated samples provide the incoherent dynamic structure over a wide time range. Elastic scans probing the lipid tail dynamics display clear evidence of a main melting transition that is significantly lowered in the presence of trehalose. Lipid headgroup mobility is considerably restricted at high temperatures and directly associated with the dynamics of the sugar in the mixture. Molecular simulations provide a detailed overview of the dynamics and their spatial and time dependence. The combined simulation and experimental methodology offers a unique, molecular view of the physics of systems commonly employed in cryopreservation and lyophilization processes.

**P29 9 Protein crystals on phase-separating model membranes** SULIANA MANLEY, MARGARET HORTON, SZYMON LESZCZYNSKI, ALICE GAST, *Massachusetts Institute of Technology* We study the interplay between the crystallization of proteins tethered to membranes and separation within the membranes of giant unilamellar vesicles (GUVs) composed of DOPC, sphingomyelin (SM), and cholesterol. These model membranes phase separate into coexisting liquid domains below a miscibility transition temperature. This phase separation captures some aspects of the formation of lipid rafts in cell membranes and demonstrates the influence of membrane composition on raft formation. Real cell membranes have a much more complicated structure. There are additional physical constraints present in cell membranes, such as their attachment to the cytoskeleton and the presence of membrane bound proteins. The self-association of membrane proteins can influence the membrane phase behavior. We begin to investigate these effects on model tethered protein- loaded membranes by incorporating a small amount of biotin-X- DPPE into our GUVs. The biotinylated lipid partitions into a cholesterol-poor phase; thus, streptavidin binds preferentially to one of the membrane phases. As streptavidin assembles to form crystalline domains, it restricts the membrane mobility. We examine the effect of this protein association on lipid phase separation, as well as the effect of the lipid phase separation on the crystallization of the tethered proteins.

**P29 10 Model systems to investigate the effect of cholesterol on the transfection efficiency of lipoplexes** ALEXANDRA ZIDOVSKA, HEATHER M. EVANS, KAI EWERT, CYRUS R. SAFINYA, *Materials, Physics, and Molecular, Cellular and Developmental Biology Departments, Santa Barbara, CA 93106* Motivated by its important role in lipid-mediated gene delivery, we have studied the effect of cholesterol on membrane fusion. While recent work in our group has identified the membrane charge density as a critical parameter for transfection efficiency (TE) of lamellar, DOPC containing cationic lipid-DNA (CL-DNA) complexes [1-3], this model cannot fully explain the effect of cholesterol, suggesting that a different mechanism is responsible for the observed enhancement of TE. A model system using negatively charged giant vesicles has been developed to mimic the interaction of the cell membrane with CL-DNA complexes containing cholesterol. Differences in fusogenic properties have been observed as a function of the amount of cholesterol present in the CL-DNA complexes, and a fluorescence resonance energy transfer based assay was employed to quantify this effect. X-ray diffraction confirms that the lamellar structure seen with CL- DNA complexes is retained with the addition of cholesterol. Funding provided by NIH GM-59288 and NSF DMR-0503347. [1] A.J. Lin et al, Biophys. J., 2003, V84:3307-3316. [2] K. Ewert et al, J. Med. Chem., 2002, V45:5023-5029. [3] A. Ahmad et al., J. Gene Med., 2005, V7:739-748.

**P29 11 Had a drink last night? How alcohol interacts with biological membranes** MIKKO KARTTUNEN, *Helsinki University of Technology, Finland* MICHAEL PATRA, *Lund University, Sweden* EMPPU SALONEN, EMMA TERAMA, ILPO VATTULAINEN, *Helsinki University of Technology, Finland* ROLAND FALLER, BRYAN LEE, *University of California, Davis* JUHA HOLOPAINEN, *University of Helsinki* We have performed extensive 100 ns molecular dynamics simulations to study the effect of methanol and ethanol on two different lipid bilayer sys-

tems (POPC and DPPC) in the fluid phase at 323 K [1,2]. We studied both structural changes induced by the alcohols and the dynamics of the system. It turned out that ethanol was able to penetrate the membranes whereas methanol was not able to do so. In particular, ethanol prefers to be accommodated in the vicinity of the lipid headgroup region. We also determined the dependence of lipid chain ordering on ethanol concentration and quite surprisingly found that to be non-monotonous. We explain that in terms of modified surface tension [2]. Finally, we determined lifetime of hydrogen bonds to be about 1 ns and found that be in excellent agreement with NMR results. [1] B.W. Lee, et al, Fluid Phase Equilibria 225, 63-68 (2004) [2] M. **P29 12 Solid domain rafts in lipid vesicles and scars*** SLAVA CHUSHAK, *Iowa State University* ALEX TRAVESSET, *Iowa State University and Ames lab* The free energy of a crystalline domain coexisting with a liquid phase on a spherical vesicle may be approximated by an elastic or stretching energy and a line tension term. The stretching energy generally grows as the area of the domain, while the line tension term grows with its perimeter. We show that if the crystalline domain contains defect arrays consisting of finite length grain boundaries of dislocations (scars) the stretching energy grows linearly with a characteristic length of the crystalline domain. We show that this result is critical to understand the existence of solid domains in lipid-bilayers in the strongly segregated two phase region even for small relative area coverages. The domains evolve from caps to stripes that become thinner as the line tension is decreased. We also discuss the implications of the results for other experimental.

**P29 13 Efficient calculation of mechanical properties of multicomponent phospholipid bilayers with Monte Carlo simulations** MANAN CHOPRA, EMMANOUIL DOXASTAKIS, NICHOLAS L. ABBOTT, JUAN J. DE PABLO, *UW Madison* We present a systematic study of the mechanical properties of multicomponent phospholipid bilayers. Two sets of systems are considered. The first consists of a mixture of DioleoylPhosphatidylethanolamine (DOPE) and DioleoylPhosphatidylcholine (DOPC) phospholipids. These two molecules have different head groups but the same chain length. The second system consists of a mixture of DilauroylPhosphatidylcholine (DLPC) and DistearoylPhosphatidylcholine (DSPC); these molecules have different chain lengths but the same head group. We use atomistic and coarse grain models, coupled to advanced Monte Carlo simulation techniques, to examine the structure and mechanical properties of the bilayers. Our results for pure systems are in quantitative agreement with experiment. Experimental data for mixed bilayers are not available, but our results indicate that their mechanical behavior is highly non-linear, a finding that we can interpret in terms of the composition and the resulting structure of the mixtures.

**13:51**
**P29 14 Roughness effect on vesicle adhesion characterised by a novel micropipette-based technique** MARIE-JOSEE COLBERT, ADAM N. RAEGEN, KARI DALNOKI-VERESS, CECILE FRADIN, *Physics and Astronomy, McMaster University* Numerous biological processes have to go through a cell adhesion process, which make the fundamental study of the adhesion of cells on solid substrate a key research topic in cellular biophysics. We will present our work on the adhesion of a single vesicle on a substrate. A vesicle is held at the end of a micropipette mounted on a micromanipulator and put into contact with a surface. We developed a novel technique to directly measure adhesion using the spring-constant of an L-shaped micropipette when pulling the vesicle from the substrate. The substrate is made of a micropatterned polymer film coated with a thin layer of gold to promote adhesion with the vesicle. The effect of the surface roughness can therefore be carefully characterized.

**P29 15 Structure of Cholesterol Helical Ribbons, Self-Assembling Biological Springs.*** B. KHAYKOVICH, C. HOSSAIN, A. LOMAKIN, J. McMANUS, D. E. MONCTON, G. B. BENEDEK, *Department of Physics and Materials Processing Center, Massachusetts Institute of Technology, Cambridge, MA* Helical ribbons with characteristic pitch angles form spontaneously in a variety of quaternary surfactant-lipid-sterol-water solutions. These helical ribbons form in a variety of axial lengths, widths and radii. Surprisingly, however, they all have pitch angles of either 11 or 54[r]. Our X-ray diffraction studies of individual ribbons confirm that the remarkable stability of each of the two pitch angles is related to a crystalline nature of the ribbons. The small size (of 100 x 10 x 0.1 $\mu m^3$) and the significant curvature of the ribbons produce weak and broad Bragg peaks. Therefore, novel methods are used to analyze these data. The structure of these ribbons is similar to that of cholesterol monohydrate. Interestingly, there is an evidence for a superlattice structure, resembling that found in thick films of cholesterol grown at the air-water interface.

**P30 1 Properties of Organic Molecules at Metal Surfaces.**
FEDERICO ROSEI, *Universite du Quebec*

The adsorption and selfassembly of organic molecules at surfaces has recently been investigated extensively, both because of the fundamental interest and for prospective applications in nanoelectronics and nanophotonics [1, 2].

Moleculemolecule and moleculesubstrate interactions can be tuned by the appropriate choice of substrate material and symmetry. Upon molecular adsorption, surfaces typically do not behave as static templates, but often rearrange dramatically to accommodate different molecular species [3, 4]. This presentation reviews recent experimental work using Scanning Tunneling Microscopy, which is providing new insight into fundamental properties such as molecular diffusion [5, 6] and selfassembly via surface templating [7] and hydrogen bonding driven by co-adsorption [8]. **P30 2 Direct measurements of contact resistances in asymmetric pentacene thin-film transistors with polyaniline and gold electrodes** KWANG SEOK LEE, TIMOTHY SMITH, JOUNG EUN YOO, KEITH STEVENSON, YUEH-LIN (LYNN) LOO, *Department of Chemical Engineering, Department of Chemistry and Biochemistry, University of Texas at Austin* We have fabricated asymmetric pentacene thin-film transistors with one gold electrode and one polyaniline (PANI) electrode connected to the same pentacene channel. Surface potential measurements reveal large potential drops at the gold/pentacene contact, but not at the PANI/pentacene contact during operation. We observe, however, some potential drop along the PANI electrode outside the scan window due to the bulk resistance of PANI. To minimize the potential drop across the PANI electrode, we have fabricated asymmetric devices with one exposed gold electrode, and one PANI-coated gold electrode. The surface potential profiles of these asymmetric devices with the PANI-coated gold electrode as the source electrode and the exposed gold electrode as the drain electrode, and vice versa, reveal no additional potential drop across the PANI-coated gold electrode. Quantification of the contact resistance indicates that the PANI/pentacene contact is significantly less resistive than the gold/pentacene contact whether the PANI-coated gold electrode is used as the source, or the drain electrode. Additionally, charge injection from the exposed gold electrode and the PANI-coated electrode appears to be more difficult than charge extraction from these electrodes.

**P30 3 Nm-resolution studies of Au/molecular-film/GaAs junctions using ballistic electron emission microscopy (BEEM)** C. MARGINEAN, C. TIVARUS, J.P. PELZ, *The Ohio State University* HOSSAM HAICK, DAVID CAHEN, *The Weizmann Institute* BEEM was used to image and quantify lateral homogeneity and energy band alignments at molecule/electrode interfaces in Au/dC-X/GaAs structures, where dC-X are dicarboxylic ligands with X= H, $OCH_3$, $CF_3$, CN, or $CH_3$ [1]. Transport through such junctions was proposed to be dominated by ''pinholes'' in the dC-X film, with the Au/GaAs Schottky barrier height (SBH) at pinholes modified by the surrounding molecular film dipole [1]. BEEM images of dC-$CH_3$ with $V_{tip} < \sim 1.38$ eV indeed revealed isolated 20-40 nm sized ''pinholes'' with measured local SBHs ranging from 0.90 – 1.0 eV, consistent with the model [1]. However, between the pinholes we also observed a new conduction channel for $V_{tip} > \sim 1.38$ eV, possibly due to transport through the LUMO of the dC-$CH_3$ film itself. BEEM measurements for the other –X groups also showed non-uniform, film-dependent SBH, but for those films the pinholes were too dense or the films too transparent to resolve isolated pinholes. All dC-X films were stable under the BEEM hot-electron flux. [1] H. Haick et al., Adv. Mater. **16**, 2145 (2004).

**P30 4 A Possible Mechanism For Photoinduced Effects In Molecule-Based Magnets** SERKAN ERDIN, MICHEL VAN VEENENDAAL, *Dept. of Physics, Northern Illinois University, DeKalb, IL, 60615 & Argonne National Laboratory,Advanced Photon Source, Argonne, IL 60439* A mechanism based on charge transfer processes between ligand and metal, for photoinduced effects on magnetic order that are observed in manganese-tetracyanoethylene molecule-based magnet is proposed. In order to support the mechanism, Monte Carlo calculations for a double exchange model with antiferromagnetic interaction between nearest neighbor manganese core spins, $J_{AF}$ on two dimensional metal-ligand lattice are performed. Depending on strength of $J_{AF}$ and the number of electrons in the system, total average magnetization and average angles of core spins are calculated.

**P30 5 The electronic structure and polymerization of a self-assembled monolayer** DANQIN FENG, DAVID WISBEY, *University of Nebraska-Lincoln* YIAN TAI, *Universität Heidelberg* YAROSLAV LOSOVYJ, *Center for Advanced Microstructures and Devices* MICHAEL ZHARNIKOV, *Universität Heidelberg* PETER DOWBEN, *University of Nebraska-Lincoln* Irradiation-induced modifications of electronic structure in the monomolecular insulator [1,1';4',1''-terphenyl]-4,4''-dimethanethiol (TPDMT) films have been investigated by photoemission and inverse photoemission. A dominant effect is cross-linking of the TPDMT film, which result in a quasipolymeric material with a smaller gap between the highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) but improved the dielectric properties. The cross-linking processes are also accompanied by changes in molecular orientation. The photoemission intensities of organic molecular layers generally obey the Debye-Waller temperature dependence but not always. With the example of a monomolecular film formed from [1,1';4',1''-terphenyl]-4,4''-dimethanethiol, we show that pronounced deviations from Debye-Waller temperature behavior are possible and are likely caused by temperature dependent changes in molecular orientation.

**P30 6 A first-principles study of $\pi$-stacking in charged oligothiophenes in the presence of counterions** NICHOLAS MILLER, *DMSE, Massachusetts Institute of Technology* DAMIAN SCHERLIS, *Universidad de Buenos Aires* NICOLA MARZARI, *DMSE, Massachusetts Institute of Technology* We investigate the structural and electronic properties of charged oligothiophenes and of their $\pi$-stacking interactions with extensive density-functional theory (PBE, B3LYP) and post-Hartree-Fock (MP2) calculations. We pay particular attention to the role of counterions and of the solvation medium in tuning the balance between electrostatic repulsion and chemical bonding, including explicitly hexafluorophosphate counterions, and exploring the role of polarizability and surface tension for different solvents. Our calculations show that Coulomb's repulsion of the charged oligothiophenes is rapidly screened by solvation, counterions, or both, leading to stable $\pi$-dimerized systems (or higher stackings) where binding is driven by $\pi$-bond hybridization. Furthermore, we studied the charge-transfer properties of the counterion-oligomer system, as well as site preferences for counterions, highlighting the relevance of a proper treatment of correlations and self-interaction in describing the electronic-structure of these systems.

**P30 7 Orientation of Fluorophenols on Si(111)** FAN ZHENG, *University of Wisconsin-Madison* J.L. McCHESNEY, *Lawrence Berkeley National Lab* XIAOSONG LIU, F.J. HIMPSEL, *University of Wisconsin-Madison* Oriented adsorption of switchable organic molecules at surfaces is an important prerequisite for single molecular electronics [1, 2]. As model systems we select polar fluorophenols with tailored dipole moments and investigate their adsorption on the Si(111)7$\times$ 7 surface by near edge x-ray absorption fine structure spectroscopy (NEXAFS). A strong polarization dependence of the $\pi^*$ transitions is observed in fluorinated phenols, while phenol itself is isotropic. A quantitative model is developed to convert polarization-dependent NEXAFS data into orientational information. The model includes three angular degrees of freedom, two of them fixed and the other with a Gaussian distribution. Such a situation is encountered in a variety of self-assembled monolayers (SAMs) with tailored end groups [3]. [1] T. A. Jung, R. R. Schlittler, J. K. Gimzewski, Nature **386**, 696, (1997) [2] A. J. **P31 2 Separation of single-walled carbon nanotubes into metallic and semiconducting groups: a simple and large-scale method** JING LU, *Mesoscopic Physics Laboratory, Department of Physics, Peking University, Beijing 100871, Peoples Republic of China.* Y. MAEDA, *Department of Chemistry, Tokyo Gakugei University, Tokyo 184-8501, Japan* Separation of a large number of single-walled carbon nanotubes (SWNTs) into groups each with specifically metallic and semiconducting properties is an extremely important task for technology application. Even though effective methods (1, 2) have been devised, they suffer from drawbacks such as either the yield is low (3) or expense is high (4). In this work, we study the problem from a theoretical approach, we notice that based on the first principles calculations the binding strengths of methylamine to the semiconducting [13, 0] SWNT are only 36$\sim$ 61% of that to the metallic [7, 7] SWNT, which suggests that the amines is much more attractive toward the pure metallic than the semiconducting SWNTs. Therefore starting from as-prepared SWNTs and with the assistance of amines, we achieved SWNTs with enriched metallic properties over semiconducting in a convenient and large-scale manner. (1) D. Chattopadhyay, L. Galeska, F. Papadimitrakopoulos, Journal of the American Chemical Society 125, 3370 (MAR 19, 2003). (2) H. P. **P31 3 Polaron superconductivity model for Li-doped nanotube-zeolite composite** XIANXIANG HUANG, PING SHENG, *Department of Physics and Institute of Nano Science and Technology, The Hong Kong University of Science and Technology* We propose a polaron superconductivity model for Li-doped nanotube-zeolite composite, in which the 4 Angstrom carbon nanotubes are embedded in the zeolite matrix, with a nanotube-nanotube wall separation of less than 10 Angstroms. The small separation implies inevitable nanotube-nanotube coupling, leading to a 3D anisotropic superconductor. Here we calculate the mean-field superconducting transition temperature based on the fact that each adsorbed Li atom, situated in the middle of the nanotube, donates an electron to the nanotube so as to form an ion-electron system. In addition, the Li ion is trapped in a shallow well formed by the (5,0) nanotube, with a periodicity of 4.3 Angstroms. So the

Li vibration resembles that of an optical phonon. We have evaluated both the electron-electron interaction and the electron-phonon interactions in the presence of the screening effect, and solved the Eliashberg-Gorkov equation to obtain the superconducting transition temperature.

**11:51**

**P31 4 Theoretical Model for a Carbon Nanotube-Based Magnetometer at Non-Zero Temperatures** VLADIMIR DOBROKHOTOV, CHRIS BERVEN, *University of Idaho* We present a complete description of electronic current in metallic single-walled carbon nanotubes under the influence of axially oriented magnetic fields at nonzero temperatures. We include in our model [1] the diameter of the carbon nanotube, the temperature and length of the nanotube. We find that the current in a zigzag carbon nanotube that is metallic at zero magnetic field is strongly modulated by varying the magnitude of an axially oriented magnetic field. We use this property, to propose a design of a carbon nanotube based directional magnetometer that could be designed to sense magnetic fields from 1 T to 8 T and at temperatures from 0 K up to 100 K. [1] Vladimir Dobrokhotov and Christopher Berven, ''Electronic Transport Properties of Metallic CNTs in an Axial Magnetic Field at nonzero Temperatures: A Model of an Ultra-small Digital Magnetometer,'' accepted for publication 11-2005 Physica E

**12:03**

**P31 5 Effect of Short-Range Electron Correlation in Nanotubes** ANDREW KINCHEN, RUSSELL SELVA, YURIY MALOZOVSKY, *Southeastern Louisiana University* We study the effect of short-range electron correlation in the zigzag and armchair carbon nanotubes (CNT). We derived the dynamic pair interaction potential between two electrons in the tubule incorporating Hubbard type local field factor. The dispersion of plasma modes at different values of angular momentum, and chirality angle and single-particle excitations are derived as well. We also evaluate the self-energy part due to the interaction of an electron with acoustic mode.

**12:15**

**P31 6 Electron Standing Waves in Semiconducting Carbon Nanotubes: Spatially-Resolved Scanning Tunneling Spectroscopy** SE-JONG KAHNG, *Department of Physics, Korea University* HAJIN KIM, SUNGJUN LEE, YOUNG KUK, *School of Physics and Center for Science in Nanometer Scale, Seoul National University* Electronic modulation patterns were observed, from the gap states of semiconducting single-wall carbon nanotubes, using spatially-resolved scanning tunneling spectroscopy. Some modulations show single peaks, with the period twice of the lattice constants, while others show double peaks. Both modulations are localized within a few nano-meters, enclosed by exponential decay functions. The modulation patterns are well understood in terms of the squared wavefunctions, derived from the simple quantum mechanical potential well models. Our model can be applied to the bound states of metallic carbon nanotubes as well.

**12:27**

**P31 7 Electronic structure of carbon nanotubes adsorbed on Si(001) vicinal surfaces.** S. BERBER, A. OSHIYAMA, *University of Tsukuba* We have investigated adsorption of carbon nanotubes on Si(001) vicinal surfaces using Density Functional Theory total energy and electronic structure calculations. Energetically favorable adsorption orientations and positions of carbon nanotubes were searched by total energy calculations, and detailed atomic structure of carbon nanotubes adsorbed at most probable adsorption sites have been obtained by full structure relaxation. Adsorption energy shows both direction and site dependence since the carbon nanotube form covalent bonds with the clean vicinal surface. Charge transfer between the nanotube and the surface happens mainly at the interface, which results in a quasi one-dimensional electron channel. Electronic states of carbon nanotube and silicon surface are highly rehybridized and mixed. A metallic carbon nanotube could behave as small gap semiconductor depending on adsorption site. Insertion of $sp^3$ bonded carbon atoms in $sp^2$ bond network introduces energy gap in electronic structure of the nanotube near Fermi level. This energy gap could be eliminated if there are surface states available for charge transfer. But such surface states are not available for particular nanotube directions, and non-metallic electronic structure appears. Dangling bond states of silicon surface, which appears as energy bands near the Fermi level, attracts electrons from the nanotube provided that these states are localized near the nanotube. Termination of surface dangling bonds in the vicinity of adsorbed nanotube could help tune the electronic properties of adsorbed nanotube.

**12:39**

**P31 8 The II-VI nanostructure zoo** PHILIP LINDAN,* *School of Physical Sciences, University of Kent* SAMANTHA LISTER, *School of Physical Sciences, University of Kent* We present predictions of a completely new family of nanotubes, related nanostructures and fullerene-like cages formed from the II-VI semiconductor mercury telluride. Our predictions are supported by first-principles calculations on the structures. The structures are remarkable in several ways: They are all more stable than the planar form of HgTe from which they are formed; they are radically altered from the tetrahedral bulk forms, and a strong interaction with the electronic structure results in a semimetal-semiconductor transformation; and for the larger armchair tubes isomerisation leads to striking structures formed from heavy modification of the tube, accompanied by large changes in the bandgap. For the nanotubes two simple rules for preferred coordination of Hg and the Hg-Te-Hg bond angles explain the structural stability of the nanotubes, and the formation of their exotic isomers. The cage structures are based upon the Archimedean and Platonic solids, where key requirements in terms of numbers of vertices, number of triangular faces and their connectivity determine the viable subset of structures.

**P31 9 Nonlinear ac conductivity of disordered Luttinger liquids*** BERND ROSENOW, *Physics Department, Harvard University, USA* THOMAS NATTERMANN, *Insitut fuer Theoretische Physik, Universitaet zu Koeln, Germany* We consider low energy charge transport in one-dimensional electron systems with short range interactions under the influence of a random potential. At zero temperature, the linear ac conductivity vanishes like $\sim \omega^2(\ln(1/\omega))^2$. Much less is known about the *non-linear conductivity*. At zero temperature and frequency, charge transport is only possible by tunneling of charge carriers, which can be described by instanton formation. The nonlinear dc conductivity is characterized by $I \sim \exp(-\sqrt{E_0/E})$ provided the system is coupled to a dissipative bath [1]. Combining RG and instanton methods, we calculate the nonlinear ac conductivity and discuss the crossover between the nonanalytic field dependence of the

electric current at zero frequency and the linear ac conductivity at small electric fields and finite frequency [2].[0.5cm] [1] S. Malinin, T. Nattermann, and B. Rosenow, Phys. Rev. B **70**, 235120 (2004). [2] B. Rosenow and T. Nattermann, accepted for publication in Phys. Rev. B; preprint cond-mat/0408042.

**P31 10 Renormalization of a single impurity potential of arbitrary strength in a Tomonaga-Luttinger liquid*** KENJI KAMIDE, YUJI TSUKADA, SUSUMU KURIHARA, *Department of Physics, Waseda University, 3-4-1, Okubo, Shinjuku, Tokyo 169-8555* We study the renormalization flow of a single impurity potential of arbitrary strength in a Tomonaga-Luttinger liquid (TL). It is known that an impurity potential in TL is effectively renormalized by electron-electron interaction, with different manners in weak and strong potential limits for spin dependent models $K_s \neq 1$. This fact strongly suggests that the fixed points of an impurity potential should shift as varying potential strength. In order to determine the scaling fixed points at arbitrary potential strength, we extend boundary bosonization scheme to the problem of arbitrary potential strength, and calculate the local density of states (LDOS) as a function of temperature and distance from the impurity. The impurity scaling flow is determined from the ratio between LDOS at the boundary and in the bulk. For $K_s = 1$, the phase boundary is given by $K_\rho = 1$ irrespective of the potential. For $K_s \neq 1$, we find that the fixed points shift from $K_\rho \sim 2 - K_s$ to $K_\rho = 1/K_s$ as increasing the potential strength from 0 to $\infty$. We also discuss how the scaling behavior appears in transport experiments.

**P31 11 Adsorbed monolayers on suspended single-walled carbon nanotubes** ZENGHUI WANG, JIANG WEI, ROBERT DORMAIER, OSCAR VILCHES, DAVID COBDEN, *University of Washington* A monolayer of adsorbates on a single-walled carbon nanotube presents the possibility of extending earlier studies of two-dimensional monolayer systems on graphite to the quasi-one-dimensional regime, by effectively imposing cylindrical boundary conditions. The monolayer can be detected either via its effect on the nanotube's conductance or by using the nanotube itself as a vibrating microbalance. Many adsorbates are known to affect the conductance, through a variety of mechanisms. Amongst these are $O_2$ and the noble gases Xe and Kr, whose phases and ordering on 2D graphite are well known. Our experiments so far have indicated that the presence of an $O_2$ layer on a nanotube close to liquid nitrogen temperatures can be detected using a threshold shift. We are now fabricating individual suspended nanotube devices with the initial aim of studying cylindrical commensurability effects on the phases of noble gases using the microbalance technique.

**P31 12 Superplastic single-walled carbon nanotubes** J.Y. HUANG, S. CHEN, Z. WANG, K. KEMPA, S.H. JO, *Department of Physics, Boston College, Chestnut Hill, MA 02467* Y.M. WANG, *Lawrence Livermore National Laboratory, Livermore, CA 94550* G. CHEN, *Department of Mechanical Engineering, MIT, Cambridge, MA 02139* M.S. DRESSELHAUS, *Department of Physics, Electrical Engineering and Computer Science, MIT, Cambridge, MA 02139* Z.F. REN, *Department of Physics, Boston College, Chestnut Hill, MA 02467* Theoretical prediction on the maximum achievable tensile strain of a single-wall carbon nanotube (SWCNT) is less than 20%, but experiments indicate a much lower attainable strain of less than $\sim$ 6%. Here we report that, at temperatures of above 2000[r]C, SWCNTs deform superplastically, with a tensile elongation to failure nearly 280%, and a diameter reduction of fifteen times. With this remarkable dimension change, the electronic property changes correspondingly from a metal with a pseudogap to a semiconducting state with a tunable gap up to 2 eV. Such superplastic deformation originates from plastic deformation mechanism dominated by the nucleation and motion of the kinks as well as atom diffusion in SWCNTs at high temperatures. Variable range hopping conduction is observed in the localized state due to scattering by point defects and kinks in the quasi-one-dimensional system.

**P31 13 Unoccupied electronic states of Multiwall Carbon Nanotubes Arrays** PATRICIO HÄBERLE, SAMUEL HEVIA, RODRIGO SEGURA, WLADIMIR IBÁÑEZ, *Universidad Técnica Federico Santa María, Valparaíso, Chile* We have grown multiwall carbon nanotube (MWCNT) arrays by CVD both from pyrolysis of Fe-Phthalocyanine and decomposition of Acetylene on Fe covered $SiO_2$/Si(111) substrates. The characteristic diameter of the tubes is 50 nm for both type of samples. Even though the films show good alignment in the bulk, they do present some disorder of the tubes at the top of the films. Inverse photoemission spectra from these samples are similar to those obtained from HOPG. The main differences are in: the non existence of what has been recognized as an image charge state on graphite and some additional intensity very close to the Fermi level ($\varepsilon_F$). A similar intensity has been measured previously by photoemission in a symmetrical position with respect to $\varepsilon_F$. This increased metallic character could, at this point, be interpreted as defects from the closure of the tubes or as a manifestation of van Hove oscillations in the unoccupied density of states.

**13:51**

**P31 14 Electrostatics of Straight and Wiggly Nanotubes in External Electric Field*** MIKHAIL RAIKH, EUGENE MISHCHENKO, *University of Utah* Distribution of charge induced in a straight nanotube (NT) by external electric field parallel to the NT axis is found as a function of the NT length and radius. As the voltage drop along the NT exceeds the gap, positive and negative charge regions emerge at the NT ends. These regions are separated by a neutral strip at the NT center. External field is unscreened within the neutral strip, while it is strongly suppressed outside the strip. For a NT of a wiggly shape, the induced charge distribution represents alternating positively and negatively charged regions separated by neutral strips.

**11:15**

**P32 1 Effects of high magnetic fields on the spin-glass states in disordered manganites** NOBORU MIURA, PETER KERSCHL, NADJA V. KOZLOVA, KONSTANTIN NENKOV, KATHRIN DOERR, *IFW, Dresden, Germany* ALEXANDER KIRSTE, MICHAEL VON ORTENBERG, *Humboldt University, Berlin, Germany* DAISUKE AKABOSHI, YASUHIDE TOMIOKA, YOSHINORI TOKURA, *CERC, AIST, Tsukuba, Japan* IFW, DRESDEN TEAM, HUMBOLDT UNIVERSITY, BERLIN TEAM, CERC, AIST, TSUKUBA TEAM, Magnetization and magnetoresistance were measured in single crystals of random alloys $RE_{1-x}AE_xMnO_3$ (RE and AE denote the rare-earth and alkaline-earth ions at the perovskite A-site) in pulsed high magnetic fields up to 50 T with a long time duration ( $\sim$ 10 ms) and up to 140 T with a short time duration ( $\sim \mu$s). The crystals exhibit the spin glass behaviors at low temperatures in zero field. In high magnetic fields, $Sm_{1-x}(Ba_{1-y}Sr_y)_xMnO_3$ showed prominent metamagnetic transitions, whereas $RE_{1-x}Ba_xMnO_3$ (RE=Sm, Eu, Gd) showed a smooth magnetization saturation with just kinks in the derivative of the magnetization. Moreover, in the metamagnetic phase transitions, peculiar time dependence and the prehistory dependence were found in the hysteresis of the magnetization. It was also found that the magnetization is accompanied with a colossal magnetoresistance. These behaviors were interpreted in terms of the developments of the clusters and the orbital orders by magnetic fields, which are dependent on the average A-site ionic radius and the randomness.

**P32 2 What is new for spin-glass in a quasi-2D system*** WEI BAO, *Los Alamos National Lab* YING CHEN, *NIST* YIMING QIU, *NIST* J.E. LORENZO, *CNRS Grenoble* J.L. SARRAO, *Los Alamos National Lab* DEREK HO, *NIST* MIN Y. LIN, *NIST* In conventional spin glasses, magnetic interaction is not strongly anisotropic and the entire spin system is believed to be frozen below the spin-glass transition temperature. Along *any* direction, spin correlations are highly disordered. In $La_2Cu_{0.94}Li_{0.06}O_4$, for which the in-plane exchange interaction dominates the interplane one, only a fraction of spins with antiferromagnetic correlations extending to neighboring planes become spin-glass. The remaining spins with only in-plane antiferromagnetic correlations remain spin-liquid at low temperature. Spin correlations are highly disordered only along the interlayer direction, but highly ordered in-plane. Such a novel partial spin freezing out of a two-dimensional spin-liquid observed in this cold neutron scattering study is likely due to a delicate balance between disorder and quantum fluctuations in the quasi-two dimensional $S=1/2$ Heisenberg system.

**P32 3 Spin Glasses at the Bond Percolation Threshold*** EMILIANO MARCHETTI, STEFAN BOETTCHER, *Physics Department, Emory University, Atlanta GA* Low energy excitations for the Edwards-Anderson model on hyper- cubic lattices at the bond percolation threshold $p_c$ are investigated. At $T = 0$, $p_c$ separates paramagnetic and spin glass phases. At the ''edge'' of the ordered state, these excitations are characterized by a distinct scaling exponent. This exponent allows to determine the shape of the phase boundary, $T_c(p) \sim (p - p_c)^{\phi}$, for $p \to p_c^+$, which is experimentally measurable in $d = 3$. At $p_c$, very large spin glass systems can be studied with an *exact* reduction algorithm[1] to produce accurate scaling behavior. For more information, see http://www.physics.emory.edu/faculty/boettcher/

**P32 4 Spin-glass correlations in classical dipoles** VADIM OGANESYAN, *Yale University* We present analytic mean-field and high-temperature expansion results on thermodynamics of classical Ising dipoles in the strongly diluted regime. These display a broad distrubution of couplings resulting in strong enhancement of the spin-glass transition temperature from the naive estimate. We comment on reliability of these results and their relationship to other approaches.

**12:03**

**P32 5 Computing Barriers in Spin Glasses** A. ALAN MIDDLETON, *Syracuse University* The energy barriers $E_B$ between low-lying states in spin glasses are expected to scale as a power of the system size: $E_B \sim N^{\psi/d}$ for $N$ spins in a $d$-dimensional spin glass. Whether the barrier exponent $\psi$ is equal to the stiffness exponent $\theta$ (where the cost of minimal large scale excitations scales as $N^{\theta/d}$) is an unsolved question in general. In an attempt to solve this question with some rigor in large theoretical spin glass samples, numerical simulations for barriers in spin glasses on a hierarchical lattice have been carried out, using an exact algorithm for computing the barrier to the monotone growth of connected domains. The resulting $\psi$ is sensitive to the distribution of weights on the bonds between spins. These distributions give different weights to bonds that appear at different stages of the hierarchical generation of the lattice. Results for $\psi$ and $\theta$ will be presented for various lattices, including variations of Cayley trees and lattices that satisfy Migdal-Kadanoff approximations, and distributions that plausibly emulate finite-dimensional spin glasses.

**P32 6 The End of Aging in a Spin Glass** GREGORY KENNING, *Department of Physics, Indiana University of Pennsylvania* GILBERTO RODRIGUEZ, *Department of Physics, University of California Riverside* RAYMOND ORBACH, *Department of Energy, Office of Science* Aging phenomena in complex systems has been used as an important tool to investigate the physics of complexity. In particular aging effects in spin glasses, measured using the Thermoremenant Magnetization (TRM) decays, have been instrumental as a probe of complex equilibrium and non-equilibrium dynamics. Current theoretical and experimental analysis suggest that the TRM decay of spin glasses is mainly composed of two terms; The ''stationary'' term which does not depend on the sample history and dominates the short time decay ( $<$ 1s) and a long time aging term which depends on the samples history. We report finding that aging found in spin glass materials, has a finite lifetime and that after aging has ended there is a third component of the magnetization decay. This decay is independent of the waiting time, logarithmic in nature and part of the same mechanism that produces aging. Finally we find that the logarithmic decay

implies a maximum aging time (MAT) that is very strongly dependent on temperature and ranges from short times near the spin glass transition temperature to many times the current best estimates of the age of the universe for low temperature.

**12:27**

**P32 7 Memory and aging effect in hierarchical spin orderings of stage-2 $CoCl_2$ graphite intercalation compound** MASATSUGU SUZUKI, ITSUKO SUZUKI, *SUNY-Binghamton* MOTOHIRO MATSUURA, *Fukui University of Technology* Stage-2 $CoCl_2$ graphite intercalation compound undergoes two magnetic phase transitions at $T_{cl}$ (= 7.0 K) and $T_{cu}$ (= 8.9 K). The aging dynamics of this compound is studied near $T_{cl}$ and $T_{cu}$. The intermediate state between $T_{cl}$ and $T_{cu}$ is characterized by a spin glass phase extending over ferromagnetic islands. A genuine thermoremnant magnetization (TRM) measurement indicates that the memory of the specific spin configurations imprinted at temperatures between $T_{cl}$ and $T_{cu}$ during the field-cooled (FC) aging protocol can be recalled when the system is re-heated at a constant heating rate. The zero-field cooled (ZFC) and TRM magnetization is examined in a series of heating and reheating process. The magnetization shows both characteristic memory and rejuvenation effects. The time ($t$) dependence of the relaxation rate $S_{ZFC}(t) = (1/H)\mathrm{d}M_{ZFC}(t)/\mathrm{dln}t$ after the ZFC aging protocol with a wait time $t_w$, exhibits two peaks at characteristic times $t_{cr1}$ and $t_{cr2}$ between $T_{cl}$ and $T_{cu}$. An aging process is revealed as the strong $t_w$ dependence of $t_{cr2}$. The observed aging and memory effect is discussed in terms of the droplet model.

**P32 8 Bose glass vs. Mott glass in site-diluted S=1 Heisenberg antiferromagnets** TOMMASO ROSCILDE, *Max-Planck-Institut fuer Quantenoptik - Germany* STEPHAN HAAS, *Department of Physics and Astronomy - USC* Making use of large-scale quantum Monte Carlo simulations, we investigate the ground-state phase diagram of the square-lattice S=1 Heisenberg antiferromagnet with strong single-ion anisotropy and in presence of site-dilution of the magnetic lattice. Mapping the spins onto Holstein-Primakoff bosons, the single-ion anisotropy is seen to play the role of a repulsive on-site potential for the bosons. The clean limit of the model shows an anisotropy-driven quantum phase transition from an XY ordered (superfluid) phase to a quantum disordered (Mott insulating) phase. A similar transition is also driven by the application of a uniform field on the disordered state. Adding site dilution to the model, the non-trivial interplay between quantum fluctuations and lattice randomness gives rise to a novel quantum-disordered Mott-glass phase in zero field, with a gapless spectrum and yet a vanishing uniform susceptibility. Upon applying a field, such phase is turned into a Bose glass, with gapless spectrum and finite susceptibility. The above picture is directly relevant for experiments on doped quasi-low-dimensional Ni compounds, such as the recently investigated $NiCl_2$-4SC$(NH_2)_2$ (V.S. Zapf et al., condmat/0505562).

**12:51**

**P32 9 Impurity effects on frustrated ferro- and ferrimagnets in one dimension** MASANORI KOHNO, XIAO HU, *Computational Materials Science Center, National Institute for Materials Science, Tsukuba 305-0047, Japan* We have investigated impurity effects on magnetization for frustrated one-dimensional ferro- and ferrimagnets. Using the density-matrix renormalization group method and the exact diagonalization method, we confirmed that the magnetization decreases significantly by doping non-magnetic impurities. In a special case, the magnetization can vanish due to a single impurity in finite chains. Introducing the picture of magnetic domain inversion, we numerically investigated the impurity-density dependence of magnetization. In particular, we show that the magnetization substantially decreases down to less than 60% from that of the corresponding pure system by doping an infinitesimal density of impurities. We also formulate conditions for the materials which may show this anomalous impurity effect.

**13:03**

**P32 10 Frustrating interactions in oxides induced by non-magnetic impurities** SHIU LIU, *University of California, Irvine* SASHA CHERNYSHEV, *University of California, Irvine* An antiferromagnetic host material doped with non-magnetic impurities, such as Zn-doped $La_2CuO_4$, is generally believed to represent an excellent model case of the site-dilution of a magnetic substance. We demonstrate that there exist a significant qualitative correction to such a picture: an impurity can induce substantial frustrating interactions between spins that are nearest neighbors of the impurity site. Not only this effect explains discrepancies between experimental data and the site-dilution theory, but it could also lead to some important modification of the behavior of doped antiferromagnets close to the percolation. We study the 2D, $S = 1/2$ copper-oxide plane with Zn impurities starting from the microscopic three-band Hubbard model. We show that, for a wide range of the model parameters, the substantial superexchange interactions between the next- and next-next-nearest neighbor Cu spins around the impurity site can be generated via the virtual transitions through the oxygen orbitals. Surprisingly, the interaction across the impurity $J''_{Zn}$ is greater than the next-nearest neighbor interaction $J'_{Zn}$ due to a partial cancellation of the super- and the cyclic exchanges for the latter. This study is completed by the $T$-matrix calculation of the staggered magnetization $M(x)$ as a function of Zn doping $x$. The predicted range of $J'_{Zn}$ and $J''_{Zn}$ agrees with the values needed to explain experimental deviation of $M(x)$ from the results of the site-dilution theories.

**P32 12 Charge degrees of freedom in frustrated lattices** JOSEPH BETOURAS, *Lorentz Institute, University of Leiden* FRANK POLLMAN, *Max Planck Institute for Physics of Complex Systems, Dresden, Germany* KIRILL SHTENGEL, *Department of Physics, University of California Riverside* PETER FULDE, *Max Planck Institute for Physics of Complex Systems, Dresden, Germany* We explore systematically the charge degrees of freedom in frustrated lattices. A model of spinless fermions on a checkerboard lattice with nearest-neighbor hopping t and Coulomb repulsion V is used at half and quarter fillings. Quantum fluctuations reduce the classical macroscopic degeneracy. For the strongly correlated limit V >> t, an added electron decays into two quasiparticles with fractional charge. We study the classical correlations and, by means of quantum field theory as well as axact diagonalisation, we also investigate the possibility of a confined or deconfined phase as well as the statistics of these quasiparticles.

**13:39**
**P32 13 Probing the Almeida-Thouless line away from the mean-field model** HELMUT G. KATZGRABER, *Theoretische Physik, ETH Zurich* A. PETER YOUNG, *University of California Santa Cruz* In order to test the existence of a spin-glass phase in a field at finite temperatures, results of Monte Carlo simulations of the one-dimensional long-range Ising spin glass with power-law interactions in the presence of a (random) field are presented. By tuning the exponent of the power-law interactions, we are able to scan the full range of possible behaviors from the infinite-range (Sherrington-Kirkpatrick) model to the short-range model. A finite-size scaling analysis of the correlation length indicates that there is no transition in a field with non-mean field critical behavior at zero field. This suggests that there is no Almeida-Thouless line for short-range Ising spin glasses away from the mean-field regime.

**P33 1 Atomistic Simulation of Size Effects in Bending a Single Crystal*** N. SCOTT WEINGARTEN, *The Catholic University of America* ROBIN SELINGER, *Kent State University* We perform atomistic Monte Carlo simulations of bending a Lennard-Jones single crystal in two dimensions. In examining initial yield, we find an apparent ''reverse'' size effect. However, when strain rate effects are taken into account, we demonstrate that the size effect disappears. Once geometrically necessary dislocations coalesce to form grain boundaries, we observe a size effect of the usual kind, e.g. smaller samples support a higher scaled bending moment than larger samples. We compare simulation results with recent experiments on bending of highly annealed nanowires [B. Wu et al, Nature Matls 4, 525, 2005.] Finally, we observe a topological instability in the evolution of a grain boundary intersecting a free surface under compressive stress. The grain boundary buckles and nucleates a protruding grain, suggesting a novel mechanism for the formation of a hillock on a compressed metal surface.

**11:27**
**P33 2 Analytical calculation of energy barrier for dislocation nucleation from a crack tip** SERGIO PICOZZI, *George Washington University* ROBIN SELINGER, *Kent State University* In a ductile material a crack subjected to a subcritical applied load may respond by emitting dislocations via thermal activation. Computer simulations show the activation energy to be strongly dependent on the applied stress. To understand this result we use conformal mapping techniques to analyze the interaction of a straight screw dislocation with a parallel crack in a strip geometry. The energy barrier for dislocation escape from the crack tip is calculated explicitly and it is found to be a sensitive function of the applied stress, in qualitative agreement with simulation results. Scaling properties of the activation energy are also determined. This analytical result permits us to formulate hypotheses regarding the factors controlling the observed strain rate. To test such hypotheses we finally calculate the strain rate as a function of temperature and applied stress and compare our results with observations.

**11:39**
**P33 3 XRay Scattering in a Deformed Crystal by a Phase Field Method** ROBB THOMSON, *retired* MARISOL KOSLOWSKI, *Purdue Univ.* RICHARD LESAR, *LANL* We demonstrate the use of a phase field method for dislocated crystals, developed by one of us, for computing the scattering of Xrays. The model addresses deformation on a single slip plane by dislocations of a single burgers vector interacting with a set of point obstacles. The obstacles are introduced in two modes; one randomly on the slip plane, and the second in straight ''walls.'' The obstacles simulate blocking interactions by dislocations on different slip planes, and the ''walls'' represent the intersection of a secondary slip plane with the primary plane being simulated. In the small angle case, the scattering source is the local dilatation induced by the dislocations on the slip plane, and in the Bragg case, the scattering source is the change in local lattice constant. The small angle results show scattering with oscillations attributable to the width of the ''walls.'' In the Bragg case, the Laue spots are broadened by the dislocations, and the results directly confirm the picture of dipolar wall scattering introduced many years ago by H. Mughrabi.

**11:51**
**P33 4 Atomistic Dislocation Dynamics in Phase Field Crystals: Long Time Scale Properties** JOEL BERRY, *McGill University* K.R. ELDER, *Oakland University* MARTIN GRANT, *McGill University* The fundamental dislocation processes of glide, climb, and annihilation are studied on diffusive time scales within the framework of a continuum field theory, the Phase Field Crystals (PFC) model. Glide and climb are examined for single edge dislocations subjected to shear and compressive strain, respectively, in a two dimensional hexagonal lattice. It is shown that the natural features of these processes are reproduced without any explicit consideration of elasticity theory or ad hoc construction of microscopic Peierls potentials. Particular attention is paid to the Peierls barrier for dislocation glide/climb and the ensuing dynamic behavior as functions of strain rate, temperature, and dislocation density.

It is shown that the dynamics are accurately described by simple viscous motion equations for an overdamped point mass, where the dislocation mobility is the only adjustable parameter. The critical distance for the annihilation of two edge dislocations as a function of separation angle is also presented.

**12:03**
**P33 5 Studies of the Dislocation Glass** GERGELY ZIMANYI, *UC Davis* BOTOND BAKO, ISTVAN GROMA, GEZA GYORGYI, *Eotvos Lorand University, Budapest, Hungary* We report the large scale simulations of 2D dislocation systems with overdamped dynamics. 40,000-1,000,000 dislocations were studied with a combination of coarse graining, Fast Fourier Transform and stochastic methods. Both glide and climb processes were considered, as well as the local rotation of crystal axes. Simulations were performed at zero and finite temperatures, with and without dislocation annihilation. When climb processes were included, the system exhibited the formation of dislocation cells/patterns even in equilibrium, without the application of shear. This is in close correspondence with recent experiments on GaAs by P. Rudolph et al. (2005). The distribution function of cell sizes can exhibit a fractal dimension. At long times the system shows glassy dynamics. In particular, aging was observed through the waiting time dependence of the correlations and the effective diffusion. In certain parameter ranges the formation of cells leads to an initial exponential decay of correlations. This is followed by the growth of cells, generating a power law temporal decay in the long time domain. Data for both time domains and for all waiting times can be collapsed onto a single master curve when a t/tw scaling is applied.

**12:15**
**P33 6 Nonlinear acoustic effects from dislocation-based hysteretic kinking solids under stresses** PETER FINKEL, *Thomson/Rowan University* MATHIEU FRASCZKIEWICZ, *Drexel University* MICHEL BARSOUM, *Drexel University* We argue that proposed recently mechanism explaining inelastic hysteresis in non-linear elastic systems indeed can be explained by means of formation of dislocation-based incipient kink bands (IKB). Using acoustic waves we investigated possible dislocation related mechanisms responsible for nonlinear dynamic response of IKB solids. In this work, for the first time we observed IKB formation and reversibility directly using acoustic coupling technique (ACT) measuring ultrasonic waves attenuation as a function of stress and acoustic emission signatures during compression test of nanolaminated layered ternary carbide (MAX phases) samples. We confirm here that the dynamic behavior of these non-linear elastic systems is due to the interaction of dislocations with the stress waves.

**P33 7 Simulations of Nano-indentation and Shear Banding in Amorphous Solids.**
MICHAEL FALK, *University of Michigan, Department of Materials Science and Engineering*

Molecular dynamics simulations of a number of amorphous systems reveal the structural changes that accompany plastic localization. We have simulated both two-dimensional and three-dimensional systems in nanoindentation[1], uniaxial tension[2] and compression in plane strain[3]. The degree of strain localization depends sensitively on the quench rate during sample preparation, with localization only arising in more gradually quenched samples. Careful analysis of the strain rate dependence of the localization allows us to extrapolate to the low strain rate limit. This analysis reveals a transition from localized flow to homogeneous flow at a critical value of the potential energy per atom prior to testing. This transition occurs in both two- and three- dimensional systems. The transition appears to be associated with the k-core percolation of short range order (SRO) in the two-dimensional system[2]. We have used a generalization of the Frank-Kasper criterion to identify SRO in the three-dimensional systems. Only in certain systems does this method predict a percolation transition corresponding to the transition in mechanical behavior. We discuss the non-uniqueness of this measure of SRO, and consider whether a more rigorous definition could be derived which applies to systems far from the hard-sphere limit.

**P33 8 A statistical model of plastic deformation in disordered media** MEHDI TALAMALI, DAMIEN VANDEMBROUCQ, STÉPHANE ROUX, *Unité Mixte CNRS/Saint-Gobain* Plastic deformation at the macroscopic scale is assumed to stem from series of successive localized plastic events. A random elastic limit is associated to each site of a discrete mesh. Using a quasi-static driving, one site at a time undergoes plastic shear. The local plastic threshold is then renewed. The localized slip induces long range elastic interactions of quadrupolar symmetry. These additional internal stresses are then used to determine the next weakest site. The model gives rise to a macroscopic plastic flow, corresponding to a genuine depinning transition. We obtain an asymptotic macroscopic yield stress. The transient regime can be associated to a hardening phenomenon of pure statistical origin. Beyond the average plastic behavior we observe stress fluctuations following a universal distribution (only dependent on the system size $L$). Shear deformation presents at all scales spatial and temporal fluctuations of universal character. We observe shear band-like structures which persist only during a finite time $\tau \propto L^{z}$ and which present a clear anisotropic character with a system size dependent width $w \propto L^{\zeta}$.

**P33 9 Scaling laws in fracture of metallic glasses** X.K. XI, *Department of Physics and Astronomy, University of North Carolina, Chapel Hill, North Carolina 27599-3255, USA* D.Q. ZHAO, M.X. PAN, W.H. WANG, *Inst Phys, Chinese Academy of Sciences, Beijing 100080, China* Y. WU, *Department of Physics and Astronomy, University of North Carolina, Chapel Hill, North Carolina 27599-3255, USA* J.J. LEWANDOWSKI, *Dept. of Mater Sci & Eng, Case Western Reserve University, 10900 Euclid Avenue, 44106 Cleveland, Ohio, USA* Brittle metallic glasses themselves can be seen as a model system to study the mechanical properties of metallic based glassy materials. We report a brittle Mg-based bulk metallic glass which approaches the ideal brittle behavior. However, a dimple-like structure is observed at the fracture surface by high resolution scanning electron microscopy, indicating some type of 'ductile' fracture mechanism in this very brittle glass. We also show a clear scaling correlation between the fracture toughness and plastic process zone size for various glasses. The results indicate that the fracture in brittle metallic glassy materials might also proceed through the local softening mechanism but at different length scales. The full text of this work has been published under the title itFracture of Brittle Metallic Glasses: Brittleness or Plasticity by the authors in Physical Review Letters 94, 125510 (2005).

**P35 1 Atomic-Scale Modeling of Shape Stability-Regimes and Stacking in InAs/GaAs Quantum Dot Nanostructures** THOMAS HAMMERSCHMIDT, PETER KRATZER, MATTHIAS SCHEFFLER, *Fritz Haber Institute of the Max Planck Society, Faradayweg 4-6, 14195 Berlin, Germany* From a thermodynamic point of view, quantum dot (QD) growth is governed by the balance between energy gain due to strain relief and energy cost due to formation of QD side facets and edges. Both contributions are accounted for by an interatomic potential of the Abell-Tersoff type that we developed recently. We relax realistic InAs/GaAs QD nanostructures using this interatomic potential and compare the resulting total energies. To investigate the experimentally observed shape sequence of 'hut'-like QD's dominated by {317} facets and 'dome'-like QD's dominated by {101} facets, we compare the energy of a homogenous InAs film and differently sized InAs QD's with either shapes. We identify three regimes: For coverages below about 1.9 monolayers InAs the film is most stable, followed by small 'hut'-like QD's and larger 'dome'-like QD's. This is in line with the experimentally deduced critical coverage for the 2D to 3D growth transition, and the shapes of small and larger QD's. We can also explain the growth correlation in QD stacks: Our calculated potential-energy surfaces of free-standing QD's in different lateral positions above overgrown QD's show an energy gain of about 20 meV per In atom for the experimentally observed vertical QD alignment.

**11:27**

**P35 2 Raman Spectroscopy of InAs/GaAs Quantum Dots Patterned by Nano-indentation** MARTIN MUNOZ, *Physics Department, Virginia Commonwealth University* LINDSAY HUSSEY, *Physics Department, Virginia Commonwealth University* DURIG LEWIS, *Physics Department, Virginia Commonwealth University* CURTIS TAYLOR, *Mechanical Engineering Department, Virginia Commonwealth University* EUCLYDES MAREGA, *Department of Physics, University of Arkansas* AJAY MALSHE, *Mechanical Engineering Department, University of Arkansas* Patterns of InAs/GaAs quantum dots (QDs) grown by the combination of nanoindentation technique and molecular beam epitaxy were studied. The resulting QDs tend to preferentially nucleate on indented areas rather than other regions. We studied the strain on the indentations, regions surrounding the indents, and non-indented areas. The QD LO mode for the patterned areas shifted by 8 cm-1 when compared to the non-patterned area. The biaxial strain in the indented areas producing this shift is four times larger than that in non-indented areas, explaining the QD preference within these areas. This larger strain suggests that QDs on the indentations can be formed by depositing a smaller InAs amount than that required to form QDs on non-indented areas, thus obtaining QDs only on the pattern.

**11:39**

**P35 3 Self-Assembled Unstrained InGaAs Quantum Dashes** ALEXANDER UKHANOV, *US Naval Research Laboratory* ALLAN BRACKER, GEORO BOISHIN, JOE TISCHLER, JIM CULBERTSON, We describe a technique for MBE-based fabrication of unstrained quantum dashes with $Al_xIn_yGa_{1-x-y}As$ alloys lattice-matched to InP substrates. Templates for lattice-matched quantum dash growth are obtained by combining molecular beam epitaxy with itin situ etching by arsenic bromide. A seed layer of self-assembled InAs quantum dashes is converted into nanotrench templates through overgrowth followed by strain-enhanced etching. We have explored limitations on the accessible range of alloy compositions imposed by the etch process and found that strain-induced etching is limited to compounds with low Al content. Nanotrench templates can be filled with lattice-matched alloys of varied compositions to define barriers and quantum wires that could lead to optoelectronic devices in a spectral range around 1.5 $\mu$m. Here we also present Atomic Force Microscopy and Photoluminescence data obtained from self assembled unstrained $In_{0.53}Ga_{0.47}As$ Quantum Dashes.

**11:51**

**P35 4 Microanalysis of quantum dots with type II band alignments** WENDY SARNEY, JOHN LITTLE, STEFAN SVENSSON, *US Army Research Laboratory* We will discuss the structural characterization of a system consisting of undoped self-assembled InSb quantum dots having a type II band alignment with the surrounding $In_{0.53}Ga_{0.47}As$ matrix. This differs from systems using conventional type-I quantum dots that must be doped and that rely on intersubband transitions for infrared photoresponse. Type II dots grown in a superlattice structure combine the advantages of quantum dots (3-dimensional confinement) with the tunability and photovoltaic operation of the type II superlattice. We grew a high surface density of InSb quantum dots with a narrow distribution of sizes and shapes and free of dislocations within the body of the dots. The dots are relaxed due to an array of misfit dislocations confined at the basal dot/matrix interface. This makes burying the dots with InGaAs not feasible without generating dislocations due to the large dot/matrix lattice mismatch. We are experimenting with strain-compensating or graded strain overlayers to lower the lattice mismatch.

**12:03**

**P35 5 Feasibility Study of Directed Self-Assembly of Semiconductor Quantum Dots** LAWRENCE FRIEDMAN, JIAN XU, *Pennsylvania State University* Strain mismatched semiconductors are used to form Self-Assembled Quantum Dots (SAQDs). An important step in developing SAQD technology is to control randomness and disorder in SAQD arrays. There is usually both spatial and size disorder. Here, it is proposed to use spatially varying heating as a method of to direct self-assembly and create more ordered SAQD arrays or to control placement of single dots or dot clusters. The feasibility of this approach is demonstrated using a 2D computational model of Ge dots grown in Si based on finite element analysis of surface diffusion and linear elasticity.

**12:15**

**P35 6 Controlling the self-assembly of Ge quantum dots grown by pulsed laser deposition** MOHAMMED HEGAZY, HANI ELSAYED-ALI, *Old Dominion University* Growth dynamics and morphology of self-assembled Ge quantum dots (QD) on Si(100)-(2x1) by nanosecond pulsed laser deposition are studied by in situ reflection high-energy electron diffraction (RHEED) and post deposition atomic force microscopy (AFM). The effects of the laser fluence and substrate temperature on the QD formation are investigated. The QD density increased dramatically (from $3\times 10^7$ $cm^{-2}$ to $6.3\times 10^8$ $cm^{-2}$), while the average lateral size decreased (from 362 nm to 107 nm) when the laser fluence was increased from 23 J/$cm^2$to 70 J/$cm^2$. Their shape also changed from large huts, observed at 23 J/$cm^2$, to domes observed at the highest fluence. At 150° C, misaligned QDs formed resulting in diffused RHEED pattern. At 400° C and 500° C, transmission RHEED patterns were observed indicating the growth of oriented hut and dome QDs. Around 600° C, the QDs were formed on top of textured surfaces.

**12:27**

**P35 7 Defect engineering in periodic gradient-index optical thin films** MATTHEW HAWKEYE, ANDY VAN POPTA, JEREMY SIT, MICHAEL BRETT, *University of Alberta* For thin film deposition with obliquely incident vapour flux, ballistic shadowing limits growth to nucleation sites, forming a porous columnar microstructure. Combined with advanced substrate rotation in a technique known as glancing angle deposition (GLAD), precisely controlled nanoscale architectures are formed. In situ variation of the angle of incidence provides dynamic control of the resulting film porosity, allowing the design of continuously varying periodic refractive index profiles to produce thin film interference filters. Intentional nanostructural defects can be introduced, such as uniaxial and biaxial constant index layers or index profile discontinuities, creating defect modes in the filter optical stopbands. Structural and optical characterizations of these periodic structures were performed, with the goal of understanding the relationship between the spectral properties of the film and the engineered nanostructure, demonstrating the high degree of control obtainable over the resulting filter properties using the GLAD process.

**12:39**

**P35 8 Strontium titanate transformation to highly conductive nanolayers** VLADIMIR BUTKO, *Brookhaven National Laboratory* DAVID REAGOR, *Los Alamos National Laboratory* Developing fabrication methods for electronically active nanostructures is an important challenge of modern science and technology. Fabrication efforts for crystalline materials have been focused on state-of-the-art epitaxial growth techniques. These techniques are based on deposition of precisely controlled combinations of various materials on a heated substrate. We report a method that does not require deposition and transforms a nanoscale layer of a complex crystalline compound into a new material using low energy Ion Beam Preferential Etching (IBPE). We demonstrate this method by transforming a widely used insulator model system, SrTiO3, into a transparent conductor. Most significantly, the resistivity decreases with decreasing temperature as 2.5 power of T and eventually falls below that of room temperature copper. These transport measurements imply a crystal quality in the conduction channel comparable to that obtained with the highest quality growth techniques. The universality of low energy IBPE implies wide potential applicability to fabrication of other nanolayers. David W. Reagor, Vladimir.Y. Butko, Nature Materials, v.4, 593, August 2005.

**12:51**

**P35 9 Dependency of quantum pumping on transmission mode and dot size** KAI-MING LIU, SHIH-YING HSU, *Department of Electrophysics, National Chiao Tung University, Hsinchu, Taiwan* We have used e-beam lithography to fabricate sub-micron metal gates on a two dimensional electron gas with mean free path on the order of several micrometers. Negative biases were applied to the metal gates to confine electrons in a small area ( $\sim \mu m^2$) forming a so-called quantum dot. Two quantum point contacts (QPCs) served the entrance and exit of electrons in the dot are located in line. Quantum charge pumping phenomena of the open dot in the absence of an external bias was observed using two independent ac voltages with the same frequency, $1\sim$ 80MHz, but a phase difference between them. Similar pumping results were reported by Marcus et al. earlier. However, due to the differences in the geometrical arrangements, the behaviors are somehow different including that our pumping current is one order more magnitude bigger and does not increase linearly with frequency for the entire measuring range. Moreover, we found that the pumping current seems increase with decreasing transmission mode numbers of the two QPCs. When the mode number goes to zero and the open dot transforms to closed dot, the pumping current vanishes. The results and measurements of the dependences of quantum charge pumping on transmission mode and dot size will be presented and discussed.

**13:03**

**P35 10 Local Density of States of a Quantum Point Contact Near Pinchoff** LINDSAY MOORE, DAVID GOLDHABER-GORDON, *Stanford University* Over the last decade, there has been great interest in how electrons flow through a quantum point contact (QPC) as it is just opened up, before a fully transmitting 1D conduction channel is available. Remarkably, there does not seem to be a smooth transition from tunneling to ballistic transport. Instead, a shoulder appears in the conductance versus channel width, at a conductance of roughly 0.7 times that of an open spin-degenerate channel. Experiments have built a consensus that this so-called ''0.7 structure'' is related to electron spin and electron-electron interaction, but the detailed description remains controversial. To study this system, we have made devices where one of the two QPC gates is actually a tunnel barrier to a third lead, fabricated on a GaAs/AlGaAs heterostructure. With this third lead, it is possible to probe the density of states in the QPC channel from the side as the QPC opens from pinchoff through the first channel. We acknowledge support from the ONR Young Investigator Program, Award No. N00014-01-1-0569 and a Research Corporation Research Innovation Award, No. RI1260.

**13:15**

**P35 11 Single electron transistors in GaN/AlGaN heterostructures.*** H.T. CHOU, D. GOLDHABER-GORDON, *Stanford Univeristy* M.J. MANFRA, *Bell labs* R.J. MOLNAR, *MIT* We study transport properties of two single-electron transistors (SETs) in a GaN/AlGaN heterostructure. The first SET accidentally formed in a quantum point contact near pinchoff. Its small size produces large energy scales: a charging energy of 7.5 meV, and well-resolved excited states. The second, intentionally-fabricated SET is much larger. Hundreds of consecutive, uniformly-spaced Coulomb oscillations yield a charging energy of 0.85 meV. Excited states are not resolvable in Coulomb diamonds, and Coulomb blockade peak height remains constant with increasing temperature, indicating that transport is through multiple quantum levels even at the 450 mK base electron temperature of our measurements.

*The work at Stanford was sponsored by the Office of Naval Research Young Investigator Program under award no. N00014-01-1-0569 and Packard Fellowship.

**13:27**

**P35 12 Current Biased Real Time Charge Detection in a Single Electron Transistor** KENNETH MACLEAN, SAMI AMASHA, DOMINIK ZUMBUHL, IULIANA RADU, MARC KASTNER, *Massachusetts Institute of Technology* MICAH HANSON, ARTHUR GOSSARD, *University of California, Santa Barbara* Measurements of charge fluctuations in an AlGaAs/GaAs single electron transistor (SET) are presented. The SET consists of a lateral quantum dot created by confining a two-dimensional electron gas using nanometer-size surface electrodes. The charge on the quantum dot is detected by changes in conductance of a nearby quantum point contact. We discuss noise and bandwidth characteristics of our charge detection method, which uses commercially available voltage amplifiers. Our real time charge detection capabilities are used to investigate charge dynamics on the SET in a magnetic field parallel to the two-dimensional electron gas. This work is supported by the U.S. Army Research Office under Contract No. W911NF-05-1-0062, by the National Science Foundation under Grant No. DMR-0353209, and in part by the NSEC Program of the National Science Foundation under Award No. PHY-0117795.

**13:39**

**P35 13 Real Time Electron Hopping Phenomena in a Single-Electron Transistor** SAMI AMASHA, KENNETH MACLEAN, DOMINIK ZUMBUHL, IULIANA RADU, MARC KASTNER, *Massachusetts Institute of Technology* MICAH HANSON, ARTHUR GOSSARD, *University of California, Santa Barbara* Utilizing a current-biased quantum-point-contact charge sensor, we observe electrons hopping on and off a AlGaAs/GaAs single-electron transistor (SET) in real time. An electron tunnels between the extended states in the leads and the lowest-energy state localized in the lateral quantum dot created by nanometer-size surface electrodes. We observe changes in the tunneling rates, caused by the spin splitting in a magnetic field B applied parallel to the 2DEG. We have also observed single-electron photo-ionization of the SET by application of microwave radiation. This work is supported by the ARO (W911NF-05-1-0062), the NSF (DMR-0353209) and in part by the NSEC Program of the NSF (PHY-0117795).

**13:51**

**P35 14 Shot noise and strong feedback effects in nanoelectromechanical systems** STEVEN BENNETT, *McGill University* AASHISH CLERK, *McGill University* Quantum nanoelectromechanical systems have attracted much attention recently, offering potential for applications as well as insight into fundamental physics. Using a quantum noise approach, we study theoretically a nanomechanical oscillator coupled to a superconducting single-electron transistor (SSET). Incoherent Cooper pair tunneling processes in the SSET can lead to a negative damping instability, where the oscillator's amplitude increases as it absorbs energy from the SSET[1]. Here, we focus on the current noise of the SSET in the negative damping regime, in which the growing amplitude of the oscillator becomes large enough that the motion of the oscillator and the dynamics of the SSET depend strongly on each other. We describe the inherent non-linearity of this regime using effective, energy-dependent damping and temperature, and discuss characteristic timescales for dynamics in the system. The current noise is of particular interest because it can be directly observed, and current experiments are probing this regime[2].

**P35 15 Finite size effects in the decay of metastable states in one-dimensional resonant tunneling structures*** OLEG TRETIAKOV, *Johns Hopkins University* KONSTANTIN MATVEEV, *Argonne National Lab* We study the current switching in a double-barrier resonant tunneling structure in the regime where the current-voltage characteristic exhibits intrinsic bistability, so that in a certain range of bias two different steady states of current are possible. Near the upper boundary $V_{th}$ of the bistable region the upper current state is metastable, and because of the shot noise it eventually decays to the stable lower current state. We find the time of this switching process in strip-shaped devices, with the width small compared to the length. The mean switching time $\tau$ increases exponentially as the bias $V$ is tuned inside the bistable region from its boundary value $V_{th}$. The one-dimensional geometry of the problem enables us to obtain analytically exact expressions for the exponential factor and to calculate the prefactor of $\tau$ for an arbitrary length of the strip. Furthermore, we evaluate the

mean time of switching in ring-shaped devices, with the widths small compared to their diameters.

**P36 1 Photoluminescence from a gold nanotip as an example of tabletop Unruh-Hawking radiation.** IGOR SMOLYANINOV, *University of Maryland* Conversion of zero-point quantum fluctuations into real thermal photons which may occur in a curved space-time is the main mechanism behind the Hawking radiation and the Unruh effect [1]. Up to date no experimental verification of these effects and the related dynamical Casimir effect has been reported. Here we argue that the recently observed infrared photoluminescence from a gold nanotip, which is mediated by surface plasmons (SP) propagating over a curved metal tip surface [2], constitutes an example of such zero-point to real photon conversion. Since SP wavelength may be very short, a surface plasmon wave packet propagating along a curved metal surface with radius of curvature $R \sim 1$ micrometer may be considered as a classical particle (this would correspond to the ray optics approximation). The centripetal acceleration of such particle may be as large as $a \sim c^2/R \sim 10^{22}g$. According to Ref. [1], such particle perceives vacuum as a bath of thermal radiation with temperature $T = \hbar a/2\pi kc \sim 1000K$. Nonlinear optical mixing of SPs with the thermal quanta from this bath looks like infrared photoluminescence in the laboratory reference frame. This work was supported in part by NSF grants ECS-0304046, CCF- 0508213 and ECS-0508275. [1] W.G. Unruh, Phys.Rev.D 14, 870 (1976). [2] M.R. Beversluis, A. Bouhelier, and L. Novotny, Phys.Rev.B 68, 115433 (2003).

**11:27**
**P36 2 Surface plasmon dielectric waveguides** CHRISTOPHER DAVIS, IGOR SMOLYANINOV, YU-JU HUNG, *University of Maryland* We demonstrate that surface plasmon polaritons can be guided by nanometer scale dielectric waveguides on top of a gold film. In a test experiment plasmons were coupled to a curved 3 micrometer radius dielectric stripe, which was 200 nm wide and 138 nm thick using a parabolic surface coupler. This experiment demonstrates that using surface plasmon polaritons the scale of optoelectronic devices based on dielectric waveguides can be shrunk by at least an order of magnitude.

**11:39**
**P36 3 Synthesis and Optical Properties of Star-shaped Gold Nanoparticles*** COLLEEN NEHL, *Physics and Astronomy Department, Rice University* HONGWEI LIAO, *Chemistry Department, Rice University* JASON HAFNER, *Physics and Astronomy, Chemistry Departments, Rice University* Here we describe the synthesis, structure, and optical properties of ca. 100 nm star-shaped gold nanoparticles. Seed mediated, surfactant directed synthesis yields nanoparticle solutions sufficiently monodisperse that extinction spectra reveal plasmon bands representative of their structure. Single particle spectroscopy measurements demonstrate that these nanoparticles exhibit multispectral, multidirectional polarized scattering. Through correlated structural characterization by electron microscopy, each scattering component can be assigned to the different points on the star-shaped structure. The plasmon resonances were also found to be extremely sensitive to the local dielectric encironment, yielding sensitivities as high as 1.41 eV photon energy shift per refractive index unit. These properties suggest that the star-shaped gold nanoparticles may be highly valuable for certain biosensing and microscopic imaging paradigms.

**11:51**
**P36 4 Nanorice: a new hybrid nanostructure** P. NORDLANDER, D. BRANDL, F. LE, H. WANG, N.J. HALAS, *Rice University* The plasmon hybridization method [1] is applied to nanorice, a new metallic nanostructure which combines the properties of two popular tunable plasmonic nanoparticle geometries: nanorods and nanoshells. The particle consists of a prolate spheroidal dielectric core and a thin metallic shell, bearing a remarkable resemblance to a rice grain. The nanorice particle shows far greater geometric tunability of the optical resonance, larger local field intensity enhancements and far greater sensitivity as a surface plasmon resonance (SPR) nanosensor than any previously reported dielectric-metal nanostructure. The tunability of the nanorice particle arises from the interaction of primitive plasmons associated with the inner and outer surfaces of the shell. The results from plasmon hybridization are compared to FDTD simulations. [1] E. Prodan and P. Nordlander, J. Chem. Phys. 120(2004)5444-5454

**12:03**
**P36 5 Photonic Crystal Effects in Surface Enhanced Raman Scattering from Nanocluster/Nanoshell Arrays*** KE ZHAO, *University of Tennessee* HONGXING XU, *Institute of Physics, Chinese Academy of Science & Lund University, Sweden* BAOHUA GU, *Oak Ridge National Laboratory* ZHENYU ZHANG, *Oak Ridge National Laboratory & University of Tennessee* We study the local optical properties of one-dimensional solid nanosphere dimer arrays with large array spacings, using the generalized Mie theory. We have obtained a large Raman cross section enhancement with magnitude of $10^{11}$ purely by electromagnetic effects, which is higher if compared with that of an isolated nanosphere dimer and in the literature. A coupled dipole approximation is used to understand this enhancement and the plasmon resonance shift relative to the isolated dimer. We have also studied the nanoshell dimer array and found even higher enhancement with magnitude of $10^{13}$. Our studies show that the nanoshell arrays with

proper spacings have clear advantages in single molecule surface enhanced Raman spectroscopy (SMSERS).

*Supported by DOE.

**12:15**

**P36 6 Strongly anisotropic optical composites** JUSTIN ELSER, *Oregon State University* EVGENII NARIMANOV, *Princeton University* VIKTOR PODOLSKIY, *Oregon State University* We study the macroscopic electromagnetic properties of nanostructured meta-materials formed by plasmonic nanowires embedded in a dielectric host. We show that nanowires have a significant effect on the effective dielectric constant of the system even in the case when their concentration is below 15%. The effect of dielectric properties of nanowires as well as the effect of inclusion concentration, shape and local configuration disorder on effective dielectric constant is explored via numerical simulations. Further, we develop an analytical description of the effective dielectric properties of nanowire composites and study the limit of its validity. We demonstrate that it is possible to use plasmonic nanowire composites to construct strongly anisotropic low-loss optical materials. Proposed applications include polarizers, reflectors, high-energy-density nano-waveguides, and the recently discovered non-magnetic low-loss left-handed media.

**12:39**

**P36 8 Role of Cylindrical Surface Plasmons in Enhanced Optical Transmission** MICHAEL HAFTEL, *Naval Research Laboratory* CARL SCHLOCKERMANN, GIRSH BLUMBERG, *Bell Laboratories, Lucent Technologies* We investigate the role of cylindrical surface plasmons in enhancing the optical transmission from nanoarrays of dielectric coaxial cylinders embedded in a metal film. Finite difference time domain (FDTD) simulations identify transmission peaks at long wavelengths as being associated with the fields produced by the individual coaxial cylinders, and these peaks move out to increasingly long wavelengths as the dielectric ring becomes narrower. An analysis of cylindrical surface plasmon dispersion relations show that these peaks are due to resonances from surface plasmons propagating on the cylindrical metal-dielectric interfaces whose wave functions increasingly overlap as the ring narrows. The counterintuitive behavior of the wavelength of the peak is a direct consequence of the negative dielectric constant of the metal film and would not occur for a perfectly conducting or dielectric film. This resonant surface plasmon mechanism closely accounts for the dependence of the position of the simulated transmission peaks on ring geometry and the length of the coaxial cylinders.

**12:51**

**P36 9 Plasmonic properties of non-concentric nanoshells** Y. WU, H. WANG, N.J. HALAS, P. NORDLANDER, *Rice University* The plasmon hybridization method [1]is applied to nanoeggs, i.e., nanoshells with a non-concentric (offset) core. In contrast to concentric nanoshells, the particle exhibits a multitude of dipole active plasmon resonances. These resonances are formed by hybridization of the multipolar plasmon resonances associated with the inner and outer surfaces of the metallic shell. The reduced symmetry introduced by the offset of the core causes a significant admixture of dipolar components in all plasmon modes. The hybridization is shown to depend strongly on the asymmetry of the particle. The results compare very well with results from FDTD simulations. The non-concentric nanoshell particles are shown to provide large electric field enhancements on open-ended surfaces. [1] E. Prodan and P. Nordlander, J. Chem. Phys. 120(2004)5444-5454

**13:03**

**P36 10 Plasmonic properties of the metallic nanosphere/thin wire system.** FENG HAO, P. NORDLANDER, *Rice University* The plasmon hybridization method [1] is applied to a metallic nanosphere positioned near an infinitely long metallic wire. The plasmon resonances of the sphere are found to be shifted and to depend on the polarization of the incident light. In the limit of a thin wire, a virtual state consisting of propagating low energy wire plasmons is induced. The state is similar in nature to the virtual thin film state recently predicted and observed for a nanosphere near a thin metallic film [2]. [1] E. Prodan and P. Nordlander, J. Chem. Phys. 120(2004)5444-5454. [2] F. Le, N. Z. Lwin, J.M. Steele, M. Kall, N.J. Halas, and P. Nordlander, Nano Lett. 5(2005)2009-2013.

**P36 11 Optical Response of Metal Nanoparticle Chains** KIN HUNG FUNG, CHE TING CHAN, *The Hong Kong University of Science and Technology* The excitation of surface plasmon on metal nanoparticles is interesting to many researchers because of its variety of applications. By arranging nanoparticles in different ways, many interesting properties can be observed. For metal nanoparticle chains, there is a red (blue) shift on the plasmon resonant frequency for longitudinal (transverse) excitation. We present the results on this splitting of plasmon resonant frequency for Ag nanoparticle chains with diameters around 10nm, calculated by the multiple scattering theory (MST) and the ways to understand the results using simple models. MST calculations are performed on the extinction of finite silver nanosphere chains embedded in glass matrix. The transmission and reflection of an infinite 2D arrays of silver nanospheres are also calculated to understand the interaction between nanoparticle chains. The results are in agreement with recent experiments. The splitting of plasmon-resonance modes associated with different polarizations of the incident light is further understood by employing simple models. Results on the effect of order and disorder in nanoparticle chains are also presented.

**13:27**

**P36 12 Emergence of collective plasmon excitation in a confined one-dimensional electron gas** ZHE YUAN, *Department of Engineering Physics, Chalmers University of Technology* SHIWU GAO, We present a theoretical study of the electronic excitation in a confined one-dimensional electron gas [1], which is utilized to model atomic chains created in recent experiments. The length

dependence of the excitation spectra is obtained from the linear response theory within the random phase approximation and time-dependent density functional theory. As the length of the chains increases, the dipole excitation spectra shows a transition from electron-hole pair excitations to collective plasmon excitation. The trend of the length-dependent plasmon resonance is predicted, and the nature of the plasmon resonance is also elaborated. [1] Shiwu Gao and Zhe Yuan, Phys. Rev. B 72, 121406(R) (2005).

**13:39**

**P36 13 Electron energy-loss spectroscopy study of surface plasmons in Au nano-particles.** CHENG-HSUAN CHEN, MING-WEN CHU, *Center for Condensed Matter Sciences, National Taiwan University, Taipei, Taiwan* JIN-PEI DENG, CHUNG-YUAN MOU, *Department of Chemistry, National Taiwan University, Taipei, Taiwan* We have studied the surface plasmon excitations of $\sim$ 10 nm Au nano-particles with various shapes (such as sphere, rod, and triangle) by electron energy-loss spectroscopy (EELS) using a 0.2 nm electron probe in a scanning transmission electron microscope (STEM). EELS spectra were investigated as a function of distance from the probe to the nano-particle surface, i.e., the impact parameter, and four surface plasmon peaks at 10, 15, 24, and 33 eV could be identified in the loss spectra in the 10 to 40 eV range where the dielectric constant of Au is positive (and still less than one). These high energy surface excitations are anomalous and in sharp contrast to the well-known surface plasmon of Au at 2.4 eV in the visible spectral range where the dielectric constant is negative. Spectral imaging studies also conclusively show that these high energy surface excitations are indeed localized at the surface of the nano-particles.

**13:51**

**P36 14 Plasmons in the metallic nanoparticle-film system as a tunable impurity problem** F. LE, N.Z. LWIN, N.J. HALAS, P. NORDLANDER, *Rice University* We show that the plasmon resonances of a metallic nanoparticle interacting with a metallic film is an electromagnetic analog of the spinless Anderson-Fano model [1]. The three characteristic regimes of this model are realized here, where the energy of the nanoparticle plasmon resonance lies above, within, or below the energy band of surface plasmon states. The latter regime is experimentally observed and identified. Our approach [1] is generalized to describe a nanoshell on a metallic film and to account for the screening effects caused dielectric backgrounds. These three interaction regimes are controlled by film thickness and the aspect ratio of the nanoshell. The results are compared with Finite-Difference Time-Domain (FDTD) simulations using realistic dielectric functions. [1] F. Le, N. Z. Lwin, J.M. Steele, M. Kall, N.J. Halas, and P. Nordlander, Nano Lett. 5(2005)2009-2013.

**14:03**

**P36 15 Surface plasmon interference spectroscopy of metal films*** VITALII VLASKO-VLASOV, *Argonne National Laboratory* ULRICH WELP, *Argonne National Laboratory* ANDREAS RYDH, *ANL and Dept. of Physics, Stockholm University* JOHN PEARSON, *Argonne National Laboratory* Circular nanoslits manufactured by focused ion beam in silver films were used to excite surface plasmon polaritons and to generate plasmon interference patterns. Changes of the plasmon interference periods at changing the excitation wavelength were imaged by a near-field scanning optical microscope and scaled by the known nanostructure dimensions allowing precise plasmon wavelength measurements. The plasmon dispersion curves for our film thickness were calculated in different approximations and a proper fitting function for the experimental data was chosen. This allowed to retrieve the frequency dependence of the dielectric function of our silver film, which is different from usually cited Johnson-Christy and Palik data but falls in the range of values reported in literature. The results of fitting indicate to the important role of losses, which can not be neglected in definition of the real part of the dielectric constant even in the Drude region. Our technique is a useful tool for the local characterization of the dielectric function sensitive to the structure of metal films potential for photonics applications.

**P38 1 Optical Study of Optimally Doped and Overdoped YBCO*** MINGHAN CHEN, D.B. TANNER, *Department of Physics, University of Florida, Gainesville FL 32611-8440, USA* G. HAMMERL, J. MANNHART, *Center for Electronic Correlation and Magnetism, Institute of Physics, Augsburg University, Augsburg 86135, Germany* Thin films of the optimally-doped and overdoped high temperature superconductor ($YBa_2Cu_3O_{7-\delta}$ and $Y_{0.7}Ca_{0.3}Ba_2Cu_3O_{7-\delta}$ with $T_c$ = 90 K and 79 K, respectively) have been investigated by optical spectroscopy in the ab-plane. In the normal state, with increasing the carrier concentration in the $CuO_2$ planes, spectral weight is lost in the high-frequency charge-transfer band and transferred to lower frequencies. With increased doping, the free-carrier (Drude-like component) plasma frequency increases, consistent with a charge density increase. However, the superfluid density decreases in this regime (overdoped region) and a substantial normal-fluid component still exists in the low frequency part of the optical conductivity well below $T_c$.

**11:27**

**P38 2 The optical conductivity of Ortho II $YBa_2Cu_3O_{6.5}$.** THOMAS TIMUSK, JUNG-SEEK HWANG, JING YANG, SERGEI SHARAPOV, JULES CARBOTTE, *McMaster University* DOUG BONN, RUIXING LIANG, WALTER HARDY, *University of British Columbia* The a-axis optical properties of the ortho II phase of YBCO (every other chain filled, $T_c$ = 59 K) were derived from reflectance data over a wide frequency and temperature range. Above 200 K the spectra are dominated by a broad background of scattering that extends to 1 eV. Below 200 K, in the normal state, a shoulder in the reflectance signals the onset of scattering at 400 $cm^{-1}$. Below the superconducting transition temperature the superconducting condensate appears. Its spectral weight is consistent, to within experimental error, with the FGT sum rule and with independent measurements of Gd ESR. We also compare our data with magnetic neutron scattering on samples from the same source that show a strong resonance at 31 meV. Extrapolating the optical conductivity to zero frequency yields the

dc resistivity of Ortho II which is in good agreement with four-probe measurements. We find that the scattering rates can be modeled as the combined effect of the neutron resonance, a bosonic background and a density of states with a pseudogap.

**11:39**

**P38 3 Optical conductivity of $Bi_2Sr_2CuO_6$ in the optimally and overdoped regimes** R.P.S.M. LOBO, D. LYZWA, N. BONTEMPS, *ESPCI-CNRS, Paris, France* Z.Z. LI, H. RAFFY, *LPS, Université de Paris Sud, Orsay, France* $Bi_2Sr_2CuO_6$ has a much lower critical temperature ($T_c^{Max} \sim 20$ K) than other single layer cuprate superconductors, making this compound very useful to investigate normal state properties of cuprates. In addition, it is possible to oxygenate this material to a relatively high degree of overdoping ($T_c < 5$ K). We measured, from room temperature to 5 K, the optical conductivity of the same $Bi_2Sr_2CuO_6$ film thermally treated to be in the optimally and overdoped regimes. The in-plane resistivity in the optimally doped regime depends lineraly on the temperature. It develops a positive curvature in the overdoped regime as expected from its more Fermi liquid like behavior. Surprisingly, despite its linear resistivity, the frequency dependent scattering rate in the optimally doped sample has a quadratic behavior. We will discuss our results in terms of the possible scenarios for the normal state conductivity and infer its effects on the superconducting state.

**11:51**

**P38 4 Doping and temperature dependent optical properties of $Bi_2Sr_2CaCu_2O_{8+\delta}$** JUNGSEEK HWANG, THOMAS TIMUSK, *McMaster University* GENDA GU, *Brookhaven National Laboratory* MARTIN GREVEN, HIROSHI EISAKI, *Stanford University* We report on the ab-plane reflectance of underdoped (UD), optimally doped (OPT), and overdoped (OD) $Bi_2Sr_2CaCu_2O_{8+\delta}$ (Bi-2212) samples [$T_c$ = 69 K(UD), 96 K (OPT), 82 K (OD), 80 K (OD: annealed from the OPT sample), 65 K (OD) and 60 K (OD)]. We analyzed the measured reflectance data and previous data of two underdoped Bi-2212 samples ($T_c$ = 67 K (UD) and 82 K (UD)) to extract the doping dependent optical constants. Bi-2212 is one of the most important cuprate systems widely studied by ARPES and tunnelling. We also calculate the doping dependent dc resistivity from extrapolation of the optical conductivity and the doping dependent superfluid density and the optical self- energy by using the extended Drude model. With these quantities in hand, we will discuss some current issues: the kinetic energy change at $T_c$, the role of the magnetic resonance mode, and a possible quantum critical point.

**12:03**

**P38 5 Polarization dependence of charge-transfer excitations in $La_2CuO_4$** LI LU, GUILLAUME CHABOT-COUTURE, *Department of Applied Physics, Stanford University, Stanford, California 94305* JASON HANCOCK, *Stanford Synchrotron Radiation Laboratory, Stanford University, Stanford, California 94309* OWEN VAJK, GUICHUAN YU, *Department of Physics, Stanford University, Stanford, California 94305* KENJI ISHII, JUN'ICHIRO MIZUKI, *Synchrotron Radiation Research Center, Japan Atomic Energy Research Institute, Hyogo 679-5148, Japan* DIEGO CASA, THOMAS GOG, *CMC-CAT, Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 60439* MARTIN GREVEN, *Department of Applied Physics, Stanford University, Stanford, California 94305* We have carried out an extensive resonant inelastic x-ray scattering (RIXS) study of $La_2CuO_4$ at the Cu K-edge. Multiple charge-transfer excitations have been identified using the incident photon energy dependence of the cross section and studied carefully with polarizations E//c and E //ab. An analysis of the incident photon energy dependence, the polarization dependence, as well as the K-edge absorption spectra, indicates that the RIXS spectra reveal rich physics about the K-edge absorption process and momentum-dependent charge-transfer excitations in cuprates.

**12:15**

**P38 6 Evidence of an anisotropic charge-excitation gap in stripe-ordered $La_{2-x}Ba_xCuO_4$ with $x = 1/8$ *** C. C. HOMES, S. V. DORDEVIC, G. D. GU, Q. LI, T. VALLA, J. M. TRANQUADA, *Condensed Matter Physics & Materials Science Dept., Brookhaven National Laboratory* The *ab*-plane optical properties of a cleaved single crystal of $La_{2-x}Ba_xCuO_4$ for $x = 1/8$ ($T_c \simeq 2.4$ K) have been measured over a wide frequency and temperature range. The low-frequency conductivity is Drude-like and shows a metallic response with decreasing temperature. However, below $\simeq 60$ K, corresponding to the onset of charge-stripe order, there is a rapid loss of spectral weight below about 40 meV, resulting in a major reduction in the number of free carriers. This suggests a partial gapping of the Fermi surface. Surprisingly, the sample is still metallic and becomes a superconductor at low temperature. This material is a striking example of how charge and spin stripe order, metallic behavior and superconductivity can coexist.

**12:27**

**P38 7 Anisotropic Drude response in $Mg(B_{1-x}C_x)_2$** TERUHISA KAKESHITA, SERGEY LEE, *SRL-ISTEC* SETSUKO TAJIMA, *Osaka University* SRL-ISTEC TEAM, OSAKA UNIVERSITY COLLABORATION, There exists an unsolved issue on $MgB_2$ that a plasma edge estimated from optical spectra so far is conspicuously inconsistent with a band calculation. It is mysterious since experimental band dispersions by ARPES are marvelously coincident with the band calculation. We report on a- and c-axis optical responses in $Mg(B_{1-x}C_x)_2$ using small single crystals and a FTIR spectrometer combined with an optical microscope. It was verified that the Drude responses show the anisotropy between a- and c-axis. The observed plasma frequencies $\omega_{p'}$ are considerably small compared to a theoretical value ( $\sim$ 7eV), whereas the bare ones $\omega_p$, estimated from a sum rule of optical conductivity $\int d\omega\sigma(\omega) = (\pi/2)\omega_p^2 = (\pi/2)\varepsilon_\infty\omega'^2_p$, are fairly coincident with it. We also discuss an effect of carbon-substitution on carrier concentration and scattering rate in a multiband system. This work was supported by the New Energy and Industrial TechnologyDevelopment Organization(NEDO) through ISTEC as the Collaborative Research and Development of Fundamental Technologies for Superconductivity Applications.

**12:39**

**P38 8 Mode coupling effect in infrared spectra of $Tl_2Ba_2Ca_{n-1}Cu_nO_x$ (n=1, 2, 3)** N.L. WANG, Y.C. MA, *Institute of Physics, Chinese Academy of Sciences, Beijing 100080* We performed in-plane optical reflectance measurements on $Tl_2Ba_2Ca_{n-1}Cu_nO_x$ with n=1, 2, 3. The single crystals were successfully grown by flux method with maximum $T_c$=90 K, 109 K, and 119 K for n=1, 2, 3, respectively. For all three phases near optimal doping, the reflectance roughly has a linear-frequency dependence in the normal state, but displays a pronounced knee

structure followed by a dip-like feature at higher frequency below $T_c$. Such characteristic features were commonly ascribed to the coupling of electrons with a bosonic mode. Very remarkably, we found that the energy levels of those features scale with $T_c$ for the three phases. The results suggest against a phonon origin for the bosonic mode. We also investigated the spectral evolution with doping for Tl-2201 crystals in the overdoped side. We found that the mode coupling effect weakens with doping and disappears in the heavily overdoped sample. Meanwhile, the optical scattering rate evolves from a linear- $\omega$ dependence to a shape with upward curvature in the normal state. Both the temperature and frequency dependence of the scattering rate can be described by a power law relation. Compared with ARPES results, we suggest that the overall decrease of the scattering rate may mainly originate from the increase of the quasiparticle life time near the $(\pi,0)$ region in the Fermi surface.

**12:51**
**P38 9 A Complete Charge Model For The High $T_c$ Superconductivity** YOUNG HOON KIM, PEI HERNG HOR, *University of Houston* Focusing on the recent transport, far-infrared (far-IR), and neutron scattering data, we establish a model for the high temperature superconductivity (HTS) built on the two-dimensional (2D) square electronic lattices in the $CuO_2$ planes and their three-dimensional ordering. We demonstrate that our model captures all the essential physics that bring about a coherent picture of the HTS and offers the key to the mechanism for the HTS.

**13:03**
**P38 10 Temperature Dependent of the Optical Spectral Weight in Correlated Metal $Nd_{1-x}TiO_3$(x=0.095)** JING YANG, JUNGSEEK HWANG, THOMAS TIMUSK, *Department of Physics and Astronomy, McMaster University* ATHENA SAFA-SEFAT, JOHN E. GREEDAN, *Department of Chemistry, McMaster University* We investigated the infrared reflectance of $Nd_{1-x}TiO_3$, which is a hole-doped transition-metal-oxide system. In the metallic sample with $x=0.095$ (hole concentration=3 $x=0.285$), the partial optical spectral weight, $\omega(\Omega,T) = \int_0^\Omega \sigma_1(\omega,T)d\omega$, turns out to be a linear function of $T^2$at different cutoff frequencies. Recent optical studies of LSCO [1] and BSCCO [2] also found that the optical spectral weight varies quadratically with temperature, i.e. $\omega(\Omega,T) \simeq \omega_0 - B(\Omega)T^2$, in both superconductors and nonsuperconducting metals. The coefficient $B(\Omega)$ was considered as a ''thermal response'' of the carriers. In our study, for $Nd_{1-x}TiO_3(x=0.095)$, $B(\Omega)$ exhibits distinct features which we compare to both cuprates and conventional metals. [1] M. Ortolani et al., Phys. Rev. Lett. **94**, 067002 (2005). [2] H. J. A. Molegraaf et al., Science **295**, 2239 (2002).

**P38 11 Phonon Shifts at the Superconducting Transition in it $\kappa$-(BEDT-TTF)$_2$-Cu(NCS)$_2$*** C. N. KODITUWAKKU, C. A. BURNS, X. WANG, *Dept. of Physics, Western Michigan University* H. SINN, A. SAID, A. ALATAS, *Advanced Photon Source, Argonne National Laboratory* We have measured the phonon spectra above and below the superconducting transition in it $\kappa$-(BEDT-TTF)$_2$-Cu(NCS)$_2$. This organic superconductor has a transition temperature near 10K. These measurements were carried out using inelastic x-ray scattering at sector 3ID at the Advanced Photon Source. The incident x-ray energy was 21.657 keV and the resolution of the spectrometer was about 2.0 meV. We have observed significant phonon shifts at several energies in these spectra at several points in the Brillouin zone. Here we discuss the behavior of the phonons and possible reasons for the shifts.

**P39 1 Effect of Spin Fluctuations on Electron-Phonon Superconductivity.***
IGOR MAZIN, *Naval Research Laboratory*

Most of our intuition regarding conventional superconductivity is derived from the McMillan formula. What are often believed to be generic properties of the Eliashberg equations, in reality hold only in the regime where the McMillan formula is applicable. I will show how common beliefs, such as a monotonic relation between the reduced gap and the coupling constant, or an exponential behavior of the NMR relaxation with the gap as the activation parameter, fail for more complicated spectral functions. Most interestingly, I will demonstrate that our conventional wisdom totally fails us in the rapidly developing field of superconductors near a magnetic instability. In particular, I will derive (and test against numerical solutions of the Eliashberg equations) an analogue of the McMillan formula, fully accounting for the pair-breaking effect of spin fluctuations, and will show that these *increase* the phonon isotope effect, sometimes by as much as a factor of two. This is counterintuitive and opposite to the effect of the high-energy Coulomb interactions (the so-called Coulomb pseudopotential). I will also discuss the possibility of observing this effect in specific materials, such as $MgCNi_3$. This work has been done in collaboration with Oleg Dolgov (MPI Stuttgart) and Alexander Golubov (U. Twente).

**P39 2 Properties from spin-phonon coupling in high-$T_C$ superconductors: $HgBa_2CuO_4$ and $La_{(2-x)}Sr_xCuO_4$** THOMAS JARLBORG, *DPMC, University of Geneva, Switzerland* The mechanism of spin-phonon coupling (SPC) in high-$T_C$ copper oxides is explored from band calculations on LSCO and HBCO systems. The LMTO band calculations, based on the local density approximation, are made for cells containing frozen phonon displacements and/or spin waves within the CuO plane. The virtual crystal approximation is used for studies of hole doped systems. The main result is that phonons are favorable for spin waves and vice-versa, and that pseudogaps appear naturally in the band structures of striped materials with strong SPC. The wave length of the spin-phonon modulation is related to doping, and the mutual enhancement of SPC is strongest when the non-doped system is close to an anti-ferro magnetic ground state. The calculated band results are used for modelling of different properties, such as isotope effects, phonon softening, shear dependences and T-variations. The results are discussed and compared with experiment. It is speculated that perpendicular SPC, with different behavior along x- and y-directions, can produce double gap structures. A moderate correction to LDA, which stabilizes the AFM state for the undoped material, will enhance the coupling constant for spin fluctuations $\lambda_{sf}$ for doped cases. These results suggest that properties of high-$T_C$ superconductors should depend both on phonons and magnetic fluctuations.

**P39 3 Superconductivity of Li, Al and K under pressure** GIANNI PROFETA, *Univ. di L'Aquila (Italy)* C Franchini[β], N. N. Lathiotakis[†], A. Floris[†β], A. Sanna[β], M. A. L. Marques[†], M. Lüders[‡], S. Massidda[β], E. K. U. Gross[†], A. Continenza*. * *CASTI - INFM and Dip. Fis., Univ. di L'Aquila, I-67010 Coppito (L'Aquila) Italy;* [β] *SLACS INFM and Dip. Fis., Univ. di Cagliari, I-09042 Monserrato (Ca), Italy;* [†] *Institut für Theoretische Physik, Freie Universität Berlin, Arnimallee 14, D-14195 Berlin, Germany;* [‡] *Daresbury Lab., Warrington WA4 4AD, United Kingdom* Extreme pressure strongly affects the superconducting properties of ''simple'' metals, like Li, K and Al. Using the new ab-initio method of density functional theory of the superconducting state, we report investigations on the superconducting properties of dense Li, K and Al. Our results show an unprecedented agreement with experiments, assess the predictive power of the method over a wide range of densities and electron-phonon couplings, and provide predictions for K, where no experiments exist so far. For fcc K we predict a superconducting phase transition at 18 GPa, with a maximum critical temperature of about 2 K at 23 GPa, the pressure where the crossover between the fcc and the K *III* structure experimentally occurs. We studied the effect of pressure on the electronic and vibrational properties of alkali, showing a progressive phonon softening near the K point of the Brillouin zone and a concomitant enhancement of the electron-phonon coupling constant $\lambda$.

**12:15**

**P39 4 Superconductivity of Alkali Metals under High Pressure** LEI SHI, DIMITRIOS PAPACONSTANTOPOULOS, *School of Computational Sciences, George Mason University* We calculated the superconductivity properties of alkali metals under high pressure using the results of band theory and the rigid-muffin theory of Gaspari and Gyorffy. Our results suggest that at high pressures Lithium, Potassium, Rubidium and Cesium would be superconductors with transition temperatures approaching 10-20 K. Our calculations also show that Sodium would not be a superconductor under high pressure even if compressed to less than half of its equilibrium volume. We found that the compression of the lattice strengthens the electron-phonon coupling through a delicately balanced increase of both the electronic and phononic components of this coupling. This increase of the electron-phonon coupling in Li is due to an enhancement of the s-p channel of the interaction, while in the heavier elements the p-d channel is the dominant component.

**12:27**

**P39 5 Superconductivity and Lattice Instability in Compressed Lithium from Fermi Surface Hot Spots** DEEPA KASINATHAN, JAN KUNES, RICHARD SCALLETAR, WARREN PICKETT, *University of California, Davis* AMY LAZICKI, CHOONG-SHIK YOO, *Lawrence Livermore National Labratory, Livermore, CA* HELGE ROSNER, *Max-Planck Institute for Chemical Physics of Solids, Dresden, Germany* Lithium, a simple metal not superconducting above 5mK at ambient pressure, becomes a 20 K superconductor at 50 GPa. This high $T_c$ is shown to arise from critical (formally divergent) electron-phonon coupling to the transverse phonon branch along intersections of Kohn anomaly surfaces with the Fermi surface. First principles linear response calculations of the phonon spectrum and spectral function $\alpha^2F(\omega)$ reveal (harmonic) instability already at 25 GPa. Our results imply that the fcc phase is anharmonically stabilized in the 25-38 GPa range.

**12:39**

**P39 6 DFT Study of the Single-Band Layered TMO $LiNbO_2$** ERIK YLVISAKER, *UC Davis* WARREN PICKETT, *UC Davis* We establish using first principles methods that $LiNbO_2$ is a realization of a triangular lattice ''single band'' system. The bandwidth (less than 2 eV) suggests the interesting possibility of correlation effects that should be kept in mind. We present a tight-binding model for the valence band of $LiNbO_2$, composed primarily of Nb $d_{z^2}$ states, finding that intralayer second neighbor hopping $t_2$100 meV is dominant over the significantly smaller first neighbor interactions $t_1$70 meV. The nearest neighbor coupling is strongly modified by oxygen displacements, and the electron-phonon coupling may provide the coupling mechanism for superconductivity in Li-deficient samples ($T_c \approx 5$K). We will present the Nb-centered Wannier function, which provides insight into this unusual electronic structure. Calculations of the Born effective charges for the metal ions are also found to have anisotropy that reflects the layered nature of the electronic bonding. Their deviation from formal charge values indicates important covalent character, which is also evident in the Wannier function.

**P39 8 Gap anisotropy in density functional theory of the superconducting state** A. FLORIS, *Freie Universität Berlin Germany* A. CONTINENZA, C. FRANCHINI, E.K.U. GROSS, N.N. LATHIOTAKIS, M. LÜDERS, M. MARQUES, S. MASSIDDA, G. PROFETA, A. SANNA, The discovery of superconductivity in $MgB_2$ ($T_c$ = 39.5K), with the clear presence of two gaps, has renewed the interest not only in electron-phonon mediated superconductivity, but also on the problem of anisotropic superconductivity. Here we use the recently introduced density functional theory of the superconducting state, that allows calculations of material-specific properties without the use of any adjustable parameters. The method, extended to $\mathbf{k},\mathbf{k}'$ resolved matrix elements of phonon-mediated and coulomb interactions, allows for a fully $\mathbf{k}$-resolved gap structure. Within this approach, we obtain the critical temperature and the two gaps of $MgB_2$ in good agreement with experiment. We will report on the existence of two different gaps also in Pb, and show that this is related to the different strength of the electron-phonon coupling associated with the two bands crossing the Fermi level. The calculated anisotropy is in good agreement with experiment. The same aproach is used for Nb3Sn, where recent experiments (Guritanu et al., Phys. Rev. B 70, 184526 (2004)) point to a possible two-gap behaviour. Our calculations show how our formalism is able to capture, in absence of any ad-hoc model, the features of multi-gap superconductors.

**13:15**

**P39 9 Band structure trend in cuprates and correlation with T *cmax*** OVE JEPSEN, EVA PAVARINI, WENHUI XIE, OLE KROGH ANDERSEN, *Max-Planck-Institute FKF, Germany* INDRA DASGUPTA, *IIT Bombay, India* TANUSRI SAHA-DASGUPTA, *S. N. BoseCenter, Calcutta, India* Parameters in model Hamiltonians are derived from LDA band structures for cuprate high $T_c$ superconductors. The materials and structural dependences of these are discussed. The most essential material dependent parameter is the range of the intralayer hopping. Furthermore, the range of this hopping correlates with $T_c$, i.e. materials with larger hopping ranges have higher maximum $T_c$'s.

**13:27**

**P39 10 First-Principles Construction of the Zhang-Rice singlet: Role of the apical oxygen in the mobility of the doped hole.*** WEI KU, WEI-GUO YIN, *Condensed Matter Physics & Materials Science Department, Brookhaven National Laboratory, Upton, NY 11973* The Zhang-Rice singlet (ZRS) has been well accepted as the most relevant low-energy states in high $T_c$ cuprates. Based on a novel Wannier state analysis [1] of the LDA+$U$ electronic structure, a realistic ZRS is constructed from properly orthogonalized local Cu $d_{x^2-y^2}$ and symmetric combination of O-p states ($p^{(s)}$), leading to a realistic derivation of low-energy effective t-t'- t''-J Hamiltonian. Interestingly, symmetrized apical oxygen $p_z$ orbital with the Cu $d_{z^2}$ symmetry is found to be close to the ZRS in energy ( 0.7 eV) and thus significantly facilitates the hopping to the second and third nearest neighbors. **P39 11 Band structure and Fermi surface of $Ba_2Ca_3Cu_4O_8F_2$** WENHUI XIE, OVE JEPSEN, OLE K. ANDERSEN, *Max-Planck-Institut FKF Stuttgart Germany* ZHI-XUN SHEN, *Stanford University* Recently Y. Chen itet ital. have measured the Fermi Surface (FS) of the fluorinated four $CuO_2$ layer superconductor, $Ba_2Ca_3Cu_4O_8F_2$, using angular resolved photoemission spectroscopy (ARPES). Surprisingly, they found only two large ($\pi$, $\pi$) centered hole FS sheets, while four would have been expected. In order to investigate the reason for this we have performed first-principles electronic band structure calculations for this compound. As expected four antibonding copper-oxygen bands cross the Fermi level of which the two have dominantly orbital character on the two inner-layers and the other two have most orbital character on the outer-layers. The splitting between these bands is, however,much smaller than the splitting between the two measured FS sheets. The fluorine were claimed to replace all apical oxygens, however, by partly substituting apical oxygen as well as oxygen in the four $CuO_2$ layers by fluorine, good agreement with the experimental FS could be obtained.

**13:51**

**P39 12 The role of the Fermi surface sampling in first-principles calculations of electron-phonon coupling*** FELICIANO GIUSTINO, MARVIN L. COHEN, STEVEN G. LOUIE, *University of California at Berkeley* A quantitative understanding of the electron-phonon interaction is crucial to the understanding of conventional and possibly high-$T_c$ superconductivity, as well as to the study of transport and spectroscopic (such as optical and photoemission) properties of bulk and nanoscale systems. Despite the enormous interest in calculating electron-phonon interaction from first principles, present methods carry severe practical limitations. We present here a comparative study of several existing methods for computing this quantity. We show that, independent of the approximation adopted, a common computational bottleneck is that the Fermi surface must be sampled with extremely high accuracy, leading to prohibitively expensive calculations for complex systems. We also reformulate the problem of evaluating phonon linewidths in terms of self-consistent linear response theory, and demonstrate our approach through application to magnesium diboride.

**11:15**
**P40 1 Solid state technologies for quantum computers.**
DAVID DIVINCENZO, *IBM Research Division*

Impressive progress is now being made in realizing the rudiments of quantum computers in solid state devices. I will discuss two of them. First, single electron quantum dots now offer a higly coherent spin state for use as a qubit. Decoherence effects, arising from hyperfine interactions and the spin-orbit interaction, are well on their way to being understood and controlled. Second, Josephson junction devices, in many forms, are showing promise as qubits. The dynamics of these electric circuits can be designed to exhibit a wide variety of quantum effects; good two-level systems can be produced by careful design, and careful schemes for decoupling from the environment. Coupling to harmonic modes offer a wide variety of ''quantum optic'' realizations in the microwave regime.

***Contributed Papers***

**P40 2 CNOT logic for Josephson phase qubits** MICHAEL GELLER, EMILY PRITCHETT, ANDREW SORNBORGER, *University of Georgia* MATTHIAS STEFFEN, JOHN MARTINIS, *University of California, Santa Barbara* Josephson junctions have demonstrated enormous potential as qubits for scalable quantum computing architectures. Here we study the speed and fidelity of four controlled-NOT gate implementations designed for capacitively coupled phase qubits. One gate applies to qubits fixed permanently in resonance, two require varying the dc current bias, and the fourth applies to permanently detuned qubits. Realistic simulations suggest that these implementations can be demonstrated with good fidelity using existing superconducting circuits.

**12:03**
**P40 3 Violation of Bell's Inequality using Josephson Phase Qubits** MARKUS ANSMANN, R. BIALCZAK, N. KATZ, E. LUCERO, R. MCDERMOTT, M. NEELEY, M. STEFFEN, E.M. WEIG, A.N. CLELAND, J.M. MARTINIS, *UC Santa Barbara* Recent improvements of the measurement visibility and coherence times in Josephson Phase Qubits have enabled first tests of two-qubit quantum gates and examination of quantum phenomena using these devices. Here, we present an experiment in which we attempt to violate Bells Inequality, which would be further proof that the system at hand behaves in a truly quantum mechanical way. The violation of Bells Inequality is the primary argument against the possible existence of a hidden- variable-theory as an alternative to quantum mechanics. This experiment illustrates the use of coherent control over capacitatively coupled qubits with always-on coupling, including the establishment of the system in eigenstates of the coupling, e.g. the singlet state. Single qubit rotations combined with a simultaneous, fast, high-visibility read-out allow for state- tomography on the system.

**P40 4 Experimental State Tomography using Superconducting Quantum Bits** M. STEFFEN, M. ANSMANN, R. BIALCZAK, N. KATZ, E. LUCERO, R. MCDERMOTT, M. NEELEY, E.M. WEIG, A.N. CLELAND, J.M. MARTINIS, *UC Santa Barbara* The superconducting approach to building a scalable quantum computer has enjoyed tremendous successes in the past several years with coherence times now sufficiently long to implement quantum gates on a system with coupled qubits. In order to quantify the performance or fidelity of the gates, quantum state tomography is required. Successful state tomography relies on high measurement fidelities and the ability to perform arbitrary rotations in the transverse plane of the Bloch sphere. Here, we have made significant progress towards overcoming these challenges and present, for the first time, experimental data on single and two-qubit state tomography.

**12:27**
**P40 5 Towards single shot read-out in circuit quantum electrodynamics (QED)** ANDREAS WALLRAFF, DAVID SCHUSTER, ALEXANDRE BLAIS, JAY GAMBETTA, LUIGI FRUNZIO, JOE SCHREIER, BLAKE JOHNSON, ANDREW HOUCK, WILL BRAFF, HANNES MAJER, MICHEL DEVORET, STEVE GIRVIN, ROB SCHOELKOPF, *Depts. of Applied Physics and Physics, Yale University* In recent experiments we have demonstrated the resonant coherent coupling of individual photons to a single qubit implemented as a Cooper pair box in a high quality superconducting cavity [1]. In the non-resonant case, the dispersive coupling between the qubit and the cavity field is used to perform quantum non-demolition (QND) measurements of the qubit state [2]. Using this read-out technique we have performed high visibility measurements of Rabi oscillations and Ramsey fringes [3]. Here we present a detailed experimental and theoretical analysis of the cavity response for continuous and pulsed measurements in a wide range of cavity drive amplitudes. We also discuss an optimal read-out strategy for qubits in a continuous QND measurement and aim at demonstrating single shot read-out in the circuit QED architecture [4]. [1] A. Wallraff et al. Nature (London) 431, 162 (2004) [2] D. I. Schuster et al. Phys. Rev. Lett. 94, 123602 (2005) [3] A. Wallraff et al. Phys. Rev. Lett. 95, 060501 (2005) [4] A. Blais et al. Phys. Rev. A 69, 062320 (2004)

**12:39**

**P40 6 Coherent control in circuit QED** ALEXANDRE BLAIS, JAY GAMBETTA, ANDREAS WALLRAFF, DAVID SCHUSTER, LUIGI FRUNZIO, JOHANNES MAJER, STEVEN M. GIRVIN, ROBERT J. SCHOELKOPF, *Yale University* Superconducting charge qubits fabricated inside a transmission line resonator have been used to successfully demonstrate strong interaction of an artificial atom with a single photon [1]. This architecture has also been used to show high-visibility and long coherence time ($T_1 \sim 7\ \mu$s, $T_2 \sim$ 500 ns) Rabi oscillations [2] and in the detailed study of measurement-induced dephasing [3]. Here we will discuss protocols to realize one and two-qubit logical gates in circuit QED. These are based on resonant and off-resonant irradiation of the transmission line resonator. First experimental results towards the realization of these gates will be presented. Supported by NSA and ARDA under ARO Contract No. W911NF-05-1-0365 and the NSF under Grants No. ITR-0325580 and No. DMR-0342157. [1] A. Wallraff et al., Nature 431, 162 (2004). [2] A. Wallraff et al., Phys. Rev. Lett., 95, 060501 (2005). [3] D. Schuster et al., Phys. Rev. Lett., 94, 123602 (2005).

**P40 7 Superconducting SET backaction on the Cooper-pair box** JOHANNES MAJER, BENJAMIN TUREK, *Yale University* AASISH CLERK, *McGill University* STEVEN GIRVIN, ROBERT SCHOELKOPF, *Yale University* KEVIN BLADH, DAVID GUNNARSSON, PER DELSING, *Chalmers Institue of Technology* We report on measurements of the backaction of a superconducting single electron transistor (SSET) measuring a Cooper-pair box qubit. During the weak, continuous measurement made by the SSET, the charge noise acts on the Cooper-pair box. The quantum nature of that noise is able to dephase, relax and even excite the qubit. This noise depends strongly on the operating point of the SSET. We operate the SSET near the double Josephson quasiparticle (DJQP) feature, where the backaction of the SSET is well understood (A. Clerk, et al., Phys. Rev. Lett. 89, 176804 (2002)), and where there are no quasiparticle poisoning effects. Measurements of the relaxation time of the Cooper- pair box reveal the symmetric component of the quantum noise and measurements of the steady-state polarization reveal the anti-symmetric component. Both measurements vary as expected with SSET operating point and confirm this model of SSET backaction.

**13:03**

**P40 8 Information Flow in the Readout of a Superconducting Quantum Bit** I. SIDDIQI, R. VIJAY, M. METCALFE, E. BOAKNIN, C. RIGETTI, L. FRUNZIO, R. SHOELKOPF, M.H. DEVORET, *Yale University* Quantum computation requires efficient and well controlled coupling between qubits. Superconducting qubits can be strongly coupled using passive electrical circuit elements, but one of the major remaining challenges is to eliminate uncontrolled coupling to parasitic degrees of freedom. I will present experimental results on charge qubits integrated with a novel readout device – the Josephson bifurcation amplifier (JBA). New experiments using the improved readout fidelity and speed of the JBA quantify parasitic losses and shed light on their mechanism.

**13:15**

**P40 9 Mach-Zehnder-type Interferometry in a Strongly Driven Persistent-Current Qubit*** WILLIAM OLIVER, *MIT Lincoln Laboratory* YANG YU,† *MIT EECS Department* JANICE LEE, *MIT EECS Department* KARL BERGGREN, *MIT EECS Department* LEONID LEVITOV, *MIT Physics Department* TERRY ORLANDO, *MIT EECS Department* We have demonstrated Mach-Zehnder-type interferometry with a niobium superconducting persistent-current qubit. The qubits ground and first-excited states exhibit an anti-crossing. Driving the qubit with a large-amplitude harmonic excitation sweeps it through this anti-crossing two times per period. The induced Landau-Zener (LZ) transitions act as coherent beamsplitters, and the accumulated phase between LZ transitions varies with the driving amplitude. We have observed quantum interference fringes as a function of the driving amplitude for 1 to 20 photon excitations. We present and discuss these results.

**P40 10 Double Quantum Dot Molecule Coupled with Single-Electron Transistors for Quantum Computation Applications*** LIMIN CAO, PHILLIP WU, FABIO ALTOMARE, A. M. CHANG, *Department of Physics, Duke University, Durham, NC 27708* M. R. MELLOCH, *School of Electrical Engineering, Purdue University, West Lafayette, IN 47907* We describe the fabrication of a series-coupled double quantum dot (DQD) with side-coupled single-electron transistors (SETs). The DQD are intended to work as qubits, and the SETs perform the quantum spin measurements. The device was fabricated on a GaAs/AlGaAs heterostructure using a one-step, two-angle, evaporation of aluminum. Our design is compatible with modern semiconductor techniques, and if proven successful, can readily be scaled into larger integrated qubit systems with spin manipulation and measurement circuitry. Our preliminary experimental results indicate that both the QDs and SETs have single-electron tunneling behaviors with good reproducibility. We will report on progress towards the in-situ detection of the spin and charge of a single electron trapped in the semiconductor quantum dots.

**13:39**

**P40 11 Charge fluctuation induced dephasing of exchange coupled spin qubits*** XUEDONG HU, *University at Buffalo, SUNY* S. DAS SARMA, *University of Maryland* Exchange coupled *spin* qubits in semiconductor nanostructures are shown to be vulnerable to dephasing caused by *charge noise* invariably present in the semiconductor environment. This decoherence of exchange gate by environmental charge fluctuations arises from the fundamental Coulombic nature of the Heisenberg coupling, and presents a serious challenge to the scalability of the widely studied exchange gate solid state spin quantum computer architectures. We explore the properties of the resulting exchange gate errors, and estimate dephasing times for coupled spin qubits in a

wide range (from 1 nanosecond up to more than 1 microsecond) depending on the exchange coupling strength and its sensitivity to charge fluctuations in a particular nanostructure.

*We acknowledge support by NSA, LPS, and ARO.

**P40 12 Solid-state quantum teleportation between nanomechanical modes** L. TIAN, S. M. CARR, *National Institute of Standards and Technology, 100 Bureau Drive, Stop 8423, Gaithersburg, MD 20899* We study a quantum teleportation scheme between two nanomechanical modes without local interaction. The nanomechanical modes are connected by and linearly coupled to the continuous variable modes of a superconducting circuit made of transmission line and Josephson junctions. The phase sensitive measurement during the teleportation can be conducted by a superconducting single electron transistor operated as an rf mixer. Using a Wigner function approach, we calculate the fidelity of transferring coherent state under finite temperature and non-unit detector efficiency. We show that a fidelity above the classical limit of 1/2 can be achieved for a large range of parameters.

**14:03**
**P40 13 Spin transport and quasi 2D architectures for donor-based quantum computing** AUSTIN FOWLER, *Institute for Quantum Computing, University of Waterloo, Canada* LLOYD HOLLENBERG, ANDREW GREENTREE, CAMERON WELLARD, *ARC Centre of Excellence for Quantum Computer Technology, University of Melbourne, Australia* The original Kane quantum computer architecture is based on a single line of $^{31}P$ atoms spaced a few tens of nm apart in an isotopically pure $^{28}Si$ lattice with electrodes above and between donor atoms. This architecture suffers from major technical issues including strong spatial oscillations in the nearest neighbour donor electron exchange coupling strengths at the scale of a single lattice site and an inability to limit the effect of a given electrode to its nearest donor or donor pair. Through the introduction of a new donor electron spin transport mechanism, a 2D donor electron spin quantum computer architecture is proposed. This new architecture addresses the exchange coupling and cross-talk issues, as well as a host of other physical barriers to implementation.

**P41 1 Luminescence and Raman based real time imaging of ferroelectric domain walls.***
VOLKMAR DIEROLF, *Physics Department, Lehigh University*

Novel methods for real-time imaging of ferroelectric domain walls open up new possibilities for advancing physical understanding of domain wall structure, properties, and defect interactions. Instead of destructive chemical etching and subsequent optical or electron microscopy, domain walls are imaged nondestructively in real-time by photoluminescence microscopy using dilute doping by rare earth ions as designer defects whose luminescence is affected by the domain walls. Uisng a combination of high spatial and spectral site-selectvity in laser confocal and near field opptical microscopy, domain structure changes on a 100 nm length scale can be observed with a temporal resolution of 5ms, as demonstrated in $LiNbO_3$ and $LiTaO_3$. Imaging using Raman spectroscopy (that does not require rare earth doping) will also be described. These new imaging methods reveal that domain wall widths and structures are velocity-dependent, and they provide active, real time feedback needed for precise laser-writing of ferroelectric domain patterns.

**P41 2 Study of Ferroelectric Domains in a Phase Separated Multiferroic Mixture by Variable Temperature Electrostatic Force Microscopy*** ALEX DE LOZANNE, TIEN-MING CHUANG, WEIDA WU, CASEY ISRAEL, *Department of Physics, University of Texas at Austin* CHENGLIN ZHANG, SANG-WOOK CHEONG, *Department of Physics and Astronomy, Rutgers University* We present a variable temperature Electrostatic Force Microscopy (VTEFM) study on a mixed multiferroic crystal. The sample was synthesized by the floating zone method. It was cut and polished with the surface normal to the growth direction. The chemical phase separation is clearly seen by polarized optical microscopy. The transition temperature is about 25K and 900K for the two different phases. The VTEFM images taken at 77 K reveal the ferroelectric domains, with typical sizes in the order of micrometers.

**P41 3 A new fundamental limit of ferroelectric devices and its domain dynamics in ultrathin ferroelectric $BaTiO_3$ films** J.Y. JO, D.J. KIM, Y.S. KIM, T.W. NOH, *ReCOE & School of*

*Physics,Seoul National University, Seoul 151-747, Korea* T.K. SONG, *Department of Ceramic Science and Engineering, Changwon National University, Changwon, Kyungnam 641-773, Korea* J.-G. YOON, *Department of Physics, University of Suwon, Gyunggi-do 445-743, Korea* Phenomena in ultrathin ferroelectric (FE) films, such as the critical thickness and the domain structures, have attracted much interest for a few years. We fabricated fully-strained $SrRuO_3/BaTiO_3/SrRuO_3$ capacitors, whose $BaTiO_3$ layer thicknesses were between 5 and 30 nm, using the laser molecular beam epitaxy. We found that rapid decay of net polarization occurs due to large depolarization field [1]. Using the Monte-Carlo simulations, this decay can be explained by the domain formation dynamics, governed by the domain nucleation process. We found a universal relation between the decay exponent and nucleation energy barrier, regardless of film thickness and temperature. This universal relation will provide a fundamental thickness limit for practical FE devices, set by net polarization decay. [1] D. J. Kim et al. Phys. Rev. Lett, in press.

**P41 4 Raman Studies of Ferrolectric Domain Walls in Lithium Tantalate and Niobate*** PAVEL CAPEK, GREG STONE, VOLKMAR DIEROLF, *Physics, Lehigh University* CHAD ALTHOUSE, VENKAT GOPALAN, *MS&E, Pennsylvania State University* The local structure of ferroelectric domain walls and its dependence on intrinsic defects and dopants is of great interest both from a basic science and a application point of view. For instance, in the ferroelectrics $LiNbO_3$ and $LiTaO_3$ that are widely used in nonlinear and electro-optical devices, the stability, shape, switching fields and smallest achievable domain size are determined by the defect concentration. Using confocal Raman spectroscopy we investigated the perturbation of the phonon modes across a domain wall as a function of sample stoichiometry (i.e.: the number of intrinsic defects. For all samples, we find that in the spectral vicinity of the $E(TO_8)$ and $E(TO_9)$ the Raman intensity is enhanced in the domain wall region. In order to elucidate the origin of this enhancement, we investigate the directional dispersion of the observed change and perform measurements under variation of pump and probe light polarization and sample orientation. On the basis of these results, we will discuss structural models of the domain wall.

**12:39**

**P41 6 Distribution function of random electric fields in disordered ferroelectrics thin films** VLADIMIR STEPHANOVICH, ELENA KIRICHENKO, *Institute of Mathematics and Informatics, Opole University* We present the calculation of first moment $E_0$ and variance $\Delta E$ of distribution function of random fields in a ferroelectric of finite size. This defines completely the distribution function in gaussian limit. Specific calculations have been performed for the case of slab-shaped ferroelectric thin film. We have shown that $E_0$ and $\Delta E$ can be expressed through the integrals from first and second degree of Green's function of such confined geometry ferroelectric in $k$ - space. To obtain the Green's function, we solve the differential equation minimizing Landau free energy of a ferroelectric with respect to the boundary conditions on its surfaces. We show, that the distribution function of random fields in the finite-size ferroelectric differs from that of the unbounded bulk material. For example, both $E_0$ and $\Delta E$ depends on film thickness $L$. Knowledge of this distribution function permits to calculate the observable physical properties of ferroelectric thin films made from ferroelectric relaxors. Our method of calculation of $E_0(L)$ and $\Delta E(L)$ can be easily generalized for ferroelectric of arbitrary shape.

**12:51**

**P41 7 Interface Induced Ferroelectric Phase Transformation in SrTiO3.** DAWN BONNELL, *University of Pennsylvania* RUI SHAO, GERD DUSCHER, *North Carolina State University* MATTHEW CHISOLM, *Oak Ridge National Lab* The transport properties across bicrystal interfaces in SrTiO3 are quantified with 4-pt probe, Hall measurements, scanning impedance microscopy and scanning tunneling microscopy. The properties are related to the structure determined by transmission electron microscopy, energy loss spectroscopy and first principles calculations. An anomaly in the temperature dependence of the transport properties arises from the charge trapped at the interface, which induces dipole ordering adjacent to the boundary. This represents the first observation of interface induced ferroelectricity in SrTiO3.

**13:03**

**P41 8 Nanoscale structural dynamics of ferroelectric thin films** ALEXEY GRIGORYEV, DAL-HYUN DO, DONG-MIN KIM, CHANG-BEOM EOM, PAUL EVANS, *University of Wisconsin-Madison* ERIC DUFRESNE, BERNHARD ADAMS, *Advanced Photon Source, Argonne National Laboratory* The emerging capability to visualize dynamical phenomena at small scales in both distance and time simultaneously has important implications in understanding ferroelectric materials. We have used time-resolved synchrotron x-ray microdiffraction to probe polarization switching and piezoelectric response at the sub-nanosecond time scale and the sub-micrometer spatial scale in lead zirconium titanate thin films. Based on time resolved maps of the polarization and piezoelectric distortion, the polarization switching domain wall velocity can be measured directly. The magnitude of this velocity and its scaling with electric fields suggest that significant improvements in switching speed can be made in optimized thin film structures.

**13:15**

**P41 9 External and internal magnetic-field effects on ferroelectricity in orthorhombic rare-earth manganites** H. KUWAHARA, K. NODA, M. AKAKI, *Dept. of Phys., Sophia Univ.* We report the dielectric and magnetic properties of the perovskite $(Eu,Y)MnO_3$ crystal *without* the presence of the $4f$ magnetic moments of the rare earth ions. The subject compound, $(Eu,Y)MnO_3$,

was controlled the average ionic radius of the $A$ site so that it was the same as that of $TbMnO_3$ in which the intriguing magnetoelectric effect has been recently discovered. The (Eu,Y)$MnO_3$ crystal was found to have two distinct ferroelectric phases with polarization along the $a$ ($P_a$, $T \leqslant 23$K) and $c$ ($P_c$, $23\text{K} \leqslant T \leqslant 25$K) axes in the orthorhombic $Pbnm$ setting in a zero magnetic field. In addition, we have demonstrated a magnetic-field-induced switching between these ferroelectric phases: $P_a$ changed to $P_c$ by the application of magnetic fields parallel to the $a$ axis ($H_a$). In analogy to the case of $P_c$ in $TbMnO_3$, this result is possibly interpreted as follows. In the case of (Eu,Y)$MnO_3$, Mn $3d$ spins rotate in the $ab$ plane and $P_a$ would emerge in a zero field. In the $H_a$, the field will force the spins to rotate in the $bc$ plane, in which $P_c$ would be stabilized. Magnetization measurements supported this interpretation: We confirmed the change of the spin rotation axis of the helix from the $c$ axis to the $a$ axis induced by application of the $H_a$ because there is no $4f$ moments acting as an internal magnetic field and interacting with the $3d$ spins. Results obtained with other rare-earth manganites such as (Gd,Tb)$MnO_3$ and (Eu,Ho)$MnO_3$ will be presented.

**13:27**

**P41 10 Dielectric and vibrational properties of crystalline and amorphous high-k lanthanum aluminate** PIETRO DELUGAS, VINCENZO FIORENTINI, ALESSIO FILIPPETTI, *SLACS-CNR and University of Cagliari, Italy* High-k oxides are the focus of intense research for their applications in MOS and FLASH devices. A material currently in focus is $LaAlO_3$, with a dielectric constant of 23-24 in the crystal phase, and similar values of around 20-22 in the amorphous phase (although values as low as 15 have also been reported). We have studied $LaAlO_3$ in both phases [1] to identify possible reasons for this apparent conservation of the dielectric properties upon amorphization. Amorphous samples were generated by melt-and-quench using a combination of pair potentials and ab initio dynamics. The linear response density-functional perturbation-theory approach was used to study dynamical response and phonons. We indeed find a large dielectric constant ( 24) in the amorphous: the rationale is that the expected reduction of the anomalous effective charges is compensated by the appearance of new low-frequency (weakly) IR-active modes, whose character is a mixture of La translations (IR in the crystal) and Al-O octahedra rotations (Raman in the crystal). A similar behavior is expected in any rare earth aluminate exhibiting a similar perovskite-related structure (e.g. scandates). 1) P. Delugas, V. Fiorentini, and A. Filippetti, Phys. Rev. B 71, 134302 (2005), and to be published.

**13:39**

**P41 11 Composition dependence of the diffuse scattering in relaxor $(1\text{-}x)Pb(Mg_{1/3}Nb_{2/3})O_3\text{-}xPbTiO_3$ $(0 \leqslant x \leqslant 0.40)$** M. MATSUURA, K. HIROTA, *ISSP The University of Tokyo* P. M. GEHRING, *NIST Center for Neutron Research* ZUO-GUANG YE, W. CHEN, *Department of Chemistry Simon Fraser University* G. SHIRANE, *Deapartment of Physics Brookhaven National Laboratory* We have studied composition dependence of diffuse scattering in the relaxor system $(1\text{-}x)Pb(Mg_{1/3}Nb_{2/3})O_3\text{-}xPbTiO_3$ (PMN-$x$PT) with $x = 0$, 10, 20, 30, and 40% by neutron diffraction. The addition of ferroelectric $PbTiO_3$ (PT) modifies the ''butterfly'' and ''ellipsoidal'' diffuse scattering patterns observed in pure PMN ($x = 0$), which are associated with the presence of randomly oriented, polar nanoregions (PNR). The spatial correlation length $\xi$ derived from the width of the diffuse scattering increases from 12.6 Å for PMN ($x = 0$) to 350 Å for PMN-20%PT, corresponding to an enlargement of the PNR. The integrated diffuse scattering intensity, which is proportional to $\chi''$, grows and reaches a maximum at $x = 20\%$. Beyond $x = 30\%$ PT, a concentration very close to the morphotropic phase boundary (MPB), no diffuse scattering is observed below $T_C$, and well-defined critical behavior is observed. By contrast, the diffuse scattering for $x \leqslant 20\%$ persists to low temperatures, where the system retains an average cubic structure ($T_C = 0$). We can simulate the wave vector dependence of the diffuse scattering by assuming that it arises from the condensation of a soft transverse-optic (TO) phonon.

**13:51**

**P41 12 Multiresonance, multifrequency spectroscopy of rare-earth and transition ions in ferroelectrics.** GALINA MALOVICHKO, *Physics Department, Montana State University* VALENTIN GRACHEV, *Physics Department, Montana State University* The usual scheme of many methods for material investigation includes an emitter of electromagnetic waves and detectors for the wave registration. Typical output of one-frequency methods is an image with a space resolution of about the used wavelength. The methods are very successful for the study of lattice structures, their transformations at phase transitions, domains etc. Another approach uses sweeping of the frequency or another external parameter: electric or magnetic field, pressure etc. Typical result of a measurement is a spectrum or a dependence of measured characteristic on the sweeping parameter. The spectra do not contain direct evidence about the space structure of a lattice or defects. However, they contain very important information about the energetic characteristics of interactions of lattice ions, intrinsic and extrinsic defects. We present results of multifrequency research of defects in oxide crystals involving optical spectroscopy, microwave and radiofrequency spectroscopy: electron paramagnetic resonance, and electron nuclear double resonance.

**14:03**

**P41 13 Femtosecond Spectroscopy of $LuMnO_3$** SHITAO LOU, *Department of physics and Astronomy, Rutgers University* FRANK M. ZIMMERMANN, ROBERT A. BARTYNSKI, NAMJUN HUR, SANG-WOOK CHEONG, *Department of Physics and Astronomy, Rutgers University* Hexagonal $LuMnO_3$ manganite is a ferroelectric and strongly frustrated antiferromagnetic crystal. Strong coupling between lattice, electronic, and magnetic degrees of freedom makes it a promising electronic material. We have used femtosecond pump-probe spectroscopy to study the interaction of electron excitations with lattice vibrations in real time. Optical excitation of a Mn $d_{(x^2-y^2),(xy)} \rightarrow d_{(3z^2-r^2)}$transition served as the primary excitation step. With both pump and probe beam polarization perpendicular to the c axis, the probe reflectivity shows a sharp drop due to saturation of the transition, recovering on a timescale of 1 ps. We also observed displacive excitation of a coherent optical phonon vibration at 3.6 THz, which is assigned to an A1 symmetry mode involving Lu ion motion along the c axis. This mode was excited in longitudinal (LO) and transverse mode (TO) geometries. While the LO-TO frequency splitting is small ( $< 0.1$ THz), a remarkable phase reversal of the reflectivity curve was observed. This is attributed to a large linear electro-optic effect (Pockels effect), induced by the THz electric field associated with the LO mode.

**P42 1 Dissociation of $CaIrO_3$-type $MgSiO_3$ in the gas giants*** KOICHIRO UMEMOTO, RENATA WENTZCOVITCH, *Minnesota Supercomputing Institute and Department of Chemical Engineering and Materials Science, University of Minnesota* PHILIP ALLEN, *Department of Physics and Astronomy, Stony Brook University* $CaIrO_3$-type $MgSiO_3$ is the planet-forming silicate stable at pressures and temperatures (PTs) beyond those of Earth's core-mantle boundary. We have found using first principles quasiharmonic free energy computations that this mineral dissociates into MgO and $SiO_2$ at PTs expected to occur in the cores of the gas giants ( $> \sim$10 Mbar, 10,000 K). This transformation should be important also for modeling the internal structure of two recently discovered terrestrial exoplanets: a dense Saturn orbiting HD149026b and a super Earth orbiting GJ876d. We propose a low pressure route experiment to confirm this dissociation.

**P42 2 Thermal Electrons and Thermal Conductivity in Oxide Minerals at P and T Relevant to Terrestrial Exoplanets*** PHILIP B. ALLEN, *Stony Brook University* KOICHIRO UMEMOTO, *University of Minnesota* RENATA M. WENTZCOVITCH, *University of Minnesota* The recent discovery of an extrasolar planet, with 7.5 times the mass of the Earth, has prompted investigation of a new range of parameter space, 3 times higher in temperature T and 10 times higher in pressure P than the Earth's mantle. We estimate thermal conductivity k(T) of minerals under these extreme conditions. The radiative portion of k(T) is large above the mid-lower post-perovskite mantle, where T reaches 5000-6000K. At T higher than 5000 K, free electron carriers are thermally activated with the population n(T) increasing as exp(-E*/2kT), where E* is the band gap energy of around 5 eV. Free carriers damp electromagnetic waves at frequencies below the plasma frequency, estimated to be close to 1 eV, shutting down radiative heat transport. Although thermal holes have low mobility, we find that thermal electrons are quite mobile, with small effective masses and weak scattering. Therefore, they become dominant carriers of heat. We predict electrical resistivity as low as 1000 micro-ohm cm.

**P42 3 Elasticity of MgO Under Direct Pressure Measurement: Insights on Current Pressure Scales.*** BAOSHENG LI, *Stony Brook University* KELLY WOODY, *Division of Water Supply, The State of Tennessee* ROBERT LIEBERMANN, *Department of Geosciences, SUNY Stony Brook* Recent high pressure studies indicated that the inaccuracy and inconsistency of the pressure scales used for pressure determination in different studies might be an importance source that gives rise to the apparent discrepancy in the derived phase equilibrium and physical properties for mantle minerals. In this study, P and S wave velocities and unit cell parameters (density) of MgO are measured simultaneously up to 11 GPa 1073K using combined ultrasonic interferometry and in-situ X-ray diffraction techniques, from which the elastic bulk and shear moduli as well as their and temperature pressure derivatives are obtained independent of pressure. These properties are subsequently used to calculate the primary pressures at the observed strains for comparison with those derived from previous proposed MgO pressure scales. Additionally, a comparison of the primary pressure obtained from MgO with those inferred from the enclosed internal pressure calibrant (NaCl) gives an opportunity to evaluate the Decker NaCl scale as well. Our results suggest that current pressure scales may bear larger uncertainties than originally claimed.

*The research is supported by NSF grant EAR00135550.

**11:51**

**P42 4 A high PT scale based on density functional calculations of MgO*** Z. WU, R.M. WENTZCOVITCH, *Department of Chemical Engineering and Materials Science and Minnesota Supercomputing Institute, University of Minnesota, Minneapolis, MN 55455, USA* B. LI, *Mineral Physics Institute, Stony Brook University, Stony Brook, NY 11794, USA* K. UMEMOTO, *Department of Chemical Engineering and Materials Science and Minnesota Supercomputing Institute, University of Minnesota, Minneapolis, MN 55455, USA* In situ crystallography based on diamond anvil cells have recently been extended to the multi-Mbar regime. Temperatures in these experiments have crossed the 2,000 K mark. Yet, current high PT standards of calibration produce too large uncertainties to the point of inhibiting clear conclusions regarding the importance of certain phenomena for planetary processes at these high PTs, e.g., the post-perovskite transition in Earths mantle. We propose a calibration based on thermal equations of state (EoS) of MgO obtained from LDA quasiharmonic (QHA) calculations. These EoSs agree very well with several calibrations at relatively low PTs. This gives further support to our predictions made within the range of validity of the QHA.

**P42 5 Phase stability and elasticity of $CaSiO_3$ perovskite at high pressure and high temperature from Ab inito molecular dynamic calculations** DONALD WEIDNER, LI LI, *Stony Brook University* JOHN BRODHOLT, DARIO ALFE, DAVID PRICE, *University College London* STONY BROOK UNIVERSITY COLLABORATION, UNIVERSITY COLLEGE LONDON COLLABORATION, We report the dynamics of the structure and elastic properties of CaSiO3 perovskite from itab initio molecular dynamics (AIMD) calculations at high pressure (P up to 130 GPa) and high temperature (T up to 5000K). Our calculations indicate three separate stability fields: metrically orthorhombic, tetragonal and cubic, with the tetragonal phase dominating the pressure and temperature region between room temperature and 4000K. The cubic phase is not entirely stabilized even at temperatures of the Earth's lower mantle. Calculated X-ray diffraction patterns indicate small super- lattice reflections that could result from the octahedral rotations throughout the P-T region investigated. The calculated elastic constants and velocities are independent of temperature at constant volume. Referenced to room pressure and 2000K, we find: Grûneisen parameter is $\gamma(V) = \gamma0(V/V0)q$ with $\gamma0 = 1.53$ and $q = 1.02(5)$, and the Anderson Grûneisen param-

eter is given by ($\alpha$/ $\alpha$0) = (V/V0)$\delta$T in which $\alpha$0 = 2.89 x 10-5 K-1 and $\delta$T = 4.09(5). Using the third order Birch Murnaghan equation of state to fit our data, we have for ambient P and T, $K_0$ = 236.6(8) GPa, $K_0$' = 3.99(3), and $V_0$ = 729.0(6) Å3.

**12:15**

**P42 6 Computational study of the pressure behavior of post-perovskite phases** RAZVAN CARACAS, *Geophysical Laboratory, Carnegie Institution of Washington* RONALD COHEN, *Geophysical Laboratory, Carnegie Institution of Washington* The recent discovery of the post-perovskite phase transition ($CaIrO_3$ structure) in $MgSiO_3$ has lead to theoretical and experimental investigations of silicates, germanates and oxides that could take this structure. We have employed density functional-theory to explore a series of new compounds with the post-perovskite structure under pressure. We analyze the effects of the Si substitution by tetravalent cations on the perovskite-to-post-perovskite transition and on the crystal structure of post-perovskite. Cations $Ti^{4+}$ and $Zr^{4+}$ prefer the post-perovskite structure. We also explore the sesquioxides $Al_2O_3$ and $Rh_2O_3$ and compare their structural evolution with the one of $MgSiO_3$. For $Rh_2O_3$ we observe an enhancement of the ionic character of the type II structure with pressure.

**P42 7 Thermodynamics of $Mg_2SiO_4$ liquid from first principles molecular dynamics simulations** NICO DE KOKER, LARS STIXRUDE, *University of Michigan* As the main medium through which planetary differentiation occurs, silicate liquids have a central role in the study of the Earth. We determine the structural and thermodynamic properties of $Mg_2SiO_4$ liquid using first principles molecular dynamics in the framework of density functional theory and the local density approximation (LDA). Calculations, performed in the canonical ensemble with a Nose thermostat, span a range of pressures (0 - 150 GPa) and temperatures (3000 - 6000 K). Simulations are performed over 3000 time steps (femto seconds), yielding the total energy and average pressure from which the equation of state, heat capacity and Gruneisen parameter are determined. Preliminary results show that, in addition to the increase in Si coordination with pressure, about one third of the O atoms are not bound to Si at low pressure, a fraction which vanishes with increased Si coordination.

**12:39**

**P42 8 Dissociation of Ringwoodite investigated by first principles*** YONGGANG YU, RENATA WENTZCOVITCH, TAKU TSUCHIYA, KOICHIRO UMEMOTO, JUN TSUCHIYA, *Minnesota Supercomputing Institute and Department of Chemical Engineering and Materials Science, University of Minnesota* DONALD WEIDNER, *Center for High Pressure Research and Department of Geosciences, State University of New York, Stony Brook, NY 11794, USA* RENATA WENTZCOVITCH'S GROUP AT UNIVERSITY OF MINNESOTA TEAM, DONALD WEIDNER'S GROUP AT STATE UNIVERSITY OF NEW YORK AT STONY BROOK COLLABORATION, The dissociation of Ringwoodite, $Mg_2SiO_4$ gamma-spinel, into MgO and $MgSiO_3$ perovskite is believed to be associated with the 660-km discontinuity in Earth's mantle. Details of this transition are important to clarify its effect on mantle convection: it is believed to inhibit flow across the ''660'' discontinuity. We have investigated the phase boundary using quasiharmonic free energy computations within the LDA and GGA. Once more the GGA transition pressure, $P_{tr}$, is higher and in much better agreement with the limited experiments available. The higher GGA $P_{tr}$ can be rationalized by close inspection of the relationship between GGA and LDA functional forms. Our predictions of density, bulk modulus, and bulk velocity jumps across the transition are consistent with seismic observations.

**P42 9 Structure and freezing of $MgSiO_3$ liquid in Earth's interior** BIJAYA KARKI, *Louisiana State University* LARS STIXRUDE, *University of Michigan* Silicate liquids are primary agents of mass and heat transport, yet little is known of their physical properties or structure over most of the mantle pressure regime. We have applied density functional theory within the local density approximation to the study of silicate liquids via Born-Oppenheimer first principles molecular dynamics. The simulations are performed in the NVT ensemble with a Nose thermostat. We find that over the pressure regime of Earth's mantle the mean Si-O coordination number increases nearly linearly with compression from four-fold to six-fold. The Grüneisen parameter of the liquid increases markedly on compression, in contrast to the behavior of mantle crystalline phases, and in accord with expectations based on the pressure-induced change in structure of the liquid. The density contrast between liquid and crystal decreases nearly five-fold over the mantle pressure regime and is 4 % at the core-mantle boundary. The melting curve, obtained via integration of the Claussius-Clapeyron equation yields a melting temperature of 5400 $\pm$ 600 K at the core mantle boundary. Our results support the notion of buoyantly stable silicate melts at the core-mantle boundary.

**P42 10 A laboratory method for modeling synthesis of coesite in the earth's surface by combining local mechanical collision with shear stress and high static pressure.** WEN-HUI SU, SHU-E LIU, *Center for the Condensed-Matter Science and Technology, Harbin Institute of Technology, Harbin 150001, P. R. China* DA-PENG XU, WEI-RAN WANG, *Center for Rare-Earth Solid State Physics, Jilin University, Changchun 130023, P. R. China* XIAO-MEI LIU, *Center for the Condensed-Matter Science and Technology, Harbin Institute of Technology, Harbin 150001, P. R. China* A laboratory method of combining the high-energy mechanical ball milling and high static pressure has been suggested for modeling synthesis of coesite in the earth's surface. A window of milling time, a mechanical collision-induced intermediate phase of $\alpha$-quartz and its condition of easily crystallizing into coesite induced by high static pressure 3.0 GPa, 923 K, $<$ 1.0 min have been discovered. The condition has a much shorter synthesizing time and lower synthesizing critical pressure than that obtained before. The Raman spectrum for the coesite synthesized by the present method has the biggest number of peaks, and have covered over the information of those natural and synthesized coesite reported before. Here We clarify the implications of the coesite synthesized by this method in geo-science, and suggest another possible formation mechanism of coesite in the earth's surface, which is different from the hypothesis of plate subduction-exhumation in the earth that was based on the coesite formation condition of high static pressure in laboratory.

**P42 11 Novel Perovskite Compounds Synthesized under Elevated High Pressure.*** C.Q. JIN, Q.Q. LIU, X.M. QIN, *Institute of Physics, Chinese Academy of Sciences* High pressure synthesis is very powerful to stabilize new compounds with perovskite-like structure, as it has been very well established in the studies of Earth mantle. This has been widely demonstrated in the research of transition metal oxides. Here we introduce some new transition metal compounds that have been recently synthesized under elevated high pressure.

**13:27**

**P42 12 Structure of $MgO(MgSiO_3)_n$ in Earth's Lower Mantle: ab initio calculations** PATRIC OULEVEY, MOHAMMED SAHNOUN, *Department of Chemistry, University of Fribourg, CH-1700 Fribourg, Switzerland* SIMONPIETRO DI PIERRO, *Laboratoire de Sciences de la Terre, UMR CNRS 5570, École Normale Supérieure de Lyon, France* BERNARD GROBÉTY, *Department of Mineralogy, University of Fribourg, CH-1700 Fribourg, Switzerland* CLAUDE DAUL, *Department of Chemistry, University of Fribourg, CH-1700 Fribourg, Switzerland* Ruddlesden-Popper (RP) compounds are composed of alternating perovskite-type and rocksalt-type structural elements. $MgSiO_3$ and MgO are found as separate phases in Earth's lower mantle. Both structural elements occur also in the hypothetical RP-series $MgO(MgSiO_3)_n$. It is interesting to explore the high pressure-high temperature stability of such RP-structures. Using the augmented plane wave implementation of Density Functional Theory we investigate the structural stability at lower mantle conditions of the member with $n = 1$ e.g. $Mg_2SiO_4$. The goal of the present calculations is to test the stability of this Ruddlesden-Popper phase relative to $\gamma$-$(Mg,Fe)_2SiO_4$ and the assemblage $MgSiO_3$-perovskite + MgO magnesiowüstite. We will present our results of this study.

**13:39**

**P42 13 Heat capacity measurements of sub-milligram quantities of mantle minerals** DAVID W. COOKE, F. HELLMAN, *University of California at Berkeley* A. NAVROTSKY, M. DOROGOVA, C.E. LESHER, *University of California at Davis* Knowledge of heat capacities and standard entropies of mantle minerals is necessary for thermodynamic modeling of high P-T equilibria. However many of these materials can only be prepared in milligram quantities in a multianvil apparatus or in microgram quantities in a diamond anvil cell. This eliminates traditional adiabatic calorimetry techniques for Cp measurements. Our microcalorimeters have been used to successfully measure thin films, multilayers, and magnetic single crystals. Using these ''calorimeters on a chip,'' we are measuring the heat capacity of the $Fe_2SiO_4$ olivine and spinel polymorphs from 2 K to room temperature. This will provide a direct measurement of the entropy of the olivine-spinel transition and will uncover possible magnetic phase transitions at low temperature in the spinel phase. We would like to thank the DOE for funding this research.

**P42 14 Carbon under extreme conditions: phase boundaries from first-principles theory** ALFREDO A. CORREA, *Physics Department, University of California, Berkeley* STANIMIR A. BONEV, *Department of Physics, Dalhousie University, Halifax* GIULIA GALLI, *Department of Chemistry, University of California, Davis* We present predictions of diamond and BC8 melting lines and their phase boundary in the solid phase, as obtained from first principles calculations. Maxima are found in both melting lines, with a triple point located at $\sim$ 850GPa and $\sim$ 7400K. Our results show that hot, compressed diamond is a semiconductor which undergoes metalization upon melting. On the contrary, in the stability range of BC8, an insulator to metal transition is likely to occur in the solid phase. Close to the diamond/ and BC8/liquid boundaries, molten carbon is a low-coordinated metal retaining some covalent character in its bonding up to extreme pressures. Our data provide constraints to the carbon equation of state, which is of critical importance to devise models of, e.g., Neptune, Uranus and white dwarf stars, as well as of extra-solar carbon planets. This work was performed under the auspices of the U.S. Dept. of Energy at the University of California/Lawrence Livermore National Laboratory under contract no. W-7405-Eng-48.

**P42 15 Synthesis of New Cubic $C_3N_4$ Phase under High Pressure and High Temperature** LI CHUNG MING, PAVEL ZININ, *University of Hawaii* YUE MENG, *Argonne National Laboratory* XIU-RU LIU, SHI MING HONG, *Southwest Jiaotong University, China* YI XIE, *University of Science and Technology of China* Synchrotron-based X-ray diffraction studies were carried out on a graphite-like $C_3N_4$ ($g$-$C_3N_4$) phase subjected to high pressures up to 38 GPa and high temperatures of up to 3000 K using the laser-heated diamond-anvil cell. Laser-heating the sample to 1800 K at pressure between 20 and 38 GPa, a new set of diffraction pattern appeared, showing positively that a high-pressure phase was formed. Upon decompression of the post-lasered sample to 1 atmospheric pressure, the X-ray diffraction peaks of high-pressure phase were replaced completely by a new pattern, thus demonstrating a new metastable phase was formed retrogressively. X-ray diffraction data on the recovered phase show that it is a new cubic phase that does not match to any high-pressure phases in $C_3N_4$ predicted theoretically.

## SESSION P43: NOVEL PHASES IN QUANTUM GASES

**11:15**

**P43 1 Stability of Bosonic atomic and molecular condensates near a Feshbach Resonance** SOURISH BASU, ERICH MUELLER, *Laboratory of Atomic and Solid State Physics, Cornell University, Ithaca, New York 14853* Fermions near a Feshbach resonance exhibit a smooth crossover between a Bose-Einstein condensed state of molecules and a BCS superfluid of Cooper pairs. We study the analogous problem in Bosons, where there is a possibility of a phase transition between a molecular condensate (MC) and an atomic condensate (AC). We show that on the mo-

lecular side of the resonance at low densities, a MC-AC continuous transition is precluded by the AC state having a negative compressibility [cond-mat/0507460]. Instead, there is a mechanical collapse to a liquid-like state, analogous to a first order phase transition. We predict that sufficiently high densities (beyond those currently achieved in experiments) will push the system beyond its tricritical point and allow a continuous MC-AC phase transition.

**11:27**

**P43 2 Phase diagram of Bose-Fermi mixtures in one-dimensional optical lattices** LODE POLLET, MATTHIAS TROYER, *Institut Theoretische Physik, ETH Zurich, CH - 8093 Zurich, Switzerland* KRIS VAN HOUCKE, STEFAN ROMBOUTS, *Subatomaire en Stralingsfysica, Universiteit Gent, B - 9000 Gent, Belgium* The ground state phase diagram of the one-dimensional Bose-Fermi Hubbard model is studied in the canonical ensemble using a quantum Monte Carlo method. We focus on the case where both species have half filling in order to maximize the pairing correlations between the bosons and the fermions. In case of equal hopping we distinguish between phase separation, a Luttinger liquid phase and a phase characterized by strong singlet pairing between the species. True long-range charge density waves exist with unequal hopping strengths.

**11:39**

**P43 3 Luttinger's theorem and Phase Transitions in Bose-Fermi mixtures** STEPHEN POWELL, *Yale University* SUBIR SACHDEV, *Harvard University* HANS PETER BUCHLER, *University of Innsbruck* A mixture of bosonic and fermionic atoms with a Feshbach resonance between the two can exhibit a range of phases as the energy of a fermionic bound state is varied. In each uniform phase a generalized statement of Luttinger's theorem can be made regarding the two Fermi surfaces, one associated with the atomic fermion and one with the bound-state molecule. The various phases can then be characterized by their different Luttinger constraints, which also depend on the presence or absence of a bosonic condensate. Interesting parallels can be drawn between this system and two others: the transition to the fractionalized Fermi liquid in Kondo lattice models, and fermion-pair condensation in the presence of mismatched Fermi surfaces.

**11:51**

**P43 4 Spontaneous Symmetry Breaking and Defect Formation in a Quenched Ferromagnetic Spinor Bose-Einstein Condensate** LORRAINE SADLER, JAMES HIGBIE, MUKUND VENGALATORRE, SABRINA LESLIE, DAN STAMPER-KURN, *University of California, Berkeley* We observe spontaneous symmetry breaking in a spinor Bose condensate of $^{87}$Rb that is quenched across a quantum phase transition to a ferromagnetic state. Using high spatial resolution maps of the vector magnetization of the condensate, we directly observe the spontaneous formation of inhomogeneous ferromagnetic regions separated by unmagnetized defects. The growth of these ferromagnetic regions are due to a dynamical instability, which determines their typical size and the time for their formation in accord with our observations.

**12:03**

**P43 5 Thermodynamic properties of Bose-Hubbard model.** BARBARA CAPOGROSSO-SANSONE, NIKOLAY PROKOF'EV, BORIS SVISTUNOV, *Department of Physics, University of Massachusetts, Amherst, Massachusetts 01003* We perform Monte Carlo simulations of bosons in a three-dimensional optical lattice. We present accurate data for the ground state phase diagram and for the finite-temperature thermodynamic properties, including specific heat and entropy. Our data form a basis for an accurate thermometry of the system.

**12:15**

**P43 6 Existence of Roton Excitations in Bose Einstein Condensates: Signature of Proximity to a Mott Insulating Phase** ZAIRA NAZARIO, DAVID I. SANTIAGO, *Stanford University* Within the last decade, artificially engineered Bose Einstein Condensation has been achieved in atomic systems. Bose Einstein Condensates are superfluids just like bosonic Helium is and all interacting bosonic fluids are expected to be at low enough temperatures. One difference between the two systems is that superfluid Helium exhibits roton excitations while Bose Einstein Condensates have never been observed to have such excitations. The reason for the roton minimum in Helium is its proximity to a solid phase. The roton minimum is a consequence of enhanced density fluctuations at the reciprocal lattice vector of the stillborn solid. Bose Einstein Condensates in atomic traps are not near a solid phase and therefore do not exhibit roton minimum. We conclude that if Bose Einstein Condensates in an optical lattice are tuned near a transition to a Mott insulating phase, a roton minimum will develop at a reciprocal lattice vector of the lattice. Equivalently, a peak in the structure factor will appear at such a wavevector. The smallness of the roton gap or the largeness of the structure factor peak are experimental signatures of the proximity to the Mott transition.

**12:27**

**P43 7 Supersolid Bosons on Frustrated Optical Lattices** STEFAN WESSEL, *Institute for Theoretical Physics III, University of Stuttgart, Germany* MATTHIAS TROYER, *Institute for Theoretical Physics, ETH Zurich, Switzerland* We consider an ultra-cold Bose gas on a triangular optical lattice subject to nearest neighbor repulsion, and determine the phase diagram using quantum Monte Carlo simulations. Already in the hard-core limit the system is found to exhibit an extended supersolid phase emerging from an order-by-disorder effect as a novel way of a quantum system to avoid classical frustration. We analyze the nature of the supersolid phase and its stability in competition with phase-separation, which we find to occurs in other regions of parameter space. Possible experimental realizations of our scenario and extensions to other lattice geometries are discussed as well as the connection to the physics of frustated quantum antiferromagnets.

**12:39**

**P43 8 Frustrated two-dimensional XY models with cold atoms in optical lattices** ANTON BURKOV, EUGENE DEMLER, *Harvard University* We consider a system of cold bosonic atoms in a rotating optical lattice at finite temperature. We show that such system exhibits a non-trivial dependence of the condensation temperature and the superfluid order parameter on the vortex density due to commensuration effects of the vortex and optical lattices.

We identify several vortex filling/lattice geometry combinations for which the vortex ordering pattern exhibits subtle order-by-disorder effects due to an interplay between multiple degeneracy of frustrated vortex configurations and thermal fluctuations.

**12:51**

**P43 9 Winding Numbers in Rotating Bose Gases** ALEXIS G. MORRIS, *University of Calgary* DAVID L. FEDER, *University of Calgary* The exact ground states of zero-temperature rotating Bose gases confined in quasi-two-dimensional harmonic traps are investigated numerically, for small numbers of alkali atoms. As the rotation frequency increases, the interacting Bose gas undergoes a series of transitions from one quantum Hall state to another. By tracking the change in ground state energy with an applied phase twist, we are able to calculate the winding (Chern) number characterizing the topological nature of the various bosonic quantum Hall states.

**13:03**

**P43 10 Parafermionic states in rotating Bose-Einstein condensates** NICOLAS REGNAULT, *LPA, ENS-Paris, France* THIERRY JOLICOEUR, *LPTMS, Orsay, France* Rotating Bose-Einstein condensates in a trap are the place of a very rich physics. It has been predicted that, under appropriate conditions, they will behave like two dimensional electron systems in the fractional quantum Hall effect regime. In addition to the usual fractions, more exotic phases have also been predicted at filling factor $\nu = k/2$. These parafermionic states are described by the Read-Rezayi (RR) wave functions. We study how the system size and interaction act on the overlap between the true ground state and corresponding RR state. The quasihole excitations of the RR states are known to obey non-Abelian statistics. We numerically evaluate the degeneracy of these states and show it is in agreement with a formula given by E. Ardonne. We compute overlap between low-energy true eigenstates and quasihole ground states, and discuss in which cases such description is valid.

**13:15**

**P43 11 Quantum magnetism with multicomponent polar molecules in an optical lattice** RYAN BARNETT, DMITRY PETROV, MIKHAIL LUKIN, EUGENE DEMLER, *Harvard University* We consider dipolar molecules in an optical lattice prepared as a mixture of states with angular momentum $\ell = 0$ and $\ell = 1$. The $1/r^3$ interaction between molecules for this system is produced by exchanging a quantum of angular momentum between two molecules. We show that Mott states of such systems have a large variety of non-trivial spin orderings including SDW state at a wavevector that can be controlled by changing parameters of the system. As the Mott insulating phase is melted, we also show that an interesting winding in the phase of the order parameter can occur. Finally, we consider ways of detecting such phases experimentally.

**13:27**

**P43 12 Biaxial nematic phase of two dimensional disordered rotor models and spin-one bosons in optical lattices** JEAN-SEBASTIEN BERNIER, *University of Toronto* KRISHNENDU SENGUPTA, *Saha Institute of Nuclear Physics* YONG BAEK KIM,* *University of Toronto* We show that the ground state of disordered rotor models with quadrupolar interactions can exhibit biaxial nematic ordering in the disorder-averaged sense. We present a mean-field analysis of the model and demonstrate that the biaxial phase is stable against small quantum fluctuations. We point out the possibility of experimental realization of such rotor models using ultracold spin-one Bose atoms in a spin-dependent and disordered optical lattice in the limit of a large number of atoms per site and also suggest an imaging experiment to detect the biaxial nematicity in such systems.

**P44 1 Interlayer magnetoresistance as a probe of the quantum coherence of electronic excitations in layered metals** MALCOLM KENNETT, *Simon Fraser University* ROSS McKENZIE, *University of Queensland* Angle-dependent magnetoresistance oscillations (AMRO) have been used as a powerful tool to map out Fermi surfaces in layered metals, such as organic metals, strontium ruthenate, and an over-doped cuprate. We derive a general formula for AMRO in systems with anisotropic interlayer hopping, anistropic in-plane scattering and an anisotropic 2*d* Fermi surface. We discuss the ability of AMRO to discriminate between coherent transport when there is a 3*d* Fermi surface and weakly incoherent transport, where there is hopping between 2*d* Fermi surfaces that are only defined in each layer. We illustrate these ideas by comparison with experimental measurements of AMRO in thallium cuprate [1]. [1] N. E. Hussey *et al.*, Nature **425**, 814 (2003).

**P44 3 Unified Theory of Magic Angles and Interference Commensurate Oscillations.** SI WU,*ANDREI LEBED,† *Dept. of Physics, University of Arizona* HEON-ICK HA, *Dept. of Physics, Harvard University* MICHAEL NAUGHTON, *Dept. of Physics, Boston College* We suggest the unification theory of angular magnetoresistance oscillations in low-dimensional metals with open sheets of Fermi surfaces. It is based on an idea that effective space dimensionality of electron spectrum and electron wave functions is changed at some special directions of a magnetic field. These 1D -> 2D dimensional crossovers are shown to be due to interference effects, which occur when electrons move in the extended Brillouin zone in a magnetic field. Our quantum mechanical approach allows to derive an equation which describes analytically

both Magic Angles and Interference Commensurate oscillations in resistivity component, perpendicular to conducting layers, and reveals their common physical origin. We compare our results with experimental data obtained on $(TMTSF)_2ClO_4$ and $(TMTSF)_2PF_6$.

**P44 4 Lebed Magic Angles in $(TMTSF)_2X$ Probed by Torque, Transport and NMR*** J.I. OH, *Boston College* K. KOBAYASHI, *Princeton University* P.M. CHAIKIN, *NYU* J. SHINAGAWA, *UCLA* S.E. BROWN, *UCLA* M.J. NAUGHTON, *Boston College* We have investigated the Lebed effect [1] in the quasi −1D molecular organic conductor (TMTSF)2X for magnetic fields in the b′ −c* −plane, via angle−dependent torque, magnetoresistance, and NMR relaxation rate. In torque versus field angle measurements for X = ClO4 at 0.1 K, we observed distinct field induced spin density wave (FISDW) transitions but, to within our experimental accuracy of 3× 10−11 Nm, we found no evidential anomalies at the Lebed magic angles. We compare this result with earlier reports of torque measurements in X = ClO4 [2] and 77Se NMR relaxation rate measurements in X = PF6 [3]. In fixed angles T− (NMR) and B−sweeps (torque and magnetoresistance) in the vicinity of magic angles, no change in the FISDW position was observed. These measurements suggest that magic Lebed orientations have no effect on the metal−FISDW transition. [1] A. G. Lebed, JETP Lett. **43**, 174 (1986). [2] M. J. Naughton et al., Phys. Rev. Lett. **67**, 3712 (1991). [3] W. Wu et al., Phys. Rev. Lett. 94, 097004 (2005).

**P44 5 Thermoelectric power and Nernst effect studies in the metallic and field-induced spin density wave states in $(TMTSF)_2ClO_4$** EUN SANG CHOI, JAMES S. BROOKS, *NHMFL/Florida State University* HAEYONG KANG, YOUNJUNG JO, WOUN KANG, *Ewha Womans University, Seoul, Korea* We have measured the angular dependence of thermoelectirc power (TEP) and Nernst effect of $(TMTSF)_2ClO_4$. At low temperatures and in the metallic state, Nernst effect shows giant resonant signals around the Lebed magic angles, while TEP is small without noticiable angular dependence. This behavior is very similar to what was observed in $(TMTSF)_2PF_6$ in the metallic state [Wu et al., Phys. Rev. Lett. **91** 56601(2003)]. By entering the field-induced spin density wave (FISDW) state, both TEP and Nernst signal show complicated behaviors reflecting the FISDW subphase transitions. Remarkably, the resonant Nernst effect still persists in the FISDW state and with even lager amplitude. By increasing the perpendicular field above ~ 6.5 T, both TEP and Nernst effect becomes small again at all angles. Our Nernst effect results are inconsistent with some proposed models for the metallic state of $(TMTSF)_2PF_6$, which may suggest this phenomenon is beyond the Fermi liquid description.

**12:15**

**P44 6 Coexistence of spin density wave and triplet superconductivity in quasi-one-dimensional Bechgaard salts** WEI ZHANG, CARLOS SA DE MELO, *Georgia Institute of Technology* The interplay between magnetic order and superconductivity is a very important problem in condensed matter physics. In the quasi-one-dimensional (quasi-1D) organic conductor $(TMTSF)_2PF_6$, an antiferromagnetic state charaterized by a spin density wave (SDW) order neighbors a triplet superconducting (TSC) state on the pressure-temperature phase diagram. Experiments [1,2] suggest a coexisting region of SDW and TSC orders in the vicinity of the phase boundary. We consider a tight-binding quasi-1D electron system, and construct the Ginzburg-Landau (GL) free energy with two order parameters. In the absence of a magnetic field, the rotational symmetry of this system is broken due to spin anisotropy and spin-orbit coupling. Thus, the GL free energy has a similar form as the ordinary $\phi_1$-$\phi_2$ model, except additional gradient terms. We calculate the GL coefficients microscopically and obtain a phase diagram in zero magnetic field. This phase diagram shows a coexistence region for SDW and TSC. Reference: [1] T. Vuletic *et al.*, Eur. Phys. J. B **25**, 319 (2002). [2] I. J. Lee *et al.*, Phys. Rev. Lett. **94**, 197001 (2005).

**P44 7 Anomalous temperature dependence of the single-particle spectrum in the organic conductor TTF-TCNQ** NEJAT BULUT, *IMR, Tohoku University and CREST, Japan Science and Technology Agency* HIROAKI MATSUEDA, *Department of Physics, Tohoku University* TAKAMI TOHYAMA, *IMR, Tohoku University* SADAMICHI MAEKAWA, *IMR, Tohoku University and CREST, Japan Science and Technology Agency* The angle-resolved photoemission spectrum of the quasi-one-dimensional organic-conductor TTF-TCNQ exhibits an unusual temperature dependence in the sense that a transfer of spectral weight over an energy range of $\approx$ 1iteV takes place as the temperature decreases below 260$K$. In order to investigate the origin of this behavior, we have performed Dynamical Density-Matrix-Renomalization-Group (DDMRG) calculations at zero temperature and Quantum Monte Carlo (QMC) calculations at finite temperatures for the single-particle spectral weight of the doped one-dimensional (1D) Hubbard model. We present DDMRG and QMC results for a range of the model parameters of the 1D Hubbard model and make comparisons with the photoemission data. In addition, we present zero-temperature DDMRG results on the doped 1D Hubbard-Holstein model in order to explore how the electron-phonon coupling influences the single-particle spectrum in 1D correlated conductors.

**12:39**

**P44 8 Multiple spin sites in an organic conductor without magnetic ions.*** TAKAHISA TOKUMOTO, *FSU/NHMFL* YUGO OSHIMA, *Tohoku University, Japan* DAVID GRAF, *NHMFL* JAMES BROOKS, *FSU/NHMFL* JOHAN VAN TOL, *NHMFL* LOIUS-CLAUDE BRUNEL, *NHMFL* GEORGE PAPAVASSILIOU, *National Hellenic Research Foundation, Greece* The anisotropic low dimensional organic conductors are attractive because of the variety of ground states with unusual and exotic electronic properties. One of them is tau-[P-($S$, $S$)-DMEDT-TTF]$_2$($AuBr_2$)$_{1+y}$ [where y~ 0.75 and P-($S$, $S$)-DMEDT-TTF stands for pyrazino-($S$, $S$)-dimethyl-ethylenedithio-tetrathiafulvane], which has tetragonal crystal structure with unit cell dimensions **a**=**b**=7.3546 Å and **c**=67.977 Å[1]. Even though there are no magnetic ions in the

compound, transport measurements show magnetic ordering at low temperature and in magnetic fields. To investigate the origin of the magnetic behavior, we are conducting an ESR study. We do observe multiple resonances which indicate the existence of the multiple spins although the system does not contain magnetic ions. Moreover, the in-plane angular dependent ESR measurements reveal 4 fold symmetry. Both in-plane and out of plane ESR signal show evidence of antiferromagnetic behavior below 12 K. It is possible that the ion stoichiometric charge transfer (1+y) is the origin of the magnetic effects. Further analysis will be presented.

**12:51**

**P44 9 Investigating the Charge Ordering Pattern in the Organic Spin Ladder $(DT\text{-}TTF)_2Cu(mnt)_2$*** S. BROWN, J. T. HARALDSEN, J. CAO, J. L. MUSFELDT, *University of Tennessee, Knoxville* M. MAS-TORRENT, C. ROVIRA, *Institut de Ci ència de Materials de Barcelona, Spain* J. C. DIAS, R. T. HENRIQUES, M. ALMEIDA, *Instituto Tecnológico e Nuclear, Portugal* Quantum spin ladders have attracted considerable interest as intermediaries between one-dimensional chains and two- dimensional square lattices. In order to elucidate the charge ordering pattern in a model organic spin ladder, we measured the temperature-dependent infrared spectra of the organic spin- ladder candidate $(DT\text{-}TTF)_2Cu(mnt)_2$. We interpret the results within the context of recent theoretical predictions of various charge ordering patterns in spin ladders [1]. Comparision with spectra of the isostructural Au analogue and neutral DT-TTF compound aid in this analysis. [1] R. T. Clay, S. Mazumdar, Phys. Rev. Lett. **94**, 207206 (2005)

**P44 10 Magnetic field effects on the coexisting Bond-Charge-Density waves in the quasi-one-dimensional quarter-filled bands*** SUMIT MAZUMDAR, *University of Arizona* R. TORSTEN CLAY, *Mississippi State University* Magnetic field effects on spin-Peierls systems have been of interest for a long time. The theoretical phase diagram consists of three different regions containing the homogenous dimerized and undimerized phases, and a magnetic phase consisting of a soliton lattice or an incommensurate phase. We have investigated numerically spin excitations and magnetic field effects on the bond-charge-density wave (BCDW) that appears below the spin-Peierls transition in the quarter-filled band organic charge transfer solids (CTS), with the specific goal of determining whether the simplest phase diagram, obained within the spin model, applies also to the quarter-filled band where both charge and spin degrees of freedom exist. We also discuss recent experiments in quarter-filled band CTS within the context of our theory.

**P44 11 Temperature dependent competition between charge-ordering and spin-Peierls transition in $(TMTTF)_2X$: the role of quantum phonons*** R. T. CLAY, *Mississippi State University* R. P. HARDIKAR, *Mississippi State University* S. MAZUMDAR, *University of Arizona* The $(TMTTF)_2X$ salts are quasi-one-dimensional materials with complex phase diagrams that feature a large number of ordered states including superconductivity. The ground states of these materials are often spin-Peierls (SP) states. However, at intermediate temperatures (100 K) a transition to a charge ordered state is also present, which may compete with the ground state SP ordering. We investigate numerically models for these materials that include three components: electronic interactions, bond-coupled phonons, and Holstein-type phonons coupled to the local charge density. These three components have different energy scales are hence expected to dominate at different temperatures. We explicitely include finite phonon frequency in our calculations using quantum Monte Carlo methods. We present charge, spin, and bond susceptibilities as a function of temperature and discuss recent experiments on these materials.

**13:27**

**P44 12 Discrete breather energy thresholds in Discrete Nonlinear Schrodinger (DNLS) systems Discrete breather energy thresholds in Discrete Nonlinear Schrodinger (DNLS) systems** JUN ZHOU, JEROME DORIGNAC, DAVID CAMPBELL, *Boston University* The DNLS equation has been used successfully to model physical systems as varied as the Holstein polaron, the Davydov soliton, local modes of small molecules and, more recently, optical wave guide arrays and Bose-Einstein condensates trapped in optical lattices. In addition, the DNLS also governs the slow modulations of plane waves in Klein-Gordon systems (network of oscillators). In one dimension and for a cubic nonlinearity, the DNLS is known to support discrete breather solutions - time-periodic, spatially localized excitations - with arbitrary low energy (or norm). In contrast, for higher nonlinearities or in higher dimensions, an energy (norm) threshold is known to exist, below which discrete breathers cannot be found. Using two different approaches to treat the DNLS equation–namely, an exponential ansatz and the so-called ''single nonlinear impurity'' approximation– we derive analytical expressions for these energy thresholds and compare them to the exact numerical solutions.

**13:39**

**P44 13 Bipolaron phase diagram of the 1D adiabatic Holstein-Hubbard model in the strong coupling limit** JEROME DORIGNAC, JUN ZHOU, DAVID CAMPBELL, *Boston University* We derive the phase diagram for bipolarons in the one-dimensional adiabatic Holstein-Hubbard model in the strong coupling (small hopping) limit. We show the existence of a threshold value for the Coulomb interaction beyond which the ground state of the system consists of two free polarons (infinitely far apart from each other). This result, obtained by means of an exact perturbative expansion, cannot be reproduced by the usual exponential ansatz for the wave function.

**13:51**

**P44 14 First-Principles Study of Electronic Structure in $\alpha$-$(BEDT\text{-}TTF)_2I_3$ at Ambient Pressure and under Uniaxial Strains.*** HIORI KINO, *National Institute for Materials Science* TSUYOSHI MIYAZAKI, We calculate the electronic structure of $\alpha$-$(BEDT\text{-}TTF)_2I_3$ at 8K and room temperature at ambient pressure and under the uniaxial strains along the a- and a-axes within the density functional theory. We discover itanisotropic Dirac cone dispersion near the chemical potential. We also extract the orthogonal tight binding parameters to analyze physical properties. An investigation of the electronic structure near the chemical potential clarify that effects of the uniaxial strain along the a-axis is

different from that along the b-axis. The Dirac cone dispersion yields the linear density of states to give $T^2$ dependence of the carrier density upto about 100K. It may explain the experimental findings not only qualitatively but also quantitatively.

**P44 15 Power-law Current-Voltage Characteristics of Charge-Ordered Organic Crystals $\theta$-(BEDT-TTF)$_2$MZn(SCN)$_4$ (M =Cs, Rb)** YAMAGUCHI TAKAHIDE, TAKAKO KONOIKE, KENGO ENOMOTO, MITSUKA NISHIMURA, TAICHI TERASHIMA, SHINYA UJI, *National Institute for Materials Science, Japan* HIROSHI M. YAMAMOTO, *RIKEN(The Institute of Physical and Chemical Research), Japan* We have measured the current-voltage characteristics of charge- ordered organic crystals $\theta$-(BEDT-TTF)$_2$MZn(SCN)$_4$ (M=Cs, Rb) in a low current range down to $10^{-13}$ A. The current-voltage characteristics follow the power law $I \propto V^a$ with a large exponent (e.g., $a = 8.4$ at 0.3 K for M=Cs) over a wide range of currents. The power-law characteristics are attributed to electric field-induced unbinding of electron- hole pairs which are thermally excited in the background of the two-dimensional charge order. From analysis of crossover electric fields from ohmic to the power-law characteristics, we obtain strong evidence that the electron-electron Coulomb interaction is significantly long-ranged, i.e., the screening length is greater than 10 molecule sites. A novel magnetoresistance effect, possibly due to the Pauli exclusion principle, is also presented.

**SESSION P45: STRUCTURAL AND FERROELECTRIC PHASE TRANSITIONS**

**P45 1 Structural symmetry of $Cd_2Re_2O_7$ from nonlinear optics** JESSE C. PETERSEN, MICHAEL D. CASWELL, J. STEVEN DODGE, *Department of Physics, Simon Fraser University, Burnaby, British Columbia, Canada* JIAN HE,*DAVID MANDRUS, *Department of Physics and Astronomy, The University of Tennessee, Knoxville and Solid State Division, Oak Ridge National Laboratory* $Cd_2Re_2O_7$, a superconducting metallic pyrochlore, undergoes a second-order structural phase transition at 200 K from a cubic to tetragonal lattice. Landau theory predicts that any second-order cubic-to-tetragonal phase transition must also possess an order parameter associated with broken inversion symmetry. By observing optical second-harmonic generation, we provide a direct demonstration that the 200 K transition in $Cd_2Re_2O_7$ involves broken inversion symmetry. Moreover, we have used the polarization dependence of SHG to refine the crystal structure. We find that the low-temperature crystal symmetry is that of the $F\bar{4}2m$ space group.

**P45 2 X-ray absorption spectroscopy on the phase transition of $Cd_2Re_2O_7$** SHIH-WEN HUANG, *Department of Electrophysics, National Chiao Tung University* J. M. CHEN, *National Synchrotron Radiation Research Center* H. T. JENG, *Institute of Physics, Academia Sinica* J-Y LIN, *Institute of Physics, National Chiao Tung University* J. M. LEE, *National Synchrotron Radiation Research Center* H. D. YANG, *Department of Physics, National Sun Yat Sen University* KENG LIANG, *National Synchrotron Radiation Research Center* H. BERGER, *Department of Physics, EPF Lausanne, CH-1015 Lausabbe* Pyrochlore $Cd_2Re_2O_7$ has received considerable attention and investigated extensively because of its manifold phase transitions accompanied by profound physical properties. In this study, the relations among the electronic structure, phase transition, and some physical properties of $Cd_2Re_2O_7$ single crystals have been investigated. We conducted the X-ray diffraction as well as Re $L_{2,3}$-edge extended X-ray absorption fine structure (EXAFS) at different temperatures to investigate the local structure of $Cd_2Re_2O_7$ and temperature-dependent O $K$-edge X-ray absorption near edge structure (XANES) to probe its electronic structure during the phase transition. We also performed the band structure calculations to understand the DOS near the Fermi level of $Cd_2Re_2O_7$ at different temperatures.

**11:39**

**P45 3 Pressure effects on a low carrier density metal's infrared response** N. PETER ARMITAGE, *University de Geneve* RICCARDO TEDIOSI, *University de Geneve* LASZLO FORRO, *Ecole Polytechnique Federale de Lausanne* DIRK VAN DER MAREL, *University de Geneve* We have performed pressure and temperature dependent infrared studies of semi-metal bismuth. Along with other semi-metals such as graphite and antimony, bismuth is a material of much current interest due to the interesting properties resulting from an extremely low carrier density, small effective mass, and long mean free path. A novel optical setup has been developed to measure low temperature infrared responses at pressures of up to 17kbar. We observe massive changes in bismuth's optical and infrared conductivity as a function of temperature and pressure. We discuss the origin of these changes both in terms of simple band structure effects, as well as in terms of the correlation effects that are expected in this very low-carrier density metal.

**11:51**

**P45 4 Ferroelectric phase transition in the incommensurate phase of the $K_2SeO_4$ crystal** TIGRAN ASLANYAN, *Institute for Physical Research, Armenian National Academy of Sciences* It is shown that in the incommensurate (IC) phase of the $K_2SeO_4$ crystal a phase transition takes place to the ferroelectric IC phase, prior to the lock-in transition to the triple-period commensurate phase. Such a behavior is due to the Lorentz microscopic electric field, which is induced by the IC domains on approaching the lock-in transition temperature. The proposed behavior of the $K_2SeO_4$ crystal explains the second-harmonic generation, observed in the IC phase, near the lock-in transition. It explains also the observed drop in the crystal's elastic constant c55 near the lock-in transition, which corresponds to a significant decrease of the z-polarized sound velocity in the x-direction. Continuous increasing of the polarization in the ferroelectric IC phase manifests itself as a continuous decreasing of the sound velocity. In the same

model one can explain also the observation of an overdamped Raman scattering in the z(xz)y geometry in the low temperature range of the IC phase existence. Dielectric properties of the ferroelectric crystals with artificially fabricated domains are discussed.

**12:03**

**P45 5 Normal and superconducting state properties of the $(Pr_{1-x}Nd_x)Os_4Sb_{12}$ system*** PEI-CHUN HO, WILLIAM YU-HASZ, TATSUYA YANAGISAWA, NEIL FREDERICK, NICHOLAS BUTCH, TODD SAYLES, JASON JEFFRIES, BRIAN MAPLE, *Physics & IPAPS/UCSD* YUICHI NEMOTO, TERUTAKA GOTO, *Grad. Sch. Sci. & Tech./Niigata U., Japan* Our previous experimental studies of the $(Pr_{1-x}Nd_x)Os_4Sb_{12}$ system revealed that: (1) superconductivity and ferromagnetism from both end compounds were suppressed almost monotonically toward $x = 0.55$, (2) retention of the antiferroquadrupolar order phase in $(Pr_{1-x}Nd_x)Os_4Sb_{12}$ to higher values of $x$ than in $Pr(Os_{1-x}Ru_x)_4Sb_{12}$, (3) two possible CEF energy level schemes in $NdOs_4Sb_{12}$, in which the ground state is either the $\Gamma_6$ doublet or $\Gamma_8^{(2)}$ quartet. Recent ultrasonic measurements in the $NdOs_4Sb_{12}$ sample ($x = 1$) revealed softening of the $C_{44}$ mode, which indicated that the CEF ground state in this compound is more likely to be the $\Gamma_8^{(2)}$ quartet. The lattice parameter in $(Pr_{1-x}Nd_x)Os_4Sb_{12}$ seems to increase slightly from $PrOs_4Sb_{12}$ ($x = 0$) toward $NdOs_4Sb_{12}$ ($x = 1$). The T-x and H-x phase diagrams related to superconductivity, ferromagnetism, antiferroquadrupolar order, and the CEF energy level scheme for the $(Pr_{1-x}Nd_x)Os_4Sb_{12}$ system for $0 \leqslant x \leqslant 1$ will be discussed.

*The research at UCSD is funded by U.S. DOE and NSF; the research at Niigata U. is supported by the Grant-in-Aid for Scientific Research Area ''Skutterudites'' of MEXT, Japan.

**P45 6 Elastic properties of ferromagnetic heavy fermion system $SmOs_4Sb_{12}$** YOSHIKI NAKANISHI, TOMOAKI TANIZAWA, TAKUYA FUJINO, ATSUSHI SUGIHARA, PEIJIE SUN, MASAHITO YOSHIZAWA, *Graduate School of Engineering, Iwate University* HITOSHI SUGAWARA, *Faculty of Integrated Arts and Sciences, The University of Tokushima* DAISUKE KIKUCHI, HIDEYUKI SATO, *Deoartment of Physics, Tokyo Metropolitan University* We report the elastic constants of the heavy fermion system $SmOs_4Sb_{12}$ by means of an ultrasonic measurement. A steep decrease associated with the ferromagnetic transition was observed at around 2 K in elastic constants C11, (C11-C12)/2 and C44. Furthermore a characteristic increase, possibly due to the ''rattling-motion'' was observed around 15 K in the elastic constants. The variation of the onset temperature and a degree of the increase as a function of the ultrasonic frequency is reasonably reproduced in terms of the Debye-type dispersion. The obtained parameters describing the rattling-motion such as a relaxation time, an activation energy and a mean square displacement will be discussed as compared with those of an isostructural compound $PrOs_4Sb_{12}$.

**12:27**

**P45 7 High-Energy X-Ray Study of Short Range Order and Phase Transformations in Ti-V** INGO RAMSTEINER,*ANDREAS SCHOEPS, HARALD REICHERT, HELMUT DOSCH, *Max-Planck-Institute for Metals Research Stuttgart, Germany* Phase transformations, especially precipitation processes, are a key factor in alloy design. Understanding these processes in the framework of statistical thermodynamics requires knowledge about the atomic interaction potentials between the alloy constituents. Experimentally, these parameters can be accessed via the diffuse x-ray scattering caused by the configurational short range order and lattice distortions. We employ a bulk sensitive high energy technique to study both phenomena simultaneously in situ, probing macroscopic single crystals in transmission geometry. The data recorded by a 2D detector reveal Bragg reflections from the precipitates superimposed on the diffuse scattering of the matrix. We present a detailed study of bcc Ti-V, a typical titanium $\beta$-alloy. The diffuse scattering is mainly due to lattice distortions induced by the atomic size mismatch. Depending on the annealing temperature, growth and dissolution of hcp $\alpha$-Ti precipitates and minute fractions of TiC are observed. HRTEM experiments have been conducted to complement our results.

**12:39**

**P45 8 Reversible Magnetostriction with Temperature in Single Crystal $Tb_5Si_{2.2}Ge_{1.8}$** A.P. RING, H.L. ZIEGLER, T. LOGRASSO, D. SCHLAGEL, J.E. SNYDER, *Materials and Engineering Physics Program, Ames Laboratory* D.C. JILES, *Wolfson Centre for Magnetics, Cardiff University, Cardiff, Wales, UK* The magnetostriction changes that accompany the phase transitions of single crystal $Tb_5(Si_{2.2}Ge_{1.8})$ have been investigated at temperatures between 20 K and 150 K, by measurements of the reversible component of the magnetostriction along the crystallographic ''a'' axis. Over this temperature range the shape and slope of the magnetostriction curves change, which are indicative of changes in the magnetic state, crystal structure and magnetic anisotropy. Results show a phase transition that occurs near 106 K (onset-completion range 100 - 116 K). The abrupt nature of the strain transition, its unusual hysteresis, and its temperature dependence appear to indicate a first order phase transition which can be activated by applied magnetic field or temperature. Magnetostriction measurements at temperatures below the transition region show a magnetostriction of small overall magnitude but with a high, temperature dependent anisotropy. Funded by USDoE-Office of Basic Energy Sciences

**12:51**

**P45 9 Magnetic phase transition and spin dynamics in Li(Ni1-xFex)PO4** JIYING LI, DAVID VAKNIN, JEREL ZARESTKY, *Ames Laboratory and Department of Physics and Astronomy, Iowa State University, Ames IA 50011* JAE-HO CHUNG, *NIST Center for Neutron Research, National Institute of Standards and Technology, Gaithersburg, MD 20899* Elastic and inelastic neutron scattering techniques were used to study the magnetic phase transition and spin dynamics in pure and Fe substituted LiNiPO4 single crystals. Pure LiNiPO4 undergoes a first-order magnetic phase transition from a long- range ordered incommensurate phase to an antiferromagnetic ground state at TN = 20.8 K. With the substitution of Fe for Ni, the magnetic phase transition changes from first-order to second-order, and moreover, the long-range ordered incommensurate phase of pure LiNiPO4 between 20.8 K to 21.5 K was suppressed in the LiNi0.75Fe0.15PO4 sample. Inelastic neutron scattering revealed a 2 meV energy gap and an anomalous soft mode in the spin wave dispersion curve along the [010] direction for pure LiNiPO4. For LiNi0.8Fe0.2PO4, however, the energy gap was reduced to 0.9 meV and the anomaly along the [010] direction reduced. The spin-wave dispersion curves were simulated using a Heisenberg Hamiltonian with Dzyaloshinski-Moriya interactions.

**P45 10 Phonon Anomalies in the Martensitic Phase of $Ni_2MnGa$*** S.M. SHAPIRO, *Brookhaven National Laboratory, Upton, NY* P. VORDERWISCH, *Hahn-Meitner Institute, Berlin, Germany* K. HRADIL, H. SCHNEIDER, *ICP, U. of Goettingen, Germany* $Ni_2MnGa$ is a cubic ferromagnetic shape memory alloy exhibiting phonon anomalies as precursors to the Martensitic phase transformation. By cooling in a small magnetic field (1.5T) through its transformation temperature it is possible to obtain a single domain of the tetragonal Martensite phase. One can, therefore, measure the phonon dispersion curves in the Martensite phase and compare them to the high temperature cubic phase. The TA branch propagating along the [qq0], with polarization along [q-q0], shows an anomaly near the wavevector of the charge density wave (CDW) peak at q=0.425, which differs from q=0.33 observed in the cubic phase. Most interesting is a new acoustic-like branch emerging from the CDW peak. This will be discussed in relationship to phasons and amplitude modes observed in other incommensurate systems.

**P45 11 Medium-range Structure of $La_{2-x}Sr_xCuO_4$ ($0.0 < x < 0.3$) by Pulsed Neutron PDF Analysis** JIN NAKAMURA, *University of Tennessee* THOMAS PROFFEN, *Los Alamos National Laboratory* TAKESHI EGAMI, *University of Tennessee and Oak Ridge National Laboratory* We studied the local and medium-range atomic structure in high- temperature superconductor (HTSC) $La_{2-x}Sr_xCuO_4$ ($0.0 < x < 0.3$) by the pulsed neutron pair-density function (PDF) analyses. The measurement was made with the NPDF of LANSCE, LANL. Because of the high $Q$-resolution of the NPDF the PDF was determined up to 20 $nm$. The measured PDF was compared with that calculated for the average structure determined by the Rietveld analysis of the same data. We found that the measured PDF deviates from the calculated PDF in two different ways. For $x = 0.16$ - 0.3 deviations were seen up to about 3 $nm$, strongly related to the oxygen in the $CuO_2$ plane displaced along the $c$-axis. These deviations reflect local fluctuations between the orthorhombic and tetragonal phases. A more interesting deviations were seen for $x = 0.04$ - 0.16 up to 2 $nm$ for all compositions. The lengthscale of this local fluctuation corresponds to the in-plane coherence length, suggesting that the structure that supports HTSC may be different from the average structure, and the size of the local domains is not limited by the dopant concentration. Further implications are discussed.

**13:27**

**P45 12 Inelastic neutron scattering study of $YBaFe_2O_5$** SUNG CHANG, *Ames Laboratory* P. KAREN, *Department of Chemistry, University of Oslo* M. P. HEHLEN, F. R. TROUW, *Los Alamos National Laboratory* R. J. MCQUEENEY, *Department of Physics and Astronomy and Ames Laboratory* $YBaFe_2O_5$ belongs to a new class of oxides with the chemical formula $RBaM_2O_5$ ($R$ = rare-earth, $M$ = transition metal), based on the perovskite structure with a doubled unit cell pyramids of five-coordinated $M$-sites. The $M$-site is mixed valent in the stoichiometric formula unit (with an average valence of +2.5). Therefore, charge and orbital ordering phenomena can exist on the $M$-site and be studied without introducing disorder. The charge ordered phase of $YBaFe_2O_5$ is unusual, since it does not satisfy the Anderson criterion (i.e. it is not the lowest energy electrostatic arrangement of charges), but rather orders into alternating chains of 2+/3+. This indicates that other interactions, such as electron-phonon coupling, are necessary to arrive at the chain structure. Here, we present the results of an inelastic neutron scattering study of polycrystalline $YBaFe_2O_5$. We find the spectrum of phonon and magnetic excitations are clearly modified at the charge- and magnetic ordering temperatures: $T_{CO} = 308$ K and $T_N = 430$ K, respectively.

**SESSION P46: FQHE**

**11:15**

**P46 1 Measuring Exchange Interactions by Tunneling Deep Into the Quantum Hall Liquid** O.E. DIAL, R.C. ASHOORI, *Massachusetts Institute of Technology, Cambridge, MA 02139* L.N. PFIEFFER, K.W. WEST, *Bell Laboratories, Lucent Technologies, Murray Hill, New Jersey 07974, USA* We present measurements of the tunneling density of states of a two dimensional electron gas (2DEG) in GaAs at energies up to 10 meV above and below the Fermi energy. Using time domain capacitance spectroscopy (TDCS), we determine the current-voltage (IV) characteristics for tunneling perpendicularly between a gated 2DEG and a 3D electron continuum separated by a thin tunneling barrier. In TDCS, sharp pulses are applied to the sample while measuring displacement currents from electrons entering or leaving the 2DEG, allowing tunneling IV measurements without direct electrical contact to the 2DEG. We observe changes in the Landau level structure far from the Fermi surface as we fill and empty individual Landau levels by varying the electron density and magnetic field. This provides a unique measurement of the exchange enhanced spin splitting of empty and filled Landau levels.

**11:27**

**P46 2 Thermal Dephasing in the Laughlin Quasiparticle Interferometer** F.E. CAMINO, WEI ZHOU, V.J. GOLDMAN, *Stony Brook University* We report experiments on thermal dephasing of the Aharonov-Bohm oscillations in the novel Laughlin quasiparticle (LQP) interferometer, [1] where quasiparticles of the 1/3 FQH fluid execute a closed path around an island of the 2/5 fluid. In the $10.2 \leqslant T \leqslant 141$ mK temperature range, qualitatively, the experimental results follow a thermal dephasing dependence expected for an electron interferometer, and show clear distinction from the activated behavior observed in resonant tunneling and Coulomb blockade devices, both in the chiral Luttinger liquid ($\chi$LL) and the Fermi liquid regimes. The data fit very well the $\chi$LL dependence predicted for a $g = 1/3$ two point-contact LQP interferometer. [2] The fit yields a value of the chiral edge excitation velocity, $u = 1.4 \times 10^4$ m/s obtained for the first time for a continuous FQH edge excitation spectrum. The small deviation from the zero-bias theory seen below 20 mK indicates yet unrecognized source of experimental decoherence, not included in theory. [1] F. E. Camino et al., Phys. Rev. B **72**, 075342 (2005). [2] C. de C. Chamon et al., Phys. Rev. B **55**, 2331 (1997).

**11:39**

**P46 3 Flux Period Scaling in the Laughlin Quasiparticle Interferometer** WEI ZHOU, F.E. CAMINO, V.J. GOLDMAN, *Stony Brook University* Aharonov-Bohm superperiod was rececently reported for electron interferometer devices in the quantum Hall regime, where electron paths circle a 2D electron island. The electron island main confinement is produced by etch trenches, into which front gate metal is deposited. We determine experimentally the A-B period $\Delta_B$ at several front gate voltages $V$ for electrons ($f = 1$) and Laughlin quasiparticles (2/5 embedded in 1/3). For moderate $|V| \leqslant 300$ mV, on each QH plateau, we find linear dependence of $\Delta_B$ on $V$. For $f = 1$, the electron A-B path area $S$ can be found from $\Delta_B$ using flux quantization condition $\Delta_\Phi = S\Delta_B = h/e$ for the flux period $\Delta_\Phi$. The A-B area enclosed by the $f = 1/3$ edge channel (the 2/5 island area) is not known independently if the FQH flux period is not known a priory. The front gate voltage dependence of $\Delta_B$ provides such independent determination of the 2/5 island area. The directly measured values of $\Delta_B$ and its slope $d\Delta_B/dV$ can be combined to derive the voltage $V(1e)$ attracting a unit charge to the area of the A-B path, assuming $S$ is known. For a many-electron ( $\sim$ 2000) 2D disc of radius $r$, the product $rV(1e)$ should be approximately constant, independent of the QH filling or the area. Thus the $f = 2/5$ island area can be determined directly with a $\sim$ 10% accuracy, which is quite sufficient to distinguish the physically reasonable possibilities of the flux periods $5h/e$, $5h/2e$, $1h/e$, and $h/2e$.

**P46 4 Extracting fractional statistics from superperiodic Aharonov-Bohm oscillations** EUN-AH KIM, STEVEN KIVELSON, *Stanford University* We consider a quantum Hall interferometer in which the quasiparticles of a fractional quantum Hall (FQH) liquid with filling factor $\nu_1 = 1/3$ propagate around a large ring of radius $r_1$, which is encircles an island with a smaller radius $r_2$ occupied by FQH liquid with filling factor $\nu_2 = 2/5$. We study the conductance oscillations that result from the incompressibility of the FQH liquid occupying the island and the constructive interference condition for the quasiparticles encircling the outer ring. Since the constructive interference condition depends on both the magnetic flux enclosed by the encircling path and the statistical phase gained by the encircling quasiparticle due to the presence of quasiparticles in the island, such conductance oscillations can be used to detect signatures of fractional statistics. We find that oscillatory period depends on both radii, $r_1$ and $r_2$. We discuss the relation between our results and the recent experiments by F.E. Camino, W. Zhou and V.J. Goldman in the context of our model.

**P46 5 Resonant tunneling in fractional Hall effect** CHUNTAI SHI, *Department of Physics,104 Davey lab,The Pennsyvania State University* JAINENDRA JAIN, *Department of Physics,104 Davey lab,The Pennsyvania State University* We study theoretically the possible transitions of a fractional quantum Hall island surrounded by another fractional quantum Hall state, induced by either the variation of the magnetic field or a backgate voltage, and find a rich set of possibilities in addition to the one considered previously[1],The elementary transitions correspond to the addition or removal of a composite fermion from the edge or the interior of the island; combinations of elementary transitions may occur simultaneously due to electrostatic constraints. Relevance to a recent experiment[2] is considered, which measures the resonant tunneling of composite fermions through their quasi-bound states around such a 2/5 island surrounded by the 1/3 sea. It is shown that the results are consistent with the notion of fractional braiding statistics, but can be explained on the basis of fractional charge alone. We also perform calculations based on microscopic composite fermion wavefunctions of finite systems to test the theoretical considerations. [1]J.K.Jain, S.A.Kivelson, and D.J.Thouless, Phys.Rev.Lett.**71**, 3003(1993). [2]F.E.Camino, W.Zhou, and V.J.Goldman, Phys.Rev.B **72**, 075342(2005).

**P46 6 Electronic Mach-Zehnder interferometer as a tool to probe fractional statistics** KAM TUEN LAW, DIMA FELDMAN, *Brown University* YUVAL GEFEN, *Weizmann Institute of Science* We study transport through an electronic Mach-Zehnder interferometer recently devised at the Weizmann Institute. We show that this device can be used to probe statistics of quasiparticles in the fractional quantum Hall regime. We calculate the tunneling current through the interferometer as the function of the Aharonov-Bohm flux and voltage bias, and demonstrate that its flux-dependent component is strongly sensitive to the statistics of tunneling quasiparticles.

**P46 7 Pauli-like principle for Abelian and non-Abelian FQHE quasiparticles*** F. D. M. HALDANE, *Princeton University* A general formulation of condensed matter physics describes the Hamiltonian as $H_0 + H_1$, where $H_0$ is a positive ''topological'' Hamiltonian with a highly-degenerate zero-energy ground state (extensive $T = 0$ entropy) and $H_1$ is the ''physical'' Hamiltonian that splits this huge multiplet. Usually, $H_0$ is a non-interacting Hamiltonian, with zero modes that form a simple Fock space spanned by Wannier orbitals of low-energy electron bands, or a Landau level, etc. Systems of Laughlin FQHE quasiholes are described by a more general $H_0$ that removes low-relative-angular momentum two-particle states from the zero-mode spectrum, and the non-Abelian Moore-Read and Read-Rezayi quasihole systems involve removal of $n > 2$ particle states. The latter are candidates systems for topological quantum computation. The zero-modes count has been previously obtained by counting the number of linearly-independent polynomials of various types. I give a simpler Pauli-principle-like formulation that transparently gives the counting rules, and allows the creation of subsets of lowest-Landau-level Slater determinant states from which the zero-mode states can be constructed. This aids numerical diagonalization of $P_0H_1P_0$, where $P_0$ is the projection into the zero-modes space of $H_0$, for exact-diagonalization simulations of the manipulations of non-Abelian quasiparticles proposed for topological quantum computations.

**P46 8 Quantitative study of the non-Abelian statistics of quasiholes and quasiparticles in the nu=5/2 paired Hall state** CSABA TOKE, JAINENDRA JAIN, *Penn State University* We analyze quantitatively various properties of a collection of quasihole and quasiparticle excitations of the paired composite fermion state, described by a Pfaffian wave function proposed by Moore and Read (Nucl.Phys.B 360, 362, 1991), which are relevant to the validity of the notion of non-abelian braiding statistics. Working in the spherical geometry, we study the coupling of two quasiholes as a function of their distance by evaluating both the density profile and the interaction energy of a quasihole pair. Further, we perform a numerical study to check whether the $2^{n-1}$ independent

states of $2n$ quasiholes are almost degenerate, i.e. the coupling between these states is exponentially suppressed as a function of their separation, which will be crucial for any practical realization of non-Abelian statistics. We also compare the exact diagonalization spectra of the Coulomb interaction in the second Landau level and the model three-body contact interaction for which the Pfaffian state and its quasihole variants are known to be exact. Based on the connection between Halperin's 331 state and the Pfaffian state (Greiter, Wen, and Wilczek, PRL 66, 3205, 1991) we construct a class of quasiparticle wave functions, which we study with respect to both the three- body contact interaction and the Coulomb interaction to test their accuracy.

**P46 11 An Exact Solution for the Half-filled Lowest Landau Level** EMIL BERGHOLTZ, ANDERS KARLHEDE, *Stockholm University* We present an exact solution for the interacting electron gas in the half-filled lowest Landau level on a thin torus. The low energy sector consists of non-interacting, one-dimensional, neutral fermions (dipoles). The ground state, which is homogeneous, is the Fermi sea obtained by filling the negative energy states and the excited states are the gapless neutral excitations out of this one-dimensional sea. We identify this ground state as a version of the Rezayi-Read state, and find that it develops continuously, as the circumference grows, into the Rezayi-Read state that is believed to describe the observed metallic phase in the two-dimensional system. This suggests a Luttinger liquid description of the half-filled Landau level.

**13:27**

**P46 12 One-Dimensional Theory of the Quantum Hall System** ANDERS KARLHEDE, EMIL J. BERGHOLTZ, *Stockholm University* We consider the lowest Landau level on a torus as a function of its circumference $L_1$. When $L_1 \to 0$, the ground state at general rational filling fraction is a crystal with a gap—a Tao-Thouless state. For filling fractions $\nu = p/(2pm + 1)$, these states are the limits of Laughlin's or Jain's wave functions describing the gapped quantum Hall states when $L_1 \to \infty$. For the half-filled Landau level, there is a transition to a Fermi sea of non-interacting neutral dipoles, or rather to a Luttinger liquid modification thereof, at $L_1 \sim 5$ magnetic lengths. This state is a version of the Rezayi-Read state, and develops continuously into the state that is believed to describe the observed metallic phase as $L_1 \to \infty$. Furthermore, the effective Landau level structure that emerges within the lowest Landau level follows from the magnetic symmetries.

**13:39**

**P46 13 Competing liquid and solid orders at $\nu = 1/5$** CHIACHEN CHANG, CSABA TOKE, *Department of Physics, The Pennsylvania State University* GUN SANG JEON, *School of Physics, Seoul National University, Seoul, Korea* JAINENDRA K. JAIN, *Department of Physics, The Pennsylvania State University* The lowest Landau level states at very low filling factors are accurately understood as topological quantum crystals of composite fermions. At higher fillings (but still in the lowest Landau level), on the other hand, the system forms an incompressible composite-fermion liquid. However at $\nu = 1/5$, both descriptions fail to give an accurate account to the true ground state. Our numerical calculations show that for small systems the crystal has lower energy than the liquid, and only for $N \geqslant 10$ does the liquid become the ground state. We find that a linear combination of the CF liquid and the CF crystal wave functions provides an excellent account of the actual state for small systems. These results indicate that the 1/5 fractional Hall state is highly susceptible to the formation of composite fermion crystallites in it. We will discuss the relevance of these results to experiment, and also the possibility of inducing a liquid-solid transition at 1/5 by tuning the interaction.

**13:51**

**P46 14 Electric field effects in the Hall conductivity*** ALEJANDRO KUNOLD, *Departamento de Ciencias Básicas, Universidad Autónoma Metropolitana-Azcapotzalco, Av. San Pablo 180, México D. F. 02200, México* MANUEL TORRES, *Instituto de Física, Universidad Nacional Autónoma de México, Apartado Postal 20-364, México Distrito Federal 01000, México* We study the Hall conductivity as a topological invariant under the influence of an intense electric field. We consider a model of a 2DEG in a two-dimensional lattice in the presence of an applied in-plain electric field and perpendicular magnetic field. The Hall conductivity is determined from quasiclassical calculations. In the presence of an electric field the longitudinal quasi-momentum is quantized leading to the appearance of a magnetic Stark ladder, in which the bands of the Hofstadter butterfly are replaced by a series of quasi discreet levels. We show that the transverse conductivity of this levels is an integer topological invariant independent of the intensity of the electric field thus leading to an integer Hall conductivity.

**P46 15 Measurement of Spin Excitations in the Fractional Quantum Hall Regime of 1/2< $\nu$ < 1** JUN YAN, *Columbia University* YANN GALLAIS, *Columbia University* ARON PINCZUK, *Columbia University, Bell Labs* LOREN PFEIFFER, *Bell Labs* KEN WEST, *Bell Labs* We use inelastic light scattering methods to investigate quasiparticle excitations of the fractional quantum Hall liquid in the filling factor range 1/2< $\nu$ < 1. The long wavelength spin wave mode at the Zeeman energy shows intriguing behavior. The mode is observed at the filling factors nu=1, 2/3 and 3/5 of the quantized Hall states but its intensity collapses for filling factors away from these states. In the filling factor range 1/2< $\nu$ < 2/3 spin excitations are observed below the Zeeman energy. These modes are interpreted as spin flips where the composite fermion Landau level quantum number and spin orientation change. The spectral lineshapes of spin flip excitations suggest a spin polarization transition between $\nu$=3/5 and $\nu$=2/3 [1]. [1] Irene Dujovne et al, PRL 95, 056808 (2005)

**Q1 2 Effect of Hydrogen Bonding End Groups on the Bulk Diffusion of Polymers** KATHLEEN SCHAEFER, CRAIG HAWKER, EDWARD KRAMER, *UCSB* Multiple hydrogen bonding (MHB) groups are being incorporated into an increasingly wide variety of polymer architectures, from short difunctional oligomers to high molecular weight multifunctional random copolymers. The addition of even weakly binding groups can have a drastic effect on rheological properties; generally this is due to dimerization of complementary groups, but these can also interact with the surrounding polymer matrix. To better understand this process we have synthesized linear polymers with a single hydrogen bonding end group and compared their bulk diffusion behavior to non-functional linear polymers. Deuterated poly(benzyl methacrylate) was synthesized via RAFT polymerization; the dithioester chain end was displaced by heating in the presence of an excess of radicals derived from AIBN or a functional azo compound. Thin films ( $\sim$ 100nm) of deuterated polymer were cast onto thick films ( $>$ 500nm) of protonated polymer and these bilayers annealed at various temperatures. The depth profiles of the bilayers were measured by dSIMS and fit to the solution of the diffusion equation to determine diffusion coefficients and the effect of a single hydrogen bonding end group on motion through the polymer matrix.

**Q1 3 Thermal Conductivity of Carbon Nanotube/Liquid Nanofluid** THOMAS ACCHIONE, FANGMING DU, JOHN FISCHER, KAREN WINEY, *Department of Material Science and Engineering, University of Pennsylvania* Nanofluids have been shown to be a potential heat-transferring medium due to nanofillers superior thermal conductivity and larger surface areas. Multiwall carbon nanotubes (MWNT) have quickly attracted much attention in this nanofluid field because of their unique thermal conductivity. Our studies on MWNT nanofluid show that there is a modest improvement in thermal conductivity at a high nanotube loading, $\sim$ 35% increase for a 1wt% MWNT nanofluid. We attribute this increase to the formation of a nanotube network with a higher thermal conductivity. However, at low nanotube loadings, $<$ 0.03wt%, we observe a decrease in thermal conductivity with the increase of the loading, $\sim$ 30% decrease for a 0.02wt% nanofluid. A thermal void mechanism is proposed to explain this unexpected decrease. Molecular size and polarity of the matrix liquids have been studied to gain more insights on the heat transportation inside nanofluids.

**Q1 4 Experimental and Theoretical Study of Raman Spectra of Polyisobutylene*** PRADEEP KUMAR, JAMIE MESSMAN, BRIAN ANNIS, *Chemical Sciences Division, Oak Ridge National Laboratory, Oak Ridge TN 37831* BOBBY SUMPTER, *Computer Science and Mathematics Division, Oak Ridge National Laboratory, Oak Ridge TN 37831* CHARLES FEIGERLE, *Department of Chemistry, University of Tennessee, Knoxville TN 37996* The effects of strain induced partial crystallization, partial deuteration, molecular weight and temperature on the Raman spectra of polyisobutylene (PIB) are determined. The Raman spectra of stretched PIB are correlated with the development of crystallinity as found by X-ray diffraction. One of the spectral regions altered by the stretching is in the vicinity of 200 $cm^{-1}$ which is often attributed to disordered longitudinal modes. The results are compared with spectra computed from $1^{st}$ principles electronic structure calculations using Density Functional Theory and Hartree-Fock approaches on model PIB systems.

**Q1 5 Examining the origin of spatial shear-rate variation in Couette flow of entangled polymer solutions** THOMAS Y. HU, *Unilever Research, CT* AMY PHILIPS, SHI-QING WANG, *Department of Polymer Science, University of Akron* The objective of this work is to determine the time-dependent velocity profile in Couette flow of entangled polymer solutions. In comparison to other flow apparatuses including cone-plate and sliding plate assemblies, the Couette flow can potentially avoid the complications arising from the boundary conditions. Both rheological and particle imaging velocimetric measurements have been carried out on model solutions to compare with results obtained for a cone-plate cell [1] and to shed light on the nature of non-homogeneous shear flow in the stress plateau region. [1] Tapadia, P.; Wang, S. Q. itPhys. Rev. Lett., in press (2005).

**Q1 6 Opening the black-box of entangled polymers in flow: A first time-resolved velocity profile determination upon step**

**shear** PRASHANT TAPADIA, SHAM S. RAVINDRANATH, SHI-QING WANG, *Department of Polymer Science,The University of Akron* We have recently revealed that entangled polymer solutions undergo a discontinuous bulk flow transition under controlled shear stress due to a chain entanglement-disentanglement transition (EDT) [1]. The implication of such results is far reaching, the least of which is that the assumed ithomogeneous shear would not occur in the stress plateau region, invalidating the previous efforts to explore the constitutive behavior of entangled polymers. The present work [2] applied a particle-tracking velocimetric method developed in our lab and confirmed the inevitable consequence of the EDT: presence of a spatial variation of the shear rate across the sample thickness in a cone-plate shear cell. The explicit velocity profile evolution sheds light onto such common features as shear overshoot during startup shear. [1] Tapadia, P.; Wang, S. Q. itPhys Rev. Lett, **91**, 198301 (2003); Tapadia, P.; Wang, S. Q. itMacromolecules **37**, 9083 (2004). [2] Tapadia, P.; Wang, S. Q. itPhys. Rev. Lett., in press (2005).

**Q1 7 Influence of Neutralization Methods on the Self-Assembly of Nanoscale Ionic Aggregates in Ionomers.** NICHOLAS BENETATOS, KAREN WINEY, *Department of Materials Science and Engineering, University of Pennsylvania, Philadelphia, Pa, 19104* Recent results show that scanning transmission electron microscopy (STEM) and small angle x-ray scattering (SAXS) have been used to obtain complementary morphological information for solvent cast poly(styrene-itran-methacrylic acid) (SMAA) ionomers neutralized with copper. In order to systematically explore the affect of neutralization methods on the nanoscale morphology, materials were isolated by three different methods: solvent casting, solution annealing, and precipitation. Each of these methods allows for a different rate of polymer structure formation. While solvent cast and solution annealed Cu-SMAA films exhibit isotropic ionomer scattering peaks and similar morphologies in STEM, the precipitated powder shows no scattered intensity in the region of the ionomer peak. These data suggest that isolating the polymer by precipitation induces a metastable morphology in which the ionic aggregates are only partially formed or are not uniformly distributed throughout the material. Upon thermal treatment, the scattering pattern of the precipitated powder begins to resemble that of the solvent cast films. SAXS and STEM experiments are underway to further investigate the nanoscale self-assembly mechanism.

**Q1 8 Cylindrical Polyelectrolyte Brushes*** RIKKERT NAP, IGAL SZLEIFER, *Department of Chemistry, Purdue University, 560 Oval Drive West-Lafayette, IN 47907* Polyelectrolytes tethered to a cylindrical surface are investigated. The surface can either be formed by e.g. another polymer, a carbon nanotube, or protein chain. The cylindrical polyelectrolyte brush is of interest to us because it forms a model system for the description of the properties of aggrecan, which is one of the main components of cartilage. We used a molecular theory to theoretically investigate the properties of aggrecan. We computed the potential of mean force between two aggrecan molecules. The influence of the cylindrical geometry, the salt concentration, and the pH of the solution upon the conformation of the aggrecans, was investigated. The findings for cylindrical electrolyte brushes were contrasted with the behavior of planar electrolyte brushes, which revealed a large influence of the geometry upon the properties of the brush layer.

*This research was supported by NSF-NIRT 0403903.

**Q1 9 Poly(Ethylene-Methacrylic Acid) Ionomers Neutralized by Solution and Melt Methods** CHRISTOPHER CHAN, *Department of Chemical and Biomolecular Engineering, University of Pennsylvania* KAREN WINEY, *Department of Material Science and Engineering, University of Pennsylvania* Poly(ethylene-methacrylic acid) has been traditionally neutralized in the melt although other methods, including solution, are also possible. Different neutralization methods may introduce morphological differences in the polyethylene crystallites and ionic aggregates. While the crystallization of the polyethylene chains can be controlled through thermal history, the ionic aggregates form during neutralization and there is no evidence to date of morphological changes after neutralization. In this study, we examine the effect of neutralizing 50% of the acid groups in P(E-itran-3.87%-MAA) with a weak zinc base in solution as compared with in the melt. We have found that solution neutralization with slow precipitation as compared with melt neutralization does not affect the size and distribution of the ionic aggregates. STEM indicates spherical aggregates in a liquid-like disorder with diameter of 2.84 nm $\pm$ 0.42 in the solution neutralized polymer as compared with 2.83 nm $\pm$ 0.56 in the melt neutralized polymer and X-ray scattering interpreted with the Yarusso-Cooper model has parameters of 0.88 nm in diameter versus 0.89 nm.

**Q1 10 Structure calculations for hydrated ionomer membranes*** PHILIP TAYLOR, MEHDI HAMANEH, *Case Western Reserve University* The structure of the perfluorinated ionomer Nafion is determined by a process of partial phase separation in which the ionic components form clusters within a matrix of hydrophobic material. The dipoles associated with the ionic groups tend to order in such a way as to form head-to-tail sequences. In this study we are investigating the effects of hydration on the structure and formation of the ionic clusters and their associated internal electric fields by a combination of atomistic molecular-dynamics simulations and analytical theory. We find that a useful concept is the vorticity of the electric dipole moments and its dependence on hydration. Various procedures have been used in order to develop realistic pictures of the nature of the ionic clusters and their interconnectedness, as the presence of continuous pathways through a Nafion membrane is a determining factor in the transport of protons in polymer-electrolyte membrane fuel cells.

*Work supported by the U. S. Department of Energy

**Q1 11 Direct observation of enhanced mobility near the surface of polymer nanocomposite thin films*** TADANORI KOGA, C. LIN, J. JIANG, J. KOO, M. RAFAILOVICH, J. SOKOLOV, *Stony Brook University* S. NARAYANAN, D. LEE, *Argonne National Lab.* L. LURIO, *Northern Illinois Univ.* S. SINHA, *UC San Diego* The x-ray photon correlation spectroscopy (XPCS) technique with grazing-incident geometry is currently being used to probe surface dynamics of a planer film on microscopic length scales. Sinha et al.[1] have shown that the viscosity of a polymer thin film could be derived from the relaxation rate of thermally induced surface roughness. As a further application of XPCS, we studied surface dynamics of polymer nanocomposite thin films. A combination of thiol-functionalized gold nanoparticles (4 nm in diameter, 4wt%) and polystyrene was chosen as a model system. The high x-ray contrast of Au nanoparticles enabled us to monitor their Brownian motion associated with polymer chain dynamics. In addition, making use of the advantage that the x-ray penetration depth can be tuned by varying the incidence

angle of the incoming beam, we could measured the Brownian motion at the topmost 10 nm of the film and in the bulk separately. As a result, it was found that the diffusion coefficient for the Brownian motion was 50% greater at the surface than in the bulk. That is, the viscosity of the polymer is much lower at the surface. [1] H. Kim, et al. itPhys. Rev. Lett., 90, 683020 (2003).

*This work was supported by the SRC-NY CAIST funding and by NSF (the Garcia MRSEC).

**Q1 12 Viscosity Measurements of Very Thin Polymer Films** CHUNHUA LI, TADANORI KOGA, CLIVE LI, JUN JIANG, *State University of New York at Stony Brook* LAURENCE LURIO, *Northern Illinois University* SUNIL SINHA, *University of California San Diego* SURESH NARAYANAN, *Argonne National Laboratory* MIRIAM RAFAILOVICH, JONATHAN SOKOLOV, *State University of New York at Stony Brook* STATE UNIVERSITY OF NEW YORK AT STONY BROOK TEAM, UNIVERSITY OF CALIFORNIA SAN DIEGO COLLABORATION, NORTHERN ILLINOIS UNIVERSITY COLLABORATION, ARGONNE NATIONAL LABORATORY COLLABORATION, We reported that the viscosity of ultra thin polymer films can be measured by three independent techniques: Bilayer dewetting measurements where the viscosity is derived from dewetting velocity; X-ray Photon Correlation Spectroscopy (XPCS) where the viscosity is determined from the relaxation rate of thermally induced surface roughness and Dynamic Secondary Ion Mass Spectroscopy (DSIMS) where the viscosity is derived from the measurements of the tracer diffusion coefficient. The results from three different techniques are in good agreement with each other. The scaling relationship, $\eta \sim$ Mw PS, yielded from dewetting and XPCS measurement was in excellent agreement with the bulk scaling of 3.4 and the prediction from reptation theory.

**Q1 13 Tethered Ligand-Receptor Binding in Confined Environments** G. LONGO, *Purdue University* I. SZLEIFER, *Purdue University* The binding of small proteins with ligands that are attached to polymers tethered to a surface is studied using a molecular theory. The effects of changing the intrinsic binding equilibrium constant, the polymer surface coverage, the polymer molecular weight, and protein size are studied. The results are compared with the case where the ligands are directly attached to the surface without a polymer acting as a spacer. Within biological range of binding constants the protein adsorption is enhanced by the presence of the polymer spacers. There is always an optimal surface coverage for which ligand-receptor binding is a maximum. This maximum increases as the binding energy or the polymer molecular weight increases. The presence of the maximum is due to the ability of the polymer bound proteins to form a thick layer by dispersing the ligand in space to optimize binding and minimize lateral repulsions. The binding of proteins is reduced as the size of the protein increases. The orientation of bound proteins can be manipulated by proper choice of the grafted layer conditions. A surface modified with a mixture of long ligand-conjugated polymers in low surface density and short polymers in high surface coverage will present optimal binding properties at the same time as nonspecific adsorption of proteins onto the surface is suppressed. The results of the theoretical calculations can be used in the design of experimental systems, providing the kind of polymer and the surface coverage required to optimize ligand-receptor binding.

**Q1 14 Growth of poly-DL-lysine hydrobromide single crystal on mica(001) surfaces.*** DIPAK GOSWAMI, XIAOGANG LIU, YI ZHANG, JOHN OKASINSKI, KHALID SALAITA, PENG SUN, MICHAEL BEDZYK, CHAD MIRKIN, *Northwestern University* CHAD A. MIRKIN COLLABORATION, MICHAEL J. BEDZYK COLLABORATION, We present a method for controlling the initiation and kinetics of polymer crystal growth using atomic force microscope tip coated with poly-DL-lysine hydrobromide (PLH). PLH form triangular prisms on freshly cleaved mica(001) surfaces. These prisms grow in a parallel or anti parallel fashion, which indicates epitaxial growth of the crystal with respect to underling mica lattice. Back reflection Laue on mica (001) surface along with optical microscopy measurements guided us to propose a model which showed that two preferred prism orientations exist along [100] direction of the mica lattice. Grazing incidence oscillation x-ray diffraction measurements revealed that the prisms grown on mica are single crystal with a lattice that has an in-plane orientational epitaxy with the underlying mica lattice. We have observed two growth exponents for the growth of the edge length of the PLH prisms. This reveals that in the early stage of the growth, the prisms grow faster and then the growth rate decreases.

**Q1 16 Transport along freely suspended actin cortex models in a controlled microfluidic environment** SIMON SCHULZ, TAMAS HARASZTI, WOUTER ROOS, CHRISTIAN SCHMITZ, JENS ULMER, STEFAN GRAETER, JOACHIM P. SPATZ, *Max-Planck-Institute for Metals Research, New Materials and Biosystems; University of Heidelberg, Biophysical Chemistry, 70569 Stuttgart, Germany* Arrays of microfabricated pillars are constructed to serve as a template for mimicking the actin cortex of cells. The three-dimensional template surface prevents interaction of the actin filaments hanging between pillars. A special flow-cell design enables applying flow around a network of actin freely suspended between polydimethylsiloxane pillars. This opens new possibilities to study the mechanics of two-dimensional actin networks as a function of actin-crosslinkers, to observe the active diffusion of molecular motors operating on pending networks and to investigate the alternations in the transport of microscopic particles, coated by different proteins and molecular motors, along these actin cortex models under the drag of flow. The stiffness of the F-actin can be tuned by bundling through various

cross-linkers. Additionally, actin filaments act as tracks for guiding passive and active transport of cargo such as organelles or microspheres by molecular motors like myosin-V. These transport problems are biomimetic studies of tracks and external driving force on a statistical process of two-dimensional networks isolated from the complicated and undetermined cellular environment.

**Q1 17 Time-resolved electric force microscopy of charge traps in polycrystalline pentacene films** MICHAEL JAQUITH, *Department of Chemistry and Chemical Biology, Cornell University* ERIK MULLER, *Department of Physics, Cornell University* JOHN MAROHN, *Department of Chemistry and Chemical Biology, Cornell University* The microscopic mechanisms by which charges trap in organic electronic materials are poorly understood. Muller and Marohn recently showed that electric force microscopy (EFM) can be used to image trapped charge in working pentacene thin-film transistors [E. M. Muller *et al*, *Adv. Mater.* **17** 1410 (2005)]. We have extended their work by imaging trapped charge in pentacene films with much larger grains. In contrast to the previous study in which charge was found to trap inhomogeneously throughout the transistor gap, we find microscopic evidence for a new trapping mechanism in which charges trap predominantly at the pentacene/metal interface in large-grained devices. We have also made localized measurements of the trap growth over time by performing pulsed-gate EFM experiments. Integrated-rate kinetics data supports a charge trap mechanism which is second order in holes, e.g., holes trap in pairs, although the charge-trapping rate appears to depend on gate voltage.

**Q1 18 Shear flow induced unfolding of collapsed polymers.*** ALFREDO ALEXANDER-KATZ, ROLAND NETZ, *Technical University Munich* In the process of clotting in small vessels, platelets form a plug in an injured zone only in the presence of a protein known as the von Willebrand Factor (vWF). The absence or malfunction of the vWF leads to a bleeding disorder, the so-called von Willebrand disease. It is believed that the protein is collapsed (or globular) when released into the blood flow, and that it undergoes a transition at high shear rates that allows it to bind platelets. Using hydrodynamic simulations of a simple model of the vWF in shear flow, we show that a globular polymer undergoes a globule-stretch transition at a critical shear rate. Below this threshold shear rate the polymer remains collapsed and slightly deformed, while above it the chain displays strong elongations in the direction of the flow. Finally, we discuss the relevance of our results in the case of blood flow, and compare them to the physiological values present in the body.

**Q1 19 Dynamics of polar guest molecules contained in cryptophane molecular crystals** ERICK WINSTON, ROBERT HORANSKY, MATTHEW MYERS, JOHN PRICE, *The University of Colorado, Boulder* JAROSLAV VACEK, *Academy of Sciences of the Czech Republic* Cryptophanes are a class of molecules with an interior cavity which can be occupied by smaller guest molecules non-covalently. In cases where the guest molecules are free to tumble within the cryptophane, and where the cryptophanes can be crystalized, it is possible to create ordered arrays of reorienting guest molecules. By using dipolar guests such as the methyl halides, the guest motions can be observed by dielectric spectroscopy and guests may order via strain or dipole-dipole interactions. We will present the results of dielectric spectroscopy experiments on single crystals of iodomethane in cryptophane-A. The observed rotational barriers are compared to computational molecular mechanics calculations based on the X-ray structure of the complex.

**Q1 20 Tethered Polymer Interactions with Attractive Surface Potentials** RYAN VAN HORN, JOSEPH X. ZHENG, HUIMING XIONG, WILLIAM Y. CHEN, KYUNGMIN LEE, RODERIC P. QUIRK, *University of Akron* BERNARD LOTZ, *Institut of Charles Sadron* EDWIN L. THOMAS, *MIT* AN-CHANG SHI, *McMaster University* STEPHEN Z.D. CHENG, *University of Akron* Due to their surface modification capabilities, tethered polymer chains have been a research focus for several years. Experimental and theoretical work has been done to understand the conformations and interactions of these systems at varying tethering densities. A new technique developed in our group makes it possible to use single crystals of crystalline-amorphous diblock copolymers to study tethered polymer chains. These systems have controlled density through defined fold numbers and controlled MW through living polymerization. Zheng and coworkers found that the reduced tethering density is 3.7 for the onset of interchain interaction and 14.3 for the highly-stretched brush. This work provides, for the first time, the values of these two onsets with high certainty; however, the systems studied do not provide general results. Both systems had repulsive interactions between the surface and the tethered chains. In order to broaden the scope of the physics behind tethered polymer chains, the study should include systems with attractive potentials. Preliminary studies of one such system, PMMA-b-PLLA, will be presented.

**Q1 21 Single crystal engineering of block copolymers*** HUIMING XIONG, JOSEPH X. ZHENG, RYAN M. VAN HORN, Y. GUO, RODERIC P. QUIRK, STEPHEN Z. D. CHENG, In the past two decades, tethered polymer systems have attracted attention due to, not only their theoretical interests, but also their applicable potentials. Usually, physical adsorption, ''grafting to'' and ''grafting from'' methods have been used to fabricate polymer brushes on solid substrates. Recently, we have proposed a novel method which can achieve narrow molecular weight distribution, and precisely control the tethering density by using amorphous-crystalline block copolymers. With a constant molecular weight of the crystalline block and crystallization temperature, the thickness of single crystals and thus, the number of folds are fixed. This leads to a constant tethering density. We can thus adjust the tethering density by controlling the thickness of the single crystals by changing undercooling and molecular weights of the crystalline blocks. Systems of triblock copolymers with one crystalline block at one end or in the middle will generate diblock copolymer brushes or mixed and/or unmixed polymer brushes. The morphologies of polymer brushes can be controlled by the crystallization condition of single crystal. Mutually, the tethered polymer brushes could also affect crystallization of the crystalline block.

**Q1 22 Overall Crystallization Kinetics of Polymorphic Poly (propylenes)** YSELA CHIARI, KIMBERLY THOMPSON, RUFINA ALAMO, *FAMU-FSU College of Engineering, Department of Chemical and Biomedical Engineering, Tallahassee, Fl* The isothermal crystallization of propylene ethylene random copolymers evolves with a simultaneous formation of two polymorphic forms, monoclinic crystals (alpha form) and orthorhombic crystals

(gamma form). The relative content of each modification changes during crystallization. The content of gamma crystals developed at high levels of transformation increases with the concentration of ethylene and with the crystallization temperature. The overall crystallization kinetics of copolymers with an ethylene content ranging from 0.8 to 7.5 mol % were followed by DSC and analyzed according to classical Avrami kinetics. For most copolymers, fits with single stage nucleation and growth models were poor. Following structural models for lamellar growth that account for epitaxial gamma branching from alpha surfaces, the experimental data were modeled with parallel two-stage crystallization kinetics with excellent fits up to 80 % transformations. The Avrami exponents obtained from the fits are consistent with a 3-D spherulitic growth with instantaneous nucleation for alpha and homogeneous nucleation (linear with time) for the gamma phase.

**Q1 23 Melting in Copolymer Blends** BUCKLEY CRIST, *Northwestern University* It is observed that the melting temperature $T_m$ of polyethylene is insensitive to blending with a melt-miscible random ethylene copolymer. On the other hand, the $T_m$ of an ethylene-rich copolymer is depressed strongly when blended with a less ethylene-rich copolymer. If A is a homopolymer that does not cocrystallize with B, the standard thermodynamic prediction for $T_m$ employs the small entropy of mixing of entire chains. The situation is quite different if A and B are random copolymers with different amounts of non-crystallizable comonomers. Copolymer melting is based on the mixing of crystallizable and non-crystallizable monomers during fusion, calculated for sequences, not for entire chains. In essence, $T_m$ for the copolymer blend depends on the total concentration of crystallizable monomers from both blend components, regardless of the chain to which a particular sequence belongs. This concept adequately accounts for the observations above.

**Q1 24 Ultra-Small Angle Neutron Scattering Study of Polyethylene Crystallization from Solution*** HOWARD WANG, NARAYAN DAS, KAIKUN YANG, *Department of Materials Science and Engineering, Michigan Technological University, Houghton, MI 49931* Crystallization of polyethylene in deuterated toluene solution has been investigated using time-resolved ultra small angle neutron scattering for the first time. Both slit-smeared and de-smeared scattering spectra were analyzed using Guiniers law to obtain time-dependent structural information. The average lateral dimension of crystallites grows linearly with time, while the degree of crystallinity increases as square of time. The results suggest that the number density of nuclei remains constant during the crystal growth.

*This work is supported by an NSF Career Award

**Q1 25 Holographic Patterning and Crystallization of a Semicrystalline polymer** MICHAEL BIRNKRANT, *Drexel University* CHRISTOPHER LI, *Drexel University* LALGUDI NATARAJAN, VINCENT TONDIGLIA, RICHARD SUTHERLAND, *Science Applications Intl Corp* TIMOTHY BUNNING, *Air Force Research Laboratory* Manufacturing dynamically controlled multifunctional photonic structures for application in optical elements and waveguides is crucial to control the flow of light. Holographic Patterning (HP) is a simple, fast and attractive means to fabricate complex photonic structures. During the HP process, a photopolymerizable syrup is exposed to two or more coherent laser beams. The resulting anisotropic photopolymerization leads to the spatial distribution of a crosslinked network polymer and homopolymer poly ethylene glycol (PEG). The HP of low molecular weight PEG and thiol-ene reactive monomers produced a long range uniform layered structure. The difference in refractive indexes of PEG and crosslinked polymer network results in unique transmission spectra and diffraction efficiencies. Furthermore, upon heating the holographically patterned PEG produces a red shift in the reflected wavelength of the material which reverses upon cooling. Closer analysis through X-ray scattering has found that PEG crystals contained within the confined layers preferentially crystallize.

**Q1 26 Comparative Determinations of Orientation in Injection-Molded Thermotropic Liquid Crystalline Copolyester (TLCP) Plaques** ROBERT BUBECK, *Michigan Molecular Institute* STANLEY RENDON, WESLEY BURGHARDT, *Northwestern University* DANIEL FISCHER, *NIST* Two-dimensional wide-angle X-ray scattering (2D-WAXS) in transmission and C K edge near edge X-ray adsorption fine structure (NEXAFS) spectroscopy were used to characterize anisotropy and catalog orientation states in injection-molded plaques fabricated under varying conditions using two commercial TLCP copolyesters. The observed 2D-WAXS patterns are usually bimodal in character due to contributions from the core and skin regions that result from extensional and shear flow, respectively, in the mold. Deconvolution of the 2D-WAXS patterns permits one to gain a measure of the Hermans orientation parameter of the core and skin for finite thicknesses of the plaques. The NEXAFS in partial electron yield mode is sensitive to the orientation of the molecular pi orbital of backbone phenyl groups of the top 3 nm of a surface. Updated analyses of the NEXAFS results indicate much greater localized molecular orientation at the very surface of the samples than for the more general orientations for the core and skin derived from the WAXS. The NEXAFS results are generally consistent with those obtained by using surface specific attenuated total reflectance Fourier transform infra-red spectroscopy.

**Q1 27 Coupling of Lithium-Polymer Complexes and Electric Field: Routes to Enhance the Alignment of Block Copolymer Thin Films** JIA-YU WANG, JULIE LEISTON-BELANGER, SURESH GUPTA, *University of Massachusetts, Amherst* TING XU, *Cold Neutrons for Biology and Technology (CNBT) at NIST* Recently, the unexpected experimental results indicated that lithium ionic impurities in block copolymer thin films might assist applied electric filed to overcome the interfacial interactions so that the alignment of microdomains was enhanced.1 But some questions are still open: whether lithium ions aid in overcoming interfacial interactions, what is the nature of the interactions of the lithium ions with the polymer chains, and what is the driving forces in this process? We designed a method to introduce lithium chloride into polystyrene-block-poly(methyl methacrylate) (PS-b-PMMA) copolymer thin films. The IR results show that lithium-PMMA complexes in copolymers were formed. These lithium-PMMA complexes markedly enhanced the dielectric constant of PMMA block. Thus the critical electric field strength for aligning the microdomains is significantly decreased so that the external electric field can overcome the interfacial interactions and increase the alignment of microdomains. The addition of ionic salts into one block of a diblock copolymer opens up a potential route to fabricate the long-range ordered nanostructures of block copolymer thin films. [1] Xu T.; Goldbach J. T.; Leiston-Belanger J.; Russell T. P. Colloid Polym. Sci., 2004, 282, 927.

**Q1 28 Structure of Rod-Coil Block Copolymer Thin Films** R.A. SEGALMAN, B.D. OLSEN, *University of California Berkeley and Lawrence Berkeley National Lab* The self-assembly of rod-coil block copolymers confined to thin films demonstrates new and unusual surface effects. Since the rod block does not experience chain stretching and instead undergoes liquid crystalline interactions, the surface induced order of the block copolymer system is drastically modified. Thin films of a model rod-coil block copolymer, poly(alkoxyphenylene vinylene-b-isoprene), form islands or holes with lamellae oriented primarily parallel to the substrate. These parallel lamellae form grains bounded by defect regions consisting of lamellae oriented out of the plane of the film. These defects appear to have long-range interactions with the surrounding grains resulting in regular, angular grain boundaries. As film thickness is increased toward 10 lamellar spacings, the surface induced order dies off and the lamellae at the vacuum interface are entirely oriented perpendicular to the substrate. We will discuss the kinetics of grain growth and the penetration depth of surface induced ordering as a function of thermal history.

**Q1 29 Renormalized One-Loop Theory of Fluctuations in Homopolymer Blends and Diblock Copolymer Melts** PIOTR GRZYWACZ, DAVID MORSE, *University of Minnesota* We construct a perturbation theory for the effects of composition fluctuations in polymer mixtures, which we apply to both binary homopolymer blends and diblock copolymer melts. The inverse structure function is divided into an inverse intramolecular correlation function and a direct correlation function, which are calculated separately to first order in a loop expansion. We show that corrections to mean-field theory that are sensitive to local fluid structure, as reflected by a dependence on the value of a microscopic cutoff length, can be absorbed into $q$-independent changes in the value of the direct correlation function (which is closely related to the Flory-Huggins $\chi$ parameter) and changes in statistical segment lengths. Predictions are presented for the changes in radii of gyration of chains in a binary solution near the critical point (which are extremely small) and for the behavior of the stucture factor in a block copolymer melt near the order-disorder transition.

**Q1 30 Investigation of the Phase Behavior of Amphiphilic Triblock Copolymers (PAA-itb-PMA-itb-PS in Mixed Solvents** KELLY HALES, HONGGANG CUI, ZHIBIN LI, DARRIN POCHAN, *Dept. of Materials Science and Eng, Univ. of Delaware* ZHIYUN CHEN, QAI KI, KAREN WOOLEY, *Dept. of Chemistry, Washington Univ. at St. Louis* Unique morphologies have been prepared from amphiphilic triblock copolymers of poly(acrylic acid)-b-poly(methyl acrylate)-b-polystyrene in water/tetrahydrofuran (THF) solvent mixtures. The length of the acrylic acid block and the methyl acrylate block were held constant for each copolymer while the polystyrene block length was varied. For self- assembly, the block copolymers were dissolved in THF in the presence of a divalent, organic counterion and water was added slowly. This resulted in a variety of unique structures including polymer nanoparticles with internal block phase separation, bulk phase separation, spherical micelles, cylindrical micelles, disks, as well as toroidal (ring-like) assemblies. The specific structure formed was dependent on the architecture of the triblock copolymer, the amount of counterion present, and the water to THF volume ratio. The focus of this work is the basic understanding and characterization of the phase separated structures present in low water content solutions. The understanding of this bulk phase behavior and its effects on the assemblies formed at higher water contents will be presented. Transmission electron microscopy (TEM), cryo-TEM and neutron scattering were used to examine the copolymer solutions.

**Q1 31 Overall static conformation of chain molecules in nanoscopic cylinders** KYUSOON SHIN, *School of Chemical and Biological Engineering, Seoul National Univeristy* JUIN-TAI CHEN, *Department of Polymer Science and Engineering, University of Massachusetts, Amherst* PRIYANKA DOBRIYAL, *Chemistry Department, University of Massachusetts, Amherst* PAPPANNAN THIYAGARAJAN, *Argonne National Laboratory* THOMAS RUSSELL, *Department of Polymer Science and Engineering, University of Massachusetts, Amherst* We explore the overall static conformation of chain molecules in nanopores. We used anodized aluminum oxide membrane with hexagonally packed, regular-sized nanopores with the pore diameter of 15 nm. Via strong capillary action, we have successfully filled different size polystyrene (molecular weight range 20,000 to 3,000,000) in these membranes. Polymers, whose size in the bulk is much larger than the diameter of the nanopores, should deform due to the confinement and the spatial configuration of the chain must deviate from that seen in the bulk. By examining the single chain scattering of the polymer confined within the nanopores via small angle neutron scattering, we examine whether the chain retains its random conformation or elongate along the nanopore.

**Q1 32 Effects of shear flow on reactive coupling of polymer chains at melt interfaces** JIANBIN ZHANG, *Department of Chemical Engineering and Materials Science, University of Minnesota* TIMOTHY LODGE, *Department of Chemical Engineering and Materials Science and Department of Chemistry, University of Minnesota* CHRISTOPHER MACOSKO, *Department of Chemical Engineering and Materials Science, University of Minnesota* The coupling reaction of functional polymers at static polymer-polymer interfaces is typically much slower than that at interfaces formed during mixing (see, for example, Reference 1). We have demonstrated that the imposed simple shear can accelerate coupling reactions at flat interfaces. For amine-terminal polystyrene ($PS\text{-}NH_2$)/anhydride terminal poly(methyl methacrylate) (PMMA-anh), the PMMA-anh conversion under dynamic oscillation even at strain amplitude as small as 1% is seven times that under static conditions. Reaction time and temperature and the total interfacial area were maintained the same. Similar behavior was found for both bilayer and multilayer samples. Under steady simple shear, the reaction conversion and the rate of interfacial area generation are comparable to that of batch mixing.
Macosko, C. W.; Jeon. H. K.; Hoye, T. R. Prog. Polym. Sci. **2005**, 30, 939.

**Q1 33 Cation Effects on Electroactive Responses of Conjugated Polymers*** XUEZHENG WANG, ELISABETH SMELA, *Dept. of Mech. Engr., UMCP* The ions present in the electrolyte in which a conjugated polymer actuator is cycled are known to affect performance such as response time and volume changes. Understanding how speed, force, strain, etc. are affected by ion size and other ion characteristics is critical to applications, but is not yet well understood. In this paper, we first present effects of monovalent and divalents cation mass on transport velocity and volume change in polypyrrole doped with dodecylbenzenesulfonate, PPy(DBS), which is a cation-transporting material. Volume change,

measured by mechanical profilometry, was greatest for $Li^+$ and decreased in order of atomic mass: $Na^+$, $K^+$, Rb, and $Cs^+$. This was expected because prior studies had shown that the ions are hydrated when they enter the PPy, and $Li^+$ has the largest hydration shell. Ion transport, measured by phase front propagation experiments, was also fastest for $Li^+$, however, contradicting the expectation that larger species would move more slowly. Possible explanations based on hydration shapes and ion-chain interactions will be discussed. In this paper, we also present effects of ion mixtures: $Li^+/K^+$ and $Li^+/Mg^{2+}$. The results show that small amount of slow moving ions increases the response time drastically. The experiments also show that the $Mg^{2+}$ ions are trapped in the polymer films and influence electroactivity of conjugated polymers.

*We would like to acknowledge funding through DuPont's Young Professor Grant and the Laboratory of Physical Sciences while completing this research.

**Q1 34 Modeling self-oscillation and waves in a reactive polymer gel** VICTOR YASHIN, ANNA BALAZS, *Department of Chemical Engineering, University of Pittsburgh, Pittsburgh, PA* We model the self-oscillation and wave propagation phenomena in a swollen polymer gel that participates in the Belousov-Zhabotinsky (BZ) reaction. The BZ reaction causes variations in the gel volume through reduction-oxidation changes of a metal catalyst, which is covalently bonded to the polymer chains. We employ the Oregonator model to describe the BZ reaction kinetics. The Flory and Flory-Huggins models are used to describe the gel elasticity, and the polymer-solvent interactions, respectively. We identify the model parameters that yield the oscillatory behavior, and demonstrate that the kinetics of the BZ reaction can be significantly affected by coupling the reaction to the polymer gel dynamics. To simulate the traveling waves of swelling-deswelling, we utilize the gel lattice spring model, which we have developed recently, and is equivalent to the two-fluid model. We demonstrate and discuss the effects of mechanical constraints on the generation and propagation of 1D and 2D swelling-deswelling waves in the reactive gel.

**Q1 35 Measuring the Local Modulus of Soft Polymer Networks** JESSICA ZIMBERLIN, ALFRED CROSBY, *University of Massachusetts* Biological tissues often rely upon local ''heterogeneities'' to define their structure –property relationship. An example is the integrated layered structure of the mitral valve. For most native tissues, these ''heterogeneities'' are attributed to the local arrangement and structure of the collagen fibril network. To guide the development of tissue scaffolds, we characterize and understand these structure-property relationships on local length scales. In our research we have developed a method to determine the local modulus at specific points within a material. The method involves inducing cavitation and monitoring the pressure of the cavity instability. This pressure is directly related to the local modulus of the material. Initial results focus on the network development of poly vinyl alcohol hydrogels. We monitor the process of gelation and the mechanical response of these hydrogels on length scales similar to their pore structure.

**Q1 36 Monte Carlo Simulation of Reversibly Associating Networks*** SHIHU WANG, CHUN-CHUNG CHEN, ELENA E. DORMIDONTOVA, *Macromolecular Science and Engineering, Case Western Reserve University, Cleveland, OHIO 44106* We applied Monte Carlo simulations to study the reversible network formation through oligomers end-functionalized by ligands capable of complexation in 3:1 ratio with metal ions acting as crosslinkers. By varying the oligomer concentration and metal-to-oligomer ratio, we studied the fractions of different associating species and the molecular weight distribution. The conditions for network formation (over the percolation threshold) were determined using three different criteria, which lead to similar results. The molecular weights of species in the corresponding sol and gel phases were obtained along with the fractions of small rings, dangling ends, and network mesh sizes. An analytical model based on the equilibrium among different associating species and classical gelation theory modified to account for unequal reactivity/cooperativity was developed. The predictions of the analytical model are in good agreement with the simulation results, which compare favorably with experimental observations.

*This work was supported by the NSF Career Award CHE-0348302

**Q1 37 Formation of nanoparticles during melt mixing a thermotropic liquid crystalline polyester and sulfonated polystyrene ionomers** HYUKSOO LEE, *Samsung Electro-mechanics Co.* LEI ZHU, *University of Connecticut* R. A. WEISS, *University of Connecticut* The formation of nanoparticles and the mechanism of their formation in a blend of a thermotropic liquid crystalline polyester (LCP) and the zinc salt of a lightly sulfonated polystyrene ionomer (Zn-SPS) were investigated using Fourier transform infrared, thermogravimetric analysis, and gas chromatograph-mass spectroscopy. Transmission electron microscopy and wide-angle X-ray scattering were used to study the morphology of the blends and structure of nanoparticles. The origin of nanoparticle formation appeared to be related to the development of phenyl acetate chain ends on the LCP that arose due to a chemical reaction between the LCP and residual catalytic amounts of zinc-acetate and/or acetic acid that were present from the neutralization step in the preparation of the ionomer. The origin of formation and kinetics of the nano-particle formation and the mechanical and rheological properties of these nanocomposites are briefly discussed.

**Q1 38 Characterization of Release Mechanism in Polymeric Drug Delivery Systems** ARTHUR JAMES LAPLANTE, ROBIN MARIE PLACHY, KAORU AOU, JAKE FERGUSON, SHAW LING HSU, *Polymer Science and Engineering Department, University of Massachusetts* Our polymeric drug delivery system is based on our understanding of phase behavior of polymers [e.g poly(lactic acid)], low molecular drugs and various solvents used in processing. Clearly the different morphologies achieved, based on different phase separation kinetics, can affect drug release rates. Release of drugs, in most cases, involves the exchange between the extraction media and drug. We have characterized the transport behavior using a number of unique techniques. Reflectance infrared spectroscopy has given us a detailed description of the release rate of drugs into the extraction media. Surface plasmon resonance has shown the overall mass loss. UV-visible spectroscopy has yielded the concentration of drug in the solution. These measurements are compared to the release mechanism based on Fickian diffusion. The two step release rates observed can only be explained by taking into account differences in the morphological features of the phase separated films.

**Q1 39 Transport behavior of small molecules out of various poly (vinylidene fluoride) copolymer morphologies** SURIYAKALA RAMALINGAM, GUOLIN WU, FENG YI, SHAW LING HSU, *Polymer Science and Engineering Department, University of Massachusetts* Due to its biocompatibility, durability and existence of various crystalline states, poly (vinylidene fluoride) (PVdF) have been used in medical applications. In this study, the hydrophobic poly (VdF-hexafluoropropylene) polymeric matrix was used to develop a durable matrix system and to control the transport of small molecules by diffusion. Films of this family of copolymers have been prepared from various solutions and with different thermal history. Various morphological features in terms of degree of crystallinity, crystalline phase and segmental orientation can be obtained. These morphological features at different length scales have been characterized by AFM, X-ray and confocal Raman microscopy. The changes in morphology and microstructures are especially interesting when the films of this family of copolymers are prepared using the electrospray technique. The dispersion of small molecular weight component in the various films has been evaluated. Their transport behavior has also been characterized.

**Q1 40 An Analysis of the Solidification Process in Immiscible and Crystallizable Polymer Blends.** YOUNG GYU JEONG, NATALIA POGODINA, SHAW LING HSU, *Polymer Science and Engineering Department, University of Massachusetts Amherst* Despite the tremendous number of studies in this area, the solidification process of binary and ternary blends is not clearly understood. Here we report the solidification process of immiscible and crystallizable blends, composed of crystallizable polyester and noncrystallizable polyether, in terms of crystallization kinetics, morphological features, and interaction between domains and matrix. All blends exhibited phase-separated morphology with polyester-rich dispersed domains and polyester-poor continuous matrix. The local composition, morphological features, crystallization and solidification process were characterized using $^1$H-NMR, optical microscopy, DSC, and small-amplitude oscillatory viscometry, respectively. The local composition and crystallinity in polyester-rich and –poor phases were varied, depending on blend composition and/or crystallization temperature. The solidification process of blends with low polyester content of 10-30 wt% was dominated by crystallization of the polyester-poor phase. The ultimate viscosity of the overall blend was also lower than that of the polyester-poor phase. The high ultimate viscosity in the polyester-poor phase was associated with the percolated morphology of 'curved leaf'-shape crystallites.

**Q1 41 The Role of Percolation in the Rheological Behavior of Binary and Ternary Blends.** NATALIA POGODINA, YOUNG GYU JEONG, SURIYAKALA RAMALINGAM, SHAW LING HSU, *Polymer Science and Engineering Department, University of Massachusetts Amherst* The rheological behavior of binary and ternary blends involving polyether [e.g. poly(propylene glycol) (PPG)], crystallizable aliphatic polyester [e.g. poly(hexamethylene adipate) (PHMA)] and acrylic copolymers has been studied. The phase behavior of these polymer mixtures at different temperatures is extremely fascinating depending on the nature of the polymers used. The morphological features formed during cooling from elevated temperatures involve phase separation and polyester crystallization. The existence of a percolating solid was established based on evidence from rheological (oscillatory shear) and morphological studies. Typically the blends form a phase-separated droplet-matrix morphology. The transition from the liquid to the solid state has been explicitly correlated to the crystallization behavior of the polyester poor phase. A step increase in the elastic (storage) modulus is observed at a precisely determined PHMA content. The high elasticity can be explicitly explained in terms of the percolation model. The contributions of the domains, interfacial layer and the matrix to the percolation ability of the blend are also discussed.

**Q1 42 Production of Exfoliated Polyethylene-Organoclay Nanocomposites and Its Effect on Mechanical Properties and Thermal Stability.** CYNTHIA PIERRE, JOHN M. TORKELSON, *Northwestern University, Evanston, IL 60208* Low density polyethylene (LDPE)-organoclay nanocomposites as well as linear low density polyethylene (LLDPE)-organoclay nanocomposites are prepared using solid-state shear pulverization (SSSP). The organoclay content in each nanocomposite is 5 wt%. X-ray diffraction indicates that the nanocomposites are exfoliated, because the basal beak at 3.6 degrees for organoclay is nearly eliminated in the nanocomposites made by SSSP. Transmission electron microscopy (TEM) provides further evidence that the nanocomposites are significantly exfoliated. Upon 2 hour annealing at temperatures 25 K above the melt transition of the polymer, x-ray diffraction patterns remain unchanged, indicating that the exfoliated structure of the nanocomposites is kinetically stable in the melt state of the polymer. Due to the stiffness of the clay sheets, the Young's modulus is increase $\sim$ 20% by nanocomposite formation. Thermogravimetric analysis reveals that the onset temperature of degradation is increased by $\sim$ 5 K in the nanocomposites and that the initial degradation of the nanocomposites is retarded relative to neat polymer up to 5% loss of sample weight.

**Q1 43 Oxygen Permeation as a Quantitative Means of Ranking Exfoliation in Polymer-Clay Nanocomposites.** KOSMAS G. KASIMATIS, CYNTHIA PIERRE, AMANDA M. WALKER, JOHN M. TORKELSON, *Northwestern University, Evanston, IL 60208* A series of polymer-clay nanocomposites have been made by solid-state shear pulverization (SSSP), which yields good exfoliation of clay based on x-ray diffraction and transmission electron microscopy results, and by melt mixing, which yields relatively little exfoliation of clay based on similar characterization. Here we demonstrate the utility of oxygen permeation as a quantitative tool for ranking exfoliation levels in polymer-clay nanocomposites; the basis for this approach is related to the fact that greater exfoliation of clay will lead to a more tortuous diffusion path for oxygen in the polymer matrix and thereby a reduction in permeability coefficient. A greater than factor of 3 reduction in permeability coefficient has been achieved in polymer clay nanocomposites processed by SSSP. A comparison of permeation results will be made to other characterization and properties that are known to reflect exfoliation.

**Q1 44 Origins of Linear Viscoelastic Behavior of Polymer-Nanoparticle Composites** VICTOR PRYAMITSYN, VENKAT GANESAN, *University of Texas at Austin* We use computer simulations to study the mechanisms governing the linear viscoelasticity behavior of composites of spherical nanofillers dispersed in polymer melt matrices. Our results suggest that particles can influence the viscoelastic properties of the system by a variety of different mechanisms. On the one hand, the particle-induced effects on the dynamics of polymer segments modify the relaxation

spectrum of the polymers. Secondly, particle jamming effects lead to slow relaxations and substantial enhancements in elasticity. Finally, our results suggest that the strain field distortion caused by the presence of rigid inclusions also affects the overall modulus of the composite. For our model system, we delineate the regimes and frequencies at which the different effects manifest and also suggest how the picture can be generalized for parametric conditions different from our simulations.

**Q1 45 Effect of Molecular Weight on Load Transfer in Nanotube / Polymer Composites** MINFANG MU, *Department of Materials Science and Engineering* FANGMING DU, *Department of Chemical and Biomolecular Engineering* RETO HAGGENMUELLER, KAREN WINEY, *Department of Materials Science and Engineering* The tensile moduli of nanocomposite fibers are being investigated with attention to the molecular weight of the polymer. Nanocomposites composed of single wall carbon nanotube (SWNT) and poly(methyl methacrylate) (PMMA) were prepared by our coagulation method and processed into composite fibers using melt fiber spinning. SWNT in the fibers are aligned and the nanotube - nanotube interactions are diminished, so that, the mechanical load on SWNT is mainly from polymer - SWNT interactions. The tensile moduli along the direction parallel to the SWNT were characterized at 1.0 mm / sec with the fiber length of 25.4 mm. At a weight-average molecular weight (Mw) 25 kDa, the tensile moduli of PMMA are the same with the composites. However, when the Mw is increased to 100kDa, the tensile moduli are improved greatly by adding SWNT. This indicates that the load in the composites is transferred to the SWNT more efficiently at 100 kDa molecular weight. A micromechanics model was used to relate the elastic shear stress on the polymer - SWNT interface to the polymer chain length. It showed that with increasing polymer chain length, the interfacial shear stress was enhanced. This study demonstrates the importance of the molecular weight of the polymer matrix to the load transfer in nanocomposites.

**Q1 46 Templated Nanocarbon Black Nanocomposite Electrodes for Rechargeable Lithium Batteries** OZGE AKBULUT, *MIT* ELSA A. OLIVETTI, *MIT* DONALD R. SADOWAY, *MIT* ANNE M. MAYES, *MIT* In this work, the fabrication of high energy density electrode materials for solid-state rechargeable batteries via block copolymer templating schemes was investigated. Atom transfer radical polymerization was used to synthesize the copolymer template poly((oligooxyethylene) methacrylate)-itblock-poly(butyl methacrylate), POEM-b-PBMA. Continuous, nanoscale phases of vanadium oxide were subsequently grown within the POEM domains of the microphase-separating block copolymer using sol-gel synthesis from a vanadium alkyoxide precursor. The in situ growth of cathodic components in ion-conducting POEM domains allows for control of morphology and increases the interface-to-volume ratio, thereby escalating the specific electrode area over which faradaic reactions can occur and decreasing ion diffusion distances within the electrode. Films incorporating up to 34 wt% $V_2O_5$ were flexible and semi-transparent. To achieve necessary electronic conductivity, the incorporation of nanocarbon black was investigated. Hydrophilic surface modification of carbon black nanoparticles provided a mechanism for their selective incorporation into POEM domains. Transmission electron microscopy (TEM) and small angle x-ray scattering (SAXS) were performed to probe the morphology of the nanocomposite electrodes.

**Q1 47 Creep and Recovery Behaviors of a Polythiophene-based Electrorheological Fluid** DATCHANEE CHOTPATTANANONT, *Chiangmai University* ANUVAT SIRIVAT, *PPC, Chulalongkorn University* We investigate the creep response of poly(3-thiopheneacetic acid) (PTAA) particles doped with perchloric acid. With increase of applied stress, these suspensions exhibit an evolution from a linear viscoelastic response, with three components of instantaneous elastic strain, retarded elastic strain and viscous strain, to a nonlinear viscoelastic response, where the retarded elastic and viscous strains monotonically decrease and a plastic contribution to the instantaneous strain grows, followed by a viscoplastic solid behavior, with fully plastic instantaneous strain, and finally a transition from plastic solid to a plastic liquid at the yield stress. With increase of electric field strength at fixed particle concentration and applied stress, the viscoplastic response diminishes, and more elastic behavior ensues. For highly-doped samples, at high electric field strengths, a fully elastic solid response is observed in the linear viscoelastic regime. The equilibrium compliance, $J_C$ and steady state recoverable compliance $J_R$, were investigated as a function of electric field strength, particle concentration and particle conductivity. The results are interpreted in terms of the field-induced formation of thick fibrillar aggregates spanning the gap between the electrodes, each consisting of bundles of particle strings.

**Q1 48 Electric Field Generated Stress Moduli in Polythiophene/Polyisoprene Elastomer Blends** TOEMPHONG PUVANATVATTANA, ANUVAT SIRIVAT, *PPC, Chulalongkorn University* The effects of crosslinking ratio and electric field strength on the rheological properties of polyisoprene and polythiophene/polyisoprene (Pth/PI) blendss were investigated as potential electroactive actuator. Electrorheological properties of polyisoprene and blends were measured under the oscillatory shear mode with the applied electric filed strength varying from 0 to 2 kV/mm. The dynamic moduli, G′ and G″, of the pure polyisoprene depend on the crosslinking ratio and the electric filed strength; the storage modulus (G′) increases but the loss modulus (G″) decreases with increasing crosslinking ratio. The storage modulus (G′) and the loss modulus (G″) of the pure polyisoprene fluid exhibit no change with increasing electric field strength. For PI with the crosslinking ratios of 2, 3, 5 and 7 (PI_02, 03, 05 and 07), the storage modulus sensitivity, $\Delta G'/G'_o$, increases with electric field strength and attains maximum values of 10%, 60%, 25%, and 30% at the electric field strength of 2 kV/mm, respectively. The loss modulus (G″) of the PI with the crosslinking ratios of 2 and 3 increases with the electric field, but for the blends of the crosslinking ratios of 5 and 7, it decreases. For the blends of polythiophene with PI at concentrations of 5%, 10% and 20% by vol, G′ and G″ are generally higher than those of pure polyisoprene.

**Q1 49 Electromechanical response of a silicone elastomer containing PPV** SUMONMAN NAIMLANG, ANUVAT SIRIVAT, *PPC, Chulalongkorn University* Electrorheological properties of PDMS gel and PPV/PDMS blend were investigated experimentally under an oscillatory shear mode at the temperature of 27°C to determine the effects of crosslink ratio, electric field strength and doping level. For the pure PDMS gels, the storage modulus, G′, increases with increasing crosslinking ratio and electric field at all frequencies between 0.1-100 rad/s. When an electric field is applied, the polymer molecules become polarized resulting in the interaction through the electrostatic force between the polarized

PDMS molecules. The PDMS gel system with the crosslinking ratio of 0.01 possesses the highest G sensitivity to electric field. For the PPV/PDMS blends (PPV/PDMS_10), the dynamic moduli, G′ and G″, are higher than those of pure PDMS in the absence of electric field because PPV particles act as a filler in PDMS matrix. The G′ sensitivity of PDMS increases up to 35% at the electric filed strength of 2 kV/mm. Moreover, the doped PPV/PDMS blend (doped PPV (1:10)/PDMS_10) shows the highest G′ sensitivity (170%) due to interacting electrostatic forces between electric field induced dipole moments of the conductive molecules.

**Q1 50 Creep and Recovery of Electroactive Polyaniline Suspension** PIYANOOT HIAMTUP, ANUVAT SIRIVAT, *PPC, Chulalongkorn University* Creep and recovery behaviors of the PANI/silicone oil suspensions were investigated under applied electric field to explore the effects of field strength and particle concentration. The data show that, at any applied shear stress, the creep curves of this ER fluid showed a large instantaneous elastic response, whereas the retarded elastic and the viscous responses were very small and they disappeared as applied stress was increased. After the removal of applied stress, the strain decreased but did not completely relax to its original value indicating that the fluid exhibited a partially elastic recovery. However, it was noted that the recovery after stress removals disappeared when the strain was higher than the critical values $\sim$ 0.4-0.5, independent of particle concentration and field strength. It was also found that creep resistance of EB/Silicone oil suspension were clearly dependent on both field strength and particle concentration.

**Q1 51 Anisotropy of Electroactive Strain in Textured Polypyrrole Actuators** RACHEL PYTEL, EDWIN THOMAS, IAN HUNTER, *Massachusetts Institute of Technology* Polypyrrole has been extensively studied as an electroactive material, but these studies have provided little insight to the influence that morphology has on actuation at the nanoscale. By discovering and exploiting the connection between nanoscale transport events and macroscale active strain, we can learn how to process polypyrrole and other conducting polymers for improved electroactive device performance. We show that by controlling polymer chain configuration and packing, a conducting polymer actuator can be engineered that shows a significantly larger macroscopic electroactive response for a given set of driving conditions. We utilize different modes of deformation to impart orientation textures that can be observed via synchrotron x-ray diffraction and electronic and ionic resistance measurements. Certain textures enhance pathways for ion transport between polymer chains, resulting in an anisotropic electroactive strain response that can be harnessed when making polypyrrole-driven devices. This response provides valuable insight to the mechanism of polypyrrole actuation on the nanoscale, supporting a mechanism where counterions migrate to locations between the oriented polymer chains.

**Q1 52 Detecting composition and monomer sequence distribution in random copolymers with interaction chromatography** JUNWON HAN, CHANG Y. RYU, *Rensselaer Polytechnic Institute* JAMES J. SEMLER, JAN GENZER, *North Carolina State University* We demonstrate that interaction chromatography (IC) is capable of discriminating among both the chemical composition and monomer sequence distribution in random copolymers. By fine-tuning the separation conditions in the IC (solvent type and stationary phase type), we were able to delineate the effect of both their chemical composition and the monomer sequence distribution of partially brominated polystyrenes on chromatographic retention. The degree of bromination and the 4-BrS sequencing was controlled by varying the bromine concentration in the reaction vessel, bromination reaction time, and solvent temperature. Our experiments suggest that 1) the blockiness of 4-BrS adsorption segments can further enhance the surface affinity of the copolymer chains at a fixed copolymer chemical composition, and 2) the adsorption-based molecular recognition of copolymer chains occurs by cooperative and synergistic adsorption of segments on surfaces along with neighboring adsorptive segments.

**Q1 53 Interplay between polymer and nanopore sizes for polymer adsorption in nanopores** CHANSU KIM, CHANG Y. RYU, *Rensselaer Polytechnic Institute* We investigated the adsorption and desorption of monodisperse polystyrene (Mw: 4K $\sim$ 3M) in cyclohexane into nanoporous silica (Rp, radius of pore: 4, 7, 14, and 24nm; particle diameter: 7 micron) to understand the interplay between polymer coil size and nanopore size for the polymer adsorption in nanopores. Regardless of the pore sizes, two regimes of polymer nanopore adsorption have been identified to universally describe the surface access (adsorbed mass per unit area) in terms of the relative size interplay, Rg/Rp. When polystyrene is much smaller than pore, the surface access increases with the radius gyration, Rg, essentially following the adsorption behavior on the flat surface. When polystyrene is similar or larger than pore, the surface access in nanopore surface is smaller than that on the flat surface. From SEM, we found morphological evidence to support that the steric crowding of polystyrene chains occurs at the nanopore entrance to offer the limited accessibility of polymers into the pore surfaces.

**Q1 54 Recent developments in multivariant surface-tethered polymer assemblies** RAJENDRA BHAT, MICHAEL TOMLINSON, JASON STONE, JAN GENZER, *N.C. State University* Surface-tethered polymer brushes prepared via surface-initiated controlled/''living'' radical polymerization represent an effective tool for tuning the physico-chemical properties of surfaces. We have recently developed methods leading to assemblies of surface-tethered polymers with continuously varying grafting density, molecular weight, and composition. In this presentation, we will demonstrate how these assembling concepts can be utilized to: 1) study the kinetics of surface-initiated controlled/''living'' radical polymerization, 2) systematically study the phase behavior of diblock and triblock copolymers upon exposure to selective solvents, 3) study the behavior of block copolymer polyampholyte brushes, and 4) explore the wettability transitions (superhydrophobic/superhydrophilic) using thermoresponsive polymer brushes on topologically corrugated substrates.

**Q1 55 Evaporation and interdiffusion of solvent in polymer films** MESFIN TSIGE, *Southern Illinois University Carbondale* GARY S. GREST, *Sandia National Laboratories* Solvent evaporation from homopolymer and heteropolymer films along with the interdiffusion of solvent into these films is studied using large scale molecular dynamics and grand canonical Monte Carlo simulations. As the solvent evaporates, a sharp increase in polymer density at the film/vapor interface is observed. The rate of solvent evaporation, for both homopolymer and heteropolymer films is found to decrease exponentially with time. For multiblock films

the resulting domain structure is found to be strongly affected by the relative stiffness of the two blocks. In the interdiffusion study, the shape of the solvent concentration profile and the weight gain by the film can be related to the diffusivity. For homopolymer films, although the diffusivity is found to be strongly concentration dependent especially as one approaches the glass transition temperature of the polymer, the weight gain scales as $t^{1/2}$ for all cases studied, which is expected for Fickian diffusion. For a multiblock copolymer film in which the stiffer block is below the glass transition temperature is also studied, even though the solvent swells only the softer block of the copolymer, the weight gain by the film remains Fickian.

**Q1 56 Adsorption of Biodegradable Diblock Copolymers PEO-PLA and PEO-PCL to Colloidal Polystyrene** KAREN A. MURPHY, JESSICA M. MENDES, DANIEL A. SAVIN, *University of Vermont* A series of amphiphilic block copolymers composed of poly (ethylene oxide) and either poly(lactide) or poly($\epsilon$-caprolactone) (PEO-PLA, PEO-PCL respectively) were synthesized and their solution properties studied using dynamic light scattering. The synthesis was performed using the same PEO macroinitiator while varying the fraction of the hydrophobic block. These materials were found to self-assemble in aqueous media with the hydrodynamic radius increasing with increasing hydrophobic fraction. In order to ascertain the potential for use of these materials as degradable coatings in delivery applications, block copolymers were adsorbed to colloidal polystyrene and the thickness of the adsorbed layer determined from changes in the hydrodynamic size. The adsorbed thickness ranged from 4 - 10 nm with varying block ratio, polymer concentration and colloid concentration. In general, the adsorption of PEO-PCL to colloidal polystyrene resulted in larger adsorbed thickness compared with PEO-PLA.

**Q1 57 Optical Properties of Molecules and Molecular Aggregates Adsorbed on Solid Surfaces. First Principle Study.** ALEXANDER GAVRILENKO, MIKHAIL NOGINOV, CARL BONNER, VLADIMIR GAVRILENKO, *Center of Materials Research, Norfolk State University, Norfolk VA 23504* Equilibrium atomic geometries of Ferrocene and Rhodamine 6G (R6G) dye molecules adsorbed on Si(111) and Ag(111) surfaces respectively are studied using density functional theory. Equilibrium atomic geometries are obtained through total energy minimization method. Electron energy structure and optical properties are calculated using generalized gradient approximation method with itab initio pseudopotentials. Modifications of electronic surface structures of Ag(111) and Si(111) caused by the adsorption of molecules as well as charge transfer between molecules and solids are studied. Red or blue shifts of optical absorption spectra of R6G dye molecules after aggregation in *J*- or *H*-dimmers respectively are predicted. Calculated optical absorption spectra are interpreted in terms of inter-molecular and molecular-solid interactions. Results of the calculations are discussed in comparison with experimental data.

**Q1 58 Wetting Morphologies in Triangular Grooves*** KRISHNACHARYA KAREH, MARTIN BRINKMANN, STEPHAN HERMINGHAUS, RALF SEEMANN, *MPI for Dynamics and Self-Organisation, D-37073 Goettingen* BRUCE LAW, *Kansas State University, Manhattan, KS 66506* We studied the wetting behavior of liquids in triangular grooves with chemically homogeneous walls. Droplets form elongated morphologies with negative mean curvature for contact angles, $\theta$, smaller than 90° minus half the opening angle of the groove. For larger $\theta$, the liquid either forms elongated filaments of finite length and positive mean curvature or drop-like morphologies. For in situ manipulation of small amounts of liquid on this substrate topography, we used electrowetting which allows varying $\theta$ as a function of the applied Voltage. The filling and drainage behavior of these grooves were studied as a function of time and $\theta$. In contrast to grooves with rectangular cross section, the liquid filaments in triangular grooves undergo a dynamic instability when being quenched from a filling to a non-filling situation. The liquid filament breaks up into isolated droplets with a preferred distance which compares favorably with a straightforward theoretical model.

*This work was partly funded by the German Science Foundation under grant number SE1118 within the priority program Nano- and Microfluidics SPP 1164.

**Q1 59 Freezing of Polymer Thin Films and Surfaces: The Small Molecular Weight Puzzle** STEPHAN HERMINGHAUS, RALF SEEMANN, *MPI for Dynamics and Self-Organization, D-37073 Goettingen* KARIN JACOBS, *Saarland University, D-66123 Saarbruecken* KATHARINA LANDFESTER, *University of Ulm, D-89069 Ulm* Experimental observations (ellipsometry, scanning force microscopy (AFM), and nuclear magnetic resonance (NMR)) of the freezing behavior of thin supported films as well as the free surface of atactic polystyrene are reported, taken at a particularly small molecular weight of 2 kg/mol. Remarkably, we find the same effect of reduction of the glass transition temperature, Tg, as observed earlier with much longer molecules. Furthermore, surface melting is observed by NMR, with the molten layer thickness similar to what has been observed with larger molecular weight. We conclude that molecular geometry effects cannot account for these observations, and that a consistent explanation must be presentable in a continuum picture. Based on the capillary wave spectrum of the free surface and of the supported films, we present such a model, and find that it accounts very consistently with all observations made so far with polystyrene.

**Q1 60 Film Formation with Reactive Hydrophobic and Polar Groups in Aqueous Solution: A Bond-Fluctuating Computer Simulation Model*** SHIHAI YANG, SAMUEL BATEMAN, RAS PANDEY, MAREK URBAN, *University of Southern Mississippi* We study film formation with reactive hydrophobic ($H$) and polar ($P$) components in evaporating aqueous ($A$) solution by Monte Carlo simulation to model the polyurethane film growth. Each component is represented by mobile particles with appropriate molecular weight, interaction, and reaction functionality on a simple three-dimensional lattice $L_x \times L_y \times L_z$ with an adsorbing substrate. $H$ and $P$ react by forming fluctuating covalent bonds proceeding from the substrate with probability $P_B$. Bonds may also be formed between $H$ and $A$ when $A$ is considered reactive. Growth of the film thickness ($h$) and surface roughness ($W$) are studied at a range of temperature ($T$). With non-reactive $A$, the saturated film thickness ($h_s$) and roughness ($W_s$) decay first before increasing linearly on raising the temperature. With reactive $A$, a fast increase of $h_s$ at low temperature is followed by a slow increase at high temperature. $W_s$ also shows non-monotonic dependence on temperature.

**Q1 61 Enhancement of X-ray Reflectometry for the Depth-Profiling of Polymer Films using Polymeric Substrates*** MARIA I. LYGERAKI, HARIS RETSOS,† SPIROS H. ANASTASIADIS,‡ *Foundation for Research and Rechnology - Hellas, Heraklion Crete, Greece* CHRIS TOPRAKCIOGLU, ALEKOS A. VRADIS, *University of Patras, Rion Patras, Greece* YVES GALLOT, *Institut Charles Sadron, Strasbourg, France* The investigation of the internal structure of thin polymer films on conventional substrates by X-Ray reflectometry is restrained due to the high electron densities of these substrates compared to those of most polymers. A methodology is proposed and applied to circumvent this problem by utilizing polymeric substrates of appropriate thickness and roughness, which can be reproducibly deposited on the standard substrates in order to render them invisible to the X-rays. The resolution of the X-ray reflectometry is significantly enhanced as illustrated utilizing thin films of PS-b-PMMA diblock copolymers of various thicknesses. The proposed methodology will allow the study of internal polymer interfaces using in-house diffractometers/reflectometers.

**Q1 62 Switchable Adhesion Properties From Low and High $T_g$ Polymeric Brushes** HARIS RETSOS, YVETTE TRAN, *E.S.P.C.I., PARIS* GANNA GORODYSKA, ANTON KIRIY, MANFRED STAMM, *I.F.P. Dresden, Germany* COSTANTINO CRETON, *E.S.P.C.I., PARIS* We investigated the adhesive properties of mono-component and bi-component polymeric brushes chemically grafted on silicon wafers from end-functionalized hydrophilic and/or hydrophobic chains by using the technically simple 'grafting to' method. The charge state and the molecular organization of high $T_g$ brushes could be varied reversibly by exposure to appropriate solvents or by varying the grafting density. Adhesive properties were tested against soft pressure-sensitive-adhesives (hydrophobic & hydrophilic) with a probe method. In the case of low $T_g$ brushes, an increase in contact time could selectively improve the adhesion with the soft hydrophobic or hydrophilic adhesive layer. This is due to reorganization of the interface at the molecular scale leading to the formation of entanglements or favorable interactions between the polymer brush and the polymers in the soft adhesive.

**Q1 63 Principles of resonant soft x-ray reflectivity – a novel tool in polymer research** CHENG WANG, TOHRU ARAKI, SHANE HARTON, *NC State University* TADANORI KOGA, *SUNY Stony Brook* HARALD ADE, *NC State University* Resonant soft x-ray reflectivity (RXR) has been reported to be a potentially excellent tool for the study of polymer thin films [1]. To further delineate the applicability of this method, detailed principles about RXR will be discussed. Near the carbon 1-s absorption edge, the complex index of refraction $n = 1-\delta-i\beta$ is changing rapidly as a function of photon energy in a manner that strongly depends on the chemical moieties of the polymer. This leads to enhanced contrast between two polymers at specific energies when compared to hard x-rays. This contrast enhancement mimics the contrast enhancement achieved through deuteration used in neutron reflectivity, yet does not require special chemical procedures. PS/PMMA, PBrS/PMMA, PS/SAN, PS/P2VP and PCHMA/PMMA bilayers were characterized by RXR at beamline 6.3.2 at the Advanced Light Source. For a subset of these samples, RXR results were directly compared to hard x-ray reflectivity characterization that uses a fourier analysis method [2], and the results showed good agreement. [1]C. Wang, T. Araki, and H. Ade, Appl. Phys. Lett. 87, 214109 (2005). [2]O. H. Seeck et al., Appl. Phys. Lett. 76, 2713 (2000).

**Q1 64 Calorimetric Tg and Heat Capacity of Polystyrene Thin Films*** YUNG KOH, GREGORY McKENNA, SINDEE SIMON, *Texas Tech University* The glass transition temperature and the absolute heat capacity of polystyrene thin films were measured using the step-scan method of differential scanning calorimetry. The glass transition temperature is found to be depressed 8 K for a sample of stacked 17 nm thick films and Tg is depressed 3 K for a sample of stacked 61 nm thick films. The results are consistent with data in the literature for the Tg depression in supported polystyrene films although our films are expected to be ''freely standing'' for the initial DSC scan. In addition, the absolute heat capacity in both the liquid and glassy states decreases with decreasing film thickness, the step change in heat capacity at the glass transition temperature decreases with decreasing film thickness, and the breadth of the transition region increases with decreasing film thickness. The effect of heating the thin film samples to 135 [r]C, approximately 40 [r]C above their Tgs, is a slight increase in the absolute heat capacity and a slight increase in Tg. No significant changes occur on subsequent scans. The ''thin film'' morphology is maintained in spite of scanning to above Tg where the stacked film sample is expected to lose its free surface.

*Funding from NSF DMR 0304640 is gratefully acknowledged.

**Q1 65 Dissipative particle dynamics simulations of dilute polymer solutions confined in a slit with interactive surfaces** WENHUA JIANG, *Department of Chemistry, The University of Memphis, Memphis, TN 38152* JIANHUA HUANG, *Department of Chemistry, The University of Memphis, Memphis, TN 38152; Department of Chemistry, Zhejiang Sci-Tech University, Hangzhou, 310018, China* MOHAMED LARADJI, *Department of Physics, The University of Memphis, Memphis, TN 38152* YONGMEI WANG, *Department of Chemistry, The University of Memphis, Memphis, TN 38152* Dynamics of polymer chains in confined geometries are significantly different from that in a bulk solution. Understanding the confinement effect on the chain dynamics is of great value to applications of microfluidic devices. We applied dissipative particle dynamics (DPD) to study polymer chain dynamics confined in slits with interactive surfaces. We first examined the dynamics and the static properties of polymers in dilute bulk solutions. After correcting for the effect of finite box size, our results unambiguously confirmed that the DPD has correctly accounted for hydrodynamic interaction within a polymer chain. We then extended the simulation to polymer solutions confined in a slit with interactive surfaces. For purely repulsive surfaces, the dynamics and the static properties of polymers show a broad crossover from a free solution to a confined solution. The attractive interactions of polymers with the walls were found to retard the dynamics of the chains significantly. The influence of surface interactions on polymer dynamics will be presented.

**Q1 66 Dissipative particle dynamic simulations of solvent flow through nanometer sized smart channel coated with stimuli**

**responsive polymer brush** JIANHUA HUANG, *Department of Chemistry, The University of Memphis, Memphis, TN 38152; Department of Chemistry, Zhejiang Sci-Tech University, Hangzhou, 310018, China* MOHAMED LARADJI, *Department of Physics, The University of Memphis, Memphis, TN 38152* YONGMEI WANG, *Department of Chemistry, The University of Memphis, Memphis, TN 38152* Various efforts have been focused on the development of smart materials which can respond to environmental stimuli such as pH or temperature. Nanometer sized channels coated with such stimuli responsive polymers can serve as smart gating or smart valve that are of interest for applications such as controlled drug release and tunable permeation and separations of toxic solutes. These systems involve the interplay of solvent flow with the structure of polymer brush in response to the external stimuli. We applied dissipative particle dynamic (DPD) method to investigate solvent flow through such smart channels. The external stimuli are modeled by the change in solvent quality that causes polymers undergoing a coil-to-globular transition. We investigate the ability of such smart channel to control the solvent flow under different stimuli. The interplay of the solvent flow and the properties of polymer brush are studied at the molecular level. The effects of the grafted density and the layer thickness of polymer brush on its controlling ability have also been investigated.

**Q1 67 Exfoliation of stacked sheets: effects of temperature and platelet size by a Monte Carlo simulation*** BARRY FARMER, *Air Force Research Laboratory* RAS PANDEY, *University of Southern Mississippi* Can a layer of stacked sheets (coarse grained description of clay platelets) exfoliate in a solvent? Computer simulations are performed to address this question with a stacked layer of four sheets. A sheet is modeled by nodes tethered together by fluctuating bonds on a cubic lattice; sheets of sizes $12^2 - 64^2$ are considered. The initial distance between sheets is small and kept constant for different sets of stacked sheets. There is an attractive interaction between sheets, i.e., their nodes and the empty lattice sites, the effective solvent medium. Nodes execute stochastic movement with the Metropolis algorithm subject to bond fluctuation and excluded volume constraints. Simulations are performed at different temperatures. Visual analysis shows that the exfoliation depends on the size of the sheet and temperature. We find that it is easier to exfoliate smaller sheets and that the exfoliation is enhanced by raising the temperature. The exfoliation becomes very slow for large sheets at low temperatures due to longer relaxation times.

*We acknowledge supports from the Materials and Manufacturing Directorate of the Air Force Research Laboratory.

**Q1 68 Correlations of System Mobility with Various Scalar Metrics** JULIEANNE HEFFERNAN, ROBERT BACA, JOHN McCOY, *New Mexico Institute of Mining and Technology* JOANNE BUDZIEN, DOUGLAS ADOLF, *Sandia National Laboratories* Molecular dynamic simulations of chain systems were performed in order to investigate the relationships between the system mobility and thermostatic quantities. Systems consisted of pearl-necklace chains along with single site penetrants. Both attractive and repulsive systems (based on the cut-off of the Lennard-Jones potential) were simulated. The diffusion coefficients, D, for the chains and penetrants were then found for a variety of temperatures (T) and density combinations. D/T was found to be a single-valued function of a thermostatic quantity that we denoted as a ''scalar metric.'' Four scalar metrics were found. Since, through the master curve, the mobilities for all temperature-density points can be extrapolated to a single zero, a unique ideal glass transition can be proposed to exist. Consequently, a scalar metric can be used as a ''distance'' measure to this ideal glass transition.

**Q1 69 A Monte Carlo Study of Frozen Lattices on Curved Surfaces** A. HEXEMER, E. J. KRAMER, G. H. FREDRIKSON, *UCSB* V. VITELLI, D. R. NELSON, *Harvard* We compare the defect structure and density of particles confined on 2d surfaces with different curvatures as well as different surface morphologies. All simulations are performed using a smart Monte Carlo algorithm while the particle system is cooled from a melted state to zero degree temperature. The surfaces show similar defect patterns. At low maximum Gaussian curvature a hexagonal lattice wraps defect-free onto the curved surface. We then observe a critical maximum curvature at which the creation of defects lowers the potential energy of the lattice with respect to the defect-free lattice. At this critical value we observe free dislocations located at the inflection points of the surface. Further increase in curvature results in the creation of more free dislocations which organize in grain boundaries aligned along the shortest connection between the positive and negative Gaussian curvature areas. A stronger curvature leads to the creation of free disclinations. The $-60^o$ disclinations are pinned to the area of positive curvature while the $+60^o$ disclinations occupy the negative areas. The transition from the defect free lattice to a defected lattice as the lowest energy state is compared to an analytic expression derived from continuum mechanics.

**Q1 70 A Molecular Dynamics Study of the Odd-Even Effect in Self-Assembled Monolayers*** LAWRENCE HERMAN, *United States Naval Academy, Midshipman First Class* PAUL MIKULSKI, *United States Naval Academy, Physics Department* JUDITH HARRISON, *United States Naval Academy, Chemistry Department* Classical Molecular Dynamics has been used to examine the friction in model systems consisting of an amorphous hydrocarbon tip sliding across self-assembled monolayers consisting of well-ordered densely-packed pure linear hydrocarbon chains. An odd monolayer composed of C13 chains is compared against an even monolayer composed of C14 chains at a number of loads. Periodic Boundary Conditions imposed in the horizontal plane are used to model infinite monolayers. The friction of the odd monolayer is seen to be roughly twice as large as that of the even monolayer at all loads. The difference is attributable to the differing orientation of terminal chain groups in odd versus even monolayers. Analysis of net forces exerted by the entire set of tip atoms on individual monolayer atoms lends insight into specific properties associated with the observed frictional difference.

**Q1 71 Fabrication of Biopolymer Nanofibers of Hyaluronic Acid via Electrospinning** DENICE YOUNG,* *North Carolina State University* HAILEY QUEEN,† *North Carolina State University* WENDY KRAUSE,‡ *North Carolina State University* Electrospinning is a novel technology that uses an electric field to form fibrous materials from a polymer solution. Unlike traditional spinning techniques, electrospinning can produce fibers on the order of 100 nm that can be utilized in applications where nanoscale fibers

are necessary for successful implementation, including tissue engineering. Hyaluronic acid (HA) is a widely used biopolymer found in the extracellular matrix and currently marketed in medical applications for joint lubrications and tissue engineering. The high viscosity and surface tension of HA make it an unlikely candidate for electrospinning processes as viscosity is an important parameter in successful electrospinning. To promote HA fiber formation by electrospinning, the effects of salt (NaCl), which is used to reduce the viscosity of aqueous HA solutions; molecular weight of the HA; and an additional biocompatible polymer (e.g., PEO) are under investigation.

**Q1 72 Influence of D-Penicillamine on the Viscosity of Hyaluronic Acid Solutions** JING LIANG, *North Carolina State University* WENDY E. KRAUSE, *North Carolina State University* RALPH H. COLBY, *The Pennsylvania State University* Polyelectrolyte hyaluronic acid (HA, hyaluronan) is an important component in synovial fluid. Its presence results in highly viscoelastic solutions with excellent lubricating and shock-absorbing properties. In comparison to healthy synovial fluid, diseased fluid has a reduced viscosity. In osteoarthritis this reduction in viscosity results from a decline in both the molecular weight and concentration of hyaluronic acid HA. Initial results indicate that D-penicillamine affects the rheology of bovine synovial fluid, a model synovial fluid solution, and its components, including HA. In order to understand how D-penicillamine modifies the viscosity of these solutions, the rheological properties of sodium hyaluronate (NaHA) in phosphate-buffered saline (PBS) with D-penicillamine were studied as function of time, D-penicillamine concentration (0 – 0.01 M), and storage conditions. Penicillamine has a complex, time dependent effect on the viscosity of NaHA solutions—reducing the zero shear rate viscosity of a 3 mg/mL NaHA in PBS by itca. 40% after 44 days.

**Q1 73 Electrospinning of Biocompatible Nanofibers** ANDREW J. COUGHLIN,* *North Carolina State University* HAILEY A. QUEEN, *North Carolina State University* SETH D. McCULLEN, *North Carolina State University* WENDY E. KRAUSE, *North Carolina State University* Artificial scaffolds for growing cells can have a wide range of applications including wound coverings, supports in tissue cultures, drug delivery, and organ and tissue transplantation. Tissue engineering is a promising field which may resolve current problems with transplantation, such as rejection by the immune system and scarcity of donors. One approach to tissue engineering utilizes a biodegradable scaffold onto which cells are seeded and cultured, and ideally develop into functional tissue. The scaffold acts as an artificial extracellular matrix (ECM). Because a typical ECM contains collagen fibers with diameters of 50-500 nm, electrostatic spinning (electrospinning) was used to mimic the size and structure of these fibers. Electrospinning is a novel way of spinning a nonwoven web of fibers on the order of 100 nm, much like the web of collagen in an ECM. We are investigating the ability of several biocompatible polymers (*e.g.*, chitosan and polyvinyl alcohol) to form defect-free nanofiber webs and are studying the influence of the zero shear rate viscosity, molecular weight, entanglement concentration, relaxation time, and solvent on the resulting fiber size and morphology.

**Q1 74 Structure and interactions of human respiratory mucin** KIRSTIN PURDY, *University of Illinois at Urbana Champaign* JOHN SHEEHAN, MICHAEL RUBINSTEIN, *University of North Carolina* GERARD WONG, *University of Illinois at Urbana Champaign* Human respiratory mucin plays a crucial role in the pathology of Cystic Fibrosis lung infections. Mucin is a flexible, linear polyelectrolyte, characterized by its many charged oligo-carbohydrate side chains that give it its bottle-brush structure. The macroscopic properties of a mucin suspension are known to change drastically with changes in ion concentration and solution pH, but little is known about the effect of these variables on individual mucin structure. We present preliminary results on the structural response of individual human respiratory mucin molecules to variations in concentration of ions of different valences via small angle x-ray diffraction.

**Q1 75 Theoretical simulation of compression of single bovine carbonic anhydrase II molecule by AFM tip** KATSUNORI TAGAMI, MASARU TSUKADA, *Waseda University, Japan* Based on all-atom force field model called CHARMM, we calculated the force distance curves of the single bovine carbonic anhydrase II molecule adsorbed on the graphite surface in the UHV condition. The AFM tip is modeled by the graphite sheet of monolayer thickness. The force distance curves show the nonlinear feature which can be classified into three regions, i.e., the attractive, weak repulsive, and strong repulsive force regions. We found that in the second region the surrounding alpha helices are compressed while in the third region the core beta sheets are also compressed. This finding indicates that the heterogeniousity in a single protein molecule can be measured by the AFM. We will also discuss the effect of the temperature on the force distance curves.

**Q1 76 Self Assembly of $\beta$-Hairpin Peptides into Hydrogel Networks: Tuning Supramolecular Properties Through Molecular Design** TUNA YUCEL, *Materials Science and Engineering, University of Delaware* CHRIS MICKLITSCH, JOEL SCHNEIDER, *Chemistry and Biochemistry, University of Delaware* DARRIN POCHAN, *Materials Science and Engineering, University of Delaware* Monomeric peptides were designed to undergo reversible, intramolecular folding with external stimuli (e.g. pH, temperature, salt) to form $\beta$-hairpins that consequently self assemble into a hydrogel network rich in $\beta$-sheet. The design was composed of a turn sequence ($V^DPPT$) flanked by extended strands containing alternating lysine and valine residues. The hydrophobicity of the peptides was altered through replacing valine residues in the arms with residues such as, norvaline, norleucine and isolecine. Circular dichroism spectroscopy illustrated that random-coil to $\beta$-sheet transition could be tuned from $35^oC$ to below $5^oC$ at pH 9, while the transition pH at $T_{room}$ could be shifted from pH 9 down to pH 7. TEM illustrated that all peptides self-assembled into fibrilar networks. Single fibril dimensions were 3 nm as measured using TEM and small-angle neutron scattering, consistent with the proposed self-assembly mechanismof

fibrils with a molecular bilayer cross-section. There was a direct correlation between fibril morphology and consequent changes in the nature of junction points and gel rigidity as observed by TEM, and oscillatory rheology, respectively.

**Q1 77 Flory $\chi$ of the homologous series of deuterated polystyrene-b-poly(n-alkyl methacrylates): small angle neutron scattering and theoretical studies** DU YEOL RYU, *Yonsei University* KRISTOPHER A. LAVERY, THOMAS P. RUSSELL, *University of Massachusetts at Amherst* JUNHAN CHO, *Dankook University* DONG HYUN LEE, JIN KON KIM, *Pohang University of Science and Technology* We have performed small angle neutron scattering and theoretical studies of the homologous series of deuterated polystyrene-b-poly(n-alkyl methacrylates) from methyl to n-hexyl groups that cover from UODT (upper order-disorder transition) to LODT (lower DOT), and barotropic to baroplastic behavior. It was shown that the effective Flory $\chi$ from the measurements reveal a monotonic dependence on 1/T for UODT (methyl, n-hexyl) systems and a complicated dependence for LDOT (ethyl to n-pentyl) systems. The recently developed compressible random-phase approximation (RPA) analysis has been applied to the copolymers to interpret in a unified way such diversified temperature and pressure dependence of $\chi$ and the transitions. Specific interactions (SI) and compressibility were incorporated through the RPA interaction fields in this theoretical approach. It was argued that the SI gives a major contribution to the LDOT behavior and the complicated dependence of $\chi$ on 1/T. The compelling changes in $\chi$ and the pressure responses of transitions according to the pendant group size were also interpreted successfully with the theory.

**Q1 78 A new field-theoretic simulation method for compressible systems containing block copolymers** JUNHAN CHO, *Dankook University* A new field-theoretic simulation method based on a compressible random-phase approximation (RPA) theory has been suggested to understand the self-assembly behavior and its pressure responses of compressible systems containing block copolymers. Finite compressibility is incorporated in the free energy functional for the dissipative dynamics through effective RPA interactions that account for the excluded volume and the attractive nonbonded interactions. It was shown for A-b-B copolymer melts in unconfined or confined geometry that basic equation-of-state parameters completely characterizing given block components readily yield stable and metastable morphologies without any presumed symmetry over a wide range of temperature-pressure-composition space. It was demonstrated that the simulation tool is capable of predicting in a unified way the self-assembly behavior not only exhibiting nanoscale ordering either upon cooling or reversely upon heating, but also revealing barotropicity and baroplasticity. The simulation of the self-assembly behavior of multiblock copolymers with diverse molecular architectures and also of block copolymers in a solvent covering from complex patterns to micellar structures was also discussed.

**Q1 79 Stability of the orthorhombic *Fddd* phase in diblocks using Landau theory of weak crystallization** AMIT RANJAN, DAVID MORSE, *Department of Chemical Engineering and Materials Science, University of Minnesota* Recent numerical SCFT caculations by Tyler and Morse [*Phys. Rev. Lett.*, **94**, 208302, 2005] predict a stable orthorhombic network phase with space group *Fddd* in weakly segregatd diblocks. In this work, we examine the stability of the *Fddd* phase using Landau theory. Our analysis and results suggest that *Fddd* structure with a special unit cell is expected to be a stable phase not only in weakly segregated diblocks but in any other weakly ordered material.

**Q1 80 Depletion interaction effects on diblock copolymer micelles in selective solvents** SAYEED ABBAS, TIMOTHY LODGE, *Department of Chemical Engineering and Materials Science, University of Minnesota* Block copolymers form micelles when dissolved in a selective solvent for one block. At higher concentrations the micelles pack into ordered microstructures. When non-adsorbing homopolymer is added to the solutions, we observe that the ordered morphologies can be disordered. Due to the addition of homopolymer the repulsive inter-micellar interactions are screened, which leads to the melting of the ordered microstructures. This phenomenon is analogous to depletion interactions in colloid/polymer mixtures. We have chosen the polystyrene-b-polyisoprene dissolved in dialkyl phthalates, as our model system. To these solutions polystyrene homopolymer is added. The molecular weight of the homopolymer has a significant effect on the phase behavior of the system. Our goal is to study the changes in phase behavior induced by addition of homopolymers and explore the underlying parameters which control the phase behavior.

**Q1 81 Order-Disorder Transition and Critical Micelle Temperature in Concentrated Block Copolymer Solutions** MOON JEONG PARK, KOOKHEON CHAR, *Seoul National University* JIN KON KIM, *Pohang University of Science and Technology* TIMOTHY P. LODGE, *University of Minnesota* The phase behavior of symmetric styrene-isoprene diblock copolymers in selective solvents in the vicinity of the order- disorder transition (ODT) was investigated by SANS and rheology. To understand morphological changes in more detail, one of the blocks is deuterated and the scattering length density of the solvents used were identical to the corona chains. We examined two different ODTs: body-centered cubic/disorder and hexagonal cylinder/disorder, with similar SANS results in both cases. With increasing temperature, the micellar aggregation number decreases, and the core radius is roughly maintained by the increased solvent swelling of the core. The critical micelle temperature is experimentally described by an abrupt decrease in the size, aggregation number, and volume fraction of micelles, which is approximately 20-30 C higher than the TODT. Rheological measurements, however, revealed a distinct plateau in elastic modulus just above the temperature of cylinder/disorder. The structure is attributed to the micellar congestions due to the slow break-up of cylindrical domains into an equilibrium distribution of micelles. An isothermal frequency sweep in this regime indicated a very long relaxation time and the transient response significantly depends on solvent selectivity. Possible origins of the remarkable solvent selectivity dependence are also discussed.

**Q1 82 Crystallization studies of polyethylene -poly(ethylene glycol) graft copolymers*** P.R. MARK, G.E. HOVEY, N.S. MURTHY, K. BREITENKAMP, M. KADE, T. EMERICK, *University of Massachusetts, Amherst* Structure and crystallization behavior of three copolymers obtained by grafting poly (ethylene glycol) (PEG) chains to polyethylene (PE) main chain was investigated by variable temperature x-ray diffraction and thermal

analysis. The results show that PEG side chains and PE main chains crystallize into separate domains. This is especially true when grafted chains are long (50 and 100 repeat units), in which the PEG domains are same as in PEG homopolymer both in structure and in melting behavior. In the copolymer with shorter chains (25 repeat units), the PEG crystals are not distinct and melting is broad. The PEG domains can be dissolved in water or ethanol without altering the mechanical integrity of the film. PE crystallites in both samples are similar to that in PE homopolymer. For instance, the thermal expansion of the basal cell plane (a- and b-axes) of the PE domains agrees well with that of PE homopolymer over the entire temperature range from ambient to melt. However, the chain-axis dimension PE-lattice in the copolymer is shorter by $\sim$ 0.05 Å and the basal dimensions are larger by $\sim$ 0.05 Å. The changes in these dimensions due to the changes in the length of the grafted PEG chains were investigated.

**Q1 83 Electroluminescence Emission of Fully Conjugated Heterocyclic Aromatic Rigid-rod Polymer Doped in itMulti-wall Carbon Nanotube** JEN WEI HUANG, SHIH JUNG BAI, *National Sun Yat-Sen University* Carbon nanotube and poly-*p*-phenylenebenzobisoxazole (PBO) contain fully conjugated rod-like backbone entailing excellent optoelectric properties and solvent resistance. Rigid-rod polymer PBO is only soluble in methanesulfonic acid or Lewis acid. itMulti-wall carbon nanotube (*M*WNT) was dissolved in a Lewis acid solution of PBO for dispersion of nanotube, and then spun for thin film. *M*WNT concentration in the films was from zero up to 5 wt. %. Compared to that of pure PBO film, composite films of *M*WNT doped PBO showed same UV-Vis absorption peaks which were enhanced with *M*WNT concentration but without overlapping electron orbitals to effect their energy gaps. All films were excited by He-Cd laser with excite wavelength of 325 nm for photoluminescence (PL) response. All PL spectra had maximum wavelength peak at 540 nm indicative of yellow-green light emission. For light emitting diodes, *M*WNT doped PBO would decrease threshold voltage for about 2 V. At 0.1 wt. % of *M*WNT, the composite device emission current was increased up to two orders of magnitude than the PBO diodes without *M*WNT. Further increase of *M*WNT caused a successive decrease in electroluminescence emission intensity attributed to a quench effect form aggregation of *M*WNTs.

**Q1 84 Layer Effects of Photovoltaic Heterojunction of Fully Conjugated Heterocyclic Aromatic Rigid-rod Polymer Poly-*p*-phenylenebenzobisoxazole** JEN WEI HUANG, SHIH JUNG BAI, *National Sun Yat-Sen University* Poly-*p*-phenylenebenzobisoxazole (PBO) contains fully conjugated rod like backbone entailing excellent optoelectronic properties and superior stabilities. Polystyrenesulfonate: poly(2,3−dihydrothieno−1,4−itdioxin) (PEDOT:PSS) is a hole transferring medium which could be spun in to a thin-film between indium-tin-oxide (ITO) and PBO to exhibit highly sensitive photovoltaic (PV) effect. PEDOT: PSS and PBO for medadonor-acceptor interlayer and made photoinduced charge transfer. Optimal absorption PV cell thickness for PBO was about 71nm. By using a layer of lithium fluoride (LiF) as an electron transferring layer, the most open circuit voltage (Voc) and short circuit current (Isc) were achieved at a LiF thickness of 1 nm. The Voc increased from 0.7 V to 0.9 V and the Isc increased one and half times.

**Q1 85 Induced Interaction between Polypyrrole and $SO_2$ via Molecular Sieve 13X** BOONCHOY SOONTORNWORAJIT, ANUVAT SIRIVAT, *PPC, Chulalongkorn University* Electrical conductivity sensitivity and interaction mechanisms between polypyrrole(Ppy)/molecular sieve 13X composites and $CO_2$, CO, and $SO_2$ were investigated. Polypyrrole was synthesized and composites were fabricated from dry mixing and dispersing zeolite particles into the Ppy matrix particles, and followed by compressing into a pellet form. Effects of zeolite concentration, cation type, and cation concentration were investigated. The electrical conductivity in air of Ppy doped with naphthalene-2-sulfonic acid($\beta$) sodium salt increased monotonically with the doping level. There were negligible negative electrical conductivity responses of Ppy and its composites when exposed to $CO_2$, and CO in contrast to definite positive responses towards $SO_2$ in which the interaction was irreversible. Undoped Ppy and doped Ppy composites at 10% v/v of zeolite13X content possessed the highest sensitivity to $SO_2$; beyond this volume fraction the sensitivity was reduced with increasing molecular sieve 13X content. The composites of unmodified 13X, with $Na^+$ fully present within its cavity, gave the greatest electrical conductivity sensitivity towards $SO_2$. The sensitivity of Ppy/13X composite to $SO_2$ diminished when the cation $Na^+$ was exchanged to other alkali cations in this decreasing order: $Cs^+$, $K^+$, and $Li^+$.

**Q1 86 Influence of Green Fluorescent Protein (GFP) Nanoparticles on the Optical and Mechanical Properties of Silk in Bio-Nanocomposites with Photonic Properties** SUREEPORN KOOMBHONGSE, RONALD EBY, *Dept. of Polymer Science, U. of Akron* SHARON JONES, MARK WALKER, RAJESH NAIK, *Air Force Research Laboratory, WPAFB, OH* KATHRYN WAHL, *The Naval Research Laboratory* We are examining the influence of Green Fluorescent Protein (GFP) nanoparticles on optical properties and mechanical properties of silk in bio-nanocomposites membranes. Liquid solutions of GFP have previously been shown to exhibit significant intrinsic two-photon absorption, coupled with fluorescent emission in the visible. The nonlinear absorption and emission of GFP have been shown to saturate at high pump intensities, and upconverted lasing of a GFP-doped polymer film has previously been demonstrated. The observed saturation intensity increases cubically with increasing GFP concentration, suggesting that better access to the intrinsic nonlinearity might be possible at higher concentrations than are possible in liquid solution. Silk and GFP solutions were mixed and cast at different concentration. The nonlinear optical properties of these membranes were examined by two-photon absorption measurements using near-infrared femtosecond pulses. Transmission and upconverted fluorescence of focused near-infrared pulses (780nm, 160fs pulsewidth) is being investigated.

**Q1 87 Fluctuations and Phase Transition-Like Phenomena of a Filled Elastomer Under Deformation** XIAORONG WANG, MINDAUGAS RACKAITIS, *Bridgestone CRT* Fluctuations, critical phenomena and phase transitions have drawn much attention for many years. But, no report anticipates that an elastomer containing fillers under gentle deformations will show similar effects. In this presentation, we show that a filled rubber system under about 2% strain may display feature fluctuations that could be associated with a transition from an elastic solid state to a dispersed fluid state and that is reminiscent of critical phenomena.

**Q1 88 Controlling the interaction between two rolling microcapsules on elastic substrates** ANNA BALAZS, ALEXANDER ALEXEEV, ROLF VERBERG, *Chemical Engineering Department, University of Pittsburgh, Pittsburgh, PA* We study the interaction between two rolling capsules, which model polymeric microcapsules or blood cells. Each capsule consists of an elastic shell that is filled with a viscous fluid. The capsules are driven by an imposed flow to roll along a compliant substrate. To model this multi-component system, we combine the lattice Boltzmann model for fluid dynamics and the lattice spring model for the micromechanics of elastic solids. This technique allows for a dynamic interaction between moving, elastic walls and the surrounding fluid. We determine how the mechanical properties of the substrate and the capsules, and the characteristics of the imposed flow, affect the dynamic behavior of two closely placed capsules. We find that the stiffness of the capsules and the substrate affects the relative motion of the capsules on the surface, i.e., by tuning the mechanical properties, the separation between the capsules can be increased or decreased as they move along the surface. The results provide guidelines for designing micro-reactors that utilize elastic capsules to transport reagents and carry out reactions.

**Q1 89 Tunable Nanoparticle Arrays by Immobilizing Nanoparticles on Polymer Single Crystal Surface*** BING LI, CHRISTOPHER LI, *The Department of Materials Science and Engineering, Drexel University* 2-Dimensional nanoparticle (NP) array has been extensively investigated and a number of techniques are available for fabricating this unique structure. One remaining technical challenge is controlling the inter-particle spacing, which could directly leads to numerous applications. We herein report a novel means to achieve tunable NP arrays by immobilizing AuNPs on polymer single crystal surface. The single crystals of thiol-terminated polyethylene oxide (PEO) were incubated in a monodisperse gold sol. Strong Au-S chemical bonds were formed between the AuNPs and the PEO single crystal surfaces. The inter-particle spacing was controlled by the crystallization temperatures, thus the thickness of the PEO single crystals, the incubation time, and the annealing temperatures after incubation. This research might lead to a novel method to fabricate NP arrays with controlled inter-particle distance from a few nanometers to $\sim$ 100 nm distances.

*This work is supported by NSF Career Award and 3M nontenured faculty grants

**Q1 90 Assessment of structure, dynamics, and stability of HPC microgel nanoparticles in good and poor solvents** KIRIL STRELETZKY, *Cleveland State University* JOHN McKENNA, *Cleveland State University* JERRY HILLIER, *Cleveland State University* RAMI MOHIEDDINE, *Case Western Reserve University* Microgel nanoparticles formed in aqueous solutions of neutral polymer hydroxypropylcellulose (HPC) is a promising drug carrier system due to their ability to solubilize hydrophobic drugs and to serve as vesicles for controlled drug delivery and release. Microgel was synthesized through self-association of amphiphilic HPC molecules at room temperature by lowering polymer phase-transition with salt addition and consequent cross-linking and dialysis. Dynamic Light Scattering and Optical Probe Diffusion techniques were used to study structure and dynamics of microgel of different polymer composition in good and poor solvents. We found the size distribution of microgel to be broad and multimodal in good solvents and narrow and unimodal in poor solvents, indicating shrinking of the nanoparticles. We present comparative analysis of microgel and HPC chain dynamics in good solvents and near good-poor solvent transition. The comparison with polymer transport properties gives important insights into the structure, dynamics, and, potentially, drug delivery capabilities of HPC microgel.

**Q1 91 Optical Effects on Laser Ablated Polymer Surfaces** R.D. PRABHU, R. GOVINTHASAMY, N.S. MURTHY, Laser ablation of poly (ethylene terephthalate) and polyimide films were investigated using Excimer-UV laser. SEM analyses indicate the presence of rings for a wide range of ablation parameters (fluence, frequency and number of pulses). It is proposed that the particles present in the plasma plume could cause the incident laser light to diffract, similar to the optical effects observed in the femtosecond laser ablation of solids. The polymer surface provides a perfect medium to register the optical signatures as seen in the SEM images. The fringe-spacings observed in the images are compared with the theoretical diffraction patterns and the height of the plasma particles above the surface is estimated using an optimization scheme. The results of the analysis are consistent with experimentally observed dynamics of the plasma plume. It is proposed that such optical effects could be a routine feature in the laser ablation of polymers. The significance of such artifacts for lithography is discussed.

**Q1 92 Lessons from Biology: How Patterns Control Adhesion** EDWIN CHAN, ALFRED CROSBY, TINA THOMAS, *University of Massachusetts* Polymer adhesion impacts applications from biomedical devices to semiconductor processing, yet our fundamental control of this property remains a challenge. Nature has shown us through numerous examples (e.g. gecko to lotus leaf) that a powerful strategy for tuning adhesion lies in the development of hierarchal structures at an interface. Although nature has demonstrated this solution, our understanding on using this approach effectively is relatively unexplored. In this work, we seek to understand the inter-relationship between material structure, patterns, and performance (i.e. adhesion) for soft, polymer materials. We present an overview of the importance of length scales in adhesion, our overall strategy, and results on the adhesion of soft elastomers to inorganic surfaces. Through these results, we explain critical scaling relationships that demonstrate the potential for using patterns to tune adhesion, while also illustrating the wide range of mechanisms through which patterns can interact with a polymer interface.

**Q1 93 Elastomer Friction: Understanding Schallamach Waves.** CHARLES RAND, ALFRED CROSBY, *University of Massachusetts, Department of Polymer Science and Engineering* From the dynamics of biomaterial interfaces to the interpretation of nanoscale characterization of polymer interfaces, the friction of soft polymer layers is critical to a wide range of advanced materials. In 1971, Schallamach discovered that friction of soft, elastomeric interfaces is often dominated by the onset and propagation of elastic instabilities in the form of surface waves[1]. Although significant contributions have been made, the fundamental relationship between the polymer structure and Schallamach waves has not been established. We present our results on the development and propagation of Schallamach waves at model, soft interfaces using a custom-built instrument. Our goal is to decouple the interfacial and bulk contributions to the onset and propagation of

these friction-dominating waves. Using interfaces of polydimethylsiloxane and fused silica, we observe critical transitions in the behavior of Schallamach waves and develop qualitative models to link these transitions to interfacial properties. (1)Schallamach, A.;Wear 1971,17, 301-312.

**Q1 94 On Fundamentals of Filler Reinforcement: an Investigation Using Polymeric Nanoparticles** XIAORONG WANG, *Bridgestone Americas, Center for Research & Technology* We investigate the filler reinforcing mechanisms and the interactions using polymer-grafted nanoparticles [1,2] of various brush lengths and densities in polymer matrices of various molecular weights. We find that the modulus enhancement and its nonlinearity vary and depend on the distance of the system approaching the critical state, and that simple laws of corresponding state could describe the phenomena. [1]. Chem. Phys, 2004, 16, 121.; ACS Proceedings: PMSE, March, 2006. [1]. USP6437050; 6689469; 6872785; 6875818; 6956084.

**Q1 95 AFM-TEM observations of effect of ''melt'' time on polytetrafluoroethylene morphology.*** J.P. KALISH, R.A. WILLIAMS, J. WANG, P.H. GEIL, *University of Illinois* T.-C. LONG, P. XU, *W. L. Gore & Assocs., Inc.* TEM observations of PTFE dispersion particles dispersed on glass and held at 350 [r]C or above for various times indicates that individual, $>$ 0.1 mm long molecules wander individually on the substrate and can, with time in the ''melt,'' aggregate and form either flat-on or on-edge, folded chain single crystals. If ''trapped'' by cooling before aggregation, on-edge, single molecule, single crystals can form. All on-edge crystals, both individually and as the shish of shish-kebabs, have a ''double-striation'' appearance, suggested to arise from nucleation of the Pt/C shadowing material, used for the TEM image, on the folds at the top edge of the crystals.[1] AFM observations have confirmed these suggestions and, furthermore, indicate the nascent, rod-like dispersion particles of a ''nano-emulsion,'' with a volume corresponding to a single molecule, have faceted ends. Combined with the TEM and ED observations that the molecular axis is parallel with the rod axis, not only must chain-folding occur during polymerization but the chain folds must be staggered on the end surfaces.

*This research was supported, in part, by the NSF Polymer Program. The TEM and AFM facilities used were supported, in part, by DOE through Grant DEFG02-91-ER45439.

**Q1 96 Depth Profiling of $^{13}$C Labeled Polymers using Secondary Ion Mass Spectrometry** SHANE HARTON, FRED STEVIE, HARALD ADE, *NC State University* Deuterium labeling is known to change the thermodynamic properties of polymers and polymer blends (e.g. surface tension and bulk phase behavior). Anomalous segregation of dPS to an hPS:dPS/hPMMA interface has been recently observed, where the hPS:dPS blend is well within the single phase region of the phase diagram. Therefore, to probe various physical phenomena at polymer interfaces, such as chain mobility or reactive chain coupling, alternative labels must be established in order to provide a true tracer. It has been found that $^{13}$C labeling provides a true tracer for depth profiling of $^{13}$C-PS in $^{13}$C-PS:hPS and $^{13}$C-PS:hPS/hPMMA blends, with no observable segregation of $^{13}$C-PS to the $^{13}$C-PS:hPS surface or $^{13}$C-PS:hPS/hPMMA heterogeneous interface (Harton et al. Patent Pending). $^{13}$C-PS was synthesized with $\alpha$, $\beta$ $-$ $^{13}$C substituted styrene (33% v/v with 77% unlabeled styrene) using atom transfer radical polymerization with a low polydispersity ($M_w/M_n$ = 1.2). A magnetic sector instrument was used for this analysis to separate $^{13}$C from $^{12}$C$^1$H. This requires a mass resolution ($m/\Delta m$) of $\sim$ 3000, which cannot be achieved with a quadrupole (typical $m/\Delta m \sim$ 300) thereby eliminating its use for depth profiling of $^{13}$C labeled polymers. Mass spectra of labeled and unlabeled PS were also analyzed using time-of-flight (ToF) SIMS to demonstrate the possibility for detection of high molecular weight fragments as a function of depth.

**Q1 97 Solvent mediated assembly of Nanoparticles confined in Mesoporous Alumina*** KYLE ALVINE, DIEGO PONTONI, PETER PERSHAN, *Harvard University* OLEG SHPYRKO, *Center for Nanoscale Materials, ANL* DAVID COOKSON, *Australian Nuclear Science and Technology Organization* KYUSOON SHIN, THOMAS RUSSELL, *University of Massachusetts, Amherst* FRANCESCO STELLACCI, *Massachusetts Institute of Technology* OLEG GANG, *Center for Functional Nanomaterials, BNL* In-situ small angle x-ray scattering measurements of the solvent mediated assembly of 2 nm diameter Au-core colloidal nanoparticles inside mesoporous alumina are presented. The evolution of the self-assembly process was controlled reversibly via solvent condensed from vapor. Measurements of the absorption & desorption of solvent showed strong hysteresis upon thermal cycling. In addition, the capillary transition for the solvent in the nanoparticle-doped pores was shifted to greater under-saturation by a factor of four relative to the expected value for the same system sans nanoparticles. Analysis indicated that a cylindrical shell super-structure of the nanoparticles is maintained throughout the addition and removal of liquid solvent. Nanoparticle nearest-neighbor separation increased and the in-shell order decreased with the addition of solvent. The process was reversible with the removal of liquid. Isotropic clusters of nanoparticles were also observed to form temporarily during desorption of the liquid solvent and disappear upon complete removal of liquid.

*This work was supported in part by NSF Grant No. 03-03916

**Q1 98 APPLICATIONS POSTER SESSION**

**Q1 99 Beam propagation through a thermo-optic waveguide switch** CHANGBAO MA, EDWARD VAN KEUREN, *Georgetown University, Department of Physics* We present simulations and experiments of a thermo-optic waveguide switch using a novel 3-d wide angle beam propagation algorithm. The switch is based on a Y-branch directional coupler, with two microheaters embedded beneath both sides of the Y-branch. These two microheaters act to generate an inhomogeneous temperature profile, by which most of the energy of the light signal propagating in the waveguide will be shifted to one of the two branches. The oblique sections of the waveguides require that the second order terms in the beam propagation method be included in the simulation. Both the thermo-optic effects and beam propagation will be investigated to optimize the parameters of the device.

**Q1 100 Semiconductor lasers in optical communication band with very broadband tunability** GAGIK SHMAVONYAN, *State Engineering University of Armenia* Because the optical fiber has the low-loss window covering from below 1300 nm to above 1600 nm, devices used for optical communication are required to have the broadband characteristics. Several types of non-identical multiple quantum wells had been experimented. One has five 6 nm $In_{0.67}Ga_{0.33}As_{0.72}P_{0.28}$ quantum wells and two 15 nm $In_{0.53}Ga_{0.47}As$ quantum wells, bounded by 15 nm $In_{0.86}Ga_{0.14}As_{0.3}P_{0.7}$ quantum barrier. One type of the non-identical multiple quantum wells has been used to fabricate the semiconductor optical amplifiers for semiconductor lasers with broadband tunability. Inserting the semiconductor optical amplifier in an external-cavity configuration with a grating as the feedback, the external-cavity semiconductor laser is tunable from 1295 nm to 1570 nm, which covers almost the entire low-loss window of the optical fiber. Also, using reflected-type grating telescope configuration, we are able to simultaneously generate two wavelengths. The two lasing wavelengths are tunable from a few nm separation to 170 nm separation. Simultaneous generation of two wavelengths at 1344 nm and 1514 nm in optical communication band is demonstrated.

**Q1 101 Near Field Measurement of Broad Area Laser Diodes by Utilizing Near-Field Scanning Microscope** SOON IL JEONG, JOO IN LEE, *Korea Research Institute of Standards and Science* IL KI HAN, YOUNGCHAI YOO, KYOUNG CHAN KIM, JIN DONG SONG, WON JUN CHOI, WON JO CHO, JUNG IL LEE, *Korea Institute of Science and Technology* SI HYUNG CHO, *Potomac Optronics* MARIO DAGENAIS, *University of Maryland* NANOSURFACE GROUP TEAM, NANO DEVICE RESEARCH CENTER TEAM, POTOMAC OPTRONICS COLLABORATION, ELECTRICAL & COMPUTER ENGINEERING TEAM, It is well known that the filamentation in the broad area laser diodes (BALD) is closely related to the linewidth enhancement factor ($\alpha$-value). While normal $\alpha$ values in the multiple-quantum well (MQW) structure are 2$\sim$ 4, it is expected and calculated that $\alpha$ values in quantum dot (QD) are under 1. This means that the filamentation in the BALD with QD structure would be delayed until higher current level. In this study, we report the difference of near field between QD and QW BALDs by utilizing near-field scanning optical microscope (NSOM). $\alpha$ value in the QD BALD was measured to be around 0.6, while in the QW around 2. It was observed that the BALD with QD kept single mode beam under higher current level than the BALD with QW. This result shows another evidence that QD structure might be more adequate for high power laser diodes with single mode beam characteristics.

**Q1 102 Niobium Hot Electron Bolometer Development for Terahertz Detection*** MATTHEW REESE, *Yale. Univ.* DANIEL SANTAVICCA, *Yale Univ.* LUIGI FRUNZIO, *Yale Univ.* DANIEL PROBER, *Yale Univ.* We have developed both diffusion and phonon cooled Hot Electron Bolometers (HEBs) for detecting weak signals in the submillimeter or terahertz range. The device consists of a superconducting microbridge between two non-superconducting reservoirs. We use niobium as our superconductor and aluminum as our normal metal. The goal of the research is to produce very fast (100 MHz) direct detectors for spectroscopic use, and high bandwidth mixers. We will report the performance as both heterodyne and direct detectors. The microscopic properties of the devices, including the effects of the superconducting proximity effect have also been studied.

*Research Support by NSF-AST and NASA GSRP

**Q1 103 A Magneto-Electric Microwave Filter** A.S. TATARENKO, G. SRINIVASAN, *Oakland University* M.I. BICHURIN, *Novgorod State University, Russia* A new class of electric field-tunable ferrite-ferroelectric microwave band-pass filter is discussed. The electric field tunability is possible through magneto-electric (ME) interactions. The mechanical deformation due to piezoelectric effect in an electric field manifests as a magnetic field shift in the ferromagnetic resonance (FMR) for the ferrite. The filter was fabricated with an ME resonator consisting of bi-layers of 30-110 micron thick (111) yttrium iron garnet (YIG) films and lead zirconate titanate (PZT). The bilayer was positioned between input and output antenna in a microstripline structure. The device insertion loss was measured as a function of frequency f, bias magnetic field *H* (applied parallel to bilayer plane) and the electrical field *E* applied across PZT. The minimum insertion loss was 4-5 dB at 5-10 GHz. The off-resonance losses were about 20 dB. The E-field tunability was 120 MHz for E = 3 kV/cm for bilayers with 110 micron thick YIG. The ME microwave filters discussed here are miniature in size, would facilitate high-speed operation, and are compatibility with integrated circuit technology. – The work was supported by grants from ARO, ONR and NSF.

**Q1 104 A method for anhysteretic magnetization and magnetostriction measurement of a thin ferromagnetic films as a function of an applied isotropic stresses** PETER FINKEL, *Thomson/Rowan University* ED GARRITY, *Thomson* A new method of the stress dependant anhysteretic magnetization and magnetostriction measurements in a thin-film ferromagnetic materials is described. This method is based on conventional vibrating sample magnetometer system combined with the specially designed loading fixture providing sizable uniaxial stresses on thin film and wires. For determining uniaxial stresses in thin-film and wires anisotropic ferromagnetic samples contactless method was developed. Stresses are deduced from characteristic resonant frequency of the sample vibrating in the special fixture and verified using pulse propagation velocity monitoring. Vibration of the sample is measured remotely using a laser Doppler vibrometer. This contactless method has been demonstrated for membrane thickness down to 50 $\mu$m and stresses up to 1GPa. Estimated accuracy of this method is better than 0.2%. This method was applied to measure anhysteretic permeability and magnetization curve of Ni-Fe as a function of stress and temperature. This technique was also shown to be able also used to measure magnetostriction coefficient as a function of external magnetic field.

**Q1 105 Characterization of Binding Strengths of DNA on Various Indium Tin Oxide Conducting Substrates Using Surface Electrophoresis for Genomic Studies/Applications** MICHAEL DING, *Glen Cove High School* ELI HOORY, JONATHAN SOKOLOV, MIRIAM RAFAILOVICH, *Stony Brook University* STONY BROOK UNIVERSITY TEAM, We have analyzed DNA-surface interactions on solid surfaces using surface electrophoresis with λ Hind-III DNA. Laser scanning fluorescence microscopy on YOYO-labeled DNA was used to image molecules exiting deposited drops for different surfaces, buffer concentrations, DNA concentrations, and electric field

strengths. PET Indium Tin Oxide (ITO) and ITO coated glass were studied by varying TBE buffer concentrations from $10^{-2}$X to 3X, DNA concentrations from 5$\mu$g/ml to 50$\mu$g/ml and electric fields from 3 to 7 V/cm. We have obtained defined circular DNA droplets on these surfaces and observed DNA strands being pulled from the outer ring by the electric field. Various adsorption mechanisms and models of mobility will be discussed. Support from the NSF MRSEC program is gratefully acknowledged.

**Q1 106 Shift of Optical Absorbance with Pressure in Star Polymers** JOHN FERGUSON, *AF Research Laboratory, Materials and Manufacturing Directorate, WPAFB, OH 45433* BARRY LONG,* *Physics Dept., Juniata College, Huntingdon, PA 16652* The optical absorbance dependence on pressure is studied for star polymers dispersed (less than 1% wt./wt.) in either polymethylmethacrylate or polycarbonate. The star polymer is composed of a hyperbranched core and $\pi$-conjugated polymer arms. The optical absorbance red shifts with increasing pressure and is expected to be due to increase in the conjugation length. The sensitivity on pressure is greater with the star polymers than for a pure linear polymer of the conjugated arm. The proposed enhancement mechanism is a non-uniform distribution of strain in analogy with the impact toughening of a matrix material by multidimensional additives.

*Work performed under Wright State Univ. REU Program

**Q1 107 Novel biocompatible and biodegradable ultrathin films of poly (L-Lactic acid) by plasma polymerization** YI-HSIN CHANG, CHUN-CHIH CHANG, YING-CHU CHEN, A. C.-M. YANG, *Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan* Y. C. LIU, *Department of Life Science, National Tsing Hua University, Hsinchu, Taiwan* Ultra-thin films ( $\leqslant$ 50 nm) of biodegradable poly (L-lactic acid) were prepared through efficient RF plasma synthesis. The surface morphology of deposited films was amorphous and molecularly uniform (Ra = 0.7 nm). The chemical compositions as determined from FTIR and NMR demonstrated extraordinarily high retention of ester groups with a small fraction of chain cross-linking that could be controlled by process parameters. The chemical routes of the polymerization were described and discussed. This versatile thin film coating technique is very useful for surface engineering of general biomedical devices and implants for improved biocompatibility. In addition, PLLA polymerized in the liquid phase by plasma was also explored and will be presented. This work is supported by National Science Council of Taiwan.

**Q1 108 Terawatt picosecond $CO_2$ laser** DANIIL STOLYAROV, IGOR POGORELSKY, IGOR PAVLISHIN, MARCUS BABZIEN, KARL KUSCHE, *Brookhaven National Lab* V. PLATONENKO, *Moscow University* VITALY YAKIMENKO, *Brookhaven National Lab* We present the design of a powerful $CO_2$ laser that generates short 3 ps pulses with energy exceeding 10 J/pulse. The output of a conventional 1 atm TEA oscillator undergoes pulse shortening via a semiconductor switching method in combination with nonlinear Kerr cell. Pressure broadening of $CO_2$rotational line in the 10 atm regenerative amplifier and the 9 atm final amplifier allows amplification of the short pulse up to several terawatts in peak power without pulse distortion. Present applications of the terawatt $CO_2$laser include various methods of laser acceleration of relativistic electron beams, generation of high-intensity X-rays via Thomson scattering, ion acceleration, etc.

**Q1 109 Synthesis and thermoelectric properties of $Na_xCoO_2$ single crystal*** QING JIE, YUFENG HU, QIANG LI, *Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory* $Na_xCoO_2$ has been known to be a potential thermoelectric material because of its large thermoelectric power and low resistivity. Recently, $Na_xCoO_2 \cdot yH_2O$ was discovered as a superconductor with a transition temperature $T_c$ of about 5K. Further understanding of the electron structure and properties of this material need larger samples of $Na_xCoO_2$single crystal. In our work, $Na_xCoO_2$ single crystals were grown by flux method. It was found that choosing an appropriate slow cooling temperature region can increase the size of the single crystals grown by this method. The size of the largest single crystal is about $5\times 4 \times 0.02mm^3$. The structure and thermoelectric properties of these crystals will be discussed.

*This work was supported by the U. S. Dept. of Energy, Office of Basic Energy Science, under contract No. DE-AC-02-98CH10886.

**Q1 110 Excitation of surface dipole and solenoidal modes on toroidal structures** MARK JACK, MARIO ENCINOSA, *Florida A&M University* The time-dependent Schrodinger equation inclusive of curvature effects is developed for a spinless electron constrained to motion on a toroidal surface and subjected to circularly and linearly polarized waves in the microwave regime. A seven-state basis set is employed with the goal of determining the character of the surface currents as the system is driven at a resonance frequency that selects for a solenoidal mode. Trajectory methods are used as a means of visualizing the character of the induced surface currents. Optical transitions into solenoidal modes of excitation can be observed.

**Q1 111 Magnetically Modulated Optical Nanoprobes: Live Cells and Bioassay Diagnostics** BRANDON H. McNAUGHTON, JEFFREY N. ANKER, RAOUL KOPELMAN, *University of Michigan, Applied Physics Program; University of Michigan, Chemistry* CALEB J. BEHREND TEAM, KAREN KEHBEIN TEAM, XIAOJING WANG TEAM, Fluorescent techniques are frequently used for chemical analysis in biological samples because fluorescent dyes produce strong signals that can be easily read with conventional photodetectors, spectrometers, and cameras. Magnetic techniques are used for chemical analysis and measurements of physical viscosity/elasticity because strong magnetic forces and torques are easily applied to magnetic particles without shielding or interference from biological samples. Combining fluorescence detection with magnetic manipulation of metal hemisphere coated ''Magnetically Modulated Optical Nanoprobes'' (MagMOONs) provides the best features of both techniques. We describe fabrication of uniform magnetic half-coated particles and MagMOON applications for immunoassays, intracellular chemical sensing, and passive or active viscosity measurements on a single particle and ensemble level that is based, in part, on a newly discovered effect: critical slipping of rotationally driven nanoparticles.

**Q1 112 Phonon engineering of electronic transport in hybrid nanotubes** ALEXANDER A. BALANDIN, VLADIMIR A. FONOBEROV, *Nano-Device Laboratory (http://ndl.ee.ucr.edu), Dept. of Electrical Engineering, University of California, River-*

*side, CA 92521* Recently, a number of biological nanoscale objects, including tobacco mosaic viruses (TMV), have been employed as templates for assembly of inorganic nanostructures. This approach can potentially lead to a new method of fabrication of nanoelectronic circuits beyond conventional CMOS. Here we theoretically demonstrate that in addition to their role as nanotemplates [1], the elastically soft TMVs can improve electron transport in the nanotubes grown on them [2]. In the simulated hybrid nanostructures, which consist of silicon or silica nanotubes on TMVs, the confined acoustic phonons are found to be redistributed between the nanotube shell and the acoustically soft virus enclosure. As a result, the low-temperature electron mobility in the hybrid TMV-silicon nanotube can increase up to a factor of four compared to that of an empty silicon nanotube [2]. Our estimates also indicate an enhancement of the low-temperature thermal conductivity in the TMV-silicon nanotube, which can lead to improvements in heat removal from the hybrid nanostructure-based circuits. The authors acknowledge the support of MARCO and its Functional Engineered Nano Architectonics (FENA) Focus Center. [1] W.L. Liu, K. Alim, A.A. Balandin et al., Appl. Phys. Lett. 86, 253108 (2005); [2] V.A. Fonoberov and A.A. Balandin, Nano Lett. 5, 1920 (2005).

**Q1 113 Nanoscale Silicon Particles in Sandwich Structures Fabricated on Silica Wafers: HRTEM and EDX Techniques as Imaging Tools** PAVAN SINGARAJU, KRISTINA E. LIPINSKA-KALITA, *Department of Electrical and Computer Engineering, University of Nevada Las Vegas* THOMAS HARTMANN, LONGZHOU MA, *Harry Reid Center for Environmental Studies, University of Nevada Las Vegas* BISWAJIT DAS, *Department of Electrical and Computer Engineering, University of Nevada Las Vegas* The use of silicon in optical applications is limited by its small and indirect band gap. However, recent observations of photoluminescence in porous Si and in Si ultra fine particles suggest that Si nanoclusters may become a promising material for optical applications. The nanometric Si clusters have a band gap enlarged into the visible range and quantum confinement effect is believed to be the mechanism for light emission. The ability to control the size and structure of nanoparticles would allow the fabrication of structures with desired electrical and optoelectronic properties for device applications. Nanosized Si particles with controlled diameter were fabricated on silica substrate wafers using an specially designed ultra-high vacuum nanocluster deposition apparatus. We present the structural characterization and composition studies of the fabricated nanostructures using high resolution transmission electron microcopy (HRTEM), x-ray diffraction (XRD) and energy dispersive x-ray (EDX).

**Q1 114 Hydrogen uptake in single-walled carbon nanotubes synthesized by the hydrogen arc plasma jet method.** L.A. MORENO-RUIZ, J. ORTIZ-LOPEZ, *Escuela Superior de Fisica y Matematicas, Mexico* A. DE ITA DE LA TORRE, J.S. ARELLANO-PERAZA, G. FLORES-DÍAZ, *UAM-Azcapotzalco, Mexico* Carbon nanotubes were synthesized by a modified electric arc discharge method under hydrogen atmosphere using a catalytic mixture of powders with composition C/Ni/Co/Fe/FeS. The samples were characterized with transmission and scanning electron microscopy, Raman spectroscopy and thermo-gravimetric analysis. Unpurified samples contain 20 wt% of carbon nanotubes, 2 wt% of other forms of carbon and 78 wt% of catalytic metals. Adsorption/desorption of hydrogen in unpurified samples at atmospheric pressure measured with gravimetric methods was of the order of 2 wt%. Samples for these measurements were prepared with a three-step treatment: (i) oxidation in air for 30 min at 500 °C, (ii) ball- milling for 1 hr, and (iii) second oxidation in air for 30 min at 500 °C. This treatment was applied to eliminate other forms of carbon as well as to shorten the tubes and open their caps. Hydrogen desorption was also measured in degassed samples (400 °C for 20 min in vacuum) which adsorbed $H_2$ while cooling to room temperature. Desorption in degassed/hydrogenated samples is a two-step process which we attribute to distinct desorption characteristics of nanotubes and of residual oxidized metal catalysts.

**Q1 115 Theoretical investigation of catalysed MgH2** PETER LARSSON, C. MOYSES ARAUJO, *Condensed Matter Theory Group, Physics Department, Uppsala University, Box 530, 751 21, Uppsala, Sweden* J. ANDREAS LARSSON, *Tyndall National Institute, Lee Maltings, Prospect Row, Cork, Ireland* PURU JENA, *Department of Physics, Virginia Commonwealth University, Richmond, Virginia 23284-2000* RAJEEV AHUJA, *Condensed Matter Theory Group, Physics Department, Uppsala University, Box 530, 751 21, Uppsala, Sweden* MgH2 has attracted much attention for being a good hydrogen storage material due to its light weight, low manufacturing cost and high storage capacity (7.6 wt%). But its slow absorption/desorption kinetics and high dissociation temperature (nearly 300[r]C) limit its practical applications for hydrogen storage. To overcome this, much effort has been paid mainly by making nanocrystalline Mg and/or by adding alloying elements. In this work, we provide a theoretical investigation of the electronic and structural properties of pure and M-doped MgH2 (with M=Sc, Ti, V, Fe, Ni, Al). We have made calculations for both the crystalline state and 1.0 nm particles. The self-consistent total energy calculations are performed within density functional theory using the VASP package for crystals and TURBOMOLE package for clusters. One aim of this study is to see if the alloying elements can weaken the Mg-H bonds, resulting in improved thermodynamics and faster kinetics. Another one is to understand the differences in the thermodynamics of clusters and crystals.

**Q1 116 Fabrication and Structural Studies of Nanostructured Alumina Templates Using X-Ray Diffraction and EDX Techniques** KRISTINA E. LIPINSKA-KALITA, PAVAN SINGARAJU, BISWAJIT DAS, *Department of Electrical and Computer Engineering, University of Nevada Las Vegas* We have previously developed a thin film template based nanostructure fabrication technique that is applicable for the development of high performance photonic devices. The template is created by the anodization of thin film aluminum deposited on an arbitrary substrate and contains nanoscale pores inside which a nanoscale material could be synthesized. An alumina template is characterized as a nonstoichiometric, amorphous film that is optically transparent over a wide spectral range and is also electrically insulating, which makes it a perfect embedding material for nanoscale devices. We investigated the formation of thin film alumina templates on various substrates, under different fabrication conditions. The final template structure was found to depend on the structure of the starting aluminum film (free standing or deposited on another substrate). We show that pre-anodization annealing of the substrate can dramatically alter the stoichiometry as well as the microstructure of the final template, changing it from amorphous to nanocrystalline.

**Q1 117 The adsorption and photo-degradation of oxalic acid at the $TiO_2$ surface.** CECILIA MENDIVE, *Universitaet Hannover, Germany* MIGUEL BLESA, *CNEA, Argentina* DETLEF BAHNEMANN, *Universitaet Hannover, Germany* Oxalic acid is the simplest model compound to study the heterogeneous photocatalytic oxidation of pollutants on $TiO_2$ containing more than one carboxylate group. We have carried out a study of a system of an oxalic acid solution in contact with a thin film of $TiO_2$ particles employing ATR - FTIR in combination with quantum chemical calculations. Thus, possible adsorption structures have been identified and molecular dynamic simulations have been used to compare their predictions with the experimental data. It was found that the adsorption of oxalic acid on $TiO_2$ in the dark can be explained in terms of two surface complexation modes for the anatase phase and only one surface complexation mode for the rutile phase. We have found that under illumination one of the complexes on the anatase phase preferably undergoes photo-degradation. At the same time water molecules are desorbed from the $TiO_2$ surface by a thermal mechanism induced by the absorption of photons. Both processes favor the adsorption of more molecules of oxalic acid at the $TiO_2$ surface which is thus enriched in the second complexation mode. A similar mechanism was found to occur on the rutile phase. The only complexation mode appears not to be photosensitive but the $TiO_2$ surface is enriched in oxalic acid under illumination due to the replacement of photo-desorbed water molecules.

**Q1 118 Infrared photodetector based on modulation-doped quantum-dot structures*** NIZAMI VAGIDOV, *University at Buffalo* ANDREI SERGEEV, *University at Buffalo* VLADIMIR MITIN, *University at Buffalo* We investigate a device model for the quantum-dot photodetector based on modulation-doped structures (for example, the modulation-doped AlGaAs/GaAS structure with InAs quantum dots). At room temperatures, the electron momentum relaxation is determined by electron- phonon scattering. The electron mean free path is small and the photoelectron capture is conditioned by electron diffusion in the potential relief created by modulation doping. Modeling with diffusion-limited capture is used to evaluate the photodetector performance. The results show that the modulation-doped structures provide longer lifetimes of photoelectrons, which in turn improves the photoconductive gain and sensitivity.

*Supported by NYSTAR

**Q1 119 Nanoscale Metal-molecule contacts** ARTUR ERBE, SIMON VERLEGER, BERND BRIECHLE, *FB Physik, Universitaet Konstanz, Germany* Studies of the influence of the metallic contacts to the electronic transport through single or a few molecules are reported. In order to separate these influences from intrinsic molecular properties we use a number of different, versatile contacting methods. The tested molecules vary from nominally insulating molecules to molecules with conjugated charge systems. It is important that the coupling of the molecules to the electrodes is mechanically and electronically stable throughout the experiment. As a first step two different structures allowing for the change of the mechanical coupling will be analysed to find an optimal configuration. On the one hand a mechanically controllable break-junction (MCB) technique will be studied, on the other a shadow evaporation technique based on a silicon structure will be tested. Transport through the molecules can be investigated at different temperatures. First results indicate that the interplay between the metallic electrodes and the molecules depends strongly on the coupling of the electrodes to the molecules and on the packing of the molecules on the metallic substrates.

**Q1 120 All Electronic Charge Carrier Transit Time Mobility Measurements and Data Analysis in Pentacene Organic Field Effect Transistors** LAWRENCE DUNN, *University of Texas at Austin and IMRE, Singapore* DEBARSHI BASU, LIANG WANG, ANANTH DODABALAPUR, *University of Texas at Austin* In organic field-effect transistors (OFETs), the most common method of estimating mobility is to extract it from the transfer characteristics (*e.g.*, $I_d$-$V_{ds}$ and $I_d$-$V_{dg}$ curves). Time-of-flight measurements via optical excitation of charge carriers in the organic material are also used, but this technique measures the mobility of carriers perpendicular to their motion in the OFET geometry. Additionally, in some polycrystalline organic semiconductors, the optically excited time-of-flight measurements are rendered difficult due to charge trapping. We present an all-electronic time of flight method for measuring the in-plane mobility of charge carriers using an applied voltage pulse to the source of the OFET with a rise time of $<$ 60 ns. The gate of the OFET was grounded and the drain was connected to ground across a small load resistor. The transit time of the charge carriers from the source to the drain was measured by recording the voltage drop across the load resistor using a high-speed oscilloscope. The fabrication of the OFET, extraction of the charge carrier transit time from recorded data and effect of the displacement current over varying temperature and voltage step magnitudes will be discussed.

**Q1 121 Temperature dependent spectroscopy of poly[bis-(2-ethyl) hexylfluorene]/ (9,9-di- *n* -octylfluorene) copolymers*** HYEUNSEOK CHEUN, *University of Wisconsin* MICHAEL WINOKUR, *University of Wisconsin* BENJAMIN NEHLS, *University of Wuppertal* FRANK GALBRECHT, *University of Wuppertal* ULRICH SCHERF, *University of Wuppertal* A series of random polyfluorene (PF8) copolymers comprised of linear di-*n*-octyl (F8) and branched bis(2-ethylhexyl) (F2/6) units has been synthesized and characterized by temperature dependent steady-state absorption and emission spectroscopy. The F2/6 polymer is already well known for forming conformationally disordered five fold helices while the F8 polyfluorene adopts a number of distinct near-planar type conformational isomers. One of these conformational sequences is an unusual low energy absorption and emission band known as the $\beta$ phase. In these copolymers the PF chains must temporize between differing interchain packing motifs, pentagonal and planar type structures, and different main chain morphologies. Increasing the content of F2/6 monomers strongly affects the formation of the $\beta$ phase conformer, enhances the extent of conformational disorder (and the effective electron-phonon coupling strengths) and also alters the bulk structural phase behavior. There are only weak correlations between the overall phase behavior and the observed spectroscopy at temperatures below 100 °C.

*Support through NSF grant DMR-0350383 (M.J.W., H.C) is gratefully acknowledged

**Q1 122 Vapor deposited organic thin films with large third order nonlinearities for integrated nonlinear optics** BWEH ESEMBESON, JOSHUA C. MAY, IVAN BIAGGIO, *Department of Physics and Center for Optical Technologies, Lehigh University* TSUYOSHI MICHINOBU, FRANÇOIS DIEDERICH, *Laboratorium für Organische Chemie, ETH-Hönggerberg* We used vapor deposition in high vacuum to fabricate homogenous organic thin films for third-order nonlinear optics. We used small molecules that have a high third order polarizability, are robust, and can be sublimated without decomposition. The most important example is 1,1,2-tricyano-2-[(4-dimethylaminophenyl)ethynyl]ethene (TDMEE), which has a itspecific third order polarizability one order of magnitude larger than other highly nonlinear molecules. It is a member of a family of donor-substituted cyanoethynylethene molecules that has recently been found to have polarizabilities that approach Kuzyk's fundamental limit.[1] The organic thin films have a high, flat transmission above 1000 nm, a high two-photon absorption near 1200 nm, and an essentially real third order polarizability at 1.5 $\mu$m that is three orders of magnitude larger than fused silica.

[1]J. C. May et al, Opt. Lett. 30, 3057 (2005)

## Q1 123 GENERAL THEORY (THEORETICAL METHODS) POSTER SESSION

**Q1 124 The Relativity of the Photon Mass** SERGEJ REISSIG, *EFBR* In the standard model of the electromagnetic radiation, a photon is mass-less. In [1] it was showed that the puzzling question – whether a photon does or does not have a zero mass – can be however answered. According to the new viewpoint, photons can exist in two states: 1) photons have energy and collide neither with a medium nor with surfaces; 2) photons collide with a medium or a surface. In the first case (1), photons possess latent or potential energy and are invisible. In the second case (2), they are visible Wirkungsquantums according to the Planck's quantum theory. The energy of a photon could in case (1) be determined by Planck's equation $E_P^1 = hf$ and in case (2) by Einstein's formula $E_P^2 = mc^2$. By a collision (Wirkung) between a photon and a medium or surface, an energy transformation takes place: the mass-less and invisible light particle (phantom) with latent energy, is converted into a visible photon, which now possesses an impulse mass and energy. For the case that the photons ''bomb'' a surface, which moves with a velocity $v$ into the same direction as the photons, a new equation for the photon mass has been derived: $m_P = 2.2102186 \cdot 10^{-42} \cdot \lambda^{-1} \cdot [(1 - v/c)/c)(1 + v/c) \times (1 + v/c)]^{0.5}$(kg) 1. Über die Relativität der Masse und Energie des Lichtquanten, S. Reißig, 2005, http://www.efbr.org in /Publikationen.

**Q1 125 Correlation Energy of A Model Problem** MAURICIO CAMPUZANO, VASSILIOS FESSATIDIS, *Fordham University* JAY D. MANCINI, *Kingsborough College of CUNY* SAMUEL P. BOWEN, *Chicago State University* The search for new analytic methods of calculating details of the energy spectrum of strongly interacting systems has long been the vocation of both theoretical chemists and physicists. In particular, the accurate calculation of both the ground-state and correlation energies are important in settling issues relating to the exact nature of the ground-state and low-lying excited states. Furthermore there exist a number of physically relevant systems that cannot be treated by perturbation theory or in which other approximation schemes yield completely erroneous results. Exact diagonalization studies are well known to suffer from size effects, while the neglection of correlations in fluctuations in mean-field theories, although calculationally tractable, leave much to be desired. Here we wish to apply a recently developed Generalized Moments Expansion (GMX) [1] to the problem of $N$ coupled one dimensional harmonic oscillators given by the Hamiltonian: $H = \frac{1}{2}\Sigma_{j=1}^{N}(-d^2/dx_j^2 + \omega^2 x_j^2) + g^2\Sigma_{ij}^{N} x_{ij}$. Comparisons are then made with other methods such as a Lanczos tridiagonalization scheme as well as a Canonical Sequence Method approach. [1] V. Fessatidis, J.D. Mancini, R. Murawski and S.P. Bowen, Phys. Lett. A.

**Q1 126 Zero-Point Energy of the Pullen-Edmonds Hamiltonian** JAY D. MANCINI, *Kingsborough College of CUNY* VASSILIOS FESSATIDIS, MAURICIO CAMPUZANO, *Fordham University* SAMUEL P. BOWEN, *Chicago State University* Here we wish to apply the newly developed Generalized Moments Expansion (GMX) to the well-known potential

$$U = 1/2\,(x^2 + y^2) + \alpha x^2 y^2,$$

which is used to model such molecular systems as formamide and rm$C_2O_3$. Our motivation is to investigate the numerical accuracy as well as the viability of the GMX for evaluating ground-state energies of quantum Hamiltonian systems. The zero-point energy of this potential is calculated and results are compared to an analogous Lanczos (tridiagonal) matrix truncation as well as to a Canonical Sequence Method approach.

**Q1 127 Ground-State Energy of A Two-Level System with Phonon Coupling** WILLIAM J. MASSANO, *SUNY Maritime* VASSILIOS FESSATIDIS, *Fordham University* JAY D. MANCINI, *Kingsborough College of CUNY* SAMUEL P. BOWEN, *Chicago State University* The coupling of a two-level system to a quantized boson mode has been the focus of many researchers for a number of years. Applications to exciton motion, molecular polaron formation, chaos in quantum systems as well as a number of other effects in condensed matter physics have also been studied. Here we investigate the interaction of a single bosonic mode with a two-level fermionic system given by the Hamiltonian

$$H = -\delta_0\sigma_x + \sum_k \hbar\omega_k a_k^\dagger + \sum_k g_k(a_k^\dagger + a_k)\sigma_z.$$

This quantum system is used as a testing ground for a newly developed Generalized Moments Expansion, GMX($m$,$n$), of which the well-known Connected Moments Expansion (CMX) and Alternate Moments Expansion (AMX) are special cases: rmCMX= rmGMX(1,1), rmAMX=GMX(1,2). The convergence and viability of this scheme is discussed and comparisons are made with other methods.

**Q1 128 Locating Regions of Complex Zeros of the Mittag-Leffler Function $E_{\alpha,\beta}(z)$ for $2 < \alpha \leq 3$** JOHN W. HANNEKEN, TRENTON R. ENSLEY, STEPHAN T. SPENCER, B. N. NARAHARI ACHAR, *University of Memphis* The Mittag-Leffler function $E_{\alpha,\beta}(z)$, which is a generalization of the exponential function, arises frequently in the solutions of differential and integral equa-

tions of fractional order. Moreover, the zeros of $E_{\alpha,\beta}(z)$ for some values of $\alpha$ and $\beta$ are the eigenvalues of fractional differential operators. Consequently, knowledge of the zeros and their distribution is of fundamental importance. This work focuses on the distribution of zeros in the region where the Mittag-Leffler function possesses an infinite number of real zeros and a finite number of complex zeros and is restricted to the range $2 < \alpha \leq 3$ and $\beta \leq 14$.

**Q1 129 Dynamics of a Pair of Coupled Fractional Oscillators** NARAHARI ACHAR, TANYA PROZNY, JOHN HANNEKEN, *University of Memphis* The integral equations of motion of a pair of coupled fractional oscillators are obtained by generalizing the equations of motion of a pair of coupled harmonic oscillators to integrals of fractional order. The Greens function dynamic response to sinusoidal forcing is given in terms of Mittag-Leffler functions. A direct and transparent derivation of the results of Ryabov and Puzenko obtained by a tedious perturbation method is presented.

**Q1 130 A Time Dependent Approach for Computing N-N Phase Shifts and Cross Sections** BRIAN DAVIS, DAVID WEEKS, *Air Force Institute of Technology* Scattering matrix elements for n-n, n-p, and p-p collisions are computed using a new time dependent wave packet technique. Using this approach, reactant and product channel packets are prepared in the asymptotic limit on the N-N potential energy surfaces. For these calculations we are using the Argonne v18 potential package (1). The channel packets are propagated in time using the split operator method together with a unitary transformation that diagonalizes the tensor potential. Scattering matrix elements are computed from the Fourier transform of the correlation function between the evolving channel packets. Phase shifts and cross sections are computed from the scattering matrix elements. (1) R.B.Wiringa, V.G.J. Stoks, and R.Schiavilla, Phys Rev C **51** (1995) 38

**Q1 131 Tunneling Density of States for 2D Fermi Liquid*** GODFREY GUMBS, *Hunter College of CUNY* EUGENE KOGAN, *Bar-Ilan University, Israel* We calculate the Green's function for an interacting two-dimensional electron liquid whose strength of interaction is characterized by the electron density parameter $r_s$. The screened electron-electron interaction is expressed in terms of a frequency and wave vector-dependent dielectric function $\varepsilon(q,\omega)$. If this screening is neglected, the tunneling density of states (DOS) is strongly modified due to electron-electron interaction. In particular, in this case, the DOS has a dip near the Fermi energy whose width increases with $r_s$. By treating $\varepsilon(q,\omega)$ in the hydrodynamical approximation, we investigate the way in which the tunneling DOS is modified at various electron densities, due to screened interaction. Preliminary results show considerable modification of the tunneling DOS at large $r_s$ for both a noninteracting and unscreened electron system. When there is screening, the dip becomes less pronounced but survives.

*Supported by Fulbright Foundation

**Q1 132 On the quantum master equation with nonhermitian operators** CHUN-FENG HUANG, *National Measurement Laboratoy, Center for Measurement Standards, Industrial Technology Research Institue* K.-N. HUANG, *Institute of Atomic and Molecular Sciences, Academia Sinica* A quantum master equation is derived for fermions by considering a relaxation term in addition to the mean-field Hamiltonian. [C. F. Huang and K.-N. Huang, Chinese J. Phys. **42**, 221 (2004); Ralph Gebauer and Roberto Car, Phys. Rev. B **70**, 125324 (2004).] The relaxation term is symmetric with respect to particles and holes, and its loss and gain factors can be obtained by incorporating nonhermitian parts to the Hamiltonian for the decays of particles and holes, respectively. Such an equation reduces to the Markoff master equation of the Lindblad form when the electrons or holes are of the low-density distribution. On the other hand, the derived equation reduces to the quasiclassical master equation in an incoherent limit. Both the loss and gain factors induce the decoherence. From Cauchy's inequality, we can see that the decoherence is important to keep both the density matrices for particles and holes as positive operators. The positivity of the density matrix for holes, in fact, indicates the validity of Pauli exclusion principle under the derived master equation. To further investigate the decoherence, we compare the master equation for fermion to that for bosons. The gain factor of the latter equation does not induce the decoherence, which is reasonable because bosons do not need to follow the Pauli exclusion principle.

**Q1 133 The Induced Coherent Interaction of Localized Spins via Thermal Bosonic Environment.** DENIS TOLKUNOV, DMITRY SOLENOV, VLADIMIR PRIVMAN, *Clarkson University* We obtain the indirect coherent interaction between two spins induced by the bath of bosonic modes, and demonstrate that this interaction can create entanglement. We utilize a perturbative approach to obtain a quantum evolution equation for the two-spin dynamics. The induced interaction is calculated exactly. The exact solution is then used to identify the time scales for which the spins remain entangled.

**Q1 134 Pair State Analysis of the Hubbard Hamiltonian in One-Dimension** W. B. HODGE, N. A. W. HOLZWARTH, W. C. KERR, *Wake Forest University* Using two-electron states as the basis, we have analyzed the one-dimensional Hubbard Hamiltonian (HH) with periodic boundary conditions for many-electron systems. The N-electron energy eigenvalues are simply the sum of the pair energies (eigenvalues of the two-particle reduced HH) weighted by two-particle density matrix elements. We are investigating the possibility that this approach will lead to a useful approximation scheme. For many weakly correlated systems, the pair-energy sum can be truncated and still the ground state energy can be obtained with reasonable accuracy. For example, in the case of six sites at half-filling (with U/t = 1) we need only include 12 of the 45 triplet pair states and 6 of the 21 singlet pair states, and still the ground state energy can be found with only 6% error. A comparison between the exact and approximate results for this system and several others are presented.

**Q1 135 P3/2 state in New Dirac Equation** DAVID MAKER, In this talk I explain the very interesting properties of the itmost probable excited state of a itnew type of Dirac equation and singularity when applied to a itsingle type of charge 'e'. Notably this first excited state psi*psi P3/2 (state lobes) shape is a trifolium, itthree lobed. Thus for each lobe there is a (1/3)e average charge given the charge 'e' spends on average 1/3 of the time in each lobe. Thus combinations of lobes have average charge, **e/3**, 2e/3 (FRACTIONAL CHARGE) or e. The lobes itcan't leave (ASSYMPTOTIC FREEDOM) or move so are NONRELATIVISTIC. The singularity of this Dirac equation results in containment at

about.6 Fermi, the TOTAL CHARGE is still '**e**'(explaining away the need for COLOR), etc. Most importantly the Frobenius series solution to this new Dirac equation also gives accurate hadron eigenvalues. You quickly see that you are getting here all the properties of quarks (identified here as individual lobes) obtained in a very simple way from the movement of a single unit charge 'e' using this new Dirac equation. There appears no simpler way to explain all these many quark properties.

**Q1 136 Some Interesting Symmetries of the Gravitational Stress Energy Tensor.** JOSEPH D. RUDMIN, *James Madison University* Some thoughts are presented on a few symmetries found in the Gravitational Stress Energy Tensor, with implications for black holes, fermion masses, and unification theories.

**Q1 137 ''Hidden Kinetic Energy'' and ''Mass-Electric'' Principle** PHILIP CHU, *Avery Dennison* A hypothesis is proposed which suggests another fundamental energy equation of Special Relativity. Another relativistic variance is described which gives self-consistent definition of Lagrange Function for both classical and relativistic dynamics. This hypothesis leads to a new ''Hidden Kinetic Energy'' concept as well as a new ''Mass-Electric'' Principle.

**Q1 138 Acceleration of Markov Chain Monte Carlo Simulations through Sequential Updating** RUICHAO REN, GERASSIMOS ORKOULAS, *University of California, Los Angeles* Strict detailed balance is not necessary for Markov chain Monte Carlo simulations to converge to the correct equilibrium distribution. In this work, we propose a new algorithm that only satisfies the weaker balance condition. The new algorithm is based on sequential updating moves with a small fraction of randomness to eliminate possible oscillatory effects. We prove analytically that the new algorithm identifies the correct equilibrium distribution. In addition, based on the properties of the diagonal elements of the underlying transition matrices, we demonstrate that the new algorithm converges faster than the Metropolis algorithm with strict detailed balance. We illustrate the efficiency of the new algorithm on the two- dimensional Ising model. The sequential update algorithm also compares well with multispin-based Monte Carlo techniques. The new method, however, is very general and can be readily extended to off-lattice continuum systems in various ensembles (canonical and grand canonical) with minor modifications. Simulation results on hard-spheres, square-well, and Lennard- Jones fluids indicate that the new method is more efficient in reducing autocorrelation times than conventional Metropolis- type of algorithms in canonical and grand canonical ensembles. Regarding off-lattice continuum fluids, autocorrelation time reduction is more substantial at higher densities due to the sequential nature of the Monte Carlo moves.

**Q1 139 Competing instabilities in correlated electronic systems in the FLEX framework** IRINA BARIAKHTAR, *Boston College* ALEXANDER NAZARENKO, *Sonic Software* JAN R. ENGELBRECHT, *Boston College* We consider the Hubbard model in the regime of strong correlations on bipartite and frustrated lattices. While it is well established that on a bipartite lattice at half filling the leading instability is in the SDW channel, upon varying the lattice symmetry and the electron concentration, competing instability channels emerge. We study possible channels such as pair, magnetic and charge correlations that can be either commensurate or incommensurate. We use the fluctuation-exchange approximation to investigate the development of, and competition between, different kinds of incipient instabilities in these particle-particle and particle-hole channels.

**Q1 140 Geometries of small cadmium selenide clusters*** MOHAN VARANASI, MICHAEL LISOWSKI, RONALD COSBY, *Ball State University* The sizes, shapes, relaxed atomic positions, eigenvalues, and total energies are calculated for selected ultrasmall CdSe clusters using SIESTA, a software package for electronic structure calculations and molecular dynamics simulations of molecules and solids. The properties of these bare clusters with small numbers of constituent atoms are studied using density functional theory (DFT) for energy calculations and the conjugate gradient approximation method in relaxing the structure to find the lowest energy configurations. The itab-initio norm-conserving pseudopotentials, the exchange-correlation approximation, and parameters used in the computations are discussed. We describe ancillary software for calculating initial atomic coordinates, testing pseudopotential transferability, and conveniently generating input data files.

*Supported by The Indiana 21st Century Research and Technology Fund.

**Q1 141 The wavefunction topography in the regime of Fano interference*** A. M. SATANIN, *Institute for Physics of Microstructures, Nizhny Novgorod, Russia* Y. S. JOE, R. M. COSBY, *Ball State University, Muncie, IN* In a point contact the wavefunctions belong to the continuum and the imaging of quantum states is based on measurements of the local density of states or the conductance. An attractive quantum dot in the 2D-waveguide can produce a Fano resonance in the conductance. We present here analytical calculations of conductance variation with the short range attractive potential for modeling the probe experiments in the regime of the Fano interference. It was shown that the wavefunction variation in the waveguide may be expressed through the Green's function of an unperturbed system if the characteristic size of the probing potential is less than the Fermi wavelength. We have found that in general the variation of the conductance depends on the phase interference of different waveguide modes. At the same time in the Fano regime in the conductance variation, there are dominant terms proportional to a resonant wavefunction. It was shown that this property suggests the possibility of extracting the wavefunction related to the Fano resonance.

*Supported by The Indiana 21st Century Research and Technology Fund and the Russian Basic Research Foundation, Grant No. 05-02-16762.

**Q1 142 A Numerical Investigation of the Non-Linear Interaction Forces in Tapping Mode Atomic Force Microscopy** NASTARAN HASHEMI, MARK PAUL, *Virginia Tech* There is an important need to measure the topography of soft materials including many of biological importance. Such soft and fragile materials can easily be damaged by the use of conventional nanoscale materials characterization instrumentation. Tapping mode atomic force microscopy routinely measures the topography of materials

with atomic resolution. For soft materials this is limited by the nonlinear contact forces imposed upon the sample by the oscillating cantilever tip. A fundamental understanding of these forces could lead to techniques capable of minimizing the possibly destructive tip-sample interactions. A physical model of the contact interactions is constructed and numerical simulations of the cantilever dynamics are presented to explore these possibilities.

**Q1 143 Analytical solutions of the Poisson-Boltzmann equation: biological applications** ANDREW FENLEY, *Virginia Tech (Physics Dept.)* JOHN GORDON, ALEXEY ONUFRIEV, *Virginia Tech (Computer Science Dept.)* Electrostatic interactions are a key factor for determining many properties of bio-molecules. The ability to compute the electrostatic potential generated by a molecule is often essential in understanding the mechanism behind its biological function such as catalytic activity, ligand binding, and macromolecular association. We propose an approximate analytical solution to the (linearized) Poisson-Boltzmann (PB) equation that is suitable for computing electrostatic potential around realistic biomolecules. The approximation is tested against the numerical solutions of the PB equation on a test set of 600 representative structures including proteins, DNA, and macromolecular complexes. The approach allows one to generate, with the power of a desktop PC, electrostatic potential maps of virtually any molecule of interest, from single proteins to large protein complexes such as viral capsids. The new approach is orders of magnitude less computationally intense than its numerical counterpart, yet is almost equal in accuracy. When studying very large molecular systems, our method is a practical and inexpensive way of computing bio- molecular potential at atomic resolution. We demonstrate the usefullnes of the new approach by exploring the details of electrostatic potentials generated by two of such systems: the nucleosome core particle (25,000 atoms) and tobacco ring spot virus (500,000 atoms). Biologically relevant insights are generated.

**Q1 144 Semi-Meissner state and neither type-I nor type-II superconductivity in multicomponent systems*** EGOR BABAEV, *Cornell University* MARTIN SPEIGHT, *Leeds University* Traditionally, superconductors are categorized as type-I or type-II. Type-I superconductors support only Meissner and normal states, while type-II superconductors form magnetic vortices in sufficiently strong applied magnetic fields. Recently there has been much interest in superconducting systems with several species of condensates, in fields ranging from Condensed Matter to High Energy Physics. Here we show that the type-I/type-II classification is insufficient for such multicomponent superconductors. We obtain solutions representing thermodynamically stable vortices with properties falling outside the usual type-I/type-II dichotomy, in that they have the following features: (i) Pippard electrodynamics, (ii) interaction potential with long-range attractive and short-range repulsive parts, (iii) for an n-quantum vortex, a non-monotonic ratio E(n)/n where E(n) is the energy per unit length, (iv) energetic preference for non-axisymmetric vortex states, ''vortex molecules.'' Consequently, these superconductors exhibit an emerging first order transition into a ''semi-Meissner'' state, an inhomogeneous state comprising a mixture of domains of two-component Meissner state and vortex clusters. We also discuss a counterpart of this state which may occur in type-I/type-II superconducting bilayers.

## Q1 145 GENERAL POSTER SESSION

**Q1 146 The St.- Petersburg State University Experiment that discovered the Photon Acceleration Effect** KONSTANTIN GRIDNEV, RUSSELL MOON, VICTOR VASILIEV, Using the principles of the Vortex Theory, it was theorized that when a photon encounters an electromagnetic field, both the velocity and the frequency of the photon will change. To prove this revolutionary idea an experiment was devised using a laser interferometer and two electromagnets. The electromagnets were arranged so that when the beam splitter divided the initial beam of laser light into two secondary beams; one of the two secondary beams passed back and forth between the two magnets. With the DC current to the electromagnets turned off, the two beams formed an interference pattern on the target screen. When the current to the electromagnets was suddenly turned on, the pattern fluctuated wildly until the two beams again reached a quiescent state creating a stable pattern on the screen; when the current to the electromagnets was suddenly turned off, again the pattern fluctuated wildly until it reached a quiescent state forming the initial stable pattern on the screen. It was determined that this new effect was a phenomenon created by the changing frequency of the laser light whose velocity is increasing as it passes between the expanding electromagnetic field of the magnets. Because it is a new phenomenon in science revealing that the speed of light is not a constant but indeed can be varied, it possesses great historical significance. It is called the Photon Acceleration Effect.

**Q1 147 The Neutral Pentaquark** RUSSELL MOON, *Consultant* FABIAN CALVO, *Consultant* VICTOR VASILIEV, *Prof., Dr.* Using the principles of the Vortex Theory, it was discovered that when the gamma ray strikes a nucleon, the positively charged pentaquark [and the $K^-$ meson] had to be created by the collision with neutron. This discovery further reveals that if the gamma ray strikes a proton it can create a Neutral Pentaquark [and a $D^+$ meson]. The neutral pentaquark will consist of an up, up, down, down, and an anti-charm quark, while the $D^+$ meson will consist of a charm and an anti-down quark. The neutral pentaquark will later decay into a neutron and $D^0$meson. Because the vortex theory also reveals that the strong force couples a proton to a neutron, the neutron that was coupled to the proton in the nucleus will also be found amid the debris particles. ## Q1 148 HIGH PRESSURE PHYSICS POSTER SESSION

**Q1 149 Partial Phonon Densities of States at the Fe-Sites in several Fe-Sn Intermetallic Compounds under Pressure*** HUBERTUS GIEFERS, *HiPSEC, Department of Physics, University of Nevada Las Vegas, Las Vegas, NV 89154-4002* MICHAEL PRAVICA, *HiPSEC, Department of Physics, University of Nevada Las Vegas, Las Vegas, NV 89154-4002* MICHAEL HU, *HPCAT and Carnegie Institute of Washington, Argonne, IL 60439* MALCOLM NICOL, *HiPSEC, Department of Physics, University of Nevada Las Vegas, Las Vegas NV 89154-4002* We studied the nuclear resonant inelastic x-ray scattering (NRIXS) of Fe-57 in several Fe-Sn intermetallic compounds up to 30 GPa. The samples ($FeSn_2$, FeSn, $Fe_5Sn_3$, and $Fe_3Sn$) were prepared in the HiPSEC laboratory with 95% enriched Fe-57 and 93% enriched Sn-119. NRIXS spectra were collected at HPCAT beamline 16-ID-D at the Advanced Photon Source. High-pressure experiments were conducted using a Paderborn-type DAC [1]. The pressure dependence of the partial phonon DOS spectra will be discussed in terms of elastic and thermodynamic parameters, such as the Lamb-Mössbauer factor, mean force constant, free energy, and Grüneisen parameters, using results from recent x-ray powder diffraction experiments of the Fe-Sn intermetallics under pressure. [1] H. Giefers et al., High Pressure Research 22 (2002) 501. [2] H. Giefers et al., J. Alloys Compd. accepted.

*Supported by DOE FC08-1NV14049. HPCAT is operated by UNLV, CIW, LLNL, CDAC, and U Hawaii. DOE W-31-109-Eng-38 supports the APS.

**Q1 150 High-Pressure Synchrotron RadiationX-Ray Diffraction and Vibrational Spectroscopic Studies of 3,3,7,7-tetrakis(difluoramino)octahydro-1,5-dinitro-1,5-diazocine (HNFX)*** CEDRIC GOBIN, JERRALIE ORWIG, MALCOLM NICOL, *High Pressure Science and Engineering Center, Department of Physics, University of Nevada Las Vegas, Las Vegas, NV 89154-4002, USA.* HNFX, 3,3,7,7-tetrakis(difluoramino)octahydro-1,5-dinitro-1,5-diazocine, belongs to a new class of compounds predicted to be potentially superior explosives or solid propellant oxidizers, the itgem-bis(difluoramino)-substituted heterocyclic nitramines [1,2]. HNFX has been studied in diamond anvil cell up to 30 GPa by synchrotron radiation x-ray diffraction, Raman and infrared spectroscopy at ambient temperature. The pressure-induced alterations in the profiles of the peaks, including their positions, widths and intensities are presented. No phase transition was observed on this range of pressure. The bulk modulus and its pressure derivative were estimated by the third-order Birch-Murnaghan isothermal equation of state up to 6.6 GPa. To the best of our knowledge, this work presents the first high-pressure investigations of HNFX and more generally of a itgem-bis(difluoramino)-substituted heterocyclic nitramine. [1] R. S. Miller; Chemistry of Energetic Materials; Ed. G. A. Olah and D. R. Squire; Chapt 4; p77; (**1996**). [2] R. D. Chapman, R. D.Gilardi, M. F. Welker, C. B. Kreutzberger; J. Org. **Q1 151 Structure phases of $MgSiO_3$ in Earth's lower Mantle: ab initio calculations** MOHAMMED SAHNOUN, PATRIC OULEVEY, *Department of Chemistry, University of Fribourg, CH-1700 Fribourg, Switzerland* BERNARD GROBETY, *Department of Mineralogy, University of Fribourg, CH-1700 Fribourg, Switzerland* CLAUDE DAUL, *Department of Chemistry, University of Fribourg, CH-1700 Fribourg, Switzerland* The Earth's mantle is divided into five layers with four major phase transitions at 410, 520, 660 and ~ 2600-km depths, due to a structural and chemical changes of its main constituent minerals. $MgSiO_3$ is believed to be a predominant mineral, at least in the upper part of the lower mantle. $MgSiO_3$ has a structural sequence from corundum-type ilmenite to $CaIrO_3$-type structure (Cmcm symmetry). First-principles calculations have been performed within the full-potential linearised augmented plane-wave method (FP-LAPW). We calculated equilibrium lattice parameters at different pressures up to 150 GPa. Four crystal structures relevant to $MgSiO_3$ were considered and they can grouped in two pairs of distinct types: **(a)** corundum-like and $Rh_2O_3$(II) structure-like, and **(b)** perovskite and $CaIrO_3$ structure-like. To investigate the structural phase transitions in $MgSiO_3$, we calculated the enthalpy (E+PV) of the four-structures as a function of pressure from 0 to 150 GPa. The intersection of the curves indicates which structure is more stable and gives the transition pressure.

**Q1 152 High-pressure X-ray diffraction study of the giant dielectric constant material $CaCu_3Ti_4O_{12}$: evidence of stiff grain surface** YANZHANG MA, *Department of Mechanical Engineering, Texas Tech University, Lubbock, TX 79409* JIANJUN LIU, *Department of Physics University of Nebraska at Omaha, Omaha, Nebraska 68182-0266* CHUNXIAO GAO, *National Laboratory of Superhard Materials, Jilin University, Changchun, China 130012* ALLEN D. WHITE, *Department of Mechanical Engineering, Texas Tech University, Lubbock, TX 79409* W. N. MEI, *Department of Physics University of Nebraska at Omaha, Omaha, Nebraska 68182-0266* JAHAN RASTY, *Department of Mechanical Engineering, Texas Tech University, Lubbock, TX 79409* We measured the high-pressure X-ray diffraction of the giant dielectric constant material $CaCu_3Ti_4O_{12}$ (CCTO) under both hydrostatic and uniaxial compressions. We found that the cubic structure of CCTO is stable up to 57 GPa. Nevertheless we observed CCTO has unusual compression behaviors under hydrostatic pressure. Specifically, the volume reduction is less than that under uniaxial compression below 25 GPa, above it the volume reduction starts to approach and finally reach the same value as that under the uniaxial compression at about 30 GPa. We explained these remarkable phenomena by using the model that the samples are composed of grains that have shells stiffer than the cores.

**Q1 153 Dynamic Ellipsometry Under Extreme Conditions*** JEFFREY H. NGUYEN, JEREMY R. PATTERSON, NEIL C. HOLMES, *Lawrence Livermore National Laboratory* Accurate temperature measurements at high temperatures and pressures require knowledge of emissivities at similar conditions. Presently, many temperature measurements at extreme conditions assume a constant ambient-condition emissivity. Development of a miniaturized ellipsometer has made it possible to measure optical properties, and thus emissivities, of materials under extreme shock conditions. We will present here past development and future directions of the miniaturized ellipsometer for use in high pressure-high temperature experiments. We will also discuss applications of

the technique including phase transitions under dynamic compression, observed changes in the complex dielectric constants of various solids and water. Since emissivity can be determined from the complex dielectric constants, we expect emissivity to change upon phase transition. We will present here results on various solid-solid, solid-liquid and liquid-solid phase transitions. In particular, we will focus on the change in emissivity at the $(\alpha, \epsilon)$ phase boundary in Fe and its implications for the Fe phase diagram.

*Work performed under the auspices of the U.S. DOE at the University of California/Lawrence Livermore National Laboratory under contract W-7405-ENG-48.

**Q1 154 Ab Initio Studies of $MgSiO_3$ Post-Perovskite*** FEIWU ZHANG,[†] ARTEM OGANOV,[‡] *ETH Zurich* Recent discovery of a post-perovsike phase of $MgSiO_3$ was considered as a new era in the studies of the Earth's deepest mantle. This discovery provides some explanations for many puzzling problems of the Earth's D'' layer (pressures $\sim$ 120-136 GPa, temperature $\sim$ 2000-4000 K), such as the large seismic anisotropy, heterogeneity, variable depth, strong shear wave velocity discontinuity at the top, and anticorrelation between shear and bulk sound velocities. High pressures and temperatures existing in planetary interiors dramatically alter the structure and properties of materials, but are difficult to reproduce in the laboratory. Present-day quantum-mechanical simulations often give accuracy sufficient for geophysical or planetological purposes. The key roles of the $MgSiO_3$ post-perovsike phase transition will be addressed by further theoretical studies, including elasticity and anelasticity, electrical conductivity, radiative conductivity, energetics of stacking faults, effects of impurities on stability and properties of post-perovskite.

## Q1 155 QUANTUM FLUIDS AND SOLIDS POSTER SESSION

**Q1 156 Supersolid $^4$He Likely Has Nearly Isotropic Superflow*** WAYNE M. SASLOW, *Texas A&M University* SHIVAKUMAR JOLAD, *Penn State University* We extend previous calculations of the zero temperature superfluid fraction $f_s$ (SFF) *vs* localization, from the fcc lattice to the experimentally realized (for solid $^4$He) hcp and bcc lattices. The superfluid velocity is assumed to be a one-body function, and dependent only on the local density, taken to be a sum over sites of gaussians of width $\sigma$. Localization is defined as $\sigma/d$, with $d$ the nearest-neighbor distance. As expected, for fcc and bcc lattices the superfluid density tensor is proportional to the unit tensor. To numerical accuracy of three-places (but no more), the hcp superfluid density tensor is proportional to the unit tensor. This implies that a larger spread in data on $f_s$, if measured on pure crystals, is unlikely to be due to crystal orientation. In addition, to three decimal places (but no more) the curves of $f_s$ *vs* $\sigma/d$ are the same for both the hcp and fcc cases. An expected value for the localization gives an $f_s$ in reasonable agreement with experiment. The bcc lattice has a similar curve of $f_s$ *vs* $\sigma/d$, but is generally smaller because the lattice is more dilute.

*Supported in part by DOE Grant No. DE-FG03-96ER45598.

**Q1 157 2D Imaging of Anti-relaxation Coating Quality Using Regionally Specific Hyperfine Polarization*** K. ZHAO, Z. WU, *Department of Physics, Rutgers University, Newark, NJ 07102* We show that the hyperfine polarization in the vicinity ($\sim 10^{-5}$ cm) of cell surfaces can be used as a novel way to quantify and map the regional surface property inside optical pumping cells. In silicone-coated cells our method allows us to image the regional quality of the coatings, revealing for the first time the existence of areas that have strikingly different qualities.

*Support from ONR is acknowledged.

## Q1 158 ATOMIC, MOLECULAR & OPTICAL (AMO) PHYSICS POSTER SESSION

**Q1 159 Improved Guillemin-Zener wave function useful in molecular and chemical physics.** ODIL YUSUPOV, Classical Guillemin-Zener[1] wave function for primary diatomic molecular system – molecular hydrogen ion have shown high accuracy and quality of exponential functions basis. We want to submit improved compact wave function useful in study quantum mechanic. Compact electronic wave function for ground state of molecular hydrogen ion is $\Psi$ = N*(**exp(-a1***$\xi$)**+c*exp(-a2***$\xi$))*( **cosh(-b1***$\eta$)**+d*cosh(-b2***$\eta$)) where N - normalization factor, $\xi$ and $\eta$ are spheroidal coordinates of electron, a1,a2,b1,b2 – nonlinear variational parameters, c and d - linear variational parameters. By optimization of energy functional we found optimal values of this parameters for any internuclear distance R. For example, at R=2 a.u.: a1= 1.4345, a2= 1.9753, b1= 0.5399, b2= 1.3001, c= -0.332876, d= 0.592279. Electronic energy of molecular hydrogen ion with this 4-term wave function equals -1.10263418 a. u. and very close to the ''exact'' value – 1.10263422 a.u. The comparison was shown that our improved wave function equivalent to about 25- term standard mathematical expansion in spheroidal coordinates. This function can be used in educational physics as well as for molecular theory, chemical physics, theory of few particle coulomb systems, etc.
V.Guillemin, C.Zener. Proc. Natl.Acad. Sci. U.S., 15, 314, (1929)
T.K.Rebane and O.N.Yusupov. Opt. and spectr. 72, 6, 1289 (1992)

**Q1 160 Breathing modes and stability of trapped two-component ultracold atoms*** CHOU-CHUN HUANG, WEN-CHIN WU, *National Taiwan Normal University* The breathing modes and stability of trapped two-component ultracold atoms are studied using a variational method. We consider a boson-boson, a boson-fermion, and a fermion-fermion mixture in a 3D isotropic harmonic trap and in a 1D optical lattice. When the two compo-

nents are miscible, the corresponding in-phase and out-of-phase breathing mode frequencies are calculated against the value of the inter-component interaction. The stability of the two-component system is shown to have strong correlation with the behaviors of breathing modes.

*Supported by the National Science Council of Taiwan.

**Q1 161 Semiclassical time-independent description of rapidly oscillating fields on a lattice in the Kapitza approximation.** JEAN-PIERRE GALLINAR, *Depto. de Fisica, Universidad Simon Bolivar, Aptdo. 89000, Caracas 1080A, Venezuela* We investigate a semiclassical dynamics driven by a high-frequency ($\omega$) field, plus a static arbitrary potential on a one-dimensional tight-binding lattice. We find -in the spirit of the Kapitza pendulum- an effective, time-independent potential $V_{eff}(x)$ that describes the average motion to order $\omega^{-2}$. This effective potential depends on the static external potential $V(x)$, on the lattice constant ''$a$'' and on the applied high-frequency field $f(x,t)$. One obtains that

$$V_{eff}(x)/m = a^2/2\, V^2(x) - a^2 E V(x) + a^4 \int dx (V(x) - E)^2\, \partial/\partial x \left[ \sum_{n=1}^{\infty} f_n^2(x)/\omega^2 n^2 \right].$$

Where ''$m$'' and ''$E$'' are, respectively, the effective mass and unperturbed energy of the particle's average motion, and $f_n(x)$ is the n-th Fourier component of the driving field. Where appropriate, our results should be suitable for the description of semiclassical electronic motion in a crystal lattice and/or atomic motion in an optical one.

**Q1 162 Role of Broken Gauge Symmetry in Transport Phenomena Involving Neutral and Charged Particles in Finite Lattices** SCOTT CHUBB, *Remote Sensing Division, Naval Research Laboratory* As opposed to the conventional, approximate theory of electrical conduction in solids, which is based on energy band, quasi-particle states in infinite lattices, a rigorous theory exists that can be used to explain transport phenomena, in finite lattices, at reduced temperature, through the effects of a broken gauge symmetry: The loss of translational invariance with respect to Galilean transformations that maintain particle-particle separation. Implications of this result in areas related to the transport of hydrogen (H) and its isotopes in nano-crystalline structures of palladium (Pd) and of neutral, coherent atomic waves in finite, optical lattices are presented. These include: 1. The prediction of a novel variant of a known, phenomenon, Zener/Electronic Breakdown in insulators, in which ions in nano-scale palladium-deuteride (PdD) crystals (as opposed to electrons in insulating crystals) that initially, effectively, are confined to particular regions of space, begin to move, spread-out, and conduct charge after they are subjected to an applied, external (constant) electric field for a sufficiently long period of time; and 2. A rigorous treatment of scattering at low temperatures that can be used to identify critical time- and length- scales for problems related to the transport of neutral atomic matter waves in finite, optical lattices, in the presence of gravitational fields.

**Q1 163 Quantum-degenerate Bose-Fermi mixtures on one-dimensional optical lattices** PINAKI SENGUPTA, *University of Southern California* LEONID P. PRYADKO, *University of California, Riverside* Using a quantum Monte Carlo method, mean field theory, and a strong-coupling expansion, we map out the ground state phase diagram of a mixture of ultracold bosons and spin-polarized fermions in a one-dimensional optical lattice. The properties of the uniform phases and their stability toward phase separation into pure boson and pure fermion phases are studied in detail over a wide range of chemical potentials for boson-boson and boson-fermion interactions ranging from weak to strong coupling limits. The nature of different phases is characterized by computing the charge stiffness, bosonic superfluid stiffness, and density-density correlation functions.

**Q1 164 Computer Simulations of Quantum Computational Operations Performed on the Vibrational Energy Levels of Small Molecules** DANIEL WEIDINGER, *University of Illinois* MARTIN GRUEBELE,* *University of Illinois* The vibrational energy levels of a molecule can be regarded as a register for quantum information. An applied electric field (provided by a shaped laser pulse) will transform the state vector of the molecule in a manner that can be regarded as a quantum computational operation. Optimization algorithms have been developed and computer simulations have been run to determine the optimum laser pulses to act as specific operators. Simulations of 1-, 2-, 3-, and 4-qubit gates have been run using 2-, 4-, 8-, and 16-level tracts of vibrational energy levels, respectively. Simulations have been generated to model a realistic experiment using available technology. In the case of thiophosgene ($SCCl_2$), vibrational levels on the ground electronic state may be coupled via one or several energy levels on an excited electronic state. The coupling is provided by a single femtosecond laser pulse, which is shaped according to parameters consistent with available pulse shapers. Within these parameters, pulses have been simulated that perform gates such as the CNOT (4 levels) and Hadamard (2 levels) with fidelities over 95 %. The limiting factors for efficacy of the shaped pulse in performing the gate—such as the number of ground state vibrational levels involved—have been explored.

*Principal Investigator

**Q1 165 Autler-Townes splitting in a sodium molecular-ladder scheme*** CHIN-CHUN TSAI, RAY-YUAN CHANG, *Deparment of Physics, National Cheng-Kung University, Tainan, 70101, Taiwan* THOU-JEN WHANG, CHUEN-PING CHENG, *Department of Chemistry, National Cheng-Kung University, Tainan 70101, Taiwan* We report results from studies of the Autler-Townes (AT) splitting observed in sodium dimer using optical-optical double resonance spectroscopy. In our experiment, a single line $Ar^+$ laser at 4727 Å pumps the thermally populated ground state level $X\,^1\Sigma_g^+(v'' = 1, J'' = 37)$ of $Na_2$ to the intermediate $B\,^1\Pi_u(v' = 9, J' = 38)$ level. Then, a single mode cw Ti:sappher or dye laser couples to the higher Rydberg states. The signals are detected by monitoring the UV fluorescence from the triplet *gerade* states back to the $a\,^3\Sigma_u^+$ state via collision energy transfer. Unlike all the other intermediate levels pumped by different $Ar^+$ laser lines, this strong transition populated the $B\,^1\Pi_u(v' = 9, J' = 38)$ level leads to an AT splitting on all the levels observed in the higher Rydberg states, for example, 3, 5, 6, $7\,^1\Pi_g$ states and 3, 5, $6\,^1\Delta_g$, states.

*We greatly acknowledge the support of the National Science Council, Taiwan.

**Q1 166 Sensitive detection of lead monofluoride** CHRIS MCRAVEN, *Homer L Dodge Department of Physics and Astronomy, The University of Oklahoma* SIVAKUMAR POOPALSINGAM, *Homer L Dodge Department of Physics and Astronomy, The University of Oklahoma* NEIL SHAFER-RAY, *Homer L Dodge Department of Physics and Astronomy, The University of*

*Oklahoma* The ground-state of lead monofluoride maybe uniquely sensitive to an electron electric dipole moment. Here we report on a radical-beam source of PbF and sensitive resonance-enhanced-multiphoton ionization detection of the molecule.

**Q1 167 Simple Analytic Theory of Cold Atom Feshbach Resonance Scattering** PAUL JULIENNE, *NIST* BO GAO, *U. of Toledo* Magnetically tunable Feshbach resonances have been used very successfully in cold atomic gases to study a variety of condensed matter phenomena. We describe a simple analytic theory, in excellent agreement with full quantum scattering calculations, for the near-threshold resonant scattering 2-body T-matrix for magnetically tunable Feshbach resonances in ultracold atomic collisions. The theory is based on the analytic properties of the exact solutions to the Schrodinger equation for the van der Waals potential, and is characterized by 5 parameters: the scattering length, van der Waals coefficient, and reduced mass of the background entrance channel, the coupling width of the resonance, and the difference in magnetic moments between the separated atoms and the resonance level. The resonance scattering phase shift is completely characterized by two functions, an energy-dependent width and an energy-dependent shift, which are analytic functions of the background van der Waals potential. The theory permits a simple classification of resonances as open- or closed-channel dominated, and gives insight into the nature of atom pairing in scattering states. The excellent quality of the theory is illustrated by calculations of above-threshold scattering for the fermionic isotopes K-40, and Li-6 and for bosonic Rb-85.

**Q1 168 Role of the van der Waals interaction in atom-diatom reaction dynamics at low temperatures*** PHILIPPE F. WECK, NADUVALATH BALAKRISHNAN, *University of Nevada Las Vegas, Las Vegas, NV 89154* JOAO BRANDAO, CARLA ROSA, WENLI WANG, *Universidade do Algarve, 8005-139 Faro, Portugal* Quantum-mechanical scattering calculations are reported for the $O(^3P) + H_2$ collision at energies close to the reaction threshold with emphasis on the sensitivity of the reaction dynamics to the van der Waals interaction. The dynamics has been investigated using the lowest $^3A''$ GLDP potential energy surface developed by Rogers et al. [J. Phys. Chem. A **104**, 2308 (2000)] and its recent BMS1 and BMS2 extensions by Brandão et al. [J. Chem. Phys. **121**, 8861 (2004)] which explicitly include the van der Waals interaction. Quasiclassical trajectory calculations on all three potential energy surfaces are also reported to explore the validity of this method near the reaction threshold and to assess the importance of quantum effects at low temperatures.

*This work was supported by NSF grant PHYS-0245019, DOE grant DE-FG36-05GO85028, the Research Corporation, and the FCT under the POCTI/CTA/41252/2001 Research Project, cofinanced by the European Community Fund, FEDER.

**Q1 169 Liouville-Space Descriptions for Intense-Field Coherent Electromagnetic Interactions*** VERNE JACOBS, *Naval Research Laboratory* Liouville-space (reduced-density-operator) descriptions are developed for coherent electromagnetic interactions of quantized electronic systems, taking into account environmental decoherence and relaxation phenomena. Applications of interest include many-electron atomic systems and semiconductor nanostructures. Time-domain (equation-of-motion) and frequency-domain (resolvent-operator) formulations are developed in a unified manner. In a preliminary semiclassical perturbative treatment of the electromagnetic interaction, compact Liouville-space operator expressions are derived for the linear and the general (nth order) non-linear electromagnetic-response tensors. Intense-field electromagnetic interactions are treated by an alternative reduced-density-operator approach based on the Liouville-space Floquet-Fourier representation.

*Work supported by the Office of Naval Research, the Defense Advanced Research Projects Agency, and the Department of Energy.

**Q1 170 High Intensity Ultrashort Pulse Interactions with Dielectric Filters** SARAH DUNNING, CARL M. LIEBIG, W.M. DENNIS, *University of Georgia* Modern ultrafast laser systems are capable of generating optical pulses of sufficient intensity to induce nonlinear effects in several of the materials used in thin-film dielectric optical filters. Such effects degrade the performance of these devices at high intensities. In this paper we describe computer simulations used to investigate the interaction of high intensity ultrashort laser pulses with three dielectric filters: a quarter- wave dielectric stack, a rugate filter, and an idealized rugate filter, with a continuously varying refractive index. Using the finite-difference time-domain (FDTD) technique, we simulated the reflection of optical pulses (with pulse widths in the range 5–100 fs and peak intensities up to $\sim$ 10 TW/cm$^2$) from all three devices. The simulated low intensity reflective properties were found to be in excellent agreement with calculations using the characteristic matrix method. For high intensity pulses a decrease of the filter reflectance and a distortion of the reflected pulse was observed.

**Q1 171 Study of ultrafast nonlinear pulse shaping effect of strained saturable Bragg reflector (SSBR) with coherent quantum control technique** CHAO-KUEI LEE, CHIA-CHEN HSU, *IEO, NSYSU* In this work, a strained saturable Bragg reflector (SSBR) for passive mode-locking of Ti:sapphire lasers was investigated by pulse shaping technique. Incident pulses of several wavelengths and with zero, positive, or negative chirp were employed. A Kramers-Kronig relation like behavior of pulse shaping factor in the strained quantum well was observed. The phenomenon is attributed to anomalous dispersion and higher order nonlinearity.

**Q1 172 Nearly Perfect Squeezing of the Signal mode in Parametric Oscillation with Coherent and Squeezed pumping*** DANIEL ERENSO, *Middle Tennessee State University* A degenerate parametric oscillator operating above threshold is studied when the cavity is injected by a squeezed vacuum field at the second harmonic frequency. We presented a different method of finding the Wigner function for the intracavity modes. We use the solution of the quantum Langevin equation for the signal and pump modes to construct the steady-state Wigner function for the joint pump-signal mode. Then, the one-mode Wigner functions for the signal and pump modes are derived and the corresponding phase space is studied. These functions are used to determine the quantum fluctuations in the intracavity signal and pump mode field quadratures. The results have shown that nearly perfect suppression of quantum noise can be achieved in both the signal and pump modes. We have also studied the spectrum of the squeezing for cavity output signal mode; our result reveals nearly perfect squeezing can be achieved by controlling the relative cavity damping rates between the signal and pump modes. The second-order

intensity correlation for zero time delay also studied for each mode and it is found that intracavity photons are always bunched, independent of the relative phase of the squeezed vacuum field with respect to the driving coherent field.

*This work was supported in part by the Geier fund from the Tennessee Board of Regents

**Q1 173 Time-dependent phenomena of electron-electron and electron-hole pairs confined in quantum dots** TETSURO SATAKE, MASAKAZU MURAGUCHI, KYOZABURO TAKEDA, *Waseda University* We report time-dependent (TD) phenomena of electron-electron (ee) and electron-hole (eh) pairs confined in 2D quantum dots (QDs). We solved TD Schrodinger equation numerically, under the assumption of the Hartree-type wave function with the singlet spin state for both pairs of ee and eh. The individual (e's and h's) QD orbitals are expanded by the basis of the real spatial mesh. We further combined Poisson's equation to determine the pair's coulomb interaction in QDs. The stationary ground states are first obtained by the scf-calculation. In accordance with the QD size, both of ee and eh pairs are characterized by confined, intermediate and free states, and the difference among them is more distinctive in ee pairs than in eh pairs. The coulomb repulsion calculated by Poisson equation extends the confined region, because of its logarithmic distance-dependence due to 2D QD. The TD change in the coulomb interaction induces the non-resonative oscillations among the individual eigen-states. The projection of the calculated pair's wave function into the QD single electron stationary states reveals that the resulting frequency is determined with the competition between the coulomb interaction and the size of QDs.

## Q1 174 PHYSICS EDUCATION POSTER SESSION

**Q1 175 Physical activities to enhance an understanding of acceleration** S.A. LEE, *University of Toledo* On the basis of their everyday experiences, students have developed an understanding of many of the concepts of mechanics by the time they take their first physics course. However, an accurate understanding of acceleration remains elusive. Many students have difficulties distinguishing between velocity and acceleration. In this report, a set of physical activities to highlight the differences between acceleration and velocity are described. These activities involve running and walking on sand (such as an outdoor volleyball court).

**Q1 176 Motion Sensors in Introductory Physics Laboratory and beyond.** PONN MAHESWARANATHAN, *Winthrop University* Motion sensors are commonly used to collect data in a typical computer-based introductory physics laboratory. It is part of the group of sensors that comes with an initial purchase of an interface. It is an important piece of equipment for the first year physics curriculum. It is used in position, velocity, and acceleration experiments as well as in momentum conservation, impulse-momentum theorem, and simple harmonic motion. In this paper its use will be expanded to few more experiments and lecture demonstrations pointing out its limitations and some of the pitfalls. A review of the websites that deal with motion sensors and computer assisted experiments will also be presented. In addition, their use in alarm and automation systems and surveillance technology will be introduced as an extrapolation to real world applications.

**Q1 177 Using the Open Source Physics Library to Teach Statistical and Thermal Physics*** HARVEY GOULD, HUI WANG, *Clark University* JAN TOBOCHNIK, NICHOLAS TUNG, *Kalamazoo College* Statistical and thermal physics is becoming an increasingly important part of the undergraduate and graduate curriculum due in part to the the availability of inexpensive and powerful computational resources and the importance of statistical concepts in much of current research in physics and related areas. We will show examples of curriculum materials for teaching topics in statistical and thermal physics with a focus on Java programs written using the Open Source Physics library. Examples of simulations will be demonstrated.

*Supported in part by NSF DUE-0442481 and DUE-0127363.

**Q1 178 Propagation of a pulse trough a Lorentz dispersive thin film using the Finite Difference Time Domain** JESUS MANZANARES-MARTINEZ, ADRIAN NAVARRO-BADILLA, RAUL ARCHULETA-GARCIA, *Universidad de Sonora* We consider the evolution of the main signal in a Lorentz dispersive thin film. The signal is a Gaussian-sine modulated pulse that is excited outside the thin film. We illustrate the change of the group velocity as the pulse changes its central frequency and we discuss the conditions to have a superluminal behavior. The results obtained are illustrated with animated graphics that obtained with our implementation of the Finite Difference Time Domain.

**Q1 179 Including Nanoscale Investigations in a General Introductory Physics Course*** KURT VANDERVOORT, STEPHANIE BARKER, RAUL TORRICO, *Physics Department, California State Polytechnic University, Pomona, CA 91768* Modules were developed to introduce atomic force microscope (AFM) applications into a general introductory physics course. The goal was to elucidate fundamental concepts in optics at the nanoscale that would complement existing investigations at the macroscale, and to expose students to advanced instrumentation at an early level. The nanoscale investigations were inserted where necessary and were used to help define and delineate the various topics in optics. In a lab on lenses, students first use the AFM to view smooth glass and rough glass at the microscopic level, illustrating the range of applicability of geometrical optics. In a physical optics lab, students measure patterns from diffraction gratings and then view the grating at the microscopic level, revealing groove spacings and a new feature, the blaze angle. Further investigation yields from the blaze angle a way to separate the effects of the single slit diffraction envelope from the multiple slit interference pattern. Another lab investigates the height of the bumps on a CD surface and exposes students to a direct application of destructive interference. These and other examples will be presented.

*Funding was provided by the National Science Foundation Nanotechnology Undergraduate Education program, award # 0406533.

**Q1 180 Deposition and Solidification of PPV Precursor*** EDWARD BURDETTE, *Grove City College* HANS HALLEN, *North Carolina State University* Future high performance polymer films will be comprised of molecules oriented in the plane of the substrate. As a first step, a mixture of poly(p-xylene tetrahy-

drothiophenium chloride) in methanol was spun onto a sapphire substrate. These samples were fabricated over a range of spin-coating times, methanol solution concentrations, and number of drops of solution. Analysis with an ellipsometer revealed that layer thickness is independent of spinning period and applied solution volume, and decreases as the parts per volume of methanol increases. Furthermore, the samples were exposed to various wavelengths of UV-visible radiation to determine the optimal wavelength for driving these precursor molecules into a solid thin film, insoluble in methanol. Light from a mercury arc-lamp with a wavelength of 365 nm was found to solidify the precursor within five minutes of exposure most effectively.

*Research sponsored by the National Science Foundation Research Experiences for Undergraduates Program in the Department of Physics, grant number DMR-0353719

**Q1 181 Complex Permittivity of Powder Metal Compacts by Cavity Perturbation Technique*** CHRIS LYNCH,[†] EARNIE JOHNSON, JUNKUN MA, NICHOLAS MISKOVSKY, GARY WEISEL, BROCK WEISS, DARIN ZIMMERMAN,[‡] *The Pennsylvania State University, Altoona College* We present measurements of the complex permittivity of powder metal compacts using microwave cavity perturbation techniques. Using a 2.45GHz, $TM_{010}$ microwave cavity operating in conjunction with a vector network analyzer, we have systematically measured the real ($\varepsilon$') and imaginary ($\varepsilon$'') parts of the effective complex permittivity of pure, powder metal, cylindrical samples (0.25in by 0.25in). By placing these in the electric-field antinode, the dielectric properties at microwave frequencies are obtained by comparison with the expected change in the cavity Q by perturbation theory. We have studied the effect of varying particle size and green density as means to understand the absorption and heating of powdered metals in microwave fields. We acknowledge the additional work of undergraduates Kelly Martin and Charles Smith, who assisted in the setup of experimental apparatus, sample preparation, and data acquisition.

**Q1 182 Microwave Heating and Pre-sintering of Copper Powder Metal Compacts in Separated Electric and Magnetic Fields*** KELLY MARTIN,[†] EARNIE JOHNSON, JUNKUN MA, NICHOLAS MISKOVSKY, GARY WEISEL, BROCK WEISS, DARIN ZIMMERMAN,[‡] *The Pennsylvania State University, Altoona College* We present results of microwave heating and pre-sintering of pure copper metal powder compacts. Using a 2.45GHz, WR284 microwave system operating in TE102 single mode resonance, we have systematically studied the microwave heating and pre-sintering behavior of various copper powder metal compacts as a function of particle size and green density. Cylindrical samples (0.25in by 0.25in) were positioned in either the magnetic– or electric–field antinode, allowing the study of the separate effects of the two fields. The results show significant differences in heating rates and sample microstructure (SEM) even when average sample temperatures are below half the melting point of bulk copper. Numerical simulations of the absorption and heating have been developed to check the consistency of the experimental results. We acknowledge the additional work of undergraduate students John Diehl, John Rea, Charles Smith, and Devin Spratt, who assisted in the setup of experimental apparatus, sample preparation, and data acquisition.

*The work is supported by grants from the National Science Foundation (DMR-RUI 0406584) and The Pennsylvania State University

**Q1 183 Expected Properties and Experimental Signals of Bose-Einstein Condensates** MONA ALI, *Wellesley College, Wellesley, Massachusetts 02481* COURTNEY LANNERT, *Wellesley College, Wellesley, Massachusetts 02481* We have studied the expected response of Bose Einstein Condensed (BEC) atoms subject to various experimental probes. In the first part of this project, we modeled BEC atoms passing through a double slit and predicted the interference patterns that are expected to form on the screen. We contrast these interference patterns with those from thermal atoms and compare the patterns from condensed atoms with varying levels of inter-atomic interactions. This gives an experimental signature of the presence of BEC in the system as well as the strength of interactions. The second part of our project considers the response of BEC atoms trapped in an optical lattice, subject to an external oscillatory magnetic field. This system is modeled as having two discrete hyperfine energy states and we find the expected transitions between these states for the BEC atoms. The transitions are found to be similar to the Rabi oscillations observed with non-BEC atoms, subject to the same probe, with some notable differences.

**Q1 184 Variational Wavefunction Monte Carlo on Two-Dimensional Lattices** XINXIN DU, *Wellesley College, Wellesley, Massachusetts 02481* COURTNEY LANNERT, *Wellesley College, Wellesley, Massachusetts 02481* We apply numerical methods to the study of many-electron systems, in particular the cuprates, by using variational wavefunction Monte Carlo methods to search for the groundstate wavefunction. We investigate some of the current proposed models and wavefunctions for these compounds, in particular, the t-J model and the t-J model with ring-exchange on two- dimensional square lattices. We compute the energy of the Spin Density Wave (SDW) groundstate wavefunctions for the half- filled Heisenberg antiferromagnetic using the computing algorithm outlined by Gros. This verifies the agreement of the results with the current literature on the Heisenberg model. With the addition of the ring-exchange terms, we compare the energies of the Resonating Valence Bond state, the Gutzwiller state, the superconducting state, and the SDW state. This allows us to study the relationship between the non-magnetic and antiferromagnetic phases of the system at half- filling. The introduction of holes on the lattice allows us to simulate the relationship between the superconducting and the insulating phases of the magnet.

**Q1 185 A Fluorescence Spectroscopic Study of Cytochromes P450 1A2 and 3A4.** GLENN MARSCH, *Grove City College* F.P. GUENGERICH, *Vanderbilt University* JOSHUA INKS, *Grove City College* Fluorescence spectroscopy was used to study cytochromes P450 1A2 and 3A4. Spectra of P450s were acquired in the presence and absence of acrylamide quencher. In both P450s, quenching revealed three distinguishable species of amino acid fluorescence, with maxima at 297, 323, and 345 nm. The 345 nm

tryptophan fluorescence was quenched by low levels of acrylamide; the 297 nm tyrosine fluorescence was resistant to quenching. The 323 nm fluorescence was observed at intermediate concentrations of quencher. Stern-Volmer plots of P450 quenching were non-linear, but were well-fitted to a superposition of linear plots for each fluorophore species. The effect of P450 1A2 binding on pyrene fluorescence was also examined. Upon binding to P450 1A2, the intensity of the 383 nm pyrene vibronic band was decreased relative to the intensities of the 372 and 393 nm bands. Fluorescence quenching of pyrene and other ligands upon binding to P450s will be used to evaluate distances between ligands and the P450 heme moiety by fluorescence resonance energy transfer. Fluorescence quantum yields of ligands, overlap integrals, and Förster distances of many ligand-heme donor-acceptor pairs were calculated. Steady-state spectra and time-resolved data of bound ligand will be used to calculate substrate-heme distances in the P450 enzymes.

**Q1 186 Ferroelectric switching of KDP ($KH_2PO_4$) and doped KDP:Cr simultaneously studied by the epr and Mertz methods*** FRANCISCO RODRIGUEZ PEREZ, JUAN FRAGOSO, PAUL HARRIS, MARISELA APARICIO, KENNETH ULIBARRI, MONICA MARCIAL-ARMENTA, TIMOTHY USHER, *California State University San Bernardino* Preliminary experimental results on ferroelectric switching in KDP will be presented. Additionally, a modified closed cycle cryogenic system for epr will be presented. Our goal is to reconcile differences in (epr) spectroscopy and the Mertz method on the simple ferroelectric, KDP/$KH_2PO_4$. A closed cycle cryogenic system, capable of reaching temperatures well below the Curie point of KDP (123K) was modified to accommodate the two measurements. The epr measurements probe the bulk of the KDP and favors slow ferroelectric domain switching while the Mertz method probes the surface and favors fast switching. A compromise in switching time between epr and Mertz is necessary. Preliminary results show the expected splitting in the epr lines near 1.45 kG. The Mertz data show switching currents consistent with the nucleation and domain growth model. The switching times are on the order of 20 microseconds for temperatures of approximately 100K. In addition to doped KDP we plan to investigate irradiated KDP and DKDP.

*NASA Grant No. 0051-0078 DOD Control No. ISP02-EUG15 NSF DMR-0116744

## Q1 187 QUANTUM INFORMATION, CONCEPTS, AND COMPUTATION POSTER SESSION

**Q1 188 Quantum amplification in the presence of decoherence** JAE-SEUNG LEE, ANATOLY KHITRIN, *Department of Chemistry, Kent State University, Kent, Ohio, 44242-0001* A one-dimensional Ising chain irradiated by weak resonant transverse field is a simple analytically solvable model of quantum amplification [Phys. Rev. A **71**, 062338 (2005)]. Operation of any practical device would be affected by decoherence. Here we present the results of the effect of decoherence on amplification dynamics. The dynamics of a 100-spin chain perturbed by random phase kicks of individual spins has been studied numerically. Time evolution of the total polarization is monitored for different strengths of decoherence. It is shown that decoherence decreases the maximum coefficient of amplification in this model. In the limit of strong decoherence, quantum dynamics resembles classical diffusion.

**Q1 189 Quantum manipulation and simulation using Josephson junction arrays** XINGXIANG ZHOU, ARI MIZEL, *The Pennsylvania State University* We discuss the prospect of using quantum properties of large scale Josephson junction arrays for quantum manipulation and simulation. We study the collective vibrational quantum modes of a Josephson junction array and show that they provide a natural and practical method for realizing a high quality cavity for superconducting qubit based QED. We further demonstrate that by using Josephson junction arrays we can simulate a family of problems concerning spinless electron-phonon and electron-electron interactions. These protocols require no or few controls over the Josephson junction array and are thus relatively easy to realize given currently available technology.

**Q1 190 Abstract Withdrawn**

**Q1 191 Effect of correlated noise on a fault-tolerant quantum error correction protocol*** JAMES CLEMENS, *Miami University* JULIO GEA-BANACLOCHE, *University of Arkansas* We consider the effect of correlated noise in the context of a fault-tolerant quantum error correction protocol. The noise is represented by a set of classical fluctuating fields with partial spatial and temporal correlations. We explicitly account for the propagation of errors in the implementation of quantum circuits for ancilla verification and syndrome extraction. Errors arising from single-bit and two-bit gates are considered separately. The performance of the error correction protocol is characterized by means of the probability for an uncorrected error to occur calculated from numerical simulations of the error propagation. For single-bit gates we find that in the limit of strong correlations the crash probability is enhanced be an order of magnitude. For two-bit gates we find that the effect of correlated noise can be minimized by choosing an appropriate sequence of operations which takes advantage of the correlations.

*We gratefully acknowledge support from the US Army Research Office

**Q1 192 Modeling fluid dynamics on type II quantum computers** JAMES SCOVILLE, DAVID WEEKS, *Air Force Institute of Technology* JEFFREY YEPEZ, *Air Force Research Laboratory* A quantum algorithm is presented for modeling the time evolution of density and flow fields governed by classical equations, such as the diffusion equation, the nonlinear Burgers equation, and the damped wave equation. The algorithm is intended to run on a type-II quantum computer, a parallel quantum computer consisting of a lattice of small type I quantum computers undergoing unitary evolution and interacting via information interchanges represented by an orthogonal matrices. Information is effectively transferred between adjacent quantum computers over classical communications channels because of controlled state demolition following local quantum mechanical qubit-qubit interactions within each quantum computer. The type-II quantum algorithm presented in this paper describes a methodology for generating quantum logic operations as a generalization of classical operations associated

with finite-point group symmetries. The quantum mechanical evolution of multiple qubits within each node is described. Presented is a proof that the parallel quantum system obeys a finite-difference quantum Boltzman equation at the mesoscopic scale, leading in turn to various classical linear and nonlinear effective field theories at the macroscopic scale depending on the details of the local qubit-qubit interactions.

**Q1 193 Optimization of a quantum teleportation protocol based on collective spontaneous emission** JAMES CLEMENS, *Miami University* Recently a quantum teleportation protocol has been proposed by Chen, *et al.* in *New Journal of Physics* **7**, 172 (2005) which is based on the collective spontaneous emission of a photon from a pair of atoms. If one can successfully distinguish between the superradiant and subradiant emission channels then one can teleport the state of the second atom onto a cavity field mode with which the first atom has previously interacted. One can employ temporal resolution, spatial resolution, or both in combination, of the emitted photon in order to distinguish superradiant from subradiant emission on the basis of a single detected photon. The overall success probability of the teleportation protocol is calculated under all three detection strategies and is optimized with respect to the spacing of the two atoms.

**Q1 194 Measuring the parity of an *N*-qubit state** B. ZENG, *Department of Physics, Massachusetts Institute of Technology, Cambridge, MA 02139, USA* D.L. ZHOU, L. YOU, *School of Physics, Georgia Institute of Technology, Atlanta, Georgia 30332, USA* We present a scheme for a projective measurement of the parity operator $P_z = \Pi_{i=1}^{N} \sigma_z^{(i)}$ of *N*-qubits. Our protocol uses a single ancillary qubit, or a probe qubit, and involves manipulations of the total spin of the *N* qubits without requiring individual addressing. We illustrate our protocol in terms of an experimental implementation with atomic ions in a two-zone linear Paul trap, and further discuss its extensions to several more general cases.

**Q1 195 A Variation of the Classic Double-Slit Experiment in Quantum Mechanics** DOUGLAS SNYDER, The classic double-slit experiment in quantum mechanics was adapted previously to show that a distinct type of physical interaction between an atom with the double-slit screen through which it passes is not necessary to obtain which-way information concerning the atom. This adaptation relied on entanglement between: 1) an atom's emitting a photon in one of two micromaser cavities as the atom passes through the cavity system and 2) the atom's subsequent passage through the fixed double-slit screen. If the development of this entanglement is interrupted in a suitable fashion, it appears one can obtain complete interference as if there were no micromaser cavity system or laser through which the atom traveled on its way to the double-slit screen. It appears one can alter the development of an atomic distribution through an action that does not involve direct physical interaction with atoms that become part of the distribution. Distinct atomic distributions can be created that can convey binary information, apparently without the velocity limitation of the special theory.

**Q1 196 Circular Polarization and Quantum Spin: A Unified Real-Space Picture of Photons and Electrons** ALAN M. KADIN, *Princeton Junction, NJ 08550* It is generally believed that no simple real-space semiclassical picture can consistently explain both a quantum wave and its spin. However, it is shown here [1] that a rotating vector field carrying angular momentum leads directly to the Einstein-de Broglie relations ($E = h\nu$ and $p = h/\lambda$, the heart of quantum mechanics), assuming only quantization of spin and Lorentz invariance of the phase angle. For electromagnetism, such a circularly polarized wave packet defines the photon. A very similar picture of a massive rotating vector field maps onto a complex wavefunction obeying the time-dependent Schrödinger equation for a particle such as the electron, with $m > 0$ and $v < < c$. This real vector field rotates about the spin axis at $mc^2/h \sim 10^{20}$ Hz. This suggests a unified picture whereby all fundamental quantum particles consist of such coherent wave packets of rotating spin fields, with composite particles deriving their quantum properties from the coherent rotations of their fundamental constituents. This represents a consistent interpretation of quantum mechanics, an alternative to the conventional statistical or Copenhagen interpretation. [1] A.M. Kadin, http://arxiv.org/abs/quant-ph/0508064

**Q1 197 Paradox in Wave-Particle Duality for Non-Perturbative Measurements** ERNST KNOESEL, *Rowan University* EDUARDO FLORES, KEITH F. McDONALD, SHARIAR S. AFSHAR, In a modified double-slit experiment we determined the complementary wave and particle aspect of light in the low flux regime beyond the limitations set by Bohr's Principle of Complementarity (BPC). We inferred the presence of sharp interference fringes, while we maintain, with very high probability, the information about the particular pinhole through which each individual photon had passed. This paradoxical result poses interesting questions on the validity of BPC in cases, which employ non-perturbative measurement techniques that evade Heisenberg's uncertainty principle and/or quantum entanglement.

**Q1 198 Interconvertibility of single-rail optical qubits*** BARRY SANDERS,† *Institute for Quantum Information Science, University of Calgary* DOMINIC BERRY, *The University of Queensland* A. I. LVOVSKY, *Institute for Quantum Information Science, University of Calgary* We show how to convert between partially coherent superpositions of a single photon with the vacuum using linear optics and postselection based on homodyne measurements. We introduce a generalized quantum efficiency for such states and show that any conversion that decreases this quantity is possible. We also prove that our scheme is optimal by showing that no linear optical scheme with generalized conditional measurements, and with one single-rail qubit input can improve the generalized efficiency.

**Q1 199 Magnetic Nanoparticles itin-vivo Detection of Transplant Rejection** E.R. FLYNN, *Senior Scientific* H.C. BRYANT,* *University of New Mexico* R.S. LARSON, *UNM* D.A. SERGATSKOV,† *UNM* Superparamagnetic nanoparticles are being used to develop methodology for the itin-vivo detection and imaging of immune system attacks on transplanted organs. The signature for impending rejection of a transplant is enhanced presence of T-cells. Magnetic nanoparticles coated with specific antibodies (CD-2 and CD-3) will target and attach to these T-cells. Approximately $3 \cdot 10^5$ nanoparticles can attach to each cell. When a pulsed external magnetic field is applied to the decorated cells for a fraction of a second, magnetic moments of the nanoparticles

aligned with the field. After the pulse is switched off, the net magnetic moment decays over several seconds by the Nèel mechanism. The resulting magnetic remanence field (typically $10^{-11}$ T) is measured using a multi-channel SQUID array. We present the data from live T-cells placed in realistic kidney phantom. The detection sensitivity was $\sim 2 \cdot 10^3$ T-cells - a small fraction of the number actually invading the rejected transplant. The 7-channel SQUID array allows us to image the cell clusters with a few millimeters resolution.

## Q1 200 POST-DEADLINE POSTER SESSION

**Q1 201 The silicon di-vacancy investigated with density functional theory** RYAN WIXOM, ALAN WRIGHT, *Sandia National Laboratories* As part of a larger effort to quantitatively model the behavior of point defects in silicon, we have investigated the silicon di-vacancy using density functional theory with three different exchange-correlation functionals and super-cells containing as many as 1000 atoms. The literature on this defect contains two proposed atomic structures and disagreement on the relative stability of the configurations. Our study indicates that the determination of the ground state configuration is dependant on the particular choice for exchange and correlation. We will report on the atomic and electronic structures of this defect as well as formation.

**Q1 202 The Effect of Nanoparticles on Selective Gas Permeability of Thin Film Membranes Using Supercritical Fluid** A. HO, R. ROSENFELD, *Hebrew Academy of the Five Towns & Rochway* J. JEROME, *Stony Brook University* Y.-S. SEO, T. KOGA, M. BRONNER, J. SOKOLOV, *Stony Brook University* M. RAFAILOVICH, *Stony Brook University* The addition of inorganic nanoparticles to polymer thin films can be highly beneficial to their lubrication, strength, and UV resistance. Since nanoparticles are rigid, they do not conform to the molecular order of the film, producing nano-scale voids. Consequently, the introduction of nanoparticles into polymer films alters their porosity and this phenomenon may be exploited to engineer selectively permeable membranes. Porosity can also be introduced by swelling the films in supercritical fluids and then rapidly removing the solvent by decreasing the pressure which converts the solvent to the gas state. In order to test this hypothesis, solutions were made of nanoparticles, clay or gold, with polystyrene or poly (methyl methacrylate) polymer to observe the change in porosity and to analyze its dependence on polymer structure and on polymer nanoparticles interactions. Samples were exposed to $ScCO_2$ at two different temperatures and pressures of 36[r]C, 1200psi and 50[r]C, 1450psi. We then measured the permeability of $O_2$ and $CO_2$ gas. We found that exposure to supercritical $CO_2$ greatly increased the permeability to both O2 and CO2 gas. The degree of change in permeability in the nano-composite film depended on the particle aspect ratio and intensity in the matrix.

**Q1 203 Accurate Determination of Pyridine – Poly (Amidoamine) Dendrimer Absolute Binding Constants with the OPLS-AA Force Field and Direct Integration of Radial Distribution Functions** YONG PENG, GEORGE KAMINSKI, OPLS-AA force field and direct integration of intermolecular radial distribution functions (RDF) were employed to calculate absolute binding constants of pyridine molecules to $NH_2$ and amide group hydrogen atoms in 0th and 1st generation poly (amidoamine) dendrimers in chloroform. The average errors in the absolute and relative association constants, as predicted with the calculations, are 14.1% and 10.8%, respectively, which translate into ca. 0.08 kcal/mol and 0.06 kcal/mol errors in the absolute and relative binding free energies. We believe that this level of accuracy proves the applicability of the OPLS-AA, force field, in combination with the direct RDF integration, to reproducing and predicting absolute intermolecular association constants of low magnitudes (ca. 0.2 – 2.0 range).

**Q1 204 Cell-fibril interaction in peptide based Hydrogels relative to hydrogel stiffness** HASSNA RAMAY, JOEL SCHNEIDER, DARRIN POCHAN, *University of Delaware* Peptide hydrogels are potentially ideal scaffolds for tissue repair and regeneration due to their ability to mimic natural extra cellular matrix. The 20 amino acid peptide MAX1 has been shown to fold and self-assemble into a rigid hydrogel based on environmental cues such as pH, salt, and temperature. The hydrogel is composed of network of short fibrils that are 3nm wide and up to several hundred nm long. In addition, slight design variations in the arms of the MAX1 sequence allow for tunability of the self-assembly/hydrogelation kinetics. In turn, by controlling hydrogel self-assembly kinetics, one dictates the ultimate stiffness of the resultant network. The cell-material interaction in normal and pathological conditions is investigated by 2D and 3D cell culture. As shown by optical and laser scanning confocal microscopy, cells are viable for 3 weeks and grow in clonogenic spheroids. Characterization of the proliferation, differentiation and constitutive expression of various osteoblastic markers is performed relative to hydrogel stiffness using spectrophotometeric methods. The well-defined, fibrillar nanostructure of the hydrogel directs the attachment and growth of osteoblast cells and dictates the mineralization of hydroxyapatite in a manner similar to bone. This study will enable control over the interaction of cellular systems with the peptide hydrogel for biomedical applications.

**Q1 205 Electronic structure calculations of the CePt3Si.** ARMANDO REYES-SERRATO, DONALD HOMERO GALVAN, *Centro de Ciencias de la Materia Condensada UNAM, Ensenada BC, Mexico* In a recent paper, Bauer et al. [1] synthesized CePt3Si, a heavy fermion material with both transitions magnetic and superconducting, without inversion center in the crystal structure. This compound is very interesting from many points of view. In the present work, we report the analysis of the electronic structure of the CePt3Si in normal state. The calculation was performed with the program package WIEN2k, which use density functional theory (DFT) based on the full-potential linearized augmented plane-wave (LAPW) plus local orbital (lo) method [2]. We report band structure, total and partial densities of states, 3D density of charge and Fermi surface. We analyze the possible implications of our results in the superconductivity of this material. [1] Phys. Rev. Letter **92**, 027003 (2004). [2] http://www.wien2k.at

**Q1 206 On the origin of the peak effect in the classical superconductor $Nb_3Sn$: the role of critical fluctuations** NICOLAS MUSOLINO, ROLF LORTZ, ALAIN JUNOD, *Department of Condensed Matter Physics, University of Geneva, 24 quai E. Ansermet, CH-1211 Geneva 4, Switzerland* NAOKI TOYOTA, *Physics Department, Graduate School of Science, Tohoku University, 980-8571 Sendai, Japan* We found a sharp pronounced peak effect in the magnetization and the isothermal magnetocaloric effect of a single crystal of the classical superconductor $Nb_3Sn$. The construction of a new type of isothermal calorimeter allowed us to study the underlying thermodynamics with an extremely high resolution. A small lambda-type anomaly could be resolved superimposed on the specific heat jump at $T_c$. It follows scaling laws as expected for the presence of critical fluctuations. We interpret this feature as the first clear observation of the regime of critical fluctuations in a classical superconductor. Simultaneous measurements of the specific heat and the isothermal magnetocaloric effect reveal that the peak effect occurs at the onset of fluctuations below the $H_{c2}$ line. No indications of a thermodynamic transition as the origin of the peak effect could be found. Our investigation favours thus rather a scenario in which a vortex lattice looses its topological order more continously due to the increasing strength of thermal fluctuations upon approaching the $H_{c2}$ line.

**Q1 207 Measurement of Local Reactive and Resistive Photoresponse of a Superconducting Microwave Device*** STEVEN M. ANLAGE, *CSR, Physics Dept., University of Maryland, USA* ALEXANDER P. ZHURAVEL, *Inst. for Low Temperature Physics, NASU, Kharkov, Ukraine* ALEXEY V. USTINOV, *Physics Institute III, University of Erlangen-Nuremberg, Germany* Despite the voluminous work on the nature of nonlinear effects in high-temperature superconductors (HTS), the causes are not completely clear and remain under debate. The Laser Scanning Microscope (LSM) is a spatially-resolved method that can simultaneously measure optical and high frequency properties of HTS devices. Earlier results showed high resolution images of non-uniform microwave current distributions near the edge of a patterned transmission line structure [A. P. Zhuravel, A. V. Ustinov, K. S. Harshavardhan, and S. M. Anlage, Appl. Phys. Lett. **81**, 4979 (2002)]. We have developed a new operational mode in which the microscope separately images the resistive and inductive components of the bolometric photoresponse. The two images show interesting and dramatic differences, leading to new insights about linear and nonlinear properties of HTS microwave devices.

**Q1 208 $^{11}B$ NMR Measurements of $TbB_4$** MOOHEE LEE, B.J. MEAN, K.H. KANG, J.H. KIM, I.N. HYUN, *Konkuk University, Seoul 143-701 Korea* B.K. CHO, *GIST, Gwangjoo 500-712, Korea* $^{11}B$ pulsed NMR measurements have been performed to investigate local electronic structure and 4f spin dynamics for $TbB_4$ single crystals. $^{11}B$ NMR spectrum shows a broad peak due to the 4f local moment. $^{11}B$ NMR shift and linewidth are huge and strongly temperature-dependent. In addition, both are proportional to magnetic susceptibility, indicating that the hyperfine field at the boron site originates from the 4f spins of Tb. The shift and the spin- lattice relaxation rate show high anisotropy for field parallel and perpendicular to the c-axis. Anisotropy of the shift and the relaxation rates are analyzed with the results of magnetization to understand the microscopic details of anisotropic spin dynamics.

**Q1 209 $^{27}Al$ NMR Measurements of $YMn_4Al_8$** MOOHEE LEE, *Konkuk University, Seoul 143-701, Korea* K. H. KANG, B. J. MEAN, J. H. KIM, I. N. HYUN, *Konkuk University, Seoul 143-701 Korea* B. K. CHO, *GIST, Gwangjoo 500-712, Korea* We have performed $^{27}Al$ nuclear magnetic resonance (NMR) measurements on the single crystals of $YMn_4Al_3$. $^{27}Al$ NMR spectrum, Knight shift, spin-lattice and transverse relaxation rates, $1/T_1$ and $1/T_2$, were measured down to 4 K at 8 T. Experimental results of the Knight shift and the nuclear spin lattice relaxation rate as well as magneto-resistance and susceptibility are analyzed and discussed in conjunction with the pseudogap behavior in the spin excitation spectrum.

**Q1 210 On a partial differential equation for determining the free energy of ternary mixtures from light scattering data** GEORGE THURSTON, CARL LUTZER, *Dept Mathematics, Rochester Institute of Technology* DAVID ROSS, *Kaiser Permanente* With use of an approximation appropriate for liquid mixtures, we formulate a well- established relation for light scattering from ternary mixtures as a second-order nonlinear partial differential equation, which relates the inverse Hessian of the intensive free energy to the efficiency of light scattered near the forward direction. We examine the mathematical conditions under which light scattering data can be a suitable input for solving this equation, thereby to determine the free energy in a nearly model-independent fashion. We find that within the thermodynamically stable and metastable regions of the phase diagram, composition curves that are nearly perpendicular to the gradient of the dielectric constant are also not what are termed characteristic for the light scattering partial differential equation. This criterion, in turn, implies that free energy solutions in the neighborhood of a such a composition curve can be self-consistently constructed by combining a known free energy gradient along the curve with light scattering data in the surrounding region. These considerations suggest that an experimental method comprising light scattering in the ternary composition triangle, combined with other means of finding the needed boundary conditions along a suitable curve, should in principle be capable of determining ternary mixture free energies without adopting specific free energy models in advance.

**Q1 211 Abstract Withdrawn**

**Q1 212 Direct microscopic observations of fluctuations near critical point** ANA OPRISAN, JOHN HEGSETH, *University of New Orleans* A series of experiments were performed on in orbit to study boiling, phase separation and fluctuations taking place in pure fluids (SF6) near critical point. A specially designed apparatus (ALICE 2) allowed a precise control of fluid's temperature. Local density fluctuations were observed by illuminating a cylindrical cell filled with the pure fluid near its liquid-gas critical point using a microscope and a video recorder. The apparatus was placed in orbit where there is no gravitational limitation in the size of the fluctuations. Using image processing techniques, we were able to estimate properties of the fluid from the recorded images showing fluctuations of the transmitted and scattered light. We found that the histogram of the image can be fitted by a Gaussian and by determining its width we were able to estimate these properties. We also estimated the wave number corresponding to the maximum of the radial average of the power spectrum and the corresponding characteristic length of the fluctuations.

**Q1 213 Quantum Phase Transitions and Entanglement in the Detuned Dicke Model** RU-FEN LIU, *Phys. Depart., National Cheng Kung Univ.* CHIA-CHU CHEN, *Phys. Depart., National Cheng Kung Univ.* The quantum phase transition of mono-mode Dicke models with two atoms is discussed and analytical results are presented. For arbitrary detuning, the exact spectrum and the concurrence of entanglement are calculated for the two-atom system. It is shown that sequential quantum phase transitions occur in this system. Evidences have been found to support that quantum phase transition and concurrence are uncorrelated in this particular model. Furthermore, the results of quantum phase transition with extra mode are also discussed.

**Q1 214 Disorder and size effects in Kondo lattice nanoparticles** YANG-YUAN CHEN, P. H. HUANG, M. N. OU, *Institute of Physics, Academia Sinica, Taipei, Taiwan 115 ROC* J. M. LAWRENCE, *Department of Physics and Astronomy, University of California, Irvine, CA92717 USA* C.H. BOOTH, *Chemical Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720-8175 USA* The evolution of Kondo interactions and magnetic order with size variation was revealed by the specific heat and magnetic susceptibility in a series of $CePt_2$ Kondo lattice nanoparticles with various sizes. In addition to the magnetic order suppression with size reduction, two regimes of size dependence of Kondo temperature $T_K$ was observed. As size d decreases from the bulk down to 22 nm firstly $T_K$ slightly decreases from 4.6 K to 3.7 K, as d further decreases, inversely $T_K$ increases up to 100 K for size d=3.8 nm. It is confirmed that the size-induced lattice disorders are responsible for the result for $d \geqslant 22$ nm, while the rapid increase of $T_K$ for d =3.8 nm is attributed to the lattice contraction and quantum size effects.

**Q1 215 Potential use of combining the diffusion equation with the free Shrödinger equation to improve the Optical Coherence Tomography image analysis*** DELIA CABRERA FERNANDEZ, HARRY M. SALINAS, *Bascom Palmer Eye Institute, Miami, FL* GABOR SOMFAI, *Semmelweis University, Dept. of Ophthalmology, Hungary* CARMEN A. PULIAFITO, *Bascom Palmer Eye Institute, Miami, FL* OPHTHALMIC IMAGING GROUP, BASCOM PALMER EYE INSTITUTE TEAM, DEPT OF OPHTHALMOLOGY, SEMMELWEIS UNIVERSITY COLLABORATION, Optical coherence tomography (OCT) is a rapidly emerging medical imaging technology. In ophthalmology, OCT is a powerful tool because it enables visualization of the cross sectional structure of the retina and anterior eye with higher resolutions than any other non-invasive imaging modality. Furthermore, OCT image information can be quantitatively analyzed, enabling objective assessment of features such as macular edema and diabetes retinopathy. We present specific improvements in the quantitative analysis of the OCT system, by combining the diffusion equation with the free Shrödinger equation. In such formulation, important features of the image can be extracted by extending the analysis from the real axis to the complex domain. Experimental results indicate that our proposed novel approach has good performance in speckle noise removal, enhancement and segmentation of the various cellular layers of the retina using the OCT system.

*This study is supported by a NIH R01 EY008684-10S1

**Q1 216 Simulation of $Xe_nAr_m$ Cluster Formation in a Molecular Beam: Comparison with Photoelectron Spectroscopy** FRANCOIS G. AMAR, THOMAS J. PRESTON, *Department of Chemistry, University of Maine, Orono, ME 04469-5706* We perform direct MD simulations of the formation of mixed $Xe_nAr_m$ clusters ($500 < n+m < 3000$) in a supersonic beam as a function of initial beam conditions. We then model the $4d_{5/2}$ (Xe) and $2p_{3/2}$ (Ar) core hole photoelectron spectra of these clusters and compare them to the experimental spectra of Tchaplyguine itet al[1]. The predicted spectra are calculated as the sum of final state energy shifts of the ionized atoms (within the cluster) relative to the isolated gas phase ion using a self-consistent polarization formalism. We use the results of our earlier calculations on pure argon and xenon clusters [2] to determine the appropriate inelastic mean free path value for the signal electrons leaving the mixed clusters. These results allow us to gain a refined understanding of the size, stoichiometry, and core/shell structure of these mixed clusters. [1] M. Tchaplyguine, itet al, Phys. Rev A **69**, 031201 (2004); [2] F. Amar, itet al, JCP **122**, 244717 (2005).

**Q1 217 Helium Nanodroplets: spectroscopy and density-functional calculations** ROMAN SCHMIED, KEVIN K. LEHMANN, *Dept. of Chemistry, University of Virginia* Helium nanodroplet spectroscopy has shown to be an excellent tool for studying superfluid helium in nano-scale geometries. Experimental signatures of superfluidity are the free rotation of many molecules in helium nanodroplets, and the droplet phonon spectra observed in electronic transitions of molecular dopants. We present new results and interpretations from a study of helium nanodroplets using time- dependent density-functional theory and its normal-mode analysis.

**Q1 218 Chaotic Dynamics of a Harmonic Oscillator Interacting Linearly with a Free Particle*** ALEXANDER SILVIUS, *University of Missouri - Rolla* STEPHAN DE BIÈVRE, *Université des Sciences et Technologies de Lille* PAUL PARRIS, *University of Missouri - Rolla* We study the closed Hamiltonian dynamics of a free particle moving on a ring, over one section of which it interacts linearly with a single harmonic oscillator. On the basis of numerical and analytical evidence, we conjecture that at small positive energies the phase space of our model is completely chaotic except for a single region of complete integrability with a smooth sharp boundary showing no KAM-type structures of any kind. This results in the cleanest mixed phase space structure possible, in which motions in the integrable region and in the chaotic region are clearly separated and independent of one another. For certain system parameters, this mixed phase space structure can be tuned to make either of the two components disappear, leaving a completely integrable or completely chaotic phase space. For other values of the system parameters, additional structures appear, such as KAM-like elliptic islands, and one parameter families of parabolic periodic orbits embedded in the chaotic sea. The latter are analogous to bouncing ball orbits seen in the stadium billiard. The analytical part of our study proceeds from a geometric description of the dynamics, and shows it to be equivalent to a linked twist map on the union of two intersecting disks.

*This work supported by NSF grants DMR-0097210 and INT-0336343.

**Q1 219 Dielectric fluctuations and the origins of non-contact friction** SEPPE KUEHN, ROGER F. LORING, JOHN A. MAROHN, *Department of Chemistry and Chemical Biology, Cornell University, Ithaca, NY 14853* Dielectric fluctuations underlie a wide variety of physical phenomena, from ion mobility in electrolyte solutions and decoherence in quantum systems, to dynamics in glass-forming materials and conformational changes in proteins. Here we show that dielectric fluctuations also lead to non-contact friction. A detailed understanding of non-contact friction is essential to micromechanical systems and the continued success of high sensitivity scanned probe microcopies such as magnetic resonance force microscopy. We study non-contact friction by using high sensitivity, custom fabricated, single crystal silicon cantilevers to measure energy losses over poly(methyl methacrylate), poly(vinyl acetate), and polystyrene thin films. We present a new theoretical analysis, relating non-contact friction to the dielectric response of the film, which is consistent with our experimental observations. We believe this constitutes the first direct, mechanical detection of friction due to dielectric fluctuations, and establishes a new route to the measurement of these fluctuations at the nanoscale.

**Q1 220 Conductance Behavior of Molecularly Linked Gold Nanoparticle Films Near the Metal-Insulator Transition** JEFFREY DUNFORD, YOSHINORI SUGANUMA, AL-AMIN DHIRANI, BRYAN STATT, *University of Toronto* Self-assembled molecularly-linked metal nanoparticle films exhibit interesting electronic behavior that can range from insulating to metallic. In particular, the electronic behavior of 1,4-butanedithiol-linked gold nanoparticle films can be tuned by varying film thickness. We have investigated the temperature (T) dependence of the differential conductance (g) of 1,4-butane dithiol linked Au nanoparticle films. On the insulating side of the transition, the conductance behaves as $g = g_0 \exp[-(T_0/T)^{[**raise**]0.7ex1[**lower**]0.7ex2}]$. Qualitatively, this is consistent with an Efros- Shklovskii ''variable range hopping'' model based on a competition between Coulombic and intercluster tunnelling processes. However, we find that hopping distances are too large (62 nm to 720 nm at 100 K) to be consistent with tunneling between clusters, and tend to scale with cluster size. We propose a modified ''quasilocalized hopping'' model based on competition between single-electron cluster charging and intracluster electron backscattering to explain this temperature dependence.

**Q1 221 Spin relaxation in a GaAs quantum dot embedded inside a suspended phonon cavity*** YING-YEN LIAO, *Department of Electrophysics, National Chiao-Tung University, Hsinchu 300, Taiwan* YUEH-NAN CHEN, *Department of Electrophysics, National Chiao-Tung University, Hsinchu 300, Taiwan* DER-SAN CHUU, *Department of Electrophysics, National Chiao-Tung University, Hsinchu 300, Taiwan* TOBIAS BRANDES, *School of Physics and Astronomy, The University of Manchester P.O. Box 88, Manchester, M60 1QD, U.K.* The phonon-induced spin relaxation in a two-dimensional quantum dot embedded inside a semiconductor slab is investigated theoretically. An enhanced relaxation rate is found due to the phonon van Hove singularities. Oppositely, a vanishing deformation potential may also result in a suppression of the spin relaxation rate. For larger quantum dots, the interplay between the spin orbit interaction and Zeeman levels causes the suppression of the relaxation at several points. Furthermore, a crossover from confined to bulk-like systems is obtained by varying the width of the slab.

*This work is supported partially by the National Science Council, Taiwan under the grant numbers NSC 94-2112-M-009-019, NSC 94-2120-M-009-002 and NSC 94-2112-M-009-024.

**Q1 222 Optical properties of semiconductor nanocrystals in the tight-binding (TB) approximation** ANDREW SHABAEV, EUGENE TSIPER, ALEXANDER EFROS, DIMITRIS PAPACONSTANTOPOULOS, *Naval Research Laboratory and George Mason University* Tight-binding (TB) approach is very attractive for computing electronic properties of semiconductor nanocrystals since it can handle large numbers of atoms, and since nanocrystals of arbitrary shape can be studied. TB approach provides realistic boundary conditions at the surface, which are often defined with uncertainty in the effective mass approximation. This is especially important in small nanocrystals, where a large fraction of atoms belongs to the surface. For example, in a 1000-atom Si nanocrystal about 2/3 of all atoms have less than four nearest neighbors. Successful TB approaches, such as NRL-TB method, exist to compute electronic structure of various bulk materials. We use NRL-TB to compute electronic transitions in nanocrystals of arbitrary shape. It appears, that a given TB parameterization that yields adequate electronic structure is incomplete in terms of predicting oscillator strengths of the transitions, in contrast to a common belief. Such TB parameterization must be augmented with additional quantities that contribute to the transition dipole matrix elements between localized orbitals. We thus resolve the existing controversy, despite the arguments that these extra contributions are problematic and should not be incorporated into TB. We also discuss practical ways to calculate the extra quantities, which are not supplied by the conventional TB parameterizations.

**Q1 223 Impurity mode techniques applied to photonic crystal slabs** ARTHUR MCGURN, *Western Michigan University* A theoretical treatment is given of the modes of a photonic crystal slab containing an impurity. The photonic crystal slab is formed by embedding an hexagonal lattice array of dielectric cylinders in a background slab of uniform dielectric medium. This creates a free standing slab with a periodic patterning. The solution of Maxwell's equations for the modes of the slab are given as an expansion in the waveguide and radiative modes of a uniform slab of dielectric medium. The density of modes in frequency space is presented for the photonic crystal slab in the absence of an impurity. The impurity modes for a single site impurity introduced into the center of the photonic crystal patterning are computed using Green's function methods. Bound state impurities and in band resonances are studied and used to explain recent experimental results on photonic crystal light sources.

**Q1 224 Fabrication of nanoscale magnet-tipped cantilevers for magnetic resonance force microscopy** STEVEN A. HICKMAN, *Department of Chemistry and Chemical Biology, Cornell University* SEAN R. GARNER, *Department of Physics, Cornell University* LEE E. HARRELL, *Department of Physics, United States Military Academy* SEPPE KUEHN, JOHN A. MAROHN, *Department of Chemistry and Chemical Biology, Cornell University* Magnetic resonance force microscopy(MRFM) is a promising new technique for acquiring magnetic resonance images of a single molecule; to date we have demonstrated a sensitivity of approximately 10,000 proton spins. In MRFM the force exerted on the

cantilever, per spin, is proportional to the field gradient from the cantilever's magnetic tip. To increase the force requires shrinking the magnet size. Achieving the attonewton force sensitivity necessary to image single spins requires mitigating surface induced dissipation. We choose to meet both of these conditions by creating nanoscale magnets extending from the tips of silicon cantilevers. We will present a 50-nm wide overhanging cobalt magnet fabricated by a process involving electron beam lithography and anisotropic KOH etching. This process can be integrated into a fabrication protocol for ultrasensitive silicon cantilevers. With these cantilevers we expect a sensitivity of better than 1000 protons.

**Q1 225 Electrically Controlled Bandgap in a Chiral Material** JUAN REYES CERVANTES, AKHLESH LAKHTAKIA, *Instituto de Física UNAM* The propagation of light along the axis of nonhomogeneity of a structurally chiral medium (SCM) under the influence of a low– frequency (dc) electric field aligned along the same axis is investigated. The Pockels effect is assumed to occur, and the SCM is taken to possess locally a $\bar{4}2m$ point group symmetry. The frequency–domain Maxwell curl equations are cast in a $4\times 4$ matrix representation, and the Oseen transformation is invoked. The band structure is analyzed, as are also the eigenvectors as well as the transfer matrix. Finally, the reflection and transmission of a plane wave due to a SCM of finite thickness is considered. The low–frequency electric field is shown to control the bandgap.

**Q1 226 Organic Solar Cell with Carbon Nanotubes as Anode*** ROSS ULBRICHT, XIAOMEI JIANG, KANZAN INOUE, KAMIL MIELCZARECK, CARLOS MEDINA, SERGEY LEE, ANVAR ZAKHIDOV, Organic, polymer based solar cells present a low cost more versatile alternative to the current inorganic silicon based solar cells. In this research, carbon nanotubes have been used to replace the conventional anode used, indium tin oxide. Carbon nanotubes exhibit electronic, optical and mechanical properties desirable for polymeric based organic solar cells. In this study, an oriented muliwall carbon nanotube sheet is used as the hole collecting electrode with RR-P3HT as the donor material and PCBM as the acceptor material. An open circuit voltage of 0.57V, a short circuit current of 5.53mA/cm2, a fill factor of 0.37, and an efficiency of 1.16% has been obtained. Performance dependence on incident light intensity and spectral studies along with other various investigations are presented.

*The authors thank the Air Force Office of Scientific Research for the financial support of this work

**Q1 227 Theorems Determining Reciprocal and Nonreciprocal Properties of Negative Refractive Bi-Crystal Heterostructures** CLIFFORD KROWNE, *Naval Research Laboratory* One of the most interesting questions in regard to the negative refractive bicrystal heterostructure is what multi-terminal electronic characteristics it may possess. The heterostructure possesses a symmetry breaking operation creating asymmetric fields associated with the SO(2) rotation group [1]. Two terminal behavior may be addressed by examining generalized theorems for complex anisotropic media [2]. Applying the anisotropic reaction theorem to subregions of the heterostructure, and then to the composite structure, we find that passive nonreciprocity [3] is not possible while active nonreciprocity is possible as mentioned in [4]. Possible device applications include beam steering, and isolation devices requiring direction sensing control. Simulations show what happens to the asymmetry when making the heterostructure macroscopically using LINbO3 crystals versus using nanostructure technology which would work with ferroelectric films deposited by MBE. A fabrication effort used to build the structure, with metal patterning to test a derivative property of the asymmetry, namely terminal reciprocity/nonreciprocity, will be discussed too [5]. [1] C. M. Krowne, PRL 93, 053902, 30 July 2004. [2] C. M. Krowne, IEEE Trans. Ant. Propag. 32, 1224 Nov. 1984, [3] C. M. Krowne, IEEE Trans. MTT 53, 1345, 2005, [4] C. M. Krowne, arXiv.org/abs/cond-mat/0408369, 17 Aug. 2004. [5] Private commun. S. W. Kirchoefer, J. A. Bellotti, and J. M. Pond, 2005.

**Q1 228 Energetic Material Simulations Framework** WILLIAM MATTSON, BETSY RICE, *US Army Research Laboratory* We have created a computational framework for the easy implementation of the modeling needs of the advanced energetic materials (AEM) community, with rapid turnaround. The framework constructs simulations described in eXtensible Markup Language (XML) from a set of components in shared object libraries. The complete set of standard molecular simulation components can be combined in any fashion creating typical simulations and providing unanticipated functionality. The framework includes multimillion atom molecular dynamics in a several thermodynamic ensembles, including the recently developed uniaxial Hugoniostat method. This constrains the system to states that correspond to points on the shock Hugoniot curve. It also includes ab initio crystal prediction capability. This procedure predicts the crystal structure and density of a solid using only the molecular structure of a single molecule. This predictive capability is considered crucial to the design and development process of AEM, since one of the fundamental properties required for the initial screening of a candidate energetic material is its crystalline density.

**Q1 229 The radiation equilibrium is classical** V. GURUPRASAD, *Inspired Research, NY* By definition, standing wave modes cannot interact among themselves, plus non-zero temperature means real walls must vibrate. Modal interaction by Doppler shifts at the walls is thus an unavoidable premise in cavity equilibrium, but it also suffices to yield Planck's law itclassically, as follows. $\lambda/2$-intervals of the modes are immutable energy-bearing entities under these thermalizing interactions, like molecules in the kinetic theory, as Doppler shifts preserve phase and amplitude, thus only compressing or dilating the $\lambda/2$-intervals in time. The premise is really a conceptual aid, as energy immutability is guaranteed by definition: $E(\lambda/2) = \int_0^{\lambda/2} |a\sin(2\pi x/\lambda)|^2\, dx = \int_0^{\pi} a^2 \sin^2\theta\, d\theta$, independent of $\lambda$. Therefore, Boltzmann equipartition must be applied to these intervals, instead of to full modes as in Rayleigh-Jeans theory, and it dictates a common mean energy $u$, not $u \neq k_B T/2$ – modes are mere Fourier components, not full particulate entities. The intervals yield $E = h\nu$ with $h \equiv u$ as the number of such intervals in a mode is proportional to its frequency. Mode closure sets under the thermalizing interactions form Planck's harmonic oscillators – as the intervals are immutable, interacting modes can only differ by whole number of intervals, hence must be harmonically related, and itreplace each other by exchanging intervals. The energy expectation at any $\lambda$ is then an average over any such mode closure set, yielding Planck's law itwithout assumptions and itwithout breaking from classical physics. The result identifies $h \equiv u$ as the analogue of $k_B$ for the frequency domain.

**Q1 230 Experimental one-way quantum computation using linear optics** PHILIP WALTHER, *Institute of Experimental Physics, University of Vienna, Boltzmanngasse 5, 1090 Vienna, Austria* KEVIN RESCH, *University of Queensland, Physics Department, AUS* TERRY RUDOLPH, *QOLS, Blackett Laboratory, Imperial College London, London SW7 2BW, UK* EMMANUEL SCHENCK, *Institute of Experimental Physics, University of Vienna, Boltzmanngasse 5, 1090 Vienna, Austria* HARALD WEINFURTER, *Department of Physics, Ludwig Maximilians University, D-80799 Munich, Germany* VLATKO VEDRAL, *The School of Physics and Astronomy, University of Leeds, Leeds LS2 9JT, UK* MARKUS ASPELMEYER, ANTON ZEILINGER, *Institute of Experimental Physics, University of Vienna, Boltzmanngasse 5, 1090 Vienna, Austria* Standard quantum computation is based on a universal set of unitary quantum logic gates which process qubits. In contrast to the standard quantum model, Raussendorf and Briegel proposed the one-way quantum computer, based on a highly-entangled cluster state, which is entirely different. We have experimentally realized four-qubit cluster states encoded into the polarization state of four photons. We fully characterize the quantum state by implementing the first experimental four-qubit quantum state tomography. Using this cluster state we demonstrate the feasibility of one-way quantum computing through a universal set of one- and two-qubit operations. Finally, our implementation of Grover's search algorithm demonstrates that one-way quantum computation is ideally suited for such tasks.

**Q1 231 Direct current bias effect on the magnetoresistance of submicron spin-valve ellipses*** CHIEN-TU CHAO, S.G. LAI, JONG-CHING WU, LANCE HORNG, *National Changhua University of Education* TE-HO WU, *National Yun-lin University of Science & Technology* S. YOSHIMURA, M. TSUNODA, M. TAKAHASHI, *Tohoku University* TAIWAN SPIN RESEARCH CENTER TEAM, Submicron spin-valve devices with nonmagnetic I/V leads have been successfully fabricated using E-beam lithography in conjunction with an ion beam etching. The layer structures are SiO2/Ta(5nm)/ NiFe(2nm)/ MnIr(10nm)/ CoFe(2nm)/Cu(2.5nm)/CoFe(2nm)/NiFe(3nm)/Cu(1nm)/ Ta-O(3nm) prepared by DC sputtering. Low field ac MR measurements were carried out with an external magnetic field applied parallel to the biasing/current direction. A significant shift on minor loop, with respect to that of the non-patterned film, is associated with an antiferromagnetic coupling resulted from the pinned layer's stray field after patterning. In addition, a direct current bias was superimposed to the low field ac for the studies of joule heating and possible spin transfer torque effect. In comparison to the MR measured at various ambient temperatures Joule heating effect was identified from the resistance background change. Extra features were developed during the magnetization reversal that may be associated with spin torque effect. Details of the MR minor loops regarding to the magnetization evolution and the switching mechanism will be presented.

*Work is supported by the Ministry of Economic affairs of Taiwan.

**Q1 232 Interface Mott Transition and Colossal Electroresistance** TAKASHI OKA, *CERC, National Institute of Advanced Industrial Science and Technology (AIST)* NAOTO NAGAOSA, *University of Tokyo* Colossal electroresistance – devices with huge nonlinear $I - V$ with hysteresis – found in strongly correlated materials is now receiving wide interest as a candidate of a novel non-volatile memory. In order to design such devices, it is important to understand how phase transition takes place at the interface between SCES and an electrode. We propose a simple theoretical scheme to calculate the electronic state at such interfaces. A density matrix renormalization group (DMRG) calculation of a 1D tight binding model is performed, where we find that the Mott transition takes place, and by altering the external bias, we can change the transport property drastically from insulating to Ohmic (metallic). Next, we propose a mechanism of colossal electroresistance based on first order metal-insulator transition. In this mechanism, the switching between on and off states is realized by a hysteresis loop of bias voltage crossing the phase coexistence regime near the transition. (cond-mat/0509050, to appear in Phys. Rev. Lett.)

**Q1 233 Magnetic field effects in double-walled carbon nanotubes** ANDREA LATGE, *Universidade Federal Fluminense* DANIEL GRIMM, *Leibiniz Institute of Dresden* MAURO FERREIRA, *Trinity College - Dublin* Double-wall carbon nanotubes (DWCNs) are coaxial two-tube systems which are now considered very important from their mechanical and electronic properties. They may be achieved, for instance, by peapod-derived methods or synthetized by pulsed arc dicharge processes. The distance between both cilinders are quite the same of the one found between carbon planes in graphite structures, and the correspondent intertube electronic interactions (van der Waals energies) are also much inferior than the electronic correlation within each single tube. Here we present a theoretical discussion of electronic and transport properties of a particular family of DWCNs named commensurate structures of the armchair (n,n)@(2n,2n) and zigzag (n,o)@(2n,0) types. Emphasis is given on the role played by the geometrical aspects of the tubes and the relative atomic positions on the local density of states and conductance of the systems. We investigate the origin of the conductance suppression and the possibility of founding Aharonov-Bohm effects in the double walled carbon when applying a magnetic field along the axial direction. The field is theoretically described by following the Peierls approximation into the hopping energies and by adding a Zeeman energy in the diagonal term of the tight-binding Hamiltonian. This should be interesting not only for the basic understanding of DWCNs but also to allow a characterization upon their responses under external fields.

**Q1 234 Simple, Rapid Chirality Characterization of Single Walled Carbon Nanotubes** PHILLIP WILLIAMS, *National Institute of Aerospace* MIN NAMKUNG, *NASA Goddard Space Flight Center* CANDIS MAYWEATHER, JOSLYN PERKINS, *Spelman College* BUZZ WINCHESKI, *NASA Langley Research Center* CHEOL PARK, *National Institute of Aerospace* JUOCK NAMKUNG, *Naval Air Warfare Center* Raman scattering and optical absorption spectroscopy are used for the chirality characterization of single wall carbon nanotubes (SWNTs) dispersed in various solvent systems. Radial breathing mode (RBM) Raman peaks for semiconducting and metallic SWNTs are identified by directly comparing the Raman spectra with the Kataura plot. The SWNT diameters are then calculated from these resonant peak positions. Next, a list of (n, m) pairs, yielding the SWNT diameters within a few percent of that obtained from each resonant peak position, is established. The interband transition energies for the list of SWNT (n, m) pairs are calculated based on the tight binding energy expression for each list of the (n, m) pairs, and the pairs yielding the closest values to the corresponding experimental optical absorption peaks are selected. The results reveal the most

probable chiralities for the semiconducting nanotubes and for the metallic nanotubes present in a batch of SWNTs. Directly incorporating the Raman scattering data into the optical absorption spectra, the present method is considered the simplest practical technique currently available.

**Q1 235 Reentrant Disordering of Colloidal Molecular Crystals on 2D Periodic Substrates** MICHAEL MIKULIS, *Department of Physics, University of California, Davis* CYNTHIA REICHHARDT, CHARLES REICHHARDT, *Center for Nonlinear Studies and Theoretical Divison, Los Alamos National Laboratory* RICHARD SCALETTAR, GERGELY ZIMANYI, *Department of Physics, University of California, Davis* We study colloidal ordering and disordering on two-dimensional periodic substrates where the number of colloids per substrate minima is two or three. The colloids form dimer or trimer states with orientational ordering, referred to as colloidal molecular crystals. At a fixed temperature such that, in the absence of a substrate, the colloids are in a triangular floating solid state, upon increasing the substrate strength we find a transition to an ordered colloidal molecular crystal state, followed by a transition to a disordered state where the colloids still form dimers or trimers but the orientational order is lost. These results are in agreement with recent experiments.

**Q1 236 Behavior of $(Pb_{0.9}Ba_{0.05}Sr_{0.05})(Zr_{1-x}Ti_x)O_3$ solid solutions in the vicinity of morphotropic boundary** V. SOBOLEV, *Physics Department, South Dakota School of Mines and Technology, Rapid City, SD 57701* V. ISHCHUK, *Institute for Single Crystals of National Academy of Sciences of Ukraine, Kharkov, 61001, Ukraine* V. BAUMER, *Institute for Single Crystals of National Academy of Sciences of Ukraine, Kharkov, 61001, Ukraine* T. TEPLITSKAYA, *Institute for Single Crystals of National Academy of Sciences of Ukraine, Kharkov, 61001, Ukraine* $(Pb_{0.9}Ba_{0.05}Sr_{0.05})(Zr_{1-x}Ti_x)O_3$ series of solid solutions possess rather narrow width of the morphotropic region that does not exceed 5% (determined by X-ray diffraction studies). Using a modified ceramic technique, we obtained samples with a grain size of the order of 20-25 $\mu$m. We performed detailed investigations of piezoelectric and dielectric properties of these samples. It is shown that the temperature interval of the diffuse phase transition depends on the position of the given solid solution in the ''Ti concentration – Temperature'' phase diagram. The maximum interval is observed in the middle of the morphotropic region. There exists a temperature interval of the order of several decades of degrees above the Curie point where piezoelectric resonance can be observed. The width of this temperature interval reduces considerably when solid solution composition moves from morphotropic region.

**Q1 237 Electroabsorption of wide bandgap semiconductors GaN and ZnO: the theory and experiments** XIYAO ZHANG, *Department of Physics, North Carolina State University* ANDREW OBERHOFER, JOHN MUTH, *Department of Electrical and Computer Engineering, North Carolina State University* SEMICONDUCTOR PHOTONICS RESEARCH TEAM, Dow and Redfield developed a theoretical model in 1970's to describe the change of the broadening of exciton absorption peak and the tilting of band edge in semiconductor under an electrical field. In this work, we apply this generic model to different kinds of wide bandgap semiconductors, such as GaN and ZnO. The exciton electroabsorption problem can be treated non-perturbatively in the center-of-mass coordinate as one electron in a Coulomb potential and an electrical field. The corresponding three-dimensional Schrdinger equation was solved for the electron-hole envelope wavefunction at the origin and the density of states per unit energy by introducing parabolic coordinates. Elliot formula was then used to calculate the actual optical electroabsorption coefficient. Thermal broadening of the exciton absorption peak was considered by convoluting a Guassian function, whose line width is related to the temperature. Experimental temperature dependent absorption data of GaN and ZnO were measured from 77K to 300K. The electroabsorption spectra of GaN in an optical modulator structure have also been examined. These experiment results were used to verify the theoretical model of electroabsorption of wide bandgap semiconductors.

**Q1 238 Satellite bands in the rotational spectrum of doped helium clusters** TATJANA SKRBIC, SAVERIO MORONI, STEFANO BARONI, *INFM-DEMOCRITOS and SISSA, Trieste, Italy* Recent measurements of infrared spectra of Carbon dioxide molecules embedded in Helium droplets reveal a weak satellite band (SB) accompanying a sharp R(0) rovibrational line. By reanalyzing previous quantum Monte Carlo calculations of the rotational dynamics of various dopant molecules in Helium clusters, we find indeed evidence for rotational excitations with energies and spectral weights close to the measured values of the SB. We present new simulations, in which specifically devised imaginary-time correlation functions are introduced for an explicit theoretical characterization of individual excitations, as well as for enhanced computational efficiency in the calculation of weak spectral features. The proposed assigment of the SB to a coupled rotational state of the molecule and a ring of Helium atoms is discussed.

**Q1 239 Surface Studies of Enhanced Metal/Carbene Contacts** MARCUS LAY, *University of Georgia* GEORGE FLYNN, COLIN NUCKOLLS, GEORGE TULEVSKI, MIKE STEIGERWALD, MARK HYBERTSEN, *Columbia University* Scanning tunneling microscopy and spectroscopy (STM and STS) have proven invaluable in understanding and manipulating the physical and electronic properties of molecular-scale systems. Such systems show great promise in current and future electronic applications. Indeed, self-assembled monolayers (SAMs) composed of alkanethiols have been extensively explored as a possible route to formation of metal-organic semiconductor contacts. While S is effective in this function, it behaves more as a capacitor than a conductor at the metal-adsorbate interface. This presentation will focus on investigations of the formation of metal-carbene complexes. For molecular electronics applications, conjugated metal-carbenes are expected to exhibit significantly greater conductance in transistor applications than corresponding thiols. A particular emphasis of this presentation is the structural and electronic information yielded by ultra-high vacuum (UHV) STM/STS studies of the formation of a Ru-carbene from diazoalkane precursors. Early

theoretical predictions and UHV-STS indicate a strong coupling of the HOMO for bromophenyl diazomethane to the Ru d-band.

**Q1 240 Abstract Withdrawn**

**Q1 241 Single Photon Transport In One-Dimensional Circuit Quantum Electrodynamics Systems** JUNG-TSUNG SHEN, SHANHUI FAN, *Stanford University* Interesting transport properties of a single microwave photon emerge when a superconducting quantum bit in a cavity is coupled to a one-dimensional waveguide. Here we adopt a real-space model Hamiltonian to give a unified approach which accounts for the recent experimental results, and make new predictions on the properties of single photon transport, such as general Fano lineshape, symmetric vacuum Rabi splitting for leaky cavity at resonance, and one-photon switching capability. We further exploit the large tunability of the qubits to show that further interesting one-photon transport properties can emerge in multiple-qubit system, especially when the transition frequencies are dynamically controlled. In particular, having two qubits coupled to the waveguide gives rise to a transmission lineshape for electromagnetic wave that is analogous to the electromagneically induced transparency (EIT) in atomic system. Furthermore, by cascading these double-qubit structure together to form an array, and by dynamically tuning the transition frequency of the qubits, we show that a single photon pulse can be stopped, stored, and time-reversed in the system, leading to highly nontrivial information processing capabilities on chip. Moreover, with properly designed array, two photons can be stopped and stored in the system at the same time. Finally, the unit cell of the array can be designed to be of deep sub-wavelength scale, thereby realizes the miniaturization of the circuit.

**Q1 242 Electric Characterization of $FeSi_2$ Nanowires by Conductive-AFM** SHENGDE LIANG, *Arizona State University* Since continuing miniaturization of silicon electronics encounters the limits of lithography, silicide nanowires are proposed to act as both devices and the wires that access them in bottom-up fabrication scheme. Iron silicides nanowires can be metallic, magnetic and semiconducting depending on different phases it takes, which make it promising for nanodevices design. Here we characterized Schottky Barrier Height (SBH) of iron silicide nanowires on n-type silicon, which is not uniform ranging from 0.35 to 0.8eV with diamond coated tips. To measure electric transport properties within a single nanowire, we deposited a gold pad to partially cover one nanowire, and use diamond coated tip as another terminal. Nanowires with dimension of 5nm high by 10nm wide by several micrometer long have resistance about 20k ohm at room temperature, this is about 4 times larger than bulk iron silicide resistivity. We tried different metals coated tips and tips with different force constants. Diamond coated tips are most wear-resistant, but have highest contact resistance, which is estimated to be 20k ohm. Other metal coated tips, such as PtIr, PtCr coated tips, have lower contact resistance, less than 1k ohm, but these tips apex are easily scanned off. Suitable contact force were also calibrated to be around 200nN, too strong force will damage nanowire and tip coating layer, while too weak contact lead to high contact resistance.

**Q1 243 Novel commensurability effects in superconducting films with antidot arrays*** GOLIBJON BERDIYOROV, *Department of Physics, University of Antwerp, Belgium* MILORAD MILOSEVIC, *Department of Physics, University of Antwerp, Belgium* FRANCOIS PEETERS, *Department of Physics, University of Antwerp, Belgium* CONDENSED MATTER THEORY GROUP TEAM, Vortex pinning by arrays of microholes is already a well established tool for enhancing the critical current in superconducting films. The pronounced peaks in $j_c(H)$ characteristics at so-called matching fields are generally attributed to the collective locking of vortices to the pinning sites. However, the issues of symmetry and composition of the resulting vortex lattice are often oversimplified. We investigated in detail the vortex configurations in superconducting films with regular antidot-arrays within the non-linear Ginzburg-Landau theory, where demagnetization effects and overlapping vortex cores are fully taken into account (contrary to the London approach). In addition to the well-known matching phenomena, we predict: (i) the nucleation of giant-vortex states at interstitial sites; (ii) the combination of giant- and multi-vortices at rational matching fields; and (iii) for particular interstitial vorticity, the symmetry imposed creation of vortex-antivortex configurations.

**Q1 244 Threefold onset of vortex loops in superconductors with a magnetic core*** MAURO DORIA, *Instituto de Fisica, Universidade Federal do Rio de Janeiro, Brazil.* MILORAD MILOSEVIC, *Department of Physics, University of Antwerp, Belgium* ANTONIO ROMAGUERA, *Instituto de Fisica, Universidade Federal do Rio de Janeiro, Brazil.* FRANCOIS PEETERS, *Department of Physics, University of Antwerp, Belgium.* Superconductivity and magnetism are known to coexist inside several compounds, such as $RuSr_2LnCu_2O$ and $ErNi_2B_2C$. Recently, artificially nano-engineered superconductors with magnetic inclusions have been realized experimentally. In mesoscopic samples, where the ratio volume to area is small, the vortex patterns vary according to the sample symmetry. On the other hand, magnetic inclusions give rise to vortex loops inside the superconductor. To capture these aspects, we consider theoretically a sub-micron superconductor (e.g. sphere) with a static magnetic moment in its center in order to observe these confined vortex states. The 3D Ginzburg-Landau theory is applied and solved in the finite difference scheme, from which we obtain the very complex 3D vortex configurations. For large samples, when the influence of the boundary diminishes, we found that vortex loops always nucleate in threes. The final superconducting state is characterized by the number of created vortex loops and the number of vortex-antivortex pairs that spring to the surface.

**Q1 245 The coexistence of type-I and type-II superconductivity in mesoscopic single crystals** MILORAD MILOSEVIC, *1* FRANCOIS PEETERS, *1* ANDREAS RYDH, *2,3* MICHAEL ZACH, *2* RUOBING XIE, *2* ZHILI XIAO, *2* DANIEL ROSENMANN, *2* ULRICH WELP, *2* WAI-KWONG KWOK, *2* GEORGE CRABTREE, *2* SIMON BENDING, *4* 1 DEPARTMENT OF PHYSICS, UNIVERSITY OF ANTWERP, BELGIUM. TEAM, 2 MATERIALS SCIENCE DIVISION, ARGONNE NATIONAL LABORATORY, USA. TEAM, 3 DEPARTMENT OF PHYSICS, STOCKHOLM UNIVERSITY, SWEDEN. TEAM, 4 DEPARTMENT OF PHYSICS, UNIVERSITY OF BATH, UK. TEAM, We show that the well established criteria for type-I to type-II transitions in bulk materials do not apply to mesoscopic superconductors, as the dual point depends both on the material properties and on temperature. In electrochemically formed triangular Pb single crystals, we even found the coexistence of both types of superconductivity – while retaining Meissner behavior with increasing magnetic field all the way through the superheated phase, the sample can still capture vortices in the metastable regime. When the field is swept back, in realistic type-I structures with intrinsic pinning, the vortices can survive in the sample even when the field changes polarity, contrary to conventional behavior. All findings are substantiated by state-of-the-art 3D Ginzburg-Landau simulations and $\mu$-Hall probe measurements.

**Q1 246 An Accurate Computation of the de Haas-van Alphen frequencies and effective masses of $NbSe_2$** CHRISTOPHER HOWELLS, MICHELLE JOHANNES, IGOR MAZIN, *Naval Research Laboratory* $NbSe_2$ is a layered superconducting material with a co-existing nearly commensurate CDW. Since both the CDW and superconducting transitions are related to a Fermi Surface instability, an accurate calculation of the Fermi Surface is essential for a microscopic understanding of the physical behavior of this compound. Here we demonstrate a novel computational method for calculating the dHvA frequencies and electron effective masses of $NbSe_2$. Our computational approach employs a FLAPW calculation of the $NbSe_2$ Fermi Surfaces using 40000 k-points. We extract the extremal cross sections (located in the Gamma-K-M and A-L-H planes) into a bitmap and then compute the dHvA frequencies from the number of pixels in the cross sections averaged over an extended Brilluoin zone. The effective masses are calculated by repeating this method with the Fermi energy shifted by 0.002 Ry. Our method satisfies Luttinger's theorem to within 0.1% - a full order of magnitude more accurate than previously published calculations. We use this accuracy to predict the dHvA frequencies and effective masses of $NbSe_2$ under pressure.

**Q1 247 Bipolar surface conduction of $BaTiO_3$ in ultrahigh vacuum corresponding to electron and hole accumulation** YUKIO WATANABE, YOSUKE URAKAMI, MIZUKI YAMATO, *Kyushu University* The surface of the ferroelectric is unique due to the spontaneous polarization. One of such properties is a self-field effect [1,2]. We have reported the self-field effect of $BaTiO_3$ [2,3], which does not seem to be accepted, probably due to the suspicions about the formation of the oxygen vacancies or water absorption at the surface in ultrahigh vacuum. Here, oxygen vacancies in $BaTiO_3$ facilitate *n*-type conduction. In this talk, we present the enhancement of both *n*- and *p*-type surface conduction in $10^{-10}$ –$10^{-11}$ torr. We observed this in both top-seed-solvent-growth (TSSG) and KF-flux grown samples that are nominally pure and transparent. Furthermore, we confirmed the evident reduction of surface conductance above Curie temperature, where it agreed with the conduction without a carrier surface layer. The significant reduction of the conduction by the exposition of the surface to the low vacuum indicates that the conduction occurs really at the very thin layer at the surface. Other several experiments verify the existence of the surface carrier layer by the ferroelectric self-field (depolarization field) effect. [1] Appl. Phys. Lett.66, 1770(1995), Phys. Rev. B57, 789(1998), [2]it Phys. Rev. Lett. 86, 332(2001), [3] Focus http://focus.aps.org/story/v7/st1

**Q1 248 Directional sliding of histone octamers caused by DNA bending** PENG-YE WANG, WEI LI, SHUO-XING DOU, PING XIE, *Laboratory of Soft Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100080, China* Chromatin-remodeling complexes such as SWI/SNF and RSC of yeast can perturb the structure of nucleosomes in an ATP-dependent manner. Experimental results prove that this chromatin remodeling process involves DNA bending. We simulate the effect of DNA bending, caused by chromatin-remodeling complexes, on directional sliding of histone octamers by Brownian dynamics simulation. The simulation results show that, after a DNA loop being generated at the side of a nucleosome, the histone octamer slides towards this DNA loop until the loop disappears. The DNA loop size is an important factor affecting the process of directional sliding of the histone octamer. A model for directional sliding of histone octamers induced by chromatin-remodeling complexes is suggested. (This research was supported by National Natural Science Foundation of China, and the Innovation Project of the Chinese Academy of Sciences.) (Email: pywang@aphy.iphy.ac.cn)

**Q1 249 Oscillations of Cantilevers** J.D. TAYLOR, GAYATRI KESKAR, JAY GAILLARD, RAZVAN CIOCAN, MALCOLM SKOVE, APPARAO RAO, *Clemson University* Resonance vibration of micro and nano sized cantilevers can be used to measure elastic constants and mass, detect absorbed material, and form part of mechanically resonant filters in electronic devices. We have measured the harmonic content of cantilevers driven by electrostatic forces containing two harmonically related terms, as well as nonlinear terms and parametric terms. The results are compared to numerical simulations of the forces between the cantilever and the counter electrode and the resulting motion of the cantilever.

**Q1 250 Electrical Switching and Rectification in Carbon Nanotube Y_Junctions** JAY GAILLARD, K. YANG, *Clemson University* C. DARAIO, P. BANDARU, S. DIN, *UCSD* M.J. SKOVE, APPARAO PAO, *Clemson University* Recently, we have shown evidence for a dramatic electrical switching behavior in a Y-junction carbon-nanotube morphology [1]. The mutual interaction of the electron currents in the three branches of the Y-junction is shown to be the basis for a potentially new logic device. The Y-junction nanotubes that were prepared using our thermal CVD process [2] typically show the presence of a catalyst particle at the junction. The observed modulation of the current from an on- to an off state could be mediated by defects and the topology of the junction, or due to the presence of catalyst particle at the junction. We will compare the switching characteristics observed in a Y-junction nanotube that does not contain the catalyst particle to those reported in Ref. 1 with a view to elucidating the switching mechanism in branched nanotubes. (1) P. Bandaru et al., Nature Materials, vol. 4(9), 663-666, (2005) (2) N. Gothard, et al., Nanoletters 4, 213-217 (2004)

**Q1 251 Combined HRTEM and Auger spectroscopy evidence for the existence of grain boundary premelting in nickel-doped tungsten** JIAN LUO,* *SMSE and COMSET, Clemson University* VIVEK K. GUPTA, DANGHYOK YOON,† *SMSE, Clemson University* HARRY M. MEYER III, *HTML, Oak Ridge National Laboratory* A combined high resolution transmission electron microscopy (HRTEM) and Auger spectroscopy study has revealed the formation of 0.6 nanometer thick, nickel-enriched, ''liquid-like'' grain boundary (GB) films in Ni-doped W specimens at 95C below the bulk eutectic temperature where the bulk liquid phase is no longer stable [Appl. Phys. Lett. 87, 231902 (2005)]. The stabilization of subeutectic liquid-like grain boundary cores in this model two-component metallic alloy is phenomenologically analogous to the long-sought phenomenon of grain boundary premelting. Despite various macroscopic indications of GB structural transitions, this result, to our knowledge, is the first direct evidence for the existence of such disordered nanostructures at metallic GBs. This observation offers a new explanation to the long-standing mysterious solid-state activated sintering mechanism, where accelerated sintering is attributed to the enhanced diffusion in liquid-like GB layers. This discovery also provides insights to resolve several long-standing controversies, e.g., the mechanisms of Ni-induced abnormal grain growth and GB embrittlement.

**Q1 252 Enhanced near-field optical moiré effect.** ZHAOWEI LIU, STEPHANE DURANT, HYESOG LEE, YI XIONG, YURI PIKUS, CHENG SUN, XIANG ZHANG, We demonstrated an enhanced near-field optical Moiré effect by inserting a silver slab between two subwavelength gratings. The evanescent fields can be greatly enhanced by the surface plasmon excitation supported by the silver slab, which leads to a remarkable contrast improvement in the Moiré fringes. The crucial role of surface plasmon excitation was elucidated by numerical simulation. Experimental enhanced near-field optical Moiré effect, which agreed very well with the simulation, was also presented. This new effect can be used to extend the conventional Moiré techniques into usage of subwavelength gratings.

**Q1 253 Electroformation of Phospholipid Vesicles Monitored by Quartz Crystal Microbalance and Optical Microscopy** VADOUD HASSANZADEH NIRI, JAMES FORREST, *University of Waterloo* Quartz Crystal Microbalance with dissipation monitoring (QCM-D) and Optical Microscope were used in combination to investigate the electroformation of giant vesicles from 1,2-Dimyristoyl-sn-Glycero-3-Phosphocholine (DMPC). The gold-coated quartz crystal coated by lipid film and the ITO-coated glass slide were used as electrodes for electroformation. Immediately upon voltage application (1V, 10Hz) between the two electrodes increases in the frequency and decreases in the dissipation were observed indicating the loss of lipid from the QCM surface. Concurrently, we observed vesicles on the QCM electrode surface. By fitting the frequency shift (delta F), and dissipation change (delta D), to a viscoelastic model, we were able to find the time evolution of the lipid film thickness. By counting the vesicles in the active QCM area, and comparing it to the thickness of lost lipid, we are able to provide an upper bound for the average vesicle thickness.

**Q1 254 Hidden Variables and Placebo Effects** SHANTILAL GORADIA, God's response to prayers and placebo leads to a question. How does He respond deterministically? He may be controlling at least one of the two variables of the uncertainty principle by extending His invisible soul to each body particle locally. Amazingly, many Vedic verses support this answer. One describes the size of the soul as arithmetically matching the size of the nucleons as if a particle is a soul. One gives a name meaning particle soul (anu-atma), consistent with particle's indeterministic behavior like that of (soulful) birds flying in any directions irrespective of the direction of throw. One describes souls as eternal consistent with the conservation of baryon number. One links the souls to the omnipresent (param- atma) like Einstein Rosen bridges link particles to normal spacetime. One claims eternal coexistence of matter and soul as is inflationary universe in physics/0210040 V2. The implicit scientific consistency of such verses makes the relationship of particle source of consciousness to the omnipresent Supreme analogous to the relationship of quantum source of gravitons in my gr-qc/0507130 to normal spacetime This frees us from the postulation of quantum wormholes and quantum foam. Dr. Hooft's view in ''Does God play dice,'' Physicsword, Dec 2005 seems consistent with my progressive conference presentations in Russia, Europe, India, and USA (Hindu University) in 2004/05. I see implications for nanoscience.

**Q1 255 Electrically Tunable Chiral Materials for Spatial Light Modulators** SHIN-YING LU, LIANG-CHY CHIEN, *Chemical Physics Interdisciplinary Program and Liquid Crystal Institute, Kent State University* An electrically tunable chiral material is being used to develop a spatial light modulator in which the spectral wavelength is controlled by an electric field. We prepared a cholesteric liquid crystal cell by using a nematic host doped with chiral dopants. Upon applying an ac electric field parallel to the helical axis, different textures can be obtained. In addition to obtaining transitions among cholesteric textures by amplitude modulation, in this work we develop a scheme of switching the cholesteric liquid crystal among different textures and the reflected wavelength. We also analyzed the issue of the frequency and amplitude dependent behavior of cholesteric texture. With the combination of the amplitude and frequency modulation, reflected light with different wavelength is observed. This device can be operated in various spectrum regions as an optical filter. Furthermore, the device has good potential in display applications

**Q1 256 Polariton spectrum dependence on concentration of admixture layers in imperfect Si-superlattice.** VLADIMIR RUMYANTSEV, STANISLAV FEDOROV, ESFIR SHTAERMAN, *A.A.Galkin Physics Technical Institute of NASU* Advances in technology allowing growth of ultrathin crystalline films and periodic structures with controlled characteristics by molecular beam epitaxy has led to an increasing interest for study of excitations in perfect crystalline lattice. Investigation of disorder effects in imperfect superlattice allowing modeling the crystal properties is still of a great interest. We consider a model of superlattice as a macroscopically homogeneous system with randomly included admixture layers. The virtual crystal approach which is the method to describe quasi-particle excitations in disorder media is used. Polariton spectrum of imperfect superlattice (which is one-dimensional Si-crystal with two elements-layers in the cell) is obtained. Peculiarities of the dependence of band gap width on admixture layers concentration have been studied for different polariton branch. The results are the evidence of substantial polariton spectrum reconstruction caused by presence of defect layers.

**Q1 257 Low Background and Close Proximity Sensors of Atmospheric Gamma Radiation Following Lightning** M. GREENFIELD, M. ISHIGAKI, N. ITO, A. IWATA, K. KUBO, *Intn'l Christian U* K. KOMURA, *Kanzawa U* P. RUSCHER, W. COTTRILL, *Fla St. U.* G. AUSTIN, D. KROFCHECK, M. PEACE, P. BARKER, *Auckland U.* Atmospheric $\gamma$ radiation following lightning, 10-80% more than normal background, in excess of radon progeny attached to precipitation, which decays with a half-life of about 50 min, has been observed in Japan and at the Lightning Research Lab in Starke, Florida. This excess $\gamma$ radiation may be from the decay of radioactive ejectiles from nuclear reactions initiated by protons or photons resulting from the high potential gradients during thunderstorms. The most likely candidates for 10-100 min $\gamma$ activity resulting from reactions on atmospheric elements are $^{39}$Cl or $^{38}$Cl and/or annihilation $\gamma$ rays from positron emitters. Using a high resolution Ge detector the 1.267 MeV peak from $^{39}$Cl and excesses of the 511 MeV annihilation peak, as well as anomalous increases in the ratio of $^{214}$Bi to $^{214}$Pb (radon progeny), have been observed following thunderstorms but all with poor signal to noise ratios. Delayed activity in condensates from 10 liters of rain water with extremely low background at the underground LLRL in Ogoya, Japan is underway and activity in shielded detectors from nearby triggered lightning at the Lightning Research Lab is being planned in order to improve statistics and signal to noise ratios.

**Q1 258 NMR Studies of Water and Methanol Transport in Highly Sulfonated Membranes for Fuel Cells.*** EUGENE MANANGA, JAY JAYAKODY, AMEESH KHALFAN, STEVE GREENBAUM, *Hunter College of CUNY* THUY DONG, ZONGWU BAI, ROBERT MANTZ, *Wright Patterson Air Force Base* Pulse gradient spin echo NMR was used to characterize the diffusion of water in highly sulfonated polyarylenethioethersulfone (SPTES) polymers. The proton NMR spectra as well as the diffusion rates were determined as a function of temperature. Comparison of electrical conductivity and diffusion activation energies indicate that $H^+$ and water transport are closely correlated. Several of the membranes were selected for further study for possible applications in direct methanol fuel cells. Both water and methanol diffusion coefficients were determined for membranes equilibrated in 2M aqueous methanol solutions. Water mobility is correlated with proton conductivity whereas methanol mobility is associated with undesirable crossover effects. The membranes based on SPTES polymers present a superior water/methanol diffusion ratio to that of the widely studied NAFION membrane. Finally, the effect of hydrostatic pressure up to 2.5 kbar on diffusion has been determined. Using pressure as the thermodynamic variable allows one to compute activation volumes for molecular transport. The results obtained for SPTES materials are similar to those of other sulfonated polymers, in that the activation volume is observed to decrease with increasing water content of the membrane.

**Q1 259 Effect of $\gamma$-radiation on CdTe/CdS solar cells*** SOBIR MURATOV, *Senior teacher* Heterostructures on the base of CdTe/CdS is widely used in modern photovoltaics. It is well known that during preparation of the CdTe/CdS heterostructures and annealing solid solutions $CdTe_{1-x}S_x$ are formed due to diffusion of Te atoms into CdS and S atoms into CdTe. This work present a study of the effect of $\gamma$-radiation on CdTe/CdS solar cells. The heterostructures are prepared on 1cm$^2$ molybdenum substrate. It is found that output parameters of the cells change non-monotonicaly upon monotonic increase of the intensity of the $\gamma$-radiation. At lower intensities, short-circuit current increases and open-circuit voltage decrease, while at higher intensities short-circuit current decrease and open-circuit voltage increase with increasing the intensity of $\gamma$-radiation. It is found that the radiation-induced increase of the short-circuit current is much faster than decrease of the open-circuit voltage. As result, efficiency slightly increases with increasing the radiation intensity at low intensities and decreases at higher intensities. The reason of the non-monotonic change of the output parameters is related to generation of the radiation defects, which increases the compensation degree of the base layer. This suggestion is tested by measuring the specific resistance as a function of the $\gamma$-radiation intensity. It is found that the specific resistance also changes non-monotonically upon monotonic increase of the $\gamma$-radiation intensity, thus confirming the above suggestion.

**Q1 260 Spooky Phenomena in Two-Photon Coherent Atomic Absorption** MING-CHIANG LI, *Liceimer* Physical processes on two-photon coherent atomic absorption of multiple laser beams were discussed more than twenty five years ago. These processes can be divided into two distinct groups. In the first group, laser beams are from a single source[1,2], and in the second group laser beams are from two different sources[3]. Several experiments in the first group were carried out and have led to the 2005 Nobel Prize in physics. The second group is more interesting. Atoms are in random motion and two photons are from different sources. Classically, it is impossible for atoms to transit coherently in the absorption process, but quantum mechanically, such a transition is possible and that is one of the spooky phenomena in quantum mechanic. To assure the coherent transition, each photon as absorbed by the atom must have two possible paths of choices. If one photon has the choice and other one is not, then the atomic transitions cannot be coherent. The present talk will review various spooky phenomena associated with two-photon coherent atomic absorption, and will clarify some theoretical misunderstandings regarding these interesting transitions.

**Q1 261 Modulation of Luttinger liquid exponents in multi-walled carbon nanotubes** J. GONZALEZ, E. PERFETTO, *Instituto de Estructura de la Materia (CSIC), Madrid, Spain* S. BELLUCCI, P. ONORATO, *Laboratori Nazionali di Frascati (INFN), Frascati, Italy* We develop a theoretical framework that applies to the intermediate regime between the Coulomb blockade and the Luttinger liquid behavior in multi-walled carbon nanotubes [1]. We show that, in the crossover regime, the tunneling conductance follows a power-law behavior as a function of the temperature, with an exponent that oscillates with the gate voltage as observed in the experiments. We also evaluate the effects of a transverse magnetic field on the transport properties of the multi-walled nanotubes. For fields of the order of 4 T, we already find important changes in the band structure of the outer shells. We then predict the appearance of sensible modulations in the exponent of the conductance for higher magnetic fields, as the different subbands are shifted towards the formation of flat Landau levels. [1] S. Bellucci, J. Gonzalez and P. Onorato, Phys. Rev. Lett. 95, 186403 (2005).

**Q1 262 Superconductivity of multi-walled carbon nanotubes** E. PERFETTO, J. GONZALEZ, *Instituto de Estructura de la Materia (CSIC), Madrid, Spain* ≠wcounterbean We investigate the superconductivity of multi-walled carbon nanotubes, paying attention to the balance between the Coulomb interaction and the effective *e-e* interaction mediated by phonon-exchange. Our main aim is to confront the recent observation of sharp transitions in the resistance of multi-walled nanotubes, in situations where most part of the shells are electrically active [1]. For this purpose we will adapt the mechanism already shown for the superconductivity of nanotube ropes, where the electrostatic coupling among a large number of nanotubes leads to a drastic reduction of the Coulomb interaction [2]. We will consider in particular the interaction and Cooper-pair tunneling among a large number of shells in the multi-walled nanotubes, drawing a connection between the superconductivity of these structures and the more conventional one in the intercalated compounds of graphite.
I. Takesue *et al.*, to appear in Phys. Rev. Lett. J. González, Phys. Rev. Lett. **88**, 076403 (2002); J. V. Alvarez and J. González, Phys. Rev. Lett. **91**, 076401 (2003).

**Q1 263 Structural changes in $Bi_2Te_3$ under pressure.*** MATHEW JACOBSEN, RAVHI KUMAR, ANDREW CORNELIUS, *HiPSEC and Dep.Physics, University of Nevada Las Vegas* PETER LIERMANN, *HPCAT, Argonne National Laboratory* $Bi_2Te_3$ based compounds continue to receive intense research activities due to the enhanced figure of merit observed in the super lattice structure with $Sb_2Te_3$ [1]. Synthesis of different chemical compositions with varying particle sizes and doping has gained importance subsequently. The thermo electric properties of the new compositions strongly depend on the structure and P-T phase diagram of the parent compound $Bi_2Te_3$. In order to understand the structural properties of $Bi_2Te_3$ in detail, we have performed pressure studies up to 30GPa using insitu angle dispersive and energy dispersive x-ray diffraction techniques using a diamond anvil cell with different pressure media. $Bi_2Te_3$ is found to undergo pressure induced structural transition around 7.8 GPa to a new high pressure phase from the ambient rhombohedral phase. This transition is found to be completely reversible with a large hysteresis observed during downloading. The details of the high pressure phase and the pressure medium dependence of the transition will be discussed further. [1]. Venkatasubramanian et al., Nature, **413**, 597 (2001)

**Q1 264 EPR, Biology, and Consciousness** SHANTILAL GORADIA, *Gravity Research Institute, Inc.* It seems that Darwin, in his concluding remark (1859, p490) ruled out the possibility of cosmic connection to evolution based on the fixed law of gravity, known then. More recent Diracs Large Number Hypothesis as described in http://www.arXiv.org/pdf/physics/0210040 v1 raises a possibility that the universal constant of gravity is decreasing and all coupling constants are increasing with time, so reported by some observations. Deeper investigation of the connection between evolution and the variation of the universal constant of gravity seems worthwhile to see if it impacts the passage of time in a stronger (gravitational according to the spirit of the above archive) field and affects the aging process, and explains locality and causality in random evolutionary mutations. If there is no physical locality and causality consistent with the special theory of relativity, there must be some spiritual locality and causality at superluminal speeds to explain the implicit hidden variables. Then there is a question of how to test spiritual locality and causality. Psychic effects and dream signals look promising, if they exist and can be tested with space age technology. This is neither about religion nor about Einsteins orthodoxy in light of the spirit of EPR. This is about frontiers of science of the new millennium: biology, and consciousness.

**Q1 265 Ion Size Effect in Glow Peak Temperature in Binary Mixed Crystals Doped with Divalente Europium*** RICARDO RODRIGUEZ-MIJANGOS, RAUL PEREZ-SALAS, *Universidad de Sonora* Thermoluminiscence measurements at room temperature of ''beta'' irradiated divalent Europium doped binary mixed alkali halides with KCl and KBr components at several concentrations x in molar fraction. The experiments have been carried out to identify the effect of composition of glow peaks. A typical glow peak has been distinguished for each composition. A linear dependence of its temperature on the composition x has been found. This is associated with the size change of ions Cl and Br. Initial comparative cathodoluminiscent measurement was carried out irradiating a single sample with electrons in an electron microscopy using a 30 KV voltage. With the present results is speculated the behavior of the mixed binary crystals with components KCl and RbCl, doped with divalent Europium.

*We are grateful for support by CONACYT under proyect 2002-C02-40497 and Direction de Investigacion y Posgrado UNISON under Project ''Catodoluminiscencia por MET.''

**Q1 266 Applications of the Microchannel Plate in Accelerator Mass Spectrometry** MISGANAW GETANEH, *University of Tennessee at Martin* KEN GRABOWSKI, DAVID KNIES, CATALINA CETINA, GRAHAM HUBLER, SCOTT TUMEY, *Naval Research Laboratory* A microchannel plate (MCP) detector with active area of 10 x 2 $cm^2$ is used as a position detector for mass spectrometry applications. The MCP detects electrons scattered by an MeV ion beam as it goes through a thin Carbon foil which is placed at a $45^o$ angle with respect to the beam. The scattered electrons' transverse motion is constrained by application of uniform electric and magnetic fields parallel to the axis of the MCP. The amplified charge is deposited on a double-delay line anode. Differential timing and charge partitioning are used to determine the horizontal and vertical positions of the ion in a plane normal to the MCP axis.

**Q1 267 Evaporation Driven Microdroplet Pattern Formation in Surfactant X-77.*** K.C. CHAN, SCOTT PIERCE, *Albany State University* HEPING ZHU, *OARDC/USDA* ALBANY STATE UNIVERSITY COLLABORATION, ATRU/OARDC, USDA COLLABORATION, The evaporation of sessile solution droplets of size 300-1000 $\mu$m on two different types of surface have been investigated using digital video microscopy. It is found that when the surfactant X-77 droplet is left to evaporate on a glass surface, the droplet evaporates without reducing its diameter while the fluid within the droplet flows from the center to the pinned edge causing it to swell. The final thin solution film eventually breaks away from the edge and shrink toward the center; simultaneously the edge coalesces into smaller droplets, forming islands on once the perimeter of the droplet. When the same experiment is repeated on hydrophobic surface, the droplet is found to shrink while its edge swells then forms islands. Depending on the con-

centration of X-77, ring or even a smooth round patch in the center instead of islands are formed. Solution concentration between 0.5-10 % were used for the experiments. The dynamic transition from islands to ring to round drop again will be presented.

**Q1 268 Investigations of Wafer Scale Etching with Xenon Difluoride** K.N. CHEN, N. HOIVIK, C.Y. (BLAKE) LIN, A. YOUNG, M. IEONG, G. SHAHIDI, *IBM T. J. Watson Research Center, Yorktown Heights, NY 10598, USA* A good and uniform bulk silicon wafer etching method can be applied to the wafer thinning process in MEMS and 3D applications. In this study, the use of a Xenon Difluoride (XeF2) gas-phase etching system, operating at room temperature, has been investigated for bulk silicon wafer thinning. We investigated the Si-wafer surface morphology and profile following each XeF2 etching process cycle. Theoretical results are used to compare with the experimental results as well. A clean wafer surface by proper surface treatments is significant to achieve a uniform surface profile and morphology for XeF2 etching. A proper design of etching cycle with nitrogen ambient during etching is necessary to achieve the fastest and uniform silicon etching rate. The silicon etching rate is reported as a function of etching pressure, nitrogen pressure, and etching duration.

**Q1 269 E/T-scaling of the spin fluctuations in the Zn-Mg-Ho magnetic quasicrystal*** TAKU J. SATO, *ISSP-NSL, University of Tokyo* AN PANG TSAI, *IMRAM Tohoku University* We report inelastic neutron-scattering results on the icosahedral Zn-Mg-RE (RE: rare-earth) magnetic quasicrystals. In the Zn-Mg-RE quasicrystals, slowing down of spin dynamics starts at considerably high temperatures (about 50 K) with developing antiferromagnetic correlations, nevertheless, the spins stay paramagnetic until low-temperature freezing transitions ($T_f$ = 1.95 K for RE = Ho), indicative of strong frustration effect. Neutron inelastic scattering further reveals that for RE = Ho, the scattering function $S(Q,\hbar\omega)$ is almost temperature independent for $\hbar\omega > 0$ in a wide temperature range up to 200 K. Corresponding dynamic susceptibility for $\hbar\omega < 1.5$ meV is scaled as $\mathrm{Im}\chi(\hbar\omega,T)T^{1/3} \propto (\hbar\omega/T)^{-1/3}Z(\hbar\omega/T)$, where $Z(\hbar\omega,T) = \tanh(\alpha\hbar\omega/T)$ is the scaling function. This $\hbar\omega/T$ (or $E/T$) scaling is identical to those frequently observed in systems near a quantum critical point, such as $UCu_4Pd$. In view of the frustration-reduced low freezing temperature of the Zn-Mg-Ho quasicrystal, the $E/T$-scaling may also be indicative of the quantum criticality in this magnetic quasicrystal.

**Q1 270 Perpendicular Hot Electron Transport in the Spin Valve Photo-Diode** BIQIN HUANG, IAN APPELBAUM, *Electrical and Computer Engineering Department, University of Delaware, Newark, Delaware, 19716* The spin valve photo diode (SVPD) provides a new way to explore perpendicular hot electron transport in ferromagnetic multilayers using photoexcitation and internal photoemission. Since electrons are excited everywhere in the metallic multilayer, structure geometry is vital to optimize the magnetocurrent (MC). Initial theoretical models indicate that the MC should increase by increasing the thickness of a capping layer at the surface, but experiments demonstrate a nonmonotonic dependence resulting in an optimum capping layer thickness to maximize MC. The inconsistency between experiment and this theoretical model is also discussed, leading to a new proposal for hot electron transport in the SVPD.

**Q1 271 Wafer Bow Effect on Copper Wafer Bonding** KUAN-NENG CHEN, *Microsystems Technology Laboratories, Massachusetts Institute of Technology, Cambridge, MA 02139* RAFAEL REIF, A good bonding quality of bonded interconnects is the key factor to achieve successful three-dimensional (3D) integration applications. Prior to copper interconnect bonding in real 3D devices, fundamental researches about copper blanket film bonding should be studied. Since two wafers with large wafer bows may be difficult to contact during bonding, the bonding quality may be affected. In this study, wafer bows of different silicon wafers coated with copper and tantalum films were measured at different temperatures to simulate the wafer bow evaluation during bonding. We further investigated the bonding qualities of bonded wafers with different wafer bows after bonded at different temperatures. Dicing tests were performed to analyze the qualities of copper bonded wafers. Based on the results, a criterion of wafer bows for good copper bonding quality is suggested.

**Q1 272 Toward a model for pattern formation in thin film polymer blends** NIGEL CLARKE, *University of Durham* We outline a dynamic theory for simultaneous phase separation and dewetting in thin film polymer blends with free surfaces. Although an understanding of the processes of both dewetting and phase separation is well advanced, the coupling between the two has received little attention theoretically. We consider the coupling between surface driven instabilities and compositional instabilities in a thin film on a flat solid substrate with a free upper surface. We utilise a simple model, in which only fluctuations of composition within the plane parallel to the substrate are allowed, and neglect the possibility of fluctuations normal to the substrate. Such a model yields quantitative relationships for the stability in terms of the height of the film and the various thermodynamic parameters. From a dynamic viewpoint, the attraction of such a model is that it permits an analytical description of the early dynamic stages of an instability. Reduction of the problem from 3D to 2D is important when undertaking numerical studies on films that are nanometers thick, in which the typical lengthscales of dewetting and phase separation in the plane of the film are of the order of microns. As an example, the consequences of phase separation within a system which has already undergone considerable dewetting is highlighted by comparing with the process of phase separation when no dewetting occurs. With simultaneous dewetting, the phase separation becomes retarded and the co-continuous nature of the phases are absent.

**Q1 273 Nonequilibrium theory of polymer stretching based on the Master Equation*** HANKÉ FELIX, *Dalhousie University, Halifax, NS, Canada* HANS JÜRGEN KREUZER, *Dalhousie University, Halifax, NS, Canada* Single polymer pulling experiments such as protein unfolding measurements and dynamic force spectroscopy are increasingly done at high loading rates where equilibrium statistical mechanics is no longer applicable. I will present a theory that takes into account non-equilibrium effects using a Master Equation [PRE v. 72, 031805 (2005)]. If the molecular length is used as a stochastic variable, the transition probabilities have a simple analytic form. This theory predicts signifi-

cant differences between experimental designs using controlled end-to-end positions and those that utilize a force-control mechanism. The most prominent non-equilibrium effect is a loading rate-dependent hysteresis in the force-extension curve. Molecular relaxation close to and far from equilibrium will also be discussed in the frame-work of the Master Equation theory.

*This work was supported in part by the Office of Naval Research and the National Science and Engineering Council of Canada. F.H. wishes to acknowledge financial support from the Killam Trusts.

**Q1 274 Mechanical and Tribological Properties of Amorphous Carbon Films** J. DAVID SCHALL, GUANGTU GAO, KEVIN VAN WORKUM, JUDITH A. HARRISON, *United States Naval Academy, Department of Chemistry* Incorporation of silicon into hydrogenated amorphous carbon films has been shown to reduce film stress, make the friction coefficient less sensitive to moisture, and increase thermal stability while maintaining high hardness, low wear, and small friction coefficient. Molecular dynamics simulations utilizing the reactive empirical bond-order potential (REBO) have been used to examine the temperature dependence of the material and tribological properties of hydrogenated amorphous carbon films containing silicon. The REBO potential is one of the few potential energy functions capable of modeling chemical reactions likely to accompany sliding. Existing models for the C-Si-H potential are based on the original REBO potential developed by Brenner in 1990. These models do not calculate elastic modulus accurately. A new parameterization for the inclusion of Si into the second generation REBO potential has been developed. Calculations of elastic modulus from the second generation Brenner potential are in much better agreement with experimental values. Initial studies have shown that the inclusion of Si in amorphous carbon films increases the amount of $sp^3$ bonding in the film while decreasing the graphitic $sp^2$ content, making the films more diamond-like.

**Q1 275 Neutron Diffraction study of Ru doping in $Pr_{0.5}Ca_{0.5}Mn_{1-x}Ru_xO_3$ ($x \leq 0.10$)** KANNADKA RAMESHA, ANNA LOBET-MEGIAS, THOMAS PROFFEN, *Los Alamos National Laboratory* LUJAN NEUTRON SCATTERING CENTER TEAM, Small amount of Ru substitution ( $< 10$ %) for Mn in charge-ordered manganites destroys charge-ordering (CO) and induces ferromagnetic metallic state. To probe the dramatic role played by Ru in preventing the CO state, we have carried out neutron diffraction studies of Pr0.5Ca0.5Mn1-xRuxO3 compounds ($x = 0.0$, 0.05 and 0.10) in the temperature range 300-10 K. Evolution of lattice parameters with temperature points out that lattice distortion which accompanies charge ordering disappears on Ru doping. Also Ru doping alters the $MnO_6$ octahedron shape from 4-long/2-short type to 2-long/4-short type that suppresses the antiferromagnetic ordering and hence induces ferromagnetism through double exchange interactions. The local structure of $x = 0$, 0.05 and 0.10 compositions were analyzed using Pair Distribution Function (PDF) at 295 K and 15 K.

**Q1 276 Pressure induced structural changes in AgPb18SbTe20*** RAVHI KUMAR, *HiPSEC and Department of Physics, University of Nevada Las Vegas, Las Vegas, Nevada* ANDREW CORNELIUS, MATHEW JACOBSEN, MALCOLM NICOL, *HiPSEC and Dep.Physics, University of Nevada Las Vegas, Las Vegas, Nevada* SEIJI YONEDA, *Kanagawa University, Yokohama, Japan* The cubic chalcogenide AgPbmSbTe2+m type compounds are an important class of thermoelectric materials for which figures of merit as high as 2.2 at 800 K have been reported recently [1]. The structures of these compounds have been investigated under pressures up to 30 GPa using a diamond-anvil cell and an imaging plate with synchrotron radiation at HPCAT. Various runs were performed with different pressure media such as 4:1 methanol-ethanol and silicone fluid. The results show pressure induced structural transitions in AgPb18SbTe20. The NaCl-type cubic phase transforms to an orthorhombic phase at 6.4 GPa and then to a CsCl-type cubic structure at 14 GPa. The high pressure CsCl-type phase is stable up to 30 GPa. The ambient structure is recovered on releasing the pressure from the cell. The results will be presented in detail. [1]. K.F. Hsu etal., Science, 303, 818 (2004)

**Q1 277 Metal-insulator transition in Hubbard-like models with random hopping** MATTHEW FOSTER, *University of California, Santa Barbara* ANDREAS LUDWIG, *University of California, Santa Barbara* We study the combined effects of random hopping disorder and short-ranged interparticle interactions in half-filled Hubbard-like models of spinless and spinful fermions in $D \geq 2$ dimensions. In a given realization, the hopping disorder is chosen to break time-reversal invariance, but to preserve the special ''nesting'' symmetry responsible for the charge density wave instability of the clean, non-interacting Fermi surface. For spinless fermions, the hopping disorder may arise from the application of a random orbital magnetic field to the otherwise *clean* Hubbard-like model. For the case of spin 1/2 fermions, in addition, the spin SU(2) rotational symmetry is assumed to be broken completely, e.g. by a homogeneous spin-orbit coupling. Using a perturbative renormalization group approach [1], we identify a new, disorder-driven metal-insulator transition in $D = 2 + \epsilon$ dimensions, stabilized by the presence of the interactions. Without the ''nesting'' symmetry, these systems would be in the unitary symmetry class ''with magnetic impurities,'' where interaction effects are irrelevant [1]. [1] For a review, see e.g. D. Belitz and T. R. Kirkpatrick, Rev. Mod. Phys. 66, 261 (1994).

**Q1 278 Carrier mobility as a function of InGaAs quantum well to quantum wire transition on GaAs (311)A** WILLIAM BLACK, VASYL KUNETS, BAOLAI LIANG, YURIY MAZUR, ZHIMING WANG, JOHN SHULTZ, GREG SALAMO, *University of Arkansas* Molecular beam epitaxy is used to study self-assembly of $In_{0.4}Ga_{0.6}As$ quantum wires on GaAs (311)A. Using an InGaAs layer embedded in an AlGaAs/GaAs heterostructure, the correlation between surface morphology, photoluminescence, and electrical transport is investigated. In particular, we will present data and discuss carrier mobility as a function of InGaAs deposition and the resulting surface morphology. As the thickness of the InGaAs layer is increased, a compressive strain field develops, which is relieved at a critical thickness in the form of faceted quantum wires. Paralleling this dramatic change in morphology, the conductivity of the sample is observed to change as measured using Hall bar structures oriented both parallel and perpendicular to the quantum wires. A large anisotropy in conductivity is found to be directly correlated to changes in surface morphology and photoluminescence measurements. The surface morphology was revealed using atomic force measurements on an InGaAs capping layer that reproduced the quantum well or quantum wires embedded in the AlGaAs/GaAs heterostructure.

**Q1 279 Synthesis and Electrical Characterization of Polymer based SiC Nanofibers** SAIMA KHAN, AURANGZEB KHAN, MARTIN KORDESCH, *Department of Physics and Astronomy and CMSS program, Ohio University* Silicon carbide nanofibers have been synthesized from a precursor solution of Polyethyleneoxide (PEO) using the electrospinning technique. The morphology of the fibers was investigated using the scanning electron microscope (SEM) and Transmission electron microscope (TEM). The electrospun fibers were annealed at various high temperatures and their electrical conductivity was measured using the four point probe method. The effect of the annealing temperature on the electrical conductivity of the fibers was investigated.

**Q1 280 Highly Sensitive Micro-Hall Magnetometers Using InSb Quantum Wells** SAPTHARISHI EASWARAN, VASYL KUNETS, DOREL GUZUN, YURIY MAZUR, *University of Arkansas* MIKE SANTOS, SHEENA MURPHY, *University of Oklahoma* GREGORY SALAMO, *University of Arkansas* DEPARTMENT OF PHYSICS: UNIVERSITY OF ARKANSAS COLLABORATION, DEPARTMENT OF PHYSICS AND ASTRONOMY: UNIVERSITY OF OKLAHOMA COLLABORATION, Delta doping in the barrier of $InSb/Al_{0.12}In_{0.88}Sb$ heterostructures grown by molecular beam epitaxy are studied as micro-Hall sensors. By varying the doping level and the delta position in the barrier, full control of the two dimensional electron gas confined in InSb quantum well is achieved. For example, we demonstrate control of device parameters such as the absolute magnetic sensitivity, noise level, and device detection limit of a micro-Hall sensor. The $200\mu$m x $35\mu$m device demonstrates a detection limit of 25 nT and 11 nT at 300 K and 80 K, respectively. These limits were measured at the operating frequency of 10 kHz where 1/f noise is negligible. In addition, if spatial resolution is not needed pT detectivity can be achieved using larger sensors on the order of $1mm^2$. The devices discussed here show a low thermal drift that is less than $2\%/^oK$ and attractive signal linearity up to 0.1 T for either polarity of the magnetic field at room temperature.

**Q1 281 Optical Properties of Hydrogenated Silicon Nanoclusters: First principles study*** SEUNG MI LEE, *Korea Research Institute of Standards and Science (KRISS)* HANCHUL KIM, KYUNG JOONG KIM, DAE WON MOON, Silicon nanoclusters have significant interest due to their potential application to optoelectronic devices in visible range. Using first principles approach, we investigate the electronic and optical properties of hydrogenated silicon nanoclusters. The highest occupied molecular orbital (HOMO) – lowest unoccupied molecular orbital (LUMO) gap dependence on the cluster size show the same trend by using any exchange-correlation functionals. However, a reasonable agreement to experimental absorption spectra peak values cannot be achieved from conventional LDA or GGA functional-based calculations. Using B3LYP hybrid functional within time-dependent density functional theory, we obtain excitonic energies in quantitatively good agreement to experimental data. The passivant effect on HOMO-LUMO gap and excitonic energies will be also presented.

*Computing facility support by KISTI under the 7th strategic supercomputing applications support program

**Q1 282 Spiral structure of a frustrated spinel $CdCr_2O_4$ studied by polarized neutron techniques** M. MATSUDA, *Japan Atomic Energy Agency (JAEA)* A. OOSAWA, *JAEA* M. TAKEDA, *JAEA* M. NAKAMURA, *JAEA* E. LELIEVRE-BERNA, *ILL* K. KAKURAI, *JAEA* J.-H. CHUNG, *NIST* S.-H. LEE, *Univ. of Virginia* H. UEDA, *Univ. of Tokyo* H. TAKAGI, *RIKEN* $CdCr_2O_4$ has the spinel structure, in which geometrical frustration exists between the $Cr^{3+}$ moments located at the corners of the tetrahedron. This compound shows a transition to a spiral magnetic structure with a characteristic wave vector of $Q = (0,\delta,1)$ ($\delta \sim 0.09$) at 7.8 K, which is accompanied by a tetragonal structural distortion with the $c$ axis elongated. [1] We first performed a 1D polarized neutron analysis and determined that the $Cr^{3+}$ moments has a planer anisotropy in the $ac$ plane. Finally, spherical neutron polarimetry experiments were performed using a CRYOPAD on TAS-1 at JRR-3. It is found that the spiral structure is elliptical with the spin component $\sim$ 24% elongated along the $c$ axis. [1] J.-H. Chung *et al.*, Phys. Rev. Lett. 95, 247204 (2005).

**Q1 283 Abstract Withdrawn**

**Q1 284 Classical Nuclear Motion in Quantum Transport** CLAUDIO VERDOZZI, GIANLUCA STEFANUCCI, CARL-OLOF ALMBLADH, *Solid State Theory, Lund University-Sweden* An *ab initio* quantum-classical mixed scheme for the time evolution of electrode-device-electrode systems is introduced to study nuclear dynamics in quantum transport. Two model systems are discussed to illustrate the method. Our results provide the first example of current-induced molecular desorption as obtained from a full time-dependent approach, and suggest the use of AC biases as a way to tailor electromigration.

**Q1 285 Production of Cold NO Molecules** JASON ALEXANDER, BRYAN BICHSEL,*MICHAEL MORRISON, NEIL SHAFER-RAY, ERIC ABRAHAM, *University of Oklahoma* Although the success of laser cooling and trapping has had a major impact on atomic physics, the requirements of simple internal structure have limited its use to a few atomic species. A modified Stark guide can be used as a source for cold polar molecules by filtering the cold fraction from a thermal source. We present experimental results for the enhancement of the lowest ro-vibrational states from an effusive source of nitric oxide by the Stark guide capturing those particles with the lowest transverse velocities. By inserting a sphere in our straight guide, we block line-of-sight trajectories between the source and the output of the guide. We have implemented the principle of velocity selection, only those molecules with sufficiently low energies to reflect from the guide will make it to the output. Using a field-stabilized Rydberg time of flight technique we measure the output speed distributions from this filtered source to be between 7-20 K, depending on strength of guide field.

**Q1 286 THz Differential Radar for Detection of Weak Molecular Absorption Lines in Bio-Aerosol** HAMID JAVADI, *JPL, CA* ELLIOTT BROWN COLLABORATION,*ELAYNE BROWN COLLABORATION,† THz frequency range (300-3000 GHz) promises unique capabilities and advantages for detection of trace gases and biological aerosols immersed in the atmosphere. Tech-

niques used for microwave atmospheric remote sensing can be used within the atmospheric transmission windows to carry out standoff detection of biological markers in real time. THz spectroscopy has been used as an important new tool in investigations of atmospheric molecular gases and a wide range of airborne biological materials. We have embarked upon development of field deployable THz differential radar. Bio-aerosols are the most difficult analytes to face due to their heterogeneity in size, toxicity, and bio/chemical composition. JPL has demonstrated monolithic solid-state THz sources with impressive output power. The sources are enabled by W-band power amplifiers and planar Schottky diode multipliers. These, together with room temperature detectors (based on the same technology), allow one to make a compact and robust transmitter/receiver with sufficient sensitivity and frequency agility to carry out detailed investigation of various molecular vapors and bio-aerosols at standard temperature and pressure. Current status of the THz differential radar technology development effort along with future trends will be presented.

**Q1 287 Metal–Insulator Transition in the Flux-Flow Resistivity of Optimally Doped $YBa_2Cu_3O_{6+x}$** BENJAMIN MORGAN, *University of Cambridge* DAVID BROUN, *Simon Fraser University* RUIXING LIANG, DOUGLAS BONN, WALTER HARDY, *University of British Columbia* JOHN WALDRAM, *University of Cambridge* We have made high resolution microwave measurements of the flux-flow resistivity of optimally doped $YBa_2Cu_3O_{6+x}$ in the mixed state at temperatures down to 1.2 K. We find that the effective resistivity of the vortex cores exhibits a metal–insulator transition, with a minimum at 13 K and a logarithmically growing form below 5 K, as has been seen in the low-temperature DC resistivity of under-doped cuprates in which superconductivity has been globally suppressed. Our work is the first report of a metal–insulator transition in optimally doped $YBa_2Cu_3O_{6+x}$, and the first to be seen in a system in which superconductivity has not been globally suppressed. The transition is seen in samples of the highest quality and in magnetic fields as low as 1 T.

**Q1 288 Glassy Dynamics in the Adaptive Immune Response Prevents Autoimmune Disease** JUN SUN, MICHAEL DEEM, *Rice University* The immune system normally protects the human host against death by infection. However, when an immune response is mistakenly directed at self antigens, autoimmune disease can occur. We describe a model of protein evolution to simulate the dynamics of the adaptive immune response to antigens. Computer simulations of the dynamics of antibody evolution show that different evolutionary mechanisms, namely gene segment swapping and point mutation, lead to different evolved antibody binding affinities. Although a combination of gene segment swapping and point mutation can yield a greater affinity to a specific antigen than point mutation alone, the antibodies so evolved are highly cross-reactive and would cause autoimmune disease, and this is not the chosen dynamics of the immune system. We suggest that in the immune system a balance has evolved between binding affinity and specificity in the mechanism for searching the amino acid sequence space of antibodies. Our model predicts that chronic infection may lead to autoimmune disease as well due to cross-reactivity and suggests a broad distribution for the time of onset of autoimmune disease due to chronic exposure. The slow search of antibody sequence space by point mutation leads to the broad of distribution times.

**Q1 289 Attractions Between Like-Charged Walls Via Local Molecular Field Theory*** JOCELYN M. RODGERS, CHARANBIR KAUR,† YNG-GWEI CHEN,‡ JOHN D. WEEKS, *University of Maryland, College Park* A simple model used to explore the interaction between like-charged macroions as mediated by intervening counterions is treated with local molecular field theory (LMF). LMF has recently been extended to general Coulombic systems by splitting the Coulomb potential $1/r$ into a short-ranged core that can be explicitly simulated and a long-ranged portion treated using a mean field approach; the potential separation is determined by a physically-relevant spacing parameter $\sigma$. Here we show that LMF can treat the two-wall model system surprisingly well using an analytical Poisson-Boltzmann type technique. Also, combining self-consistent solution of LMF with simulation of the short-ranged core particles using the minimum image convention yields even more accurate results without using costly and complex Lekner or Ewald sums.

**Q1 290 Coverage and Temperature Dependence of Bond Character of Thiophene on Ge(100)** S.M. JEON, S.J. JUNG, *Dept. of Chem. and School of Mol. Sci. (BK21)* H.-D. KIM, *Beamline Research Div., Pohang Accelerator Lab (PAL)* D.K. LIM, *BK21* H. LEE, *PAL* S. KIM, *BK21* KAIST COLLABORATION, PAL COLLABORATION, We studied the adsorption and decomposition of thiophene (C4H4S) on Ge(100) using high-resolution core-level photoemission spectroscopy (HRPES) and scanning tunnelling microscopy (STM). Ge 3d, S 2p, and C 1s core level spectra show the existence of three different adsorption geometries, which are assigned to a weakly bound state, a chemisorbed bonding state ([4+2] cycloaddition reaction product), and a decomposed bonding state (desulfurization reaction product). Furthermore, we found that the ratio of the components induced by three adsorption geometries changes depending on the molecular coverage and the annealing temperature. Under 0.25 ML, the kinetically favorable weakly bound state is initially formed. As the molecular coverage is increased (over 0.25 ML), thermodynamically stable [4+2] cycloaddition reaction products are additionally produced. In addition, the temperature dependent behaviors show that the weakly bound state desorbs followed by the [4+2] cycloaddition reaction product as the molecular thiophene or may decompose to form metallocyclic compounds (C4H4Ge2) and sulfide (Ge2S). We elucidate systematically the change of the bonding states of adsorbed thiophene on Ge(100) according to the amounts of thiophene molecules and annealing temperature. Moreover, we performed density functional theory (DFT) calculations to observe the energetics of three bonding states of thiophene on Ge (100) system.

**Q1 291 Lattice Distortion Driven by Spin-Lattice Coupling** CHENGLONG JIA, JUNG HOON HAN, *Sungkyunkwan University* We analyzed lattice-coupled antiferromagnetic spin models on a variety of frustrated lattices. Inspired by the picture of a hexagonal spin cluster proposed for the paramagnetic $ZnCrO_4$ (S. H. Lee et al., Nature(2002).), we considered hexagon contraction in the *pyrochlore* lattice. Hexagon distortions give rise to mutually orthogonal arrangements of spins for nearby hexagons, and has an energy gain of $-alpha^2/2$ per spin, where $\alpha$ is the spin-lattice interaction strength. However, due to the local rotational symmetry of the $\langle S_i \cdot S_j \rangle$, mean-field theory predicts a lack of lattice

displacement in the *triangular* and *kagomé*lattices. In contrast to the valence-bond-solid(VBS) state of the Affleck-Kennedy-Lieb-Tesaki type, we argue that a type of VBS order (partial VBS, PVBS) with only four of the six bonds of the triangular lattice being filled by singlets can be stabilized through spin-lattice interactions and lead to lattice deformations as in the compound $YMnO_3$ (Seongsoo Lee et al., PRB(2005)). The ground state is derived as the direct product of states, one of which represents the conventional long-range ordered spins, and the other given by the $\sqrt{3} \times \sqrt{3}$ modulation of the valence bond amplitudes, $|GS\rangle = |LRO\rangle \otimes |PVBS\rangle$. The excitation spectrum for the modulated valence bond state is worked out within the single- mode approximation. The spectrum offers a new collective mode, which is distinct from the spin wave excitations of the magnetically ordered ground state, and in principle, observable by neutron scattering.

**Q1 292 Photonic digitizing by laser crossing in thin-film semiconductors** CHINTHAKA LIYANAGE,*ARTUR ERLACHER, BRUNO ULLRICH, *Bowling Green State University* NATALIA DUSHKINA, *Millersville University* During the last two years, we developed a straightforward laser modulation concept, which has the potential to be employed in similar ways as microelectromechanical systems (MEMS). The concept is realized by crossing two laser lines in a semiconducting thin-film on glass, i.e., by switching one of the beams, one achieves a clearly resolved (up to 30%) modulation of the other beam. In case of thin-film GaAs response times in the picosecond range are possible. We investigated the transmission mode of the modulation switch and demonstrated that the GaAs/glass interface exhibits a more effective switch as the GaAs film itself. The experiments have been carried out at room temperature with moderate laser powers on the order of 10 mW. We studied also the influence of polarization on the modulation characteristics in transmission and reflection using birefringent CdS samples. We observed that polarization variations of the green laser varies the modulation amplitude of the red transmitted and reflected ray, paving the way for polarization sensitive all-optical cross connects (OXCs) operating in the THz regime.

**Q1 293 Electronic properties of carbon tori in external fields*** F. L. SHYU, *Department of Physics, Chinese Military Academy, Kaohsiung, Taiwan* C. C. TSAI, C. W. CHIU, M. F. LIN, *Department of Physics, National Cheng Kung University, Tainan, Taiwan* Electronic states of achiral carbon tori in electric and magnetic fields are studied by the tight-binding model with the curvature effect. Electronic properties, such as electronic states, energy gaps, and density of states, are very sensitive to the changes in the direction and the magnitude of the external fields. The electric field can widen the $\pi$-electron energy width; furthermore, there are more low- and extreme-energy states. Energy gaps are drastically modulated by **E.** The complete modulation of energy gap ($E_g \neq 0$ to $E_g = 0$) happens more frequently when **E** deviates from the symmetric axis, or its magnitude is sufficiently large. The electric field could change the state degeneracy. Moreover, the modulation of electronic states is enhanced by the magnetic field.

**Q1 294 Electronic properties of multilayered nanographite ribbons in an electric field.** YUAN-CHENG HUANG, *Center for General Education, Kao Yuan University, Kaohsiung 821, Taiwan, Department of Physics, National Cheng Kung University, Tainan 701, Taiwan,* The low-energy electronic properties of the AB-stacked multilayered nanographite ribbons in an electric field are studied through the tight-binding model. They are strongly dependent on the geometric structures (the interlayer interactions, the ribbon edges, the ribbon width, and the ribbon number) and the field strength. The interlayer interactions significantly affect energy dispersions, energy gap ($E_g$), density of states (DOS), and free carriers. DOS exhibits many special structures, including plateau, discontinuities, and divergent peaks. The electric field leads to the shift of the Fermi level ($E_F$), the production of the new edge state, the change of the band gap, the alternation of the subband spacing, and the semiconductor-metal transitions. In gapless zigzag ribbons, the electric field not only lifts the degeneracy of flat bands at $E_F$ but also induces an energy gap. $E_g$ is dependent on the ribbon width and the field strength. The semiconductor-metal transitions occur in both armchair ribbons and zigzag ribbons in the increase of the electric field. The above-mentioned effects due to electric field is completely reflected in the features of DOS such as the generation of special structures, the shift of peak position, the change of peak height, and the alternation of band gap.

**Q1 295 Possible observations of microwave influences on quantum states and transition rates** ROBERT POTTER, *Coe College* SIMON BERKOVICH, *George Washington U.* A realistic interpretation of quantum phenomena leads to a conclusion that there might be a hidden mechanism guiding the transition of quantum objects. Thus, manipulations of such a mechanism may affect the regular pathways of quantum phenomena. A recently formulated hypothesis suggests that quantum phenomena on the mesoscopic scale can be influenced by microwave radiation of order 10[1]1 Hz. This frequency seems to present a watershed between observable quantum effects and classical physics. Electromagnetic activities at higher frequency exhibit characteristic quantum mechanical behavior whereas at lower frequency they present typical Maxwell waves. In the range of 10[1]1 Hz both kinds of electromagnetic activities coexist: millimeter microwaves and far-infrared quanta. The destruction of long-range quantum order in superconductors at about 10[1]1 Hz is interpreted in terms of energy gap influences. The same effect could be also responsible for a small but importunate impact of the 10[1]1 Hz radiation on biological objects. In this work, we propose to investigate the possible impacts of this radiation on quantum phenomena. This includes the study of the decay rate changes of certain nuclei when exposed to microwave radiation and electron tunneling between superconductors. The suspected mechanism could be recognized experimentally as it would imply a clear threshold effect at some point around the 10[1]1 Hz frequency.

**Q1 296 Structural and chemical changes in ultra-high-molecular-weight polyethylene due to gamma radiation-induced crosslinking and annealing in air.** ANN VIANO, KARYN SPENCE,*MATTHEW SHANKS, M. ANDREW SCOTT, RICHARD REDFEARN, CARL CARLSON, TERESE HOLM,† *Rhodes College* ASIT RAY, *Christian Brother's University* Ultra-High-Molecular-Weight-Polyethylene (UHMWPE) is used to fabricate one of the articulating surfaces used in many total joint replacements. Various sterilization and annealing methods affect the mechanical wear properties in ways still unknown at the microscopic and molecular levels. We have investigated crosslinking induced by gamma irradiation and annealing time (both done in air). TEM was used to probe the organization of crystalline lamellae in the polymer. Pyrolysis interfaced with GC-MS was

used to quantify the extent of crosslinking by identifying peaks that correlate with crosslinking structures along its backbone. Changes in lamellar stacking and the extent of the crosslinking suggest two types of crosslinking occuring in the material. Lamellar mobility is enhanced during the transitions from one type of bonding to the other, and this appears to optimize near eight hours of annealing time. Results from decomposition experiments and percent crystallinity measuresments provide further support for this postulated theory.

**Q1 297 Antiferromagnetism in Superconducting Tl2223 well below Tc*** T. IMAM, B. LAUNSPACH, V. CHIKHANI, M. SILVEIRA, *San Jose State University* L. ROBLEDO, *CSU Long Beach* J. LEE, *Uo Illinois Urbana* C. BOEKEMA, *San Jose State University* We examine transverse field (TF; 5 kOe) Tl2223 muon-spin-rotation (muSR) data to search for antiferromagnetism (AF) near and in the vortex cores. [1] The vortex frequency signals are fitted by Gaussian and Lorentzian curves. For T $<$ 0.4Tc, Lorentzians fit much better, indicating AF. Since this is especially true for the high-field side, AF appears to exist near and in the vortex cores. [1] Zero field (ZF) muSR data of flux trapping in Tl2223 recorded at 10 K are also studied. We examine signals arising from the initial vortex core, critical field, and remnants of the initial mixed state at five kOe. Three signals at 1.5 MHz, 9-10 MHz (0.7 kOe; Bc1)and 24-25 MHz (1.8 kOe; a 2D-3D transition) are observed. The 110-Oe flux arises from magnetism initially present in the vortex state [1] before the flux trapping. Its ZF fit values are consistent with the AF-vortex TF-fit parameters. Both TF and ZF-muSR evidence suggests AF exists in the Tl2223 superconductor, supporting theories that predict a magnetic origin for cuprate superconductivity. [1] J. Lee et al, J Applied Physics 95 (2004) 6906; Virtual J Applications of Superconductivity, June 2004 V6 Issue 11; www.jyi.org/volumes/volume10/issue6/articles/prudchenko.html

**Q1 298 Interacting electrons in quantum-critical crossover regime in quantum dots*** IGOR ROZHKOV, GANPATHY MURTHY, *University of Kentucky, Department of Physics and Astronomy* We present numerical study of the statistics of ground state $S_z$ in the crossover in which spin-orbit scattering is tuned in 2D quantum dots [1]. The spin-orbit interaction introduces new symmetry limits of the single-particle Hamiltonian [2]. With the help of universal Hamiltonian for this case [1] we have created a framework for calculation of spin statistics in disordered quantum dots in the large Thouless number limit. In addition we have analyzed the spin excitation spectrum in the quantum critical regime dominated by collective critical fluctuations [3].

**Q1 299 Eriksen model: neural network dynamics analysis and simulations** YUAN LIU, *Department of Physics, Princeton University* PHILIP HOLMES, *Mechanical and Aerospace Engineering and Program in Applied and Computational Mathematics, Princeton University* We analyze a connectionist neural network model of the two-alternative forced choice Eriksen task, in which subjects must correctly identify a central stimulus and disregard flankers that may or may not be compatible with it. We have analyzed a linearized version of the connectionist model for the Eriksen two-alternative forced-choice task. We show that, provided solutions remain within the central domain of the logistic function in which it may be approximated by a linear function that matches its slope g at the bias point b, analytical solutions of a decoupled, linearized model modulated by a pre-determined attention signal provide reasonable estimates of critical times at which evidence in favor of the correct and incorrect alternatives cross over for incompatible trials. We then derive estimates of accuracy as a function of response time by interrogating a drift-diffusion (DD) process with variable drift rate, fitted to outputs from the perception layer of the fully nonlinear model. We compare our results with numerical simulations of the full nonlinear model and discuss the possibility to use information theory to optimize our network model.

**Q1 300 Generation of Soft Shockwaves by High-Speed Non-Rigid Liquid Spray*** SEONG-KYUN CHEONG, *Argonne National Laboratory* KYOUNG-SU IM, CHRISTOPHER POWELL, XIN LIU, JIN WANG, MING-CHIA LAI, *Wayne State University* FUEL SPRAY TEAM TEAM, High-pressure, high-speed sprays are an essential technology in many applications, including fuel injection systems, thermal and plasma spray coating, and liquid-jet machining. Those liquid jets, often optically opaque due to the highly dense liquid droplets surrounding the sprays, can travel at supersonic speeds and generate shockwaves. It has been believed that the shock wave can be sustained through only continuous compression with dissipative and irreversible process. However, the characteristic of the shockwaves generated by the liquid jet is different from those generated by supersonic rigid objects. Unlike those created by supersonic rigid object, the soft shock wave reveals the reversible compression process followed by the decompression process behind of the shock wave front. We employed the time-resolved x-radiograph using synchrotron source to uncover ''soft'' nature of the shockwaves quantitatively, which is in good agreement with independent theoretical analysis using the computational simulation of fluid dynamics.

*This work and the use of the APS are supported by the U. S. Department of Energy under Contract No. W-31-109-Eng-38 and by the Department of Energy Office of FreedomCAR and Vehicle Technology.

**Q1 301 Shock Wave Effects on Polymer Morphology*** E. BALIZER, J. FEDDERLY, G. LEE, *Naval Surface Warfare Center Carderock Division* W. MOCK, JR., W. HOLT, *Naval Surface Warfare Center Dahlgren Division* A gas gun has been used to launch steel ogival-nosed projectiles at a selected impact velocity into steel plates with polyurea, polyurethane and polyethylene coatings. Experiments were performed for two polymer thicknesses, and with the coating cast or loosely held onto the steel plate. Recovered polyurea, polyurethane and polyethylene coatings were characterized by small angle x-ray scattering (SAX) to determine the plastic strain at the constrained metal/polymer interface and the free boundary polymer interface. The difference in plastic strain as found by SAX in polyurea shows both flow orientation and possible fibril morphology compared to only flow orientation in polyurethane and polyethylene. The relative amounts of resulting void damage at the free surface due to reflected rarefaction waves are also described.

*Research supported by ONR 331.

**Q1 302 Molecular Dynamics simulations of perpendicular tetracosane films*** MICHAEL ROTH, *University of Northern Iowa* CARLOS WEXLER, *University of Missouri - Columbia* We present the results of Molecular Dynamics computer simulations of perpendicular tetracosane ($C_{24}H_{50}$) films adsorbed onto a bilayer of tetracosane on graphite in the temperature range [100K, 500K]. Various structural and thermodynamic quantities are utilized to characterize the system's temperature evolution. The system goes from the low – temperature solid phase supporting a perpendicular third layer to the collapse of the perpendicular film near $T = 300$K to a dense, coalesced patch at high temperature.

*The authors gratefully acknowledge partial support of this work through Petroleum Research Fund grant PRF43277-B5

**Q1 303 Deterministic simulations of endohedral noble gas release from fullerene clusters*** M.K. BALASUBRAMANYA, *Texas A&M University - Corpus Christi* MICHAEL ROTH, *University of Northern Iowa* PHILIP TILTON, *Texas A&M University - Corpus Christi* BRYCE SUCHY, *University of Northern Iowa* Molecular Dynamics computer simulations are conducted on small ($N = 5$) endohedral $X@C_{60}$ clusters, where X = He, Ne, Ar, Kr and Xe. The cluster dissociates at a temperature between $T =$ 1150K and 1200K. As temperature is raised further, endohedral atoms begin leaving the cluster near $T = 4000$K. In the temperature range [4000K, 5000K] escape constants and half lives are calculated for release of the various gases. Helium exits much more quickly than any other noble gas examined, and larger species tend to exit more slowly not only because of their larger collision diameter but also because they stabilize the fullerene cage. Comparisons with and contrasts to experiment are mentioned.

*This work has been supported in part by an NSF MRI grant under the Division of Computer and Network Systems (# 0321218), and by a UNI Summer 2004 Fellowship for B.S.

**Q1 304 Systematic Study of magnetic Field Effects in Amorphous Solids at Ultra Low Temperatures.** LIDIYA POLUKHINA, SEUNGHWA RYU, DOUGLAS OSHEROFF, PHYSICS DEPARTMENT, STANFORD UNIVERSITY TEAM, The dielectric response of some amorphous solids below 100 mK is known to be sensitive to applied magnetic field. While a theoretical explanation for this phenomenon has been proposed, a systematic experimental study of different glasses in a broad parameter range is advised. We investigate and compare the behaviour of Suprasil, BK7, Aluminum-Barium-Silicate, Corning and Durane samples in the temperature range from 2 mK to 200 mK in presence of the magnetic field up to 30 milliTesla. In addition, we hope to find an amorphous solid whose dielectric constant shows no magnetic field dependence, making it suitable for thermometry in applied magnetic fields.

**Q1 305 Atomic Stability as Result of Electrodynamic Stability Condition** JX ZHENG-JOHANSSON, *IOFPR, SWE* P-I JOHANSSON, *Uppsala Univ, SWE* According to [1] an electron $e^-$ is formed of an oscillatory massless charge $-e$ in general also traveling at velocity $v$, and the resulting electromagnetic waves of angular frequency $\omega^j$, $j = \dagger$ and $\ddagger$ for generated in $+v$ and $-v$ directions. The wave energy $\hbar\sqrt{\omega^{\dagger}\omega^{\ddagger}}$ equals the charge oscillation energy $\varepsilon_q$ (with the $v = 0$ portion) endowed at the charge's creation; $\varepsilon_q/c^2$ gives the electron mass $m_e$, $c$ the wave speed. For an atomic orbiting electron, the charge's $v$ motion is along a circular (or projected-elliptic) orbit $\ell$ of radius $r$; so are its waves. (a) The waves meet in each loop with the charge, are absorbed a portion by it and reemitted, repeatedly, and thereby retained to it; the vacuum, having no lower energy levels for the charge to decay to except in a pair annihilation, is essentially a non-dissipative medium. (b) The two waves, being Doppler-differentiated for the moving source, meet each other over the loops and superpose into a beat, or de Broglie phase wave $\Psi$. $\Psi = Ce^{i(k_d\ell - \omega T)}$ is a maximum if $2\pi r_n = n\lambda_{dn}$, $n$ integer, $\lambda_d = 2\pi/k_d = (c/v)\lambda$ the de Broglie wavelength and $\lambda = 2\pi c/\omega$, and accordingly yields a stable state. The corresponding overall eigen solutions are exactly equivalent with the QM results. The classical electrodynamic stability conditions (a)-(b) entail the stability of the atomic system. [1] JX Zheng-Johansson & P-I Johansson, *Unification of Classical, Quantum and Relativistic Mechanics and the Four Forces*, Fwd Prof R Lundin, Nova Science, NY, 2005; see also B40.00003, this meeting.

**Q1 306 Domain wall soliton in a trapped spin-1 atomic Bose-Einstein condensate*** WENXIAN ZHANG, *Ames Laboratory, Iowa State University, Ames, Iowa 50011, USA* L. YOU, *School of Physics, Georgia Institute of Technology, Atlanta, Georgia 30332, USA* Solitons are interesting phenomenon in nonlinear systems, including atomic Bose-Einstein condensates. We investigate numerically a soliton state of a ferromagnetically interacting spin-1 condensate confined in a cigar shaped harmonic trap. The dynamics of this soliton, described by the coupled Gross- Pitaevskii equations within the mean field theory frame, is stable and intimately related to the recently observed domain structures in spin-1 condensate and similar to the domain wall soliton in two-component condensates. We present a rotating reference frame in which the local spin dynamics of the soliton becomes time independent.

*Supported by NSF.

**Q1 307 Near-wall turbulence structure in Poiseuille-Couette flow*** DIMITRIOS PAPAVASSILIOU, NICHOLAS SPENCER, *The University of Oklahoma* COMPUTATIONAL TRANSPORT PROCESSES TEAM, Given recent reports that ultra-hydrophobic surfaces generate slip at the wall in laminar flows, the question arises whether turbulence drag reduction can be achieved over such surfaces. If so, how is the near-wall turbulence structure affected? This work focuses on the effects that a specified wall velocity (or wall slip) can have on the turbulence field. Direct numerical simulations of a Poiseuille-Couette flow channel were used. Computations were completed for Re=5200 (based on centerline mean velocity and channel width). The runs included the cases where one wall moved with 0, 1, 2 and 4 plus velocity units in the flow direction relative to the opposite channel wall. The mean velocity maximum shifted towards the moving wall as the wall velocity increased, as well as the point at which the Reynolds stress crossed zero. The turbulence intensity was lower close to the moving wall side. The velocity correlation coefficients showed that near-wall structures became shorter. The paper will discuss the implications on slip-induced drag reduction.

**Q1 308 A methodology to separate single cells and single mitochondria to determine the location of heteroplasmy in mito-**

**chondrial DNA** JOSEPH REINER, *Physics Laboratory, NIST, Gaithersburg* RANI KISHORE, *NIST* THOMAS ALBANETTI, SARAH PEERY, ASHLEY KNIPE, AMANDA SHEETS, NICHOLAS BOIRE, KOREN DECKMAN, *Gettysburg College* BARBARA LEVIN, *CSTL-NIST* KRISTIAN HELMERSON, *NIST* A mixture of mutated and wild type mitochondrial DNA is referred to as a heteroplasmic population. Mitochondrial DNA heteroplasmies have been studied at the multi-cell level with some being linked to chronic symptoms of mitochondria-based diseases. However, the mechanism producing heteroplasmy is undetermined. One question is whether mitochondrial DNA heteroplasmies are present within single mitochondria. To address this issue we developed a protocol to isolate a single mitochondria from single human leukocyte cells. The cells from an HL-60 cell culture were labeled with Mitotracker Green FM and showed to contain a heteroplasmy at the cellular level (PCR and sequencing showed a 50/50 C/T heteroplasmy at nucleotide position 12071). In order to study heteroplasmy at the single mitochondria level a pulsed UV laser was used to lyse an individual cell. Mitochondria escaped from the cell and optical tweezers were used to transfer single mitochondria into a micropipette tip. Preliminary results suggest that single mitochondria also contain the heteroplasmy.

**Q1 309 Carrier Diffusion Model for Electrical Conductivity Response of Bi3TiNbO9 to Ambient Humidity*** RICARDO E. AVILA, *DMN, CCHEN, Cas. 188-D, Santiago, Chile* ALICIA CASTRO, *ICMM, CSIC, Madrid, Espaa* DANIEL SERAFINI, HCTOR ULLOA, *Depto. de Fsica, USACH, Santiago, Chile* The electrical properties of the metastable phase of $Bi_3TiNbO_9$ isomorphic to $\delta$-$Bi_2O_3$, in ceramic pellet form have been established. Pellets are formed by mechanochemical activation (1 to 48 h in an SPEX 8000 automatic mill), and uniaxial pressing, leading to the metastable phase in the 310 to 490 [r]C, as the activation time increases. Correspondingly, the stable Aurivillius phase forms in the 500 to 600 [r]C range. The current through pellets with $\sim$ 10 nm thick sputtered Pt electrodes increase by factors between 10 an 2000 in a transient from dry air to dew point of 10 [r]C at room temperature. The response time (10% to 90% of the current rise) is in the 15 to 30 s range, and it does not deteriorate under saline ambient, nor does it depend on the dry carrier gas (air, Ar, $N_2$, $O_2$, or 0.1% $H_2$ / He). A bulk carrier diffusion model achieves a close qualitative fit to the current response to bias and humidity cycling.

*Supported by Fondecyt Grant 1040213

**Q1 310 Influence of Gas Heating and Vibrational Kinetics on the Ionization Dynamics of Preformed Air Plasma Channels** HAROLD LADOUCEUR, ANDREW BARONAVSKI, *Naval Research Laboratory* TZVETELINA PETROVA*, *Naval Research Laboratory, NRC* An extensive self-consistent air-plasma model based upon the Boltzmann equation for the electron energy distribution function, coupled with a heavy particle kinetics was developed to study electric discharges in a preexisting air plasma column [1]. Incorporated in the model are the steady-state balance equations for various nitrogen and oxygen species in ground and excited states, as well as atomic and molecular ions. The influence of the gas temperature is accounted for by reduction of the neutral density, collisional processes such as recombination, dissociation, V-V and V-T reactions [2], and by reactions involving electronically excited states of $O_2$. The model was applied to study the influence of the gas temperature and vibrational kinetics on the breakdown processes in a preformed air plasma channel. Numerical calculations predict that electrical breakdown occurs at relatively low electric field. The calculated self-consistent breakdown electric field is $\sim$ 10 kV/cm for gas temperature of 300 K, while at temperature of 600 K it drops to $\sim$ 5.7 kV/cm, in excellent agreement with the experimentally determined breakdown electric field [1]. * NRC-NRL Postdoc [1] Tz.B. Petrova, H.D. Ladouceur, and A.P. Baronavski, 58th Gaseous Electronics Conference, 2005; San Jose, California, FM.00062 [2] J. Loureiro and C.M. Ferreira, J. Phys. D: Appl. Phys **19** (1986) 17-35

**Q1 311 Defend Science: The Attack on Scientific Thinking and What Must Be Done** JASON CURTIS, *UC Berkeley / Defend Science Project* ''In the United States today science, as science, is under attack as never before (Defend Science, defendscience-.org).'' Beyond, and underlying, the many particular attacks and outrages in different spheres and policy areas is the question of the scientific method and whether it is going to be upheld and applied, or whether – even in the realm of science itself – that method is going to be replaced by something antagonistically opposed to the scientific method. These attacks are increasingly coming from powerful forces, in and out of the Bush administration, with an extreme right-wing political agenda, a Biblical-literalist ideological agenda, and theocratic aspirations for society. Individual scientists may be atheists, agnostics, or may hold various religious beliefs, but if religious and theistic elements are forced into the definition of science, then the scientific process is undermined and science cannot really be practiced. We can and must develop a society wide battle, initiated by scientists, but involving ever growing masses of people to defend science and scientific thinking. Scientists from various fields must be mobilized to issue a public call to millions with this urgent message as the beginning of this effort. I will discuss the necessity, possibility, and some initial efforts toward developing this kind of societal movement in defense of science.

**Q1 312 Tod-Down Physics** MICHAEL SCHILLACI, *University of South Carolina* Over the past 7 years I have worked to develop two, two-semester course sequences in Theoretical and Computational Physics appropriate for undergraduate education in Physics. Covering material traditionally handled in Classical Mechanics and Electricity and Magnetism, the Theoretical Physics sequence stresses mathematical rigor, physical insight and a project- based paradigm, covering topics such as Landing on the Moon, Realistic Tidal Models, and The Solar Sail. A two- volume text (recently adopted by Mercer University) has been developed for the Computational Physics sequence and introduces students to the essentials of Maple, LaTeX and JAVA as well as web-page (HTML, JavaScript) publishing. While the bulk of the first semester is devoted to software use and algorithm development (i.e., numerical integration) wrote homework is supplemented by ''group quiz and project activities. In the second semester laboratory experiments such as the Toothpick Toss, The Not-So-Simple Harmonic Oscillator and the Chaotic Diode are performed and then computational simulations are developed using various tools (i.e., JAVA, Visual Basic, Matlab).

**Q1 313 Delayed Ionization Studies of Metal-Carbon Clusters*** KEVIN DAVIS, SAMUEL PEPPERNICK, A. CASTLEMAN, JR., *The Pennsylvania State University* Clusters of molecules, restricted to the nanometer size regime, display reduced size phenomena associated with the effects of quantum confinement. One

such occurrence, termed delayed ionization, is a fascinating phenomenon that has been observed in various metal, fullerene and metal-carbon cluster systems. Generally, favorable candidates to display delayed ionization characteristics are clusters containing a significant number of vibrational modes. Furthermore, the magnitude of the cluster's ionization potential must be in competition with its binding energy, whereby dissociation is impeded compared to ionization. The mechanism most commonly used to explain the delayed emission of electrons is termed thermionic emission. In order to interrogate this effect, delayed ionization studies are performed on early transition metal-carbon cluster systems. These clusters are produced in a laser induced plasma reactor cluster source coupled to a nanosecond ultraviolet photoionization laser, and are detected via the microchannel plates of a reflectron time-of-flight mass spectrometer. In this work, interesting delayed ionization characteristics of metal-carbon clusters will be presented in an effort to provide a better understanding of the relaxation processes that occur within clusters.

**Q1 314 Probing minimal scattering events in enhanced backscattering of light using low-coherence induced dephasing** YOUNG KIM, PRABHAKAR PRADHAN, MIN KIM, HARIHARAN SUBRAMANIAN, YANG LIU, VADIM BACKMAN, *Northwestern University* We report the first experimental evidence that the minimum number of scattering events in enhanced backscattering (EBS, also known as coherent backscattering) of light is double scattering in discrete random media, which has been hypothesized since the first observation of EBS of light. We exploit low spatial coherence illumination to dephase time-reversed partial waves outside its finite coherence area, which virtually creates a controllable coherence volume and isolates the minimal number of scattering events from higher order scattering in EBS. In addition, EBS under low spatial coherence illumination possesses unique advantageous features compared to conventional EBS: (i) The spatial coherence length of illumination can be made to be the shortest length scale (except particle sizes) in weakly scattering media such as biological tissue. (ii) A large number of the independent coherence areas provide statistical information about the optical properties of random media in a single measurement, without configuration or ensemble averaging. (iii) LEBS allows varying the spatial coherence length of illumination to control the dephasing rate externally and LEBS does not require complicated sample preparations. Thus, these characteristics of LEBS will facilitate investigations of EBS in weakly scattering random media including biological tissue.

**Q1 315 Femtosecond time-resolved optical studies of collective modes in $La_{1-x}Ca_xMnO_3$** YUHANG REN, *Physics & Astronomy, Hunter College of the City University of New York* DAIMIAN WANG, MARIANO TRIGO, *Physics, The University of Michigan* VENIMADHAV ADYAM, QI LI, *Physics, The Pennsylvania State University* ROBERTO MERLIN, *Physics, The University of Michigan* We report on time-resolved ultrafast optical measurements on a $La_{1-x}Ca_xMnO_3$ (LCMO) single crystal ($x = 0.3$) and thin film ($x = 0.33$). The differential reflectivity shows coherent GHz oscillations due to the excitation of longitudinal acoustic (LA) phonons. The wavelength dependence of the period of such oscillations allows us to determine the sound velocity and elastic constant. Above $T_C$, the measured GHz sound velocity is more than 40% larger than the sound velocity in the MHz range as determined by ultrasound measurements. The data is explained by a possible existence of polaron liquid state. Also the differential polarization shows coherent magnons in LCMO. We determine the magnetic anisotropy and spin stiffness constants from the magnetic-field dependence of the frequency of the spin waves.

**Q1 316 Quartz Crystal Microbalance Measurements of Protein Deposition onto Cross-linked polyHEMA Hydrogel** JONATHAN TEICHROEB, JAMES FORREST, *University of Waterloo* LYNDON JONES, The adsorption of various concentrations of several opthalmologically relevant proteins was measured using Quartz Crystal Microbalance (QCM). Hen egg white lysozyme HEWL, bovine serum albumin BSA, and lactoferrin were measured both individually and in various combinations as they adsorbed onto cross-linked polyHEMA substrate. Results are discussed in terms of the concentration and time dependence of total adhered protein, as well as the amount of desorbable protein. Variations seen during competitive adsorption are also presented.

**Q1 317 Magnegtic Phase Diagram and Specific Heat of the Quasi-Two-Dimensional S=1/2 Antiferromagnet $Cs_2CuBr_4$** TODD E. SHERLINE, YASUMASA TAKANO, *University of Florida* $Cs_2CuBr_4$ is an excellent laboratory model for the S=1/2 Heisenberg antiferromagnet on a triangular lattice, with a small anisotropy. In a magnetic field, the most distinguishing feature of this antiferromagnet is a magnetization plateau, which occurs at 1/3 of the saturation magnetization. Previous specific heat and magnetocaloric effect measurements in DC fields of up to 20T have been used to determine the magnetic phase diagram in this regime. However, the nature of the phase diagram is unclear in higher fields. Further specific heat and magnetocaloric effect measurements have been made in DC fields up to 32T, the results of which will be presented in order to elucidate the nature of the phase diagram above the magnetization plateau.

**Q1 318 Experiments with Ultra-cold Atoms in an Optical Lattice with Dynamically Variable Lattice Constant** JOHN HUCKANS, IAN SPIELMAN, BRUNO LABURTHE TOLRA, *Institut Galile - Universit Paris 13* J.V. PORTO, W.D. PHILLIPS, LASER COOLING AND TRAPPING TEAM, We have implemented a one-dimensional optical lattice whose periodicity may be dynamically varied with ultra-cold atoms in-situ. We have measured atom heating rates in the lattice as a function of lattice periodicity ramp velocities and profiles. We superimpose another one-dimensional lattice with fixed periodicity and measure atom diffraction as a function of the ratio of the two competing periodicities. Finally, we report interesting near field atomic diffraction results for extremely large periodicity lattices.

**Q1 319 Effect of the anisotropy factor of scattering and the finite spatial coherence length of light source on enhanced backscattering** P. PRADHAN, YOUNG KIM, HARIHARAN SUBRAMANIAN, YANG LIU, VADIM BACKMAN, *Northwestern University, Evanston, IL 60208* Enhanced backscattering (EBS) of light (also known as coherent backscattering) is a constructive self-interference effect in the backscattered direction due to the photons traveling along time-reversed paths in a disordered medium. EBS can be used for characterization of disordered media and recently been used in cancer detection. Conventional EBS is determined by the scattering transport mean free path of the me-

dium. However, the properties of EBS become more complex and richer in case of anisotropy of scattering (anisotropy factor g$>$ 0) and finite spatial coherence length (Lsc) of a light source. We report our experimental and numerical studies of the effects of g and Lsc on EBS. We demonstrate for the first time that the profile of the EBS peak varies non-monotonically with mean free path length ls, and is a double valued function of ls for a range of values of Lsc and g. Hence, the value of g can be extracted from the EBS profile, which may provide important and previously unattainable information about biological tissue in situ.

**Q1 320 Modeling Low-Coherence Enhanced Backscattering (LEBS) using Photon random walk model of Light Scattering** HARIHARAN SUBRAMANIAN, PRABHAKAR PRADHAN, YOUNG KIM, YANG LIU, VADIM BACKMAN, *Northwestern University, Evanston, IL - 60208* Enhanced backscattering (EBS) peak from a biological media with transport mean free path length ($l_s^*$) $>>$ wavelength $\lambda$, is extremely small ( $\sim 0.001^0$) making the experimental observation of such narrow peaks to be difficult. Hence, we developed a low coherence enhanced backscattering (LEBS) technique by combining the EBS measurements with low spatial coherence (LSC) illumination and low temporal coherence detection. LSC behaves as a spatial filter preventing longer path lengths and collects photons undergoing low orders of scattering. The experimental angular width of these LEBS peaks ( $\sim 0.3^0$) are more than 100 times the width of the peak predicted by conventional diffusion theory. Here we present a photon random walk model of LEBS cones to further our understanding on the unprecedented broadening of the LEBS peaks. In general, the exit angles of the scattered photons are not considered while modeling EBS peaks in diffusion regime. We show that these photon exit angles are sensitive to the low orders of scattering, which plays a significant role in modeling LEBS peaks when the spatial coherence length of the light source is much smaller than $l_s^*$. Our results show that the model is in good agreement with experimental data obtained at different low spatial coherence illumination.

**Q1 321 Highly Ordered Arrays of Silicon Nanostructures Fabricated by Reactive Ion Etching and Atomic Fluorine Etching** MARK CURTIS, PRESTON LARSON, KEVIN HOBBS, MARK KEIL, MATTHEW JOHNSON, HOMER L. DODGE DEPARTMENT OF PHYSICS AND ASTRONOMY, UNIVERSITY OF OKLAHOMA, NORMAN, OK 73019 TEAM, High density arrays of conical nanostructures have been fabricated in silicon using a combination of anodic aluminum oxide (AAO) templating and dry etching techniques. Optically, such structures appear black, indicating strong optical absorption. Such structures have applications associated with field emitters and photo-voltaic cells. Silicon directly exposed to an atomic fluorine beam yields an array of sharp silicon spikes. Using the AAO template as a mask with the fluorine beam or reactive ion etcher (RIE) results in highly ordered arrays of nanostructures. In particular, the RIE samples have conical silicon nanostructures, approximately 150 nm in height. These nano-cones are arranged in a honeycomb pattern with a center-to-center spacing of approximately 100 nm and exhibit a high degree of ordering over micron by micron areas. Characterization of these nanostructures was carried out by scanning electron microscopy and various optical techniques.

**Q1 322 Synthesis and Mechanical and Electrical Properties of Carbon Nanotubes Grown at Low Temperatures by Thermal Chemical Vapor Deposition** YUNYU WANG, LI SHI, *Department of Mechanical Engineering, University of Texas at Austin* ZHEN YAO, *Department of Physics, University of Texas at Austin* PAUL HO, *Department of Mechanical Engineering, University of Texas at Austin* Carbon nanotubes (CNTs) have shown great potentials in versatile applications such as electron sources, heat interface materials and drug delivery vehicles due to their unique aspect ratio, thermal conductivity, and biocompatibility. CNTs have also attracted wide interests in applications for the next generation microelectronics, including interconnects, mainly due to its high current carrying capacity, *i.e.* $> 10^9$ A/cm$^2$. However, CNTs have been commonly synthesized under high temperatures, e.g. $>$ 1000 $^o$C for laser ablation and arc discharge and 600-900 $^o$C for chemical vapor deposition (CVD), which is not compatible with the $<$ 450 $^o$C requirement for microelectronic technology, and makes it difficult to integrate CNTs into integrated circuit chips. In this study, we present a controlled growth of CNTs at 450 $^o$C using a simple thermal CVD method. It has been shown that a combination of catalyst choice and preheating precursors is critical for the formation of CNTs at low temperatures. As-grown CNTs have been characterized using scanning electron microscopy, where vertically aligned dense short nanotubes films with lengths of $\sim$ 400 nm have been observed. For applications in microelectronics, mechanical and electrical properties of short CNT films are tested and the results will be discussed.

**Q1 323 Magneto-Transport Studies of Molecular Beam Epitaxial Grown Osmium Silicides*** RYAN COTTIER, WEI ZHAO, FATIMA AMIR, KHALID HOSSAIN, *University of North Texas* NOUREDDINE ANIBOU, WOLFGANG DONNER, *University of Houston* TERRY GOLDING, *University of North Texas* UNIVERSITY OF NORTH TEXAS COLLABORATION, UNIVERSITY OF HOUSTON COLLABORATION, Semiconducting transition metal silicides present a possible solution to on-chip integration of optical and electronic Si-based circuitry. Two phases of osmium silicide ($OsSi_2$ and $Os_2Si_3$) are predicted to have promising optical characteristics but require additional development to fully determine their feasibility for high-quality devices. This study has been motivated by reports that $OsSi_2$ has a bandgap between 1.4–1.8eV [1, 2] and $Os_2Si_3$ may have a direct bandgap of 0.95 eV [3] or 2.3 eV [1]. In this paper we will present temperature dependent ($20 < T < 300$ K) magneto Hall measurements of molecular beam epitaxial grown osmium silicide thin films. Os and Si were coevaporated onto Si(100) substrates at varying growth rates and temperatures. XRD was performed in order to identify the silicide phases present. We will discuss our results in relation to the known phase diagrams and our growth parameters. [1] L. Schellenberg et al., J. Less-Common Met. **144**, 341 (1988). [2] K. Mason and G. Müller-Vogt, J. Appl. Phys. **63**, 34 (1983). [3] A. B. Filonov et al., Phys. Rev. B **60**(24), 16494 (1999).

**Q1 324 Electron transport studies of superconducting Pb single-electron tunneling transistors** KANG LUO, ZHEN YAO, *Department of Physics, The University of Texas at Austin, Austin, TX 78712* We investigate the electronic transport properties of superconducting Pb single-electron tunneling transistors created by electromigration of Pb nanowires. In the superconducting state,

the conductance is suppressed by a combination of the Coulomb blockade effect and the absence of density of states within the superconducting gap. The tunneling spectroscopy at 2 K shows a strong even-odd parity effect which is smeared out at 4.2 K. Upon application of a magnetic field, the superconducting state is suppressed and single-electron tunneling behavior for normal metallic nanoparticles is recovered. We will present a theoretical model and compare it with our experimental data.

**Q1 325 Session M's Speakers Promote Evolution and Deny Creation Without Reference to My Widely Published Evidence of Earth's Rapid Creation and Without Reference to My Recent Discoveries Disproving the Big Bang: Congress Should Investigate Why They Did This** ROBERT GENTRY, I have long and widely described the primordial polonium radiohalos that exist in Earth's foundation rocks all over the world in the world's leading scientific journals. The short half-lves of the relevant polonoium isotopes – 3 min for Po- 218 – requires almost instantaneous creation of the host rocks, generally the hard crystalline rocks such as granites, showing that these rocks were the product of creation, not a long slow process of evolution. My publications can be found at www.halos.com. and have been accessible to the worldwide scientific community for over two decades without being refuted. More recently I have discovered fatal flaws in the big bang theory and also a New Cosmic Model that explains eight of the major predictions of the big bang (see CERN Preprint, Ext-2003-021, and CERN Preprint, Ext-2003-022. Additional disproof is available at www.orionfdn.org, which are papers that were submitted to and received arXiv numbers, but were promptly censored from being released, and continue to be suppresed by P Ginsparg and Cornell University. This is a practice borrowed from a totalitarian state and the Congress needs to investigate why supression of evidence of creation continues. There is no excuse for Session M's speakers not to acknowledge this evidence for the Genesis six- day creation of Earth and the visible heavens.

**Q1 326 Mesoscopic light transport properties of a single biological cell: Early detection of cancer** PRABHAKAR PRADHAN, YANG LIU, YOUNG KIM, XU LI, RAMESH K. WALI, HEMANT K. ROY, VADIM BACKMAN, *Northwestern University, Evanston, IL 60208* The progression of carcinogenesis involves morphological changes in the internal structure of a biological cell. These changes are reflected in the fluctuations of refractive index within the cell at scales ranging from a few nanometers to microns. We demonstrate that these fluctuations of refractive index can be measured by our newly developed technique – partial wave spectroscopic microscopy, and can be quantified using the mesoscopic transport theory of light. Our experimental and numerical results show that the statistics of the light reflection coefficient, the statistics of the localization length and the statistics of the refractive index fluctuation agree well with the mesoscopic light transport theory. Furthermore, our results show that we can detect the progress of carcinogenesis in a single biological cell earlier than any existing technique. We conclude that biological cells are nature made interesting disordered mesoscopic systems, and the changes in the statistics of fluctuations of refractive index in a single cell are highly diagnostic for noninvasive early detection of cancer using mesoscopic theory.

**Q1 327 Hydrogenation of Semiconductors Using an Ultra-Violet Light Source*** T.D. GOLDING, *University of North Texas/ Amethyst Research* R. HELLMER, *Amethyst Research* J. H. DINAN, *U.S. Army RDECOM CERDEC NVESD* R. J. COTTIER, *U. of North Texas* L. WANG, *Evans Analytical Group* W. ZHAO, *U. of North Texas* F. AMIR, *U. of North Texas* J. HOUSE, *U. of North Texas* Hydrogenation (also referred to as passivation) of semiconductors using a plasma discharge is routine. However, the process can cause unwanted modification of the surface, and requires contact masking if control of the lateral dosage is required. We will present results of a new technique for the hydrogenation of semiconductors based on the use of an ultra-violet (UV) light. While our studies have been conducted primarily on HgCdTe, we have similar results for the hydrogenation of GaAs and InP. Using the technique of secondary ion mass spectroscopy (SIMS) we have found that D is readily incorporated into semiconductors when the surface of the semiconductor is simultaneously exposed to a hydrogen (deuterium) gas and UV light. No D is observed to be present (to within the SIMS resolution) if the sample is treated under similar conditions without the UV light present. Early studies of the temperature dependence on the D concentration verses depth indicate that the process is diffusion driven. These results strongly suggest that the UV photons are dissociating adsorbed D molecules to atomic D on the semiconductor surface. In addition to our experimental results details of theoretical modeling to account for this phenomenon will be presented.

*Work supported by the US Army and National Science Foundation

**Q1 328 Magnetic Force Microscopy of Superconducting Vortices in Ordered Arrays of Artificial Pinning Centers** JOEL KEAY, PRESTON R. LARSON, KEVIN L. HOBBS, MATTHEW B. JOHNSON, *University of Oklahoma* OPHIR M. AUSLAENDER, KATHRYN A. MOLER, *Stanford University* Ordered arrays of artificial pinning centers were fabricated in Nb thin films using anodic aluminum oxide (AAO) as a template. The nanohole arrays show only a small decrease in the superconducting transition temperature, $T_c \simeq 7.1$ K, from comparable, unprocessed Nb thin films. These artificial pinning arrays have a triangular lattice parameter of 105 nm and antidot diameters of about 50 nm. Anomalous features at the first, second and third matching fields (matching field = 2170 Oe) were observed in the magnetization half-loops of these arrays at 5 K. Magnetic Force Microscopy (MFM) was used to image the nanohole arrays above and below $T_c$. The images clearly show the nanohole lattice. Individual vortices have also been imaged and their movement within the lattice is being investigated. Preliminary measurements of the depinning force of individual vortices at low fields will be presented. This work was supported by NSF grant nos. DMR-0080054 and NSF-0132534.

**Q1 329 Interference patterns in field emission images of Multi-Walled Carbon Nanotubes** GEORGIANNA MARTIN, P.R. SCHWOEBEL, *University of New Mexico* Carbon nanotubes are of interest due to their unusual chemical and electrical characteristics and have thus been suggested for use in a wide variety of applications including field emission cathodes. However, there are indications that their emission characteristics, like those of most field emitters, are sensitive to their vacuum environment. Interference patterns in the field emission images of nanotubes have been observed by others and associated with coherent electron emis-

sion. Here we report the observation of interference patterns with either a central node or anti-node which appear to be associated with phase shifts introduced by surface adsorbates. This work is supported by the NSF under grant number ECS-0245682.

**Q1 330 Search for a ferromagnetic quantum criticality in $YbIn1_{1-x}Rh_xCu_4$** Y. TOKIWA, F. RONNING, V. FRITSCH, R. MOVSHOVICH, J.D. THOMPSON, J.L. SARRAO, *Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA* The geometrically frustrated system $YbIn_{1-x}Rh_xCu_4$ is investigated in order to search for a quantum criticality associated with ferromagnetic correlations. The undoped $YbInCu_4$ undergoes a first-order isostructural valance transition at 42K. The valance transition is suppressed with Rh substitution of $x\sim 0.3$ and ferromagnetic correlations grow with increasing Rh content as can be seen from the increasing Weiss temperature in magnetic susceptibility. We report low temperature specific heat measurements down to 50mK on $YbIn_{1-x}Rh_xCu_4$with x around suspected critical concentration $x\sim 0.6$ and discuss the relation between the ferromagnetic correlations and non-Fermi liquid behavior.

**Q1 331 Atomic-resolution Spectroscopic Imaging Scanning Tunneling Microscopy of Triple Layer Cuprate: $Bi_2Sr_2Ca_2Cu_3O_{10+\delta}$** JHINHWAN LEE, S. ILLANI, JINHO LEE, J. W. ALLDREDGE, *Cornell University* C. T. LIN, B. KEIMER, *Max-Planck Institut* J. C. DAVIS, *Cornell University* We present preliminary high spatial resolution scanning tunneling spectroscopy (STS) study of triple layer cuprate $Bi_2Sr_2Ca_2Cu_3O_{10+\delta}$. The sample is near optimally doped, with $T_c = 110$ K. The local density of states (LDOS) map shows (1) strongly heterogeneous gap distributions, (2) significantly increased average superconducting gap, (3) equivalent energy-dispersive quasiparticle interference patterns and (4) stronger and sharper coherence peaks compared to double layer cuprate $Bi_2Sr_2CaCu_2O_{8+\delta}$ of similar doping. We also have preliminary observations of the disordered bosonic mode energy distribution qualitatively similar to those of $Bi_2Sr_2CaCu_2O_{8+\delta}$.

**Q1 332 Amphiphilic diblock copolymers with adhesive properties: structure and swelling with water** PASCALE FABRE, *CRPP-CNRS 115 av. Dr. Schweitzer F-33600 Pessac* SYLWIA POIVET,* FRÉDÉRIC NALLET, KAI SCHIERHOLZ,† GINU ABRAHAM, *CRPP-CNRS* ERIC PAPON, YVES GNANOU, *LCPO, 16 av. Pey-Berland, F-33607 Pessac cedex, France* RAYMOND OBER, *Laboratoire de physique des fluides organisés, UMR CNRS-Collège de France, 11 place Marcelin Berthelot, F-75231 Paris cedex 05, France* OLIVIER GUERRET, NOUREDDINE EL-BOUNIA, *ARKELA-GRL, B.P. 34, F-64170 Lacq, France* We study asymmetric block copolymers with the simple diblock AB architecture, in the case where the longer block A is both hydrophobic and ''soft,'' whereas the shorter block B is hydrophilic and ''hard.'' Materials with such a particular combination of physico-chemical and mechanical properties have distinctive advantages, in particular for designing water-compatible adhesive materials. The phase-diagram is established, combining NMR and SAXS characterizations of the materials. The swelling with water is monitored through gravimetry and ''time-resolved'' SAXS. Indications of maintained adhesive properties in a wet environment are given.

**Q1 333 Ionisation Potentials of Metal Carbide Clusters** VIKTORAS DRYZA, *Department of Chemistry, The University of Adelaide, South Australia 5005, Australia* M. ADDICOAT, JASON GASCOOKE, MARK BUNTINE, GREGORY METHA Photo-Ionisation Efficiency (PIE) experiments have been performed on gas phase niobium and tantalum carbide clusters to determine their ionisation potentials (IPs). For TanCm ($n=3$–4, $m=0$–4) clusters an oscillatory behaviour is observed such that clusters with an odd number of carbon atoms have higher IPs and clusters with an even number of carbons have lower IPs. Excellent agreement is found with relative IPs calculated using density functional theory for the lowest energy structures, which are consistent with the development of a $2\times2\times2$ face-centred nanocrystal. For the niobium carbide clusters we observe the species $Nb_4C_5$ and $Nb_4C_6$. Initial calculations suggest that these clusters contain carbon-carbon bonding. Interestingly, the stoichiometry for $Nb_4C_6$ is half that of a metcar, $M_8C_{12}$. Preliminary data will also be shown on bimetallic-carbide clusters.
