**D33 3 Relating structure and friction: Energy dissipation during the lateral manipulation of antimony nanoparticles** U.D. SCHWARZ, *Dept. of Mechanical Engineering, Yale University* C. RITTER, *Institute of Chemistry, Humboldt University Berlin* M. HEYDE, *Fritz-Haber Institute of the Max-Planck-Society, Berlin* K. RADEMANN, *Institute of Chemistry, Humboldt University Berlin* Despite its daily-life importance, the fundamentals of friction are still insufficiently understood. In particular, the interplay between friction, ''true'' contact area, and crystalline structure at the interface is an issue of current debate. Recently, a new technique had been introduced that allows determining the threshold energy dissipated during the lateral displacement of small nanoparticles on suitable substrates as a function of the particle-substrate contact area [Ritter et al., PRB **71**, 085405 (2005)]. Here, we present results of an extensive study of antimony nanoparticles 1000 $nm^2$ to 100000 $nm^2$ in size moved in air on graphite substrates. Complementary studies by electron microscopy reveal the internal structure of the islands, showing a transition from amorphous to crystalline of the island's cores at about 10000-15000 $nm^2$ size, while the surface layers are composed of amorphous antimony oxide in all cases. However, despite the similarities of the amorphous surface layer, islands with crystalline core show significantly higher energy dissipation during motion than the ones with amorphous core. Possible reasons for this effect are discussed.

**15:30**
**D33 4 Relationship between friction and quasicrystallinity; friction anisotropy in a decagonal Al-Ni-Co quasicrystal surface** JEONG YOUNG PARK, D. F. OGLETREE, M. SALMERON, *Lawrence Berkeley National Lab. University of California, Berkeley* R. A. RIBEIRO, P. C. CANFIELD, *Ames Laboratory, Dept. of Physics & Astronomy, Iowa State Univ* C. J. JENKS, P. A. THIEL, *Ames Laboratory, Dept. of Chemistry, Iowa State Univ* We investigated the nanoscale tribological properties of a decagonal quasicrystal using a combination of atomic force microscopy (AFM) and scanning tunneling microscopy (STM) in ultrahigh vacuum. This combination permitted a variety of in situ measurements, including atomic- scale structure, friction and adhesion force, tip-sample current, and topography. We found that thiol-passivated tips can be used for reproducible studies of the tip-quasicrystal contact while non-passivated probes adhere irreversibly to the clean quasicrystalline surface causing permanent

modifications. The most remarkable results were obtained on the 2-fold surface of the Al-Ni-Co decagonal quasicrystal where atoms are arranged periodically along the 10-fold axis and aperiodically in the perpendicular direction. Strong friction anisotropy was observed on this surface, with high friction along the periodic direction, and low friction in the aperiodic direction. These results reveal a strong connection between interface atomic structure and the mechanisms by which energy is dissipated, which likely include electronic or phononic contributions, or both.

**15:42**

**D33 5 New Phenomena in High Temperature Nanofriction on Nonmelting Surfaces: NaCl(100)** TATYANA ZYKOVA-TIMAN, DAVIDE CERESOLI, *SISSA, INFM, Democritos, via Beirut 2-4, 34014 Trieste, Italy* ERIO TOSATTI, *SISSA, INFM, Democritos, ICTP, P.O. Box 586, I-34014 Trieste, Italy* High temperature nanofriction is a difficult and so far unexplored area wwhere we made an initial attack by means of simulation. Alkali halide (100) surfaces were chosen as they would not automatically liquefy under a sliding tip, even at temperatures very close to the melting point. We conducted sliding friction molecular dynamics simulations of hard tips on NaCl(100),both in the heavy ploughing, wear-dominated regime, and in the light grazing, wearless regime. Ploughing friction shows for increasing temperature a strong frictional drop near the melting point. Here the tip can be characterized as ''skating'' over the hot solid, its apex surrounded by a local liquid halo, which moves along with the tip as it ploughs on. At the opposite extreme, we find that grazing friction of a lightly pressed flat-ended tip behaves just the other way around. Starting with an initially very weak low temperature frictional force, there is a surge of friction just near the melting point, where the surface is still solid, but not too far from a vibrational instability. This frictional rise can be envisaged as an analog of the celebrated ''peak effect'' found close to Hc2 in the mixed state critical current of type II superconductors.

**15:54**

**D33 6 Nanotribological studies of Temperature Rise in a Sliding Adsorbed Film** MATTHEW WALKER, *North Carolina State University* CHERNO JAY, *North Carolina State University* JACQUELINE KRIM, *North Carolina State University* Theoretical predictions of friction-induced temperature increases at sliding interfaces in general show a wide variation, with little opportunity for experimental verification. In order to explore temperature rise in a particularly simple geometry, we have recorded isotherms of sliding Kr layers adsorbed on graphene (a one-atom thick layer of graphite) and compared them to those recorded in the past in static conditions[ J.A. Venables, itIntroduction to surface and Thin Film Processes. Cambridge University Press, Cambridge, (2000) p. 116]. We synthesize graphene on a Ni(111), which has a lattice spacing stretched approximately 2% beyond that of graphite. The Ni(111) was prepared as an electrode on the surface of a quartz crystal microbalance (QCM) so that friction measurements in sliding conditions could be recorded [J. Krim and A. Widom, Phys. Rev. B, **38**, 12184 (1988)]. Superposition of the isotherms recorded for this system were superimposed on the static volumetric phase diagrams to infer a temperature increase of approximately 15K above the temperature at which the experiments were performed. Work funded by the NSF.

**16:06**

**D33 7 The Temperature Dependence of Macroscopic Sliding Friction*** J.C. BURTON, P. TABOREK, J.E. RUTLEDGE, *University of California, Irvine* We present measurements of the static and kinetic coefficients of friction of gold-plated copper on gold-plated copper and sapphire on sapphire as a function of temperature from 10K to 400K. The measurements were done by sliding a block down a controllable incline plane and using high-speed video to extract the acceleration. The large size of our optical cryostat allowed linear motion of 7.5 cm over which to measure the acceleration. Surfaces were baked under high vacuum at 400K, and data was taken as they cooled. Preliminary results indicate that the coefficient of friction for gold plated copper surfaces change by 10 percent from room temperature to 10K.

*This work has been supported by AFOSR MURI grant # FA9550-04-1-0381.

**16:18**

**D33 8 Measurements of Coefficients of Kinetic Friction Using a Driven Harmonic Oscillator*** M. G. AGGLETON, P. TABOREK, J. E. RUTLEDGE, *University of California, Irvine* We have developed a method of measuring the kinetic coefficient of friction of various materials. Instead of the standard pin-on-disc tribometer, we have developed a driven harmonic oscillator at frequencies around 50Hz to measure friction at the millimeter to centimeter scale. The system is driven by a magnetic field and measured by a linear variable differential transducer (LVDT). Contact between a plate attached to the oscillator and a sphere provides damping due to friction. We will present results for various material combinations, as well as perform a comparison between these results and those of other researchers using a variety of techniques. This apparatus was designed with the intention of being vacuum and low temperature compatible in order to explore the temperature dependence of friction in the cryogenic regime.

*This work has been supported by AFOSR MURI grant # FA9550-04-1-0381.

**16:30**

**D33 9 Free-standing micro locomotive structures driven by the thermal modulation** ONEJAE SUL, MICHAEL FALVO, LLOYD CAROLL, TIMOTHY O'BRIEN, RICHARD SUPERFINE, RUSSELL TAYLOR, JR., SEAN WASHBURN, *Univ. of North Carolina at Chapel Hill* NANO SCIENCE RESEARCH GROUP (DEPT. OF PHYSICS AND ASTRONOMY, DEPT. OF COMP. SCI.) TEAM, As the sizes of Microelectromechanical(MEMS) devices and also the sizes of their contact to environment shrink down to micrometers, the role of contact becomes more critical in understanding and applying it for realization of mobile devices. Since the dominating forces between objects under micro regime are attractive forces such as van der Walls and capillary force, any motion will be mainly influenced by the surface forces rather than inertia. The greatest barrier to actuation is to overcome such forces while achieving net motion. This necessitates smallest contact area. Our research pushed the limits of the contact area to nanometers for minimized friction against the substrate, thus small friction requires lesser thrust and enables faster actuation. We made the inch-worm style bimorph thin film devices standing on the graphite and they are non-umbilical by design. We will first discuss the estimation of thrust, friction of a device on the graphite. We will then discuss the walking mechanism of coordi-

nating three contact tips upon repeated heating and cooling thermal cycles. Additionally we will present predictions and measurements on various properties of our devices such as deflection depending on temperature, time constant of heat/cooling, and contact sliding speeds.

**16:42**
**D33 10 Superconductivity Dependent Friction in Superheated He Films** M. HIGHLAND, J. KRIM, *North Carolina State University* We report a quartz crystal microbalance (QCM) study of sliding friction levels in $N_2$, $H_2O$ and superheated He films adsorbed on Pb(111) above and below its superconducting transition temperature. Our findings establish firmly that superconductivity dependent friction is present in a wide range, if not all, of adsorbed film systems that remain unpinned at 7K, and that on and off cycling of an externally applied magnetic field may impact friction. Changes in friction at the superconducting transition are observed to be greater for $H_2O$ and $N_2$ than for the He films, consistent with a recent theory that attributed differences in electronic friction levels to the polarity of the adsorbate [L.W. Bruch, Phys. Rev. B. **61**, 16201 (2000)]. This work was supported by NSF and AFOSR.

**16:54**
**D33 11 Friction between Polymer Brushes*** JEFFREY SOKOLOFF, *Northeastern University* A polymer brush consists of a surface with a fairly concentrated coating of polymer chains, each one of which has one of its ends tightly bound to the surface. They serve as extremely effective lubricant, producing friction coefficients as low as 0.001 or less! Polymer brushes are a promising way to reduce friction to extremely low values. They have the disadvantage, however, that they must be immersed in a liquid solvent in order to function as a lubricant. The presence of a solvent is believed to result in osmotic pressure which partially supports the load. The density profile of a polymer brush (i.e., the density of monomers as a function of distance from the surface to which the polymers are attached) is well established. What is not understood is how the interaction of polymer brush coated surfaces in contact with each other is able to account for the details of the observed low friction. For example, molecular dynamics studies generally do not predict static friction, whereas surface force apparatus measurements due to Tadmor, et. al., find that there is static friction. This is the topic of the present presentation.

**D35 1 Thermal and thermoelectric properties of individual single-walled carbon nanotubes, Bi-based and III-V nanowires.***
LI SHI, *University of Texas at Austin*

Electronic and thermoelectric materials can be nanostructured to confine electrons and phonons in one or more dimensions so as to engineer the transport and interaction of charge and heat. Various classical and quantum size confinement effects on the thermal and thermoelectric properties have been suggested by theoretical calculations, but have not been experimentally verified due to the difficulty in nanoscale thermal transport measurements. We have developed MEMS (microelectromechanical systems) sensor devices for measuring the thermal and thermoelectric properties of individual one-dimensional nanostructures. Using the sensor devices, we have observed record-high thermal conductivity and ballistic phonon transport in single-walled carbon nanotubes, suppressed thermal conductivity in semiconductor nanowires, and enhanced thermoelectric figure of merit in bismuth telluride nanowires. These findings suggest an escalating self-heating problem in nanoelectronic devices and also novel uses of nanomaterials for thermal management and for efficient thermoelectric energy conversion.

**D35 2 Ballistic Phonon Thermal Transport and Thermal Properties of Carbon Nanotubes** HSIN-YING CHIU, VIKRAM DESHPANDE, HENK POSTMA, *California Institute of Technology* CHUN NING LAU, *University of California, Riverside* CSILLA MIKÓ, LÁSZLÓ FORRÓ, *IPMC/SB, EPFL, CH-1015 Lausanne-EPFL, Switzerland* MARC BOCKRATH, *California Institute of Technology* We report electrical transport experiments, using the phenomenon of electrical breakdown to perform thermometry, that probe the thermal properties of individual multiwalled carbon nanotubes. Our results show that nanotubes can readily conduct heat by ballistic phonon propagation. We determine the thermal conductance quantum, the ultimate limit to thermal conductance for a single phonon channel, and find good agreement with theoretical calculations. Moreover, our results suggest a breakdown mechanism of thermally activated C-C bond breaking coupled with the electrical stress of carrying $10^12$ A/m$^2$. We also demonstrate a current-driven self-heating technique to improve the conductance of nanotube devices dramatically. The results of our ongoing experiments will be reported.

**15:18**

**D35 3 Aspects of the Thermal Conductivity of Nanotubes** CHIH-WEI CHANG, ADAM FENNIMORE, ANDERI AFANASIEV, DAVID OKAWA, TAKASHI IKUNO, HENRY GARCIA, ALEX ZETTL, *Physics department, University of California at Berkeley and Materials Science Division, Lawrence Berkeley National Laboratory* DEYU LI, *Department of Mechanical Engineering, Vanderbilt University, Tennessee* ARUN MAJUMDAR, *Department of Mechanical Engineering, University of California at Berkeley* We have measured the thermal conductivity of individual multiwalled carbon and boron nitride nanotubes using a microfabricated suspended device. The structure of the measured nanotubes also has been characterized by using a transmission electron microscope. We have found that the thermal conductivity of an isotopically pure BN nanotube is comparable to that of a carbon nanotube with the same diameter. The temperature dependence, the effect of deformation, and localized defects on the nanotubes' thermal transport will also be presented.

**15:30**

**D35 4 Phonon Dynamics in Carbon Nanotubes** ARUN BODAPATI, PAWEL KEBLINSKI, *Rensselaer Polytechnic Institute* PATRICK SCHELLING, *University of Central Florida* Using vibrational mode analysis of pristine and defected carbon nanotubes we will demonstrate that defects cause a change in the spatial extension and polarization of phonons leading to a consequent loss of their ballistic nature. Furthermore, to gain a more detailed understanding of thermal energy flow in defected carbon nanotubes we use molecular dynamics simulation to investigate scattering of of well-defined phonon wave-packets either by structural defects or by other phonons. The dependence of scattering of longitudinal and transverse acoustic phonons on their wavelengths will be also discussed.

**15:42**

**D35 5 Heat transport and thermal management in single walled carbon nanotubes** HAREEM MAUNE, *California Institute of Technology* MARC BOCKRATH, *California Institute of Technology* Results from our investigation of thermal transport in CVD grown Single-Walled Carbon nanotubes (SWNT) on different substrates will be reported. Chiu et al. recently showed that multi-walled carbon nanotube devices cool by ballistic phonon heat transport. To harness the remarkable thermal properties of nanotubes for thermal management, it is of interest to understand how heat energy is transported into or out of nanotubes. In this work, we investigate the breakdown power for SWNT nanotube devices using different substrate materials to determine the effect of substrate thermal conductivity on nanotube breakdown. We compare our results with those obtained with the Si/ SiO2 substrate. Our results indicate higher power dissipation on a sapphire substrate for few micron SWNTs but lower than expected dissipation for the longer length scales. We will discuss the mechanism of power dissipation and thermal transport in our devices in light of our results.

**15:54**

**D35 6 Interfacial Thermal Transport Between Single Wall Carbon Nanotubes*** JENNIFER LUKES, HONGLIANG ZHONG, *University of Pennsylvania* Due to their superior thermal conductivity, single wall carbon nanotubes have elicited great interest as potential thermal management materials, for example as fillers in polymer composites and as thermal interface materials. Recent measurements on carbon nanotube composites have revealed lower-than-expected conductivities, and thermal interfacial resistance between the nanotubes and the surrounding medium has been implicated as a key factor limiting heat flow. However, one factor that has been little-considered is the role of interfacial thermal resistance between individual nanotubes. In these composites, the nanotubes form an interconnected network and for this reason interfacial resistance at the contact points between the nanotubes is also expected to have a significant effect on thermal energy transport. Our recent modeling results indicate that a four order of magnitude reduction in nanotube-nanotube interfacial resistance is obtained as the nanotubes are brought into intimate contact. These results will be discussed in this presentation.

**D35 11 Correction Factors for 4-probe Electrical Transport Measurements with Finite Size Electrodes: Analytical and Finite Element Analysis*** E.J. ZIMNEY, G. DOMMETT, D.A. DIKIN, R.S. RUOFF, *Department of Mechanical Engineering, Northwestern University, Evanston, IL 60208* In most real specimens the current density is non-uniform through the thickness between the sense (potential) probes. Non-uniformities in the current density can result from many effects including the geometry of the specimen, the finite size of the electrodes, anisotropic behavior of the material, etc. Thus great care must be taken in extracting the correct bulk resistivity from the measured resistance. We have developed a method, based on finite element analysis, to accurately determine the bulk in-plane resistivity from collinear 4-probe resistance measurements on isotropic and anisotropic materials. The effect of boundary conditions on the measured resistivity is explored. Our finite element approach can be universally applied to 4-probe measurements on complex specimen geometries with arbitrary electrode arrangements.

**D35 12 Development of optical approaches for identifying individual graphene-based sheets on surfaces*** INHWA JUNG, RICHARD PINER, DMITRIY DIKIN, SASHA STANKOVICH, RODNEY S. RUOFF, *Department of Mechanical Engineering* MARTINA HAUSNER, *Department of Civil and Environmental Engineering, Northwestern University, Evanston, IL 60208* We are developing a light microscope-based method for identifying thin graphene-based sheets on silicon wafers with a thin dielectric layer (SiO2 or Si3N4). Different thicknesses of this dielectric layer have been tested. Optics, and experiments with these thin dielectric layers, enabled us to optimize the thickness that yields the best contrast; SiO2 is useful for discerning multiple stacked sheets and Si3N4 for identifying individual sheets. Both multiple or single wavelength sources can be used effectively. By comparing the optical images with data obtained by AFM and SEM, it has been possible to prove that our method can detect the presence of individual graphene- based sheets.

**D38 1 Scattering in $MgB_2$ produced by substitutions and damage.**
MARINA PUTTI, *University of Genova, CNR-INFM-LAMIA*

The two-gap nature of superconductivity is a unique feature of $MgB_2$that stimulates many theoretical and experimental investigations. From the beginning it was pointed out that the peculiar role of disorder in a two-gap superconductor In fact, inter-band scattering by non-magnetic impurities is expected to suppresses the critical temperature $T_c$ down to 20 K, where an equivalent one-gap BCS system stabilizes. The verification of these predictions has motivated several efforts to introduce defects in $MgB_2$ by substitutions (Al in sites of Mg and C in sites of B) and by irradiation. Substitutions modify electronic structure so that superconductivity can be influenced. To overcome this problem we studied two different kind of samples: co-doped $Mg_{1-x}(AlLi)_xB_2$ in which the disorder induced by the Mg substitution is accompanied by a rather complete charge compensation, and neutron irradiated $Mg^{11}B_2$. In both the sample series remarkable changes in the band structure are not expected. The superconducting properties of $Mg_{1-x}(AlLi)_xB_2$are compared with those of $Mg_{1-x}Al_xB_2$. All the properties scale systematically as a function of the Al content rather than electron doping. This suggests that the lattice deformations induced by Al, namely point-like defects and lattice compression, are very effective in tuning the superconducting properties. Similar conclusion can be drawn by the study of neutron irradiated samples. By increasing the neutron fluence, $T_c$ monotonously decreases down to 9 K, the resistivity raises by two order of magnitude and the cell volume increases (1.7%). Our results demonstrate that the critical temperature is suppressed by the disorder well down the value of 20 K. On the other hand, the two-gap feature evident in the temperature range above 21 K, disappears when $T_c$ is lowered down to 11 and 8.7 K a single-gap superconductivity is established.

**D38 2 Effects of helium ion damage on the two-band superconductivity in $MgB_2$ thin films** L.H. GREENE, W.K. PARK, X. LU, *U. of Illinois at Urbana-Champaign* B. MOECKLY, *Superconductor Technologies, Inc.* R. SINGH, N. NEWMAN, J.M. ROWELL, *Arizona State U.* While the two-band superconductivity in $MgB_2$ has been well established, it remains controversial whether disorder in the Mg and B planes causes enhanced inter-band scattering, band filling or both. To address this, we have performed electronic transport and point-contact spectroscopy measurements on helium-ion irradiated $MgB_2$ thin films. Two sets of samples are prepared using: a) 1 MeV $He^+$ ions with uniform doses ranging from $1x10^{15}$ to $1x10^{17}$ ions/cm$^2$; b) 2 MeV alpha particles with gradient doses. The resistivity ($T_c$) is observed to increase (decrease) monotonically with increasing dose. The conductance spectra are taken from point-contact junctions between $MgB_2$ thin films and Au tips. The $T_c$ is determined by the onset of enhanced conductance at zero bias. Our preliminary results show that the two gaps tend to merge into one gap with increasing ion damage. Detailed results including $T_c$ vs. energy gap will be presented and discussed in terms of the electronic structure change caused by ion-induced point defects. WKP acknowledges Pavel Krasnochtchekov and Robert Averback for ion irradiation experiments at UIUC. **D38 3 Effect of ion irradiation and annealing on scattering processes in MgB2** RAGHURAM GANDIKOTA, RAKESH SINGH, JIHOON KIM, BARRY WILKENS, NATHAN NEWMAN, JOHN ROWELL, *Arizona State University* ALEXEJ POGREBNYAKOV, XIAOXING XI, JOAN REDWING, SHENGYONG XU, QI LI, *Pennsylvania State University* BRIAN MOECKLY, *Superconductor Technologies Inc.* The effect of point defects introduced by ion irradiation on Tc, resistivity, and Hc2 of MgB2 films was studied. We will show that ion induced disorder in films with different as-made disorder, followed by annealing, offers advantages in the study of Hc2 of MgB2 films. Films, from three deposition processes, were damaged by 2 MeV alpha particles, followed by annealing after Tc was reduced to $<$ 10K. Damage increases Hc2 (0) in clean films, resulting in maxima ( $\sim$ 34T) near Tcs of 33K, for fields parallel to the film. For Tcs from $\sim$ 25K to below 10K, Hc2(0) decreases almost linearly with Tc. Annealing the films, after Tc has been reduced below 10K, reproduces the resistivity value but not the Hc2(0), for a given Tc. These results suggest that Tc is reduced by smearing of the density of states, and that the measured resistivity and Hc2 are determined by scattering in pi and sigma bands respectively.

**15:30**
**D38 4 Magnetic and non-magnetic substitutions in $MgB_2$ single crystals: influence on superconducting properties and structure** JANUSZ KARPINSKI, NIKOLAI D ZHIGADLO, KRZYSZTOF ROGACKI, BERTRAM BATLOGG, GETZ SCHUCK, *Laboratory for Solid State Physics ETH Zurich* ROMAN PUZNIAK, ANDRZEJ WISNIEWSKI, *Institute of Physics PAS Warsaw* RENATO GONNELLI, *Politecnico di Torino* Pure and substituted single crystals of $MgB_2$have been grown at high pressure (30 kbar) using the cubic anvil technique. The crystals

have very low residual resistivity $\rho_o(40\ \mathrm{K}) \approx 0.5$ and a sharp transition $\Delta T_c \approx 0.2$ K. Magnetic (Mn, Fe) and non-magnetic (Al, C) ions have been substituted to study their effect on superconductivity and on the impurity scattering in and between the $\sigma$ and $\pi$ bands. Single-phase $Mg_{1-x}Al_xB_2$ and $MgB_{2-x}C_x$ crystals were grown for x=0-0.3. Al and C cause a similar moderate decrease of $T_c$. Magnetic ions, such as $Fe^{3+}$ and $Mn^{2+}$ suppress $T_c$ very effectively, due to magnetic pair breaking. Superconductivity is completely suppressed for by 2% Mn. Fe substitution decreases $T_c$ less rapidly than Mn but much faster than Al and C. Carbon substitution increases the $H_{c2}$ twice, while Al, Fe and Mn substitutions decrease this field. $H_{c2}$ anisotropy decreases with all substitutions, but the temperature dependence of the anisotropy is different, due to different scattering rates in the $\pi$ and $\sigma$ bands. For Mn and Al, $\pi$ and $\sigma$ energy gaps exist up to the highest substitution level, while for C substitution, merging of these gaps is observed indicating interband scattering.

**D38 5 Evolution of two-gap superconductivity of $MgB_2$ by Al substitution** MIN-SEOK PARK, HEON-JUNG KIM, HYE-GYONG LEE, *National Creative Research Initiative Center for Superconductivity & Department of Physics, Pohang University of Science and Technology* MYUNG-HWA JUNG, YOUNGHUN JO, *Quantum Material Laboratory, Korea Basic Science Institute, DaeJeon 305-333, Republic of Korea* SUNG-IK LEE, *National Creative Research Initiative Center for Superconductivity & Department of Physics, Pohang University of Science and Technology* MIN-SEOK PARK, HEON-JUNG KIM, HYE-GYONG LEE, AND SUNG-IK LEE TEAM, MYUNG-HWA JUNG, YOUNGHUN JO, AND SUNG-IK LEE COLLABORATION, The temperature dependence of the upper critical fields ($H_{c2}(T)$) of the two-gap superconductors $Mg_{1-x}Al_xB_2$ not only for low doping level ($x < 0.1$) but also for high doping level ($0.1 \leq x \leq 0.3$) was obtained by resistivity measurements. The $H_{c2}(T)$ values were analyzed, within the dirty-limit two-gap model, using the calculated electron-phonon coupling constants and Coulomb pseudo potentials. As the Al contents increased, both $T_c$ and $H_{c2}(0)$ decreased, which was the direct manifestation of the increasing number of electrons. At the same time, the three-dimensional $\pi$ bands became much dirtier when Al was doped. In contrast, the intraband scattering of the two-dimensional $\sigma$ bands was relatively unaffected by the Al doping. These behaviors could be understood when the characters of both bands were considered. In all the samples that we investigated, the $\sigma$ bands were dirtier than the $\pi$ bands.

**D38 6 Thermal Expansion measurements on single crystals of the superconductor $MgB_2$*** JOHN J. NEUMEIER, R. BOLLINGER, C. A. M. DOS SANTOS, *Montana State University* N. D. ZHIGADLO, JANUSZ KARPINSKI, *Laboratory for Solid State Physics ETH Zürich* Thermal expansion measurements have been conducted along the a and c axes on single crystals of the superconductor $MgB_2$. The samples are platelets with typical thicknesses of 0.1 mm. The a axis lies in the plane of the platelets, this axis is typically 0.5 mm long. The measurements were conducted using a capacitive thermal expansion cell constructed entirely of fused silica; it is capable of detecting 0.1 Å changes in length. The results reveal that the linear thermal expansion $\Delta L/L = 21\text{x}10^{-4}$ and $5.2\text{x}10^{-4}$ along the c and a axes, respectively, in the temperature range $5\ \mathrm{K} < T < 300$ K. At the superconducting transition temperature $T_c$, jumps in the thermal expansion coefficient $\alpha$ are observed to be positive along both axes. Regions where $\alpha < 0$ are observed along both axes. The results are in general agreement with recently published data [1] on polycrystalline $MgB_2$. [1] J. J. Neumeier, T. Tomita, M. Debassai, J. S. Schilling, P. W. Barnes, D. G. Hinks, and J. D. Jorgensen, Phys. Rev. B. Rapid Commun. December 2005.

**D38 7 Measurements of elastic constants for single crystals of magnesium diboride** KENNETH PESTKA, J.D. MAYNARD, XIAXING XI, QI LI, *Penn State Univeristy* Important information concerning the nature of the high temperature BCS superconductor magnesium diboride, $MgB_2$, may be obtained from measurements of elastic constants with single crystal samples. As derivatives of the free energy with respect to atomic displacements, the elastic constants are a sensitive probe of the lattice environment in which all solid state phenomena occur. We have used the technique of resonant ultrasound spectroscopy (RUS) for very small samples in order to measure good quality single crystals. The samples were grown epitaxially on silicon carbide substrates using physical vapor deposition; samples were a few hundred microns wide and 600 to 750 nm thick.

**16:18**

**D38 8 Nanoscale spatial non-homogeneity of 3D $\Delta_\pi$ in $Mg_{1-x}AlB_2$ single crystals** F. BOBBA, F. GIUBILEO, A. SCARFATO, A. M. CUCOLO, *CNR-INFM SUPERMAT Lab. And Physics Dept., University of Salerno, Via S. Allende, 84081 Baronissi (SA), Italy* D. RODITCHEV, *Institut des Nanosciences de Paris, Université Paris 6 et 7, CNRS (UMR 75 88), 75015 Paris, France* N. ZHIGADLO, S. KAZAKOV, J. KARPINSKI, *Solid State Physics Laboratory, ETH Zurich, CH-8093 Zurich, Switzerland* We have performed local I(V) and dI/dV(V) measurements on high quality $Mg_{1-x}Al_xB_2$ single crystals with different Al dopings by means of Scanning Tunneling Spectroscopy (STS). Both temperature and magnetic field dependences of the conductance spectra have been studied both in S-I-N and in S-I-S configurations. The measured spectra revealed only one gap at low temperatures as expected for pure c-axis tunneling. In the case of x=0.1, the measured superconducting gap $\Delta_{\pi g}$ appeared highly non-homogeneous in its spatial distribution on nanometer scale, with an amplitude varying between 1.5 meV and 2.3 meV. In pure $MgB_2$ the evolution of the zero bias conductance (ZBC) in magnetic field clearly showed two different regimes with a fast rise up to 1 T, followed by a slower refilling of states for higher fields. This effect results smoothed in doped single crystals. Consistently with the more recent theories, in comparison with the undoped material, we have found that for x=0.1 the $\Delta_\pi$ gap value and the $H_{c2}$ critical field increase of about 15% and 30%, respectively.

**16:30**

**D38 9 Superconductivity in $Y_2C_3$** SATOSHI AKUTAGAWA, JUN AKIMITSU, *Aoyama-Gakuin University* The discovery of superconductivity in $MgB_2$ revived the enthusiasm of non-oxides materials and initiated a search for novel superconductivity in intermetallic compounds including light elements, B and C. As a part of these researches, we have reported a relatively high-$T_c$ superconductivity in $Y_2C_3$ at 18 K whose $T_c$ could be changed

from 10 K to 18 K by synthesis conditions, although this material with a maximum $T_c$ of 11.5 K has already been investigated by Krupka *et al.*. The crystal structure of $Y_2C_3$ is a body-cente red cubic ($Pu_2C_3$-type) s tructure. In this structure, Y atoms are aligned along the $< 111 >$ direction and C atoms form dimers. We synthesized a high-purity sample of the medium-$T_c$ phase ($T_c$ = 13.9 K) in $Y_2C_3$ and examined its physical properties in detail. From a specific heat measurement, the superconducting gap is estimated to be 4.50, indicating that the superconductivity in $Y_2C_3$ can be described by an *s*-wave strong coupling regime. From specific heat in various magnetic fields, the upper critical field $H_{c2}(0)$ is estimated to be 24.7 T.

**D38 10 Li-Vacancy Ordering in LiBC Phase** EBRU GUNGOR, ENGIN OZDAS, *Advanced Materials Research Group, Physics Department, Hacettepe University, Beytepe, Ankara 06800, Turkey* The discovery of a phonon mediated superconductivity in $MgB_2$ with a $T_c$ of 40 K has accelarated the scientific interest in similar layered compounds and the electronic band structure calculations showed that the high-Tc superconductivity is possible for the hole-doped layered lithium borocarbide, $Li_xBC$ [1,2]. However, the superconducting features for Li off-stoichiometric borocarbide compounds have not been observed in any experimental studies, because of the difficulties in the sample preparation. In this work, the effects of synthesis conditions on the structure of $Li_xBC$ samples with the different Li-stoichiometries and the phase stability were investigated. The structural studies showed that the intercalation process has a staging behaviour as Li intercalated graphite and a novel Li vacancy ordered structure for off-stoichiometric $Li_xBC$ phases. **D38 11 Anomalous Magnetoresistance Effects in $(CrO_2)_{1-x}$ : $(MgB_2)_x$ powders** RAGHAVA PANGULURI, B. NADGORNY, *Department of Physics, Wayne State University, Detroit, MI 48201* It is known that the electrical conduction mechanism in compressed powders and polycrystalline $CrO_2$ films is due to the intergranular tunneling. Here, we focus on the percolation effects in the $CrO_2$ powders intermixed with a superconductor, $MgB_2$. A mixture of $(CrO_2)_{1-x}$ : $(MgB_2)_x$ powders with $0 \leq x \leq 1$ were cold-pressed to form circular disks. The electrical resistance measured by a four probe technique, as expected showed a lower resistance for the mixture when compared to the pure pressed $CrO_2$. The observed hysteresis extrinsic magnetoresistance (MR) showed peaks corresponding to the coercive fields of $CrO_2$ which can be associated with the alignment of magnetization of adjacent $CrO_2$ particles. Interestingly, the MR changed signs at around the superconducting transition temperature of $MgB_2$ ( $\sim$ 40K) and also the slope of MR at high magnetic fields changed from positive to negative. We will discuss a possible origin of the observed effects, which we believe are related to the ferromagnet/superconductor interaction.

**D39 1 Electron-phonon coupling associated with charge-stripe order in cuprate superconductors*** JOHN TRANQUADA, *Brookhaven National Lab* D. REZNIK, L. PINTSCHOVIUS, *Forschungszentrum Karlsruhe* M. ITO, S. IIKUBO, M. SATO, *Nagoya Univ.* M. FUJITA, K. YAMADA, *IMR, Tohoku Univ.* G. D. GU, *Brookhaven National Lab* We have used inelastic neutron scattering to study the Cu-O bond-stretching phonon in $La_{1.875}Ba_{0.125}CuO_4$ and $La_{1.48}Nd_{0.4}Sr_{0.12}CuO_4$, two cuprate compounds that exhibit charge-stripe order. This is the phonon mode that one expects to be most sensitive to spatial inhomogeneity in the electronic structure of the $CuO_2$ planes. Besides the cosine-like downward dispersion of the mode from zone center to zone boundary, we observe a dip in the dispersion and a very large energy width ( $>$ 10 meV) at $\mathbf{q} = \mathbf{a}^*/4$. The dip and width gradually become smaller with increasing temperature. These evidences of a strong electron-phonon coupling (the dispersion dip and large energy width) have not been predicted by any conventional calculations. The nature of the connection with charge-stripe order will be discussed.

**D39 2 Magnetic Neutron Scattering Study of $Nd_{1.85}Ce_{0.15}Cu_{1-y}Ni_yO_4$ Single Crystals** INNA VISHIK, *Stanford University* GUICHUAN YU, *Stanford University* EUGENE MOTOYAMA, *Stanford University* OWEN VAJK, *National Institute of Standards and Technology* MARTIN GREVEN, *Stanford University* In order to arrive at a deeper understanding of the interplay between superconductivity and magnetism in the high-temperature superconductors, it is of interest to study the effects of impurity-doping on the copper site. A large body of work along these lines exists for hole-doped materials, yet relatively little is known about the effects of such impurities on the prototypical electron-doped material $(Nd,Ce)_2CuO_4$. In previous work, paramagnetic dopants (Ni, Fe) were shown to lower $T_c$ much more abruptly than non-magnetic ones (Zn). We grew large single crystals of $Nd_{1.85}Ce_{0.15}Cu_{1-y}Ni_yO_4$ using the traveling-solvent floating-zone technique and characterized our samples using SQUID magnetometry and DC transport measurements. Here we report on neutron scattering results for the spin correlations as a function of nickel concentration and temperature for superconducting ($y < 0.01$) and non-superconducing ($y > 0.01$) compositions.

**14:54**

**D39 3 Scattering Studies of the High $T_c$ Superconductor $La_{2-x}Ba_xCuO_4$** Y. ZHAO, S. R. DUNSIGER, B. D. GAULIN,* H. A. DABKOWSKA, *Dept. of Physics and Astronomy, McMaster University, Hamilton, Ontario, Canada.* Z. YAMANI, W. J. L. BUYERS, *Canadian Neutron Beam Centre, NRC, Chalk River Laboratories, Chalk River, Ontario, Canada* The interplay between superconductivity, magnetism and crystal structure is a central issue in the study of the high $T_c$ cuprates. The first to be

discovered, the Bednorz-Müller materials have been much less extensively studied due to the difficulty of growing large single crystals. Using floating zone image furnace techniques, we have recently successfully grown $La_{2-x}Ba_xCuO_4$ (x$\sim$ 0.095 and 0.08) single crystals on the underdoped side of the well known 1/8 anomaly. X-ray studies show a sequence of crystal structures with temperature, while incommensurate elastic peaks associated with the low temperature tetragonal phase are observed using neutron diffraction. This signature of static spin stripe order persists into the superconducting state. We discuss the relationship between the low temperature spin and lattice degrees of freedom, as well as their sensitivity to doping level.

**15:06**

**D39 4 Electronic inhomogeneities in superconducting $YBa_2Cu_3O_{6+x}$** FERENC STERCEL, *Dept. of Materials Science and Engr., University of Pennsylvania* JAE-HO CHUNG, *NIST* TAKESHI EGAMI, *Dept. of Physics and Astronomy and Department of Materials Science and Engineering, University of Tennessee-Knoxville* MASATOSHI ARAI, TETSUYA YOKOO, HYUNGJE WOO, *Dept. of Physics and Astronomy, University of Tennessee-Knoxville* MOHANA YETHIRAJ, HERB A. MOOK, *ORNL* CHRIS D. FROST, *Rutherford Appleton Laboratory, UK* FATIH DOGAN, *Dept. of Materials Science and Engr., University of Missouri-Rolla* There has been an increasing amount of experimental evidence for the presence of local electronic inhomogeneities in superconducting cuprates. Inelastic pulsed neutron scattering measurements on $YBa_2Cu_3O_{6+x}$single crystals with different oxygen concentrations show that the zone boundary softening of the in-plane LO Cu-O bond stretching mode is the same for all doping levels. In addition, the spectral weight of the softened mode increases with increasing doping. This indicates that there is a microscopic electronic phase separation in superconducting $YBa_2Cu_3O_{6+x}$. Furthermore, triple axis inelastic neutron scattering measurements on the underdoped $YBa_2Cu_3O_{6.6}$ performed at different temperatures revealed that a new local mode appears at 65 meV at higher temperatures (200 K and above). It might indicate the presence of polarons.

**15:18**

**D39 5 Spin Excitations of overdoped $La_{2-x}Sr_xCuO_4$** S. WAKIMOTO, *JAEA* R.J. BIRGENEAU, *UC Berkeley* C.D. FROST, *RAL* A. KAGEDAN, H.K. KIM, *U of Toronto* I. SWAINSON, *CRL* J.M. TRANQUADA, *BNL* K. YAMADA, *IMR* H. ZHANG, *U of Toronto* Spin excitations of LSCO in the overdoped regime have been studied by neutron scattering. Incommensurate excitations around 6 meV which are clearly observed in the $x = 0.25$ sample decrease with $T_c$ as doping increases, and finally, become unobservable at $x = 0.30$ coincidentally with the disappearance of bulk superconductivity. High-energy measurements performed at the MAPS spectrometer show remarkably weakened magnetic excitations of the overdoped samples also in the high energy region. These observations are apparently consistent with a microscopic phase separation of the overdoped samples into the superconducting and Fermi liquid phases based on muSR results. in contrast, magnetization measurements of overdoped LSCO with and without Zn impurities have revealed that the superconductivity vanishes in the overdoped regime as a result of a competition between the superconductivity and paramagnetism which is induced even in the Zn-free overdoped LSCO.

**15:30**

**D39 6 Search for Magnetic Order in Superconducting $RuSr_2Eu_{1.2}Ce_{0.8}Cu_2O_{10}$** J. W. LYNN, Y. CHEN, *NIST Center for Neutron Research, Gaithersburg, MD 20899-8562 and U. Maryland* S.K. GOH, G.V.M. WILLIAMS, *MacDiarmid Institute for Advanced Materials, Industrial Research, POB 31310, Lower Hutt, New Zealand* Neutron diffraction, polarized neutron transmission, and small angle neutron scattering have been used to investigate the nature of the magnetic order in the titled compound. The sample was made with the Eu-153 (98.8%) isotope to reduce the high neutron absorption for this element. At low T a single magnetic peak is clearly observed. A sharp spin reorientation transition (SRT) is observed around 35 K, close to the superconducting transition temperature (Tc 40K). Between the SRT and the Neel temperature of 59 K, additional magnetic reflections are observed. However, none of these can be simply indexed on the chemical unit cell, either as commensurate peaks or simple incommensurate magnetism, and the paucity of reflections at low T compels the conclusion that these arise from an impurity phase. X-ray and neutron diffraction both show that the sample does not appear to contain significant impurity phases. However, the impurity peaks exhibit strong preferred orientation, while the primary phase does not. We have been unable to observe any magnetic order that can be identified with the ruthenate-cuprate system. Additional field-dependent results will be discussed.

**15:42**

**D39 7 High-Energy Excitations near the boundary to antiferromagnetism-YBCO6.35** C. STOCK, *Physics Department, Johns Hopkins University* R.A. COWLEY, *Oxford Physics, Oxford University* W.J.L. BUYERS, *National Research Council, Chalk River* C.L. BROHOLM, *Physics Department, Johns Hopkins University* R. COLDEA, *Oxford Physics, Oxford University* C.D. FROST, *Appleton Rutherford Laboratories* R.J. BIRGENEAU, *Physics Department, University of California Berkeley* R. LIANG, D. BONN, W.N. HARDY, *Physics Department, University of British Columbia* The high-energy magnetic excitations in the cuprate superconductors have attracted considerable interest recently. We investigate magnetic excitations over the entire energy range in the heavily underdoped YBCO6.35 superconductor with a Tc=18 K. The spin response below 25 meV energy transfers is broad and has been discussed previously. The magnetic response above 25 meV is very similar to the parent insulators with similar spectral weight and spin-wave velocity. The excitations near the zone boundaries are however, much broader in energy than for the parent insulator. The onset of damping coincides approximately with the gap determined from transport measurements. This indicates that a new decay channel for spin waves becomes available above the pseudo-gap.

**15:54**

**D39 8 Spin susceptibility of underdoped cuprates: the case of Ortho-II $YBa_2Cu_3O_{6.5}$** ELENA BASCONES, *Instituto de Ciencia de Materiales de Madrid (CSIC) and Theoretische Physik, ETH-Zurich* T. MAURICE RICE, *Theoretische Physik, ETH-Zurich* Recent inelastic neutron scattering measurements found that the spin susceptibility of detwinned and highly ordered ortho-II $YBa_2Cu_3O_{6.5}$ exhibits, in both the normal and superconducting states, one-dimensional incommensurate modulations at low energies which were interpreted as a signature of dynamic stripes. We propose an alternative model based on quasiparticle

transitions between the arcs of a truncated Fermi surface. Such transitions are resonantly enhanced by scattering to the triplet spin resonance. We show that the anisotropy in the experimental spin response is consistent with this model if the gap at the saddle points is anisotropic.

**16:06**

**D39 9 Effect of Charge Inhomogeneity on the Diagonal Incommensurate Spin Correlations in $La_{2-x}Sr_xCuO_4$** MASAAKI MATSUDA, *Japan Atomic Energy Agency* MASAKI FUJITA, KAZUYOSHI YAMADA, *IMR, Tohoku Univ.* Neutron-scattering experiments are performed on Zn and Ni doped $La_{1.95}Sr_{0.05}CuO_4$ to study the impurity effect on the diagonal incommensurate spin correlations. Zn doping reduces the incommensurability and enhances the correlation length just slightly. On the other hand, Ni doping quickly destroys the incommensurability and restores N'eel ordering, indicating a strong effect on hole localization. This suggests that Ni and hole form a strongly bound state with the Zhang-Rice character, in which effective valence and spin number are trivalent and 1/2, respectively. Although it is expected that doped Ni with effective spin 1/2 does not disturb the magnetic interactions so much, the magnetic correlations are disordered considerably. This suggests that the charge inhomogeneity, caused by the random distribution of effectively trivalent Ni, disturbs the stripe formation and the magnetic correlations become disordered. This result supports the diagonal stripe state and probably rules out the spiral state, caused by the magnetic frustration, in lightly-doped $La_{2-x}Sr_xCuO_4$.

**16:18**

**D39 10 Magnetic Excitations of Stripes Near a Quantum Critical Point and Checkerboards** DAVID K. CAMPBELL, DAOXIN YAO, *Depts. of Physics and Electrical and Computer Engineering, Boston University* ERICA W. CARLSON, *Dept. of Physics, Purdue University* Competing tendencies in electronic systems with strong correlations can lead to spontaneous nanoscale structure, pattern formation, and even long-range spatial order. There has been continued interest in various charge and spin spatial order, including ''stripe'' and ''checkerboard'' phases. We explore the magnetic excitations of stripe and checkerboard phases within a semiclassical spin wave approximation. We show that simple checkerboard patterns are incompatible with recent neutron scattering experiments, while stripes near a quantum critical point (i.e. with weak coupling across the domain walls) exhibit much of the behavior seen in recent neutron scattering experiments on high temperature superconductors. At low energies, the spin wave cones of weakly coupled stripes have weight strongly peaked on the inner branches. As energy is increased, a saddlepoint produces a resonance peak, followed by a square-shaped continuum rotated 45 degrees from the low energy peak direction. We discuss the connection to recent high energy neutron scattering data on the cuprates, as well as the relation to quantum spin fluctations.

**16:30**

**D39 11 Effect of spin-orbit scattering on the observed time-reversal violating phase in the Pseudogap phase of the Cuprates** VIVEK AJI, CHANDRA VARMA, *UC Riverside* Fauque et al. [1] have recently reported observing the predicted symmetry breaking [2] in the Pseudogap region in the phase-diagram of the Cuprates, which had also been earlier inferred from dichroism in ARPES. Following Wu et al. [3], we study the effects of spin-orbit scattering inthe observed symmetry breaking. We study the following issues: spin-current, accompanying orbital currents, symmetry of any accompanying spin-order, and the effect of an external magnetic-field on the ordered state. 1. Fauque et al., arXiv.org/cond-mat/0509210; 2. M.E. Simon and C.M.Varma, Phys.Rev. Lett. 89, 247003 (2002) 3.Wu et al., arXiv.org/cond-mat/0505544

**16:42**

**D39 12 $^{17}O$ and $^{139}La$ NMR in a single crystal $La_{2-x}Ba_xCuO_4$, $x = 1/8$*** BEN-LI YOUNG, N. J. CURRO, *Condensed Matter and Thermal Physics, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA* J. HAASE, H.-J. GRAFE, B. BÜCHNER, *Leibniz Institute for Solid State and Materials Research Dresden, P.O. Box 270116, Dresden 01171, Germany* M. HÜCKER, G. D. GU, *Physics Department, Brookhaven National Laboratory, Upton, New York 11973-5000, USA* We have performed $^{17}O$ and $^{139}La$ nuclear magnetic resonance (NMR) in a single crystal of $La_{2-x}Ba_xCuO_4$ with $x = 1/8$, in order to investigate how the static spin and charge structures, as revealed by neutron scattering, influence the NMR spectrum. We measured the NMR intensity of the $^{17}O$ and $^{139}La$ nuclei, as well as the $^{17}O$ nuclear quadrupole resonance frequency ($\nu_Q$) at several different temperatures. We will discuss possible correlation between the $^{17}O$ signal intensity and $\nu_Q$ as a function of temperature due to the stripe phase.

*Supported by I2CAM Junior Scientist travel program.

**16:54**

**D39 13 NMR studies of $Pr_{2-x}Ce_xCuO_{4-y}$ ($x = 0.15$ and 0.17) at high magnetic field** GUOQING WU, S.E. BROWN, W.G. CLARK, *UCLA Physics and Astronomy* R.L. GREENE, *Univ. Maryland* H. BALCI, *UIUC Physics* P. KUHNS, A.P. REYES, W.G. MOULTON, *NHMFL* Recent charge and thermal transport measurements on the electron- doped high-$T_c$ superconductor $Pr_{2-x}Ce_xCuO_{4-y}$ (PCCO) show unusual behavior in the superconducting dome at the doping level going from $x = 0.15$ (optimally doped) to 0.17 (overdoped), such as quantum phase transition and electron paring symmetry changes, suggesting a possible connection between the superconductivity and other competing phases like antiferromagnetism. We report the $^{63,65}Cu$-NMR spectrum in PCCO single crystals with $x = 0.17$ in a high magnetic field $B_0$, and contrast their properties with those of $x = 0.15$. The temperature dependence of the $^{63,65}Cu$-NMR Knight shift is dominated by the negative isotropic hyperfine coupling to the field-induced $Pr^{3+}$ ion moment, and changes little between $x = 0.15$ and 0.17. The $^{63,65}Cu$-NMR linewidths are propotional to the applied magnetic field $B_0$, but affected by the doping, indicating the existence of other sources besides the $Pr^{3+}$ ion moment that contributes to the static local field distribution at the Cu nuclei. The work at UCLA is supported at UCLA by NSF Grants DMR-0334869 (WGC) and 0203806 (SEB).

**17:06**

**D39 14 Impurity effect on nuclear magnetic relaxation due to orbital hyperfine interaction** A. KNIGAVKO, B. MITROVIC, K. V. SAMOKHIN, *Physics Department, Brock University, St. Catharines, Canada* We show that the nuclear magnetic relaxation rate $1/T_1$ due to the coupling of nuclear spin to the orbital moment of itinerant electrons is sensitive to impurity scattering in both normal and superconducting states. In the clean case $1/T_1$ diverges because of the contribution from distant currents, while in the dirty case its magnitude is controlled by the parameter $k_F l$, where $l$ is the electron mean free path. In the superconducting state temperature dependence of $1/T_1$ becomes significant.

**17:18**
**D39 15 On electron-hole symmetry and phase separation in some electron doped cuprates** LEV GOR'KOV, *NHMFL, Florida State University* GREGORY TEITEL'BAUM, *Zavoiskii Institute, Kazan',Russia* Analyzing the experimental NMR data for electron-doped cuprates, we concluded that the Coulomb effects caused by doping lead to dynamical spatial phase separation that contributes to the nuclear spin relaxation. Remarkable, the ''infinite-layer'' $Sr_{0.9}La_{0.1}CuO_4$ reveals unexpected electron-hole symmetry. Its $^{63}$Cu nuclear spin relaxation rate is the sum of a constant and the temperature dependent components, moreover, the latter turns out to be identical to the $1/63T_1(T)$-behavior in the stoichiometric $YBa_2Cu_4O_8$. Connection to fluctuation of a magnetic sub-phase is discussed.

**D40 1 From Quantum Foundations to Quantum Gravity.**
LUCIEN HARDY, *Perimeter Institute*

Quantum theory is a probabilistic theory with fixed causal structure. General relativity is a deterministic theory with dynamic causal structure. It seems likely then that a theory of quantum gravity will be a probabilistic theory with dynamic causal structure. Work in the foundations of quantum theory provides insight into how to build a framework for such theories. In this way we can hope that insights coming from quantum foundations can guide us in constructing a theory of quantum gravity.

***Contributed Papers***

**15:06**
**D40 2 Quantum Mechanics in Terms of Symmetric Measurements** CHRISTOPHER FUCHS, *Bell Labs, Lucent Technologies* In the neo-Bayesian view of quantum mechanics that Appleby, Caves, Pitowsky, Schack, the author, and others are developing, quantum states are taken to be compendia of partial beliefs about potential measurement outcomes, rather than objective properties of quantum systems. Different observers may validly have different quantum states for a single system, and the ultimate origin of each individual state assignment is taken to be unanalyzable within physical theory—its origin, instead, comes from prior probability assignments at stages of physical investigation or laboratory practice previous to quantum theory. The objective content of quantum mechanics thus resides somewhere else than in the quantum state, and various ideas for where that ''somewhere else'' is are presently under debate. What is overwhelmingly agreed upon in this effort is only the opening statement. Still, quantum states are not Bayesian probability assignments themselves, and different representations of the theory (in terms of state vectors or Wigner functions or C*-algebras, etc.) can take one further from or closer to a Bayesian point of view. It is thus worthwhile thinking about which representation might be the most propitious for the point of view and might quell some of the remaining debate. In this talk, I will present several results regarding a representation of quantum mechanics in terms of symmetric bases of positive-semidefinite operators. I also argue why this is probably the most natural representation for a Bayesian-style quantum mechanics.

**15:18**
**D40 3 Influence-free states on compound quantum systems** HOWARD BARNUM, *Los Alamos National Laboratory* CHRISTOPHER FUCHS, *Bell Laboratories, Lucent Technologies* JOSEPH RENES, *Institüt für Theoretische Physik, Universität Erlangen* ALEXANDER WILCE, *Dept. of Mathematical Sciences, Susquehanna University* Probability states for bipartite local measurements and correlations between local measurements are considered, in general and when the local systems behave quantum-mechanically. We review the facts that in general allowing local measurements conditional on classically communicated results from the other site imposes no-signalling in the direction opposite communication, and that in the locally quantum case, two-way no-signalling restricts states to be in the dual of the cone of unentangled states, isomorphic to that of positive maps. We show that in the ''decomposable'' subcone, generated by quantum states and their partial transposes, the extremal quantum states and extremal partial transposes remain extremal. And we show that decomposable states do not violate Cirelson inequalities. We show that locally-quantum no-signalling states must be combined in a thoroughoing no-signalling fashion. Thus Alice and Bob cannot consistently accumulate a sequence of independent states of this nature (as they might a supply of shared Bell states to use in entanglement distillation) while having available the full panoply of quantum observables and operations at their respective sites. The relation of no-signalling to the ''closest-to-Bayesian'' conditional quantum dynamics of C. Fuchs will also be touched on.

**D40 4 Liouville mechanics with an epistemic restriction and Bohr's response to EPR** TERRY RUDOLPH, *Imperial College* STEPHEN BARTLETT, *University of Sydney* ROBERT SPEKKENS, *Perimeter Institute* We introduce a toy theory that reproduces a wide variety of qualitative features of quantum theory for degrees of freedom that are continuous. Specifically, we consider classical mechanics supplemented by a constraint on the amount of information an observer may have about the motional state (i.e. point in phase space) of a collection of classical particles – Liouville mechanics with an epistemic restriction (This may well be how Heisenberg initially understood the Uncertainty Principle). We develop the formalism of the theory by deriving the consequences of this ''classical uncertainty principle'' on state preparations, measurements, and dynamics. The result is a theory of hidden variables, although it is not a hidden variable model of quantum theory because of its locality and noncontextuality. Despite admitting a simple classical interpretation, the theory also

exhibits the operational features of Bohr's notion of complementarity. Indeed, it includes all of the features of quantum mechanics to which Bohr appeals in his response to EPR. This theory demonstrates, therefore, that Bohr's arguments fail as a defense of the completeness of quantum mechanics.

**15:42**

**D40 5 Negativity and contextuality are equivalent notions of nonclassicality** ROBERT SPEKKENS, *Perimeter Institute for Theoretical Physics* An important problem in the foundations of quantum theory is the identification of the precise manner in which quantum theories differ from their classical counterparts. Two notions of nonclassicality that have been investigated intensively are: (1) negativity, that is, the necessity of negative values in real-valued representations of quantum states such as the Wigner representation, and (2) contextuality, that is, the impossibility of a hidden variable model of quantum theory wherein the representation of measurements is noncontextual (also known as the Bell-Kochen-Specker theorem). We shall argue for a particular way of generalizing and making precise both of these notions. With the refined versions of each in hand, it becomes apparent that they are in fact one and the same notion of nonclassicality. It follows that any proof of contextuality is also a proof of negativity and vice-versa.

**15:54**

**D40 6 Epistemic Excess Baggage of Hidden Variable Theories** NICHOLAS HARRIGAN, TERRY RUDOLPH, *Imperial College London* In Quantum Mechanics (QM) preparations of a system are represented by density operators acting on the associated Hilbert space. An ontological ('hidden' variable) model however, views preparations as being described by probability distributions (known as epistemic states) over a set of 'hidden' variables. We investigate restrictions on the efficiency of any such model of QM through studying its preparation contextuality, a property that one can prove to be possessed by ontological models. This property implies the existence of cases wherein more than one distinct epistemic state must be associated with a single density operator in order to correctly reproduce QM predictions. Traditional proofs of preparation contextuality have exhibited scenarios in which it can only be seen that an ontological model must associate more than one epistemic state with some density operator, the exact number being uncertain. We investigate the existence of upper or lower bounds on the number of distinct epistemic states that an ontological model must associate with density operators in order to reproduce QM statistics. The bounds obtained are yet another clue as to how one might quantify the non-classical nature of QM. We provide some speculation on how these results may shed light on the difficulty of simulating quantum mechanical systems on a classical computer.

**16:06**

**D40 7 Pushing the Experimental Limits of Bell Inequalities** JOSEPH ALTEPETER, EVAN JEFFREY, PAUL KWIAT, *University of Illinois at Urbana-Champaign* Using pairs of polarization-entangled photons, we report measurements of Bell's inequalities near the limits of physically allowable violations. As there are several methods by which one can judge the significance of a violation, we report the largest violation to date measured in both standard deviations (2417-sigma) and absolute size (2.826 +/- 0.005). These extremely precise and extremely non-classical results were obtained by carefully characterizing each experimental loss and inefficiency. Unfortunately, accounting for these losses and inefficiencies in the system requires auxiliary assumptions, assumptions which strictly fail to exclude local hidden variable models, and therefore also fail to rigorously test local realism. We therefore additionally report on progress towards a ''loophole-free'' test of Bell's inequality, whereby these experiemental losses and inefficiencies are virtually eliminated, and along with them, the need for auxiliary assumptions about the nature of the systems being measured.

**16:18**

**D40 8 Can Two-photon Correlation of Chaotic Light Be Considered as Correlation of Intensity Fluctuations?*** GIULIANO SCARCELLI, VINCENZO BERARDI, YANHUA SHIH, *University of Maryland, Baltimore County* Unlike first-order correlation, which is considered as a coherent effect of the electromagnetic field, the second-order correlation of radiation is considered as the classical statistical correlation of intensity fluctuations. The first second-order correlation experiment was demonstrated by Hanbury Brown and Twiss (HBT) stimulating a debate about the classical or quantum nature of the phenomenon. Although quantum models of HBT experiment have been attempted, the classical statistical interpretation has been widely accepted. The concept of intensity fluctuation has even been extended to quantum models: ''photon bunching'' is a phenomenological extension to quantum theory of the statistical correlation on photon number fluctuations. We argue that two-photon correlation phenomena, including HBT, have to be understood as a two-photon coherent effect: quantum interference between two-photon probability amplitudes. To do so, we present a ''ghost'' imaging experiment of chaotic light to show that the classical understanding in terms of intensity fluctuations does not give a correct interpretation for the observation. From a practical point of view, this experiment shows the possibility of having high contrast lensless two- photon imaging with chaotic light, suggesting imaging applications for radiations for which no effective lens is available.

**D40 9 Predictability sieve, pointer states, and the classicality of quantum trajectories** DIEGO DALVIT, *Los Alamos National Laboratory* JACEK DZIARMAGA, *Jagelonian University* WOJCIECH ZUREK, *Los Alamos National Laboratory* We study various measures of classicality of the states of open quantum systems subject to decoherence. Classical states are expected to be stable in spite of decoherence, and are thought to leave conspicuous imprints on the environment. Here these expected features of environment-induced superselection (einselection) are quantified using four different criteria: predictability sieve (which selects states that produce least entropy), purification time (which looks for states that are the easiest to find out from the imprint they leave on the environment), efficiency threshold (which finds states that can be deduced from measurements on a smallest fraction of the environment), and purity loss time (that looks for states for which it takes the longest to lose a set fraction of their initial purity). We show that when pointer states – the most predictable states of an open quantum system selected by the predictability sieve – are well defined, all four criteria agree that they are indeed the most classical states. We illustrate this with two examples: an underdamped harmonic oscillator, for which coherent states are unanimously chosen by all criteria, and a free particle undergoing quan-

tum Brownian motion, for which most criteria select almost identical Gaussian states (although, in this case, predictability sieve does not select well defined pointer states.) Reference: D.A.R. Dalvit, J. Dziarmaga, and W.H. Zurek, Phys. Rev. A 72, 062101 (2005).

**16:42**
**D40 10 Decoherence from Spin Environments** FERNANDO CUCCHIETTI, *Los Alamos National Laboratory* JUAN PABLO PAZ, *Universidad de Buenos Aires* WOJCIECH ZUREK, *Los Alamos National Laboratory* We examine two exactly solvable models of decoherence – a central spin-system, (i) with and (ii) without a self–Hamiltonian, interacting with a collection of environment spins. In the absence of a self–Hamiltonian we show that in this model (introduced some time ago to illustrate environment–induced superselection) generic assumptions about the coupling strengths can lead to a universal (Gaussian) suppression of coherence between pointer states. On the other hand, we show that when the dynamics of the central spin is dominant a different regime emerges, which is characterized by a non–Gaussian decay and a dramatically different set of pointer states. We explore the regimes of validity of the Gaussian–decay and discuss its relation to the spectral features of the environment and to the Loschmidt echo (or fidelity).

**16:54**
**D40 11 The Afshar Experiment and Complementarity** RUTH KASTNER, *University of Maryland, College Park* A modified version of Young's experiment by Shahriar Afshar demonstrates that, prior to what appears to be a ''which-way'' measurement, an interference pattern exists. Afshar has claimed that this result constitutes a violation of the Principle of Complementarity. This paper discusses the implications of this experiment and considers how Cramer's Transactional Interpretation easily accomodates the result. It is also shown that the Afshar experiment is isomorphic in key respects to a spin one-half particle prepared as ''spin up along x'' and post- selected in a specific state of spin along z. The terminology ''which way'' or ''which-slit'' is critiqued; it is argued that this usage by both Afshar and his critics is misleading and has contributed to confusion surrounding the interpretation of the experiment. Nevertheless, it is concluded that Bohr would have had no more problem accounting for the Afshar result than he would in accounting for the aforementioned pre- and post- selection spin experiment, in which the particle's preparation state is confirmed by a nondestructive measurement prior to post-selection. In addition, some new inferences about the interpretation of delayed choice experiments are drawn from the analysis.

**17:06**
**D40 12 Robust Weak Measurements** JEFF TOLLAKSEN, *George Mason University* YAKIR AHARONOV, *George Mason University, University of S. Carolina, and Tel Aviv University* We introduce a new type of weak measurement which yields a quantum average of weak values that is robust, outside the range of eigenvalues, extends the valid regime for weak measurements, and for which the probability of obtaining the pre- and post-selected ensemble is not exponentially rare. This result extends the applicability of weak values, shifts the statistical interpretation previously attributed to weak values and suggests that the weak value is a property of every pre- and post-selected ensemble. We then apply this new weak measurement to Hardy's paradox. Usually the paradox is dismissed on grounds of counterfactuality, i.e., because the paradoxical effects appear only when one considers results of experiments which do not actually take place. We suggest a new set of measurements in connection with Hardy's scheme, and show that when they are actually performed, they yield strange and surprising outcomes. More generally, we claim that counterfactual paradoxes point to a deeper structure inherent to quantum mechanics characterized by weak values (Aharonov Y, Botero A, Popescu S, Reznik B, Tollaksen J, Physics Letters A, 301 (3-4): 130-138, 2002).

**17:18**
**D40 13 Quantum of Information** CASLAV BRUKNER, ANTON ZEILINGER, *Institute of Experimental Physics, University of Vienna, Boltzmanngasse 5, 1090 Vienna, Austria* The violation of local realism is today a well established experimental fact. From it follows that either locality or realism or both cannot provide a foundational basis of Nature. Relaxing the locality condition would essentially not change the epistemological structure of classical physics but only extend its limits. Abandonment of reality, however, would require a radical revision of the conceptual background of all our theories so far. Is a novel conceptual basis of quantum theory feasible, in which the impossibility of defining external reality independent and prior to observation naturally emerges? We suggest the finiteness of information content of a quantum system as providing such basis. Any realistic theory that could arrive at an accurate prediction of a particular event would require the system to carry information as to which specific result will be observed for all possible future measurements. Because the system cannot carry more information than is in principle available, there must exist measurements for which individual events contain an element of irreducible randomness. Quantum entanglement arises from the possibility that information in a composite system resides more in the correlations than in properties of individuals. In the talk we will report on recent efforts towards providing derivations of the elements of the Hilbert space structure from the quantization of information.

**D42 2 Real Time Observation of DNA Nanotube Assembly*** LISA VAL VERDE, FYGENSON GROUP TEAM, DNA nanotubes are of interest for applications ranging from nanofabrication to biophysical studies. The DNA Nanotubes used in this research are self-assembling structures composed of DNA double-crossover tiles. These tiles are simply two connected helices composed of five single stranded DNA oligomers. Each tile exposes four sticky ends responsible for the linkage between neighboring tiles. This linkage creates the nanotube lattice, with intrinsic curvature. The curvature orients each tile with a $60^o$ angle from the previous one so that six tiles make up the circumference of a nanotube. Nanotube stability depends on conditions such as ionic strength and temperature. A PCR machine is used to anneal the strands into nanotubes. A duplicated annealing process was constructed under a light microscope. PVP (polyvinyl prolidone) coated glass both confined the DNA nanotubes to a 2-3 $\mu$m focal plane and prevented them from sticking to the sample surface. By the time the tubes were long enough to track ( $\geqslant$ 3 $\mu$m), they continued to lengthen primarily via end-to-end joining with some reaching lengths greater than 100 $\mu$m. These observations helped define more efficient annealing protocols that resulted in tubes with fewer imperfections.

**D42 3 Laser Assisted Cancer Immunotherapy: Mapping of the Necrosis Zone*** MEGAN FITZMAURICE, PRADIP BANDYOPADHYAY, *Hendrix College* The primary goal of this project is to assess the degree of thermal damage in malignant tumors using Laser Assisted Cancer Immunotherapy (LACI). In our laboratory, superficial tumors were grown in Balb/c mice by injection (s.c.) of the highly aggressive metastatic mammary cell line CRL-2539. When the tumors reached 5-7 mm in diameter, Indocyanine Green, a light absorbing dye, and Glycated Chitosan, the immunoadjuvant, were injected into the tumors. Following injection, the tumors were irradiated interstitially with an infrared Diode laser (1-15 W) operating at 805nm. Following the laser therapy, at a particular temperature, the tumors were excised at various time intervals ranging from immediately after treatment to 120 hours later. Using a Hematoxylin and Eosin stain, each slide was examined under the light microscope to map out the thermal damage induced by the diode laser and the dye-immunoadjuvant combination. The goal of this experiment is to quantify and map the thermal damage for $55^o$C, $65^o$C and $75^o$C, and to determine the temperature range that evokes maximum immune response.

**D42 4 Interstitial Laser Irradiation of Solid Tumors in Laser Assisted Cancer Immunotherapy** LINDSAY EVANS, *Hendrix College* PRADIP BANDYOPADHYAY, *Hendrix College* Laser Assisted Cancer Immunotherapy (LACI) is an experimental therapeutic approach in cancer treatment. Current experiments in our laboratory begin with growing superficial tumors 5 to 7 mm in diameter in BALB/C mice using the CRL-2539 cell line. Tumor sizes were measured with a vernier caliper prior to injection of light absorbing dye (Indocyanine Green, ICG) and immunoadjuvant (Glycated Chitosan, GC). These measurements were continued during the post-therapy period. After injection with the ICG and GC, the mice underwent interstitial irradiation of the tumor with a diode laser operating at 804 nm. Microthermocouples were inserted into the tumor and the laser power was varied in order to monitor the temperature and keep it within in the desired range. Tumors were irradiated at $55^o$C, $65^o$C, and $75^o$C to find out at which temperature the maximum amount of tumor necrosis and strong immune response could be elicited. The growth of the tumors after the LACI treatment will be plotted to show the affect of the therapy at different temperatures. The data suggest that the growth rate of the tumors is slowed down considerably using this approach. * This work is supported by a grant from The National Institutes of Health.

**D42 5 Laser Assisted Cancer Immunotherapy: Surface Irradiation** JOSHUA WILSON, *Hendrix College* HSIN-WEI CHEN, *Hendrix College* PRADIP BANDYOPADHYAY, *Hendrix College* Experiments in our laboratory incorporate a non-invasive approach to treat superficial tumors in animal models. Based on the concept of Laser Assisted Cancer Immunotherapy, surface irradiation provides good information to compare to invasive alternatives. The procedure involves injecting an immunoadjuvant (Glycated Chitosan) as well as a light absorbing dye (Indocyanine Green) directly into the tumor (5 to 7 mm in diameter). The temperature of the tumor is raised using an infrared diode laser operating at 804 nm, with a silica fiber tip placed a set distance away from the surface of the tumor. We monitor the surface temperature using non-invasive (infrared detector probe) as well as the internal temperature of the tumor using invasive (micro thermocouples) methods. This study aims at the success of the surface irradiation mode to treat solid tumors. * This work is supported by a grant from The National Institute of Health.

**D42 6 The Computer Generation of Holographic Optical Tweezers** MICHAEL DECEGLIE, RODD PRIBIK, JEREMY LYON, KERRY BROWNE, *Dickinson College* Due to their ability to apply forces on a small scale, optical tweezers are useful for a variety of biological and physical applications. The utility of optical tweezers can be extended by producing multiple traps with different characteristics from a single beam. One method for achieving this is to manipulate the phase of a trapping laser's wave front with a computer generated kinoform displayed on a spatial light modulator. We compare the performance of two algorithms for kinoform calculation, a Gerchberg-Saxton algorithm and a direct search algorithm, and discuss how they address problems inherent to computer generated holographic optical tweezing.

**15:42**

**D42 7 Growth and Evaporation of Optically Trapped Liquid Droplets Viewed with a Two Axis Microscope** SCOTT DEWOLF, LOWELL I. McCANN, *Physics Dept., University of Wisconsin-River Falls* Water droplets in air can be trapped in a single-beam optical trap (optical tweezers) for extended periods of time. The trap used in this work is a unique two axis microscope system that allows the trapped object to be viewed from the top and the side simultaneously. Both views are imaged onto a single digital camera with temporal resolution of better than 5ms. We will report on the behavior of water droplets as they grow and evaporate while in the trap. We will discuss changes in the size and shape of the droplets over time, the onset of instabilities during the evaporation process, and how the trapping laser power affects the droplet. This research was supported by an award from Research Corporation.

**15:54**

**D42 8 Leidenfrost Ratchets** MICHAEL TAORMINA, *University of Oregon* BENJAMIN ALEMAN, *University of California, Berkeley* HEINER LINKE, *University of Oregon* Properties such as asymmetry and disequilibrium can be exploited in order to obtain useful work from a physical system. Our group is investigating one particularly interesting manifestation of the ''ratchet'' effect. We find that film-boiling (leidenfrost) drops of liquid placed on an asymmetrically-structured surface experience acceleration significant enough for transport to occur even against small inclines. We believe that a viscous drag force is the mechanism for this net flow of fluid, which is supported by a thin layer of vapor. Because heat is the primary input of energy into the system, this effect could prove useful in cooling applications where a classical ''pump'' may not be ideal.

**16:06**

**D42 9 The effect of M ( M=Ti, V) and A (A=Al, Ge) on thermal transport and heat capacity of nanolayered ternary carbides $M_2AC$*** A.P. BRYAN, *Rowan University* S.E. LOFLAND, *Rowan University* J.D. HETTINGER, *Rowan University* P. FINKEL, *Rowan University* M.W. BARSOUM, *Drexel University* A. GANGULY, *Drexel University* S. GUPTA, *Drexel University* We report an investigation of the specific heat and the thermal transport of a subset of the so-called MAX-phase family of materials: $V_2GeC$, $V_2AlC$, $Ti_2GeC$ and $Ti_2AlC$. The thermal transport results are analyzed to investigate the impact of the A-group and M-element on the phonon contribution to the thermal transport. The heat capacity results are investigated to determine the impact of the same elements on the density of electronic states and the Debye temperature. We find that M-element has a more significant impact on the electronic density of states and the thermopower. The Seebeck coefficient is significantly larger in the V-containing carbides (it is nearly zero in the $Ti_2AC$ compounds), although the sign is dependent on the A-group element. The A-group element has an expected impact on the Debye temperature due to the change in atomic masses, but the phonon contribution to the thermal conductivity is largest in the $V_2AC$ compounds

**D42 10 Electron Spin Resonance of $VO_2$ thin films** K.C. MAYNES, P.H. BUNTON, D.B. BAKER, KENNETH HARTMAN, *William Jewell College* R.F. HAGLUND, JR., R. LOPEZ, A. HABALICA, *Vanderbilt University* The metal-insulator transition present in chromium doped $VO_2$ nanoscale film has been observed by electron spin resonance (ESR) spectroscopy. $VO_2$ is a highly correlated electron system with numerous practical applications pertaining to this transition, including ultra-fast optical switching and smart windows. We use $Cr^{3+}$ transition metal ions with concentration of order one percent as a probe in a 140 nm film to detect this transition. The film exhibited a four-fold decrease in chromium intensity as temperature increased through the transition temperature ( $\sim$ 67° C). ESR signal intensities were also used to characterize the hysteretic behavior of this particular transition; these results are in agreement with hysteresis observed through optical means. A discussion of how changes in ESR relaxation times affect signal intensities, as monitored through the transition, will be presented.

**16:30**

**D42 11 EPR Study of Amorphous $V_2O_5$From 125K − 370K** KENNETH HARTMAN, D.B. BAKER, K.C. MAYNES, P.H. BUNTON, *William Jewell College* S. FULLER, *Coe College* Previous EPR spectra for $V_2O_5$ at low temperatures ( $\sim$ 120K) reveal well-resolved resonances in which transitions are attributed to anisotropic hyperfine interactions. In contrast, recent results from our laboratory show EPR spectra with broad resonances that exist from 125K-370K with no apparent appearance of hyperfine interactions. EPR spin counting also indicates a high concentration ( $\sim 10^{20}$ spins/cm$^3$) of paramagnetic centers which suggests that the line widths are limited by spin-spin relaxation of the electron spin system. Current data reveal that EPR signal intensities increase more rapidly than (Temperature)$^{-1}$. In particular, a factor of $\sim$ 10 increase is seen when the temperature is decreased by a factor of 2. Possibilities for enhanced signal intensities include the presence of superparamagnetism or spin glass behavior. Current investigations are concerned with evaluations of a variety of EPR parameters over a temperature range from 125-370K.

**16:42**

**D42 12 Mean-Field Study of Magnetic Resonance for Spin-1 Condensates** ANDREW ROBERTSON, HONG LING, DAVID GROCHOWSKI, *Rowan University, Glassboro NJ* A spin-1 alkali atom has three hyperfine spin levels $|f=1,m=-1,0,+1>$ . An optical dipole trap is capable of simultaneously trapping and condensing all the hyperfine states, forming the so-called spinor Bose-Einstein condensate (BEC), where the spin degrees of freedom are virtually free. The spin-1 BEC is amenable to manipulation by magnetic field. Magnetic resonance theory is developed for a spin-1 BEC subject to both a rotating transverse magnetic field and a longitudinal magnetic field. The focus of the theory is the magnetization, which will be analyzed both analytically and numerically. Magnetization is used to probe the nonlinear two-body collisions, which strongly affect the properties of the spin-1 BEC. It is shown that while collisions modulate the population dynamics, it is the quadratic Zeeman interaction that couples the population dynamics due to collisions to the magnetization.

**16:54**

**D42 13 Width of a Ferrofluid Finger: Hysteresis and Multiple Energy Minima** NARELLE HILLIER, DAVID JACKSON,* *Dickinson College* The theoretical finger width dependence of a ferrofluid on the magnetic field in a Hele-Shaw geometry is investigated. A model of the finger enables the energy to be computed and then minimized to determine the finger width. Calculations predict a hysteresis effect as the applied magnetic field is varied. This results from the existence of two local energy minima for a range of magnetic bond numbers. Hence, for a given magnetic bond number, the stable ferrofluid configuration can be either a circle or a finger, depending on the whether the applied field is increasing or decreasing. A comparison with experimental results will be presented.

**D42 14 Design of Low Temperature AC Susceptibility Measurement Scheme for Molecular Magnets** SIMCHA KORENBLIT, BYOUNG MOON, YOONSEOK LEE, *University of Florida* REZA SULTAN, *Canterbury High School* AC susceptibility is one of the most important physical properties in many materials such as magnetic materials and superconductors. Al-

though there are many commercial AC susceptibility measurement systems which cover a broad range of temperatures, it is still a daunting task to extend their measurement range into the low millikelvins. We are currently developing a low temperature AC susceptometer for the mK range. As a part of this effort, we have developed a versatile low-cost computer controlled coil-winder to make various types of coils. We have designed primary and secondary coils and wound them using the machine, and performed characterization of the AC susceptometer. In this presentation, I will explain the basics of magnetic susceptibility, its measurement, design considerations for building an AC magnetic susceptometer, and discuss the details of an actual apparatus designed and realized by the authors.

**D43 1 Hardcore Bosons in a Rotating Lattice*** RAJIV BHAT, *JILA, NIST and CU-Boulder* LINCOLN CARR, *Colorado School of Mines* MURRAY HOLLAND, *JILA, NIST and CU-Boulder* Two of the most important themes in the developing area of quantum fluids and ultracold gases include the role of strong interactions and highly correlated effects. We study a novel and interesting problem combining these two key areas by looking at the experimentally relevant area of ultracold atoms in rotating optical lattices. This merges the effects of strong interactions generated by the lattice with the intriguing quantum effects present in the analogy of the quantum Hall effect at high rotation rate. Hardcore bosons in a 2D rotating square lattice are investigated via a modified Bose-Hubbard Hamiltonian. Our results show quantization of circulation and potential phase transitions between circulation values in which the symmetry of the ground state changes structure abruptly as a function of rotation.

**14:42**
**D43 2 Vortex lattice melting in a stack of Bose Einstein Condensates** MICHIEL SNOEK, HENK STOOF, *Utrecht University* The observation of fractional Quantum Hall liquids in rapidly rotating ultracold Bose gases is a long desired goal. Until now the experimentally accessible ratio of the numbers of particles to the number of vortices is far too high to melt the vortex lattice and to observe these states. This can be solved by means of an one-dimensional optical lattice, which divides the condensate in a stack of two-dimensional condensates in which the number of particles is strongly reduced and the quantum fluctuations are enhanced. We study the melting of a vortex lattice in such a configuration by calculating the quantum fluctuations around the classical Abricosov lattice for realistic numbers of particles and vortices. We find that the fluctuations are inhomogeneous and the lattice melts from outward to inward. Coupling neigbouring pancakes by tunneling reduces the anharmonicity as well as the size of the fluctuations and brings in the 3D regime.

**14:54**
**D43 3 Virial theorems and vortex states in confined Bose-Einstein condensates*** STAVROS KOMINEAS, NIGEL COOPER, *University of Cambridge* NIKOS PAPANICOLAOU, *University of Crete* We derive a class of virial theorems which provide stringent tests of both analytical and numerical calculations of vortex states in a confined Bose-Einstein condensate. In the special case of harmonic confinement we arrive at the surprising conclusion that the linear moments of the particle density, as well as the linear momentum, must vanish even in the presence of off-center vortices which lack axial or reflection symmetry. The effect of anharmonic confinement is also discussed. Two types of non-axisymmetric vortices have been observed to precess around the center of the condensate and they are refered to as the S-vortex and the U-vortex. We study numerically (Gross-Pitaevskii equation) and theoretically a single vortex in spherical and elongated condensates as a function of the interaction strength. For a given angular momentum the S-vortex has smaller precession frequency and a higher energy than the U-vortex in a rotating elongated condensate. We show that the S-vortex is related to the solitonic vortex and also to the dark soliton which are nonlinear excitations in the nonrotating system. In the dilute limit a lowest Landau level calculation provides an analytic description of these vortex modes. (Phys. Rev. A 72, 053609 (2005), Phys. Rev. A 72, 053624 (2005))

**D43 4 Observation of High-Temperature Superfluidity in a Gas of Fermionic Atoms.**
MARTIN ZWIERLEIN, *MIT*

Ultracold quantum degenerate Fermi gases provide a remarkable opportunity to study strongly interacting fermions. In contrast to other Fermi systems, such as superconductors, neutron stars or the quark-gluon plasma of the early Universe, these gases have low densities and their interactions can be precisely controlled over an enormous range. A major goal has been the realization of superfluidity in a gas of fermions. Our observation of vortex lattices in a strongly interacting rotating Fermi gas provide definitive evidence for superfluidity. By varying the binding energy between fermion pairs, we have studied the crossover from a Bose–Einstein condensate of molecules to a Bardeen-Cooper-Schrieffer superfluid of loosely bound pairs. The crossover is associated with a new form of superfluidity. The observed transition temperatures normalized for the density of the gas by far exceed the highest transition temperatures achieved in high-Tc superconductors. Recently, we have extended those studies to interacting Fermi gases with imbalanced spin populations and observed a quantum phase transition at a critical imbalance, which is the Pauli limit of superfluidity.

**D43 5 Vortex lattice formation in Bose-condensed gases in rotating potentials** TETSURO NIKUNI, *Tokyo University of Science* TOSHIHIRO SATO, *University of Tokyo* TOMOHIKO ISHIYAMA, *Tokyo University of Science* We study vortex lattice formation in trapped Bose-condensed gases in various types of rotating potentials by solving the time-dependent Gross-Pitaevskii equation. We discuss the detailed characteristics of the formation dynamics and the structure of vortex lattices depending on the geometry of rotating potentials.

**15:54**
**D43 6 Vortex Structure and Dynamics in Fermi Superfluid Gas*** MASAHIKO MACHIDA, *CCSE, Japan Atomic Energy Agency* TOMIO KOYAMA, *IMR, Tohoku Univ.* YOJI OHASHI, *Institute of Physics, Univ. of Tsukuba* In order to study a universal structure of the quantized vortex in Fermi superfluid Gas, we numerically calculate the generalized Bogoliubov de Gennes equation derived from the fermion-boson model and clarify how the vortex structure changes through the BCS-BEC crossover. In the numerical calculations, we concentrate on a singly quantized vortex and compare the structure for both the narrow and the broad Feshbach resonance. Numerical calculation results reveal that in the BEC regime the matter density depression at the vortex core is complete while in the BCS regime the depression at the vortex core is relatively obscure. This feature is qualitatively common for both the narrow and broad Feshbach resonances, while in profiles of the molecular boson condensate the narrow and broad cases differ. In the broad case, the profile of the molecular boson condensate is quite similar to that of the fermionic superfluid gap. In addition, we show quasi-particle spectra from BCS to BEC for both Feshbach resonance cases. The number of the low-lying quasi-particle excitations localized inside the vortex core drastically decreases as one goes to the BEC regime. This result indicates that an origin of the vortex dissipation alters between BCS and BEC.

**D43 7 Critical Current, Vortices and Fermionic Bound States in the BEC to BCS Crossover** RAJDEEP SENSARMA, MOHIT RANDERIA, TIN LUN HO, *Physics Department, The Ohio State University* We have analyzed a single vortex at $T = 0$ in a 3D superfluid atomic Fermi gas across a Feshbach resonance[1] using a fully self-consistent Bogoliubov-deGennes approach. From the current flow around a vortex we conclude that unitarity ($a_s = \infty$) is the most robust superfluid state in the entire BCS-BEC crossover, with the highest critical velocity $v_c$ of about $0.1v_F$. On either side of unitarity, $v_c$ decreases. It is determined by pair breaking on the BCS side and by collective excitations in the BEC regime. In the BCS limit, the order parameter near the vortex core shows a variation on both the scale of $k_F^{-1}$ and of the coherence length $\xi$, while away from the BCS limit only a variation on the scale of $\xi$ is seen. The density in the core rises quadratically with radial distance and is progressively depleted as one moves from BCS to BEC. The number of fermionic bound states in the core decreases as we move from the BCS to BEC regime. Remarkably, a bound state branch persists even on the BEC side reflecting the composite nature of bosonic molecules. [1] R. Sensarma, M. Randeria and T.L. Ho, cond-mat/0510761

**D43 8 Ground state description of a single vortex in an atomic Fermi gas: From BCS to Bose-Einstein condensation*** CHIH-CHUN CHIEN, *University of Chicago* YAN HE, *University of Chicago* QIJIN CHEN, *University of Chicago* K. LEVIN, *University of Chicago* We use a Bogoliubov-de Gennes (BdG) formulation to describe a single vortex in a neutral fermionic gas. It is presumed that the attractive pairing interaction can be arbitrarily tuned to exhibit a crossover from BCS to Bose-Einstein condensation. Our starting point is the BCS-Leggett mean field ground state for which a BdG approach is microscopically justified. At strong coupling, we demonstrate that this approach is analytically equivalent to the Gross-Pitaevskii description of vortices in true bosonic systems. We analyze the sizable density depletion found for the unitary regime and relate it to the presence of unoccupied (positive energy) quasi-bound states at the core center. **D43 10 Visualization and characterization of superfluid vortices in liquid helium*** DANIEL LATHROP, GREGORY BEWLEY, *University of Maryland* KATEPALLI SREENIVASAN, *International Center for Theoretical Physics* In superfluid helium 4, quantum vortices have been studied indirectly for nearly fifty years. We have discovered that micron sized solid hydrogen particles suspended within superfluid helium are attracted to and trapped by the vortex filaments and thereby make it possible to see individual vortex lines. The ability to produce the fine solid hydrogen particles is key to this new technique. We compare the line density in a steadily rotating superfluid with the Feynman prediction. Oscillating modes of the vortex array are also observed and characterized. Our observations also include periodic particle spacing on lines at low particle density, as well as complex vortex branching and networks. Our visualization technique makes it possible to observe the dynamics and geometry of vortices both in superfluid turbulence and in quench conditions passing through the phase transition.

**D43 11 Nucleation and growth of vortices in a rotating BEC*** OLEG VOROV, *Drake University* PIET VAN ISACKER, *GANIL* MAHIR HUSSEIN, *Universidade de Sao Paulo* KLAUS BARTSCHAT, *Drake University* An analytic solution of the Gross-Pitaevskii equation [1] for a rotating Bose-Einstein condensate of trapped atoms describes the onset of vorticity when the rotational speed is increased, starting with the entry of the first vortex [2] and followed by the formation of growing symmetric Wigner molecules. It explains the staircase of angular momentum jumps and the behavior of the bosonic occupancies observed in numerical studies. The universalities of this behavior [3] and its similarity to the mesoscopic superconductors are discussed. [1] O.K. Vorov, P. Van Isacker, M.S. Hussein, and K. Bartschat, Phys. Rev. Lett. 95, 230406 (2005). [2] O.K. Vorov, P. Van Isacker, and M.S. Hussein,, Phys. Rev. Lett., 90, 200402 (2003). [3] O.K. Vorov, P. Van Isacker, and M.S. Hussein, and K. Bartschat, subm. **D45 1 Charge Localization and near zero in-plane thermal expansion in layered $Na_xCoO_2$, $x \sim \frac{1}{2}$** DIMITRI ARGYRIOU, C. MILNE, O. PROKHNENKO, *Hahn-Meitner-Institut, Glienicker Str. 100, Berlin D-14109, Germany* L.C. CHAPON, P.G. RADAELLI, *ISIS Facility, Rutherford Appleton Laboratory-CCLRC,U.K.* We have used neutron powder diffraction and X-ray single crystal diffraction to investigate the lattice response to charge localization and magnetic ordering in samples with stochiometry close to $Na_{0.5}CoO_2$ over the temperature range of 2 to 600K. Our measurements show there presence of two crystallographical distinguishable Co sites but with essentially identical bond valences. This indicates only a marginal charge disproportionation between $Co^3$ and $Co^4$. Our measurements show Na-ordering achieved by de-intercalation imposes a constraint on the charge and spin-state degrees of freedom that acts as to reduce the in-plane thermal expansion to near zero values between 2 to 300K. At higher temperatures we find a phase non-reversable transition to a phase with a $3a \times [**space**]3b \times [**space**]c$ cell, wtr to the orthorhombic P*nmm* low temperature phase. This phase does not exhibit any of the anomalies observed at 52 and 87K in the magnetic susceptibility of the as made phase.

**14:42**

**D45 2 Spin Glass Statics and Dynamics in the Disordered Stacked Quantum Ferromagnet LiNiO2** J.P. CLANCY, B.D. GAULIN, S.R. DUNSIGER, S. HARAVIFARD, *Department of Physics and Astronomy, McMaster University* J.R.D. COPLEY, Y. QIU, *National Institute of Standards and Technology* We have performed time-of-flight neutron scattering measurements on polycrystalline LiNiO2 using the Disk Chopper Spectrometer at the NIST Center for Neutron Research. Similar measurements performed on its sister compound, NaNiO2, show a simple magnetic structure below Tn$\sim$ 22K consisting of ferromagnetic sheets of s=1/2 moments stacked in an antiferromagnetic (AF) fashion [1]. Our measurements on LiNiO2 illustrate the absence of magnetic order down to 1.7K. Further they provide direct evidence for a spin glass transition at 9K through a narrowing of the inelastic magnetic scattering on approaching Tg from above, along with a concomitant increase in the elastic magnetic scattering, indicative of frozen disordered moments. The inelastic magnetic scattering in LiNiO2 resembles that in NaNiO2 above Tn, suggesting that the low Q spin response is due to short-lived spin wave modes below the lowest Q AF ordering wavevector. This reinforces the picture that the simple stacked ferromagnetic ordered state displayed by NaNiO2 is precluded by mixing between the Li and Ni sublattices, which occurs in LiNiO2 at the 1-3% level. [1] M.J. Lewis et al., PRB 72, 014408 (2005).

**14:54**

**D45 3 Coexistence of f-wave superconductivity, charge order, and spin antiferromagnetism around nonmagnetic impurities in $Na_{0.33}CoO_2 \cdot 1.3H_2O$*** JIN AN, HAI-QING LIN, *Chinese University of Hong Kong* CHANG-DE GONG, *Nanjing University* To check whether charge dynamics is responsible for the superconductivity in $Na_xCoO_2 \cdot yH_2O$, we investigate local electronic and magnetic structure around a nonmagnetic impurities embedded in this material at $x = 0.33$ in the vicinity of charge instability, by using a phenomenological model within the slave-boson framework including competitions among a $\sqrt{3} \times \sqrt{3}$ charge order, antiferromagnetism and f-wave superconductivity. Around the repulsive impurities, it is found that both local charge and spin orders are induced. Furthermore, the f-wave pairing order parameter is decreased on one sublattice but increased on another honeycomb sublattice. If the charge dynamics is responsible for the superconductivity, the predicted local electronic and magnetic structure could be observed by the STM and spatial resolved NMR experiments.

**D45 4 Thermoelectric properties of $Na_{0.68}CoO_2$ on a 2D triangular lattice** MICHAEL R. PETERSON, JAN O. HAERTER, B. SRIRAM SHASTRY, *University of California Santa Cruz* $Na_xCoO_2$ at $x = 0.68$ is a material with important and interesting thermopower. Using a new formalism for computing thermal response functions, via the response to dynamical temperature gradients, in the high frequency limit a nearly frequency independent term is identified for the thermopower $S^*$, the Lorentz ratio $L^*$, and the dimensionless figure of merit $Z^*T$. We calculate, via exact diagonalization for small systems, $S^*$, $L^*$, and $Z^*T$, at all temperatures for the *t-J* model on a 2D triangular lattice exploring the model parameters relevant to the experiments by I. Terasaki *et al, (PRB* **56**, R12685 (1997)) and Y. Wang *et al, (Nature* **423**, 425 (2003)). Our objective is to understand the (large) magnitude of the thermopower, and its remarkable sensitivity to a magnetic field. We also consider the hypothetical and interesting case of the opposite sign of hopping $t \rightarrow -t$.

**15:18**

**D45 5 Jahn-Teller distortion and magnetic ordering in layered nickelates** MICHELLE JOHANNES, IGOR MAZIN, NOAM BERNSTEIN, *Naval Research Laboratory* One of the long-standing challenges in the theory of layered nickelates is that $NaNiO_2$ is antiferromagnetic and has a strong Jahn-Teller induced orbital ordering, while $LiNiO_2$ has none. A variety of hypothesis have been proposed to explain this mystery: a difference in Li/Na ionic radii, differences in the underlying electronic structure, the zero-point motion of Li ions, etc. One of the most viable propositions is that the difference is due to the presence of $Na2^+$ ions (1% or more) on the Li sites. It remains unclear whether the magnetic interaction of $Na2^+$ with the in-plane $Na3^+$ is strong enough to cancel the Li-assisted antiferromagnetic superexchange even for 1% of $Na2^+$, and what effect it has on orbital ordering. We provide quantitative arguments, based on first principles calculations and atomistic simulations, that spin and orbital orderings are unrelated, and that both are destroyed (the latter in a rather unusual way) by $Na2^+$ impurities, but for entirely separate reasons.

**15:30**

**D45 6 Pronounced increase of the thermopower in $Na_xCoO_2$ in the large-$x$ regime ($x \geq 0.75$)** MINHYEA LEE, *Physics Department, Princeton Univerisity* LILIANA VICIU, *Chemistry Department, Princeton Univerisity* LU LI, YAYU WANG, *Physics Department, Princeton Univerisity* M. L. FOO, S. WATAUCHI, R. A. PASCAL JR., R. J. CAVA, *Chemistry, Princeton Univerisity* N. P. ONG, *Physics, Princeton Univerisity* We report for the first time the systematic transport study on high doped $Na_xCoO_2$ over series of samples which lie ($0.75 \leqslant x \leqslant 1$). We discovered two distinctive regions of phase diagram exist in high Na doping level: one is characterized by largely enhanced thermopower (200 – 300 $\mu$V/K at $\sim$ 130K) yet highly metallic resistivity in $0.75 \lesssim x \lesssim 0.88$ (region I). The other (region II) is emerged in $0.89 \lesssim x \lesssim 0.97$, in which the electronic phase is mixed with the region I phase and $x = 1$ of non-conducting end compound and the mixture seems to occur mainly along the layer. We will discuss the newly revised phase diagram of the high Na part and speculate on a relation to the characteristics of Na layer.

**15:42**

**D45 7 Single-particle excitation-spectra in the Hubbard model on a kagomé lattice** WATARU KOSHIBAE, NEJAT BULUT, KENJI TSUTSUI, SADAMICHI MAEKAWA, *Institute for Materials Research, Tohoku University, Sendai 980-8577, Japan* The effects of frustration in spin systems have been studied for many years. Recently, the transport properties of the layered cobalt oxide $Na_xCoO_2$ and of related oxides have generated new interest in the frustrated systems. In the cobalt oxides, the Co ions form a triangular lattice. The hopping matrix element of electrons in the cobalt 3*d* orbitals is not isotropic, and we have shown [PRL**91**, 257003] that the triangular $CoO_2$ lattice consists of four coupled kagomé sublattices. For this reason, here, we examine the single-particle excitation spectrum of the Hubbard model on the kagomé lattice, and study the motion of a carrier in this frustrated system. We use the quantum Monte Carlo and the exact-diagonalization methods. The dispersion relation of the tight-binding model on the kagomé lattice has a flat dispersion at the top or the bottom of the energy band depending on the sign of hopping-matrix element $t$. This causes a two-fold degeneracy at the $\Gamma$ point where the flat piece of the dispersion is located. However, in the interacting system, we find that the lowest- lying states have a two-fold degeneracy at the $\Gamma$ point independent of the sign of $t$, when the Coulomb repulsion is sufficiently strong. In this talk, we will discuss these numerical results on the electronic structure of the Hubbard model on the kagomé lattice.

**15:54**

**D45 8 Squaring the Triangle: Insulating Ground State of $Na_{0.5}CoO_2$*** TING-PONG CHOY, DIMITRIOS GALANAKIS, PHILIP PHILLIPS, *University of Illinois* We demonstrate that at a filling of $n = 1.5$, an hexatic insulating state obtains in the extended Hubbard model on a triangular lattice. Composed of two tetragonal sublattices with fillings of $n = 1$ and $n = 2$, the insulating state is charge ordered and possesses an antiferromagnetic superlattice with dimension $a \times \sqrt{3}$. Two distinct energy scales arise in our model, a charge gap for the insulator and the effective exchange interaction in the antiferromagnet. Our model is capable of explaining the sign change of the Hall-coefficient as a function of temperature as well as the persistence of antiferromagnetism above the insulating state.

**D45 9 Itinerant correlated electrons on 2D and 3D triangular lattices** M. BRUEHWILER, *ETH Zuerich, Switzerland* S. M. KAZAKOV, J. KARPINSKI, B. BATLOGG, In insulating frustrated systems, where localized magnetic moments sit on the vortices of e.g. triangles or tetrahedra, competing interactions lead to a wealth of novel states of fundamental interest. Ground states of infinite degeneracy are a typical signature of such frustrated systems. While for local moments the intimate connection between spin and the lattice leads to the observed frustration effects, it is an open question to what degree itineracy modifies these features and how charge, spin, and lattice degrees of freedom are affected. In this context, the superconductivity recently discovered in 2D triangular $Na_xCoO_2 - yH_2O$ and 3D triangular $AOs_2O_6$ ($A$ = K, Rb, Cs) is of considerable interest. In order to shed light onto the above mentioned questions associated to these materials, we have performed thermodynamic and transport measurements on both the parent compound of the hydrated superconductor, $Na_xCoO_2$, and the pyrochlores $KOs_2O_6$ ($T_c = 9.5$ K) and $RbOs_2O_6$ ($T_c = 6.4$ K). We have mapped out parts of the phase diagram as a function of band filling of $Na_xCoO_2$ (varying Na content $x$) and find peculiar low-energy excitations below about 10 K. In the 3D system, we also find a significant mass enhancement by factors up to about 8 compared to band structure calculations, part of which can be attributed to electron-phonon interaction ($\lambda_{ep} = 1$ to 1.5).

**16:18**

**D45 10 Hall constant on the Icosahedral t-J model** JAN HAERTER, MICHAEL PETERSON, SRIRAM SHASTRY, *University of California at Santa Cruz* We investigate the Hall constant $R_H$ in the zero field limit through the exact diagonalization technique on small clusters within the triangular lattice t-J model. As a model system we study the icosahedron, a 12-site Platonic solid consisting solely of five fold coordinated triangles. We compare results with toroidal geometries up to 12 sites. While the high-temperature behavior of the high-frequency $R_H^*$ is quite well understood analytically, our objective is to explain the complete

T-dependence of $R_H$ in $Na_{.68}CoO_2$ as observed in experiments (Ong et al), especially in the low-T regime. Furthermore, we investigate $R_H$ as function of frequency by explicit evaluation of Kubo formulae. We compare results with existing studies of $R_H$ on square lattices.

**D45 11 Ground-state valency and spin configuration of the nickelates.** LEON PETIT, GEORGE M. STOCKS, TAKESHI EGAMI, *Oak Ridge National Laboratory* ZDZISLAWA SZOTEK, WALTER M. TEMMERMAN, *Daresbury Laboratory* The ab initio self-interaction-corrected local-spin-density approximation is used to study the electronic structure of both stoichiometric and non-stoichiometric nickelates. From total energy considerations it emerges that, in their ground-state, both $LiNiO_2$, and $NaNiO_2$ are insulators, with the Ni ion in the $Ni^{3+}$ low spin state ($t_{2g}^6 e_g^1$) configuration. We find that the substitution of Li/Na atoms by divalent impurities, drives an equivalent number of Ni ions in the $NiO_2$ layers from the JT-active trivalent low-spin state to the divalent JT-inactive state. We propose that an experimental study on $Mg_xNa_{1-x}NiO_2$ might clarify the role of $Ni^{2+}$ impurities with respect to the vanishing of long range orbital ordering in $Li_{1-x}Ni_{1+x}O_2$. (Work sponsored by the Laboratory Directed Research and Development Program (LDRD) program of ORNL (LP, GMS, TE), and by the DOE-OS through the Offices of Basic Energy Sciences (BES), Division of Materials Sciences and Engineering (LP, GMS, TE). Oak Ridge National Laboratory is managed by UT-Battelle, LLC, for the Department of Energy under Contract No. DE-AC05-00OR22725.)

**16:42**

**D45 12 Phase Diagram of the $Li_2O$-$V_2O_3$-$V_2O_5$ System at 700 °C: Correlations with Magnetic Defect Concentration in Heavy Fermion $LiV_2O_4$*** S. DAS, X. ZONG, X. MA, A. NIAZI, D.C. JOHNSTON, *Ames Lab. and Dept. Phys. Astron., Iowa State U., Ames, IA 50011* Polycrystalline samples of $LiV_2O_4$ have been synthesized with magnetic defect concentrations $n$ ranging from 0.01 mol% to 0.77 mol% and average spins $S$ from 3/2 to 4. (1) Low-temperature $T$ magnetic susceptibility $\chi$ and magnetization $M$ versus applied magnetic field $H$ isotherms were measured to determine these $n$ and $S$ values. Here we report the phase diagram of the $Li_2O$-$V_2O_3$-$V_2O_5$ ternary system at 700 °C for compositions in equilibrium with $LiV_2O_4$. This study provided a clarification of the synthesis conditions under which low and high magnetic defect concentrations can be obtained in $LiV_2O_4$. The samples were prepared using conventional solid state reaction of appropriate amounts of $Li_2CO_3$,$V_2O_3$ and $V_2O_5$. $M(H)$ isotherms and $\chi(T)$ data were obtained on many of these samples. We confirmed that the $LiV_2O_4$ phase can be obtained containing low (0.01 mol%) to high ( $\geq$ 0.5 mol%) magnetic defect concentrations and with consistently high defect $S$ values around 3 to 4. The highest $n$ values were obtained for $LiV_2O_4$ samples in equilibrium with $V_2O_3$ and the lowest values for $LiV_2O_4$ samples in equilibrium with $V_3O_5$, consistent with the results in Ref. (1). (1) S. Kondo et al., PRL **78**, 3721 (1997); PRB **59**, 2609 (1999).

**D45 13 $^7$Li NMR Study of Magnetic Defects in Heavy Fermion $LiV_2O_4$*** X. ZONG, D.C. JOHNSTON, F. BORSA, S. DAS, J. SCHMALIAN, *Ames Lab. and Dept. Phys. Astron., Iowa State U., Ames, IA 50011* A small concentration ($n \approx 0.7$ mol%) of magnetic defects within the normal spinel structure of heavy fermion $LiV_2O_4$ was recently found to have a strong effect on the $^7$Li NMR at low temperatures $T < 4.2$ K@.(1) The $^7$Li nuclear magnetization relaxation versus time after saturation, $M(t)$, changed from a pure exponential in a pure sample with $n = 0.01$ mol% to a stretched exponential for $n = 0.7$ mol%. Here we present a systematic study of the variations of the $^7$Li NMR versus $n$ for additional $n$ values from 0.05 to 0.8 mol%. Non-exponential $M(t)$ recovery was consistently obtained for samples with $n \geq 0.2$ mol% and the nuclear spin lattice relaxation rate versus temperature evolved monotonically with increasing $n$, consistent with the interpretation in Ref. (1). In addition, we obtained relaxation data for much shorter times than studied in Ref. (1), which indicate a previously unknown initial $M(t) \propto \sqrt{t}$ dependence for all samples with $n \geq 0.5$ mol%, for times $t < 20$ ms. At present, there exists no microscopic theory for the influence of magnetic defects on our $^7$Li NMR results. Phenomenological models that may help to understand the data will be discussed. (1). D. C. Johnston et al., Phys. Rev. Lett. **95**, 176408 (2005).

**D45 14 Magnetic Excitations in the Orbitally Degenerate Triangular Lattice $LiVO_2$ Studied by Inelastic Neutron Scattering** W. TIAN, *The University Of Tennessee, Oak Ridge National Laboratory* M.B. STONE, D.G. MANDRUS, B.C. SALES, R. JIN, *Oak Ridge National Laboratory* D.T. ADROJA, T. PERRING, *ISIS Facility, Rutherford Appleton Laboratory* S.E. NAGLER, *Oak Ridge National Laboratory* Inelastic neutron scattering experiments were performed to study a two dimensional triangular lattice material $LiVO_2$ (S=1, $V^{3+}$ ions) with orbital ordering involving threefold degenerate $t_{2g}$ orbitals. At $T_t \approx 500$ K, $LiVO_2$ undergoes a first order phase transition, accompanied by a large reduction in the magnetic susceptibility in the low temperature phase. It has been proposed that this phase transition is associated with the formation of trimers of $V^{3+}$ ions yielding a spin-singlet ground state. We report inelastic neutron scattering measurements on powder and single crystal samples of $LiVO_2$ carried out using the HET and MAPS spectrometers at ISIS. At low temperature, several magnetic excitations with energy transfers as large as several hundred meV were observed. We propose that the observed multiple magnetic excitations arise from the orbital ordering. Model calculations for trimers including an orbital-ordering term showing qualitatively similar spectra suggesting that localized orbiton excitations have been observed in $LiVO_2$.

**D45 15 Strong Electron correlation in the Cobaltates: a CD-MFT study** DIMITRIOS GALANAKIS, TUDOR STANESCU, PHILIP PHILLIPS, *Univ. of Illinois, Urbana-Champaign* The cobaltates $Na_xCoO_2$ with $0 < x < 1$ are highly anisotropic materials that consist of two dimensional $CoO_2$ layers separated by insulating layers of $Na^+$ ions. The structure is a triangular net of edge-sharing oxygen octahedra with the $Co$ ions occupying the center and having a valence determined by the sodium concentra-

tion. The experimental evidence suggests a strongly correlated physics similar to that of the cuprates. The main difference comes from the geometrical frustration of the triangular lattice. Their phase diagram consists of a paramagnetic metal for $x < 0.5$, a Curie-Weiss metal for $x > 0.5$ and a singular insulating state at $x = 0.5$. The properties of these phases are studied within the planar one-band Hubbard model in the framework of Cluster Dynamical Mean Field Theory (CDMFT) on a triangular lattice. The spectral function, magnetic susceptibility are obtained as a function of filling and temperature.

**D46 3 Novel low temperature surface reconstructions of GaN(000$\bar{1}$): A LT-STM investigations** KENDAL CLARK, DANDA P. ACHARYA, MUHAMMAD B. HAIDER, ARTHUR R. SMITH, SAW-WAI HLA, *Ohio University* The nitrogen polar gallium-rich GaN (000$\bar{1}$) samples are grown on sapphire (0001) substrates at sample temperature of 650 $^0$ C using r.f. N-plasma molecular beam epitaxy. During the growth, the surface is monitored by using reflection high energy electron diffraction and 3x3 and 6x6 reconstructed surface patterns have been observed. The freshly grown samples are then transferred to a low-temperature scanning tunneling microscope (LT-STM) system in an ultra-high-vacuum environment. Then the sample temperature is lowered to 75 K and 4.6 K for the STM investigations. The STM images reveal four novel low temperature reconstructions on this surface. We will also present voltage dependent STM images and tunneling spectroscopy data acquired on these structures. This work is financially supported by a NSF-NIRT grant no. DMR-0304314. (NIRT collaboration).

**D46 4 Dopant Adsorption and Incorporation at Irradiated GaN Surfaces*** QIANG SUN, *Princeton University* ANNABELLA SELLONI, *Princeton University* THOMAS MYERS, *West Virginia University* W. ALAN DOOLITTLE, *Georgia Institute of Engineering* Mg and O are two of the common dopants in GaN, but, in spite of extensive investigation, the atomic scale understanding of their adsorption and incorporation is still incomplete. In particular, high-energy electron irradiation, such as occurring during RHEED, has been reported to have an important effect on the incorporation of these impurities, but no study has addressed the detailed mechanisms of this effect yet. Here we use DFT calculations to study the adsorption and incorporation of Mg and O at the Ga- and N-polar GaN surfaces under various Ga, Mg and O coverage conditions as well as in presence of light or electron beam-induced electronic excitation. We find that the adsorption and incorporation of the two impurities have opposite surface polarity dependence: substitutional Mg prefers to incorporate at the GaN(0001) surface, while O prefers to adsorb and incorporate at the N-polar surface. In addition, our results indicate that in presence of light irradiation the tendency of Mg to surface-segregate is reduced. The O adsorption energy on the N-polar surface is also significantly reduced, consistent with the experimental observation of a much smaller concentration of oxygen in the irradiated samples.

**D46 5 Imaging surface states of GaN(000$\bar{1}$) at low temperatures*** DANDA P. ACHARYA, KENDAL CLARK, MUHAMMAD B. HAIDER, ARTHUR R. SMITH, NANCY SANDLER, SAW-WAI HLA, *Ohio University* It is known that the surface layer of nitrogen polar gallium-rich GaN (000$\bar{1}$) is semi-metallic in contrast to the bulk GaN. Such semi-metallic behavior is predicted to be contributed by surface state bands [1]. Here, we are able to image two of the surface states associated with the GaN (000$\bar{1}$) surface for the first time at liquid helium temperatures using a low-temperature scanning tunneling microscope (LT-STM). The samples, GaN(000$\bar{1}$), are grown on sapphire (0001) substrates at sample temperature of 650 $^0$ C using r.f. N-plasma molecular beam epitaxy. The freshly grown samples are then transferred to LT-STM system in an ultrahigh vacuum environment for direct investigations. The voltage dependent STM images clearly reveal novel surface features associated with these structures, which are further confirmed by tunneling spectroscopy measurements. This work is financially supported by a NSF-NIRT grant, DMR-0304314. (NIRT collaboration). [1] J. Vac. Sci. Technol. B 16(4), 2241 (1998)

*Imaging surface states of GaN(000 -1) at low temperatures

**D46 6 Surface and interface studies of GaN growth on $ZrB_2$(0001)/Si(111)** YUKIKO YAMADA-TAKAMURA, Z. T. WANG, Y. FUJIKAWA, Q. K. XUE, T. SAKURAI, *IMR, Tohoku University* J. TOLLE, P.-L. LIU, A. V. G. CHIZMESHYA, J. KOUVETAKIS, I. S. T. TSONG, *Arizona State University* $ZrB_2$ is a conductive, reflective, and lattice-matched buffer layer for GaN growth on Si. This study demonstrates the inherent suitability of $ZrB_2$ as an ideal buffer layer for growing inversion domain-free GaN films on Si using an UHV MBE-SPM system. Single crystal $ZrB_2$ films had been grown on Si(111) by the thermal decomposition of single molecular precursor $Zr(BH_4)_4$. Annealing the film at 800$^o$C in UHV was enough to remove the surface oxides and recover the atomically smooth surface. The GaN grown on the oxide-free $ZrB_2$ by plasma-assisted MBE was found to be consistently N-polar independent of the growth conditions. The films were insulating and N-polarity was demonstrated by combined itin situ RHEED and non-contact AFM study. Various interface structures were proposed and as a result of first principles calculations, a single interface structure leading to N-polar GaN growth was found most stable for the wide range of growth conditions. **D46 7 Electronic characterization of in-grown 8H inclusions in 4H-SiC using Ballistic Electron Emission Microscopy (BEEM)** K. -B. PARK, W. CAI, J. P. PELZ, *The Ohio State University* M. S. MIAO, W. R. L. LAMBRECHT, *Case Western Reserve University* X. ZHANG, M. SKOWRONSKI, *Carnegie Melon University* M. A. CAPANO, *Purdue University* Planar ''8H'' Stacking-fault inclusions (SFIs) formed during epilayer growth on an 8$^o$ miscut n-type 4H-SiC substrate were characterized using nm-resolution BEEM and first-principles electronic structure calculations. Enhanced BEEM current and a $\sim$ 0.39 eV lower local Schottky Barrier were observed along lines where these inclined SFIs intersect a thin Pt film, indicating that 8H SFIs are electron quantum wells (QWs), as observed for two types of cubic SFIs in 4H-SiC [1,2]. The measured $\sim$ 0.39 eV QW depth is close to our calculated value of $\sim$ 0.43 eV. We also observed the BEEM current amplitude and threshold voltage to be quite asymmetric with respect to the intersection lines of the SFIs with the Pt film. We will discuss on-going modeling to see if these asymmetries can be explained respectively by electron reflection from the inclined subsurface SFIs, and by the difference in spontaneous polarization between 8H- and 4H-SiC. Work supported by ONR. [1] Ding itet al., Phys. Rev. B **69**, 041305(R) (2004). [2] Park itet al., Appl. Phys. Lett. **87**, 232103 (2005).

**D46 8 Polarity effects on the electronic states of N- and Al-polar aluminum nitride surfaces** JI-SOO PARK, YINGJIE TANG, ROBERT DAVIS, ROBERT NEMANICH, *North Carolina State University* N- and Al-polar (0001) wurtzite AlN films were grown on C- and Si-polar 6H-SiC substrates, respectively. The polarity was confirmed by KOH chemical etching and atomic force microscopy (AFM) imaging. The surfaces were cleaned in situ by annealing to $\sim$ 1100$^o$C in a flux of ammonia, and X–ray photoemission spectroscopy (XPS) and UV photoemission spectroscopy (UPS) were employed to measure the electronic states at the surfaces. The results indicated a similar electron affinity for both surfaces which appears to approach a value of zero. Furthermore, it was determined that the Fermi energy (Ec-Ef) was 2.4 eV below the conduction band for N-face AlN and 3.0 eV for Al-face AlN. The 0.6eV difference in the Fermi energy indicates a difference in band bending near the surface which is discussed in terms of the built-in field induced by the polarization bound surface charges.

**16:30**

**D46 9 The Negative Electron Affinity Effect on the Thermionic Emission from Nitrogen Doped Diamond** YINGJIE TANG, FRANZ KOECK, ROBERT NEMANICH, *North Carolina State University* NORTH CAROLINA STATE UNIVERSITY TEAM, The thermionic emission properties of microwave CVD nitrogen doped diamond films with a negative electron affinity (NEA) were investigated with thermionic emission spectroscopy (TES) and UV photoelectron emission spectroscopy (UPS). At a temperature of 230$^o$C thermionic electron emission was observed with a current density $\sim$ 1nA/cm$^2$ and a minimum kinetic energy of 1.6eV relative to the Fermi level. Both the thermionic and photoemission spectra display the same sharp cutoff edge corresponding to the conduction band minimum (CBM) which is detected because of the NEA properties of films. With increasing temperature, electron emission is observed below the CBM which is attributed to tunneling phenomena from nitrogen related states and sp2 bonded defects. The emission extends to $\sim$ 1.3eV below the conduction band which would be consistent with prior measurements of the negative electron affinity of diamond surfaces. The effect of the NEA on space charge and defect related electron emission is also discussed.

**D46 10 Study of Thermally Induced Damage and its Recovery in ZnO Single Crystals by Elastic Resonant Ion Channeling** S. DHAR, D. PUGEL, S.S. HULLAVARAD, R.D. VISPUTE, S.B. OGALE, T. VENKATESAN, *Center for Superconductivity Research, Department of Physics, University of Maryland, College Park, MD 20742* ZnO is widely considered as the next generation wide-band gap material for optoelectronic device applications due to its excellent material properties. Although in recent years various studies on ZnO crystal have been made, very little is known about its response after thermal treatments. In this work, we studied the influence of thermal annealing on ZnO (0001) bulk single crystal in the temperature range of 30-1000 $^o$C by elastic resonant ion channeling and Rutherford backscattering (RBS) techniques using a 3.05 MeV He beam. After an isochronal1 h anneal, RBS-Ion channeling analysis showed the evolution of disorder in the Zn sub-lattice of the crystal with increasing annealing temperature. The maximum disorder was observed at 200 $^o$C above which it decreased. The induced disorder in the Zn sub-lattice at lower temperature ( $<$ 400 $^o$C) can almost be recovered by further annealing above 800 $^o$C. Elastic resonant ion channeling analysis, which monitors the oxygen in the near-surface region clearly revealed the evolution of thermally induced disorder in the oxygen sub-lattice with increasing temperature. In contrast to the disorder recovery of Zn sub-lattice, the disorder in oxygen sub-lattice did not recover completely. Possible mechanism on the disorder and its recovery will be discussed.

**16:54**
**D46 11 Band offset measurements on Metal/$Hf_{1-x}Si_xO_2$/Si stacks** ERIC BERSCH, *Rutgers University* SYLVIE RANGAN, *Rutgers University* ROBERT A. BARTYNSKI, *Rutgers University* ERIC GARFUNKEL, *Rutgers University* The study of high-k gate dielectric stacks with metal gate electrodes is motivated by the need to reduce the size of MOSFET devices. Controlling the band offsets between the metal/high-k/Si layers of devices is critical to reducing the leakage current through the dielectric. In order to understand the band alignment at the interfaces we have measured, for each layer of the stack, the conduction band edge (CBE) using inverse photoemission, and the core levels binding energies and valence band edge (VBE) using photoemission. For the high dielectric constant alloys $Hf_{1-x}Si_xO_2$ (x=0, $\sim$ 0.5, 1), the gap increases with x, and we will discuss the effect of x on the CBO and VBO between the silicon and the dielectric. Upon metallization with Ru or Al, Ru does not affect the position of the CBE and VBE of the dielectric, while Al induces a strong shift ( $\sim$ 0.5 eV toward higher binding energy) of the band edges. These results will be compared to other techniques, particularly internal photoemission.

**F50 1 Emergent Phenomena In Particle Physics.**
EDWARD WITTEN, *Institute for Advanced Study*

I will give a brief survey of the extent to which the notion of emergent phenomena is important in different areas of particle physics.

**20:36**
**F50 2 Revisiting Mendel and the Paradox of Gene Restoration.**
SUSAN J. LOLLE, *Purdue University*

According to the laws of classical Mendelian genetics, genetic information contained in the nuclear genome is stably inherited and is transmitted from one generation to the next in a predictable manner. Several exceptions to the principle of stable inheritance are known by all represent specialized cases where the mechanisms have been relatively well defined. We have recently demonstrated that *Arabidopsis* plants can inherit specific DNA sequence information that was not present in the chromosomal genome of their parents. This process appears to occur throughout the nuclear genome. Based on our findings we propose that this process represents a completely novel and hitherto unknown mechanism for the maintenance and inheritance of DNA sequence information.

**21:12**
**F50 3 Statistical Mechanics of Complex Networks: From the Internet to Biology.**
ALBERT-LÁSZLÓ BARABÁSI, *University of Notre Dame*

Networks with complex topology describe systems as diverse as the cell, the World Wide Web or the society. In the past few years we have learned that their evolution is driven by self-organizing processes that are governed by simple but generic scaling laws, leading to the emergence of a vibrant interdisciplinary field that uses the tools of statistical physics to explain the origin and the dynamics of real networks. One of the most surprising finding is that despite their apparent differences, cells and complex man-made networks, such as the Internet or the World Wide Web, and many communi-

cation networks share the same large-scale topology, each having a scale-free structure. I will show that the robustness against failures and attacks, with implications on drug design, the Internet's ability to survive attacks and failures, and our ability to understand the functional role of genes.

**F50 4 Condensed Matter Physics and the Nature of Dark Matter in the Universe.**
BERNARD SADOULET, *University of California, Berkeley*

The nature of dark matter, which may be 6 times more abundant that ordinary matter in the universe and make up a quarter of the energy density, remains a profound mystery. A leading hypothesis is that dark matter is made of Weakly Interactive Massive Particles (WIMPs), which may result from supersymmetry or additional spatial dimensions. If these WIMPs exist, we should be able to observe their elastic scattering on suitable targets, provided that we can recognize the nuclear recoils they are expected to produce among a background of electron recoils. Expected event rates are small (a few events /kg per year) and the energy deposition should be of the order of 15 keV. I will explain how we are trying to harness condensed matter physics at low temperature (physics of charge carriers, athermal phonons, quasiparticles in superconductors) to detect such events. Such efforts are currently led by our Cryogenic Dark Matter Search (CDMS II) experiment, which is currently ten times more sensitive than any other WIMP search in the world and we hope to obtain another factor ten in the coming two years. This effort is squarely at the intersection of condensed matter, low temperature physics, cosmology and particle physics and provide a good testimony of the Unity of Physics. CDMS II is supported by the National Science Foundation and the Department of Energy.

**G1 1 The Heartbeat of Light.**
THEODOR W. HÄNSCH, *Max-Planc Institut für Quantenoptik and Sektion Physik, Ludwig-Maximilians-Universität München*

For three decades, precision spectroscopy of the simple hydrogen atom has motivated advances in laser spectroscopy and optical frequency metrology. Recently, femtosecond laser optical frequency comb synthesizers have arrived as revolutionary tools for ultraprecise optical spectroscopy. A new absolute frequency measurement of the hydrogen 1S-2S two-photon resonance sets upper limits for possible slow variations of the time structure constant $\alpha$. Frequency comb techniques are also making it possible to control the electric field of ultrafast laser pulses, opening intriguing opportunities in attosecond physics.

**G1 4 Laser Scattering in Turbid Media.**
Q. CHARLES SU, *Intense Laser Physics Theory Unit, Illinois State University, Normal, IL 61790-4560*

Light scattering in random media is an interesting research area from a fundamental and practical point of view. On the theoretical side, the precise relationship between the Maxwell, Boltzmann and diffusion descriptions are presently not very well understood. We have examined the validity of these approaches based on numerical solution techniques. On the practical side, an improved understanding of this interaction has the potential to lead to new medical imaging devices based on lasers. We will report on our first experimental data and discuss how they can be modeled by Monte-Carlo simulations. Major portions of this research involved several undergraduate students who performed computer simulations and laboratory measurements. This work has been supported by funds from NSF and Research Corporation. S. Menon, Q. Su, and R. Grobe, Phys. Rev. Lett. 94, 153904 (2005). S. Menon, Q. Su, and R. Grobe, Opt. Lett. 30, 1542–1544 (2005).

**10:24**
**G1 5 Computational Quantum Field Theory.**
RAINER GROBE, *Intense Laser Physics Theory Unit, Illinois State University, Normal, IL 61790-4560*

I will give an overview on recent attempts to solve the time-dependent Dirac equation for the electron-positron field operator. These numerical simulations permit a first temporally and spatially resolved insight into the mechanisms of how an electron-positron pair can be created from vacuum in a very strong force field. This approach has helped to illuminate a wide range of controversial questions. Some of these questions arise for complicated physical situations such as how an electron scatters off a supercritical potential barrier (Klein paradox). This requires the application of quantum field theory to study the combined effect of the pair-production due to the supercriticality of the potential together with the scattering at the barrier involving the Pauli-principle. Other phenomena include the Schrödinger's Zitterbewegung and the localization problem for a relativistic particle. This work has been supported by the NSF and Research Corporation. P. Krekora, K. Cooley, Q. Su, and R. Grobe, Phys. Rev. Lett. 95, 070403 (2005). P. Krekora, Q. Su, and R. Grobe, Phys. Rev. Lett. 93, 043004 (2004). P. Krekora, Q. Su, and R. Grobe, Phys. Rev. **8:00**
**G2 1 Breakdown of One-Paramater Scaling in Quantum Critical Scenarios for the High-Temperature Copper-oxide Superconductors.***
CLAUDIO CHAMON, *Boston University*

We show that if the excitations which become gapless at a quantum critical point also carry the electrical current, then a resistivity linear in temperature, as is observed in the copper-oxide high-temperature superconductors, obtains only if the dynamical exponent, z, satisfies the unphysical constraint, $z<0$. At fault here is the universal scaling hypothesis that, at a continuous phase transition, the only relevant length scale is the correlation length. Consequently, either the electrical current in the normal state of the cuprates is carried by degrees of freedom which do not undergo a quantum phase transition, or quantum critical scenarios must forgo this basic scaling hypothesis and demand that more than a single correlation length scale is necessary to model transport in the cuprates. In collaboration with Philip Phillips, Univ. of Illinois at Urbana-Champaign.

**8:36**
**G2 2 Evidence for a generic quantum transition in high-Tc cuprates.**
JEFFERY TALLON, *MacDiarmid Institute, Industrial Research Ltd and Victoria University, PO Bx 31310, Lower Hutt*

The progressive evolution of physical properties with doping in the high-Tc cuprates remains a puzzle, as does the origins of superconducting pairing. This talk will focus on a broad range of physical properties that all signal the presence of a generic quantum transition near optimal doping in these materials which helps explain this unusual evolution in properties. The data includes specific heat, NMR, transport, muon spin relaxation, inelastic neutron scattering, frequency dependent IR conductivity and magnetic properties. In spite of the weight of evidence, however, some key elements appear to be missing. Reasons for this will be surveyed.

**9:12**
**G2 3 Pseudogap scaling and quantum critical end point in electron- and hole-doped cuprates.**
TAKASADA SHIBAUCHI, *Department of Physics, Kyoto University*

In spite of a large number of experiments on the anomalous pseudogap in cuprate superconductors, the real phase diagram of the pseudogap has not yet been established. We employ the interlayer tunneling transport to precisely detect the field dependence of low-energy density of states (DOS) in hole-doped $Bi_2Sr_2CaCu_2O_{8+y}$ and electron-doped $Sm_{2-x}Ce_xCuO_{4-\delta}$ crystals under high fields up to 60 T [1-4]. From a systematic analysis of negative interlayer magnetoresistance, we found a strong doping dependence of the pseudogap closing field whose Zeeman energy scales with the pseudogap energy scale, indicating a preeminent role of spin-singlet correlations in forming the pseudogap in cuprates. The results suggest no quantum critical point up to very overdoped side of the phase diagram. [1] T. Shibauchi *et al.*, Phys. Rev. Lett. **86**, 5763 (2001). [2] T. Shibauchi *et al.*, Phys. Rev. B **67**, 064514 (2003). [3] L. Krusin-Elbaum, T. Shibauchi, and C. H. Mielke, Phys. Rev. Lett. **92**, 097005 (2004). [4] T. Kawakami *et al.*, Phys. Rev. Lett. **95**, 017001 (2005).

**9:48**
**G2 4 Field-induced magnetism in a high-temperature superconductor.**
BELLA LAKE, *Hahn-Meitner Institut, Berlin*

Many physical properties of the high-temperature (high-$T_c$) superconductors are two-dimensional phenomena derived from their square planar $CuO_2$ building blocks. This is especially true of the magnetism from the copper ions electronically connected to each other via the *p*-orbitals of intervening oxygen atoms. As mobile charge carriers enter these $CuO_2$ layers, the antiferromagnetism of the parent insulators, where each copper spin is antiparallel to its nearest neighbours, evolves into a fluctuating state where the spins show tendencies towards magnetic order of a longer periodicity. For certain charge carrier densities, the quantum fluctuations are sufficiently suppressed to yield static long-period order and external magnetic fields also induce such order. Here we show, using neutron scattering measurements, that in contrast to the chemically-controlled order in superconducting $La_{2-x}Sr_xCuO_4$, the field-induced order is actually three-dimensional, implying significant magnetic linkage between the $CuO_2$ planes. The results are important because they reveal the presence of three-dimensional magnetic couplings which survive into the superconducting state, and coexist with the crucial inter-layer couplings responsible for the three-dimensional superconductivity.

**10:24**
**G2 5 Superfluid density in strongly underdoped $YBa_2Cu_3O_{6.333}$.**
DAVID BROUN, *Simon Fraser University*

Current research in high temperature superconductivity focuses on the underdoped cuprates, in the region of the phase diagram where *d*-wave superconductivity gives way to antiferromagnetism. Important clues for connecting these two states can be found in the evolution of the superfluid density $\rho_s$ with doping. $\rho_s$ is the most fundamental property of a superconductor, measuring its ability to resist perturbations to the phase of the superfluid wavefunction. In addition, the temperature dependence of $\rho_s$ provides a direct probe of the electrical current carried by the quasiparticle excitations. Here we report measurements of $\rho_s$ in ultra-high purity $YBa_2Cu_3O_{6.333}$, over a range of dopings near the boundary of the superconducting phase. We have succeeded in producing samples with sharp superconducting transitions and have harnessed the process of CuO-chain ordering to fulfill a long-held ambition in strongly correlated electron materials — continuous tunability of the carrier density in a *single sample*, with *no* change in cation disorder. We now have preliminary evidence for the production of so-called Ortho III′ oxygen order, in which every full CuO chain is separated by two empty chains. The superfluid density measurements are surprising and challenge current theoretical understanding of the underdoped cuprates. $\rho_s$ becomes anomalously small, but there is no vortex unbinding transition. The slope of $\rho_s(T)$ indicates that the current carried by the quasiparticles shrinks smoothly towards zero on approach to the Mott insulator. In addition, the correlation between $T_c$ and $\rho_s$ is sublinear, in disagreement with long-established phenomenology. In the same experiments, microwave spectroscopy of the quasiparticle conductivity has also been used to probe the evolution of the quasiparticle relaxation dynamics on the approach to the superconducting quantum critical point.

## SESSION G3: COUPLED SUPERCONDUCTING QUBITS
**Tuesday Morning, 14 March 2006; Ballroom I, Baltimore Convention Center at 8:00**
**Steven Girvin, Yale University, presiding**

**8:00**
**G3 1 Coupled superconducting qubits: A theoretical overview.**
ALEXANDER SHNIRMAN, *University of Karlsruhe, Germany*

In recent years we have witnessed great progress in quantum state engineering with superconducting qubits. Most experiments have been done with single qubits whereas several groups have reported multi-qubit manipulations. Having controllable coupling between the qubits is absolutely necessary for efficient quantum state engineering. I will overview various coupling schemes suggested in the literature. Among them are capacitive, inductive, nanomechanical, and cavity couplings. Special attention will be paid to the questions of accuracy to which the coupling can be switched off and of speed at which it can be manipulated.

**8:36**
**G3 2 High-Fidelity Measurements of Josephson Phase Qubits.**
JOHN MARTINIS, *UC Santa Barbara*

The Josephson junction is an ideal solid-state system for building electrical ''atoms'' that can function as quantum bits for a quantum computer. Recent advances in the materials and design of phase qubits have dramatically improved their coherence, with energy relaxation times as long as 500 ns and, in a separate device, measurement fidelities as high as 90%. Combined with advances in microwave electronics, full characterization of single and coupled qubit gates are now possible using quantum tomographic techniques. I will report on several ongoing experiments in our group: measurement of the evolution of a quantum state from incomplete measurement, violation of Bell's inequality in a coupled qubit, and the implementation and characterization of a CNOT gate.

**9:12**
**G3 3 Qubits in Cavities for Quantum Optics and Computing.***
DAVID SCHUSTER, *Departments of Applied Physics and Physics, Yale University*

I will describe a platform for quantum computation and quantum optics using superconducting circuits as both the linear and non-linear elements. One dimensional transmission line cavities realize well-defined microwave linear photon modes, while Cooper-pair boxes act as artificial atoms for use as qubits and strongly non-linear elements [1]. We have observed the coherent interaction between a qubit and a single photon, a feat previously only achievable in atomic systems [2]. Using such a coupling a high quality factor cavity can act as an entanglement bus where real or virtual photons mediate interactions between distant qubits [3]. The qubit-photon coupling is exploited to realize a quantum non-demolition measurement of the qubit state [4] and should also allow for direct measurement of the photon number state of the cavity

[5]. Using this measurement technique we have shown > 90% visibility and long coherence times ($T_1 \sim 7$us $T_2^* >$ 500ns) [6]. Off-resonant microwave irradiation is used to adjust qubit-cavity and qubit-qubit detunings for decoherence free control of interaction strengths. Pulsed two photon sideband transitions are shown to mediate off-resonant cavity-qubit interactions, as required to implement non-local two qubit gates. Such techniques could also be used to generate non-classical states of light. We will also discuss initial measurements on two qubits. [1] A. Wallraff et al. Nature (London) 431, 162 (2004) [2] A. Blais et al. Phys. Rev. A 69, 062320 (2004) [3] A. Blais et al. Phys. Rev. A submitted [4] D. I. Schuster et al. Phys. Rev. Lett. 94, 123602 (2005) [5] J. Gambetta et al. Phys. Rev. A submitted [6] A. Wallraff et al. Phys. Rev. Lett. 95 060501 (2005).

*In collaboration with A. Wallraff, A. Blais, J. Gambetta, L. Frunzio, J. Schreier, A. Houck, B. Johnson, J. Majer, M. H. Devoret, S. M. Girvin, R. J. Schoelkopf.

**9:48**
**G3 4 Spectroscopy of two coupled superconducting flux qubits.**
JELLE PLANTENBERG, *Kavli Institute of Nanoscience Delft*

We present measurements on a system of two flux or persistent current qubits, which are coupled by a shared Josephson junction. Spectroscopy measurements reveal the four energy levels in great detail, also showing transitions involving two photons. Remarkably good agreement was found when fitting to a simple model Hamiltonian of two magnetically coupled spins. From the fit the qubit persistent currents and energy gaps as well as the qubit-qubit coupling strength and asymmetry were derived. Coherent Rabi oscillations were induced between energy states of the coupled system, from which relaxation and dephasing times could be extracted. Conditional spectroscopy was performed by manipulating one qubit coherently and measuring the excitation spectrum of the second.

**10:24**
**G3 5 Non-local Andreev Reflection as a Source of Entangled Electrons.***
ALBERTO MORPURGO, *Kavli Institute of Nanoscience, Delft*

Cooper pairs in conventional superconductors form a robust reservoir of spin-entangled singlet ''particles.'' This has led to many theoretical proposals for the realization of ''entangler'' devices –i.e. devices capable of sourcing currents carried by entangled pairs into nanoelectronic circuits- that are of fundamental interest in the field of quantum information. These proposals rely on the possibility to ''split'' Cooper pairs by injecting the two constituent electrons into two spatially separated normal metal leads attached to a superconductors. It has been shown theoretically that such a Cooper-pair ''splitting'' process is equivalent to the process of non-local Andreev reflection, in which an electron (hole) injected from a metallic electrode connected to a superconductor is transmitted into a hole (electron) into a second, spatially separated electrode. In this talk I will discuss recent experiments[1] performed in Delft that demonstrate the occurrence of non-local Andreev reflection as a quantum mechanically phase coherent process. [1] S. Russo et al., Phys. Rev. Lett. **95**, 027002 (2005),

*Work done in collaboration with S.Russo, M.Kroug, and T.M. Klapwijk.

**G4 1 On nanostructured dispersions and toughness of semi-crystalline polymers.***
LUDWIK LEIBLER, *Matière Molle et Chimie (UMR 7167 CNRS/ESPCI), Ecole Supérieure de Physique et Chimie Industrielles, 75005 Paris*

In the past 50 years, great research efforts have been devoted to increase toughness of plastics. Today, impact strength of millions of tons of plastics used in all sorts of applications relies upon dispersing rubber particles in semi-crystalline polymers (polyolefins, polyamides or polyesters). Yet, the underlying mechanisms controlling such toughening are controversial. Based on a large body of literature and some simple observations, we propose a theory of toughening that explains the existence of an often evoked critical distance between rubber particles which controls the brittle-to-tough transition and predicts how it depends on size and concentration of particles. Our model predicts the brittle-to- tough transition temperature and emphasizes the role of crystal organization and orientation of matrix. Adding rubber particles induces a substantial loss in stiffness. We report how to obtain super-tough polymers and avoid such softening by using

nanostructured dispersions of block- copolymers. We show that block copolymers having a three-dimensional co-continuous structure are particularly attractive as they disperse in a polymer matrix very differently from a lamellar one. In particular, droplet coalescence is much less pronounced for the co-continuous structure. Our observations arise interesting general questions about break-up and coalescence of structured fluid droplets. With Laurent Corté.

*Supported by CNRS, ESPCI and Arkema.

**8:36**
**G4 2 Function in block copolymer assembly.**
MARTIN MÖLLER, *Institute of Macromolecular and Technical Chemistry, RWTH Aachen University, DWI e.V.D-52056 Aachen, Germany*

Spontaneous mesophase and colloidal organization of linear blockcopolymers in bulk and in thin films yields a wealth of well defined metastable and equilibrium structures with intriguing perspectives of new materials functionalities. Besides length, composition, and the type and number of the constituent blocks, branching and chemical transformation provides a further parameter for controlling the molecular conformation and structure. Here we will report on thermal and photo induced single molecule collapse and micellar assembly switching.for comb, palmtree blockcoplymers, as well as for amphiphilic polymer complexes as a means to introduce novel and responsive functionalities, such as motility and hydrophilic/hydrophobic switching.

**9:12**
**G4 3 Field-Theoretic Polymer Simulations: At the Frontier.**
GLENN FREDRICKSON, *University of California, Santa Barbara*

I will review our recent work on the development of a theoretical framework and numerical strategies for conducting computer simulations of polymer field theory models. We invoke Hubbard-Stratonovich and related auxiliary field transforms to convert ''particle-based'' models of polymeric fluids into statistical field theories. This transformation has the effect of replacing polymer-polymer interactions with polymer-field interactions, and renders the action complex. We have developed efficient numerical techniques for computing saddle point field configurations (mean-field or SCFT solutions), as well as for sampling field fluctuations near or away from saddle points (''field-theoretic simulations''). This talk will focus on a number of contemporary topics including: high resolution and variable cell shape SCFT, geometrically complex domains, hybrid particle-field simulations, and strategies for avoiding the sign problem. Examples of applications to polymer alloys, block copolymers, and copolymer nanocomposites will be presented.

**9:48**
**G4 4 Structural an Dynamical Properties of Some Equilibrium Polymers.**
JEAN SAUVEUR CANDAU, *Universite Louis Pasteur*

The most detailed studies on equilibrium polymers have been performed on surfactant wormlike micellar solutions. Recently the formation of reversible supramolecular polymers through H bond mediated self assembly of two homofitopic heterocomplementary monomers were reported. In apolar solvents, highly viscoelastic solutions were observed at concentrations as low as 2 mM, thus indicating a network-like structure. We have studied a supramolecular polymeric system formed through a sextuple hydrogen bonding of a Janus-type wedge and a corresponding receptor. Small Angle Neutron Scattering experiments showed that the monomers self assemble into long unidimensionnal aggregates whose local structure is independent of temperature and concentration. From the values of the cross section and the mass per unit length of the fibers it can be inferred that these fibers contain several monomolecular wires. The concentration and temperature dependences of the average polymer length were found to be similar to those of worm-like micelles. Non linear rheological experiments showed a shear-banding instability as in micellar systems. However the concentration dependence of the terminal time of the stress relaxation suggests the formation of additional transient crosslinks in the supramolecular polymeric systems resulting in a slowing down of the relaxation as in associating polymers.

**G4 5 A Lattice Model for Segmental Dynamics of Miscible Polymer Blends.***
RALPH H. COLBY, *Materials Science and Engineering, Pennsylvania State University*

Thermally-driven concentration fluctuations make local regions (at the scale of monomers) have a wide range of local compositions for weakly interacting miscible blends of long chain polymers. These fluctuations remain important hundreds of degrees from the critical temperature because the entropy (and hence free energy) of mixing is small in polymer mixtures. The connected nature of the chain biases the local composition distribution, making the range of effective compositions surrounding a given monomer extend from the self-composition to environments very rich in that type of monomer. These two polymer physics issues make blends of polymers vastly more interesting than mixtures of small molecules. Time-temperature superposition can fail and motions can persist far below the glass transition temperature of the blend; both of these results are enhanced as the glass transition contrast between the two components increases. A simple lattice model is used to describe the segmental dynamics of miscible polymer blends. Concentration fluctuations

and chain connectivity effects are calculated at the scale of the Kuhn length, by considering a central monomer to be surrounded, out to the second shell of monomers, by 24 lattice sites. Including the central monomer, fraction 5/25 = 0.2 of the lattice sites are part of the central monomer's chain (the self-composition) and the other 20 sites are occupied stochastically, while preserving connectivity of all chains. The resulting concentration distributions are mapped onto segmental relaxation time distributions for each blend component using the composition dependence of the glass transition and dynamic scaling. The predicted distributions are compared with experimental dielectric data on miscible polymer blends using three methods: (1) A Debye (single exponential) relaxation of each composition predicts dielectric loss peaks for each blend component which are too narrow because the lattice model ignores density fluctuations. (2) The empirical Havriliak-Negami distribution can be fit to the dielectric loss of each pure component and then assigned to each composition in that component's distribution in the blend. (3) The pure component data can be modeled with a Gaussian distribution of density fluctuations with times related to free volume using the Doolittle equation, and subsequently this distribution is assigned to each composition in that component's blend distribution. The relative merits of these three approaches will be discussed in detail.

**8:00**
**G5 1 Scientific Challenges in Sustainable Energy Technology.**
NATHAN LEWIS, *California Institute of Technology*

This presentation will describe and evaluate the challenges, both technical, political, and economic, involved with widespread adoption of renewable energy technologies. First, we estimate the available fossil fuel resources and reserves based on data from the World Energy Assessment and World Energy Council. In conjunction with the current and projected global primary power production rates, we then estimate the remaining years of supply of oil, gas, and coal for use in primary power production. We then compare the price per unit of energy of these sources to those of renewable energy technologies (wind, solar thermal, solar electric, biomass, hydroelectric, and geothermal) to evaluate the degree to which supply/demand forces stimulate a transition to renewable energy technologies in the next 20-50 years. Secondly, we evaluate the greenhouse gas buildup limitations on carbon-based power consumption as an unpriced externality to fossil-fuel consumption, considering global population growth, increased global gross domestic product, and increased energy efficiency per unit of globally averaged GDP, as produced by the Intergovernmental Panel on Climate Change (IPCC). A greenhouse gas constraint on total carbon emissions, in conjunction with global population growth, is projected to drive the demand for carbon-free power well beyond that produced by conventional supply/demand pricing tradeoffs, at potentially daunting levels relative to current renewable energy demand levels. Thirdly, we evaluate the level and timescale of R&D investment that is needed to produce the required quantity of carbon-free power by the 2050 timeframe, to support the expected global energy demand for carbon-free power. Fourth, we evaluate the energy potential of various renewable energy resources to ascertain which resources are adequately available globally to support the projected global carbon-free energy demand requirements. Fifth, we evaluate the challenges to the chemical sciences to enable the cost-effective production of carbon-free power on the needed scale by the 2050 timeframe. Finally, we discuss the effects of a change in primary power technology on the energy supply infrastructure and discuss the impact of such a change on the modes of energy consumption by the energy consumer and additional demands on the chemical sciences to support such a transition in energy supply.

**G5 2 High-Efficiency, Multijunction Solar Cells for Large-Scale Solar Electricity Generation.**
SARAH KURTZ, *National Renewable Energy Laborator*

A solar cell with an infinite number of materials (matched to the solar spectrum) has a theoretical efficiency limit of 68%. If sunlight is concentrated, this limit increases to about 87%. These theoretical limits are calculated using basic physics and are independent of the details of the materials. In practice, the challenge of achieving high efficiency depends on identifying materials that can effectively use the solar spectrum. Impressive progress has been made with the current efficiency record being 39%. Today's solar market is also showing impressive progress, but is still hindered by high prices. One strategy for reducing cost is to use lenses or mirrors to focus the light on small solar cells. In this case, the system cost is dominated by the cost of the relatively inexpensive optics. The value of the optics increases with the efficiency of the solar cell. Thus, a concentrator system made with 35%- 40%-efficient solar cells is expected to deliver 50% more power at a similar cost when compare with a system using 25%-efficient cells. Today's markets are showing

an opportunity for large concentrator systems that didn't exist 5-10 years ago. Efficiencies may soon pass 40% and ultimately may reach 50%, providing a pathway to improved performance and decreased cost. Many companies are currently investigating this technology for large-scale electricity generation. The presentation will cover the basic physics and more practical considerations to achieving high efficiency as well as describing the current status of the concentrator industry. This work has been authored by an employee of the Midwest Research Institute under Contract No. DE-AC36-99GO10337 with the U.S. Department of Energy.

**G5 4 Bio-inspired constructs for solar energy conversion.**
THOMAS MOORE, *Arizona State University*

Solar energy input to the biosphere is about $10^{24}$ joules/year. This makes human needs of even a projected $10^{21}$ joules/year a deceptively achievable goal. One key to global-scale use of solar energy is the synthesis of energy-rich fuel materials such as hydrogen and reduced carbon compounds. The latter have the almost inestimable advantage that the energy infrastructure for distribution and use is in place. The photosynthetic and respiratory enzymes provide paradigms for all of the important energy converting processes humans would need to achieve sustainable energy production and use. These include water oxidation, $O_2$ reduction and oxidation of energy dense organics at room temperature. These processes are carried out by biological catalysts at near thermodynamic efficiency without the use of precious metals. Copper, manganese, iron and nickel are typically used at their active sites. Energy rich organics such as ethanol and larger reduced-carbon compounds offer energy densities comparable to that of fossil fuels yet technology has not produced a low temperature catalyst for breaking carbon-carbon bonds. Biology offers myriad examples of such catalysts. Electroreductive synthesis of organics from $CO_2$ is also templated by Nature's catalysts. The challenge is clear: we must understand the structures and chemical reactivity of these catalytic sites and co-opt their essential features for human use. A number of parameters are involved and will be discussed. Even considering an artificial catalysts comprising only the atoms necessary for catalysis, the footprint is relatively large and, since biological turnover rates are often low, achieving current flows adequate for human needs in industry and transportation is problematic. A detailed understanding of efficiently coupling electromotive force to the active sites of redox enzymes will be one key to designing efficient hybrid catalytic devices. A model system for solar-driven reforming of biomass to $H_2$ will be presented.

**10:24**
**G5 5 The Status and Outlook for the Photovoltaics Industry.**
DAVID CARLSON, *BP Solar*

The first silicon solar cell was made at Bell Labs in 1954, and over the following decades, shipments of photovoltaic (PV) modules increased at a rate of about 18% annually. In the last several years, the annual growth rate has increased to $\sim$ 35% due largely to government-supported programs in Japan and Germany. Silicon technology has dominated the PV industry since its inception, and in 2005 about 65% of all solar cells were made from polycrystalline (or multicrystalline) silicon, 24% from monocrystalline silicon and $\sim$ 4% from ribbon silicon. While conversion efficiencies as high as 24.7% have been obtained in the laboratory for silicon solar cells, the best efficiencies for commercial PV modules are in the range of 17 18% (the efficiency limit for a silicon solar cell is $\sim$ 29%). A number of companies are commercializing solar cells based on other materials such as amorphous silicon, microcrystalline silicon, cadmium telluride, copper-indium-gallium-diselenide (CIGS), gallium arsenide (and related compounds) and dye- sensitized titanium oxide. Thin film CIGS solar cells have been fabricated with conversion efficiencies as high as 19.5% while efficiencies as high as 39% have been demonstrated for a GaInP/Ga(In)As/Ge triple-junction cell operating at a concentration of 236 suns. Thin film solar cells are being used in consumer products and in some building-integrated applications, while PV concentrator systems are being tested in grid-connected arrays located in high solar insolation areas. Nonetheless, crystalline silicon PV technology is likely to dominate the terrestrial market for at least the next decade with module efficiencies $>$ 20% and module prices of $<$ \$1/Wp expected by 2020, which in turn should allow significant penetration of the utility grid market. However, crystalline silicon solar cells may be challenged in the next decade or two by new low-cost, high performance devices based on organic materials and nanotechnology.

**SESSION G7: SHEAR-INDUCED PATTERNS IN COMPLEX FLUIDS AND GRANULAR MATTER**

**G7 1 Subcritical shear-induced instabilities and turbulence of visco-elastic fluids.**
WIM VAN SAARLOOS, *Leiden University*

While instabilities in normal Newtonian fluids are usually due to inertial effects, most visco-elastic instabilities are noninertial, i.e. happen at small Reynolds numbers. In polymeric fluids the viscoelastic instabilities and turbulence are due to shear-induced anisotropic elastic forces: when the so-called Weissenberg number is larger than about 1, a polymer fluid is very non-Newtonian: in this regime the fluid is anisotropic and elastic, and relaxation effects are important. After reviewing some recent experiments, I will discuss the recent progress on understanding the viscoelastic instabilities in parallel shear flows (planar Couette and Poiseuille flow). Contrary to common belief that such flows are absolutely stable in the small Reynolds number limit, our recent nonlinear amplitude analysis predicts that the transitions are subcritical. The critical Weissenberg number our analysis predicts is close to the values where in practice such flows are found to exhibit instabilities. The scenario suggested by these results shows strong resemblance to the transition to (weak) turbulence scenario in Newtonian shear flows. [1] A. N. Morozov and W. van Saarloos, *Subcritical finite-amplitude solutions in plane Couette flow of visco-elastic fluids*, Phys. Rev. Lett. **95**, 024501 (2005).

**G7 2 Shear thickening, thinning and jamming in colloidal suspensions.**
DAVID REICHMANN, *Columbia University*

A microscopic theory for shear thinning behavior in glassy colloidal suspensions is presented. This theory is tested against extensive computer simulation. The theory is extended to study non-linear viscoelastic properties, and is shown to be in remarkable agreement with the measured strain sweep dependence of the loss modulus in colloidal gels. Lastly, we present numerical simulations to address shear thinning and possible shear thickening behavior of dense colloidal suspensions with short-ranged depletion-induced attractions.

**9:12**
**G7 3 Shear Alignment of Hexagonal and Striped Patterns in Block Copolymer Thin Films.***
RICHARD REGISTER, *Princeton University*

Diblock copolymers spontaneously self-assemble into nanodomain structures: simple repeating patterns with a periodicity (typically 20-100 nm) set by the polymer molecular weight and a symmetry controlled by the relative lengths of the two blocks. Similar patterns are obtained when block copolymers are deposited onto substrates, as films with thicknesses accommodating only a few or even only one layer of nanodomains: cylindrical nanodomains form a striped pattern when viewed from above, while spheres form a hexagonal pattern. In the absence of any applied field, however, these patterns exist as a polygrain structure, with a grain size which is typically microns at most. Recently, we have developed methods to shear these thin films, producing samples free from grain boundaries and with orientational order extending over centimeters. But while excellent orientational order can be achieved by shearing, translational order is still limited to the micron scale due to isolated dislocations which remain in the sheared films (though at a markedly reduced density compared with unsheared films). Shear can be applied either with an elastomeric pad, or with a viscous fluid; in the latter case, the patterns can be induced to follow the shape of fluid flow channels of arbitrary shape and millimeter-scale width. For the striped patterns, shear alignment is effective on films containing either a single layer or multiple layers of nanodomains, but for the hexagonal pattern, two or more layers are required due to the mechanical isotropy of a two-dimensional hexagonal lattice. A threshold stress is required to achieve the limiting quality of alignment, a stress which decreases as the block copolymer's order-disorder transition temperature is approached. A simple model appears to capture the principal features of the stress, time, and temperature dependence of the alignment quality.

**G7 4 Shear banding in complex fluids: Hints from colloidal crystals.***
BENNY DAVIDOVITCH, *Harvard University*

When sheared out of equilibrium, a variety of complex fluids exhibit an unusual behavior, where bands of high and low shear rates are spontaneously formed. This phenomenon is typically attributed to a nonlinear material rheology. In this talk I will describe a similar phenomenon observed in oscillatory shear experiment on dense colloidal crystal, where the

data reflect a linear, rather than nonlinear material rheology. This observation suggests an alternative mechanism for shear banding, as a coexistence under nonequilibrium conditions between two linearly responding phases of a complex fluid. Some consequences will be discussed, such as the singular role played by near-wall pure solvent layers, and possible nonequilibrium mechanisms for selection of the observed band width.

**10:24**
**G7 5 Force fluctuations and shear banding near the jamming transition in granular materials.**
HEINRICH JAEGER, *The University of Chicago*

What are the structural changes which turn an un-jammed system that flows like a liquid into a jammed, solid-like configuration or vice versa? For granular just as for molecular systems it turns out that these changes are so subtle that so far there still has been no clean way of identifying the transition based on direct measurements of the grains' or molecules' spatial arrangements. However, in macroscopic granular systems it is possible to measure also the forces between contacting grains. At high packing densities near jamming, where nearly all particles touch neighbors, contact force measurements pick up directly and sensitively what matters most, namely changes in relative grain position. They thus can act as magnifier for even minute structural rearrangements. This talk will discuss experiments [1] able to detect a structural signature of the jamming transition by analyzing changes in the shape of the distribution of contact forces. The second part of the talk will be devoted to discussing new experimental geometries in which shear bands, usually localized to within about 10 grain diameters at the onset of shear, can become much wider. This allows for detailed studies of the shear rate profile and the associated velocity fluctuations. I will compare data we recently obtained from direct imaging by video, magnetic resonance imaging of the interior, and molecular dynamics simulations [2]. [1] E. I. Corwin, H. M. Jaeger, S. R. Nagel, Structural signature of jamming in granular media, Nature 435, 1075 (2005). [2] X. Cheng, J. B. Lechman, A. F. Barbero, G. S. Grest, H. M. Jaeger, G. S. Karczmar, M. E. Möbius, and S. R. **G8 2 Drying Mediated Pattern Formation in a Capillary-Held Polymer Solution*** ZHIQUN LIN, JUN XU, SUCK WON HONG, JIANFENG XIA, *Materials Science and Engineering Department, Iowa State University, Ames, IA 50011* We demonstrated that concentric ring patterns of high regularity could form spontaneously, simply by allowing a droplet to evaporate in a consecutive ''stick-slip'' motion in a confined geometry. The process resembled neatly stacked rows of driftwood abandoned by receding tides. The use of solutions with different concentrations and different solvents effectively mediated the evaporative loss of the solvent and the deposition time of the solute, thereby affecting the center-to-center distance between adjacent rings and the height of the ring. A theoretical calculation based on the mass conservation of the solution has, for the first time, been performed to reveal the nature of the formation of gradient ring patterns in a confined geometry. The studies demonstrate that dynamic self-assembly in a confined geometry may offer a new approach to produce gradient features, as well as a simple, versatile, generalizable approach to produce yet more complex patterns. This natural, pattern-forming process could find use in the fields such as nanotechnology and optoelectronics.

**G8 3 A network model of channel competition in fracture dissolution*** TONY LADD, *University of Florida* PIOTR SZYMCZAK, *Warsaw University* During dissolution in porous or fractured rock, a positive feedback between fluid transport and chemical reactions at the mineral surfaces may lead to the formation of pronounced, wormhole-like channels. As the dissolution proceeds the channels interact, competing for the available flow, and eventually the growth of the shorter ones ceases. Thus the number of channels decreases with time while the characteristic distance between them increases, which leads to a scale-invariant, power-law distribution of channel lengths. A simple resistor network model of the evolution of dissolving channels is constructed and its properties studied. The results are compared with pore-scale simulations of fracture dissolution using a microscopic, three-dimensional numerical model. Despite its simplicity, the resistor model is found to retain the essential features of the nonlinear interaction between the channels.

**G8 4 Fractal growth of liquid crystals as a hysteresis phenomenon** HO-KEI CHAN, INGO DIERKING, *School of Physics and Astronomy, University of Manchester, Manchester (U. K.)* Fractal percolation growth of liquid crystal phases within a supercooled isotropic liquid medium has been observed in recent years. Notable examples include the B2 phase of 'banana' mesogens [1] and the smectic C phase of a calamitic hydrogen-bonding liquid crystal [2]. Here we present a dynamical model that describes such fractal growth as well as the spherical growth conventionally observed for nematics and cholesterics. The essential idea is that the supercooled medium does not fully respond to the temperature quench immediately (hysteresis). Its fraction of space available for the phase transition only relaxes from 0 to 1 at some finite rate. Depending on the coupling between the relaxation and growth rates, the liquid crystal phase either grows as a percolation cluster of fractal dimension $D \approx 1.89$ or approaches a spherical shape of Euclidean dimension $D \rightarrow 2$. The crossover behaviour from relatively slow to fast relaxation is thoroughly investigated. Possible causes of the hysteresis for fractal growth will be discussed. [1] I. Dierking, Liq. Cryst. **8:48**

**G8 5 Patterns in type-I superconductors and their dynamics** RINKE J. WIJNGAARDEN, MARIELA MENGHINI, *Department of Physics and Astronomy, Faculty of Sciences, Free University, De Boelelaan 1081, 1081 HV Amsterdam, The Netherlands* We report on patterns and their dynamics as observed in magneto- optical experiments on type-I superconductors. We observe: (1) A stripe-spot transition that is hysteretic, leading to two modes of stripe formation: slow continuous growth and avalanche growth. (2) A wiggling instability, similar to that in ferrimagnetic garnet films. (3) A zigzag instability when a pattern of parallel lines is rotated through a sample with low pinning. (4) Breaking and reconnection of stripes as such a pattern is rotated in a sample with strong pinning. (5) Random telegraph behavior close to the depinning of such pattern in the presence of a constant driving force. The observed patterns consist of superconducting and normal domains of macroscopic size in thin lamina of type-I superconductors and are observed by an advanced magneto-optical technique. The patterns are manipulated by changing the applied magnetic field vector or by applying an electrical transport current.

**G8 6 Scaling in activated escape of underdamped systems** IRA SCHWARTZ, *Naval Research Laboratory* MARK DYKMAN, MICHAEL SHAPIRO, *Michigan State University* Noise-induced escape from potentials is ubiquitous in many areas of physics. Here, noise-induced escape from a metastable state of a dynamical system is studied close to a saddle-node bifurcation point, but in a region where the system remains underdamped. We find the activation energy of escape scales as a power of the distance to the bifurcation point. Moreover, we find two types of scaling and the corresponding critical exponents.

**9:12**

**G8 7 The Analysis of Spatiotemporal Chaos in Very Large Data Sets Generated by Electroconvective Experiments with Nematic Liquid crystals*** JOSHUA LADD, *Colorado State University* GYANU ACHARYA, *Kent State University* J.T. GLEESON, *Kent State University* Spatiotemporal chaos (STC) has been empirically observed in electrohydrodynamic convection in a planar layer of the nematic liquid crystal I52. The observed spatiotemporal dynamics is due to the interaction of two families of counter propagating waves that loose stability at onset. Thus it is possible to describe the patterns through a system of Ginzburg –Landau equations that governs the evolution of the envelopes of these waves (Denin et al, Science 1996). In this work we extract the envelopes from spatiotemporal data generated by electroconvective experiments done at Kent State University using a demodulation procedure. Once obtained it is possible to separate spatial and temporal components of the dynamics by employing the singular value decomposition. This is done in order to study the chaotic nature of the pattern. Comparison is made with numerical STC obtained from computer simulations of the Ginzburg-Landau system derived from the weak electrolyte model (itDangelmayr & Oprea, 2002) of electroconvection.

**G8 8 Pattern formation in liquids under unipolar space charge injection*** FRANCISCO VEGA REYES, *Departamento de Fisica, Universidad de Extremadura, E-06071 Badajoz, Spain* FRANCISCO J. GARCIA, *Departmento de Fisica Aplicada I, EUITA, Universidad de Sevilla, Spain* We study experimentally the hydrodynamic stability of thin liquid layers subjected to corona discharge in the air. We obtain clear direct images and movies of the observed hydrodynamic instabilities and patterns. After this we apply an image processing method that allows us to quantify the liquid interface deformation. We use a variety of liquids whose properties may differ in orders of magnitude. Particularly, we use series of liquids with different electric conductivity or viscosity while keeping constant the rest of the properties. In this way, we can track quantitatively the instabilities as a function of only one of these properties. This, together with our image processing method, allows us to study and classify the different instabilities. The peculiar properties of the electric field in the liquid interface when there is a space charge injection have not been studied until very recently. Results show clearly the influence (and relevancy) that the properties of this electric field have in the formation (or not) of the different patterns observed when the liquid properties are varied.

**G8 9 Path stability of a rising bubble*** BINZE YANG, ANDREA PROSPERETTI, *Johns Hopkins University* A millimeter-size gas bubble rises in a zigzag or spiral path in still water. A linear analysis of this process is presented assuming that the bubble has a fixed ellipsoidal shape of varying aspect ratio. The results exhibit a strong similarity to the stability features of the flow past a solid sphere. By focusing on the $m = 1$ azimuthal mode, it is found that a double-threaded wake responsible for the deviation from the vertical path develops when the aspect ratio is sufficiently large. The stability analysis of ''frozen'' states before steady conditions are achieved shows that the amount of vorticity

accumulated at the rear of the bubble plays an essential role for the instability. It is also shown that, in the common parameter ranges of interest, the instability is very sensitive to the deformation of the bubble, but relatively insensitive to the Reynolds number.

**9:48**

**G8 10 Flame Propagation with Hydrodynamic and Body-Force Instabilities** KUO-LONG PAN, *Department of Mechanical Engineering, National Taiwan University* The hydrodynamic (Darrieus-Landau) instability is an intrinsic mechanism that wrinkles the flame surface. In the nonlinear stage, propagation of flame wrinkles can evolve to a quasi-stable state characterized by a solitary wave or chaotic form with corrugated front. The underlying structures, i.e. incessant merging of near wrinkles and creation of new cells, have been studied numerically. It reveals the significance of asymmetric perturbation in breaking the symmetry. The effect of gravity was also investigated. It was found that, while wrinkled flames can be stabilized by negative gravity of moderate magnitude, the wrinkles at short wavelength, it$\lambda$, remains intact if the magnitude is small while those at long it$\lambda$ are suppressed. As such, compared to the zero-gravity state, diminishing multiplicity of cellular scales and subsequently decreasing interactions among the multi-scale wrinkles mollify the chaotic complication. When slight positive gravity is introduced, the unsteady evolution is suppressed. The somehow stabilizing effect, while in contrast to the destabilization at linear stage, is due to the coupling of D-L instability and Rayleigh-Taylor instability that prevents excitation of secondary D-L instability. If the magnitude is strong enough, however, the ordered pattern degenerates and highly irregular flame surface is formed without specific cell structure. This is a typical appearance of R-T instability caused by buoyancy.

**G8 11 Numerical Simulation of Conductivity Gradient-Induced Electrokinetic Flow Instabilities** STEPHEN BRADFORD, *UC Santa Barbara* CARL MEINHART, *UC Santa Barbara* JON POSNER COLLABORATION, JUAN SANTIAGO COLLABORATION, This research is focused on the electrokinetic flow instabilities observed in long, thin microchannels with conductivity gradients orthogonal to the streamwise direction and applied potential. This situation often occurs in field amplified sample stacking (FASS) and isoelectric focusing, where control of the instabilities is imperative. Alternatively, the inherently chaotic flow patterns can be leveraged to fabricate an efficient micromixer under specific conditions. These instabilities arise from fluid body forces generated by the action of applied electric fields on electrolyte concentration-based conductivity gradients. A model is developed to describe the phenomena in general and applied specifically to thin microchannels with the conductivity gradient perpendicular to the applied field (both DC and AC). A higher-order, depth averaged correlation is proposed to account for the out of plane effects. Numerical simulations performed using COMSOL 3.2 are compared to 2-D and 3-D simulations as well as experimental data for multiple geometries with good agreement.

**10:12**

**G8 12 Particle production in non-dissipative shock-waves** ALEXANDER ABANOV, *Stony Brook University* FABIO FRANCHINI, We study non-dissipative shock-waves in the effective hydrodynamics of some correlated one-dimensional integrable systems. The semiclassical dynamics of these systems is governed by integrable non-linear classical equations such as the Benjamin-Ono and the KdV equations. The development of non- dissipative shock-waves from a large disturbance of the fluid is described by Gurevich-Pitaevsky theory. The theory describes how the instability of a large disturbance of the fluid is resolved by producing oscillations which develop into a train of solitons at large times. We establish the connection between this classical picture and the production of quasi-particles in the underlying quantum system. The semiclassical (background) configuration can then be thought of as an effective metric in which these excitations move. This approach is done in the spirit of the original proposal of Unruh, who suggested to model the Hawking radiation from black holes by an emission of thermal sound waves from the sonic horizon in transsonic fluid flow.

**10:24**

**G8 13 Torsional Motion of Rotating Particles with Graded Couplings** H.W. TSANG, J.J. XIAO, K.W. YU, *The Chinese University of Hong Kong* Localization of excitations occurs in many physical systems. There are two common types of localization. The first type is a consequence of interference of coherent vibrational waves due to diffusive scattering like Anderson localization in lattice vibration. The other type of localization is due to confinement by impurities like defect modes. Graded systems occur in a variety of physical system. It is of great interest to analyze the localization of excitations in graded system [1]. In this work, we consider a system of rotating particles with graded torsional couplings. The steady-state solutions are solved directly from the dynamic equations. Energy is localized in the region of stronger couplings at high frequencies. A dynamic stimulation based on forced rotors is performed both for the graded linear and graded non-linear coupling potential subjected to a sinusoidal driving torque. In the small amplitude region, the results of non-linear potential are similar to those of the linear ones. The major difference is that the rotational amplitude is larger for the non-linear potential. Energy transfer may thus be more effective in the non-linear case. In the large amplitude region, chaos may occur and contribute to the localization. [1] J. J. Xiao, K. Yakubo, and K. W. Yu, Harmonic vibrational excitations in graded elastic networks: transition from phonons to gradons, unpublished.

**G8 14 Numerical simulations of inertial migration in a square duct: An investigation of multiple equilibrium positions*** BYOUNGJIN CHUN, *University of Florida* TONY LADD, In Poiseuille flow, a neutrally-buoyant particle migrates to a position that is determined by the balance of forces generated by the gradient of the shear rate and interactions of the flow field with the container walls. In a cylindrical flow, uniformly distributed particles migrate to form a stable ring located at approximately 0.6 times the cylinder radius. However, recent experiments show two interesting new observations. First the suspended particles tend to align near the walls to make linear chains of more or less equally-spaced particles, and second, at high Reynolds numbers (Re 1000), an additional inner ring of particles is formed. The inner ring is only

formed when the particle are large, of the order of 1:10 the cylinder diameter. We have used numerical simulations based on the lattice-Boltzmann method to investigate inertial migration of neutrally buoyant particles in a square duct over a range of Reynolds numbers from 100 to 1000. Our results show trains of particles being formed along the axis of the flow, near the planar equilibrium positions of single particles. At Reynolds number greater than 750, particles appear near the center of the duct as well. We will present a new mechanism to interpret and understand these results, which was discovered by examining the migration of single particles and rigid dumbbells.

**G10 1 Nanowire-based solar cell.**
PEIDONG YANG, *University of California*

Excitonic solar cells – including organic, hybrid organic-inorganic and dye-sensitised cells (DSCs) – are promising devices for inexpensive, large-scale solar energy conversion. The DSC is currently the most efficient and stable excitonic photocell. Central to this device is a thick nanoparticle film that provides a large surface area for the adsorption of light-harvesting molecules. However, nanoparticle DSCs rely on trap-limited diffusion for electron transport, a slow mechanism that can limit device efficiency, especially at longer wavelengths. Here we introduce a new version of the dye-sensitised cell in which the traditional nanoparticle film is replaced by a dense array of oriented, crystalline ZnO nanowires. The nanowire anode is synthesized via mild aqueous chemistry and features a surface area up to one-fifth as large as a nanoparticle cell. The direct electrical pathways provided by the nanowires ensure the rapid collection of carriers generated throughout the device, and a full Sun efficiency of 2.5% is demonstrated, limited primarily by the surface area of the nanowire array.

**G10 2 Structural and Conductance Change in Hydridosilsesquioxane Based Silicon Oxide Clusters Induced by an Electric Field** SAROJ NAYAK, PHILIP SHEMELLA, *Rensselaer Polytechnic Institute - Department of Physics, Applied Physics & Astronomy* Interesting results arise from the addition of a hydrogen atom to a hydridosilsesquioxane (HSQ) $Si_8O_{12}H_8$ cluster, and have been studied with density functional theory techniques. Three stable minima have been found (open, cluster, center), and energy barriers between each have been computed. Each state has different values in the HOMO-LUMO[1] energy gap, which is usually a metric for conductance. Simulating the electronic interaction with an applied electric field, we model the reactions and compute the energy barriers with and without an applied electric field. Asymmetric states with strong dipole moments will have the most energetic effects in an applied field, based on the electric field-dipole energy relation, $U = -\mathbf{p}\bullet\mathbf{E}$. We propose that the field forces the open structure to become energetically unstable, resulting in an overall loss in structures found in the open configuration and loss of the highly conducting properties. We have also modeled the critical energies points in implicit solvent, with results similar to gas phase calculations.

**G10 3 Designing Self-assembled Nanostructures: Metal-Organic Coordination Networks at Surfaces** STEVEN TAIT, NIAN LIN, SEBASTIAN STEPANOW, KLAUS KERN, *Max Planck Institute for Solid State Research* Networks consisting of organic molecules and isolated metal atoms have been demonstrated to self-assemble at surfaces. The components of the networks are designed to assemble in a desired pattern, forming periodic arrays of isolated metal atoms (or dimers) separated by organic molecule ligands. This 'bottom-up' formation of a nanometer-scale structure opens a wide range of questions related to the properties of the components of the networks: metal atom nodes, molecule ligands, and nanopores within the networks. Our group explores these properties, including the magnetic and catalytic properties of the isolated metal atoms and adsorptive properties of the nanopores within the networks. Some properties can be 'tuned' by rational design of the organic molecule size, structure, and functionality. The ability to tailor the size and functionality of nanometer-scale arrays produced by self assembly represents a fantastic opportunity for molecular recognition, heterogeneous catalysis, and other fields. We present here recent results from our group, including the use of ligands containg pyridyl groups and recent adsorption measurements on the networks.

SCHMUTTENMAER, VICTOR S. BATISTA, *Department of Chemistry, Yale University, P.O.Box 208107, New Haven, Connecticut*

*06520-8107, U.S.A.* We describe the development and application of dye-sensitized semiconductors to heterogeneous photocatalysis. itAb initio-DFT electronic structure calculations and molecular dynamics simulations combined with quantum dynamics propagation of transient electronic excitations indicate that a surface complex consisting of a catalytic Mn oxo complex adsorbed onto a $TiO_2$ substrate via a catechol-substituted terpyridine ligand can be activated by photoinduced subpicosecond interfacial electron transfer. Experimental realization of the Mn oxo surface complex, achieved by a novel sequential synthesis technique, is briefly described and computational results supporting the spectroscopic characterization of the nanoscale assembly are presented. Studying the photocatalytic reaction dynamics of these uniquely functionalized semiconductor materials offers the prospect of gaining unprecedented control over a wide range of contrathermodynamic reactions. Furthermore, such biomimetic materials capable of splitting water or fixating $CO_2$ could provide viable solutions to problems ranging from current energy concerns to reducing atmospheric greenhouse gases.

**G10 5 Silver and Gold Nanostructures: Engineering their Optical Properties for Biomedical Applications.**
YOUNAN XIA, *University of Washington*

We have focused on shape-controlled synthesis of silver and gold nanostructures. While the synthetic methodology mainly involves solution-phase redox chemistry, we have been working diligently to understand the complex physics behind the simple chemistry – that is, the nucleation and growth mechanisms leading to the formation of nanostructures with a specific shape. Polyol synthesis of silver nanostructures provides a good example to illustrate this concept. We discovered that the shape of silver nanostructures were dictated by both the crystallinity and shape of nanocrystallite seeds, which were, in turn, controlled by factors such as reduction rate, oxidative etching, and surface capping. We also exploited the galvanic replacement reaction between silver and chloroauric acid to transform silver nanocubes into gold nanocages with controlled void size, wall thickness, and wall porosity. We were able to engineer the optical properties of resulting gold nanocages with optical resonance peaks ranging from the blue (400 nm) to the near infrared (1200 nm) simply by controlling the molar ratio of silver to chloroauric acid. Thanks to their exceptionally large scattering and absorption coefficients in the transparent window for soft tissues, this novel class of gold nanostructures has great potential emerging as both a contrast agent for optical imaging in early-stage tumor detection, and a therapeutic agent for photothermal cancer treatment.

**G10 6 Aligned Silver Nanorod Array as SERS Substrates for Viral Sensing*** YIPING ZHAO, *Department of Physics and Astronomy* SARATCHANDRA SHANMUKH, *Department of Chemistry* STEPHEN B. CHANEY, *Department of Physics and Astronomy* LES JONES, *Department of Infectious Diseases* RICHARD A. DLUHY, *Department of Chemistry* RALPH A. TRIPP, *Department of Infectious Diseases, The University of Georgia* The aligned silver nanorod array substrates prepared by the oblique angle deposition method are capable of providing extremely high enhancement factors ( $\sim 10^9$) at near-infrared wavelengths (785 nm) for a standard reporter molecule 1,2 trans-(bis)pyridyl-ethene (BPE). The enhancement factor depends strongly on the length of the Ag nanorods, the substrate coating, as well as the polarization of the excitation laser beam. With the current optimum structure, we demonstrate that the detection limit for BPE can be lower than 0.1 fM. The applicability of this substrate to the detection of bioagents has been investigated by looking several viruses, such as Adenovirus, HIV, Rhinovirus and Respiratory Syncytial Virus (RSV), at low quantities ( $\sim$ 0.5uL). Different viruses have different fingerprint Raman spectrum. The detection of virus presented in infected cells has also been demonstrated.

**G10 7 Colloidal Platinum Nanoparticles: Synthesis, Structure and Properties.*** DANIEL KATZ, *Hebrew Academy of the Five Towns and Rockaway, Cedarhurst, NY* VIKAS MURALI, *Staples High School, Westport, CT* REBECCA ISSEROFF, *Stella K Abraham High School, Hewlett, NY* YUAN SUN, *Dept. Mat. Sci. & Eng., SUNY at Stony Brook* YIMEI ZHU, *Brookhaven National Laboratory, Upton, NY* VLADIMIR SAMUILOV, NADINE PERNODET, MIRIAM RAFAILOVICH, JONATHAN SOKOLOV, *Dept. Mat. Sci. & Eng., SUNY at Stony Brook* Interest in nanoparticles has risen in recent years as unique properties are being obtained from otherwise ordinary materials by reducing their sizes to molecular dimensions. We synthesized colloidal platinum nanoparticles with sizes of 1$\sim$ 8 nm through four novel chemical methods and investigated their properties. These particles had an electrical resistivity of 1$\sim$ 4 $\Omega \cdot$ m and also exhibited a ferromagnetic moment. When the particles were exposed to hydrogen we measured a 15% increase in their mass, indicating a high level of hydrogen absorption. The lattice constant was measured using HRTEM and was found to be the same as bulk Pt, even after $H_2$ exposure, indicating no lattice distortion occurred. When dermal fibroblasts were exposed to the particles, the particles disrupted cellular actin, structure, and function. Practical applications include the use of Pt particles in semiconductor chips, hydrogen storage in fuel cells and particle chemotherapy targeted against cancer cells.

**G10 8 Self organized growth of regular arrays of Pd-Au bimetallic nanoclusters on nanostructured alumina films** CLAUDE R. HENRY, *CRMCN-CNrs, Campus Luminy, 13288 Marseille* GUIDO HAMM, *CRMCN-CNRS* CONRAD BECKER, *IPTC, University of Bonn* Pd-Au clusters (1-4 nm)were grown under UHV on nanostructured alumina films in a two-step process. The alumina films, prepared by high temperature oxidation of a Ni3Al (111) surface, present an hexagonal array of defects, separated by 4.1 nm, which is a template for the growth of the bimetallic clusters. Pd and Au atoms are condensed sequentially on the alumina film, under UHV. The maximum density of metal clusters is fixed by the density of defects. The mean size of the clusters is controlled by the total amount of the deposited metals, while their composition is controlled by the ratio of the deposited amounts of the two metals. The nucleation and growth of the bimetallic clusters are followed in situ by STM. These arrays of bimetallic clusters are used as model catalysts for CO oxidation studied by molecular beam methods. The regular spatial organisation of the clusters allows the study and the correction of the reverse spillover effect of the CO during the reaction.

**G10 9 Reduction of nickel upon annealing of nickel zinc ferrite nanoparticles** S. CALVIN, *Sarah Lawrence College* S.A. MORRISON, M.D. SHULTZ, E.E. CARPENTER, *Virginia Commonwealth University* R. SWAMINATHAN, M.E. McHENRY, *Carnegie Mellon University* Nickel zinc ferrite (NZFO) nanoparticles were synthesized by two methods: radio-frequency plasma torch and reverse micellar syntheses. Upon annealing, x-ray absorption spectra of both sets of samples provided definitive evidence of a progressive reduction of nickel to an fcc metallic form. X-ray diffraction, however, does not show clear peaks corresponding to fcc nickel, suggesting the metallic crystallites are very small. In the case of the plasma torch samples, annealing under air for one hour at 900[r]C is sufficient to reduce nearly all of the nickel metal. Testing is still underway for the reverse micellar samples, but in at least one case approximately 80% nickel reduction was achieved by annealing under nitrogen for one hour at 500[r]C. To elucidate the mechanism of this reduction, a comparative study of annealing under air, nitrogen, and argon is underway, as well as thermogravimetric analysis.

**10:36**
**G10 10 Insulator − polaron conductor − metal transitions in a complex oxide $12CaO \cdot 7Al_2O_3$.** P. SUSHKO, A. SHLUGER, A. STONEHAM, *Department of Physics and Astronomy, University College London, UK* K. HAYASHI, S. MATSUISHI, M. HIRANO, H. HOSONO, *Frontier Collaborative Research Center, P.O. Box S2-13, Tokyo Institute of Technology, Japan* Recent experiments have demonstrated that a complex nano-porous oxide $12CaO \cdot 7Al_2O_3$ (C12A7) built of positively charged subnanometer cages can be converted from a transparent insulator to a transparent conductor by $H_2$ doping followed by UV-light irradiation with 4–4.5 eV photons [1]. This irradiation induces optical absorption bands with maxima at 0.4 eV and 2.8 eV and high concentrations of unpaired electrons. We use ab initio calculations to reveal the mechanism of photo-induced insulator–conductor transition and the role of H atoms in this process and to elucidate the transport properties of the electrons in this system as a function of electron concentration. Our theoretical modeling suggests that at concentration below $10^{20}$ cm$^{-3}$ electrons are responsible for the polaron type electrical conductivity with the activation energy close to 0.1 eV as well as for the optical absorption at 0.4 eV and 2.8 eV [2]. We demonstrate that, as the electron concentration exceeds $10^{20}$ cm$^{-3}$, the character of electronic conductivity changes from polaron type to metallic. [1] K. Hayashi et al., Nature **419**, 462 (2002). [2] P.V. Sushko, et al., Phys. Rev. Lett. **91**, 126401 (2003); P.V. Sushko et al., Appl. Phys. Lett. **86**, 092101 (2005).

**G10 11 Electronic control inside a molecule : towards single molecule devices** MATHIEU LASTAPIS, YURIE FUKUMA, JOHN BOLAND, *CRANN, Trinity College, Dublin* The chimerical single molecule engineering has been proven to be accessible through the use of scanning tunnelling microscopy (STM) [1]. In this field, one particularly attractive area is the study of single molecules adsorbed on semiconductor surfaces. It has been recently demonstrated that a spatial fine control of the molecular dynamics is possible through the use of tunnelling current [2]. In order to improve the electronic control of a single molecule, we are currently investigating a promising system: CaF2 on Si(111). This system has been extensively studied as a model system to deposit insulator on silicon. Here we are using this system to electronically decouple the molecule from the substrate. I will present LT STM experiments on atomically thick CaF islands on Si(111). The measured electronic properties of these islands demonstrate their potential as ideal templates to study single molecules. Finally I will present some preliminary results on N-HBC [3] adsorbed on a CaF island. [1] G. Binnig and H. Rohrer, ''In touch with atoms,'' Rev. Mod. Phys. 71, S324-S330 (1999) [2] M. **G11 1 Phase and curvature** CURT WITTIG, *University of Southern California* It is known that geometric phases play important roles in atomic and molecular science, from the Aharonov-Bohm effect including flux quantization to the Born-Oppenheimer approximation and its conical intersections. When judged from a geometrical perspective, these and related phenomena can be assigned the common parentage of quantum holonomy on curved surfaces. Moreover, this perspective can be extended to larger arenas. For example, adiabatic transport of a state in phase space is nonzero if and only if $[x, p]$ is nonzero. This yields a curvature that is equal to $\hbar^{-1}$. This talk will explore additional aspects of geometric phase: (i) the origin of the curvature in parameter space imposed by $\hbar$, and therefore by the existence of quantum mechanics; and (ii) the relationship of the curvature to matrix elements, *e.g.*, between which kinds of states.

**G11 2 A zero magnetic moment molecular probe of the electron's electric dipole moment.**
NEIL SHAFER-RAY, *Homer L Dodge Department of Physics and Astronomy, The University of Oklahoma*

The stationary states of a molecule in a pure electric field are degenerate in the sign of the projection of total angular momentum on the field axis. A lifting of this $\pm$ $M_F$ degeneracy would be an indication of CP (time reversal) symmetry violation. For heavy paramagnetic molecules, this CP violation would be attributed to an electron electric dipole moment (e-EDM) and could at once separate Supersymmetric models from the Standard Model and explain why we are made of matter instead of antimatter. A major obstacle to observing CP violation in this way is that the background magnetic-field induced splitting of the $\pm$ $M_F$ degeneracy normally dwarfs any possible electric-field induced splitting. Here we report how the physics of $^2\Pi_{1/2}$ PbF can be exploited to gain extraordinary sensitivity to the e-EDM while reducing the magnetic g factor to less than $10^{-7}$. The construction of a radical beam source of PbF, sensitive resonance enhanced multi-photon ionization (REMPI) detection of PbF, and progress toward measurement of the e-EDM are reported.

**G11 3 Ion Imaging Studies of Ultra-Cold Molecule Production**
DAVID W. CHANDLER, *Combustion Research Facility, Sandia National Laboratories* We report the cooling of molecules in a single collision between an atom and a molecule in a crossed molecular beam apparatus. In particular we will show data on cooling NO by collision with Ar and NH3 in collisiosn with Ne. We have produced in significant numbers ( $\sim 10^8$ molecules $cm^{-3}$ per quantum state) translationally cold NO($^2\Pi_{1/2}$,v′=0,j′=7.5) molecules in a specific quantum state with an upper-limit laboratory-frame rms velocity of 14.8$\pm$ 1.1 m/s, corresponding to a temperature of 406$\pm$ 28 mK. The translational cooling results from the kinematic collapse of the velocity distribution of the NO molecules after collision. We present experimental evidence to show that increasing the collision energy by a factor of $\sim$ 2.6 does not change the velocity spread of the cold NO molecules. Similarly, the energy condition for producing the cold NO does not depend on the energy of the Ar beam. However, the energy of the Ar beam does shift the scattering angle at which the cold molecules appear. We will highlight new studies on utilizing these cold molecules for collisional studies. This work was done in collaboration with Professor James Valentini of Columbia University.

**G11 4 Supersonic Molecular Beam Optical Stark Spectroscopy of MnH.*** JAMIE GENGLER, TONGMEI MA, JEREMY HARRISON, TIMOTHY STEIMLE, *Arizona State University* The large moment of inertia, large magnetic moment, and possible large permanent electric dipole moment of manganese monohydride, MnH, makes it a prime candidate for ultra-cold molecule production via Stark deceleration and magnetic trapping[1,2]. Here we report the first molecular beam production of MnH and the analysis of the Stark effect in the (0,0) $A^7\Pi - X^7\Sigma^+$ band. The sample was prepared by laser ablation of solid Mn in an $H_2$ supersonic expansion. The low rotational temperature ( $<$ 50 K) and near natural linewidth resolution ( $\sim$ 50 MHz) facilitated analysis of the $^{55}$Mn (I=5/2) and $^1$H (I=1/2) hyperfine structure. A comparison of the derived field-free parameters with those obtained from sub- Doppler optical[3] and Doppler limited infrared[4] measurements will be made. Progress on the analysis of the Stark effect will be given.

**9:12**
**G11 5 Rotation of a generalized Eckart frame in atom-diatomic molecule scattering*** FLORENCE J. LIN, *University of Southern California* A cyclic change in the shape of an atom-diatomic molecule complex can lead to net rotation of not only the complex, but also the rotating axes of a generalized Eckart frame of the complex. Large-amplitude, ''internal'' motions of an atom-diatomic molecule van der Waals complex can lead to overall rotation of the complex in the center-of-mass frame. When the total angular momentum is conserved, the net angle of overall rotation is the sum of a dynamic phase plus a geometric phase. The classical geometric phase is describable in terms of molecular rotational constants. The scattering angle of the atom in a nonreactive ''slightly sticky collision'' between an atom and a diatomic molecule in molecular beams depends on an analogous ''internal'' motion. Thus, the scattering angle of the atom is also given by the sum of a dynamic phase plus a geometric phase.

**G11 6 Two- and three-state conical intersections in complex systems** SPIRIDOULA MATSIKA, *Temple University* KURT KISTLER, ZONGRONG XU, AKIHIKO YOSHIKAWA, Nonadiabatic processes play an important role on the excited state dynamics of chemical systems. Conical intersections (actual potential energy surface crossings) of two states have been established to facilitate nonadiabatic processes of molecules and radicals in the gas phase. More recently three-state conical intersections have made their appearance and may also play a key role in nonadiabatic processes. Here we present studies where the importance of

conical intersections is being investigated in photoinitiated processes of biologically relevant systems, and particularly the nucleobases and their analogs. Large scale ab initio multireference configuration interaction methods (MRCI) are being used. Our results show the presence of many seams of two- or three-state conical intersections that can complicate the potential energy surfaces and dynamics of these systems. Solvent effects on conical intersections are first being investigated using clusters of water with the system. A mixed quantum mechanical/ classical mechanical (QM/MM) approach where the solute is described with the MRCI method will also be presented as a means to study the effect of the solvent on excited states.

**G11 8 Spectroscopic Identification of Multiple Conformers of $o,p$-$H_2 \cdots ICl$ and $o,p$-$H_2 \cdots I_2$ Complexes** JOSHUA DARR, RICHARD LOOMIS, *Department of Chemistry Washington University in St. Louis* Laser-induced fluorescence and action spectroscopy experiments have identified ro-vibronic transitions associated with multiple conformers of the $o,p$-$H_2 \cdots ICl(X,v=0)$ and $o,p$-$H_2 \cdots I_2(X,v=0)$ complexes. For each complex, the conformers with the hydrogen molecule localized at the end of the dihalogen, with a $C_{2v}$ symmetry, are more stable than the conformers with the hydrogen molecule localized in the T-shaped well, which lies orthogonally about the dihalogen bond axis. Furthermore, the conformers containing $o$-$H_2(j=1)$ and $p$-$D_2(j=1)$ are found to be more strongly bound than those containing $p$-$H_2(j=0)$ and $o$-$D_2(j=0)$. The role of multi-pole electrostatic interactions is elucidated by comparing the binding energies of the $H_2 \cdots ICl(X,v=0)$ and $H_2 \cdots I_2(X,v=0)$ complexes with $C_{2v}$ symmetries. The relative populations of the $C_{2v}$ and T-shaped conformers can be altered by changing the properties of the supersonic expansion used to stabilize the complexes. The relative populations of the $o$-$H_2 \cdots ICl(X,v=0)$ and $p$-$H_2 \cdots ICl(X,v=0)$ conformers can also be manipulated, with a population ratio of 3:1 approached by decreasing the hydrogen concentration in helium.

**G11 9 Double Resonance Spectroscopy of the $B''\bar{B}^1\Sigma_u^+$ state of $H_2$ above the double well barrier.*** ROBERT EKEY, AARON MARKS, ELIZABETH MCCORMACK, *Bryn Mawr College, Bryn Mawr, PA 19010* Double resonance spectroscopy via the $EF^1\Sigma_g^+, v'_{EF} = 6, J'$ state has been used to probe the rovibrational the itungerade double-well $B''\bar{B}^1\Sigma_u^+$ state of $H_2$. Many transitions to levels of the outer-well and the combined inner and outer-well above the barrier have been observed for the first time by detecting both molecular and atomic ion production as a function of energy by using a time of flight mass spectrometer. While significant perturbations are observed in the energy region above the double-well barrier, assignments to states with dominant inner and outer-well characteristics can still be made. Distinct dynamical behaviors of the levels below, at and above the barrier have also been observed.

**G11 10 The Department of Energy's Hydrogen Storage Activities: Challenges and Needs in Chemistry and Chemical Dynamics** SUNITA SATYAPAL, GRACE ORDAZ, JOHN PETROVIC,*CAROLE READ, GEORGE THOMAS,† *Department of Energy* Hydrogen storage is a key area of research funded by the Department of Energy. Hydrogen, the simplest diatomic molecule known, has the highest energy content of all known fuels by mass, but the practical storage of sufficient hydrogen on-board a vehicle is a significant technological challenge. Hydrogen can be stored via various mechanisms within materials such as metal hydrides (e.g. $LiBH_4$, $AlH_3$) chemical hydrides (e.g. organic liquids), and nanostructured sorbents (e.g. carbon nanotubes, clathrates). Examples of mechanisms include physisorption, chemisorption, dissociative adsorption or combinations of the above. In addition to weight and volume, the kinetics of hydrogen charging and discharging as well as durability must be addressed. A fundamental understanding of hydrogen storage to help optimize materials is critical. The technical requirements for hydrogen storage, as well as some of the promises and challenges will be presented, with a focus on what chemical dynamics and chemistry can offer in solving the challenge of hydrogen storage for transportation applications.

**G12 1 A Level-Set Method for Epitaxial Growth and Self-Organization of Quantum Dots** CHRISTIAN RATSCH, YOUNG-JU LEE, XIAOBIN NIU, RUSSEL CAFLISCH, *UCLA* We have developed an island dynamics model that employs the level-set technique to describe epitaxial growth. One virtue of this method is that the typical simulation timestep can be chosen much larger than in an atomistic simulation, even when several microscopic processes with vastly different rates are relevant. This makes it feasible to solve the elastic equations and obtain the entire strain field at every timestep of the simulation. The strain field modifies the potential energy surface, and different limits will

be discussed. We will present simulation results where we self-consistently modify the strain dependent microscopic rates for surface diffusion and detachment of adatoms from island edges. Our results for the island size distributions indicate that such strain dependent kinetic rates lead to the regularization of island sizes, and ultimately the formation and self-organization of quantum dots.

**8:12**

**G12 2 Multiscale Theory of Fluctuating Interfaces: From Self-Affine to Unstable Growth*** CHRISTOPH HASELWANDTER, *Imperial College, London* DIMITRI VVEDENSKY, *Imperial College, London* We describe a framework for the multiscale analysis of atomistic surface processes which we apply to the Wolf-Villain model for epitaxial growth. Coarse-graining is accomplished by calculating the renormalization-group trajectories from initial conditions determined by the regularized atomistic theory. All of the intermediate scaling regimes known from computer simulations are obtained, but we also find that the asymptotic behavior of two-dimensional substrates is determined by a hitherto unknown fixed point. This provides an explanation of recent experiments on Ge(001) with the intriguing conclusion that the relaxation mechanism responsible for ordered structures early in the growth process produces an instability at longer times that leads to epitaxial breakdown.

**G12 3 The Structure and Evolution of Ge Nanoscale Structures on Si(111) − Observations and Theory** SANWU WANG, *Vanderbilt University* H.F. MA, Z.H. QIN, D.X. SHI, Y.L. WANG, H.M. GUO, H.-J. GAO, S.T. PANTELIDES, *Vanderbilt University and Oak Ridge National Laboratory* We report scanning tunneling microscopy (STM) observations and first-principles calculations for the evolution of self-organized Ge nanostructures formed on Si(111)-7 $\times$ 7 for Ge coverages up to 0.5 ML and operating temperatures from room temperature to 300°C. STM measurements show that, depending on coverage and temperature, Ge atoms form various structures ranging from single-atom correlated patterns, 2-D ordered nanoscale domains, and 3-D disordered and ordered nanoclusters. First-principles theory focuses on the single-atom patterns and 2-D ordered nanostructures. We show that Ge atoms replace the Si adatoms in the initial adsorption stage. We also show that annealing of the Ge/Si(111) surface results in a partial transformation of (7 $\times$ 7) reconstructed unit cells to unreconstructed Si(111) configurations on which the Ge adatoms reside at the $T_4$ sites and form a $(\sqrt{3} \times \sqrt{3})R30°$ reconstruction.

**G12 4 Evolution of Si nanostructures on the Ge(001) surface** YASUNORI FUJIKAWA, TOSHIO SAKURAI, *Institute for Materials Research, Tohoku University* Growth of compressively strained thin films has been studied extensively for the applications in quantum devices composed of 2D quantum well and/or 1D quantum dots. Recent progress in the strain-controlled Si and SiGe high-speed devices brings increasing interest in the growth control of the oppositely strained thin films and nanostructures. In this work, we report on the morphology evolution of the Si layer formed on the Ge(001) substrate to investigate the effect of tensile strain in the growth of Si. Initially the Si layer forms a wetting layer characterized by the formation of missing dimer rows with spacing of 3-4 rows. The direction of the defect row is 90-degree rotated from the case of the Ge wetting layer on Si(001), being explained by the anisotropic strain of the dimer-row structure. Successive growth of Si results in the formation of Si islands, whose surface is composed of four {113} facets with a small (001) terrace on top. Its differences from the Ge dome structure on Si(001) composed of {113} facets and {105} facets on top can be understood by considering the tensile strain of the {105} facets [1]. [1] Y. Fujikawa et al., Phys. Rev. Lett. **88**, 176101 (2002).

**G12 5 Atomic structure and strain of Ge wetting layer on silicon** HAO CHEN, BOQUAN LI, *University of Illinois at Urbana-Champaign* JIANGUO ZHENG, *Northwestern University* JIAN-MIN ZUO, *University of Illinois at Urbana-Champaign* The atomic structure of Ge wetting layer grown on Si(001) surfaces by chemical vapor deposition at several substrate temperatures under UHV was characterized by low energy electron diffraction and cross sectional high-resolution scanning transmission microscopy. The Ge film is atomically flat with sharp interface with silicon. The surface lattice constant changes with Ge coverage. At high Ge coverage on stepped Si surface, surface relaxation is observed near step edges. The ability to modify Si surface lattice with Ge has many applications.

**9:00**

**G12 6 Quantitative Correlation of Local Stress Field and Surface Morphology in Undulated Si1-xGex/Si(100) Thin Films*** CHI-CHIN WU,† ROBERT HULL, *University of Virginia* We have performed in-situ transmission electron microscope measurements of misfit dislocation propagation velocities to quantitatively characterize the stress field variations for undulated epitaxial Si1-xGex/Si(100) thin films. For a strained Si0.7Ge0.3 film with a 30 nm mean thickness and annealed at $\sim$ 480°C, the dislocation velocity varies from 50 to 200 nm/s as the threading arm of a propagating dislocation line traverses a period of the surface morphology. Using detailed correlations we have previously developed between misfit dislocation velocities and local driving stresses, we can translate this velocity range into an effective stress on the dislocation that varies from $\sim$ 0.3 to 1.2 GPa. These results show great promise for correlating local stresses with morphology in these materials.

**G12 7 Surface Mobility Difference between Si and Ge and its Effect on Growth of SiGe Alloy Films and Islands** LI HUANG, *Fudan University, China* GUANGHONG LU, *University of Utah* XINGAO GONG, *Fudan University, China* FENG LIU, *University of Utah* Based on first-principles calculations of surface diffusion barriers, we show that on a compressive Ge(001) surface, the diffusivity of Ge is $10^2 - 10^3$ times higher than that of Si in the temperature range of 300 to 900 K; while on a tensile surface, the two diffusivities are comparable. Consequently, growth of a compressive SiGe film is rather different from that of a tensile film. The diffusion disparity between Si and Ge is also greatly enhanced on the strained Ge islands compared to that on the Ge wetting layer on Si(001), explaining the experimental observation of Si enrichment in the wetting layer relative to that in the islands.

**G12 8 Modeling the Self-Assembly of Quantum Dots in Thin Solid Films** MARGO LEVINE, *Northwestern University* ALEXANDER GOLOVIN, STEPHEN DAVIS, PETER VOORHEES, The self-assembly of quantum dots in a thin solid film caused by epitaxial stress and wetting interactions with the substrate is studied. It is shown that wetting interactions change the instability spectrum from long wave to short wave which can lead to spatially regular arrays of quantum dots. A nonlocal, nonlinear evolution equation for the film shape is derived, and the stability of dot arrays with different symmetries is studied. Regions in the parameter space are determined where spatially regular surface structures can be observed in experiments.

**9:36**

**G12 9 Island Alignment on Patterned Substrates** DEMITRIS KOURIS, *University of Wyoming* ROBERT KUKTA, *SUNY Stonybrook* A recent approach to fabricating self-assembled epitaxial nanostructures involves the use of topographically patterned substrates to control the formation of material deposits during growth. This article investigates the energetic and kinetic mechanisms that guide the positioning of strained epitaxial islands in these systems. A continuum-level model is used wherein the free energy of system consists of surface energy and strain energy. The substrate shape is represented by small amplitude sinusoidal features. An energetic phase diagram is calculated to determine which sites are most favorable—peaks, valleys, or side walls—depending on factors as substrate shape, lattice mismatch, surface energy, and the amount of material deposited. The kinetic evolution through the processes of deposition and surface diffusion is then simulated. It is found that the resulting morphology depends largely on the rate of deposition relative to surface mobility. Relatively slow deposition rates produce configurations of minimum free energy while higher deposition rates give rise to novel metastable states. Mechanisms by which various configurations arise are discussed in detail. Results are found to be in excellent agreement with published experiments.

**G12 10 Utilizing Growth Kinetics to Self-Assemble Complex SiGe Nanostructures** JENNIFER GRAY, ROBERT HULL, *University of Virginia* JERROLD FLORO, *Sandia National Laboratories* Heteroepitaxial growth of $Si_xGe_{1-x}$ on Si (001) substrates under conditions of reduced adatom mobility results in limited formation of stress-relieving islands occurring only at energetically favorable sites. These favorable sites are at the edges of shallow pyramidal pits that form at random locations on the film surface under these conditions. However, by using a focused ion beam (FIB) to pattern the substrate before growth, it is possible to controllably create pits at predefined locations. This results in the formation of four self-assembled islands at the edges of each pit. In order to obtain uniform, well ordered islands, the FIB milling parameters and Si buffer thickness must be tailored to produce pits in the strained film with dimensions equal to or smaller than the compositionally-dependent natural length scale of the islands. The ability to produce islands at specific locations is important for applications such as quantum computing where quantum dots must be arranged into logic structures. Exploiting this constraint on islanding that occurs under kinetically limited growth may therefore provide a new route to hierarchical assembly of nanostructures when combined with substrate patterning techniques.

**G12 11 Shape and Composition Map of a Prepyramid Quantum Dot** BRIAN SPENCER, *SUNY Buffalo* We present a theory for the shape, size, and nonuniform composition profile of a small prepyramid island in an alloy epitaxial film when surface diffusion is much faster than deposition and bulk diffusion. The predicted composition profile has segregation of the larger misfit component to the island peak, with segregation enhanced by misfit strain and solute strain but retarded by alloy solution thermodynamics. Vertical composition gradients through the center of the island due to this mechanism are on the order of 2%/nm for $Ge_XSi_{1-X}$/Si and 10 - 15%/nm for $In_XGaAs_{1-X}$/GaAs [PRL 95, 206101 (2005)].

**G12 12 Temperature and Flux Dependence of Unstable Growth Mode on Patterned GaAs(001)*** TABASSOM TADAYYON-ESLAMI, HUNG-CHIH KAN, *University of Maryland* SUBRAMANIAM KANAKARAJU, CHRIS RICHARDSON, *Laboratory for Physical Sciences* RAY PHANEUF, *University of Maryland* We report on the temperature and flux dependence of the growth mode of GaAs(001) during molecular beam epitaxy (MBE). Our previous results [1] for growth on patterned GaAs(001) surfaces showed that growth under typical conditions produces a transient instability. Lowering the temperature beneath $\sim$ 530 $^o$C at a growth rate of $\sim$ 0.3 nm/s produces a qualitative change in the way that the corrugations evolve. This temperature is close to that of a preroughening transition in the absence of growth [2], however on increasing the As2 flux the onset temperature for preroughening moves itup, while the onset temperature of the growth mode change moves itdown. We correlate the change in growth mode with a change in the surface reconstruction. [1] H. C. Kan, S. Shah, Tadayyon-Eslami, and R. J. Phaneuf, Phys. Rev. Lett, **92**, 146101, (2004). [2] V. P. **G12 13 Self-organized Evolution on Patterned GaAs(001) Surfaces during Homo-Epitaxial Growth*** HUNG-CHIH KAN, *Dept. of Physics, Univ. of MD, College Park, and Lab. for Physical Sciences* ERIN FLANAGAN, *Dept. of Materials Science and Engr., Univ. of MD., College Park* TABASSOM TADAYYON-ESLAMI, *Dept. of Materials Science and Engr., Univ. of MD, College Park, and Lab. for Physical Sciences* SUBRAMANIAM KANAKARAJU, CHRIS RICHARDSON, *Lab. for Physical Sciences* RAYMOND PHANEUF, *Dept. of Materials Science and Engr., Univ. of MD, College Park, and Lab. for Physical Sciences* We report on experimental characterization of morphological evolution of patterned GaAs(001) surfaces during homo-epitaxial growth. We lithographically patterned our GaAs(001) substrates with arrays of cylindrical pillars whose size and spacing are systematically varied. The growth of GaAs layers on the patterned substrate were performed in a MBE chamber at a substrate temperature of 580 [r]C. The growth rate is $\sim$ 2.7 Å/s. After each growth step, the surface topography is characterized with atomic force microscopy (AFM). AFM profiles along [-110] show that flat-topped pillars evolve into concave downward parabola whose curvature is nearly independent of the initial pillar diameter. We

also perform both physically based and phenomenological numerical calculations to simulate the growth and compare the results with our experimental observations.

**G12 14 Real-Time Studies of Ga Droplet Formation for the Directed Seeding of Semiconductor Nanopillars*** W. YE, B.L. CARDOZO, X. WENG, J.F. MANSFIELD, R.S. GOLDMAN, *University of Michigan* The directed self-assembly of low-dimensional semiconductor structures has been achieved using a variety of approaches to producing topographical patterns. However, an approach for producing highly ordered arrangements of nanostructures with well-controlled shapes and size distributions has yet to be developed. Therefore, we are exploring the seeded-assembly of semiconductor nanocrystal and nanopillars on substrates topographically patterned using a focused-ion-beam (FIB). For nanopillar formation, we have seeded ordered arrays of holes with controlled concentrations of Ga droplets using FIB implantation. These holes have nearly uniform sizes and shapes. By controlling the ion beam energy, current, and size, hole arrays with various sizes, depths, and periodicities may be produced. Interestingly, after scanning the ion beam over the patterned area, Ga atoms diffuse to the holes and agglomerate, leading to the formation of ordered arrays of nearly uniform sized Ga dots. We will discuss the mechanisms of Ga droplet formation and present real-time studies of Ga droplet dynamics and their interaction with various gases. We will also discuss the use of these ordered arrays of Ga dots as catalysts for vapor-liquid-solid growth of semiconductor nanopillars.

**G12 15 Real-Time UV-FEL PEEM of Silicide Nanostructure Coarsening Dynamics on Si(100)** MATTHEW ZEMAN, *North Carolina State University* WOOCHUL YANG, *Dongguk University* ROBERT NEMANICH, *North Carolina State University* The coarsening dynamics of nanoscale silicide ($TiSi_2$, $ZrSi_2$, $HfSi_2$) islands on Si(100) are observed in ultra high vacuum using tunable ultra-violet free electron laser (UV-FEL) excitation for photo electron emission microscopy (PEEM). The UV-FEL PEEM is employed for real-time, in situ observation of the nanostructure dynamics and evolution during continuous annealing at high temperatures (1200°C). In situ movies will be presented which detail the coarsening processes where the silicide nanostructures grow via Ostwald ripening and attractive migration and coalescence (AMC). AMC is a coarsening process where nearby islands are observed to migrate attractively towards each other and subsequently coalesce. This process has been attributed to the growth-decay flow of the island edges driven by a non-uniform chemical potential around the islands. This non-uniform chemical potential is predicted to result in an island shape distortion due to the local flux of adatoms from/onto the inner- facing edges of the coalescing islands. This non-uniform chemical potential is observed as an increase in the island radius along the migration direction as well as a decrease in the radius of curvature of the inner facing (growing) edges of the coalescing islands.

## SESSION G13: FOCUS SESSION: SPECTROSCOPY OF BIOMOLECULES FROM ISOLATED MOLECULES TO CELL ENVIRONMENT IV

**G13 1 Laser spectroscopy probes of biomolecular conformation: Valley-to-valley searches for molecular-scale mountain passes.***
TIMOTHY ZWIER, *Purdue University*

This talk will describe recent studies of the spectroscopy and conformational isomerization dynamics of isolated gas-phase biomolecules with several flexible coordinates. These studies employ conformation-specific excitation and detection, taking advantage of the unique infrared and ultraviolet signatures of the individual conformations when cooled in a supersonic expansion. The examples given will include recent studies of the bichromophore 3-(4-hydroxyphenyl)-N-benzyl-propionamide (HNBPA) and of the 'double-chain' molecule O-(acetamidoethyl)-*N*-acetyltyramine (OANAT). In collaboration with Jasper Clarkson, Esteban Baquero, Virgil Shubert, Tracy LeGreve and William James, Dept. of Chemistry, Purdue University.

**G13 2 Ultrafast dynamic exchange of hydrogen bonds.**
ROBIN HOCHSTRASSER

Measurements of H-bond dynamics in solutions aim to obtain energetics and equilibrium dynamics of making and breaking these bonds. Two dimensional IR with fs pulses can follow both the vibrational kinetics associated with H-bonds and the dynamic effects of exchange on vibrational coherence. The principles are analogous to those from 2D-NMR chemical exchange but the 2D IR measures dynamics on the fs to ps time scales and exchange is coupled to ultrafast

spectral diffusion. Therefore distinctive types of reactions can be accessed by 2D IR. Results will be presented for CN vibrators in liquid methanol and carbonyl and NH groups of peptides in water and methanol. In all examples the solute modes act as probes of the dynamics of the surrounding liquid structures. As a consequence the exchange coupling between different vibrators that results in energy transport along the chains of peptides is also seen. This research was supported by NSF-CHE, NIH-GM and by an NIH Resource Grant all to RMH.

**G13 4 Probing the conformation of DNA by time-resolved fluorescence*** ANITA JONES, ROBERT NEELY, ELEANOR BONNIST, DAVID DRYDEN, *University of Edinburgh* DALIA DAUJOTYTE, SAULIUS GRAZULIS, SAULIUS KLIMASAUSKAS, *Institute of Biotechnology, Vilnius* THOMAS LENZ, ELMAR WEINHOLD, *University of Aachen* The fluorescent adenine analogue, 2-aminopurine (AP), is a widely used probe of DNA structure and dynamics. We have investigated the time-resolved fluorescence of AP-labelled duplexes in single crystals, in solution and in frozen matrices, to elucidate the influence of interbase interaction and base dynamics on the photophysics of AP. DNA undergoes conformational change in response to interaction with agents such as enzymes and drugs. Base flipping, induced by DNA methyltransferase enzymes, is a remarkable example of conformational distortion; the target nucleotide is rotated around the phosphate backbone, out of the duplex and into the enzyme active site. We will report the first time-resolved fluorescence measurements of single crystals of AP-labelled DNA duplexes complexed with methyltransferase enzymes (M.HhaI and M.TaqI). Correlation of these results with studies on the analogous solution-phase systems shows that the fluorescence response of AP is a definitive indicator of the base flipping mechanism. Moreover, the AP decay parameters provide detailed information on the nature of the interaction between enzyme and duplex.

**G13 5 Conformational Structure Determination of Biomolecules in the Gas Phase using Broadband Fourier Transform Microwave Spectroscopy** BROOKS PATE, *University of Virginia* GORDON BROWN, BRIAN DIAN, KEVIN DOUGLASS, DAVID PRATT, *University of Pittsburgh* LEONARDO ALVAREZ, We have recently developed a true broadband Fourier transform microwave (FTMW) spectrometer that obtains the rotational spectrum in the 7.5 – 18.5 GHz range with 50 kHz resolution for each individual valve pulse in a molecular beam spectrometer. The ability to observe an 11 GHz broad rotational spectrum for each valve pulse is particularly useful for experiments where the molecular beam source conditions require optimization and in cases where the biological sample decomposes over a time scale of a few minutes. The high resolution of the measurement makes it possible to unravel the conformational complexity of gas phase biomolecules. Conformational assignments of the pure rotational spectrum of p-methoxyphenethylamine (MPEA) will be presented to illustrate the capabilities of the spectrometer. The spectrometer can also be employed in laser-FTMW double-resonance experiments where the conformational assignments in the pure rotational spectrum are used to automatically assign absorption features in either vibrational or electronic spectra.

*Invited Papers*

**G13 6 Probing secondary structures of peptide chains using gas phase laser spectroscopy.**
MICHEL MONS, *Lab. Francis Perrin, CEA/CNRS, Saclay, 91191 Gif-sur-Yvette, France*

A bottom-up approach involving conformer-specific IR studies of short peptide sequences enables us to map the intramolecular interactions that shape the peptide backbone, in particular those H-bonds that are responsible for stability and formation of secondary structures in proteins, like turns or helices. The combination of laser-desorption of solid samples coupled to the efficient cooling in a supersonic expansion makes it possible to isolate in the gas phase the lowest conformations of the energy landscape of small flexible biomolecules. The low temperature achieved enables spectroscopists to record UV spectra in which the contribution of each conformer populated can be distinguished and the corresponding conformation identified using IR/UV double resonance spectroscopy. Data collected are directly comparable to the best quantum chemistry calculations on these species and therefore constitute a severe test for the theoretical methods used. It will be shown how investigation of sequences with an increasing number of building blocks permits to deduce the robust structural trends of a peptide backbone: i) local conformational preference of the backbone in one-residue chains, ii) in capped dipeptides, the competition between a succession of local conformational preferences and

overall folded structures, in which a different type of H-bonding scheme, involving distant H-bonding sites along the backbone, takes place: in particular beta-turns, the secondary structure responsible for chain reversals, and finally iii) evidence for the spontaneous helical folding (short 3-10 helix) of three-residue chains will be presented, illustrating the relative weakness of the H-bonding in these molecular assemblies.

**G13 7 Permanent Electric Dipole Moments of Four Tryptamine Conformers in the Gas Phase. A New Diagnostic of Structure and Dynamics.*** DAVID PRATT, TRI V. NGUYEN, *University of Pittsburgh* Rotationally resolved electronic spectroscopy in the gas phase, in the absence and presence of an applied electric field, has been used to determine the charge distribution of a cross section of the energy landscape of tryptamine (TRA). We report the magnitude and direction of the permanent electric dipole moments of the four TRA conformers GPyout, GPyup, GPhup and Antiup in their $S_0$ and $S_1$ electronic states. Each dipole moment is unique, providing a powerful new tool for conformational analysis of biomolecules in the gas phase. A comparison of the results for the different conformers of TRA reveals that the position and orientation of the ethylamine side chain plays a major role in determining both the permanent and induced electric dipole moments of the different species in both electronic states

**G13 8 Thermodynamics of Membrane Proteins: Kinetics** DIPTI SHARMA, ATIN MANDEL, JOSE ARGUELLO, GERMANO IANNACCHIONE, *Worcester Polytechnic Institute* An AC-Calorimetric study of membrane proteins was performed at various scan rates in order to probe the energetics and dynamics of the unfolding mechanism. Two thermophilic (Archaeoglobus Fulgidus: AfCopA and AfCopA+ATP) and one mesophilic (E. Coli: EcCopA) membrane proteins were studied at scan rates of 5 and 30 K/hr. Clear signatures of the protein unfolding were found whose character was dependent on the presence of ligands and scan rate. The slower scan rate data reveal a much broader temperature range of unfolding with evidence of a two stage unfolding process. Comparison between the two scan rates indicates that the kinetics of the first unfolding process is complex while the second primary feature represents the stability limit of that particular protein.

**10:48**
**G13 9 Conformational Isomerism in 1-Heptanal** JONATHAN M. FISHER, LI-HONG XU, *University of New Brunswick* R.D. SUEMRAN, *National Institute of Standards and Technology* BROOKS PATE, KEVIN DOUGLASS, *University of Virginia* The rotational spectrum of 1-heptanal has been recorded over the 10 GHz to 22 GHz region using a pulsed-molecular-beam, Fourier transform microwave spectrometer. The spectrum has been analyzed using the jb95 spectral analysis program. The spectra of thirteen conformational isomers have been identified and assigned in the rich soup of observed transitions. Transitions of these isomers have relative intensities that are well above the intensity level of the onset of $^{13}C$ isotopomers, which are a factor of 100 down in intensity. In addition to the above 13 isomers, two additional spectra were identified and assigned that belong to dimers that consist of 1-heptanal and one water molecule. In order to map the observed spectra to conformational geometries, high-level itab initio calculations have been carried out. All fifteen observed conformers have been associated with itab initio determined structure configurations. In general, the agreement in rotational constants and dipole intensity pattern between the itab initio results and the experimentally observed spectra is quite good.

**G15 2 Elastic properties of monoclinic $Gd_5(Si_2Ge_2)$** O. SVITELSKIY, A. SUSLOV, T.A. LOGRASSO, D.L. SCHLAGEL, V.K. PECHARSKY, K.A. GSCHNEIDNER, JR., *Ames Laboratory, Iowa State University, IA50011* $Gd_5(Si_2Ge_2)$ is an alloy characterized by a giant magnetocaloric effect ($\Delta T/\Delta B \sim 8K/2T$) and a colossal strain (up to 10,000ppm) that exist due to a magnetic- martensitic phase transition occurring close to the room temperature. Because of these unique properties, $Gd_5(Si_2Ge_2)$ has a potential for energy efficient environmentally friendly refrigeration and actuation uses. We show the results of the first-ever ultrasonic study of a single crystal of this alloy. Sound speeds measured in a number of different geometries allowed us to determine the full elastic constant tensor for this material in the monoclinic phase. The anisotropy of elasticity of the crystal is demonstrated by the polar plots of the speed of sound, Young's modulus and linear compressibility in all three main crystallographic planes. The pure modes directions are determined. The bulk modulus is estimated at $2.58 \times 10^{11} dynes/cm^2$ and the Debye temperature at 250 K. Work in Ames is supported by the US DOE. Work in NHMFL is supported by the In-House Research Program, NSF and State of Florida.

**8:24**
**G15 3 Explanation of the discrepancy between the theoretical and experimental yield stresses in bcc metals** ROMAN GROGER, VACLAV VITEK, *University of Pennsylvania, Department of Materials Science and Engineering* We propose a mesoscopic model that is capable to explain the factor of 2 to 3 discrepancy between experimentally measured low-temperature

yield stresses of bcc metals and those typically determined by atomistic simulations of an isolated screw dislocation. The model suggests that the reason for this discrepancy is that in reality the glide of the screw dislocations is cooperative, as commonly observed at low and intermediate temperatures. In this case the stress needed to move the most highly stressed screw dislocation in an array of dislocations and simultaneously operate a dislocation source is estimated to be about a factor of 2 to 3 lower than the Peierls stress of an individual screw dislocation. Since the above-mentioned discrepancy has been encountered not only in bcc metals but also, for example, for the prism slip in hexagonal crystals, the proposed model is likely to hold more generally.

**8:36**

**G15 4 Optical Investigation of the Effects of Substrate Orientation on Oxidation of Single Crystal beta-nickel aluminum (NiAl)** SERIF URAN, *Pittsburg State University* MARCOS H. GRIMSDITCH, *Argonne National Laboratory* BOYD W. VEAL, *Argonne National Laboratory* PAUL, A. PAULIKAS, *Argonne National Laboratory* Nondestructive optical techniques have been used to study the oxidation of low-index crystal faces of single-crystal beta-nickel aluminum (NiAl) as a function of temperature. Using these techniques, residual stress, phase composition, and thickness of the scales were determined at various temperatures. The oxidation of the three low-index surfaces, (001), (110) and (111) exhibit discernible differences. Consistently lower stress values are observed on (001) surfaces. Fluorescence and Raman results indicate a higher concentration of theta-aluminum oxide (Al2O3) on (001) faces and lower concentrations on (111) faces at all temperatures between 800 and 1200 Celsius degrees. Although the residual stresses are higher on (110) faces, these are the only surfaces which maintain adherence up to 1450 Celsius degrees. All surfaces exhibit a stress anomaly between 1200 and 1250 Celsius degrees.

**8:48**

**G15 5 Short-Range Order Effects on the Thermodynamic Properties of the $Ni_3Al$ Alloy*** ALEX ANTONELLI, BERNARDO MEIRELLES, *Universidade Estadual de Campinas* CAETANO MIRANDA, *Massachussetts Institute of Technology* The reasons for the substantial changes induced by disorder in the thermodynamic properties of the $Ni_3Al$ alloy still remain controversial. While several computational studies have found a significant increase in both vibrational entropy and volume as the alloy becomes disordered, there is also evidence that these properties remain unchanged upon disordering. In this work, we present a computational study of the excess vibrational entropy and excess volume of the disordered $Ni_3Al$ alloy, in which, we focused on the interplay between short-range order and long-range order effects on these properties. Using the Simulated Annealing optimization technique, we obtained several structures that exhibit no long-range order, but have different degrees of short-range order. Excess vibrational entropies were computed using an empirical potential, while excess volumes were obtained using both: an empirical potential and itab initio techniques. Our calculations indicate that, both excess vibrational entropy and excess volume are substantially reduced in alloys that have no long-range order but have some degree of local order. Both methodologies used to model the alloy give rise to similar results for the excess volume, indicating that the short-range effects are not an artifact of how the system is modelled.

**G15 6 Molecular Dynamics Study of Self-Interstitial Atoms in BCC Metals: Crystallization in Mo and ferromagnetic Fe** DANIEL FINKENSTADT, DIMITRIOS PAPACONSTANTOPOULOS, MICHAEL MEHL, *Naval Research Laboratory* Among point defects, the self-interstitial atom (SIA) is less well investigated than its relative, the atomic vacancy. Experimentally, the SIA is important for understanding of embrittlement in irradiated materials, however there are other processes in which the SIA may also be important, namely, the solidification and crystallization, at the atomic scale, of matter from the amorphous state. Amorphous structure may be treated within the context of density functional theory as a network of SIA and vacancies. We will present tight-binding molecular dynamics (TBMD) studies of interactions between SIA, vacancies, surfaces and interfaces, within bcc-based metals, with focus on Mo and ferromagnetic Fe. We will show, via TBMD simulation, that structural transformation and mass transfer are facilitated and made rapid by the presence of a SIA. Results are compared, as a benchmark, to previous plane-wave pseudopotential results for SIA formation energies.

**9:12**

**G15 7 Atomic displacements in binary alloys** YEVGENIY PUZYREV, *Oak Ridge National Laboratory* J.S. FAULKNER, *Florida Atlantic University* G. E. ICE, C.J. SPARKS, *Oak Ridge National Laboratory* Molecular dynamics calculations are used to model the thermal and static displacements in copper and copper-gold alloys. Adjusted embedded atom potentials that give very accurate atomic sizes for the pure metals are used. The agreement with experiments supports the argument that this is a reliable approach for predicting displacements, and will be useful in interpreting experimental data on atomic displacements in metals and alloys. The positions of the atoms in a binary alloy at temperature $T$ at all times $t$,$\mathbf{R}_i(t)$, can be found using molecular dynamics (MD)[1] if the forces on the atoms are known. It is still necessary to use supercells, but they can contain thousands of atoms. The set of $\mathbf{R}_i(t)$ contains all the information about both static and thermal displacements. Of course, MD is a classical theory, and the only quantum mechanical effects appear in the construction of the forces.

**G15 8 First-Principles Predictions of Ordered Structures in Fe-Ni Alloys*** S. V. BARABASH, V. BLUM,[†]A. ZUNGER, *NREL* The observed ordered fcc Fe-Ni compounds are $L1_2$ $FeNi_3$ and (possibly metastable) $L1_0$ FeNi. Little is known about ordering tendencies in Fe-rich fcc alloys (stable at high $T$ at all compositions), despite the immense technological importance of such materials. We studied the $T = 0$ and finite-$T$ ordering in fcc Fe-Ni alloys, employing the mixed-basis cluster expansion approach built on *ab initio* input formation enthalpies. We address explicitly the fact that Fe-Ni alloys may occur in either of three distinct ferromagnetic phases: high-spin (HS) fcc, low-spin (LS) fcc, and bcc phases. We distinguish between fcc- and bcc- based structures by analyzing the coordination of the nearest neighbors, and between HS and LS fcc phases by analyzing the total magnetic moment and performing series of fixed-moment calculations. We cluster expand the properties of HS ferromagnetic fcc alloys, providing a special attention to the unstable HS fcc Fe end- point. We further compare the stability of our studied HS fcc compound

structures with alternative LS fcc and with bcc compound structures. For Fe-rich alloys, we find that due to instability of HS fcc Fe with respect to tetragonal deformations, the alloys have an exceptionally strong tendency to form (100) superlattices. For Ni-rich alloys, we predict new unsuspected ordered Fe-Ni compounds.

**G15 9 Interplay between diffusive and displacive transformations: A Phase-Field approach** RAJEEV AHLUWALIA, MATHIEU BOUVILLE, *Institute of Materials Research and Engineering, IMRE* The phase-field method has been extensively used to study martensitic (displacive) transformations. However they have been studied ''in isolation.'' We study the competition between the diffusionless martensitic transformation and a diffusive phase transition which involves phase separation. Phase separation occurs if diffusivity is high enough whereas martensite will form only if little diffusion can occur. A complete description of martensite-forming materials should incorporate both difuusive as well as diffusionless modes of structural change. We use phase-field simulations to study the interplay between these diffusive and displacive phase transformations at different temperatures. TTT (temperature-time-transformation) diagrams can thus be obtained. We study the role of the temperature-dependence of diffusivity on the microstructure and TTT diagrams, by strengthening or weakening this dependence keeping other parameters unchanged.

**G15 10 Lattice Dynamics of Hydrogenated Austenitic Steels** SERGEY DANILKIN, *ANSTO* ANSTO TEAM, We investigated hydrogen vibrations in of Fe-18Cr-10Ni and Fe-25Cr-20Ni austenitic steels doped in H gas atmosphere at pressures up to 7 GPa with maximum H content about H/Me=0.9. In case of less stable Fe-18Cr-10Ni alloy formation of the martensite phase was observed after hydrogen treatment [1]. Inelastic neutron scattering measurements were performed with spectrometers FANS at NIST and TOSCA at ISIS. Experiments show broad H peak in energy spectrum of scattered neutrons at frequencies above the metal band modes. Vibrational energy of H atoms in studied steels decreases from 132 meV at H/Me=0.0033 to 111 meV at H/Me=0.9 due to lattice dilatation [2]. The energy dependence of H modes on interatomic distance is compared with experimental data on other Me-H systems. The broadening of the H modes at H contents from 0.003 to 0.4 - where the single broad peak is observed - is most probably connected with the Me-H force constant disorder. At higher H contents - where H-peak has the two-component structure - the H-H interaction becomes important resulting in the dispersion of the optical phonon branches. [1]. M. Hoelzel, S.A. Danilkin, H. Ehrenberg, et al., Mat. Sci. Eng., 2004, v. A384, p. 255. [2]. M. Hoelzel, V. Rajevac, S.A. Danilkin, et al., J of Phys. – Cond. Mat., 2005, v. 17 (23), p. 3537.

**G15 11 Ab initio calculations of MAX phases $M_2TlC$ (M = Ti, Zr, Hf), and $M_2GaN$ (M = Ti, V, Cr)** SANJAY KHARE, SUNIL PATIL, JACOB WARNER, *Department of Physics, University of Toledo, Toledo, OH 43606* MAX phases have been a subject of interest recently [cf. M. W. Barsoum Prog. Solid St. Chem. 28, 201 (2000).] because of their useful mechanical, electrical and thermal properties. Here we have studied two groups of $M_2AX$ : (i) M = Ti, V, Cr, A = Ga and X = N and (ii) M = Ti, Zr, Hf, A = Tl and X = C. We calculated the lattice parameters, bulk modulus B and local electronic density of states (LDOS) of these phases using first-principles total energy calculations. Our computed lattice structural parameters match the experimental values within 5% for all six materials. Values for B were computed to be (i) 158, 170, and 180 GPa and (ii) 125, 120, and 131 GPa for the first and second group respectively. These values suggest that $Ti_2TlC$, $Zr_2TlC$ and $Hf_2TlC$ maybe the softest of all the MAX phases explored so far. The total density of states shows that all six materials are conducting. The major features in LDOS are i) the hybridization of the M d orbitals with X p orbitals and (ii) M d orbitals with A p orbitals.

**G15 12 Thermal transport and heat capacity of $Ti_3AlCN$ and $Ti_2AlC_{0.5}N_{0.5}$*** T. H. SCABAROZI, M. BARSOUM, A. GANGULY, S. GUPTA, *Department of Materials Engineering, Drexel University* S.E. LOFLAND, J.D. HETTINGER, P. FINKEL, *Department of Physics and Astronomy, Rowan University* We report an investigation of the specific heat and the thermal transport of a subset of the so-called MAX-phase family of materials $Ti_3AlCN$ and $Ti_2AlC_{0.5}N_{0.5}$ .The thermal transport results are analyzed to investigate the impact of mixing C and N on the X-sites. The heat capacity results are investigated to determine if this mixing influences the density of electronic states. We find that these mixtures have larger thermal conductivities than $Ti_3AlC_2$, $Ti_2AlN$ or $Ti_2AlC$ ($Ti_3AlN_2$ has not yet been synthesized). This increase has been attributed to an increase in the phonon thermal conductivity due to solid solution hardening. An increased elastic modulus is consistent with this result and the fact that the Debye temperature increases in the mixture and is in excess of 700K.

**G15 13 Electrical and structural properties of Tantalum nitride thinfilms near metal-insulator transition** LEI YU, RAKESH SINGH, JOHN ROWELL, NATHAN NEWMAN, *Dept. of Chemical and Material Engr., Arizona State Univ.* LIN GU, *Dept. of Physics, Arizona State Univ.* The resistivity of thin-film $Ta_xN$ can be tuned through the metal-insulator (MI) transition by adjusting the nitrogen partial pressure during the reactive sputtering process. Recent study show that NbTiN/$Ta_xN$/NbTiN structures with $Ta_xN$ tuned in this range can produce Josephson junctions with a high IcRn product and other device parameters required for the next generation of superconductive RSFQ circuits. Despite the practical possibilities, very little is known about transport over the small length scales associated with transversing the barrier. To address this issue, we focus on the transport and structural properties horizontally through NbTiN/$Ta_xN$/NbTiN structures and transversely across single $Ta_xN$ films for a wide range of $Ta_xN$ thicknesses. When TaxN films are deposited onto oxidized Si wafers, the resistivity (measured in the direction perpendicular to film growth) increases as films become thinner (from 500 nm to 20 nm). Surprisingly, the converse is found for NbTiN/$Ta_xN$/NbTiN structures. The conductivity of TaxN near the MI transition has temperature dependence of $\sigma(T) = \sigma(0) + AT^n$, common in disordered metallic systems. Our analysis of transport has allowed us to discern the role of percolation transport and the change in material parameter as a function of film thickness.

**G15 14 Alpha-plutonium's low-temperature elastic constants*** J. B. BETTS, A. MIGLIORI, H. LEDBETTER, D. DOOLEY, D.A. MILLER, *Los Alamos National Laboratory* Using resonant-ultrasound spectroscopy, we measured alpha-plutonium's polycrystal elastic constants between 18 and 344 K. All elastic constants – bulk, shear, extension, longitudinal moduli and Poisson ratio – behave smoothly during cooling, indicating no significant phase transition: electronic, magnetic, or structural. Both principal elastic constants (bulk and shear) increase about 30% upon cooling from 300 to 0 K, a large change among metals, which we attribute to 5*f*-electron delocalization. From the low-temperature elastic constants, we computed that the Debye temperature equals 205 K, exceeding significantly most previous estimates. From the bulk-modulus/temperature slope itdB/itdT, we computed that the Gruneisen parameter equals 5.1, intermediate among previous estimates using other approaches. Alpha-plutonium shows an unusually high shear-modulus/bulk-modulus ratio $G/B$, thus a low Poisson ratio: 0.18. Within 0.5%, the Poisson ratio shows temperature invariance; its small negative slope being opposite expectation. Again, we attribute this exceptional behavior to 5*f*-electron localization.

**G16 2 Mid-infrared transmission and reflection measurements of degenerately doped quantum wells*** A. J. HOFFMAN, L. ALEKSEYEV, E. E. NARIMANOV, C. GMACHL, *Princeton University* D. L. SIVCO, *Lucent Technologies* Degenerately doped quantum wells are proposed as a non-magnetic left-handed material in the mid-infrared wavelength range. Such anomalous wave propagation is predicted for waveguides with highly anisotropic dielectric constants. [V. A. Podolskiy, et al. Phys.Rev. B **71**, 201101 (2005)] Three samples consisting of 85 Å AlGaAs/InGaAs quantum wells and barriers were prepared. Doping densities of $1.7\text{x}10^{19}$ $cm^{-3}$ and $1.1\text{x}10^{19}$ $cm^{-3}$ were used for the degenerately doped samples and compared to a control sample doped $2\text{x}10^{17}$ $cm^{-3}$. Reflectance and transmittance as a function of incident angle, wavelength, and polarization were measured. Strong resonances were observed at 10.9 $\mu$m and 13.2 $\mu$m, respectively, for the two highly doped samples over a wide range of experimental incident angles (35[r] – 75[r]) for the relative reflectance of transverse magnetic to transverse electric polarization. No such resonances were observed for the low-doped sample or a highly doped bulk InGaAs sample.

**G16 3 Imaging with negative-refraction planar waveguides** ROBYN WANGBERG, *Oregon State University* EVGENII NARIMANOV, *Princeton University* VIKTOR PODOLSKIY, *Oregon State University* We study the electromagnetic properties of planar waveguides with non-magnetic strongly anisotropic dielectric cores. We develop an analytical description of the mode propagation in these systems and show that their index of refraction can be either positive or negative depending on the configuration. We further demonstrate that it is possible to combine planar waveguide structures to build a planar lens. We study the far-field resolution limit of such a lens and show that it is feasible to achieve resolution better than the free-space diffraction limit. The coupling to and from planar waveguide systems is also explored.

**G16 4 Super-Lensing and Sub-Wavelength Antennas in Mid-IR Using Silicon Carbide*** GENNADY SHVETS, DMITRIY KOROBKIN, YAROSLAV A. URZHUMOV, CHRISTIAN ZORMAN, *The University of Texas at Austin* Extraordinary properties of SiC in mid-infrared (negative dielectric permittivity and small losses) make it an ideal building block for making negative index meta-materials in that important part of the electromagnetic spectrum. We report on a series of experiments demonstrating that thin films of SiC can be used as a ''perfect'' near-field lens. We have theoretically designed and experimentally implemented a super-lens ion mid-IR using SiC. We also report excitation of electrostatic resonances of two structures based on a submicron film of crystalline silicon carbide: (a) nano-holes drilled in the free-standing SiC membrane, and (b) metallic nano-posts evaporated on the SiC membrane. Applications of nano-hole resonances to excitation of magnetic moments in nano-structured SiC and development of negative index materials will be discussed, as will be the prospects of using nano-structured SiC films for laser processing of materials on a nanoscale.

**G16 5 Surface Enhanced Raman Scattering from Vertical Arrays of Silver Nanowires** G. CHEN, *Department of Physics, The Pennsylvania State University, University Park, PA 16802 USA* J. HABIB, *Illuminex Corporation* T. RUSSIN, H.G. GUITIERREZ, PETER EKLUND, *Department of Physics, The Pennsylvania State University, University Park, PA 16802* We present results of optical studies of surface plasmons and surface enhanced Raman scattering (SERS) from vertical arrays of Ag nanowires. Arrays based on Ag wires with mean diameters d=100 nm have been studied. The wires were grown electrochemically in the pores of anodic aluminum oxide (AAO). To test the SERS activity of these vertical Ag nanowires arrays, we have carried out experiments to detect pyridine on the surface of the nanowires. The SERS enhancement factor is found to be in the order of $10^6$ compared to the Raman signal from bulk liquid. We also studied the surface plasmons of these nanowire arrays in transmission with the incident photon wavevector approximately parallel to the wire axis. Calculations of the plasmon resonances have been made and are found in reasonable agreement with the data.

**9:24**

**G16 6 Modeling Surface Plasmon Enhanced Contact Lithography** MATTHEW ARNOLD, RICHARD BLAIKIE, *MacDiarmid Institute for Advanced Materials and Nanotechnology, Electrical and Computer Engineering, University of Canterbury, New Zealand* Surface Plasmon Enhanced Contact Lithography (SPECL) is a technique for improving sub-wavelength image quality by placing a noble metal beneath the imaging layer in the near-field of a mask. Previous computational [1,2] and experimental[3] studies suggest that that SPECL can improve process latitude compared to pure contact techniques, but future investigations will benefit from a better understanding of the underlying mechanism. We present some numerical simulations, and interpret the results in terms of balanced interference of the ''sources'' consisting of the mask at the top and coupled plasmons at the bottom. Reflected evanescent fields are amplified by a factor that increases with the lateral propagation constant, and hence the usual ''phase'' decay is partially compensated. The observation of an optimal coupling distance is consistent with the inverse relationship between coupling distance and plasmon amplitude compared to the mask fields. Finally we present some data relevant to future experimental exploration. [1] R.J. Blaikie, and S. J. McNab, Assoc. of Asia Pacific Physical Societies Bull. **11**(3), 15 (2002). [2] D.B. Shao, and S.C. Chen, Opt. Express **13**, 6964 (2005). [3] D.B. Shao, and S.C. Chen, Appl. Phys. Lett. **86**, 253107 (2005).

**G16 7 A model for the influence of granularity in a negative refractive index metamaterial lens*** KEVIN WEBB, JIA-HAN LI, *Purdue University* An important goal in building a negative refractive index metamaterial lens at optical frequencies is the achievement of sub-wavelength image resolution. In assigning an effective medium negative refractive index, the electric and magnetic dipoles (which give rise to negative permittivity and permeability) need to be dense relative to the wavelength, i.e., operation near the center of the first Brillouin zone is a prerequisite. Sub-wavelength imaging requires good performance for a significant portion of the evanescent plane wave spectrum. We use a model comprised of discrete regions with negative permittivity and permeability, calculate the effective medium parameters, and show the impact of granularity level (scatterer density) on the performance of a discrete lens, using the slab lens as a reference. We thus arrive at a measure of metamaterial density required to achieve significant improvement over traditional lensing approaches.

*Supported in part by DOE and NSF.

**9:48**

**G16 8 Circuit elements at optical frequencies: A synthesis of first principles electronic structure and circuit theories** C. TANG, R. RAMPRASAD, *Department of Materials Science and Engineering, University of Connecticut* We present a new first principles based method to determine the equivalent circuit representations of nanostructured physical systems at optical frequencies. This method involves the determination of the frequency dependent effective permittivity of two constructs: an ordered composite system consisting of physical nano-elements using density functional theory, and an ordered arrangement of impedances using transmission line theory. Matching the calculated effective permittivity functions of these two constructs has enabled a mapping of the physical nano-system to its equivalent circuit. Specifically, we will show that silicon nanowires and carbon nanotubes can be represented as a series combination of inductance, capacitance and resistance. Once this mapping has been reasonably accomplished for a variety of physical systems, the nano-elements can be combined suitably to result in equivalent circuit topologies appropriate for optical and nanoelectronic devices, including left-handed (or negative refractive index) materials.

**10:00**

**G16 9 1-D, 2-D and 3-D Negative-Refraction Metamaterials at Optical Frequencies: Optical Nano-Transmission-Line and Circuit Theory** NADER ENGHETA, *University of Pennsylvania* ANDREA ALU, *University of Pennsylvania* In recent years metamaterials have offered new possibilities for overcoming some of the intrinsic limitations in wave propagation. Their realization at microwave frequencies has followed two different paths; one consisting of embedding resonant inclusions in a host dielectric, and the other following a transmission-line approach, i.e., building 1-D, 2-D, or 3-D cascades of circuit elements, respectively, as linear, planar or bulk right- or left-handed metamaterials. The latter is known to provide larger bandwidth and better robustness to ohmic losses. Extending these concepts to optical frequencies is a challenging task, due to changes in material response to electromagnetic waves at these frequencies. However, recently we have studied theoretically how it may be possible to have circuit nano-elements at these frequencies by properly exploiting plasmonic resonances. Here we present our theoretical work on translating the circuit concepts of right- and left-handed metamaterials into optical frequencies by applying the analogy between nanoparticles and nanocircuit elements in transmission lines. We discuss how it is possible to synthesize optical negative-refraction metamaterials by properly cascading plasmonic and non-plasmonic elements in 1-D, 2-D and 3-D geometries.

**G16 11 Numerical Calculations of the Magnetic Susceptibility of Split Gold Nanorings** JEREMY NEAL, BAHMAN TAHERI, PETER PALFFY-MUHORAY, *Liquid Crystal Institute, KSU* Metamaterials consisting of split ring resonators have shown negative permeabilities at microwave frequencies. A key challenge is the realization of such a negative index material in the visible spectrum. We consider here the magnetic susceptibility of cut gold nanorings as function of frequency. We have carried out numerical calculations of the polarizability of such particles using the Discrete Dipole Approximation of Draine and Flatau. We present our results for the magnetic susceptibility of different nanoparticle geometries, and compare our results with theoretical estimates. Since the susceptibilities are strongly anisotropic, liquid crystal-like orientationally ordered assemblies of such nanostructures may be useful in realizing bulk optical NIM materials.

**10:36**

**G16 12 Consequences of Spatial Antisymmetry on Light.*** ANGELO MASCARENHAS, BRIAN FLUEGEL, *NREL* When light traverses an interface across which the permittivity, $\varepsilon$, and permeability, $\mu$, change sign, it undergoes negative refraction and the medium with negative values of $\varepsilon$ and $\mu$ must be interpreted as having a negative refractive index $n = -\sqrt{\varepsilon\mu}$. In the past few years this has been experimentally demonstrated by several groups. We have analyzed light propagating in lattices comprised of 2-D tilings in which alternating tiles are made up of media with refractive index whose values alternate in sign acoss tile boundaries. Using both numerical ray tracing and wave equation expansion, we show that when the tiling belongs to certain antisymmetric plane groups, every light ray is exactly bound into a closed, lossless path. The extension to antisymmetric 3-D space groups is also discussed. The study provides unique insights into the consequences of spatial antisymmetry on light.

**G16 13 Measured polarization rotation loss in negative index metamaterials*** JOHN DEROV, BEVERLY TURCHINETZ, EVERETT CRISMAN, DRAYTON HANNA, ALVIN DREHMAN, *U. S. Air Force Research Lab* The loss mechanisms in left-handed or negative refractive index metamaterial are still not well understood, even for the most common volumetric form using split ring resonators and posts at microwave frequencies. Loss due to polarization rotation, which can only be determined in free space experiments, is both a significant and neglected mechanism. We have measured rotation angles as large as 25 degrees after transmission through negative index media. Polarization rotation is observed as a radiative loss since it reduces the co-polarized power transmitted through the medium. The apparent loss can be reduced by optimizing the receiver polarization. We have measured metamaterial shaped as wedge prisms and rectangular blocks, thereby including and excluding refraction effects. Wedge prisms necessarily include refraction effects. The rectangular blocks can exclude or include refraction by changing the incident angle from normal to oblique. We have investigated whether the polarization type of the transmitted wave is linear or elliptical by using circularly polarized receiver antennas. The results of these measurements will be presented and discussed.

**G17 1 The scanned-probe microscope as nano-metrology tool*** YING XU, K. MOLONI, M.G. LAGALLY, *nPoint, Inc., Madison WI 53714 www.npoint.com* Metrology is an essential requirement in the microelectronics industry. As features in computing and memory devices (and also in the flat-panel, hard disc, and CD/DVD industries) reach farther into the nanoscale, their metrology becomes increasingly difficult. Scanned–probe microscopes (SPMs) offer potential solutions. SPMs can produce images with resolution down to the atomic level. However, because of inherent nonlinearities, conventional SPMs possess poor metrology capabilities. Nanometrology requires closed-loop scanning, high throughput, and long-term stability, with subnanometer lateral and vertical resolution and extreme scan flatness over 100s of $\mu$m. We have developed metrology scanners suited for high-precision scanning and positioning applications. They have ultralow out-of-plane motion error ( $<$ 1 nm over 100 $\mu$m scan area). A DSP-based controller enhances the scanner performance. Advanced control algorithms improve dynamic characteristics of the system significantly by reducing phase lag and settling time. The motion control system routinely achieves sub-nanometer resolution and accuracy with high working bandwidth and long-term stability. Using the performance of these metrology scanners we propose a vision of a complete SPM-based CD metrology tool that will enable nanometrology of future generations of electronic devices.

**G17 2 Optical metrology of sub-wavelength critical dimensions of lines on Si wafers** B.M. BARNES, R. ATTOTA, T.A. GERMER, JAY JUN, E. MARX, H. PATRICK, M.T. STOCKER, R.M. SILVER, *NIST, Gaithersburg, MD* As semiconductor manufacturing progresses toward the 65 nm technology node, nondestructive characterization is required for the repeatable fabrication of devices. Optical metrology offers an advantageous solution in both cost and throughput, as the use of visible or uv light is less expensive to implement than scanning probe techniques and will offer greater flexibility as a parallel measurement process. The major impediment to using optics in the critical dimension (CD) metrology of features within the sub- wavelength regime is often thought to be the diffraction limit. However, comparisons of data to theoretical modeling can yield quantitative linewidth values.

Simulations indicate that sensitivity to changes in CD below 20 nm is accessible by using structured illumination, for example reducing the illumination numerical aperture (INA). To increase the rigor of this analysis, we have imaged single, isolated lines of Si on Si with it$\lambda = 546$ nm light with an INA$=0.11$. Although the lines measured in this case range in width nominally from 200 nm to 950 nm, the engineered illumination demonstrated here is directly applicable to the extensibility of optical metrology to technologically relevant dimensions. We also demonstrate that CD sensitivity can be enhanced further by collecting images as a function of focus position, mining additional linewidth information contained in the three-dimensional interference field above the sample.

**8:24**
**G17 3 Measurement of Thicknesses of High-$\kappa$ Gate-Dielectric Films on Silicon by Angle-Resolved XPS** CEDRIC POWELL, *NIST, Gaithersburg* WERNER SMEKAL, WOLFGANG WERNER, *Technical University of Vienna* We report on the use of a new NIST database for the Simulation of Electron Spectra for Surface Analysis (SESSA) in measuring thicknesses of candidate high-$\kappa$ gate-dielectric materials ($HfO_2$, $HfSiO_4$, $ZrO_2$, and $ZrSiO_4$) on silicon by angle-resolved XPS. For conventional measurements of film thicknesses, effective attenuation lengths (EALs) have been computed for these materials from SESSA as a function of film thickness and photoelectron emission angle (i.e., to simulate the effects of tilting the sample). These EALs are believed to be more accurate than similar EALs obtained from the transport approximation because realistic cross sections are used for both elastic and inelastic scattering in the film and substrate materials. We also present ''calibration curves'' showing calculated ratios of selected photoelectron intensities from thin films of $HfO_2$ on Si with an intermediate $SiO_2$ layer. These ratios provide a simple and convenient means of determining the thicknesses of $SiO_2$ and $HfO_2$ films for particular measurement conditions.

**8:36**
**G17 4 Terahertz Spectroscopy as a non contact estimation technique of defect states in high dielectric constant materials** AMARTYA SENGUPTA, APARAJITA BANDYOPADHYAY, *New Jersey Institute of Technology* HAKAN ALTAN, *City College of New York* JOHN FEDERICI, HAIM GREBEL, *New Jersey Institute of Technology* A large number of gate dielectric materials have been examined during the past few years to replace Silicon dioxide in the MOSFET industry to reduce gate leakage currents for microfabrication of devices. Among them, Hafnium based materials have become a very promising candidate. In the reported work, the effect of Hafnium dioxide films on p-type silicon substrates has been investigated and compared with conventional dielectric material, Silicon dioxide, using CW visible pump/THz probe spectroscopy. Drude analysis of the experimentally obtained differential transmission spectra evaluates the electric permittivity of the interfacial layer and the calculated defect density is found to be higher for $HfO_2$than for $SiO_2$which agrees with Hall measurements. Additional measurements on Silicon Nitride deposition and photoresist coated p+ Silicon on p-type silicon wafers without any oxide gave an interfacial defect density 50 times higher than that of $SiO_2$/p+ interface. Results indicate that the mobility of the layer underneath Hafnium is less than that of Silicon. Hence the present study emphasizes the advantage of THz spectroscopy as a non-contact tool for semiconductor metrological applications.

**8:48**
**G17 5 3D-Imaging of Non-spherical Silicon Nanoparticles Embedded in Silicon Oxide by Plasmon Tomography** AYCAN YURTSEVER, *School of Applied and Engineering Physics, Cornell University, Ithaca, NY 14850* MATTHEW WEYLAND, DAVID A. MULLER, We apply plasmon tomography to construct three-dimensional images of silicon nanoparticles in a silicon dioxide matrix, a materials system of interest for optical and storage devices, and at a level of detail and resolution not possible by conventional microscopies. We find that silicon particles with complex morphologies and high surface to volume ratios are dominant rather than the commonly assumed near-spherical structures. These results would affect quantum-confined excitons and interface density of states and, thus, the optical properties of this material. Our findings might explain some of the puzzles related with this material, including the broad photoluminescence band.

**G17 6 Metrology for new microelectronic materials.**
ERIC VOGEL, *NIST*

Traditional scaling of the CMOS Field-Effect-Transistor (FET) has been the basis of the semiconductor industry for 30 years. The 15 year horizon of the International Technology Roadmap for Semiconductors (ITRS) is reaching a point which ''challenges the most optimistic projections for the continued scaling of CMOS (for example, MOSFET channel lengths of roughly 9 nm).'' As silicon CMOS technology approaches its limits, new device structures and computational paradigms will be required to replace and augment standard CMOS devices for ULSI circuits. These possible emerging technologies span the realm from transistors made from silicon nanowires to heteroepitaxial layers for spin transistors to devices made from nanoscale molecules. One theme that pervades these seemingly disparate emerging technologies is that the electronic properties of these nanodevices are extremely susceptible to small perturbations in structural and material properties such as dimension, structure, roughness, and defects. The extreme sensitivity of the electronic properties of these devices to their nanoscale physical properties defines a significant need for precise metrology. This talk will provide an overview of emerging devices and materials, and, through example, an overview of the characterization needs for these technologies.

**G17 7 Internal dielectric interface: $SiO_2$- $HfO_2$** ONISE SHARIA, ALEX DEMKOV, GENADI BERSUKER, BYOUNG HUN LEE, Hafnia is the leading candidate to replace silica as the gate dielectric in CMOS technology. Typically, hafnia films are deposited by atomic layer deposition (ALD) on the oxidized surface of a silicon wafer. The oxide could be native or thermally grown. Therefore, the high-k dielectric film is not in direct contact with Si, but rather with silicon dioxide. We investigate theoretically the atomic structure of the $SiO_2$-$HfO_2$ interface, its energretics, and thermodynamic stability with respect to oxygen exchange across the interface. We have examined the electronic properties of the interface including the band discontinuity using density functional theory. To model the interface we build a supercell structure by connecting $\beta$-crystobalite (crystalline silica polymorph) and cubic hafnia. This model, while being obviously rather simplistic allows for systematic study of the dielectric thickness effects, and consistent placement of defects with respect to the interface. The striking atomic feature of the calculated interface structure is three-fold coordinated interfacial oxygen atoms connected to one Si and two Hf neighbors. The Si-O and Hf-O bond lengths are 1.62 and 2.1 Å, respectively. The energy of the interface is estimated to be in the range of 900-4000 erg/cm$^2$ depending on the oxygen chemical potential. The structure has no states in the gap, and the estimated valence band offset agrees well with the MIGS theory. We discuss the effect of vacancies on the band alignment, and possible implications of our results to Si-$SiO_2$-$HfO_2$-Metal stacks.

**G17 8 Nanometer-resolution measurement and modeling of lateral variations of the effective work function at metal-bilayer /oxide interfaces** W. CAI, K. -B. PARK, J. P. PELZ, *Dept. of Physics, The Ohio State University* Future CMOS technology will require metal gates with a ''tunable'' effective work function (EWF) to precisely adjust the transistor turn-on voltage. It was shown using itmacroscopic $C - V$ measurements that this could be done by adjusting the thickness of a very thin low-EWF metal covered by a high-EWF metal film (or vice-versa) on a $SiO_2$ film [1,2]. We are using nm-resolution Ballistic Electron Emission Microscopy (BEEM) and Internal Photemission (Int-PE) to investigate whether a 5-nm Pt/1.4-nm Al/$SiO_2$ gate stack has a itlaterally inhomogeneous energy barrier at the metal/$SiO_2$ interface, produced by nm-sized pinholes in the thin Al film. Initial measurements of the average BEEM threshold voltage vs. applied oxide bias do in fact suggest an inhomogeneous energy barrier at the interface. Further BEEM and Int-PE measurements and finite-element electrostatic simulations are on-going, and will be discussed. Work supported by the Semiconductor Research Corp. [1] Gao et al., Mat. Res. Soc. Symp. Proc. 765, D1.4.1-6 (2003). [2] I.S. Jeon et al., IEDM-04, 303 (2004).

**G17 9 Is the oxygen vacancy the dominating charge trap in hafnia based MOSFETs?** JACOB GAVARTIN, DAVID MUNOZ-RAMO, ALEXANDER SHLUGER, MARSHALL STONEHAM, *University College London, U.K.* GENNADI BERSUKER, *SEMATECH, TX, U.S.A.* One of the factors affecting performance of high-k based MOSFETS is the instability of the threshold voltage, $V_T$, attributed to a high concentration of the carrier traps in the dielectric stack. Bulk oxygen vacancies in $HfO_2$ had been suggested as dominating electric traps, although this has not been unambiguously proved. We present ab initio calculations of the vacancies and divacancies in the monoclinic $HfO_2$ with the charge states $+2,+1,0,-1,-2$. Recent electrical I-V measurements probing $V_T$ relaxation under pulsed electrical stress [1] infer that: 1. The charge trapping under the applied stress is significantly faster than de-trapping following stress release suggesting significance of lattice relaxation upon trapping. 2. The kinetics of this $V_T$ relaxation is multiexponential with dominating activation energies in the range and 0.25-0.45 eV. We juxtapose the experimental data with the energetic parameters obtained from the calculations and consider whether the charge trapping and de-trapping by the variously charged vacancy levels accounts for all available experimental trends. **G17 10 Resistive Switching of Individual Dislocations in Insulating Perovskites – A Potential Route Towards Nanoscale Non-Volatile Memories.** KRZYSTOF SZOT, WOLFGANG SPEIER, GUSTAV BIHLMAYER, RAINER WASER, *CNI & IFF, FZ Juelich* Electrically controlled resistive switching effects have been reported for a broad variety of binary and multinary oxides in recent years. In particular, titanates, zirconates, and manganites have been in the focus of the studies. In many cases, the mechanism of the switching and the geometrical extension of the phenomenon (filaments vs. bulk) are still under discussion. In this work, we present evidence for a redox-based switching mechanism and we indicate a potential route towards highly scalable non-volatile memories based on this switching effect. The challenge our work is to utilize resistive switching mechanism with the aim to construct itactive electronic elements on a real nanoscale level, here by reversibly switching the electrical properties of individual dislocations by electrical stimuli. We demonstrate that standard undoped $SrTiO_3$ single crystals, utilized as a model system, exhibit a switching behavior along filaments based on dislocations, mediated by oxygen transport. For this, we employed a three-step procedure: the crystals were, at first, annealed at elevated temperatures under reducing conditions, then exposed to 200mbar $O_2$ pressure at room temperature, and finally subjected to an electric field under ultrahigh vacuum (electroformation). This treatment induced in a metal-insulator ($SrTiO_3$)-metal (MIM) system a transition to metallic state. A hysteretic behavior appears after dynamical polarization of the MIM structure at the maximum electroforming currents. The shape of the I/V curve has the typical signature for bi-stable switching known for these types of perovskites. The positive temperature dependence of the resistance of the low- (LRS) and the high-resistance (HRS) state clearly identifies both states to be metallic in character. The inhomogeneity of the electrical transport becomes directly evident from a simple optical inspection and the conductivity maps as measured by LC-AFM of a planar structure. One can trace the formation of the filaments,

emerging from the cathode and propagating towards the anode during the electroformation process. These filaments are well-oriented along the $< 100 >$ -axis of the crystal and show a discrete and granular substructure on the nano-scale. The similarity in lateral distribution of exit points (spots) of conducting nano-filaments with respect to the distribution of etch pits suggests that the electrical transport along dislocations determines the micro- and meso-scopic electrical transport phenomena. Our results suggest that a dedicated contact arrangement is required to handle the filamentary conduction in a practical way by using macroscopic electrodes. At the same time, it emphasizes the need to control the relevant processes on the level of individual dislocations. With LC-AFM it is possible to specifically address single dislocations crossing the surface with adequate spatial resolution and use the conducting cantilever as the nano-electrode through galvanic point contact. We succeeded to initiate the local electroformation process for a single dislocation by applying a dc bias to the tip of the cantilever. Such nano-prepared dislocations reveal bi-stable switching behavior between a linear and a non-linear $I/V$-characteristics. The dynamic range of the electrical resistance covers at least 3 to 4 orders of magnitude at read-out voltages of 0.1 V. In order to develop a microscopic model for the filament, we performed first-principles calculations of extended, linear defects in $SrTiO_3$. Our analyse of electronic structure for extended defects with TiO enrichment establish that already subtle changes in O-content are sufficient to modulate the electronic properties and provide the necessary self-doping capability with a reversible transition between non-metallic and metallic behaviour. We propose a model for the resistive switching in $SrTiO_3$ based on the modulation of the electrical properties through electrical stimuli in a small segment of an orthogonal network of dislocations. Switching in our case corresponds then to an electrochemical ''closing'' or ''opening'' of the single dislocation in the uppermost portion of the network. Our results show that the switching behaviour in single-crystalline $SrTiO_3$ is an inherent property of the material and can be easily activated by external stimuli. Due to the availability of dislocation densities up to $10^{12}$ $cm^{-2}$ in single crystals and thin film, one can even envisage to approach the Tbit regime, as long as the dislocations can be successfully arranged into registered superstructures. In summary, evidence is given that the electrical conductance of individual dislocations in a prototype perovskite, $SrTiO_3$, can be switched between a low and a high conducting state by the application of an electrical field. We demonstrate on the basis of itab initio calculations and measurements with a scanning probe microscope SPM that the modulation of the electrical properties is related to the induced change in oxygen stoichiometry and the self-doping capability with a local insulator-metal transition along the core of the dislocations. A model is presented based on a three-dimensional network of such a filamentary structure to analyze the bi-stable resistive switching in the macroscopic metal-insulator-metal (MIM) structure. Our results show that electrically addressing individual dislocations in single crystals as well as epitaxial thin films provides a dynamic range for switching between low and high conducting states which covers several orders of magnitude in resistance and can be of technological interest for the application in Tbit non-volatile memory devices.

**G17 11 Electrical characteristic of metal-oxide-semiconductor with $NiSi_2$ nanocrystals embedded in oxide layer** JENN-KAI TSAI, IKAI LO, M.H. GAU, Y.L. CHEN, P.H. YEH, T.C. CHANG, PHYSICSDEPARTMENT, CENTER FOR NANO-SCIENCE & NANOTECHNOLOGY, NATIONAL SUN YAT-SEN UNIVERSITY, KAO TEAM, DEPARTMENT OF MATERIALS SCIENCE AND ENGINEERING, NATIONAL TSING HUA UNIVERSITY, HSINCHU, TAIWAN, REP COLLABORATION, The nano-structured electronic devices have received more attention recently. Metal-oxide-semiconductor structure with $NiSi_2$ nanocrystals embedded in the oxide layer, $HfO_2/SiO_2$, has been fabricated. Comparing with conventional ones, it could be operated under lower voltage and faster program/erase speed and has better endurance and retention. We have measured the temperature-dependent tunneling V-I curve on these $HfO_2/SiO_2$ nano-structured devices for the temperature from 1.2K to 300K. The results show an abnormal electrical characteristic. The tunneling V-I characteristics appear a new threshold voltage in the low temperature region, from 30K to 100K, while applied a negative voltage. The abnormal threshold voltage disappears when the temperature higher than 150K or lower than 30K. We attribute the new threshold voltage to the discrete quantum states of $NiSi_2$ nanocrystals in the oxide layer.

**G17 12 Photoemission Studies of Nitrided Hafnium Silicates for High-$\kappa$ Dielectrics** ANOOP MATHEW, KORHAN DEMIRKAN, *University of Delaware* CHANG-GONG WANG, GLEN WILK, *ASM America Inc.* ROBERT OPILA, *University of Delaware* Nitrided hafnium silicates are strong candidate materials for replacing the $SiO_2$ gate dielectric in transistors for low standby power applications. Integrating these materials with the silicon substrate of the channel or metal gates open up a variety of interfacial issues. Photoelectron spectroscopy with its sensitivity to local chemical bonding is an invaluable tool for investigating these interfaces. Hafnium silicates were deposited using Atomic Layer Chemical Vapor Deposition and subsequently nitrided. A maximum entropy based algorithm was used to non-destructively reconstruct concentration profiles as a function of depth from angle resolved photoemission data and a good correlation was obtained from depth profile data obtained using Medium Energy Ion Scattering. Nitrogen is seen to diffuse towards the gate stack/silicon interface at higher temperatures. Trends in the nitrogen and oxygen profiles suggest replacement of the oxygen with the nitrogen during nitridation. These films were rapid thermally annealed to study their phase stability, and shifts in the photoelectron spectra reveal behavior that is not entirely consistent with what would be expected with previously reported phase segregation of these films into pure $HfO_2$ and $SiO_2$. Interfacial charge associated with these systems is reflected in the photoemission spectra, and this complements observations from other techniques.

**G18 1 Excitons in the optical properties of nanotubes.***
CATALIN SPATARU,† *UC Berkeley and LBNL, Berkeley, CA 94704*

We present *ab initio* calculation of self-energy and electron-hole interaction (excitonic) effects on the optical spectra of single-walled carbon and BN nanotubes. We employed a many-electron Green's function approach that determines both the quasiparticle and optical excitations from first principles. We found important many-electron effects that explain many of the puzzling experimental findings in the optical spectrum of these quasi-one dimensional systems, and the calculated spectra are in excellent quantitative agreement with measurements. In carbon nanotubes, excitons can bind by as much as one eV in semiconducting nanotubes[a)]. We discovered that bound excitons also exist in metallic carbon nanotubes with binding energy of many tens of meVs[a)]. Excitonic effects are shown to be even more inportant in BN nanotubes than in carbon nanotubes. Unlike the carbon nanotubes, theory predicts that excitons in some BN nanotubes are comprised of coherent superposition of transitions from several different subband pairs[b)]. We have also calculated the radiative lifetime of excitons in semiconducting carbon nanotubes. Assuming a thermal occupation of bright and dark exciton bands, we find an effective radiative lifetime of the order of 10 ns at room temperature, in good accord with recent experiments[c)]. **a)** C.D. **G18 2 Exciton radiative lifetime in carbon nanotubes** VASILI PEREBEINOS, JERRY TERSOFF, PHAEDON AVOURIS, *IBM - Watson Research Center* The optical properties of carbon nanotubes are dominated by excitons, and the exciton radiative lifetime determines the optical efficiency. We calculate the exciton radiative lifetime as a function of tube diameter and chirality, finding an unusual nonmonotonic temperature dependence [1]. This reflects the crucial role of exciton bands that are optically inactive, due to spin or parity, below the optically active exciton. We determine the scaling with diameter of the singlet-triplet and parity forbidden exciton splittings. We also calculate the exciton dispersion, finding a non-parabolic behavior of the optically active band. Excitons that thermalize into low-energy optically inactive bands cannot contribute to light emission, unless they are thermally excited into the active band, resulting in reduced emission yield at low temperature. However, in real systems there is typically some symmetry breaking, which mixes optically allowed and forbidden bands; and as a result, some emission is still possible from the nominally forbidden bands. This may account for the multiple emission peaks and complex temperature dependence seen in some experiments. [1] NanoLett. 5 DOI: nl051828s (2005).

**G18 3 Magnetic brightening of ''dark'' excitons in carbon nanotubes** S. ZARIC, J. KONO, *Dept. of Elec. & Comp. Engineering, Rice Univ.* X. WEI, *NHMFL, Florida State Univ.* R. H. HAUGE, R. E. SMALLEY, *Chemistry Dept., Rice Univ.* We have measured polarized-excitation photoluminescence (PL) on micelle-suspended single-walled carbon nanotubes (SWNTs) in aqueous solution in external magnetic fields ($B$) up to 45 T at room temperature. Each PL peak, corresponding to a specific chirality, splits into two in a $B$ and the amount of splitting increases with $B$. The magnetic field dependence of the relative intensities of the two peaks reveals that the lower-energy peak increases in intensity (or ''brightens'') with increasing $B$. These results can be understood in terms of ''magnetic brightening'' of an excitonic state that is ''dark'' at 0 T. Namely, recent calculations taking into account intervalley Coulomb mixing in semiconducting SWNTs predict the existence of a dark excitonic state at an energy $\Delta_X$ below the lowest optically active (bright) excitonic state. On the other hand, magnetic flux it$\phi$ threading a nanotube removes the intervalley degeneracy which is seen in absorption measurements as peak splittings by an amount $\Delta_{AB}$ proportional to it $\phi$ (when it$\phi/\phi_0 \leqslant$ 1/6, it$\phi_0$: magnetic flux quantum). While two equally-bright excitonic peaks are predicted and observed at high fields ($\Delta_{AB} > > \Delta_X$), [1] magnetic brightening is expected at lower fields ($\Delta_{AB} \sim \Delta_X$), which is consistent with our observations. **G18 4 Diameter and chirality dependence of exciton properties in carbon nanotubes** RODRIGO CAPAZ, *Instituto de Fisica, UFRJ, Brazil* CATALIN SPATARU, *U. C. Berkeley* SOHRAB ISMAIL-BEIGI, *Yale University* STEVEN LOUIE, *U. C. Berkeley* We calculate the binding energies and sizes of excitons in carbon nanotubes using a symmetry-based, effective-mass, variational method. This approach provides exciton binding energies in good agreement with available first-principles results and its simplicity allows calculations for a variety of diameters ($d$) and

chiralities. The exciton binding energies present an overall decrease with $1/d$, with strong chirality dependence and family behavior. The exciton sizes scale with $d$, also showing family behavior. We also address the important issue of bright-dark exciton splittings, which are found to decrease as $1/d^2$. Dependence of these properties on the dielectric screening will also be addressed, in the light of recent experimental measurements. This work was supported in part by the NSF under Grant No. DMR04-39768, and the U.S. DOE under Contract No. DE-AC03- 76SF00098.

**G18 5 Nearly quantitative fitting of exciton energies and exciton binding energies of semiconducting single-walled carbon nanotubes (S-SWCNTs) within a $\pi$-electron model*** ZHENDONG WANG, *University of Arizona* SUMIT MAZUMDAR, *University of Arizona* We use to Pariser-Parr-Pople $\pi$-electron Hamiltonian, which has been widely used to understand the excitonic energy spectra of $\pi$-conjugated polymers, to determine the energy spectra of S-SWCNTs. For the Coulomb interaction parameters, we use the screened Ohno parameters that were successfully used before for the quantitative fitting of the excitonic energy spectrum of poly-(paraphenylenevinylene)[1]. In order to take into account of the curvature effects, we use a $\pi$-electron nearest neighbor hopping integral that is substantially smaller than the standard 2.4 eV. With these modified parameters we are able to fit the lowest two exciton energies of a very large number of S-SWCNTs. We make detailed comparisons between the calculated and experimental[2]. We also obtain a binding energy of $\sim$ 0.4 eV for the lowest exciton of S-SWCNTs with diameters $\sim$ 0.8 nm, in agreement with experiments.

**G18 6 Determination of the exciton binding energy in single-walled carbon nanotubes** TODD KRAUSS, ZHENJIA WANG, HERMENEGILDO PEDROSA, LEWIS ROTHBERG, *University of Rochester* The optical properties of single-walled carbon nanotubes (SWNTs) are intrinsically important for potential applications in photonics and also provide insight into their structural and electrical properties. Absorption and emission of semiconducting SWNTs are dominated by excitonic effects, but a determination of central features such as exciton binding energies remains elusive. We will present measurements of the exciton binding energy in SWNTs using resonance Raman scattering of isolated SWNTs under an electrochemical bias. The Raman intensity under an applied voltage is sensitive to state filling and enables a determination of the (electronic) gap between the second Van Hove singularities in densities of states for electrons and holes in specific semiconducting SWNTs. On the other hand, Raman scattering preferentially selects sets of SWNTs whose excitonic transitions (optical gap) are resonant with the incident and scattered photon energies. Simultaneous measurement of the electronic gap and exciton resonance allows us to infer binding energies for the exciton of 0.49 and 0.62 eV for tubes with structural (n,m) indices (10, 3) and (7, 5), respectively. Analogous Raman and electrochemical studies in metallic SWNTs imply the absence of a sharp excitonic feature.

**G18 7 Nanotube exciton spectrum: Triangular quantum well model.** SLAVA V. ROTKIN, *Lehigh University, Physics Department, 16 Memorial Dr E, Bethlehem, PA 18015, e-mail: rotkin@lehigh.edu* ALEXEY G. PETROV, *Ioffe Institute, St.Petersburg, Russia* The analytical solution for the problem of NT-exciton is found using the approximation for the **screened** Coulomb potential between the electron and hole. We derive the screening via calculating a self-consistent dielectric function with **both spatial and time dispersion** taken into account, $\varepsilon(\vec{q},\omega)$, which characterizes the response to the $\vec{q}$ component of the Coulomb potential at the frequency $\omega$. The latter corresponds to the energy of the exciton and is to be sought. We calculated the RPA dielectric function of the SWNT in the orthogonal tight-binding approach. Then, the inverse Fourier transform of the screened Coulomb potential gives the shape of the potential well for the electron-hole pair (direct Coulomb interaction term). We show that this screened potential can be approximated by a triangular quantum well, which model allows ananlytical solutions for the exciton wavefunction and the binding energy. The exchange term is short-ranged and can be added as the delta-function barrier in the middle of the well. The exciton binding energy is calculated to be a universal function of $E_g$, the one-particle band gap, $R$, the NT radius and $\lambda$, the electric length in the triangular quantum well potential. The effective Bohr radius is also a universal function of $R$ and $\lambda$. The analytical expression for the oscillator strength of the optical transition is presented.

**G18 8 Theory of electroabsorption in semiconducting single-walled carbon nanotubes*** HONGBO ZHAO, SUMIT MAZUMDAR, *University of Arizona* Eletroabsorption (EA) is a standard nonlinear optical technique to probe the excitonic characteristics of semiconductors.[1] In the context of single-walled carbon nanotubes (SWCNTs) the advantage of EA is that it can directly probe the excitons associated with higher bands, which lie in the continuum region of the lowest band, and cannot be probed by other nonlinear optical techniques like photoinduced absorption or two-photon absorption. Although currently it is still difficult to carry out EA experiments, because it requires separation of semiconducting SWCNTs from metallic ones, theoretical calculations can provide a benchmark results for future study. We have calculated EA for several S-SWCNTs with both zigzag and chiral tubes.[2] For the lowest exciton we find the usual Stark shift, the emergence of absorption due to two-photon states and continuum band. We also find unusual and interesting behavior of the higher energy excitons from second band.

**G18 9 Interactions between individual carbon nanotubes studied by Rayleigh scattering spectroscopy** TONY HEINZ, *Columbia University* FENG WANG, MATTHEW SFEIR, LIMIN HUANG, X.M. HENRY HUANG, YANG WU, JAEHEE KIM, JAMES HONE, STEPHEN O'BRIEN, LOUIS BRUS, Single-walled carbon nanotubes (SWNTs), with diameters of nanometers and lengths up to millimeters, represent highly one-dimensional (1D) systems. Because all the carbon atoms of a SWNT lie on its

surface, the physical properties of SWNTs depend sensitively on local environment.[1] In particular, the electronic properties of SWNTs are altered by inter-tube coupling whenever nanotube bundles are formed. We examine such inter-tube interactions experimentally at the single nanotube level. This is achieved by applying Rayleigh scattering spectroscopy [2] to probe the optical transitions of individual SWNTs in their isolated and bundled forms. Upon bundling, the transition energies of SWNTs are observed to undergo red shifts of tens of meVs, without any significant line broadening. These inter-tube coupling effects can be understood as arising from the mutual dielectric screening of SWNTs in a bundle. 1. Kong, J., et al., Science, **287,** 622 (2000). 2. **G18 10 Exciton dynamics in DNA suspended SWNT agglomerates: From delocalized to one-dimensionally confined excited states** JARED J. CROCHET, *Vanderbilt University* MICHAEL ARNOLD, *Northwestern University* MARK HERSAM, *Northwestern University* ZIPENG ZHU, *Vanderbilt University* TOBIAS HERTEL, *Vanderbilt University* Exciton dynamics in chirality enriched, DNA suspended single-wall carbon nanotube agglomerates are studied using linear absorption, spectrofluorimetry, and ultrafast pump-probe spectroscopies. Suspended SWNT ropes with controlled diameter are isolated using isopycnic density gradient fractionation. Photoluminescence quantum yields are found to decrease with increasing rope diameter concomitantly to a broadening and redshift of exciton transitions. Spectrally resolved optical transients reveal that excited state dynamics are characterized by an increase of $E_{11}$ subband exciton decay rates as the rope size increases. These findings are discussed in terms of the roles of intertube coupling and exciton delocalization.

**G18 11 Raman characterization of electronic transition energies of metallic single-wall carbon nanotubes** HYUNGBIN SON, *Department of Electrical Engineering and Computer Science, MIT, Cambridge, MA* ALFONSO REINA CECCO, *Department of Materials Science And Engineering, MIT, Cambridge, MA* JING KONG, *Department of Electrical Engineering and Computer Science, MIT, Cambridge, MA* MILDRED DRESSELHAUS, *Department of Electrical Engineering and Computer Science and Department of Physics, MIT, Cambridge, MA* Theoretical studies using extended tight-binding model are shown to reproduce the optical transition energies of single-wall carbon nanotubes (SWNTs) obtained by experimental studies. However, some of the optical transitions for metallic SWNTs predicted by theory are not reported in previous experimental studies. We present that Raman characterization on a large number of individual SWNTs reveals these missing optical transitions. The intensity variations of different optical transitions are attributed to electron-phonon matrix elements.

**G18 12 Inelastic X-ray Scattering Studies of Plasmons in Carbon Nanotubes** M. H. UPTON, *Brookhaven National Laboratory* D. CASA, T. GOG, *Argonne National Laboratory* J. MISEWICH, J. P. HILL, *Brookhaven National Laboratory* D LOWNDES, G. ERES, *Oak Ridge National Laboratory* We report preliminary inelastic x-ray scattering measurements of the plasmon dispersions in oriented multi- and single- walled carbon nanotubes (M- and S-WCNT) and compare them to the plasmon dispersion in graphite. Two plasmon bands are observed dispersing along the nanotubes' axes: the $\pi$ and $\pi + \sigma$ plasmon bands. The $\pi + \sigma$ plasmon band exhibits an apparent systematic variation in energy. Specifically, it has a lower energy in MWCNT than in graphite, and a still lower energy in SWCNT. The energy of the $\pi + \sigma$ plasmon band is determined by the plasma frequency of the material, which is proportional to the square root of the electron density. We postulate that the energy shift is a result of a surface effect – the electron wave function extends past the surface, lowering the average electron density in the bulk. The higher surface-to-volume ratio of the mostly SW sample would then lower the plasmon frequency with respect to the MWCNT sample and graphite. Thus, the systematic variation in plasmon frequency may be explained by a lowering of the net electron density by the surfaces in S- and M-WCNT. Work performed at BNL and the Advanced Photon Source was supported by the US DOE under contracts No. DE-AC02-98CH10886 and No. W-31-109-Eng-38 respectively.

**G18 13 Atomic Entanglement in Carbon Nanotubes.*** IGOR BONDAREV, BRANISLAV VLAHOVIC, *North Carolina Central University* The development of materials that may host quantum coherent states is a critical research problem for the nearest future. Recent progress in the growth of centimeter-long small-diameter single-walled carbon nanotubes (CNs) [1] and successful experiments on the encapsulation of single atoms into CNs [2], stimulate the study of dynamical quantum processes in atomically doped CN systems. We have recently shown [3] that atomic states may be strongly coupled to vacuum surface photonic modes in the CN, thus forming quasi-1D cavity polaritons similar to those observed for quantum dots in semiconductor nanocavities [4], which were recently suggested to be a possible way to produce the excitonic qubit entanglement [5]. Here, we show that, being strongly coupled to the (resonator-like) cylindrical nanotube environment, the two atomic quasi-1D polaritons can be easily entangled as well, thus challenging a novel alternative approach towards quantum information transfer over centimeter-long distances. C.T. FOXON, B.L. GALLAGHER, *U. of Nottingham* A.H. MACDONALD, *U. of Texas* M. POLINI, *NEST-INFM, Pisa* M. SAWICKI, *Polish Academy of Science* J. KOENIG, *Ruhr-Universitat* We report on a comprehensive combined experimental and theoretical study of Courie temperature trends in (Ga,Mn)As ferromagnetic semiconductors. Broad agreement between theoretical expectations and measured data allows us to conclude that $T_c$ in high-quality metallic samples increases linearly with the number of uncompensated local moments on $Mn_{Ga}$ acceptors, with no sign of saturation. Room temperature ferromagnetism is expected for a 10% concentration of $Mn_{Ga}$. Based on the analysis of magnetotransport and magnetization data we find no fundamental obstacle to substitutional $Mn_{Ga}$ doping in high-quality materials beyond our current maximum level of 6.8%, although this achievement will require further advances in growth control. Modest charge compensation does not limit the maximum $T_c$ possible in ferromagnetic semiconductors based on (Ga,Mn)As. Ref: Jungwirth et al. Phys. Rev. B 72, 165204 (2005).

**G19 2 Spin and Charge Relaxations in Magnetic and Nonmagnetic Narrow-gap Semiconductors** K. NONTAPOT, A. GIFFORD, T. MERRITT, G. A. KHODAPARAST, *Department of Physics, Virginia Tech.* S. J. CHUNG, N. GOEL, M. B. SANTOS, *Department of Physics and Astronomy, University of Oklahoma* T. WOJTOWICZ, X. LIU, J. K. FURDYNA, *Department of Physics, University of Notre Dame* In light of the growing interest in spin-related phenomena and devices, there is now renewed interest in the science and engineering of narrow gap semiconductors. Narrow gap semiconductors offer several scientifically unique features such as a small effective mass, a large g-factor, a high intrinsic mobility, and large spin-orbit coupling effects. We will discuss our recent time resolved studies on InSb quantum wells with symmetric and asymmetric confinement potentials and InMnSb ferromagnetic structures with different Mn contents. We have measured the carrier and spin dynamics by degenerate and non-degenerate pump-probe and Kerr effect spectroscopy at different temperatures and laser intensities in these unique structures with strong spin-orbit interaction. **G19 3 Spin Waves in GaMnAs/GaAs Superlattices** D. M. WANG, R. MERLIN, *University of Michigan* Y. J. CHO, X. LIU, J. K. FURDYNA, *University of Notre Dame* We report on the spin-wave behavior of GaMnAs/GaAs superlattices as a function of the thickness of the nonmagnetic layer. Spin-wave frequencies were determined from time-domain magnetic Kerr measurements using a standard pump-probe setup. We studied two superlattices grown by molecular beam epitaxy on GaAs (001) substrates and, for comparison purposes, a single 120-nm-thick $Ga_{0.955}Mn_{0.045}As$ layer. The superlattices consist of 6 repetitions of 20-nm-thick $Ga_{0.955}Mn_{0.045}As$ layers separated by either $d = 3$ or 6 nm of GaAs. For magnetic fields $H < 0.22$ T, applied along the magnetic easy axis [100], the thin film and the superlattices exhibit a nearly $d$-independent mode of frequency it$\nu \cong 5 + 33$itH (GHz), whereas the sample with $d = 6$ nm shows a second oscillation at it $\nu \cong 7 + 33$itH (GHz), which we assign to a higher-order confined spin-wave. The existence of this mode is tentatively ascribed to a reduction in the coupling between neighboring magnetic layers.

**G19 4 Measurement of the *s-d* exchange coupling in GaMnAs quantum wells.***
MARTINO POGGIO,† *Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106*

The discovery of ferromagnetism in zinc-blende III-V Mn-based compounds and the realization that this collective magnetic behavior is mediated by delocalized or weakly localized holes has given a technological impetus for developing a clear picture of the carrier-shell exchange couplings. Surprising results regarding the magnitude and sign of the exchange between *s*-like conduction band electrons and electrons localized in the *d*-shell of the $Mn^{2+}$ impurities point to deficiencies in the current theory which has successfully described experimentsin II-VI DMS within a higher regime of doping[1]. Measurements of coherent electron spin dynamics in $Ga_{1-x}Mn_xAs/Al_{0.4}Ga_{0.6}As$ quantum wells with $0.003\% < x < 0.2\%$ show an antiferromagnetic (negative) *s-d* exchange coupling, $N_0\alpha$. The magnitude of $N_0\alpha$ varies as a function of width of the quantum well, which is consistent with a large and negative contribution due to kinetic exchange. MBE growth conditions are optimized in order to produce GaMnAs with low defect densities in which coherent spin dynamics can be observed optically, while at the same time incorporating enough Mn to make the *s-d* coupling observable. Polarization-resolved photoluminescence and reflectance measurements reveal the effects of *p-d* exchange between carriers in the valance band and spins localized on Mn sites. Light Mn doping is also seen to maximize the carrier electron spin lifetime, indicating the importance of the Dyakonov-Perel decoherence mechanism in these structures.

**G19 5 Confinement engineering of s-d exchange interactions in GaMnAs quantum wells*** N.P. STERN, R.C. MYERS, M. POGGIO, A.C. GOSSARD, D.D. AWSCHALOM, *Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106* Recent measurements of coherent electron spin dynamics have observed antiferromagnetic *s-d* exchange coupling between conduction band electrons and electrons localized on $Mn^{2+}$ impurities in GaMnAs quantum wells[1]. Here we discuss systematic measurements of the *s-d* exchange interaction in $Ga_{1-x}Mn_xAs/Al_yGa_{1-y}As$ quantum wells with different confinement potentials using time- resolved Kerr rotation spectroscopy. Extending previous investigations of the well width dependence of the *s-d* exchange, $N_0\alpha$, we find that the magnitude of the exchange parameter, $N_0\alpha$, varies as a function of both well width and well depth ($y$). Both phenomena reduce to a general dependence on confinement energy, which is well-fit to a model taking into account the effect of kinetic exchange and band mixing on the exchange parameters.

**G19 6 Controlled placement of Mn acceptors in GaAs (110) surfaces: Crystal orientation and spacing dependences for interactions between Mn acceptors*** DALE KITCHEN, ANTHONY RICHARDELLA, ALI YAZDANI, *Princeton University* We report a controlled incorporation process substituting single Mn atoms into acceptor sites in GaAs (110) surfaces using a low temperature scanning tunneling microscope (STM). The incorporation process brings a Ga atom to the surface as an adsorbate loosely bound to the Mn that has replaced it in the lattice. Displacement of a Ga atom away from the substituted Mn via STM manipulation isolates the Mn atom in the surface layer acceptor configuration. In this acceptor configuration Mn atoms give rise to strong in-gap energy levels, with unusual and detailed spatial structure of highly anisotropic character. Modifications to this in-gap resonance level and its structure occur under controlled placement of two closely spaced Mn acceptors, revealing a striking dependence upon crystal orientation and spacing. For certain pair orientations, strong bonding/antibonding-like interactions split the in-gap level of the single Mn state, while the in-gap levels of other pairs of comparable spacing but different orientation are degenerate with the isolated Mn state.

**G19 7 Magnetic and Chemical Depth Profiles of an Exchange-Biased MnO/GaMnAs Bilayer** BRIAN KIRBY, *Los Alamos National Laboratory* JULIE BORCHERS, *National Institute of Standards and Technology* JIM RHYNE, MICHAEL FITZSIMMONS, *Los Alamos National Laboratory* XINYU LIU, JACEK FURDYNA, *University of Notre Dame* There is a great deal of interest in development of high Curie temperature (Tc) ferromagnetic (FM) semiconductors for use in spintronic applications. GaMnAs may be a candidate for such applications, as it shows true long range FM order among Mn at Ga sites, and has a relatively high Tc (up to 173 K). For many device applications, the ability to pin the magnetization of a FM semiconductor to a preferred direction is highly desirable. This can be achieved by exchange coupling a GaMnAs layer to an adjacent antiferromagnetic (AFM) layer in order to produce an exchange-bias in the FM layer. We report on polarized neutron reflectivity and x-ray reflectivity studies of a GaMnAs film exchange biased by an AFM MnO overlayer. Using the depth sensitivity of these reflectivity techniques, we have chemically and magnetically characterized the MnO/GaMnAs interface, and have investigated the magnetization reversal process by comparing the magnetic depth profile at the coercive field to the profile at magnetic saturation.

**G19 8 Asymmetric Planar Hall Effect in (Ga,Mn)As/MnO Exchange-Biased Structures** ZHIGUO GE, W. L. LIM, S. SHEN, Y. Y. ZHOU, X. LIU, J. K. FURDYNA, M. DOBROWOLSKA, *Department of Physics, University of Notre Dame, Notre Dame, IN 46556* We report the observation of asymmetric Planar Hall Effect (PHE) in a series of exchange-biased (EB) (Ga,Mn)As/MnO ferromagnetic (FM)/antiferromagnetic (AFM) bilayer structures after field cooling. The process of magnetization reversal was systematically studied by PHE measurements by varying the direction of the in-plane applied magnetic field. The analysis of experiment results based on the Stoner-Wohlfarth model (including domain nucleation and expansion in the FM layer) revealed that two magnetization reversal mechanisms are present in these EB systems due to the exchange coupling between MnO and (Ga,Mn)As: the magnetization reversal undergoes either a full circle or a half circle, depending on the direction of the applied field relative to the cooling field. Our model is confirmed by the close agreement between experimental data and theoretical predictions for the angular dependence of the exchange bias and of the coercive field. Supported by NSF Grant DMR02-45227.

**G19 9 Non-collinear giant magnetoresistance in (Ga,Mn)As/p-GaAs/(Ga,Mn)As trilayers** GANG XIANG, MENG ZHU, BEN LI SHEU, PETER SCHIFFER, NITIN SAMARTH, *Physics Dept., Penn State University, University Park PA 16802* Giant magnetoresistance (GMR) due to spin-dependent scattering has been extensively studied in ferromagnetic metal multilayers. However, the effect has eluded observation in ferromagnetic semiconductor multilayers where other sources of magnetoresistance (MR) are usually dominant. Here, we report the possible observation of GMR in (Ga,Mn)As/p-GaAs/(Ga,Mn)As trilayers. Samples are designed such that the (Ga,Mn)As layers have distinct coercive fields and the p-GaAs spacer layer has a conductivity comparable to the (Ga,Mn)As layers. We measure longitudinal and transverse MR using Hall bars oriented along different crystalline directions and observe signatures consistent with GMR when the relative magnetization orientation in the two (Ga,Mn)As layers switches between collinear and non-collinear arrangements. Our measurements show that these signatures are distinct from other known sources of MR and further suggest that the observed GMR is associated with spin-dependent scattering at interfaces. Supported by DARPA, ONR and NSF.

**G19 10 Magnetic anisotropy of (Ga,Mn)As formed by Mn ion implantation and pulsed-laser melting** Y. J. CHO, Z. GE, Y. Y. ZHOU, X. LIU, M. DOBROWOLSKA, J. K. FURDYNA, *Department of Physics, University of Notre Dame, Notre Dame, IN 46556* M. A. SCARPULLA, O. D. DUBON, *Lawrence Berkeley National Laboratory, Berkeley, CA 94720* We report on the magnetic anisotropy of (Ga,Mn)As formed by Mn ion implantation followed by pulsed-laser melting. Three specimens with different Mn doses have been systematically studied by SQUID magnetometry, magnetotransport and ferromagnetic resonance. The sample corresponding to the lowest Mn dose does not show any measurable magnetic anisotropy. With increasing Mn doses, however, complex magnetic anisotropy behavior clearly emerges. In particular, the high-Mn-dose samples show unambiguous in-plane uniaxial and cubic anisotropy, similar to that observed in (Ga,Mn)As layers grown by LT-MBE. As these samples were produced by a different processing method, this result lends credence to the hypothesis that the in-plane cubic symmetry breaking is intrinsic to the dilute (Ga,Mn)As phase. Furthermore, in contrast to LT-MBE grown (Ga,Mn)As, these specimens show small perpendicular uniaxial anisotropy, which can be interpreted by a small built-in compressive strain due to the absence of Mn interstitials characteristic of these specimens. Finally, we also observe that a super-paramagnetic phase with distinct perpendicular magnetic anisotropy exists in these specimens. An investigation into the origin of this second magnetic phase is in progress.

**G19 11 Gating in ferromagnetic semiconductor*** F. ALTOMARE, A. M. CHANG, *Department of Physics, Duke University, Durham, NC 27708* Y. J. CHO, X. LIU, J. K. FURDYNA, *Department of Physics, University of Notre Dame, Notre Dame, IN 46556* Ferromagnetic semiconductors have the potential of revolutionizing the way current electronic devices work: more so, because they are compatible with current fabrication lines and can easily be integrated with today technology. Particular interest lies in III-V Diluted Magnetic Semiconductor (DMS), where the ferromagnetism is hole-mediated and the Curie temperature can therefore be tuned by changing the concentration of free carriers[1]. In these systems, most of the effort is currently applied toward the fabrication of devices working at room-temperature: this implies high carrier density accompanied by low mobility and short mean free path. We will report our results in exploring devices with low hole concentration and Curie temperature ( $\sim$ 4 K) and we will discuss the effect of local gating[2] in light of possible applications to the fabrication of ferromagnetic quantum dots.

**G19 12 Trapping and manipulating magnetic domain walls in patterned (Ga,Mn)As devices** K. F. EID, GANG XIANG, O. MAKSIMOV, A. BALK, N. SAMARTH, *Physics Department and Materials Research Institute, Penn State University, University Park PA 16802.* We report magnetoresistance measurements that probe the trapping and manipulation of magnetic domain walls (DWs) in multi-element (Ga,Mn)As devices that include both vertically patterned (step-etched) microstructures [Yamanouchi et al, Nature 428, 539 (2004)] and laterally-patterned nanostructures. We exploit post-fabrication annealing to yield devices in which different elements have distinct switching fields, thus allowing us to establish stable antiparallel magnetization states separated by single DWs. We then use current pulses to manipulate DWs in these devices, and observe current-induced DW motion in some sample geometries. We describe ongoing efforts to map out the variation of electrically-driven DW motion with factors such as current amplitude, sample temperature and sample geometry. Supported by DARPA/ONR.

**G19 13 2D patterned ferromagnetic semiconductors for planar spintronics** ROUIN FARSHCHI, IAN SHARP, MIKE SCARPULLA, EUGENE HALLER, OSCAR DUBON, *Univ. of California, Berkeley, CA 94720, Berkeley Lab, Berkeley, CA 94720* JEFFREY BEEMAN, *Berkeley Lab, Berkeley, CA 94720* SOONJOO SEO, PAUL EVANS, *Univ. of Wisconsin, Madison, WI 53706* Fabrication of III-Mn-V ferromagnetic semiconductors by way of Mn ion implantation followed by pulsed laser melting (II-PLM) allows for the unique possibility of lateral patterning using optical and e-beam lithography. We have performed II-PLM on resist patterned substrates to create isolated ferromagnetically active $Ga_{1-x}Mn_xAs$ regions embedded in a GaAs substrate. We have prepared a uniform $Ga_{1-x}Mn_xAs$ film as well as a sample patterned with an array of $Mn^+$-implanted 100$\mu$m x 100$\mu$m squares that covers the equivalent of one-quarter the sample. The saturation magnetization of the patterned sample reflects this one-quarter implant area, and both samples display a $T_C$ of $\sim$ 100 K suggesting a similar maximum Mn concentration. The electrical and magnetic properties of this and other lateral structures consisting of sub-micron spaced active regions will be presented. This work was supported by the U.S. Department of Energy under contract No. DE-AC02-05CH11231.

**G20 1 Loss of Ferromagnetism at the Surface of in-situ cleaved $La_{1.28}Sr_{1.72}Mn_2O_7$** JOHN W. FREELAND, *Advanced Photon Source, Argonne National Laboratory* KEN GRAY, JOHN F. MITCHELL, *Materials Science Division, Argonne National Laboratory* JERALD KAVICH, RICHARD KODAMA, *Dept. of Physics, University of Illinois, Chicago* Instability of surface magnetism in the manganites is currently an area not well understood. In our previous work using exploring loss of ferromagnetic (FM) order at the surfaces of layered manganites, we found clear evidence for an intrinsic insulating non-FM surface layer atop adjacent ferromagnetic subsurface layers. [1] The presence of a non-FM surface layer of one bilayer thickness was observed by x-ray resonant magnetic scattering (XRMS), and point contact tunneling results showed this layer to be insulating. Although that study involved samples cleaved in air, our surface-sensitive spectroscopy indicated they were not chemically degraded. Here we present the XRMS results from samples cleaved under UHV con-

ditions at 75 K. The XRMS shows the same interference effect due to the loss of FM order in the surface layer, thus supporting our earlier claim that the magnetic instability is not related to the preparation conditions. This research was supported by the U.S. Department of Energy, Office of Science, under Contract No. W-31-109-Eng-38. [1] J.W. Freeland, K.E. Gray, L. Ozyuzer, P. Berghuis, Elvira Badica, J. Kavich, H. Zheng and J.F. Mitchell, Nature Materials 4, 62 (2005)

**G20 2 Surface Structural Phases of $Ca_{2-x}Sr_xRuO_4$*** R.G. MOORE, V.B. NASCIMENTO, *Univ of TN, Knoxville, TN 37996* JIANDI ZHANG, *Florida Intl Univ, Miami, FL 33199* ISMAIL NLS, R. JIN, D. MANDRUS, E.W. PLUMMER, *Oak Ridge Natl Lab, Oak Ridge, TN 37831 and Univ of TN, Knoxville, TN 37996* Surface structural phases of $Ca_{2-x}Sr_xRuO_4$ (CSRO) are investigated using Low Energy Electron Diffraction (LEED-IV). The surface structure and phases are compared to the bulk phases in this layered material. Normally at a crystal surface the reduced atomic coordination enhances electron-electron correlations, if there is not a reconstruction, and stabilizes the Mott-insulating phase resulting in higher MIT temperatures than in the bulk. Surprisingly, $Ca_{1.9}Sr_{0.1}RuO_4$ exhibits an unusual surface MIT 20K lower than the bulk. The properties of CSRO are extremely sensitive to the $RuO_6$ octahedral orientation. LEED-IV shows no symmetry change associated with the MIT, but small distortions of the $RuO_6$ octahedral that drive the surface MIT. In addition, the tetragonal-to-orthorhombic surface phase transition near the Quantum Critical Point at $x=0.5$ is investigated and contrasted with the bulk phase transition.

**G20 3 LEED study of TMOs surfaces** V.B. NASCIMENTO, R.G. MOORE, *The Univ of Tennesse, Knoxville, TN 37996* J. RUNDGREN, *Theory of Materials, Phys Dept, Royal Inst of Tech, SE-10691, Stockholm, Sweden* JIANDI ZHANG, LEI CAI, *Florida International Univ., Miami, FL 33199* R. JIN, D. G. MANDRUS, E.W. PLUMMER, *Oak Ridge National Lab, Oak Ridge, TN 37831* In contrast with the case of metals and semiconductors, the final theory-experiment agreement obtained for LEED $I-V$ data for TMOs is generally not very satisfactory. One reason is that the calculations of the phase shifts for metal oxides is not a straightforward procedure due to the charge transfer. In this work we address this issue of phase shift generation for TMOs by determining the structure of the (001) surface of $Ca_{1.5}Sr_{0.5}RuO_4$, a prototype layered TMS system. The adoption of an optimized muffin-tin potential approach, as proposed by Rundgren, has enabled reaching an acceptable final theory-experiment agreement. Our results indicate that the determination of an energy dependent inner potential plays a key role in the final agreement. *Work supported jointly by NSF and DOE (DMS) NSF -DMR-0451163, NSF DMR-0346826 and by U.S. DOE under DE-FG02-04ER46125 and DE-AC05-00OR22725.

**G20 4 Orbital ordering at the surface of the layered manganite $La_{0.5}Sr_{1.5}MnO_4$*** Y. WAKABAYASHI, *Photon Factory, High energy accelerator research organization, Japan and Brookhaven National Lab.* S. GRENIER, M.H. UPTON, J.P. HILL, C.S. NELSON, *Brookhaven National Laboratory* J.F. MITCHELL, *Argonne National Laboratory* J-W. KIM, P.J. RYAN, *Argonne National Laboratory and Ames Laboratory, Iowa State Univ.* A.I. GOLDMAN, *Ames Laboratory, Iowa State Univ.* Surface x-ray diffraction measurements were made on a (001) cleaved surface of the orbitally ordered layered manganite, $La_{0.5}Sr_{1.5}MnO_4$ at X22C and X21 at the NSLS and at 6ID at the APS. The termination of crystal by a surface gives rise to rods of scattered intensity normal to that surface; so-called crystal truncation rods. The intensity distribution along such rods is sensitive to details of the surface order. In principle, similar rods should arise from the surface termination of orbital order. We have successfully observed such orbital truncation rods for the first time. We find that the intensity distribution of the orbital rod has a slightly steeper $L$ dependence than that for the allowed Bragg rods, indicating that the surface roughness of the orbital ordering is larger than the crystallographic roughness. As the transition temperature is approached, this orbital roughness is seen to increase.

**G20 5 Surface Modification of CMR Perovskite Manganite Thin Films using Atomic Force Microscopy** DAVID SCHAEFER, RAJESWARI KOLAGANI, CAMERON BOLLING, JOHN SUNDERLAND, ANTHONY DAVIDSON III, *Towson University* TYLER BRADLEY, *Towson High School* BONNIE LUDKA, *James Madison University* TOWSON UNIVERSITY TEAM, TOWSON HIGH SCHOOL TEAM, JAMES MADSION UNIVERSITY TEAM, Nanolithography using the atomic force microscope (AFM) is emerging as a promising tool for nanotechnology. We report our results of AFM- induced nanoscale surface modifications in thin films of the CMR manganite material $La_{0.7}Ba_{0.3}MnO_3$. CMR manganite materials have been demonstrated to be useful for a variety of technological applications including magnetic sensors and bolometric infrared detectors. AFM induced surface modifications would enable the realization of such sensors in nanotechnology applications. We have obtained reproducible patterns on these films in the form of nanoscale dots and lines induced by the AFM tip. We have studied these feature dimensions as a function of tip bias voltage, exposure time and humidity. We find that the feature heights are considerably larger on manganite thin film surfaces than those induced on silicon surface under similar conditions. Additionally, the speed of reproducible writing is also found to be significantly higher on the manganite films.

**G20 6 Time-dependent Surface Electronic Structure of $EuB_6$*** J.D. DENLINGER, *Lawrence Berkeley National Lab* F. WANG, J.W. ALLEN, *U. of Michigan* HAN-OH LEE, Z. FISK, B. DELLEY, *Paul Scherrer Institut* R. MONNIER, *ETH-Zürich* J. LOBO-CHECA, T. OKUDA, J. OSTERWALDER, *U. of Zürich* The surface electronic structure of UHV-cleaved divalent hexaboride $EuB_6$ is investigated using angle-resolved photoemission and the time-dependence of the Eu 4d-character X-point electron pocket, B-p band structure and Eu 4f states are characterized. Surface-slab LDA calculations allow identification in the data of a distinct surface-related band residing in the bulk-projected band gap along X-M and energy-shifted surface-atom Eu 4f states re-

sulting from an electric dipole at the highly ionic surface. The X-point electron pocket size is observed to initially increase in size and then recede to zero occupation. Similarly the Eu 4f surface component initially increases in binding energy and then reverses direction and loses intensity. This behavior is explained in terms clustering of mobile surface Eu atoms on the freshly cleaved surface, followed by adsorption of residual gases.

**G20 7 Formation and stability of surface oxides and oxide surfaces of the O/Cu system: First-principles investigations** ALOYSIUS SOON, MIRA TODOROVA, *School of Physics, the University of Sydney, Australia* BERNARD DELLEY, *Paul-Scherrer-Institut (PSI)* CATHERINE STAMPFL, *School of Physics, the University of Sydney, Australia* Copper-based catalysts are important for several industrial reactions, e.g., the low-temperature water-gas-shift reaction and for methanol oxidation reactions. Despite this, very little is presently known about the surface structure, about the atomic and molecular processes involved and the associated reaction pathways. As a first step towards a microscopic understanding, we use density-functional theory to investigate chemisorption of oxygen on Cu(111), and the stability of surface oxides and oxide surfaces. Surface oxide structures are found to be energetically favoured over chemisorbed oxygen even at coverages as low as $\frac{1}{16}$ ML. Taking into account the pressure and temperature through the framework of itab initio thermodynamics [1,2] however, shows that for the conditions relevant to technical catalysis, bulk oxide structures are the appropriate ones to consider. Our results are compared to the behavior of other O/transition-metal systems. [1] K. Reuter, C. Stampfl and M. Scheffler, in Handbook of Materials Modeling, Volume 1, Fundamental Models and Methods, Sidney Yip (Ed). [2] C. Stampfl, Catal. Today 105, 17 (2005).

**G20 8 Thermal transport in strongly correlated multilayered nanostructures*** JAMES FREERICKS, *Department of Physics, Georgetown University* VELJKO ZLATIC, *Institute of Physics, Zagreb, Croatia* The formalism for thermal transport in strongly correlated multilayered nanostructures is developed. We employ inhomogeneous dynamical mean-field theory and the Kubo formula to derive relevant thermal transport coefficients, which take the form of matrices with respect to the planar indices. We show how to define the local versions of the current and heat current operators so that heat-current correlation functions can be easily evaluated via the Jonson-Mahan theorem. Thermal transport in nanostructures is complicated by the fact that the thermal current need not be conserved through the device, and a given experimental set-up determines both how the thermal current can change through the device and how the steady-state temperature profile can be determined. Formulae to analyze classic experiments such as the Peltier and Seebeck effects, the thermal conductivity, and for running a thermoelectric cooler or power generator are also discussed.

**G20 10 Density-Functional Study of the Two-Dimensional Electron Gas at the Perovskite Titanate Interface*** RANJIT NANDA, ZORAN POPOVIC, SUNITA THULASI, SASHI SATPATHY, *University of Missouri* Oxide superlattices and microstructures hold the promise for creating a new class of devices with unprecedented functionalities. Density-functional studies[1] of the recently fabricated, lattice-matched perovskite titanates[2] $(SrTiO_3)_n/(LaTiO_3)_m$ reveal a classic wedge-shaped potential well for the monolayer structure, originating from the Coulomb potential of a charged La sheet. The potential in turn confines the electrons in the Airy-function-localized states. This resulting two-dimensional electron gas may be described in terms of the simplified jellium model[3] and it describes reasonably well the observed charge modulation of the Ti atoms near the interface. Concerning magnetism, it is suppressed for the monolayer $LaTiO_3$ structure, while in structures with a thicker $LaTiO_3$ part, bulk antiferromagnetism is recovered, with a narrow transition region separating the magnetic $LaTiO_3$ and the non-magnetic $SrTiO_3$. 1. **G20 11 Lattice relaxation, electronic screening, and spin and orbital phase diagram of $LaTiO_3/SrTiO_3$ superlattices** SATOSHI OKAMOTO, ANDREW MILLIS, *Department of Physics, Columbia University* NICOLA SPALDIN, *Materials Department, University of California, Santa Barbara* The effect of lattice relaxation on the electronic charge density, band structure, and phase diagram in oxide heterostructure, $LaTiO_3/SrTiO_3$ superlattices, the structure grown and measured by Ohtomo *et al.*[1], is investigated using density functional theory LDA and LDA+$U$ (VASP implementation). We observe substantial ferroelectric-like distortion of $TiO_6$ octahedra at the nearest-to-La region which screens the electrostatic force originating from $La^{3+}$ ion reducing the charge density in the La-rich region. We determine the changes in the low energy electronic Hamiltonian caused by the lattice relaxation and investigate the consequences for the ground state phase diagram using the Hartree-Fock approximation. Finally, we present a detailed comparison with previous calculations which neglected the lattice effect. [2] Support from DOE ER 46169. [1] Ohtomo et al., Nature **419**, 378 (2002). **G20 12 Total energy calculations for magnetic $La_{2/3}S_{1/3}rMnO_3/SrRuO_3$ bilayers** YONGBIN LEE, BENJAMIN CAES, BRUCE HARMON, *Ames Laboratory US DOE* . Recently positive exchange bias was reported for ferromagnetic $La_{2/3}Sr_{1/3}MnO_3/SrRuO_3$ (LSMO/SRO) bilayers which indicated anti-ferromagnetic exchange interaction across the interface [1]. To address the physical origin of this anti-ferromagnetic exchange interaction, we have performed first principles calculations with both ferro, and anti-ferromagnetic interface structures. We have found that the anti-ferromagnetic interface is preferred to ferromagnetic case energetically. The calculations indicate the interfacial O 2p orbitals and their interaction with Mn, Ru spin polarized 3d orbitals are critical for this anti-ferromagnetic interface preference. In this talk, we will discuss the total energy calculations with various magnetic structures near the interface. [1] X. Ke et al. Appl. Phys. Lett. **84**, 5458 (2004)

**10:24**
**G20 13 Electronic and magnetic properties of Mn/Si superlattices*** C.Y. FONG, MEI QIAN, KAI LIU, *Department of Physics, UC Davis* We recently predicted a monolayer of Mn doped in 31 layers of Si, a Mn/Si digital ferromagnetic heterostructure, is a half metal. [1] In order to explore the possibility of realizing large magnetoresistance effect, we extend our studies to superlattices composed of periodically embedded monolayers of Mn in Si. By using a first-principles algorithm, we determine whether a superlattice can exhibit half metallic behavior. We then investigate the dependence of the half metallic properties on the thickness of the Si spacer. The energetics of the ferromagnetic and antiferromagnetic phases will be compared for each half metal. For the minimum Si spacer, the band structure near the Fermi energy of the superlattice showing half metallic properties will be given. We also analyze the character of the states at the Fermi energy as well as the associated Fermi surface. [1] M. C. Qian, et al. to appear in Phys. Rev. Lett.; cond- mat/0508269.

**G20 14 Electrostatic Interface Tuning in Correlated Superconducting Heterostructures*** NATALIA PAVLENKO, THILO KOPP, *Institute of Physics, Center for Electronic Correlations and Magnetism, University of Augsburg* EP VI TEAM, In high-temperature superconducting oxide films, transverse electric fields have been used to switch between superconducting and insulating states by electrostatically tuning the free carrier density. We analyze d-wave pairing within a microscopic model for heterogeneous multilayer systems and show that a coupling to electric dipoles and phonons at the interface of cuprate film and dielectric gate localizes the injected charge and leads to a superconductor-insulator transition [1]. We find that in the correlated oxide films, the strong interface polaron effect is inherently related to the stabilization of interface charge ordering and inhomogeneous states. The formation of such states results in a dramatic modification of the doping dependent phase diagram close to and above the optimal doping which is expected to shed light on recent electric field-effect experiments with HTSC cuprates. [1] N. Pavlenko and T. Kopp, Phys. Rev. B, in print (2005).

**G20 15 Quartet formation at (100)/(110) interfaces of d-wave superconductors*** ARNO KAMPF, *University of Augsburg* ARMANDO ALIGIA, *Centro Atomico Bariloche* JOCHEN MANNHART, *University of Augsburg* Across a faceted (100)/(110) interface between two $d_{x^2-y^2}$-superconductors the structure of the superconducting order parameter leads to an alternating sign of the local Josephson coupling. Describing the Cooper pair motion along and across the interface by a one-dimensional boson lattice model, we show that a small attractive interaction between the bosons strongly enhances their binding at the interface. As a consequence we propose that electrons tunnel in quartets across an interface with a staggered sequence of 0- and $\pi$-junction contacts. We connect this finding to the recently observed $h/4e$ oscillations in bicrystalline (100)/(110) SQUIDs of cuprate superconductors.

*Work supported by the DFG through SFB 484

## SESSION G21: COLLOIDS IV: POLYMERIC AND COLLOID-POLYMER SYSTEMS

**G21 1 Self Assembly of Temperature-Sensitive Capsules using PNIPAm Microspheres*** D. B. LAWRENCE, *University of Massachusetts Amherst Physics* T. CAI, Z. B. HU, *University of North Texas* M. MARQUEZ, *INEST Group, Phillip Morris USA* A. D. DINSMORE, *University of Massachusetts Amherst Physics* We present a method for self assembly of novel semi-permeable capsules (colloidosomes) exhibiting temperature-dependent size and surface properties. These hollow micro-capsules are composed of micron-sized PNIPAm-co-acrylic acid particles that exhibit a reversible size transition at $32^oC$. The PNIPAm particles self-assemble at the spherical interface between 2-Octanol and water droplets. Electrostatic cross-linking with the di-block copolymer Poly(butadiene-b-N-methyl 4-vinyl pyridinium iodide) locks the particles in place, forming a rigid, elastic membrane that remains after the 2-Octanol/Water interface is removed. Such self-assembled capsules retain the temperature sensitivity of the PNIPAm particles from which they are constructed, and exhibit reversible size transitions. Controlled variation of the permeability and potential applications in controlled release will be discussed.

*We acknowledge support from the Kraft Foods, Inc. NanoteK consortium.

**8:12**
**G21 2 Femtonewton Measurements of Polymer-Mediated Colloidal Interaction** SVEN BEHRENS, *BASF* HELMUT AUWETER, *BASF* The stability of colloidal dispersions hinges on the repulsive interaction between the particle surfaces. This interaction can be modified by adsorbed polymer and further tuned by the response of the adsorbate layer to changes in the surrounding solution.Total internal reflection microscopy has been used in this study to investigate the effect of charged and neutral polymer

adsorbates on the interaction of a colloidal particle with a flat substrate. The results were correlated with light scattering studies of the employed polymers in solution and of polymer-coated particles; they reveal a subtle interplay of steric, electrostatic, and van der Waals forces.

**8:24**

**G21 3 Phase Behavior of Charged Colloid-Polymer Mixtures: A Simulation Study*** BEN LU, ALAN R. DENTON, *Department of Physics, North Dakota State University* We present a Monte Carlo simulation study of mixtures of charged colloids and nonadsorbing polymers. The multicomponent mixture of colloidal macroions, microions (counterions and salt ions), polymers, and solvent is modeled as an effective two-component mixture of pseudomacroions and neutral polymers. The pseudomacroions are assumed to interact via effective electrostatic interactions[1] (screened-Coulomb pair potential and one-body volume energy) and the polymers are treated as effective spheres that have hard interactions with the colloids but are mutually ideal. Previous studies have identified the volume energy as the driving force for phase separation of deionized colloidal suspensions[2] and polymer depletion-induced attraction as the origin of colloid-polymer demixing. Here we apply the Gibbs ensemble Monte Carlo method to the effective binary mixture to examine the combined influences of electrostatic and depletion-induced interactions on phase behavior.

*Support from the National Science Foundation (grant DMR-0204020) is gratefully acknowledged.

**G21 4 Demixing of Charged Colloid-Polymer Mixtures: Variational Theory[1]** SHRIKANT SHENOY, ALAN R. DENTON, *Dept. of Physics, North Dakota State University* We investigate thermodynamic phase behavior of mixtures of charged colloids and neutral nonadsorbing polymers using a variational method for the free energy. The mixture of macroions, microions, and solvent is first mapped onto an effective one-component system of pseudomacroions that interact via effective electrostatic interactions. The polymers are modeled as effective spheres that have hard interactions with the colloids but are mutually ideal. The charged colloid-polymer mixture is then mapped onto an Asakura-Oosawa model with effective colloid and polymer diameters[2]. The free energy is approximated by combining thermodynamic perturbation theory for the colloids with free-volume theory for the polymers and minimizing with respect to the effective colloid diameter. Phase diagrams are computed by a coexistence analysis that ensures equality of pressures and of chemical potentials of all species in the two phases. The resultant phase behavior depends sensitively on colloid charge, polymer-to-colloid size ratio, and composition. Electrostatic repulsion between colloids is found to stabilize the mixture against polymer depletion-induced demixing, consistent with previous predictions[3] and experimental observations. [1]Support from the National Science Foundation (grant DMR-0204020) is gratefully acknowledged. [2]A. R. Denton and M. Schmidt, *J. Chem. Phys.* **122**, 2449111 (2005).

**8:48**

**G21 5 Preparation of PHSA-PMMA stabilizer for model hard sphere systems** ANDREW HOLLINGSWORTH, *New York University* WILLIAM RUSSEL, *Princeton University* CARLOS VAN KATS, ALFONS VAN BLAADEREN, *Utrecht University* Sterically-stabilized colloidal particles are an excellent model hard-sphere system used by many groups. One of the original stabilizers used for such systems was developed and patented by ICI more than 30 years ago. It consists of a 'comb-like' stabilizer of a poly(12-hydroxystearic acid) which is soluble in aliphatic hydrocarbons. These pendant PHSA chains are grafted to an insoluble poly(methyl methacrylate) backbone that strongly adsorbs to polymer particles and thus provides a means of anchoring stabilizer to particle surfaces. Unfortunately, the PHSA-g-PMMA stabilizer is not commercially available. Furthermore, the three-step procedure (Antl, et al. 1986) is generally regarded by non-chemists as technique intensive and time-consuming. We have systematically studied the PHSA-PMMA stabilizer synthesis with the goal of taking the mystery out of the protocol and making the entire synthesis reproducible. Several important details, not published in the literature, will be discussed, along with the analytical results from mass spectroscopy, proton NMR, acid titration and gel permeation chromatography, all of which were used to characterize the polymer and its precursors.

**9:00**

**G21 6 Self-assembly of Asphaltenes: Enthalpy, Entropy of Depletion and Dynamics at Crossover I-experimental** NATALIA LISITZA, DENISE FREED, PABITRA SEN, YI-QIAO SONG, *Schlumberger-Doll Research* The continuous rise of global demand for energy and the difficulty of significantly increasing production have driven the petroleum industry to develop much more difficult oil reservoirs, such as deep-water fields. Asphaltenes, naturally-occurring large aromatic molecules in crude oils, are known to be the ''cholesterol'' of petroleum because they self-associate to form solid aggregates and eventually clog the production pipes and the rocks. An extraordinary amount of work using many analytical techniques has been applied to elucidate the properties of asphaltenes. However, many fundamental issues, such as the molecular architecture and the aggregation mechanisms, are still in debate. Here we use NMR to detect asphaltene aggregation in toluene solutions and to obtain both the enthalpy and entropy of this process. We observe an abrupt drop of the asphaltene diffusion constant which is indicative of a molecular conformation (shape) change. This change is intimately related to or possibly a prerequisite of the aggregation. The entropy of aggregation was found to be positive due to the excluded volume effect for the solvent. This is reminiscent of the depletion entropy force, which is considered to be the driving force for the aggregation of much large artificial nanoparticles.

**9:12**

**G21 7 Self-assembly of Asphaltenes: Enthalpy, Entropy of Depletion and Dynamics at Crossover II - theoretical** DENISE FREED, NATALIA LISITZA, PABITRA SEN, YI-QIAO SONG, *Schlumberger-Doll Research* NMR spin-relaxation is directly sensitive to molecular dynamics and is therefore an excellent tool for studying the formation of nano-aggregates. When aggregates form, the molecular rotations are slowed down, and the spin-relaxation rate is enhanced, which reduces the NMR signal. This gives rises to a remarkable kink in the NMR signal intensity at the Critical Nano-Aggregate Concentration (CNAC). In this talk, we use Debye's two-state model for micelle formation to describe

asphaltene aggregation. We use the temperature dependence of the CNAC to determinate the enthalpy and entropy of aggregation. The enthalpy is negative, as expected, and indicates that the aggregate formation is energetically favorable due to $\pi$-stacking interactions. On the other hand, we find that the entropy is positive, which is quite a surprise. We propose that this increase comes from the depletion entropy of the solvent. As asphaltene molecules aggregate, the free volume available for the solvent molecules increases, giving rise to a depletion effect. An estimate of the depletion entropy from the sizes of asphaltene and toluene (solvent) is very close to the measured entropy gain. We will also discuss the applicability of Debye's two-state model to aggregate formation in asphaltene solutions.

**9:24**

**G21 8 Molecular Diffusivities of Asphaltene Monomers by Fluorescent Correlation Spectroscopy** BALLARD ANDREWS, *Schlumberger-Doll Research* RODRIGO GUERRA, *Harvard University* PABITRA SEN, *Schlumberger-Doll Research* OLIVER MULLINS, *Schlumberger-Doll Research* Many analytical techniques have been applied to elucidate the properties of asphaltenes due to their extraordinary importance in the petroleum industry. However, many fundamental issues such as the molecular size are still in debate. Using Fluorescence Correlation Spectroscopy (FCS) we measure the translational diffusion coefficient of asphaltene molecules in toluene at extremely low dilutions. To avoid focal volume artifacts common in FCS we use a scaling procedure to determine asphaltene diffusivities relative to known molecules such as porphyrins, perylene and quantum dots. We estimate a diffusion coefficient for the asphaltene molecules of 0.3, $10^{-5}$ $cm^2$/sec at room temperature. This value agrees with recent estimates from NMR studied at 10-100 fold higher concentrations. The Stokes-Einstein equation implies that the unaggregated hydrodynamic diameter of asphaltene monomers is 15-25 Å.

**9:36**

**G21 9 Novel emulsions stabilized by pH and temperature sensitive microgels** TO NGAI, *The Chinese University of Hong Kong* HELMUT AUWETER, *BASF* SVEN BEHRENS, *BASF* Poly(N-isopropylacrylamide-co-methacrylic acid) (PNIPAM-MAA) microgel particles in aqueous solution exhibit a volume phase transition that can be induced by changes of either pH or temperature. In the swollen state, these microgels self-assemble at an octanol-water interface and can be used to stabilize surfactant-free oil-in-water emulsions. This stabilizing efficiency is retained even in the collapsed state, provided that the microgels are fully charged. At very low charge (low pH), on the other hand, the microgels migrate completely into the oil phase, and the emulsion breaks. In an intermediate regime of practical interest the emulsion stability can be tuned by small adjustments of pH or temperature. Because of this unprecedented stability control, we believe that such stimulus-responsive charged microgels have a great potential for applications in the field of cosmetic or pharmaceutical formulations. Conceptually they belong to a new class of emulsifiers combining properties of both classical surfactants and solid particles.

**9:48**

**G21 10 Internal Dynamics of Double Emulsion Creams and Polymer-Dispersed Complex Droplets** HU GANG, *Hong Kong Baptist University* The availability of monodisperse double emulsions allows for detailed study of their stability and rheological properties. Practical use of double emulsions concerns the structure and structural evolution of the complex droplets. The usually achievable size of the complex droplets ranges from a micrometer to tens of micrometers. To obtain a homogeneous system, a double emulsion has to be in the form of cream or gel to avoid macroscopic phase separation. However, immobilizing the double emulsion drops does not cease the full dynamics since the internal smaller droplets are also subject to thermal agitation. The ability to track the evolution of the internal encapsulated phase is essential to the understanding of the kinetic stability of a new formulation. Conventional light scattering encounters significant difficulties to probe the structure of concentrated emulsions while diffusing-wave spectroscopy (DWS) shows a unique advantage. We prepare monodisperse W/O/W double emulsions and apply DWS to study the structure of double emulsion creams and gels. We also test the sensitivity of DWS when the amount of encapsulated phase is varied by induced coalescence or osmotic gradient.

**G21 11 Quasi-two-dimensional equilibrium and non-equilibrium thermodynamics of thin liquid films stabilized by colloidal particles*** JERZY BLAWZDZIEWICZ, *Yale University* ELIGIUSZ WAJNRYB, *IPPT, Warsaw, Poland* Due to the presence of oscillatory structural forces, static and dynamic properties of thin liquid films stabilized by colloidal particles, micelles, or macromolecules differ from the properties of particle-free films. During drainage process, particle-stabilized films often form a stepwise structure with coexisting regions (phases) of uniform but different thickness. We describe film phase equilibria using a quasi-two dimensional thermodynamic formalism. The key quantity in our approach is the film tension. We show that the particle contribution to this quantity results from the anisotropy of the particle osmotic-pressure tensor in the film. The quasi-2d description is also developed for non-equilibrium film states. We show that the motion of particle-stabilized films is analogous to the dynamics of a two-dimensional compressible fluid - the film thickness plays the role of mass density per unit area and film tension the role of pressure. In the linear-response regime, the film dynamics is characterized by the shear and extension viscosity coefficients. There are also two independent kinetic coefficients relating the particle flux to the gradients of the normal osmotic pressure and particle chemical potential. For a film stabilized by a suspension of hard spheres we have calculated these coefficients using a multipolar-expansion methods combined with a flow reflection technique.

*Supported by NASA grant NAG3-2704 and NSF grant CTS-0348175

**G21 12 Dynamics, Rectification, and Fractionation for Colloids on Flashing Substrates** ANDRAS LIBAL, *University of Notre Dame* CHARLES REICHHARDT, *Los Alamos National Laboratory* BOLDIZSAR JANKO, *University of Notre Dame* CYNTHIA OLSON REICHHARDT, *Los Alamos National Laboratory* We show that a rich variety of dynamic phases can be realized for mono- and bidisperse mixtures of interacting colloids under the influence of a symmetric flashing periodic substrate. These type of substrates have been attracting growing interest due to recent experimental breakthroughs that allow the creation of dynamic periodic arrays using optical and holographic techniques. With the addition of dc or ac drives, these system show phase locking, jamming, and new types of ratchet effects. We studied these effects in detail. The ratchet effect can be used for charge

separation of a bidisperse system. In this system, in some regimes we find that the addition of a non-rathceting species increases the velocity of the ratcheting particles. We show that these effects occur due to the collective interactions of colloids.

**10:24**
**G21 13 Formation of Extended Optical Traps by Shape-Phase Modulation - Measuring Inter-Colloidal Interactions in Tailored Potential Landscapes** YOHAI ROICHMAN, DAVID G. GRIER, *Soft Matter Research Center, Physics dept., New York* We describe methods for projecting holographic optical traps whose potential energy wells are extended along specified curves, typically a straight line, and whose intensity profiles also can be tailored. This class of optical traps is useful for manipulating elongated nano-items, creating anisotropic potential energy landscapes, and in particular for investigating the interactions and dynamics of micro-particles in reduced dimensionality. This new class of extended optical traps is created by modulating the shape and the phase of a complex hologram, projected by a phase-only diffractive optical element. We demonstrate rapid characterization of extended traps' potential wells through digital video microscopy of trapped colloidal spheres, and use arrays of calibrated traps for efficient measurement and screening of colloidal interactions.

**10:36**
**G21 14 Holographically Assembled Photonic Quasicrystals** YAEL ROICHMAN, DAVID G. GRIER, *New York University* Recently, the photonic band structure of a centimeter-scale three-dimensional icosahedral quasicrystal was measured in the microwave region and shown to feature prominent photonic band gaps at the effective Brillouin zone boundary. We demonstrate that similar two- and three-dimensional quasicrystalline photonic structures can be assembled from micrometer-scale colloidal particles through dynamic holographic optical trapping. The resulting colloidal heterostructures feature lengthscales appropriate for photonic bandgap applications at visible wavelengths, and can include specifically engineered defects such as vacancies, active centers and waveguides.

**10:48**
**G21 15 The Intermediate Scattering Function in Fluorescence Correlation Spectroscopy** RODRIGO GUERRA, *Harvard* BALLARD ANDREWS, PABITRA SEN, *Schlumberger-Doll Research* We formulate the autocorrelation function for Fluorescence Correlation Spectroscopy (FCS) $G_D(\tau)$ in reciprocal space in terms of the of the Intermediate Scattering Function ISF($\vec{k}$,$t$) and the fourier transform of the Optical Response Function ORF($\vec{k}$). In this way we may extend the use of FCS to processes that have been studied using NMR, DLS, and neutron scattering. This formalism is useful for the complicated propagators involved in confined systems and in the study of diffusion in cells: where diffusion is either restricted or permeation through membrane is important. Calculations in k-space produce approximate expressions for the ORF using cumulant expansions that are accurate for small wavevectors. This provides descriptions for longer timescales better suited for studying time-dependent diffusion $ISF([** overrightarrow **] k,t) \rightarrow exp[ - tD(t)k^2]$ and provides a natural separation of contributions from system dynamics and from optical artifacts and aberrations. We will show an explicit derivation of a semi-analytical fit function for free diffusion based on standard electromagnetic analysis of a confocal optical apparatus. This fit function is then used to analyze a representative data set and has no free fit parameters other than the diffusion constant.

**G22 1 Monte Carlo study of transverse susceptibility in ordered arrays of magnetic nanoparticles*** DIMITRIS KECHRAKOS, KALLIOPI TROHIDOU, *Institute of Materials Science, NCSR Demokritos, 15310 Athens, GR* We present Monte Carlo simulations of the field-dependent reversible transverse susceptibility (RTS) for a hexagonal array of dipolar interacting magnetic nanoparticles with random anisotropy. The thermal evolution of the RTS curves exhibits three distinct temperatures that indicate the merge of the coercive to the anisotropy peak ($T_{sw}$), the crossover from double-peak to single-peak behavior ($T_{cross}$) and the transition to the superparamagnetic state ($T_b$), successively. Above $T_{cross}$ the array exhibits positive spin correlations attributed solely to dipolar interactions. With decreasing interparticle spacing, the anisotropy peak shifts to lower (or higher) values for in-plane (or off-plane) bias-field and the coercive peak merges to the anisotropy peak indicating a transition to collective reversal of the moments. Our results are in agreement with recent RTS measurements in self-assembled Fe nanoparticles.

**G22 2 Railroading cells, microfluidic magnetic cell separation using ferromagnetic stripes** DAVID INGLIS, *Princeton Institute for the Science and Technology of Materials, Princeton University* ROBERT AUSTIN, *Princeton Universiy Dept. of Physics* JAMES STURM, *Princeton Institute for the Science and Technology of Materials, Princeton University* Magnetic cell separation has been demonstrated using recessed ferromagnetic stripes. Here we demonstrate precise control of the cell's positions using branched magnetic stripes in a microfluidic device. The technique allows magnetically separated cells to be delivered in precise locations to downstream cellular analysis components.

**8:24**
**G22 3 Directed self-assembly and detection of iron oxide nanoparticles on an InAs quantum well micro-Hall sensor** P. MANANDHAR, G. MIHAJLOVIC, W. SETYAWAN, S. VON MOLNAR, P. XIONG, *MARTECH & Dept of Phys, Florida State University* S. HONG, *Physics and NANO Systems Institute, Seoul National University* D. MAGANA, G. F. STROUSE, *Dept of Chem and Biochem, Florida State University* K. OHTANI, H. OHNO, *Laboratory for Nanoelectronics and Spintronics, Research Institute of Electrical Communication, Tohoku University* M. FIELD, G. J. SULLIVAN, *Rockwell Scientific Company LLC* Biosensors based on magnetic detection of superparamagnetic nanoparticles have potential in many bioanalysis and biomedical applications. An important step towards this goal is to assemble magnetic nanoparticles precisely on a sensing device and detect them. Here we demonstrate directed self-assembly of superparamagnetic iron oxide nanoparticles onto a micron or sub-micron sized semiconductor Hall sensor and their detection at room temperature using Hall magnetometry. Hall devices were fabricated from MBE grown InAs quantum well heterostructures using lithographical methods. Organic molecular templates were created on Au coated active Hall cross regions using dip pen nanolithography (DPN) with 16- mercaptohexadecanoic acid (MHA). Magnetic nanoparticles were then assembled specifically onto the MHA regions and characterized by detecting stray magnetic fields emanating from the nanoparticles in the presence of a magnetizing field by using phase sensitive Hall magnetometry. *This work has been supported by NSF NIRT grant ECS-0210332.

**G22 4 Biomedical Applications of Magnetic Nanoparticles and Fluids.***
DIANDRA LESLIE-PELECKY, *University of Nebraska - Lincoln*

Nanomaterials play an increasingly important role in the research, diagnosis and treatment of numerous pathologies. Biomedical applications such as drug delivery, magnetic resonance imaging and hyperthermia require magnetic nanoparticles with a large saturation magnetization that are biocompatible, form stable suspensions in water-based fluids, and can be functionalized. We use chemical synthesis and inert-gas condensation into fluids to produce biocompatible magnetic nanoparticle fluids that allow magnetic targeting of drugs and simultaneous magnetic resonance imaging. We have developed a water-dispersible oleic-acid/Pluronic/iron-oxide nanoparticle formulation that can be loaded with high doses of water-insoluble anti-cancer drugs. An external magnetic field is used to attract the nanoparticles to the treatment region and MRI is used to verify their location. A primary limitation on magnetic targeting, however, is the low moment of iron-oxide nanoparticles. Inert-gas-condensation into fluids produces iron and cobalt nanoparticles from 5-45 nm in diameter. Coating or passivation of these materials is required to prevent oxidation; however, the interaction between surface atoms and surfactant or other functionalizing molecules can greatly diminish the magnetic moment. A study of surfactant interactions with iron nanoparticles shows that the physical barrier provided by a concentric shell of polymeric surfactant offers significantly more protection against oxidation than the radial barrier formed by most linear surfactants. The talk will conclude with a brief overview of the opportunities and challenges for condensed matter and materials physicists in biomagnetic materials. This work is done in collaboration with V. Labhasetwar and T. Jain at the University of Nebraska Medical Center, and Marco Morales, Nguyen Hai, Shannon Fritz, Kishore Sreenivasan and David Schmitter at the University of Nebraska – Lincoln.

**G22 5 Neutron diffraction studies of exchange-biased Co/CoO core-shell nanoparticles** SUE INDERHEES, GLENN STRYCKER, MEIGAN ARONSON, *University of Michigan* YIMING QIU, JULIE BORCHERS, *NIST* YADONG YIN, *Lawrence Berkeley National Lab* We present neutron diffraction data on exchange-biased Co/CoO core-shell nanoparticles. Surfactant-coated Co particles were prepared by thermal decomposition of $Co_2(CO)_8$, then oxidized to form core/shell particles with a polycrytalline CoO shell. Magnetization data display strong exchange bias below the 200K blocking temperature ($T_B$), well below the Neel temperature of bulk CoO (293 K). Neutron diffraction data show a broad peak at the (1/2 1/2 1/2) antiferromagnetic CoO ordering wave vector. The anti-ferromagnetic order parameter is constant below $T_B$, and decreases with increasing temperature above $T_B$. These results demonstrate that the diminished $T_B$ in small core/shell particles is not due to a reduction of $T_N$ of the antiferromagnetic shell.

**9:24**
**G22 6 Characterization of Epsilon-Co Nanoparticles with Thin Oxide Shells** KATHRYN KRYCKA, *State Univ. of New York, Stony Brook 11794* CHI-CHANG KAO, *National Synchrotron Light Source, BNL, New York 11973* SARA MAJETICH, MADHUR SACHAN, *Dept.of Physics, Carnegie Mellon University, Pittsburgh, Pennsylvania 15213* In order to fully understand the magnetism of nanosystems it is often necessary to characterize an unavoidable thin magnetic metal-oxide shell. This is particularly challenging when the system is comprised of self-assembled nanoparticles that can neither be treated as fully ordered nor randomly distributed, as was the case for our sample which coherently close packs in regions on the micron scale. X-ray powder diffraction was used to determine that the phase of the shell was cobalt monoxide while the core remained epsilon-Co. TEM showed that the particles were spherical with an average diameter of 7 nm [1], and using small angle x-ray diffraction the nearest neighbor distance was placed at 10.3 nm. Anomalous small angle

scattering taken at several energies about the Co k-edge was used to separate the contributions of the metallic cores, metal-oxide shells, and nanoparticle packing. From this experiment radial sizes were determined for both core and shell, the details of which will be presented. 1. ''Interaction effects within Langmuir Layers and three-dimensional arrays of epsilon-Co Nanoparticles'' (in press to J. Appl. Phys.)

**9:36**

**G22 7 Inelastic Neutron Scattering on Exchange-Biased Co/CoO Core-Shell Nanoparticles** GLENN STRYCKER, SUE INDERHEES, MEIGAN ARONSON, *University of Michigan* YIMING QIU, JULIE BORCHERS, *NIST* We report results of inelastic neutron scattering on exchange biased Co/CoO core-shell nanoparticles. Data were taken using time-of-flight techniques at the Disk Chopper Spectrometer (DCS) at the NIST Center for Neutron Research, which allows observation of the dynamics of magnetic spin reversal over a range of energies and length scales. Above the blocking temperature ($T_B$) the scattering is quasi-elastic, with an amplitude that peaks at the (1/2 1/2 1/2) antiferromagnetic CoO ordering wave vector. With decreasing temperature the quasi-elastic scattering narrows, consistent with the freezing of longitudinal moment fluctuations, and becomes resolution limited near $T_B$. Below $T_B$ we observe a spectrum of inelastic excitations arising from a log-normal distribution of energy barriers. We will discuss in detail the length scale and temperature dependences of these features. Work at the University of Michigan performed under the auspices of the Department of Energy.

**G22 8 Effect of dipolar interactions on the magnetization of a cubic array of nanomagnets*** MARISOL ALCANTARA ORTIGOZA, TALAT S. RAHMAN, RICHARD A. KLEMM, *Department of Physics, Kansas State University, Manhattan, KS 66506* We investigated the effect of intermolecular dipolar interactions on an ensemble of 100 3D-systems of $5 \times 5 \times 4$ nanomagnets, each with spin $S = 5$, arranged in a cubic lattice. We employed the Landau-Lifshitz-Gilbert equation to solve for the magnetization curves for several values of the damping constant, the induction sweep rate, the lattice constant, the temperature, and the magnetic anisotropy. The dependencies of the magnetic hysteresis curves on these parameters will be presented. We also reproduce and test a previously reported magnetization curve for a 2D-system [M. Kayali and W. Saslow, Phys. Rev. B **70**, 174404 (2004)]. Although in 3D systems, dipole-dipole interactions generally diminish the hysteresis, in two- dimensional systems, they strongly enhance it. For both square two- dimensional and rectangular three-dimensional lattices with $\boldsymbol{B}||(\hat{\boldsymbol{x}} + \hat{\boldsymbol{y}})$, dipole-dipole interactions can cause large jumps in the magnetization. New results including the low-temperature quantum effects appropriate for single molecule magnets will be presented.

**G22 9 Synthesis and Characterization of Magnetic Alloy Nanowire Arrays** M. PADI, S. TALAPATRA, *Rensselaer Nanotechnology Center and Department of MS&E, Rensselaer Polytechnic Institute, Troy NY.* X. TANG, *Department of Physics, Rensselaer Polytechnic Institute, Troy,NY 12180* T. KIM, R. VAJTAI, *Rensselaer Nanotechnology Center, Rensselaer Polytechnic Institute, Troy NY.* G.V.S. SASTRY, *Department of Metallugy, Banaras Hindu University, Varanasi, India* M. SHIMA, P. AJAYAN, *Rensselaer Nanotechnology Center and Department of MS&E, Rensselaer Polytechnic Institute, Troy NY.* We report the synthesis and characterization of ordered arrays of cobalt-nickel alloy nanowires electrodeposited into the pores of anodic alumina templates (AAO). Controlled diameters, lengths and compositions of these alloys were obtained by varying the pore sizes and electro-deposition conditions. The structural and magnetic properties of the samples were investigated using scanning electron microscopy (SEM), energy dispersive X-ray spectroscopy (EDS), transmission electron microscopy (TEM) and vibrating sample magnetometer (VSM). We also present the effect of the compositional ratio of cobalt and nickel on the magnetic properties of the nanowires.

**G22 10 CoPt Nanowires by Electrodeposition*** HAFSA KHURSHID, Y. HUANG, G.C. HADJIPANAYIS, *Department of Physics, University of Delaware, Newark, DE, 19716* CoPt nanoparticles with $L1_0$structure have been studied as a promising material for high density magnetic recording due to the high anisotropy value of the $L1_0$ phase ($K=2x10^7$ ergs/cc). In this study, we prepared CoPt nanowires (up to 200nm in diameter and 100 micrometer in length) embedded in anodized alumina templates by electrodeposition. The pH values have been varied from 3 to 6 by adding diluted NaOH into the deposition bath. The wires were then annealed in a high vacuum furnace at a temperature range between $650^o$C to 750°C in order to transform their structure from the disordered fcc phase to the ordered $L1_0$ phase. A higher pH value leads to a higher coercivity and smoother loop which can be attributed to a more uniform CoPt composition through out the wires. HRTEM data of as-made samples shows that the long wires consist of both tiny nanoparticles (1-2 nm) and elongated nanorods having a single crystal fcc structure. The microstructural data is consistent with the magnetic measurements, showing a slightly preferred orientation perpendicular to the long axis of the wires with $H_c = 5$ kOe and 5.5 kOe along and perpendicular to the direction of the wires, respectively.

**G22 11 Ferromagnetism in colloidal Mn doped ZnO nanocrystals** GIL MARKOVICH, TAL MERON, EINAT TIROSH, GABRIEL SHEMER, *Tel Aviv University* Surfactant coated colloidal $Zn_{1-x}Mn_xO$ ($x=0.04\pm 0.03$) nanocrystals of average diameter of 5.5 nm were synthesized using high temperature hydrolysis of Zn(II) and Mn(II) alkoxides in a high boiling point solvent. The magnetic properties of the nanocrystals were measured both for isolated particles diluted in a hydrocarbon matrix and for a nanocrystal powder. Nanocrystals of manganese oxide and ZnO coated with manganese oxide were prepared for comparison to the $Zn_{1-x}Mn_xO$ nanocrystals. We find that the manganese ions primarily substitute zinc ions in the hexagonal ZnO lattice and part of them are ferromagnetically coupled up to room temperature even

in isolated non-interacting nanocrystals. The rest of the ions were magnetically disordered or uncoupled. Surprisingly, these small $Zn_{1-x}Mn_xO$ nanocrystals poses relatively large low-temperature magnetic coercivity and relatively high blocking temperature in the isolated form, which indicate large magnetic anisotropy. In the nanocrystal powder the coercive field decreased significantly. This study highlights the advantages of working with non-interacting single domain particles of these intriguing materials.

**G22 12 Superparamagnetic resonance in antiferromagnetic nanoparticles: systematic features in the temperature dependence*** PRASANTA DUTTA, MOHINDAR SEEHRA, *West Virginia University* Antiferromagnetic (AF) nanoparticles (NP) of dimensions $\approx$ 5 nm usually acquire significant magnetic moment even below $T_N$ due to uncompensated surface spins. This moment follows superparamagnetism (SPM) above the blocking temperature $T_B < T_N$. In this work, we will discuss some unique features in the temperature dependence of the electron magnetic resonance (EMR) spectra which have been reported in NP of ferrihydrite, NiO and $\gamma Fe_2O_3$ [1]. As T is lowered towards $T_B$ the resonance field $H_r$ decreases and the linewidth $\Delta H$ increases so that $\delta H_r \approx (\Delta H)^n$ with $n \approx 3$ is observed. This is in line with the variation expected from the demagnetizing fields of non-spherical particles [2]. From the temperature variation of the line intensity $I = (\Delta H)^2 h$ (h = peak-to-peak height), the location of $T_B$(m) and $T_B$(EMR) has been obtained [1]. For $T < T_B$(m), as $H_r$ approaches zero, the EMR line becomes highly asymmetrical, which is explained from the combined contributions of resonance at $+H_r$ and $-H_r$. [1]. **G22 13 Competition between Thermoinduced Magnetization and Uncompensated Spins** GREGORY BROWN, MARKUS EISENBACH, G. M. STOCKS, *Oak Ridge National Lab* Thermoinduced magnetization (TiM) is the ferromagnetic response predicted for nanoparticles of normally antiferromagnetic materials. Unambiguous experimental observation of this phenomenon is complicated by the effects of the particle size-distribution within a sample and the uncompensated magnetic moments within a nanoparticle. Monte Carlo calculations of nanoparticles with odd numbers of spins have been employed to resolve the competition between TiM and uncompensated spins. The magnitude of the ferromagnetic response, $\langle |M|^2 \rangle$, is easily resolved into the two phenomena. Analysis for the response along the direction of crystalline anisotropy, $\langle M_z^2 \rangle$, is complicated by the temperature-dependent relaxation of individual spins away from the anisotropy axis. These results indicate that TiM may be confirmable in nanoparticles with uncompensated spins. However, quantitative estimates of the temperature- and anisotropy-dependence of TiM are significantly affected by uncompensated moments.

**G23 1 Efficient Ab-initio Calculation of the Anomalous Hall Conductivity of Fe by Wannier Interpolation** XINJIE WANG, DAVID VANDERBILT, *Rutgers University* JONATHAN YATES, IVO SOUZA, *LBNL and University of California, Berkeley* Recently, a first-principles calculation of the anomalous Hall conductivity (AHC) of Fe as a Brillouin-zone integral of the Berry curvature was carried out and found to be in reasonable agreement with experimental results.[1] However, these authors observed extraordinarily strong and rapid variations of the Berry curvature with wavevector $k$ in the vicinity of avoided crossings and near-degeneracies in reciprocal space. A conventional first-principles calculation thus requires an extremely dense k-point mesh and is quite time-consuming. Here, we present an efficient first-principles approach for computing the AHC based on Wannier interpolation. First, a conventional electronic-structure calculation is performed for Fe, with spin-orbit included, on a relatively coarse k-point mesh. Second, maximally-localized Wannier functions are constructed by a post-processing step,[2] thus transforming the full ab-initio problem into an effective tight- binding form. Finally, the needed quantities such as Berry potentials and curvatures are interpolated onto a fine k-point mesh and used to compute the AHC. Our approach gives good agreement with conventional, less efficient first-priciples calculations.

**G23 2 Spin and charge currents and current rectification in Luttinger liquids*** B. BRAUNECKER, D. E. FELDMAN, J. B. MARSTON, *Brown University* Asymmetries in spin and charge transport properties are of great interest for spintronic and electronic applications. We show that externally-driven spin and charge currents in a Luttinger liquid model of a one-dimensional quantum wire are strongly modified by the presence of a localized magnetic or nonmagnetic scatterer. A diode effect appears at low voltages when this scatterer is spatially asymmetric, and a non-monotonous dependence of the current on the voltage is possible.[1]

**G23 3 Interplay of Rashba and itsp-d exchange couplings in magnetic 2DEGs*** FRANCISCO MIRELES, *CCMC-UNAM, Mexico.* HENRIQUE H. P. FREIRE, *IFSC, Universidade de Sao Paulo, Brazil* J. CARLOS EGUES, *IFSC, Universidade de Sao Paulo, Brazil* In diluted magnetic semiconductor (DMS) quantum wells the itsp-d exchange interaction between the itinerant conduction electrons in the well and the localized electrons in the *d*

orbitals of the Mn impurities gives rise to interesting spin-dependent physics [1]. Recently, the interplay of the Rashba spin-orbit and the itsp-d exchange interactions in Mn-based wells has been recognized via Shubnikov-de-Haas measurements [2]. While the Rashba spin-orbit has been extensively studied in non-magnetic 2DEGs, its role in DMS systems with a competing itsp-d exchange interaction has not yet been addressed theoretically. In this work we present a**it k.p** derivation of an effective Hamiltonian for a Mn-based quantum well with competing Rashba and itsp-d interactions, and show numerical results for the magnetoresistance $\rho_{xx}$ of typical magnetic 2DEGs using our effective Hamiltonian model. Our results shows interesting beating patterns of the $\rho_{xx}$ as a function of the temperature and carrier density which suggests a significant interplay between the spin-orbit and itsp-d exchange interactions, as a recent experiment observes [2]. **G23 4 Berry Phase and itAb initio Calculation of Anomalous & Spin Hall Effect.**
YUGUI YAO, *Institute of Physics, Chinese Academy of Sciences, China*

Berry phase in momentum space in spin-orbit coupled bands affects the charge and spin transport of electrons in real space, and produces fascinating new phenomena. Two examples are the anomalous Hall effect and the recently proposed intrinsic spin Hall effect. Avoiding the ambiguity introduced by model Hamiltonians, we evaluate the Berry curvature accurately for real materials by parameter-free itab initio methods. We have calculated the anomalous Hall conductivity for ferromagnetic crystals of Fe, Co, Ni, $Mn_5Ge_3$, and $CuCr_2Se_{4-x}Br_x$, and investigated the magnetization dependence and sign change, with results in quantitative agreement with experiments [1,2]. Using the itab initio technique, we have also evaluated the intrinsic spin Hall conductivity in non-magnetic semiconductors (GaAs, Si, Ge, AlAs) as well as metals (W and Cu) [3,4]. We have systematically studied how its sign and magnitude depend on strain, doping density, and frequency for the semiconductors, and found very large values for the metals. **G23 5 Emerging Magnetism at Pt Nanocontacts and Nanowires** ERIO TOSATTI, *SISSA/ICTP/Democritos Trieste* ANDREA DAL CORSO, *SISSA/Democritos Trieste* ANNA DELIN, *KTH Stockholm* ALEXANDER SMOGUNOV, *SISSA/Democritos Trieste* RUBEN WEHT, *CNEA San Martin* Nanocontacts made of transition metals that are nonmagnetic in bulk may display a possible onset of Hund's rule local nanomagnetism. Zero-temperature DFT electronic structure calculations indicate that magnetism may occur in monatomic nanowires of 4d and 5d transition metals, generally favored by tensile stress, and sometimes also by spin-orbit coupling. [1] In the particular case of a Pt monatomic nanowire, resurgence of orbital magnetism is predicted to conspire with intra-atomic exchange to give rise to a spontaneous magnetization even at zero stress. Here we expect an extraordinarily large magnetic anisotropy, spin and orbital magnetization lying strictly parallel to the nanowire axis. A Pt nanowire-like contact should thus behave as an Ising nanomagnet. Since magnetic exchange splittings generally affect the number of conducting channels crossing the Fermi level, it is likely that the ballistic conductance through a nanowire-like contact [2] will be affected by the emerging nanomagnetism of Pt. **G23 6 Atomic and electronic properties of $Ni/Al_2O_3/Ni$ magnetic tunnel junction** YOU LIN, *University of South Florida* IVAN OLEYNIK, *University of South Florida* Numerous experimental and theoretical investigations show that the spin-polarization of the tunneling current in magnetic tunnel junctions (MTJs) is not an intrinsic property of the ferromagnet alone, but depends on the electronic properties of the insulator and the ferromagnet-insulator interface. We report the results of first-principles density-functional studies of Ni_/$Al_2$_$O_3$_/Ni MTJs. The atomic structure has been studied for different interface terminations. The interfacial energetics was quantified based on the work of separation and the most stable interfacial structures have been identified. The electronic and magnetic properties have been thoroughly analyzed in the framework of local densities of states. The possibility of strongly-correlated electronic effects has also been considered by performing additional LDA+U calculations of interfacial electronic structure. We will discuss various factors that might contribute to spin polarization of the tunneling current in the MTJs.

**9:36**
**G23 7 Interface properties of nickel/organics/nickel magnetic tunnel junctions** WESLEY FABELLA, *University of South Florida* IVAN OLEYNIK, *University of South Florida* In recent years, substantial experimental efforts were directed towards developing a new class of spintronic devices based on organic polymers, oligomers and small molecules. In particular, recent experiments indicate efficient spin injection and spin transport in ferromagnet/organic systems. However, the electron and spin transport through metal-molecule-metal junctions depends crucially on the properties of ferromagnet/organics interfaces. We

performed first-principles density functional theory (DFT) calculations of nickel/organic-molecule/nickel magnetic tunnel junctions. Organic systems include both saturated alkane and unsaturated thiophene molecules. The choice of the system was made based on available experimental information. The atomic structures of metal/molecule interfaces were built and the geometries of molecule/metal interfaces were determined by optimizing the interfacial work of separation. We will discuss the electronic properties of molecule/electrode junctions including distribution of charge densities, local charges, local magnetic moments and local densities of states on individual atoms. The spin-dependent interfacial properties will be discussed in relation to spin-dependent transport in organics-based MTJs.

**G23 8 Nonequilibrium Transport in Quantum Impurity Models:(Bethe-Ansatz for open systems)** PANKAJ MEHTA, NATAN ANDREI, *Rutgers University* We develop an exact nonperturbative framework to compute steady-state properties of quantum-impurities subject to a finite bias. We show that the steady-state physics of these systems is captured by nonequilibrium scattering eigenstates which satisfy an appropriate Lippman-Schwinger equation. Introducing a generalization of the equilibrium Bethe-Ansatz - the Nonequilibrium Bethe-Ansatz (NEBA), we explicitly construct the scattering eigenstates for the Interacting Resonance Level model and derive exact, nonperturbative results for the steady-state properties of the system.

**10:00**
**G23 9 Ab initio investigation of domain walls in ferromagnetic films and wires*** HEIKE C. HERPER, PETER ENTEL, *Theoretical Physics, University of Duisburg-Essen, Lotharstrasse 1, D-47048 Duisburg* Domain walls can be viewed as special type of interfaces. In case of relatively thin domain walls a magnetoresistance effect can be observed due to the domain wall, which has been addressed in a considerable number of experimental and theoretical studies. However, only few ab initio investigations have been done in this field. We have determined the influence of domain walls on the resistance in ferromagnetic Co and Ni layers employing the fully-relativistic, spin-polarized Screened Korringa-Kohn-Rostoker method (SKKR) and the Kubo-Greenwood formula. In order to investigate the magnetoresistance in thin wires we made use of a real-space SKKR and Kubo-Greenwood method. The magnetoresistance and the formation energy of the domain walls have been calculated depending on the thickness and the type of the domain wall. As expected the formation energy decreases with increasing number of FM layers. Throughout this paper all domain walls are assumed to be oriented in the plane of layers. In order to avoid contributions from the anisotropic magnetoresistance the current flows perpendicular to the domain walls, i.e. parallel to the surface normal. The results support the predictions from Zhang and Levy concerning the width dependence of the domain wall resistance.

**G23 10 Orbital magnetic susceptibility in an integrable system** M.X. LOU, J.M.A.S.P. WICKRAMASINGHE, R.A. SEROTA, *University of Cincinnati* We investigate, analytically and numerically, the orbital magnetism of free electron gas in a rectangular box, which is a model classically integrable system. We find that both the average orbital susceptibility and its fluctuations are determined by the two-level van Vleck susceptibility that involves the last occupied (Fermi) level and the first unoccupied level. This is in line with previous results for disordered (classically chaotic) systems. The mesoscopic fluctuations, however, are much larger in integrable systems. We find that, in units of $\mu_B^2/\Delta$, where $\Delta$ is the mean level spacing, the average orbital susceptibility is $\langle|\hat{L}_{if}|^2\rangle\langle(\varepsilon_f - \varepsilon_i)^{-1}\rangle$, where $\langle|\hat{L}_{if}|^2\rangle \sim \sqrt{N}$, $L$ is the orbital angular momentum, $N$ is the number of electrons in the box, and $\varepsilon_f - \varepsilon_i$ is the level spacing (in units of $\Delta$) between the last occupied level and the first unoccupied level. $\langle\varepsilon_f - \varepsilon_i)^{-1}\rangle$ is principally divergent and hence determined by the relevant cut-off.

**G24 2 Marker Motion Measurements of Nanoparticles in Polymer Matrices** ALETA HAGMAN, *Northwestern University & Argonne National Laboratory* KENNETH R. SHULL, *Northwestern University* JIN WANG, XUEFA LI, DONG RYEOL LEE, SURESH NARAYANAN, *Argonne National Laboratory* Marker motion can be used to infer the ordering kinetics and nanoparticle dynamics in model polymer/metal nanocomposite thin films. In current experiments, the thermally evaporated gold particles (few nanometers in diameter) act as a marker layer between two polymer layers with different mobilities. The disparity in the mobility causes a marker movement towards the layer with the higher mobility. X-ray standing waves (XSWs), generated by total external reflection above a mirror surface, are used to monitor the time evolution of the gold nanoparticle distribution as the nanocomposite ultrathin films are heated above the polymer glass transition temperatures. Diffusion coefficients are obtained from the time-dependence of the nanoparticle distribution evolution. Polymer/gold interactions has shown to be system dependent, with pol(tert-butyl acrylate) (PtBa) showing weak interactions while poly(2-vinyl pyridine) (PVP) shows strong interactions as expected. Free surface effects relating to mobility will also be discussed.

**8:48**
**G24 3 Effect of Areal Density of Polymer Chains on Gold Nanoparticles on Nanoparticle Location in a Block Copolymer Template** B.J. KIM, J. BANG, C.J. HAWKER, E.J. KRAMER, *UCSB* It is well established that one block of a copolymer can interact preferentially with an inorganic substrate to produce wetting and domain orientation. We take advantage of this preferential interaction to control the location of 2.5 nm diameter Au nanoparticles coated with short thiol-terminated polystyrene ($M_n$=3.4 kg/mol) chains (PS-SH) in a symmetric poly(styrene-*b*-2 vinylpyridine) (PS-b-P2VP) diblock copolymer ($M_n$=196 kg/mol) by changing the areal density $\Sigma$ of the PS-SH on the Au. If $\Sigma \geq$ 1.6 chains/nm$^2$, the preferential interaction between the P2VP of the PS-b-P2VP and the Au surface is screened and the Au localizes in the center of the PS domains. If $\Sigma \leq$ 1.4 chains/nm$^2$, the Au

particles are localized at the PS-P2VP interface. Au nanoparticles coated with thiol terminated P2VP ($M_n$=3 kg/mol) localize in the center of the P2VP domain of the PS-P2VP over the entire range of $\Sigma$, demonstrating the localization of the PS coated Au nanoparticles at the interface at low values of $\Sigma$ is due to the unscreened Au-P2VP interaction.

**G24 4 Nanocomposite Microdomain Inversion in Au Nanoparticle/ PS-b-PFOMA Block Copolymer Films** LUCIANA MELI, YUAN LI, KEITH P JOHNSTON, *The University of Texas at Austin* PETER F GREEN, *The University of Michigan, Ann Arbor* We report that Au nanocrystals sequestered within the microdomains of self-assembled aggregates of polystyrene-b-poly(1,1',2,2'-tetrahydroperflurooctyl methacrylate) (PS-b-PFOMA) thin films are capable of following the structure-guiding matrix in a morphological transition from spherical PFOMA aggregates in a PS matrix to the inverse morphology upon supercritical CO2 (scCO2) sorption. Furthermore, the domain size of the aggregates can be finely tuned by adjusting the scCO2 density. By pretreating the particles surface with a host of ligands with different chemical affinities for the constituent blocks, we observe that the Au/diblock co-assembly process is dependent not only on the ligand size and ligand- matrix compatibility, but also on the interaction of the ligands with the interfaces that confine the film.

**9:12**

**G24 5 Dielectrophoretic alignment of montmorillonite nanoplatelet suspensions in an organic matrix** EVANGELOS MANIAS, *Materials Science and Engineering, Penn State University* GEORGIOS POLIZOS, *Penn State University* HILMAR KOERNER, RICHARD VAIA, *Air Force Research Lab/MLBP* High orientational alignment of pseudo-two-dimensional inorganic platelets in an organic matrix is achieved by external AC electric fields ( $\sim$ 0.5V/$\mu$m, rms). Namely, montmorillonite aluminosilicate platelets are organically modified by alkyl-ammonium surfactants and dispersed in an uncrosslinked epoxy. Orientation is quantified through wide angle 2D X-Ray diffraction under an AC electric field ( $\sim$ 0.05-4V/$\mu$m), following the reorientation of inorganic stacks (tactoids), resulting in Hermans orientation factors of 0.7–0.9 even at moderate field strengths. The degree of orientation dependence on the electric field frequency and strength is presented. The electrophoretic motion of the cationic surfactants as a possible mechanism to produce alignment is delineated via broadband ($10^{-2}$-$10^{7}$ Hz) dielectric relaxation spectroscopy, and dipole moment theoretical analyses. The cationic electrophoretic motion does not have any major contribution for the platelet alignment, suggesting that the primary cause is due to induced dipoles (image charges) on the dielectric inorganic platelets.

**9:24**

**G24 6 Surface morphology in dewetting polystyrene/ polyhedral oligomeric silsesquioxane (POSS) thin-film bilayers** RITUPARNA PAUL, MICHAEL C. SWIFT, JOHN R. HOTTLE, ALAN R. ESKER, *Macromolecules & Interfaces Institute, Department of Chemistry (0212), Virginia Tech, Blacksburg, VA 24061* Polymer/polymer and polymer/nanoparticle bilayers on solid substrates are common in technological applications. Dewetting or the spontaneous formation of holes in polymer films above their glass transition temperature, poses a serious problem in the nanofabrication of polymeric multilayers. This study utilizes bilayer films of polystyrene (PS) and trisilanolphenyl- POSS (TPP) as a model to investigate the morphological evolution of polymer/nanoparticle bilayers upon annealing. X-ray photoelectron spectroscopy, and optical and atomic force microscopies have been used to study dewetting as a function of annealing time and temperature. Upon annealing the PS/TPP bilayers at 200 C, the upper TPP layer undergoes instantaneous cracking and these cracks serve as nucleation sites for dewetting of the TPP and PS layers for annealing times up to 90 minutes. For annealing times longer than 90 minutes, the dewetting of TPP and PS layers is complete resulting in the formation of TPP encapsulated PS droplets.

**9:36**

**G24 7 Block Copolymer Nanocomposites for RF Magnetodielectric Applications** TA-I YANG, PETER KOFINAS, *Department of Chemical and Biomolecular Engineering, University of Maryland, College Park, MD* The aim of this research is to develop novel block copolymer nanocomposites for radio frequency applications. Block copolymers (BCP) act as templates to enhance the ordering of nanoparticles within the polymer matrix and tailor the desired electromagnetic properties such as permeability ($\mu$) and permittivity ($\varepsilon$). We incorporated iron and strontium or titanium organometallic precursors into three different polymer matrices (styrene-*b*-isoprene-*b*-styrene (SIS), styrene-b-(ethylene-ran-butylene)-b-styrene (SEBS), and sulfonated styrene-b-(ethylene-ran-butylene)-b-styrene (S-SEBS)) and then formed mixed metal oxide nanoparticles within the BCP. Preliminary experimental results demonstrated we can obtain $\mu = \varepsilon$ near 2.7 with low loss tangent (tan $\delta < 0.01$) through the 1 M to 1G Hz frequency range by utilizing SIS or SEBS with templated $Fe_20_3$/SrO nanoparticles. For the S-SEBS copolymer composites, most mixed metal oxide nanoparticles were successfully templated into BCP self-assembled patterns confirmed by TEM, and the loss tangent could be significantly reduced by heat treatment.

**G24 8 Effect of confinement on the polymer segmental motion and on ion mobility in PEO/layered-silicate nanocomposites***
SPIROS H. ANASTASIADIS,[†] KIRIAKI CHRISSOPOULOU, ATHANASIOS AFRATIS, *Foundation for Research and Technology - Hellas, Heraklion Crete, Greece* M.M. ELMAHDY, GEORGE FLOUDAS, *University of Ioannina, Ioannina, Greece* BERNHARD FRICK, *Institut Laue-Langevin, Grenoble, France* The effect of confinement on the local, the segmental and the ionic processes of poly(ethylene oxide)/montmorillonite (PEO/MMT) intercalates are investigated. X-ray diffraction, DSC and polarizing optical microscopy data show that the intercalated PEO chains remain amorphous and it is only the excess PEO chains outside the galleries that crystallize. This is also verified by the behavior of the elastic intensity of quasi-elastic neutron scattering (QENS) experiments on the same hybrids. Dielectric relaxation spectroscopy reveals that confinement results in an acceleration of the PEO segmental dynamics that display an Arrhenius temperature dependence with very low activation energy, whereas the local beta-process remains unaffected. Likewise, ionic mobility is enhanced in the nanohybrids suggesting that ion mobility is assisted by the faster PEO segmental motion.

**G24 9 Photovoltaic Responses of Solar Cells Based on Lead Selenide Quantum Dots and Conducting Polymers** XIAOMEI JIANG, SERGEY LEE, ANVAR ZAKHIDOV, *University of Texas at Dallas, Richardson, TX, 75083* RICHARD D. SCHALLER, J.M. PIETRYGA, VICTOR KLIMOV, *Chemistry Division, Los Alamos National Laboratory, Los Alamos, NM, 87545* We report on hybrid solar cells based on nanocomposites of conjugated polymers (polythiophene and polyphenylvinylene derivatives) and IR-sensitive PbSe QDs that have a size-tunable energy gap between 0.3 and 1 eV. Thin film cells show very good diode characteristics and sizable photovoltaic response. The good performance of our devices in both photovoltaic and photodiode regimes indicates quite efficient charge separation between the polymer and QD components. To elucidate the mechanism for charge separation in these composite structures, we analyze conduction and valence-band energy offsets derived from cyclic voltammetry measurements. We find the significant increase of photocurrent due to more efficient charge separation when the surface of the quantum dots was treated with pyridine to remove the surface ligand. The analysis of a spectrally resolved photocurrent measurements reveals some evidence of carrier multiplication-enhanced photocurrent in our devices. Specifically, we observe indications of a rapid increase in the photocurrent at spectral energies in correlation with the size-dependent energy gap of the QD component. The onset of this increase correlates with what is expected for the onset of carrier multiplication in PbSe QDs.

**G24 10 Electric Field Effect on Wannier- Frenkel Hybrid Exciton in a Quantum Dot Coated by an Organic Shell** QUE HUONG NGUYEN, *Physics Department, Marshall University, One John Marshall Dr., WV 25701* JOSEPH L. BIRMAN, *Physics Department, City College, CUNY, Convent Ave. & 138 Street, NY 10031* The effect of external electric field on the Wannier Mott-Frenkel hybrid excitons in the configuration of a spherical semiconductor quantum dot coated by an organic shell has been studied. The electric field reduces the exciton binding energy and shifted the resonance region where the Wannier and Frenkel exciton are strongly mixed. The quadratic Stark dependence of the hybrid exciton energy on the electric field was found for the confined Stark effect for the hybrid exciton. Upon the application of field the coupling term between the two kinds of excitons increases. An important result is the possibility of tuning the Wannier-Frenkel exciton resonance by applied electric field

**G24 11 Transport measurements in semiconductor nanocrystals capped with electroactive ligands** CLAUDIA QUERNER, *University of Pennsylvania, USA* PETER REISS, *CEA Grenoble, France* MICHAEL D. FISCHBEIN, *University of Pennsylvania* PATRICE RANNOU, *CEA Grenoble* JOEL BLEUSE, *CEA Grenoble* ADAM PRON, *CEA Grenoble* MARIJA DRNDIC, *University of Pennsylvania* Organic-inorganic hybrid materials based on semiconductor nanocrystals and $\pi$-conjugated oligomers or polymers have seen an increasing interest over the past years mainly because of their possible applications in optoelectronic devices, such as solar cells. We report here the preparation of organic-inorganic hybrids by chemical grafting of tetraaniline onto the surface of semiconductor nanocrystals, such as CdSe and PbSe. We proved by spectroscopic and spectroelectrochemical studies that the grafting reaction does not influence in a significant way the electroactivity of both systems nor does it modify the doping mechanism of the grafted ligands. By cyclic voltammetry we were able to estimate the position of the energy levels in the hybrid, which are aligned such that a charge separation can occur at the organic-inorganic interface after photo-excitation. Highly efficient photoluminescence quenching confirmed such a process. Finally, we studied photoconductivity in these materials.

**10:36**

**G24 12 Photooxidation of sugar and alcohol on $TiO_2$ surfaces: A first-pirnciples study** MAO-HUA DU, JUN FENG, SHENG-BAI ZHANG, *National Renewable Energy Laboratory* First-principles studies are carried out on $TiO_2$/sugar (alcohol) interfaces under UV illumination. A rapid charge separation takes place at the interfaces through a two-step process: (1) trapping of photo-generated carriers at the gap levels induced by the chemisorbed molecules, and (2) upon the carrier trapping, a structural transformation of the adsorbed molecules, which in turn eliminates the gap levels. The second-step here is necessary to avoid carrier recombination, and hence results in an irreversible charge separation. Such a charge transfer across the semiconductor/molecule interface leads to various oxidation and reduction processes with structural reconfigurations (bond- forming and breaking) of the surface molecules. These results reveal the underlying microscopic mechanism of photo-catalytic reactions on the $TiO_2$ surfaces. The mechanism for the observed self-assembly of TiO2/cyclodextrin wires under UV illumination will also be discussed. This work was supported by the U. S. Department of Energy, BES and EERE, under Contract No. DE-AC39-98-GO10337.

**G24 13 Directly Patterned Mesoporous Carbon and Metal-Doped Carbon Films Prepared using Block Copolymer Templates in Supercritical CO2** GAURAV BHATNAGAR, JAMES WATKINS, *University of Massachusetts - Amherst* Porous carbon and metal-doped porous carbon films have wide applications in separations, sensors, catalysis and magnetic storage applications. Conventionally prepared carbon films have micropores in the size range of 2 nm. Recent techniques for the synthesize of mesoporous carbon with 10-50 nm pores using sacrificial silica templates have limitations with respect to pore connectivity and the preparation of patterned and metal-doped carbon films. Here we report supercritical fluid-assisted infusion and phase selective reaction within pre-organized block copolymer and block copolymer/homopolymer templates to synthesize mesoporous carbon and metal doped carbon films. Well-defined mesoporous carbon films patterned at the device level with good mechanical properties and metal doped carbon films by pre-infusion of block copolymer templates with metal precursors in supercritical carbon dioxide were synthesized. Platinum doped carbon films for applications in fuel cells having good electrochemical response were produced. The preparation of cobalt containing carbon films with potential use in magnetic storage applications demonstrates the general applicability of supercritical infusion technique to produce metal cluster containing films.

**8:36**
**G25 2 Structural Transitions of F-Actin:Espin Bundles** KIRSTIN PURDY, *University of Illinois at Urbana Champaign* JAMES BARTLES, *Northwestern University* GERARD WONG, *University of Illinois at Urbana Champaign* Espin is an actin bundling protein involved in the formation of the parallel bundles of filamentous actin in hair cell stereocilia. Mutations in espin are implicated in deafness phenotypes in mice and humans. We present measurements of the F-actin structures induced by wild type and by mutated espin obtained via small angle x-ray scattering and fluorescence microscopy. We found that wild type espin induced a paracrystalline hexagonal array of twisted F-actin, whereas the mutated espin only condensed the F-actin into a nematic-like phase. The possibility of coexisting nematic and bundled actin in mixtures containing both mutant and wild type espins was also investigated.

**8:48**
**G25 3 Nonequilibrium Self-Assembly of Linear Fibers** CHENGHANG ZONG, TING LU, TONGYE SHEN, PETER WOLYNES, *University of California, San Diego* From physical viewpoint, a dynamic bio-fiber represents an interesting one-dimensional nonequilibrium system. We construct a minimal dynamic model for this type of fibers. Our model incorporates features such as realistic dynamics rules and site resolution. The steady state solutions are obtained with the nonequilibrium variational principle. The projection of steady state distributions produces an effective potential for the pure dynamic system. We demonstrate how dynamic behaviors such as catastrophe, rescue, and dynamic instability can be analyzed under the effective reaction coordinate.

**9:00**
**G25 4 Energetics and Dynamics of Constrained Actin Filament Bundling** LE YANG, *Phys. Dept., Washington University* DAVID SEPT, *Dept. of Biomedical Engineering, Washington University* ANDERS CARLSSON, *Phys. Dept., Washington University* The formation of filopodia-like bundles from a dendritic actin network has been observed to occur in vitro as a result of branching induced by Arp2/3 complex. We study both the energetics and dynamics of actin filament bundling in such a network in order to evaluate their relative importance in bundle formation processes. Our model considers two semiflexible actin filaments fixed at one end and free at the other, described using a normal-mode approximation. This model is studied by both Brownian dynamics and Monte Carlo energetics methods. In the dynamic simulations, we evaluate the time required for the filaments to interact and bind, and examine the dependence of this bundling time on the filament length, the distance between the filament bases, and the crosslinking energy. For most of the cases we have studied, the energetics and dynamics simulations give similar results for critical distance. Over a broad range of conditions, we find that the times required for bundling from a network are compatible with experimental observations.

**9:12**
**G25 5 Evolution of growth modes for polyelectrolyte bundles** G.H. LAI, OLENA V. ZRIBI, *University of Illinois at Urbana-Champaign, Dept. of Physics* GOLESTANIAN RAMIN, *University of Sheffield, Dept. of Physics* GERARD C.L. WONG, *University of Illinois at Urbana-Champaign, Dept. of Physics, Dept. of Materials Science and Engineering, Dept. of Bioengineering* F-actin is a prototypical 'hard rod' polyelectrolyte, with a charge density of $\sim$ 1e/2.5Å and a persistence length of $\sim$ 5-10 $\mu$m. In the presence of multivalent ions, F-actin can condense into close-packed bundles. In this work, we use fluorescence microscopy to study the detailed growth mode of such bundles, and show how it evolves as a function of salt concentration. Preliminary results indicate that at sufficiently high salt concentrations, the bundle width is relatively insensitive to salt concentration. Moreover, the growth mode of the system changes as a function of salt concentration, varying from lateral growth (which increases the bundle width) to longitudinal growth (which increases the bundle length).

**9:24**
**G25 6 Nanoscopic tubulin rings*** HACENE BOUKARI, *NIH* DAN SACKETT, *NIH* PETER SCHUCK, *NIH* SUSAN KRUEGER, *NIST* RALPH NOSSAL, *NIH* We describe results of analysis of fluorescence correlation spectroscopy, small-angle neutron scattering, and sedimentation measurements of nanoscopic polymer rings formed following interactions of tubulin (100 kDa) and a small peptide, cryptophycin (340 Da). Tubulin is a ubiquitous dimeric protein found in eukaryotic cells, and is the building block of microtubules, which are dynamical biopolymers involved in many critical cell functions. The peptide, which is a marine natural product, inhibits the formation of microtubules and, instead, induces the formation of the rings. Under the studied conditions these rings appear rigid, have circular geometry ( $\sim$ 25 nm dia.), are monodisperse in size (8 tubulin dimers/ring), and are stable even with tubulin concentration as low as 1 nM. Remarkably, no intermediate oligomers (partial rings or others) are observed. Further, structural and hydrodynamic modeling confirms the number (8) of tubulin dimers per ring and shows that the tubulin monomers are not spherical, consistent with their known crystallographic structure. *H. Boukari, R. Nossal, D. Sackett, and P. Schuck, PRL 93, 98106 (2004).

**9:36**
**G25 7 Deformation of DNA and Polymer Labels during End-Labelled Free-Solution Electrophoresis.** GARY W. SLATER, LAURETTE C. McCORMICK, *University of Ottawa* Recent advancements to DNA sequencing by End Labelled Free Solution Electrophoresis (ELFSE) show the promise of this novel technique which overcomes the need for a gel by using a label (or drag-tag) to render the free solution mobility of the DNA size-dependent. It is the attachment of an uncharged drag-tag molecule of a set size to all the various lengths of DNA in the sample that selectively slows down smaller DNA chains which have less force to pull the drag-tag than larger DNA. Taking advantage of the modified hydrodynamic properties of tagged DNA, ELFSE has been used to successfully sequence up to about 100 bases of DNA in the absence of a gel or other sieving. So far, only globally random coil

conformations have been associated with ELFSE, i.e. the DNA and the label together form a single, undeformed hydrodynamic unit. However, next generation labels combined with high field strengths may allow for deformation of the DNA and/or a polymer label. We present here the necessary conditions for stretching, and some of the subsequent effects on separation, highlighting possible improvements to ELFSE performance via stretching of DNA and/or the polymer label.

**9:48**
**G25 8 Ferroelectric-specific peptides as building blocks for bio-inorganic devices** BRIAN REISS, GUO-REN BAI, ORLANDO AUCIELLO, LENIDAS OCOLA, MILLICENT FIRESTONE, *Argonne National Laboratory* Combinatorial phage display methods have been used to identify a circularly constrained heptapeptide sequence, ISLLHST, that strongly associates with a perovskite ferroelectric, lead zirconium titanate, $Pb(Zr_xTi_{1-x})O_3$ (PZT). The affinity and selectively of binding to polycrystalline MOCVD deposited PZT thin films supported on $Si/SiO_2/Pt$ substrates were determined by titering and immunofluorescence microscopy, and the peptide was shown to selectively bind PZT in the presence of Pt, Si, Au, and several different photoresists. Ferroelectric properties were determined by measurement of the $P - E$ hysteresis loop on unmodified and phage bound PZT thin films, and no change in the coercive field, $E_c$, or the saturation polarization, $P_s$ was observed after contacting the PZT with aqueous buffer or phage binding. This work represents an important first step towards rendering perovskite ferroelectrics compatible with biological molecules. Work is currently underway to study how conformational and positional control of tethered biomolecules can be controlled by the surface charge and/or polarization state of PZT as well as integration into several proto-type device architectures.

**10:00**
**G25 9 Bio-based Polymer Foam from Soyoil** LAETITIA M. BONNAILLIE, RICHARD P. WOOL, *Dept Chemical Engineering, University of Delaware* The growing bio-based polymeric foam industry is presently lead by plant oil-based polyols for polyurethanes and starch foams. We developed a new resilient, thermosetting foam system with a bio-based content higher than 80%. The acrylated epoxidized soybean oil and its fatty acid monomers is foamed with pressurized carbon dioxide and cured with free-radical initiators. The foam structure and pore dynamics are highly dependent on the temperature, viscosity and extent of reaction. Low-temperature cure hinds the destructive pore coalescence and the application of a controlled vacuum results in foams with lower densities $\sim$ 0.1 g/cc, but larger cells. We analyze the physics of foam formation and stability, as well as the structure and mechanical properties of the cured foam using rigidity percolation theory. The parameters studied include temperature, vacuum applied, and cross-link density. Additives bring additional improvements: nucleating agents and surfactants help produce foams with a high concentration of small cells and low bulk density. Hard and soft thermosetting foams with a bio content superior to 80% are successfully produced and tested. Potential applications include foam-core composites for hurricane-resistant housing, structural reinforcement for windmill blades, and tissue scaffolds.

**G25 10 Calculation of the Vibrational Continuum in Helical Polymers from First Principles: Application to Single-walled Carbon Nanotubes** HADLEY LAWLER, CARTER WHITE, *Naval Research Laboratory* JOHN MINTMIRE, *Oklahoma State University* A first-principles method for calculation of the full vibrational continuum in helical polymers is presented, with application to chiral single-walled carbon nanotubes. The dynamical matrix is calculated within a helical symmetry, utilizing a cylindrical basis for nuclear displacements. Sum rules within a helical symmetry, helical speeds of sound and helical flexure modes are addressed.

**10:24**
**G25 11 Optimizing the Geometry of Patterned Polymer Separation Media** DAVID HOAGLAND, *Univ. of Massachusetts Amherst* HELMUT STREY, *Stony Brook Univ.* A quantitative understanding of polymer transport in patterned polymer separation media would guide the design of media with optimized pattern geometries. For example, one might desire to know what confinement geometry best separates linear polymers by molecular weight as a driving field is applied to a polymer mixture. By asserting that transport is controlled by steric interactions with a periodic pore structure, and that the driving field is low enough for a linearity in the relationship between transport rate and field magnitude, we have derived a simple, general expression for polymer mobility as a function of parameters characterizing polymer and pattern. Our expression can be used to derive optimized separation geometries that can be produced by micro- or nano-lithography methods. Analysis will be discussed for several pattern geometries that exert periodic constriction on migrating polymers. Financial support: UMass MRSEC

## SESSION G26: FOCUS SESSION: TRAPPING OF NANOSCALE BIOLOGICAL OBJECTS

**G26 1 The Anti-Brownian Electrokinetic Trap (ABEL trap).***
ADAM COHEN, *Stanford University*

The Anti-Brownian Electrokinetic Trap (ABEL trap) provides a means to trap and manipulate individual nanoscale objects in solution. The ABEL trap works by monitoring the Brownian motion of a single fluorescent particle of interest, and then applying a feedback electric field to the solution so that the resulting electrokinetic drift exactly cancels this Brownian motion. The ABEL trap can trap objects far smaller than can be trapped by laser tweezers. I will describe

experiments on individual trapped molecules of fluorescently labeled λ-DNA. Due to its non-perturbative nature, the ABEL trap allows us to perform the first detailed studies of the conformation of individual DNA molecules in their equilibrium, unstretched state. We find that each molecule has a spectrum of conformational modes, and we experimentally determine the transition rates between modes. We compare the data to Rouse and Zimm models of polymer dynamics.

**G26 2 The ac electrokinetic elongation mechanism of DNA.** CHRISTOPH WALTI, *University of Leeds* ANDRE GERMISHUIZEN, *University of Cambridge* PAUL TOSCH, *University of Leeds* CLEMENS KAMINSKI, *University of Cambridge* GILES DAVIES, *University of Leeds* The manipulation of molecules in a controlled manner is a crucial prerequisite for the emerging field of molecular nanotechnology. AC electrokinetics provide a powerful tool for both positioning and manipulation of molecules, as well as for inducing conformational changes in DNA. We performed three-dimensional imaging measurements of fluorescently labelled DNA strands tethered to gold microelectrodes and subjected to strong ac electric fields. The observed elongation patterns are compared with previously determined fluid flow patterns and with the electric field lines obtained from numerical simulations. We demonstrate that the major contribution to the elongation of the DNA molecules stems from the ac electrokinetic torque, supplemented by a small bias force provided by the electric-field-induced fluid flow. Further, we show that the observed restricted elongation owing to the geometry of the electrode results from a sign change in the bias force.

**8:48**

**G26 3 Tracking-FCS: Correlation Spectroscopy of Individual Particles** ANDREW BERGLUND, HIDEO MABUCHI, *California Institute of Technology* Recently developed methods for trapping and tracking fluorescent particles have already been exploited for monitoring free diffusion with high spatial accuracy. These achievements suggest the possibility of performing fluorescence correlation spectroscopy (FCS) on an individual molecule as it moves freely in solution. Such an approach may enable, for example, the investigation of heterogenous folding dynamics in protein molecules in their native environment. In this talk, we will discuss our own experimental and theoretical approach to this problem. We use a spatially modulated Gaussian excitation laser and lock-in detection in order to track fluorescent particles in two dimensions. We show that Ornstein-Uhlenbeck statistics are appropriate for describing the fluctuations of a tracked particle, and we apply a generalization of the familiar (free particle) FCS equations to the situation in which a tracked particle is observed for a long period of time. Based on the same statistical model, we calculate absolute limits on the accuracy with which a particle of a given brightness and diffusion coefficient can be tracked using similar methods. Our results establish a framework for interpreting fluorescence time series and determining the feasibility of near-term goals in single-particle tracking experiments.

**9:00**

**G26 4 Flexible polymers under spherical confinement** ANGELO CACCIUTO, ERIK LUIJTEN, *University of Illinois at Urbana-Champaign* We compute the free energy of confinement $\Delta F$ for a flexible self-avoiding polymer inside a spherical cavity. We find two different regimes depending on the degree of compression. For moderate confinement the free energy exhibits a power-law dependence on the diameter $D$ of the cavity. At larger packing fraction $\phi$, however, the excluded-volume interactions between monomers dominate and the scaling law breaks down. We demonstrate that in the low density regime $\beta\Delta F$ scales as $(R_G/D)^{3/(3\nu-1)}$, where $R_G$ is the radius of gyration of the unconstrained polymer. This behavior differs from what is observed for confinement inside an infinitely long cylinder or between parallel plates, $\beta\Delta F \sim (R_G/D)^{1/\nu}$. On the basis of our results we revisit the problem of the escape through a hole of a spherically confined polymer and provide a corrected scaling prediction for the average escape time.

**9:12**

**G26 5 Dynamic effects in alignment of biological macromolecules for diffraction experiments.*** D. STARODUB, U. WEIERSTALL, K. SCHMIDT, R. B. DOAK, P. FROMME, J. C. H. SPENCE, Molecular alignment by means of anisotropic polarizability interaction with a laser electric field is the crucial step in the recently proposed serial diffraction of non-crystallizable proteins, where protein damage is prevented by recording the x-ray diffraction pattern from an array of identically oriented proteins passing through the intersection of x-ray and laser beams. The proteins can be delivered using a periodically triggered Rayleigh beam of doped water droplets. The behavior of a small globular protein (lysozyme), a large protein complex (ribosome) and a rod-like virus (TMV) in a water droplet and a gas damping cell at various pressures is considered. Optimum conditions for alignment in terms of laser power, pressure in a damping cell and adiabatic field switch-on are discussed. The degree of molecular alignment depends on these conditions and has to be sufficient to obtain sub-nanometer resolution in the charge density maps recovered from diffraction patterns.

**G26 6 Directed Cell Assembly with Magnetic Nanowires** EDWARD J. FELTON, MARCIE JAFFEE, DANIEL H. REICH, *Department of Physics and Astronomy, Johns Hopkins University* CHRISTOPHER S. CHEN, *Department of Bioengineering, University of Pennsylvania* Control of the positioning and movement of mammalian cells in culture has a variety of important applications ranging from medical diagnostics to tissue engineering. We

have developed cell manipulation techniques that exploit the magnetic properties of high aspect ratio nanoparticles such as ferromagnetic nanowires. The large remanent magnetization of these nanoparticles permits delivery of cells bound to them to precise locations on biochips through the nanoparticles' interactions with the magnetic fields of micropatterned magnetic structures. Together with chemical functionalization of the surfaces to direct cell adhesion, a wide range of multicellular patterns can be achieved. These approaches have been used to produce directed assemblies of cells. Results of these experiments include localized heterotypic cell pairs and the extension of these techniques to cell localization in three dimensions.

**G26 7 Tracking Protein-coated Particles in 3D.***
ENRICO GRATTON, *University of California at Irvine*

The utilization of 2-photon microscopy in the field of Cell Biology is of increasing importance because it allows imaging of living cells, including those systems where UV imaging is not possible due to photobleaching or photodamage limitations. We propose a novel approach using 2-photon excitation based on the use of a scanner to produce an effective ''intensity trap.'' As the particle moves in this trap (note that there is no force applied on the particle at the power level we are using for particle detection), the detection system continuously calculates the position of the particle in the trap. As the position of the particle is calculated with respect to the trap, the scanner position is moved to minimize the ''modulation'' of the light intensity in the trap. In practice, we set the scanner to perform an orbit around the particle in about 1 millisecond. The sampling rate is chosen such that many points (32 or 64) are acquired during the orbit. An FFT (Fast Fourier Transform) is performed on the points acquired during one orbit or after a series of orbits. The DC, AC and phase of the first harmonic of the FFT are calculated. The value of the modulation varies monotonically as the distance of the particle from the center of the orbit is increased so that for every value of the modulation we can estimate the value of the distance of the particle from the center of the orbit. The phase of the first harmonic gives the angular position of the particle with respect to the scanner zero phase which is known relative to the lab coordinates. The effective bandwidth of the tracking system depends on the maximum frequency for sinusoidal oscillation of the scanner, which is about 5 kHz for our galvano-scanner and on the number of photons needed for detecting the particle against the noise. Of course, there are other important considerations. First, if the motion of the particle is too fast such that after one orbit the particle moves too far from the new position calculated based on the previous orbit, tracking is lost since the feedback mechanism is too slow. Therefore, single molecules, which in water would move across the PSF in about 0.1 ms, cannot be tracked. We need at least a macromolecule the size of a large protein (100kD) or relatively high viscosity to increase the time a fluorescent particle can be observed in the PSF. The second consideration, perhaps the most important, is that the particle should not bleach during the length of the tracking. This is not a problem for particles made of many fluorophores, such as polystyrene fluorescent beads, which are also relatively large. Surprisingly, for relatively large particles such as viruses, photobleaching did not occur.

*In collaboration with Valeria Levim, Univeristy of Illinois at Urbana-Champaign.

**G26 8 A Device of Tracking a Single Nanometer-Sized Particle in 3D with Nanometer Resolution and Millisecond Response Time.** HU CANG, *Lawrence Berkeley National Lab.* C. SHAN XU, *University of California Berkeley* DANIEL MONTIEL, *University of California Berkeley* HAW YANG, *University of California Berkeley* We demonstrate a microscope system based on a confocal setup that can 'track' a moving particle in three dimensions (3D) and 'trap' it at a target position with nanometer spatial and millisecond time resolution. This is achieved by moving a 3D piezoelectric translation stage controlled by a feedback circuit to 'cancel' the displacement of the particle. By keeping the target particle inside the confocal volume, it is now possible to perform other spectroscopic experiments on the particle simultaneously for a long time while the particle is moving freely in solutions. Our device overcomes the difficulty of single molecule spectroscopy (SMS) experiment on free moving samples.

**10:24**
**G26 9 Nanoscale molecular traps*** CHIA-FU CHOU, QIHUO WEI, JIAN GU, FREDERIC ZENHAUSERN, *Arizona State University* NATHAN SWAMI, *University of Virginia* We have constructed nanoscale molecular traps using electrodeless, or insulator-based, dielectrophoresis [1,2]. The molecular traps consist an array of nanoscale dielectric constrictions defined using electron-beam lithography on nanofluidic passages. The device was then sealed using an extremely simple room-temperature sealing process with virtually no pressure applied. Upon the application of an external ac electric field, the field will be focused at the constrictions and high field gradient can be generated to trap molecules dynamically in aqueous solutions. We demonstrated the trapping of small protein molecules in an array of these nanoscale molecular traps down to 50 nm in size. [1] C.F. Chou, J.O. Tegenfeldt, O. Bakajin, S.S. Chan, E.C. Cox, N. **G26 10 Internal Structure, Fluctuations and Micromechanical Properties of Bovine Arterial Endothelial Cells: An Optical Tweezers Study*** CAROLYN PERRETTA, SHEENA FARRELL, OLGA LATINOVIC, H. DANIEL OU-YANG, The purpose of this study is to probe the micromechanical properties of cultured bovine arterial endothelial cells by using optical tweezers to trap endogenous granular structures in the cells. A novel application of oscillating optical tweezers and coherent detection of the forced oscillation of the trapped particle enables us to measure the viscoelastic properties in soft matter with a broad frequency range and with a high data sampling rate. This study was designed to determine the difference between the viscoelasticity of the cytoskeleton around granular structures in close vicinity of the nucleus and around the cell's edge. Time dependent measurements of the mechanical properties at a fixed oscillation frequency revealed pronounced fluctuation in living cells, indicating local dynamics of the cytoskeleton around the probed particle. Possible causes for the fluctuations will be discussed.

*This experiment was made possible by funding from the NSF-DMR 0421259 and the NSF-REU Site Program at Lehigh University.

**G26 11 Atomic force microscopy electrostatic nanolithography for proteins study in wiseana iridovirus and barley chromosomes** EWA ROWICKA, OLGA MAYEVSKA, SERGEI LYUKSYUTOV, *The University of Akron, OH* MEGUMI SASOU, SHIGERU SUGIYAMA, *National Food Research Institute, Japan* Manipulation of proteins and DNA at the nanoscale has been studied using atomic force microscopy electrostatic nanolithography (AFMEN) for two different biological objects: iridovirus wiseana, and stained barley chromosomes. Partially relaxed chromosomes were characterized using scanning near field optical/atomic force microscopy based on bent-type optical probe, which was used as a cantilever for constant force AFM mode. Virus capsids and chromosomes can be treated as polarized dielectrics in strong non-uniform electric field (up to $10^9$ $Vm^{-1}$) induced by biased AFM tip. It is suspected that an electric field inside a polar medium produces energy densities sufficient for either structural changes or reorganization of the protein structure. Recent results related to manipulation of proteins using AFMEN will be presented.

**G27 1 Optimization of Large Scale Matrix Computations for Multi-length Scale Structured Matrices.***
ZHAOJUN BAI,† *University of California, Davis*

Quantum monte carlo simulation of interacting electron systems is an increasingly powerful tool in investigating many of the most fundamental properties of materials, such as their magnetic and optical response, and conductivity. However, the simulations are currently limited to a few hundred particles. The primary bottleneck is the calculation of the inverse of a multi-length and highly structured matrix. In this talk, we will report our recent progress on this problem. We first present a semi-direct solver which is numerically stable and robust by a novel self-adapting block cyclic reduction technique depending on the parameters of the problem. The new solver is more than an order of magnitude faster than existing techniques. Then we will present robust preconditioning techniques in iterative solvers which can effectively precondition the matrices at much stronger coupling and lower temperatures than had hitherto been possible.

**G27 2 Equilibration of walkers and correlation of samples in QMC simulations** D. NISSENBAUM, B. BARBIELLINI, A. BANSIL, *Northeastern U.* When using the Metropolis algorithm from an unequilibrated starting point to obtain properly distributed samples for a Quantum Monte Carlo (QMC) calculation, and when analyzing the accuracy of the results after equilibration, one needs to properly handle two factors: the time taken for the walkers to equilibrate, and the presence of correlations in the sample points after the walkers have equilibrated. Inclusion of unequilibrated data gives a bias to the computed averages, while dealing appropriately with correlated data is essential in order to obtain accurate error bars. In this connection, we are developing reliable techniques to determine equilibration time and compute observable error bars. We present a careful study of several Li clusters, ranging from the Li dimer to a cluster containing 64 Li atoms, and focus particularly on scaling properties of the equilibration time with the size of the system. Work supported in part by the US-DOE.

**G27 3 Configuration Space Renormalization (CSR): a study of fractional quantization of charge in a dual-edge fractional quantum Hall system.** EUGENE TSIPER, *George Mason University and Naval Research Lab, Washington DC* A renormalization procedure is designed to find a subspace of high relevance in a many-body Hilbert space. Substantial reduction in the basis size can be achieved while approaching the exact diagonalization results. The idea is to search for a set of many-particle configurations that contribute the largest weight to the exact solution of the many-body Schrödinger equation, without actually computing the exact solution. We start with some suitable set of $K$ configurations and find the ground state of the Hamiltonian in the many-body subspace that they span. We then retain $K' < K$ configurations by discarding the ones which have little weight. We then re-expand our set with the new configurations that have large matrix elements with those retained. When repeated, the procedure converges after several iterations and yields some optimal set of configurations. The resulting truncation of the Hilbert space is essentially many-body, and cannot be achieved by truncating or rotating the single-particle basis. I will discuss an application of CSR to model resonant tunneling between the edges in the fractional quantum Hall regime, which has been used to experimentally observe fractional quantization of electric charge. Clusters large enough to contain two unconnected edges are modeled. The results suggest fractional quantization of the quasiparticle charge in units of $e/3$ and $e/5$ at fillings 1/3 and 2/5.

**G27 4 New eigensolvers and preconditioners for large scale nanoscience simulations*** ANDREW CANNING, OSNI MARQUES, LIN-WANG WANG, CHRISTOF VOEMEL, *CRD, Lawrence Berkeley National Laboratory* STANIMIRE TOMOV, JULIEN LANGOU, *University of Tennessee* First-principles materials science calculations typically involve a self-consistent solution of the Kohn-Sham equations. These types of methods typically scale with the cube of the system size and can only be used to study systems of up to a thousand atoms. To study larger systems we use semi-empirical potentials or approximated ab initio potentials such as those constructed using the charge patching method. Using these types of potentials does not require a self-consistent solution of our effective single particle equations and we can solve directly for the few states of interest around the gap. This leads to a method that is effectively O(N) if we consider the number of states we require to be fixed as the system size increases. The solution of our single particle equations now becomes an interior eigenvalue problem for a few states around a given energy rather than the self-consistent solution for the lowest n states where n is the number of bands. I will compare different methods (conjugate gradient, Jacobi-Davidson, Lanczos) for this problem with particular emphasis on solving large nanosystems on parallel computers. **G27 5 Turbocharging time-dependent density-functional theory with Lanczos chains.**
STEFANO BARONI, *SISSA and Democritos National Simulation Center*

Using a super-operator formulation of linearized time-dependent density-functional theory, the dynamical polarizability of a system of interacting electrons is represented by a matrix continued- fraction whose coefficients can be obtained from the non-symmetric block- Lanczos method. The resulting algorithm, which is particularly convenient when large basis sets are used, allows for the calculation of the full spectrum of a system with a computational workload only a few times larger than needed for static polarizabilities within time-independent density-functional perturbation theory. The method is demonstrated with calculation of the spectrum of benzene and of fullerene, and prospects for its application to the large-scale calculation of optical spectra are discussed.

**G27 6 Large-Scale First-Principles Molecular Dynamics Simulations on the BlueGene/L Computer** FRANCOIS GYGI, *University of California Davis, Davis, CA 95616* ERIK W. DRAEGER, *Lawrence Livermore National Laboratory, Livermore, CA 94551* We present the results of large-scale First-Principles Molecular Dynamics (FPMD) simulations performed on the BlueGene/L computer, using up to 65,536 processors. Simulations involving 1000 molybdenum atoms were carried out using the Qbox code with non-local, norm-conserving pseudopotentials. A parallel efficiency of 85% can be attained when solving the same problem on partitions ranging from 512 nodes to 32,768 nodes. When using 65,536 processors, a floating point performance of 64 Tflops is reached. Optimization of the logical-to-physical mapping of tasks is essential in order to achieve this performance on the BlueGene/L torus architecture. We discuss the challenges encountered when implementing FPMD in the plane-wave, pseudopotential formalism on 10,000 processors and beyond. Part of this work was performed under the auspices of the U.S. Dept. of Energy at the University of California/Lawrence Livermore National Laboratory under contract no. W-7405-Eng-48.

**G27 7 Linear Scaling First-Principles Molecular Dynamics with Plane Waves accuracy*** JEAN-LUC FATTEBERT, *Lawrence Livermore National Laboratory, Livermore, CA 94551* FRANCOIS GYGI, *UC Davis, Davis, CA 95616* As an alternative to the Plane Waves (PW) approach for highly accurate and unbiased Density Functional Theory molecular dynamics simulations with pseudopotentials, we propose to use a real-space finite differences discretization and a localized orbitals representation of the electronic structure. As in the PW approach, the discretization error can be reduced systematically by decreasing the mesh spacing, while the truncation error due to orbitals localization constraints decreases exponentially with the size of the localization regions. Accurate atomic forces can be computed and allow microcanonical molecular dynamics simulations. Using a supercell

of 512 water molecules, we demonstrate an excellent energy conservation for localization regions large enough. We propose an explanation for the negative energy drift observed for smaller radii based on the presence of local minimas. Our implementation demonstrates an effective scaling complexity close to linear with the system size and a good parallel scaling with the number of processor.

**G27 8 Basis set limit and systematic errors in local-orbital based all-electron DFT** VOLKER BLUM, JÖRG BEHLER, RALF GEHRKE, KARSTEN REUTER, MATTHIAS SCHEFFLER, *Fritz-Haber-Institut, Faradayweg 4-6, 14195 Berlin, Germany* With the advent of efficient integration schemes,[1,2] numeric atom-centered orbitals (NAO's) are an attractive basis choice in practical density functional theory (DFT) calculations of nanostructured systems (surfaces, clusters, molecules). Though all-electron, the efficiency of practical implementations promises to be on par with the best plane-wave pseudopotential codes, while having a noticeably higher accuracy if required: Minimal-sized effective tight-binding like calculations and chemically accurate all-electron calculations are both possible within the same framework; non-periodic and periodic systems can be treated on equal footing; and the localized nature of the basis allows in principle for $O(N)$-like scaling. However, converging an observable with respect to the basis set is less straightforward than with competing systematic basis choices (e.g., plane waves). We here investigate the basis set limit of optimized NAO basis sets in all-electron calculations, using as examples small molecules and clusters ($N_2$, $Cu_2$, $Cu_4$, $Cu_{10}$). meV-level total energy convergence is possible using $\leqslant$ 50 basis functions per atom in all cases. We also find a clear correlation between the errors which arise from underconverged basis sets, and the system geometry (interatomic distance). [1] B. Delley, J. Chem. Phys. **92**, 508 (1990), [2] J.M. Soler *et al.*, J. Phys.: Condens. Matter **14**, 2745 (2002).

**G27 9 Iterative Optimized Effective Potential and Exact Exchange Calculations at Finite Temperature** N.A. MODINE, *Sandia National Laboratories* R.A. LIPPERT, *MIT Department of Mathematics* A.F. WRIGHT, R.P. MULLER, M.P. SEARS, A.E. MATTSSON, M.P. DESJARLAIS, *Sandia National Laboratories* We report the implementation of an iterative scheme for calculating the Optimized Effective Potential (OEP). Given an energy functional that depends explicitly on the Kohn-Sham wave functions, and therefore, implicitly on the local effective potential appearing in the Kohn-Sham equations, a gradient-based minimization is used to find the potential that minimizes the energy. Previous work has shown how to find the gradient of such an energy with respect to the effective potential in the zero-temperature limit. We discuss a density-matrix-based derivation of the gradient that generalizes the previous results to the finite temperature regime, and we describe important optimizations used in our implementation. We have applied our OEP approach to the Hartree-Fock energy expression to perform Exact Exchange (EXX) calculations. We report our EXX results for common semiconductors and ordered phases of hydrogen at zero and finite electronic temperatures. We also discuss issues involved in the implementation of forces within the OEP/EXX approach. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energys National Nuclear Security Administration under contract DE-AC04-94AL85000.

**G27 10 Towards an exact treatment of exchange and correlation in materials: Application to CO adsorption at transition-metal surfaces** MATTHIAS SCHEFFLER, QING MIAO HU, KARSTEN REUTER, *Fritz-Haber-Institut der Max-Planck-Gesellschaft, Faradayweg 4-6, D-14195 Berlin, Germany* We present an efficient scheme to correct the errors of density-functional theory (DFT) exchange-correlation (xc) functionals. The method locally corrects the xc interaction by analyzing clusters of the same local geometry as that of the calculations for the extended system. **The correction** is found to rapidly approach a universal dependence with cluster size, exhibiting a simple analytical behavior. As a consequence it is shown how high-quality cluster studies (e.g. using B3LYP, HF+MP2, or QMC) can be used to determine the DFT-LDA/GGA error for extended systems. The method is particularly efficient for defects in the bulk and at surfaces. — The approach is applied to CO adsorption at transition metals, where present xc functionals dramatically fail to predict the correct adsorption site.[1] The correct (experimentally confirmed) geometry is obtained by the correction scheme, and the origin of the LDA/GGA failure is discussed. **G27 11 Efficient Method for Electron-Phonon Coupling in Molecules and Nanoscale Systems** BEN POWELL, *University of Queensland, Brisbane, Queensland 4072, Australia* MARK PEDERSON, *Naval Research Laboratory* TUNNA BARUAH, *University of Texas El Paso* The coupling between electrons and phonons plays important roles in physics, chemistry and biology. However, the accurate calculation of the electron-phonon coupling constants is computationally expensive as it can involve solving the Schrödinger equation for $\mathcal{O}(3N)$ nuclear configurations, where $N$ is the number of nuclei. In analogy to the efficient field-induced extraction of IR and Raman spectra in molecules, [1] consideration of charge-induced changes in Hellman-Feynman forces as a function of electronic charge allows determination of all HOMO and LUMO electron-phonon coupling constants, including isotope dependencies, with only two SCF calculations *regardless of system size*. [2] The approach can also be used for electron-phonon interactions associated with other electronic states. The relation of this method to Janak's theorem [3] is discussed. This $\mathcal{O}(1)$ approach is numerically very stable and produces accurate results for electron-phonon coupling constants in tests on approximately 15-20 molecules ranging in size from $H_2$ to $C_{60}$. Adiabatic ionization potentials and relaxed Hubbard U parameters are presented as an example of the method. [1] D.V. Porezag and M.R. Pederson, Phys. Rev. B **54**, 7830 (1996). [2] B.J. Powell, M.R. Pederson and T. Baruah (submitted). [3] J.F. Janak, Phys. Rev. B **18**, 7165 (1978).

**G28 3 Rheo-NMR measurements of shear alignment and banding in non-ionic wormlike micelles** LOUIS A. MADSEN, EDWARD T. SAMULSKI, *University of North Carolina - Department of Chemistry* RALPH H. COLBY, *Pennsylvania State University - Department of Materials Science and Engineering* BRADLEY S. DOUGLASS, PAUL T. CALLAGHAN, *Victoria University of Wellington - Department of Physics* Orientational order produces myriad nonlinear effects in complex fluids such as polymer solutions, liquid crystals, and anisotropic colloids. Wormlike micelles (WLMs) exhibit especially fascinating rheological properties since the component molecules order relative to the tube axis, which itself acts as a supramolecular polymer backbone. Equilibria between wormlike and spherical micelles may be controlled using temperature, concentration, or additives to modulate properties (e. g., viscosity) over several orders of magnitude. We have investigated a new class of WLMs composed of non-ionic triblock copolymers (PEO-PPO-PEO) mixed with alcohol additives to stabilize the core. We have employed in-situ rheo-NMR spectroscopy and microscopy in a Couette shear cell to observe the first shear-induced alignment and banding in a non-ionic block-copolymer system. Deuterium-labeled additives exhibit gap-dependent spectral splittings, assessing the molecular alignment versus shear rate. Proton NMR microscopy probes shear banding across the Couette cell gap with resolutions down to 20 microns.

**G28 4 Reversible morphological transitions of polystyrene-b-polyisoprene micelles*** ISAAC LARUE, SERGEI SHEIKO, MIREILLE ADAM, MICHAEL RUBINSTEIN, *University of North Carolina at Chapel Hill* MARINOS PITSIKALIS, NIKOS HADJICHRISTIDIS, *University of Athens* Morphological transitions of polymer micelles have long been sought after. Until now, the only way to change morphology was through the addition of a co-solvent or homopolymer. We have demonstrated for the first time that reversible morphological transitions can be caused solely through changes in temperature. Two polystyrene-b-polyisoprene samples with the same sized PS block of 20kDa were purposefully synthesized with PI blocks of 4 and 6kDa to be near the spherical-cylindrical and cylindrical-vesicle boundaries. It was found that only small changes in temperature are needed to cause the morphological change. The cylindrical sample adopted a spherical morphology after heating from 25-35°C and the vesicle sample became cylindrical upon heating from 25-40°C. While cylindrical and vesicle micelles were once again observed after cooling the samples back to 25°C, the fraction and size of the micelles were still increasing after several weeks.

**G28 5 Growth of Nanostructured Bilayers and Vesicles by Self-assembly of ABC Mikto-arm Star Terpolymers** ZHIBO LI, MARC HILLMYER,*TIMOTHY LODGE,† *University of Minnesota, Chemistry Department* MULTICOMPARTMENT MICELLE TEAM, A new class of nanostructured vesicles and bilayers were observed from aqueous self-assembly of ABC mikto-arm star terpolymers with three mutually immiscible blocks. The micellar structures depend on the relative length of each block and can be tuned to form three classical types of micelles, i.e., sphere, cylinder, and vesicles, however with nanostructured multiple core compartments. The nanostructured vesicles grow by a three-stage process: (i) segmented wormlike micelles first self-assemble upon dissolution of terpolymers in water; (ii) then nanostructured bilayer sheets with apparently hexagonal ordered internal structures grow by consumption of already existing segmented worms, and subsequently (iii) large bilayer sheets curve and close off to form vesicles. The micellar structures at various stages were imaged by cryogenic transmission microscopy.

**G28 6 Self-Assembly of Block Copolymers in an Ionic Liquid** YIYONG HE, ZHIBO LI, TIMOTHY P. LODGE, *Department of Chemistry, and Department of Chemical Engineering and Materials Science, University of Minnesota, 55455* Amphiphilic diblock copolymers poly((1,2-butadiene)-*b*-ethylene oxide) (PB-PEO) were shown to aggregate and form well-defined micelles in an ionic liquid, 1-butyl-3-methyl imidazolium hexafluorophosphate ([BMIM][PF6]). The universal sequence of micellar structures (spherical micelle, wormlike micelle, and bilayered vesicle) were all resolved by varying the block copolymer composition. For the first time, the nanostructures of PB-PEO micelles formed in an ionic liquid were directly visualized by cryogenic transmission electron microscopy (cryo-TEM). The detailed micelle struc-

ture information was extracted from cryo-TEM and dynamic light scattering (DLS) measurements, and compared to their aqueous counterparts. The work demonstrates the feasibility of controlling micellar nanostructures of amphiphilic block copolymers in ionic liquids, and also provides important knowledge for further applications of copolymers for forming microemulsions and ion gels.

**G28 7 Controlling PS-b-PEO Morphologies by Solution Conditions** PRACHUR BHARGAVA, XIAOLIANG ZHENG, YINGFENG TU, STEPHEN Z.D. CHENG, MAURICE MORTON INSTITUTE OF POLYMER SCIENCE, THE UNIVERSITY OF AKRON TEAM, We have investigated the self-assembly behavior of amphiphilic diblock copolymer polystyrene-b-poly(ethylene oxide) (PS-b-PEO) in DMF/water and DMF/acetonitirile mixtures.The morphology of the block copolymer can be controlled in both these systems by varying copolymer concentration and solvent composition The morphologies were visualized directly by transmission electron microscopy. Increasing the water content in the DMF/water mixture or acetonitrile in the DMF/acetonitrile mixture changes the morphology from spheres to worm-like/rods and then to vesicles. Increasing the copolymer concentration shows a similar effect on the morphology. The block copolymer exhibits distinct phases of both exclusive and mixed morphologies. The morphological transitions were also captured by static light scattering and turbidity measurements. Although the trend in morphological changes is similar, there are remarkable differences in the morphological phase behavior of PS-b-PEO in the two solvent systems and thus the role of the 'selective solvent' in such systems is also evidenced.

**G28 8 Formation of Toroid Micelles: Mechanism and Size Control** HONGGANG CUI, KELLY HALES, ZHIBIN LI, DARRIN POCHAN, *Department of Materials Science and Engineering, University of Delaware, Newark, DE 19716* ZHIYUN CHEN, KAI QI, KAREN WOOLEY, *Department of Chemistry, Washington University in Saint Louis, Saint Louis, MO 63130* The toroid micelle morphology has been produced by the self assembly of poly(acrylic acid)-block-poly(methyl acrylate)-block-polystyrene triblock copolymer via interaction with organic diamines in mixed THF/H2O solution. The formation mechanism has been investigated from three aspects: (i) chain structure of organic counterions, including spacer length, chain hydrophobicity and the number of amine groups; (ii) molecular structure of triblock copolymer, including block length of polystyrene and chain architecture; (iii) variation of solution component, such as different ratios of THF to water and different ratios of amine groups to acid groups. It was found that toroids can be constructed either via a cylinder-toroid transition through elimination of high-energy, cylinder ends, or via a disc-toroid transition by disc perforation from the center. The prevalent mechanism depends on the chain length of polystyrene and the chain structure of diamines. Stability of the toroids was studied by varying the ratio of THF to water, and by applying a perturbation of either heat or sonication. Interestingly, the size of the toroids can be controlled by the amount of added diamines. The toroid morphology was characterized by means of cryo-TEM, SANS and light scattering.

**G28 9 Kinetics of chain exchange in diblock copolymer micelles** CHUN-CHUNG CHEN, ELENA E. DORMIDONTOVA, *Macromolecular Science and Engineering, Case Western Reserve University, Cleveland, Ohio 44106* Chain kinetic properties in the core of diblock copolymer micelles were studied using Monte Carlo simulations. In order to escape, a polymer chain first has to assume a compact conformation near the surface of the core. In our simulations, we studied the process of conformational changes of the core-forming block before it is ready to escape from a micelle. The radius of gyration or maximum distance of chain monomers from the core-corona interface were used as criteria to assess the compactness of the chain conformation and therefore its readiness to escape. When the chain exchange kinetics is limited mainly by the rate of conformational changes, the survival fraction of the original chains follows stretched exponential behavior. This is in contrast to theoretical predictions of a single activation process for unimer exchange in diblock copolymer micelles. In our simulations, we recover a single exponential behavior of the survival fraction only for the cases of very low escape probabilities. Increasing the width of the core-corona interface while maintaining the same aggregation number makes it easier for a chain to achieve a ready-to-escape conformation. This accentuates the stretched exponential behavior for the survival fraction which in turn shows a nearly logarithmic decay for a considerable portion of the overall time range.

**G28 10 Chain Exchange Kinetics in Diblock Copolymer Micelles: Comparison of Experimental and Simulation Results** ELENA DORMIDONTOVA, CHUN-CHUNG CHEN, *Department of Macromolecular Science and Engineering, Case Western Reserve University, Cleveland, Ohio 44106, USA* REIDAR LUND, LUTZ WILLNER, DIETER RICHTER, *Institut fuer Festkoerperforschung, Forschungszentrum Juelich, Germany* The exchange of chains between polymeric micelles in equilibrium has been studied experimentally using a novel Time Resolved Small Angle Neutron Scattering technique and modeled using Monte Carlo (MC) simulations. The experiments for PS-PB in alkanes and PEP-PEO micelles in DMF/water solutions revealed a logarithmic time dependence of the exchange kinetics. In the simulations, the time dependence of surviving chains ranges from a single exponential to stretched exponential behavior and is found to be strongly influenced by the chain conformation and escape criteria. In agreement with the experiments, a logarithmic time dependence was found in the MC simulations for an intermediate time range for micelles with a large number of escapable chains from micelle core and low probability of escaping or for micelles with a broader core-corona interface. The MC results suggest that dynamics of conformational rearrangements in a micelle core plays a decisive role in the micelle exchange kinetics.

**G28 11 Dynamics of Polystyrene-Polyisoprene (PS-PI) Micelles in Selective Solvents.** DVORA PERAHIA, *Chemistry Department Clemson University, Clemson SC 29634-0973* GANG CHENG, *Chemistry Department Clemson University, Clemson SC 29634-0973* We have recently shown that dissociation of isotropic-to-micelles phase transition of PS-PI micelles in decane

takes place gradually where the micelles dissociated into smaller ones and eventually into a unimolecular micelles where the polystyrene is surrounded by the polyisprene. In here we report the dynamics of the PS-PI block as studied by neutron spin echo experiments as the dissociation takes place. With increasing temperature the entire system becomes more dynamic as expected. However on the length scale of the size of the micelle, the diffusion is constrained up to temperatures where most of the micelles, have dissociated whereas on the segmental level the dynamics is characteristic of that of a free molecule. The dynamics with in the micelle and the nature of the dissociation transition will be discussed.

**G29 1 A Framework for Globular Proteins.***
TIMOTHY LEZON, *Pennsylvania State University*

Due to their remarkable chemical specificity and diversity, globular proteins play a crucial role in the network of molecular interactions of life. Over the past several decades, much experimental data has been accumulated on proteins, but the overarching principles that govern the general features of proteins remain largely unknown. Here, a novel framework for understanding many key attributes of globular proteins is presented. This framework suggests that the characteristics of globular proteins that make them well-suited for biological function are the emergent properties of a unique phase of matter. Implications of this picture include the provision of a fixed backdrop for molecular evolution and natural selection and design restrictions on molecular machinery. The work described here was carried out in collaboration with Jayanth Banavar and Amos Maritan.

**G29 2 Chiral Heterorecognition of Organic Molecules and Inorganic Surfaces** THOMAS GREBER, RICHARD SCHILLINGER, JOACHIM WIDER, *Physik Institut der Universitat Zurich, Switzerland* ZELIKO SLJIVANCANIN, *IRRMA, Ecole Polytechnique Lausanne, Switzerland* BJORK HAMMER, *Department of Physics and Astronomy and iNANO, University of Aarhus, Denmark* Atomic kinks on surfaces are chiral and may thus be used to distinguish left-handed from right-handed molecules. Two distinct non-mirror-symmetric conformations of D- and L-cysteine were found after adsorption on Au(17 11 9)$^S$. This demonstrates chiral heterorecognition, i.e. enantioselectivity of *S*-kinks on vicinal Au(111). The structures as determined by angle scanned X-ray photoelectron diffraction (XPD) agree well with those from density functional theory (DFT) calculations. The calculations predict adsorption energies of $\approx$ 2 eV where D-cysteine binds 140 meV stronger than L-cysteine. The classical three point contact model for molecular recognition fails to explain these findings.

**8:48**
**G29 3 Nucleotide Mutation and Amino Acid Evolution** JOSE PARRA, BERNARD GERSTMAN, *Department of Physics, Florida International University* We have found a set of nucleotide coupling propensities (ncp) that best reproduces the currently observed probability distribution of amino acids found in protein data banks. These ncp represent the biochemical potentials that produce different probabilities for different mutations within a sequence of nucleotides. We have allowed these ncp to act on a random sequence of nucleotides whose codons initially produce a random arrangement of amino acid residues. Interestingly, though the mutating action of the ncp on the chain of nucleotides results in the correct evolution of the probability of appearance of each individual amino acid towards the present distribution, there is however no evolutionary trend in major global characteristics of the amino acid distribution. We present results that show that properties of amino acids that are considered important for protein structure do not evolve on average, such as: hydrophobic/hydrophilic, size, aromatic/non-aromatic, aliphatic/non-aliphatic, helical-preference/beta-strand.

**G29 4 Quantitative modeling and data analysis of SELEX experiments** MARKO DJORDJEVIC, *Mathematical Biosciences Inst., Ohio State Univ.* ANIRVAN M. SENGUPTA, *Dept. of Physics and BioMaPS Inst., Rutgers Univ.* SELEX (Systematic Evolution of Ligands by Exponential Enrichment) is an experimental procedure that allows extracting, from an initially random pool of DNA, those oligomers with high affinity for a given DNA-binding protein. We address what is a suitable experimental and computational procedure to infer parameters of transcription factor-DNA interaction from SELEX experiments. To answer this, we use a biophysical model of transcription factor-DNA interactions to quantitatively model SELEX. We show that a standard procedure is unsuitable for obtaining accurate interaction parameters. However, we theoretically show that a modified experiment in which chemical potential is fixed through different rounds of the experiment allows robust generation of an appropriate data set. Based on our quantitative model, we propose a novel bioinformatic method of data analysis for such modified experiment and

apply it to extract the interaction parameters for a mammalian transcription factor CTF/NFI. From a practical point of view, our method results in a significantly improved false positive/false negative trade-off, as compared to both the standard information theory based method and a widely used empirically formulated procedure. This work will appear in Physical Biology. This work was supported by NIH grant GM67794. Final parts of this work were supported by NSF under Agreement No. 0112050 and NSF grant MCB-0418891.

**G29 6 Energy Dependence of Cancer Cell Irradiation** RACHEL BLACK, *Hampton University* FOR CAMI COLLABORATION, A proof-of-principle experiment was done to investigate the energy damage of beta particles on cancer cells. This study is the first of its kind that spans into the MeV range. This research seeks to provide information on the possibility of monoenergetic Brachytherapy sources, reaction mechanisms of cancer cell death and cancer genome identification. It is expected that different cancer types will respond to different energies. Protein expressions from the irradiation of breast cancer cells were identified via a 2D diagram (pH versus mass) showing a strong energy dependence. Preliminary results will be presented and discussed.

**9:36**
**G29 7 Calibration Of A System For Energy Dependence Study Of Cancer Cell Irradiation** ARIANO MUNDEN, *Hampton University* FOR CAMI COLLABORATION, Calibration of individual electron energies and dose distribution exiting a dipole magnet perpendicular at the dispersive plane was performed using a collimated scintillating fiber based detector. The dipole was constructed from two 5.08x5.08x2.54 $cm^3$ permanent magnets separated by a distance of 2 cm and having a maximum filed of about 5 kG. A 1 cm diameter collimated electron beam exiting a $^{90}Sr/Y$ radioactive with a 25 $\mu$Ci activity and a 2.28 MeV maximum energy was placed at the entrance face of the magnet. Mapping of the magnetic field was done using a Hall probe with an accuracy of about 2 G. The electron detector consisted of blue shifted scintillating fibers with thicknesses of 1 mm. The setup provides an energy resolution of about 10%. This system will be used to study the differential response of cancer cell irradiation to selected energies. We will present results and discussed the results obtained from this work.

**G29 9 Radiation Damage From Mono-energetic Electrons Up to 200 keV On Biological Systems** YURIY PRILEPSKIY, *Hampton University* FOR CAMI COLLABORATION, The electron gun of the CEBAF machine at Jefferson lab (Newport News, VA) is capable of delivering electrons with energies up to 200 keV with a resolution of about $10^{-5}$. This 1.5 GHz beam permits to generate cellular radiation damage within minutes. We have performed irradiation of cancer cells with different energies and different currents to investigate their biological responses. This study will permit to address the physical processes involved in the RBE and LET at a level that supersedes current data listed in the literature by orders of magnitude. We will discuss the experimental setup and results of the first stage of data collected with this novel system. This research is part of a global program to provide detailed information for the understanding of radiation based cancer treatments.

**10:36**
**G29 10 The cost of linearization** DANIELLE MOREL, WILLIAM B LEVY, *University of Virginia* Information processing in the brain is metabolically expensive and energy usage by the different components of the nervous system is not well understood. In a continuing effort to explore the costs and constraints of information processing at the single neuron level, dendritic processes are being studied. More specifically, the role of various ion channel conductances is explored in terms of integrating dendritic excitatory synaptic input. Biophysical simulations of dendritic behavior show that the complexity of voltage-dependent, non-linear dendritic conductances can produce simplicity in the form of linear synaptic integration. Over increasing levels of synaptic activity, it is shown that two types of voltage-dependent conductances produce linearization over a limited range. This range is determined by the parameters defining the ion channel and the 'passive' properties of the dendrite. A persistent sodium and a transient A-type potassium channel were considered at steady-state transmembrane potentials in the vicinity of and hyperpolarized to the threshold for action potential initiation. The persistent sodium is seen to amplify and linearize the synaptic input over a short range

of low synaptic activity. In contrast, the A-type potassium channel has a broader linearization range but tends to operate at higher levels of synaptic bombardment. Given equivalent 'passive' dendritic properties, the persistent sodium is found to be less costly than the A-type potassium in linearizing synaptic input.

**G29 11 Fast noniterative biexponential fluorescence lifetime imaging in the investigation of phagocyting neutrophyls**
RALUCA AURA NIESNER, *Technical University Braunschweig, Institute for Physical and Theoretical Chemistry; Society for Biotechnological Research (GBF) Braunschweig* The cofactors NADH and NADPH [NAD(P)H] belong to the principal endogenous indicators of the cellular metabolism. Since the metabolic activity of cells is given by the ratio between the concentrations of free and protein-bound NAD(P)H, the development of techniques which measure the modifications to this ratio is particularly significant. The biexponential fluorescence lifetime imaging (FLIM) is employed to discriminate between the free and the protein-bound NAD(P)H without any previous calibration. Thus a high-resolution map of the cellular metabolism, i.e. an image of the contribution of the protein-bound NAD(P)H to the cumulative NAD(P)H signal, is obtained. This method is applied in the investigation of neutrophyls phagocyting the spores of Aspergillus Fumigatus. Particularly the activation of the NADPH oxidase is studied. Since an important aspect in biological applications is to monitor the dynamics of the relevant processes, rapid techniques, e.g. fast biexponential FLIM, are needed. We implement for the first time in FLIM a noniterative method originally developed by Prony and verified it in biexponential time-domain FLIM experiments on homogenous mixtures and on different types of cells.

## SESSION G30: FOCUS SESSION: ELECTRONIC TRANSPORT IN ORGANIC FILMS

**G30 2 Scanning Tunneling Microscopy and Spectroscopy of Conjugated Oligomers at the Liquid-Solid Interface.**
STEVEN DE FEYTER, *Katholieke Universiteit Leuven*

Self-assembly - the spontaneous organization of molecules into stable, structurally well-defined aggregates - has been put forward as a possible paradigm for generating nanoscale templates under ambient conditions. A very convenient method for the formation of extended two-dimensional (2D) networks is physisorption at the liquid-solid interface. The preparation is relatively simple and scanning tunneling microscopy (STM) allows a detailed investigation of the structural aspects of the 2D patterns. A deep understanding and control of the spatial orientation and packing of pi-conjugated oligomers in self-assembled systems is indispensable for the development of future nanodevices. By means of STM, we have investigated the self-assembly of achiral and chiral pi-conjugated small organic molecules at the organic liquid-solid interface with submolecular resolution. In addition, by means of scanning tunneling spectroscopy (STS) we have investigated with molecular and submolecular resolution the electronic properties of isolated and stacked conjugated molecules at the liquid-solid interface. In the first part, we focus on the control of 2D molecular self-assembly of pi-conjugated systems driven by the molecular shape and/or by directional non-convalent interactions such as hydrogen bonding. Examples include alkylated molecules with a rhombus or triangle shaped pi-conjugated core, hydrogen bond forming p-phenylene vinylenes, and oligothiophenes. In the second part, we report on bias dependent imaging and STS experiments revealing information on the electronic properties of electron donor-acceptor-donor triads, and isolated and stacked oligothiophenes.

**9:12**
**G30 3 Directing molecular traffic by means of a nano-engineered surface.**
FABRICE CHARRA, *CEA Saclay*

The parallel manipulation of individual molecules is the ultimate goal of many current researches in nanosciences. A first route is the confinement of molecular motion until the continuum approximation breaks down and discrete-molecule effects appear, as observed in zeolite analogs or inside nanotubes. A bottom-up alternative consists in surface self-assemblies tailored at the molecular scale. Although most studies on nanostructured surfaces are still focused on their structure, the demonstrations of selective adsorptions inside single-molecule pores, the observation of rotating molecules inside an accidental bearing in a sub-monolayer film, or within self-assembled monolayers, represent pioneering first steps towards functional systems. In this context, we have demonstrated the sorting and routing of individual molecules

via surface diffusion inside bottom-up designed molecular sieves. We monitor the operation in-situ and in real time at the single-molecule scale through fast variable-temperature scanning-tunneling microscopy (STM). These studies unravel the mechanisms of molecular filtering. This permits to derive molecular-design guidelines for tuning cavity or channel selectivity. We discuss the opportunity to control optically and locally the molecular motion, using tip-induced field enhancements.

**G30 4 Determining the conductance of single molecular wire*** ALEXANDRE NDOBE, *University of Utah* VLADIMIR BURTMAN, *University of Utah* VALY VARDENY, *University of Utah* We have designed a method for determining the conductance of an isolated molecular wire from the I-V characteristic of molecular junctions. The molecular diodes were 1 $mm^2$ in area and consist of self-assembled monolayer (SAM) from a mixture of the molecular wires and non-conducting molecules that are used as spacers; coupled to two opposite gold electrodes. We studied the I-V characteristic dependence of the fabricated diodes on the ratio, *r* of wires/spacers. To obtain the number of molecular wires in the device we used multiple self-assemblies and titration techniques, as well as AFM of a small portion of the SAM surface. Our method was applied to a mixture of Me-BDT (methylbezenedithiol) molecules as wires and PT (pentathiol) molecules as spacers. For $10^{-8} < r < 10^{-3}$ we found that the device conductance is dominated by the molecular wires. From the current and obtained number of Me-BDT molecules in the device we determined the molecular conductance of Me-BDT to be 600 MΩ, in good agreement with a theoretical tunneling model.

**G30 5 Atomic-Scale Spectroscopy of Polydiacetylene Nanowires** RAJIV GIRIDHARAGOPAL, *Rice University* K. F. KELLY, *Rice University* In recent years, the appeal of organic electronic devices has spurred interest in conducting polymers, such as polydiacetylene. Polydiacetylene nanowires offer numerous possibilities for application in molecular electronics, and they are a model system for understanding conduction mechanisms in polymers. We have used scanning tunneling microscopy to investigate monolayer films of pentacosadiynoic acid formed on highly ordered pyrolytic graphite using the Langmuir-Blodgett and Langmuir-Schaeffer deposition techniques and subsequently polymerized to form polydiacetylene nanowires. By applying a novel method of microwave frequency mixing at the STM tip junction, we have obtained capacitance-voltage spectroscopic data to characterize the wires across a range of bias voltages, tunneling gap resistances, and microwave mixing frequencies.

**10:12**

**G30 6 Self-Organized Single-Crystal Polythiophene Microwires** KILWON CHO, *Pohang University of Science and Technology* DO HWAN KIM, *Pohang University of Science and Technology* Here we show a well-faceted, high-quality 1D single-crystal poly (3-hexylthiophene), P3HT microwire with unprecedented electrical characteristics such as a low resistance (0.5 MΩ), a channel current as high as 25 $\mu$A, and a well-resolved gate modulation via solution growth. We find that 1D single-crystal P3HT microwires are formed spontaneously through facile self-assembly of individual polymer chains, adopting preferential well-ordered inter-chain stacking along the wire axis. Our findings indicate that $\pi$-conjugated polymer single-crystals are capable of very efficient charge transport. This approach could lead to the development of chemical and biological sensors which are efficiently capable of electrical and /or optical monitoring. This work was supported by the National Research Laboratory Program, a grant (F0004022) from Information Display R&D Center under the 21st Century Frontier R&D Program, the BK21 Program, and the Pohang Acceleratory Laboratory for providing the synchrotron radiation source at the 4C2, 3C2, and 8C1 beam lines.

**10:24**

**G30 7 Bond resistances in molecular junctions** ANNA PAINELLI, *Universita' di Parma & INSTM UdR Parma* The description of molecular contacts is one of the hardest problems in modeling molecular junctions. In common approaches macroscopic leads ensure a finite potential drop and hence a driving force for the current. Recently, a different strategy is emerging where a steady-state DC current is forced in the molecule, by making resort to Lagrange multipliers, or by drawing a magnetic flux through the molecule. The strategy is promising, but two main problems remain to be solved: (1) the calculation of the potential drop needed to sustain the current, and (2) the definition of the potential profile along the molecule. Here the Joule law is used to evaluate the potential drop from the electrical power spent on the molecule, and continuity constraints for steady-state DC current are implemented to get information on the potential profile. Borrowing powerful concepts from the field of molecular spectroscopy, emphasis is put on the molecule, while clamping information about contacts in the molecular relaxation matrix. The molecule is described in a real-space approach, leading to a suggestive analogy between the molecule and an electrical circuit where resistances are associated with chemical bonds.

**10:36**

**G30 8 Transport Properties of SAM Molecular Diodes with Structural Tunability*** VLADIMIR BURTMAN, VALY Z. VARDENY, ALEX NDOBE, *University of Utah* A new molecular engineering approach is used to fabricate molecular junctions from self-assembled-monolayers (SAM) sandwiched between gold electrodes, with structural tunability based on two-component solid-state mixtures of molecular wires (1,4 methane benzenedithiol; Me-BDT, and molecular insulator spacers (1-pentanethiol; PT). The electrical transport of the fabricated SAM diodes was investigated at various temperatures versus the ratio r between the molecular wires and insulators. At $r < 10^{-3}$ the diodes are dominated by the isolated molecular wires dispersed in the dielectric spacer matrix; from the conductivity vs. r we determined the value for the Me-BDT molecular resistance to be $4x10^8$ Ohm. We also found that the activation energy in these devices is $\sim$ 50 meV at low bias and high temperatures; and injection barrier of $\sim$ 1.5 eV at intermediate bias and low temperatures. At $r > 10^{-3}$ Me-BDT aggregates are formed in the PT matrix resulting in additional in-plane order and substantive changes in the transport properties.

**G30 9 Electron Hopping in Conducting Polymers in the Presence Of Mobile Ions*** VLADIMIR PRIGODIN, FANG HSU, JANE PARK, ARTHUR EPSTEIN, *Physics Department, The Ohio State University, Columbus, OH 43210-1106* We present the theoretical analysis for electrochemical transistors with the conductivity governed by the gate potential through bulk charging/discharging of the active channel. The predicted I(V) characteristics do not agree with the experimental dependencies for conducting polymer based transistors [1]. We suggest that the field effect in conducting polymers is related to their structural peculiarities. The large free volume within the polymer network enables ions to easily move into and out of the polymers. The main effect of ion insertion is breaking of the percolation network by removing critical hoping sites and, as a result, producing the conductor-nonconductor transition. The application of the present mechanism to the field effect in conducting polymers is discussed. [1] J. Liu, et al., **J. Appl. Phys. 92**, 6033-6038 (2002); A.J. Epstein, et al., **Current Applied Physics**, 2, 339-343 (2002); H. Okuzaki, et al., **Synth. Met. 137**, 947-948 (2003); F.C. Hsu, et al., to be published.

**G31 1 Orbital-order-induced metal-insulator transition in manganites** SANJEEV KUMAR, ARNO KAMPF, *University of Augsburg (Germany)* PINAKI MAJUMDAR, *HRI, Allahabad (India)* We study a two-band double-exchange model with adiabatic Jahn-Teller phonons, weak antiferromagnetic superexchange and quenched disorder. This model for perovskite manganites is studied using a recently developed real space Monte-Carlo method (cond-mat/0406082). We present results for the optical conductivity and the density of states and provide a microscopic picture of the spin and orbital structures. The electron lattice coupling leads to orbital ordering at zero hole doping ($x = 0$), while the magnetism is controlled by the interplay of superexchange and double exchange interactions. We track the evolution upon hole doping of this orbital ordered insulator and locate the critical doping concentrations required for (i) the disappearance of orbital order and (ii) the emergence of the metallic behavior. We compare our results in detail with the experimental data on $La_{1-x}Ca_xMnO_3$ in the low $x$ regime.

**8:12**
**G31 2 Sequencing-Independent Delocalization in a DNA-Like Double Chain with Base Pairing*** RODRIGO CAETANO, *UNICAMP* PETER SCHULZ, *UNICAMP* The question of whether DNA is intrinsically conducting or not is still a challenger. Experiments on DNA conductivity are very controversial: Metallic, semiconducting, insulating and even superconductor behaviors have been reported. The theoretical studies of the electronics properties of DNA range from strictly one-dimensional tight-binding chains, up to ab initio calculations. Ab initio calculations give useful insight on environment influence but have to be limited to a reduced number of model DNA molecules. On the other hand strictly one-dimensional calculations deal with effectives sites instead of a base pair structure, underestimating the paring effects. Here, we focus in that intrinsic factor to show that double chains with base pairing with DNA-like correlation leads to delocalized states. We use a double-chain nearest-neighbor hopping tight-binding model to describe the system. The double chains are constituted by four different sites, representing the nucleotides (A, C, G and T). The sites in the first chain are randomly assigned, while the sites in the second chain obey the DNA pairing. The main consequence of the correlation is a localization-delocalization transition. The present result suggest the DNA is intrinsically a promising electronic material and the hidrance to DNA nanoelectronics is solely of technological nature.

**G31 3 Orientational Defects in Ice Ih: An Interpretation of Electrical Conductivity Measurements** MAURICE DE KONING, ALEX ANTONELLI, *Universidade Estadual de Campinas* ANTONIO J.R. DA SILVA, ADALBERTO FAZZIO, *Universidade de Sao Paulo* While the isolated water molecule is one of the simplest in Nature, the condensed phases of $H_2O$ reveal many complex features that still elude complete understanding. An example concerns the role of crystal defects in the peculiar electrical properties of proton-disordered hexagonal ice Ih. When an electric field is applied to an ice specimen, it becomes polarized by the thermally activated reorientation of the molecular dipoles through the motion of Bjerrum defects, which represent local disruptions of the hydrogen-bond network. While the conceptual picture of these Bjerrum defects is now well established, a quantitative understanding of their properties is still lacking, rendering a direct interpretation of experimental electrical conductivity data difficult. In this work we present a first-principles study of the structure and energetics of Bjerrum defects in ice Ih and compare the results to experimental electrical conductivity data. While the DFT result for the activation energy is in good agreement with experiment, we find that its two components have quite different values. Aside from providing new insight into the fundamental parameters of the microscopic electrical theory of ice, our results suggest the activity of traps in doped ice in the temperature regime typically assumed to be controlled by the free migration of L-type Bjerrum defects.

**8:36**
**G31 4 Scaling behavior of Film growth mechanism*** MINA YOON, LEE HO NYUNG, *Oak Ridge National Laboratory* ZHIGANG SUO, WEI HONG, *Harvard University* HANS M. CHRISTEN, DOUG LOWNDES, ZHENYU ZHANG, *Oak Ridge National Laboratory* Experimental evidence has accumulated that a strained film can grow stably on a vicinal surface. Linear perturbation analysis of the step-flow regime results in a dispersion relation which determines the persistence of the step-flow growth. The dispersion relation can also be used to probe the system parameters. Investigating the growth dynamics in the step-bunching regime, we found that there is a critical film thickness above which

step-bunching occurs. The critical thickness shows a scaling behavior depending on the terrace width and the deposition flux. Experiments show a qualitative agreement with the theory. Our results may open a way to grow films in a desired way.

**G31 5 One-dimensional Hartree-Fock calculations for electrons in a constriction** JIANG QIAN, BERTRAND HALPERIN, *Physics Department, Harvard University* WALTER HOFSTETTER, *Institut für Theoretische Physik A, RWTH Aachen* GERGELY ZARAND, *Institut für Theoreticshe Festkorperphysik, Universitat Karlsruhe* There are a number of puzzling experimental results associated with electron transport through a narrow constriction of finite length, such as the so-called 0.7 structure in the quantum point contact and the experiments on tunneling between two parallel quantum wires. To gain deeper insights into these experiments, it may be important to understand how a constriction region containing electrons at a very low-density is connected to higher density leads at each end. We have formulated Hartree-Fock methods applicable to one-dimensional models of such systems, in equilibrium or with a finite source-drain voltage. We will present results of the electron density profile and spin structures around the constriction for several models of interaction and constriction potentials. This work is supported in part by NSF grand DMR-02-33773 and PHY-01-17795.

**9:00**

**G31 6 Mixed Wannier-Bloch functions for electrons and phonons in extended disordered systems** ALFREDO PASQUARELLO, *Ecole Polytechnique Fédérale de Lausanne* FELICIANO GIUSTINO, *University of California at Berkeley* A major difficulty in the study of disordered systems arises from the inadequacy of the Bloch description of quasiparticle and collective excitations. The main alternative to the crystal momentum representation is provided by the Wannier picture. However, despite the success of the optimally localized Wannier functions in crystalline environments, their applicability to disordered systems is hindered by the lack of an explicit energy label, the latter being essential for interpreting spectroscopic data. We here introduce mixed Wannier-Bloch functions for studying electronic and vibrational spectra of extended disordered solids. These functions are designed to carry both spatial localization (Wannier character) and limited spectral broadening (Bloch character). Hence, they are best suited for associating specific spectral features to the underlying atomic-scale mechanisms. The new approach is demonstrated through applications to vitreous silica. The use of mixed Wannier-Bloch functions leads to a straightforward interpretation of the electronic spectrum of $v$-$SiO_2$ in terms of $s$ and $p$ atomic orbitals, and of the corresponding vibrational spectrum in terms of the molecular modes of the Si-O-Si bridge.

**G31 7 Quantum Monte Carlo Calculations of Transition Metal Oxides.***

LUCAS WAGNER, *Center for High Performance Simulation, North Carolina State University*

Quantum Monte Carlo is a powerful computational tool to study correlated systems, allowing us to explicitly treat many-body interactions with favorable scaling in the number of particles. It has been regarded as a benchmark tool for first and second row condensed matter systems, although its accuracy has not been thoroughly investigated in strongly correlated transition metal oxides. QMC has also historically suffered from the mixed estimator error in operators that do not commute with the Hamiltonian and from stochastic uncertainty, which make small energy differences unattainable. Using the Reptation Monte Carlo algorithm of Moroni and Baroni (along with contributions from others), we have developed a QMC framework that makes these previously unavailable quantities computationally feasible for systems of hundreds of electrons in a controlled and consistent way, and apply this framework to transition metal oxides. We compare these results with traditional mean-field results like the LDA and with experiment where available, focusing in particular on the polarization and lattice constants in a few interesting ferroelectric materials. This work was performed in collaboration with Lubos Mitas and Jeffrey Grossman.

**G31 8 First Principles Study of Formation Energies and Diffusion Mechanisms of Native Point Defects in Rutile $TiO_{2-x}$** HAKIM IDDIR, SERDAR OGUT, *University of Illinois at Chicago* NIGEL BROWNING, *University of California at Davis* We present results from first principles calculations for the formation energies and diffusion mechanisms of the oxygen vacancy ($V_O$), titanium interstitial ($Ti_I$) and titanium antisite ($Ti_O$) point defects in reduced rutile $TiO_{2-x}$. The calculations are performed in large supercells containing 240 to 270 atoms using the *ab initio* pseudopotential total energy method. As expected, the formation energy of $Ti_O$ is found to be significantly higher than $V_O$ and $Ti_I$, which have competitive formation energies as a function of the sample stoichiometry. The dominant charge states of $V_O$ and $Ti_I$ are found to be $(2+)$ and $(4+)$, respectively, for a wide range of the electron chemical potential. The calculated diffusion barriers for $Ti_I^{4+}$ are lower than those of $V_O^{2+}$, and do not present a significant anisotropy between the (100) open channels and the (110) direction. In fact, the barrier for the diffusion of $Ti_I^{4+}$ along the (100) open channels has an unexpectedly 0.1 eV higher barrier than along (110). The reasons for this observation and the implications of the present results are discussed in relation to bulk-defect assisted surface phenomena in rutile $TiO_2$.

**10:00**

**G31 9 Multifunctionality and Fluid Permeabilities of Triply Periodic Minimal Surfaces** YOUNGJEAN JUNG, *PRISM and Chemistry* SALVATORE TORQUATO, *PRISM, Chemistry, and PACM, Princeton University* It has recently been shown that triply periodic two-phase bicontinuous composites with interfaces that are the Schwartz P and D minimal surfaces are not only geometrically extremal but extremal for simultaneous transport of heat and electricity. The multifunctionality of such two-phase systems has been further established by demonstrating that they are also extremal when a competition is set up between the effective bulk modulus and electrical (or thermal) conductivity of the bicontinuous composite. We computed the fluid permeabilities of these and other triply periodic bicontinuous structures arranged on the sites of a simple cubic lattice at a porosity $\phi = 1/2$ [Y. Jung and S. Torquato, Phys. Rev. E **72**, 056319 (2005)]. We found that the Schwartz P porous medium has the largest fluid permeability among all of the six triply periodic porous media in consideration. The fluid permeabilities are shown to be inversely proportional to the corresponding specific surfaces for these structures. This leads to the conjecture that the maximal fluid permeability for a triply periodic porous medium with a simply connected pore space at a porosity $\phi = 1/2$ is achieved by the structure that globally minimizes the specific surface. We will also present specific single-length-scale, two-dimensional, isotropic multifunctional optimal microstructures at the phase volume fraction $\phi = 1/2$.

**10:12**

**G31 10 Ab Initio Structural Energetics of Bare $\beta - Si_3N_4$ Surfaces and the Interface with $Sm_2O_3$** JUAN CARLOS IDROBO, HAKIM IDDIR, SERDAR OGUT, *University of Illinois at Chicago* ALEXANDER ZIEGLER, NIGEL BROWNING, *University of California at Davis* R.O. RITCHIE, *University of California at Berkeley* Motivated by recent electron microscopy studies on the $Si_3N_4$/rare-earth oxide interfaces, the atomic and electronic structures of bare $\beta - Si_3N_4$ surfaces are investigated from first principles. The equilibrium shape of a $Si_3N_4$ crystal is found to have a hexagonal cross section and a faceted domelike base in agreement with experimental observations. The large atomic relaxations on the prismatic planes are driven by the tendency of Si to saturate its dangling bonds, giving rise to resonant-bond configurations or planar $sp^2$-type bonding. We predict three bare surfaces with lower energies than the open-ring $(10\bar{1}0)$ surface observed at the interface, which indicate that non- stoichiometry and the presence of the rare-earth oxide play crucial roles in determining the termination of $Si_3N_4$ matrix grains. We also present preliminary first principles results for the $Si_3N_4/Sm_2O_3$ interface and compare our findings to experimental observations.

**10:24**

**G31 11 Manipulation/Extraction of an Adatom from a Mound*** HANDAN YILDIRIM, ABDELKADER KARA, TALAT S. RAHMAN, *Physics Department Kansas State University* We present results of manipulation/extraction of Ag/Cu atoms from small Ag/Cu mounds on Ag(111)/Cu(111), rescpectively. Molecular dynamics (MD) and molecular static (MS) simulations were carried out using interaction potentials from the embedded atom method. Evaluation of the energy landscape in the absence of tip shows that for a Ag atom, lateral (sliding downwards) and vertical (climbing upwards) diffusion,the activation barrier is about 0.3 eV. We show that the presence of a Ag tip lowers the energy barrier for both lateral and vertical diffusion. We find that the optimum position of the tip to achieve extraction is when the tip is at the edge of the mound in front of the adatom, and at a height of 2.43 Å from the Ag adatom, for which the barriers for diffusion drop to 0.032 eV for lateral and 0.182 eV for vertical diffusion. In this case, the adatom is manipulated in the pulling mode. In the case of Cu, we found that the adatom manipulation/extraction is performed in the sliding/dragging mode.

**G32 1 Raman scattering studies of field- and temperature-dependent melting of charge order in $La_{1-x}Ca_xMnO_3$** MINJUNG KIM, HARINI BARATH, S.L. COOPER, *Dept. of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign* M. RUEBHAUSEN, *Institut fur Angewandte Physik, Univeristat Hamburg, Jungiusstrasse 11, D-20355 Hamburg, Germany* S.W. CHEONG, *Dept. of Physics and Astronomy, Rutgers University, New Brunswick, NJ* The $La_{1-x}Ca_xMnO_3$ is one of the well-known perovskite manganites that display charge ordering behavior below a charge ordering temperature $T_{co}$ for $x \geq 0.5$. In particular, the strongest ordering is shown at commensurate doping x=0.5 with the transition temperature, $T_{CO}$=160K. We investigate the field-induced melting of charge ordering in this system using field-dependent Raman scattering at different temperatures. By monitoring the field- and doping-dependence of excitations specific to the charge-ordered state, we are able to sensitively monitor the breakdown of both long-range and local charge order, and to carefully examine the stability of the charge ordered state to both doping (x) and applied magnetic field.

**8:12**

**G32 2 Theoretical study of charge, spin, and orbital order in half-doped $La_{0.5}Ca_{0.5}MnO_3$.*** DMITRI VOLJA, WEIGUO YIN, WEI KU, *BNL* Deep microscopic insights into the half-doped $La_{0.5}Ca_{0.5}MnO_3$ are obtained with a novel construction of

many-body picture derived from LDA+U and Wannier state analysis. Experimentally observed zig-zag orbital order and CE-type magnetic structure is found to have only very weak charge disproportionation. The apparent contradiction between well-defined bridge (3+) and corner (4+) Mn sites and the weak charge disproportionation is resolved naturally with occupied Wannier states centered at 3+ sites extending to 4+ and O-sites (reflecting non-negligible charge-transfer nature of the system.) Contrary to current lore, electron-electron interaction is found crucial to the long-range order in ordering the orbital and the spin. Specific experimental means of verification (e.g.: measurement of pseudospin direction) are suggested.

**G32 3 Charge versus orbital-occupancy ordering in manganites** WEIDONG LUO, MARIA VARELA, JING TAO, STEPHEN J. PENNYCOOK, SOKRATES T. PANTELIDES, *Vanderbilt University and Oak Ridge National Laboratory* It is generally assumed that density-functional theory (DFT) in the local-spin-density approximation (LSDA) or the generalized- gradient approximation (GGA) is not adequate to describe mixed- valence manganites. Here we report benchmark DFT/GGA calculations for the ground-state structural, electronic and magnetic properties for both undoped and doped $CaMnO_3$ and find the results to be in excellent agreement with available data, including new atomic-resolution Z-contrast imaging and electron-energy loss spectra. More specifically, we found that the DFT results predict two inequivalent Mn atoms in both 0.33 and 0.5 electron-doped $CaMnO_3$, in agreement with experimental evidence of $Mn^{+3}/Mn^{+4}$ oxidation state ordering. The inequivalent Mn atoms are marked by their distinctive orbital occupancies, dissimilar local Jahn-Teller distortion and different magnetic moments from DFT calculations. We also show that the spherically integrated charges associated with the two inequivalent Mn atoms are the same, and they are actually the same as in the Mn metal. This charge neutrality with different orbital occupancies is the result of self-consistency and atomic relaxations in the crystal. We conclude that DFT without additional correlations can account for the observed properties of oxidation-state ordering in this system. The impact of the results on other mixed-valence systems will be discussed.

**G32 4 Orbital and oxygen vacancy ordering in $La_{1-x}Sr_xMnO_{3-\delta}$ ($x \geq 0.8$, $\delta \geq 0.15$)** LEOPOLDO SUESCUN, *Materials Science Division, Argonne National Laboratory, Argonne, IL 60439 & Department of Physics, Northern Illinois University, DeKalb, IL 60115* BOGDAN DABROWSKI, *MSD, ANL, Argonne, IL 60439 & Dept. of Physics, NIU, DeKalb, IL 60115* JAMES MAIS, *Dept. of Physics, NIU, DeKalb, IL 60115* STANISLAW KOLESNIK, *Dept. of Physics, NIU, DeKalb, IL 60115* JAMES RICHARDSON, *Intense Pulsed Neutron Source Division, ANL, Argonne, IL 60439* JAMES JORGENSEN, *MSD, ANL, Argonne, IL 60439* We have developed synthesis method, obtained, and studied the highly Sr substituted LSM manganites. New oxygen and orbital ordered perovskite type phase $SrMnO_{2.6}$ (nominally $Sr_5Mn_5O_{13}$) was found tetragonal P4/m, a=8.61328(18) and c=3.80997(11) Å. Mn ion shows charge separation to $Mn^{3+}$ in a pyramidal and $Mn^{4+}$ in a regular octahedral coordination. Nonstoichiometry has been observed with oxygen compositions between $0.25 < \delta < 0.4$; upon oxidation a monoclinic distortion is observed. Analogous tetragonal and monoclinic phases have been found for $La_{1-x}Sr_xMnO_{3-\delta}$ ($0.3 < \delta < 0.5$) with x=0.05 and 0.2, respectively. In-situ neutron powder diffraction as well as susceptibility measurements show different magnetic arrangements below RT depending on x and $\delta$. This work was supported by the U.S. Department of Transportation and NSF-DMR-0302617.

**G32 5 A realistic approach to effective Hamiltonians for strongly correlated electron materials: Study of orbital ordering in $LaMnO_3$*** WEI-GUO YIN, DMITRI VOLJA, WEI KU, *Condensed Matter Physics & Materials Science Department, Brookhaven National Laboratory, Upton, NY 11973* We present a general scheme to the realistic derivation of many- body effective Hamiltonians, $H^{\text{eff}}$, for strongly correlated electron systems: Based on a novel Wannier state analysis of the LDA+$U$ electronic structure, relevant mechanisms can be clearly singled out and their strengths can be accurately determined by mapping $H^{\text{eff}}$ to the low-energy LDA+$U$ Hamiltonian within self-consistent Hartree-Fock mean-field theory [1]. Applying this scheme to $LaMnO_3$, the parent compound of colossal magnetoresistance manganites, we have quantified the relative importance of the effective electron-electron interaction ( $\sim$ 1.7 eV) and the Jahn-Teller splitting ( $\sim$ 0.9 eV) in ordering orbitals in $LaMnO_3$. We find that beyond the conventional Jahn-Teller picture, the electron-lattice (electron-electron) interaction alone is insufficient (sufficient) to stabilize the orbital ordering. Furthermore, our analysis indicates certain competition between different mechanisms, allowing direct experimental determination of their relative strengths. [1] W.-G. Yin, D. Volja, and W. Ku, cond-mat/0509075.

**G32 6 In-plane anisotropy of the electronic structure for the charge/orbital ordered state in half-doped Mn-oxide** Y.S. LEE, S. ONODA, Y. TOKUNAGA, J.P. HE, Y. KANEKO, *ERATO-SSS, Japan* T. ARIMA, *Tohoku University, Japan* N. NAGAOSA, Y. TOKURA, *Univeristy of Tokyo, Japan* We have investigated the in-plane anisotropy of the electronic response for the charge/orbital ordered phase in a half-doped Mn-oxide. Compared with the theoretical calculation the optical measurement with a single domain of $Eu_{1/2}Ca_{3/2}MnO_4$ reveals that the optical conductivity along the chain direction exhibits smaller optical gap and lower energy distribution of the spectral weight than along the stripe (interchain) direction. It is suggested that the electronic anisotropy reported here is attributed to the quasi-one-dimensional electron hopping which is subject to the zigzag chain-type $e_g$ orbital ordering.

**G32 7 Magnetic Excitations in the CE-type manganite $Pr_{0.5}Ca_{1.5}MnO_4$** J. A. FERNANDEZ-BACA, *ORNL and Univ. of Tennessee* FENG YE, *ORNL* SONGXUE CHI, *Univ. of Tennessee* PENGCHENG DAI, *Univ. of Tennessee and ORNL* J. W. LYNN, *NIST* R. MATHIEU, *Univ. of Tokyo* Y. TOKURA, *Univ. of Tokyo* Charge and orbital ordering (CO-OO) in doped manganites can control bulk and magnetic properties of the material. Canonical examples of the CO-OO compounds are 3D R(1-x)A(x)MnO3 and 2D R(1-x)A(1+x)MnO4 manganites near x=0.5. The magnetic ions in those systems are usually arranged in a checkerboard order, where spins of Mn3+ and Mn4+ form zigzap ferromagnetic chains coupling antiferromagnetically. Recent theoretical calculations and experimental observations suggest that the stabilization of CO-OO state in CE-type magnetic structure might be magnetic in origin. In this talk we will present our recent results on the study of the spin-wave excitations in the layered compound Pr0.5Ca1.5MnO4 with CE-type magnetic structure using inelastic neutron scattering. ORNL is managed by UT-Battelle, LLC, for the U.S. Dept. of Energy under contract DE-AC05-00OR22725. The work at UT was supported by the U.S. NSF DMR-0453804 and DOE DE-FG02-05ER46202.

**G32 8 How Cation-Covalency controls Electron Localization in t2g Perovskites** OLE KROGH ANDERSEN, ATSUSHI YAMASAKI, *Max-Planck Institute FKF, Stuttgart* EVA PAVARINI, *Forschungszentrum Juelich* In the series of perovskites, SrVO3-CaVO3-LaTiO3-YTiO3, the transition-metal d electron becomes increasingly localized and undergoes a Mott transition. By defining a low-energy Hubbard Hamiltonian in the basis of NMTO Wannier functions for the t2g LDA band and solving it in the single-site dynamical mean-field approximation, it was recently shown [1] that simultaneously with the Mott transition, the orbital fluctuations are strongly suppressed. Here, we explain the underlying chemical mechanisms [2]: Proceeding through the series, covalency between the empty large-cation-d states and the occupied oxygen-p states causes the oxygen octahedra to rotate and tilt. Moreover, since those oxygen-p orbitals which bond to the cations are the same as those which bond to the transition-metal t2g orbitals, the t2g Wannier functions exhibit residual covalency. This splits the t2g levels and reduces the width of the lowest subband. Cation covalency thus causes the electron to localize in LaTiO3 and YTiO3. [1] E. Pavarini, S. Biermann, A. Poteryaev, A.I. Lichtenstein, A. Georges, O.K. Andersen, Phys. Rev. Lett. 92 (2004) 176403. [2] E. Pavarini, A. Yamasaki, J. Nuss, O.K. Andersen, New Journal of Physics 7 (2005) 188.

**G32 9 Resonant soft x-ray diffraction from $Fe_3O_4$/MgO below the Verwey transition** C. SCHUESSLER-LANGEHEINE, J. SCHLAPPA, C. F. CHANG, H. OTT, Z. HU, L. H. TJENG, *II. Physikalisches Institut, Universitaet zu Koeln, Germany* E. SCHIERLE, E. WESCHKE, G. KAINDL, *Institut fuer Experimentalphysik, Freie Universitaet Berlin, Germany* A. TANAKA, *ADSM, Hiroshima University, Japan* The electronic structure of the low-temperature phase of magnetite ($Fe_3O_4$) has been studied for more than 60 years. In particular the question whether or to which extend the low-temperature phase is characterized by a charge order on the octahedral Fe-sites is controversially discussed. We studied this system using resonant soft x-ray diffraction at the Fe $L_{2,3}$ resonance, a technique particularly sensitive to spatial modulations of the electronic state. The resonance behaviour of the (001) peak, which is characteristic for the low temperature phase, is distinctly different from that of the also studied (001/2) diffraction peak; we assign the (001) peak to charge order with a modulation of about 16 percent of a unit charge, while the (001/2) peak is caused by a different order involving only $Fe^{2+}$ sites in octahedral environment.

**G32 10 Electronically smectic-like phase in a nearly half-doped manganite.**
FENG YE, *Oak Ridge National Laboratory*

Charge/orbital ordering is one of the most important of phenomena in doped manganites [1-3]. In this talk, I am going to present our recent neutron scattering results on the charge/orbital ordering (CO-OO) and spin ordering in the nearly half-doped perovskite manganite $Pr_{0.55}(Ca_{0.8}Sr_{0.2})_{0.45}MnO_3$ (PCSMO) [4]. On cooling from room temperature, PCSMO first enters into a CO-OO state below $T_{CO}$ and then becomes a CE-type long-range ordered antiferromagnet below TN. At temperatures above TN but below $T_{CO}$ ($T_N < T < T_{CO}$), the spins in PCSMO form highly anisotropic smectic liquid-crystal-like texture with ferromagnetic (FM) quasi-long-range ordered one-dimensional zigzag chains weakly coupled antiferromagnetically. Such a magnetic smectic-like phase results directly from the spin-orbit interaction and demonstrates the presence of textured 'electronic soft' phases in doped Mott insulators [5,6]. This work was supported by the DOE No.DE-AC05-00OR22725 with UT/Battelle, LLC and U. S. NSF DMR-0139882. This work was performed under the US-Japan Cooperative Program on Neutron Scattering. **G32 11 Spin moment over 10-300 K and the delocalization of magnetic electrons above the Verwey transition in magnetite** P. A. MONTANO, *U. of Illinois Chicago and USDOE* YINWAN LI, *U. of Illinois Chicago and Argonne National Laboratory* B. BARBIELLINI, *Northeastern U.* P. E. MIJNARENDS, *Northeastern U. and Delft University of Technology* S. KAPRZYK, *Northeastern U. and and AGH (Poland)* A. BANSIL, *Northeastern U.* In order to probe the magnetic ground state, we have carried out temperature dependent magnetic Compton scattering experiments on an oriented single crystal of magnetite ($Fe_3O_4$), together with the corresponding first-principles band theory computations to gain insight into the measurements. An accurate value of the magnetic moment $\mu_S$ associated with unpaired spins is obtained directly for the first time over the temperature range of 10-300K. $\mu_S$ is found to be non integer and to display an anomalous behavior with the direction of the external magnetic field near the Verwey transition. The anisotropy of the magnetic Compton profiles shows a dramatic jump through the Verwey temperature $T_v$ and indicates that magnetic electrons in the ground state of magnetite become delocalized above $T_v$. Work supported by the USDOE.

**G32 12 Dimensionality switching in electric conduction in FeS** TOMOHIRO TAKAYAMA, KOHSHI TAKENAKA, HIDENORI TAKAGI, *RIKEN(The Institute of Physical and Chemical Research), also at University of Tokyo and CREST-JST* Orbital degree of freedom plays an essential role in the properties of strongly correlated systems, and will be a key function in the next generation. The orbital state, namely, shape of electron cloud, can affect some macroscopic properties such as transport properties. We have indeed observed a dimensionality change in electric conduction in stoichiometric iron sulfide, FeS, as a consequence of change in orbital states. FeS crystallizes in a NiAs-based troilite structure and is an antiferromagnetic semiconductor below $T_N$ = 600 K. At $T_s \sim$ 400 K, spin-axis transition, the rotation of antiferromagnetically ordered spins of iron atoms, occurs; the spins are directed along *c*-axis at low temperatures, and they rotate and lie in *c*-plane at $T_s$. This transition involves a change in orbital states of $Fe^{2+}$ ions. The outermost electron of $Fe^{2+}$ ions spreads in basal-plane below $T_s$, while it elongates in *c*-direction above $T_s$. This change strongly couples onto the electric conduction and induces its dimensionality change from two-dimensional below Ts to three-dimensional above $T_s$. We will discuss this change in orbital states and its appearance in electric conduction.

**G32 13 First-order phase transition induced by disorder in a model for manganites** EDUARDO CASTRO, JOÃO SANTOS, *CFP and Departamento de Física, Faculdade de Ciências Universidade do Porto* The role of disorder in the physics of manganese oxides has been unveiled by a series of experiments in half-doped ordered and disordered manganites. For the ordered family a multicritical behaviour was found in the temperature vs bandwidth phase diagram, where a charge-order insulator (COI) competes with a ferromagnetic metal (FM). Chemical disorder induces a strong suppression of the transition to the COI state, effectively turning an insulator into a FM and enhancing the colossal magnetoresistive effect above the Curie temperature. Recently, a one orbital double-exchange model with cooperative phonons and quenched disorder was proposed to explain this metal-insulator transition induced by disorder. Treating the electronic degrees of freedom exactly, and the local spins and lattice distortions classically, in a variational mean-field approach, we have investigated the thermodynamic behaviour of the model in 2D systems larger by one order of magnitude than in previous works. Not only the suppression of the COI state by disorder was obtained, but we have also found that the second-order charge-order phase transition turns into first-order in the presence of intermediate disorder. This picture is consistent with experiments: first-order phase transitions are known to be present in half-doped disordered manganites which show the spectacular phenomena of the collapse of a charge-ordered state under a magnetic field.

**G33 1 Rate of Entropy Extraction in Compressible Turbulence*** MAHESH BANDI, *Department of Physics and Astronomy, University of Pittsburgh* The rate of change of entropy is measured for a system of particles floating on the surface of a fluid maintained in a turbulent steady state. This rate of entropy $\dot{S}$ equals the time integral of the two point temporal velocity divergence correlation function with a negative prefactor. The measurements satisfactorily agree with the sum of Lyapunov exponents (Kolmogorov-Sinai entropy rate) measured from previous simulations, as expected of dynamical systems that are very chaotic (Sinai-Ruelle-Bowen statistics).

**G33 2 Toward Zero Surface Tension Limit: Granular Fingering Instability in a Radial Hele-Shaw Cell** XIANG CHENG, *The James Franck Institute and Department of Physics, The University of Chicago* Because of the absence of cohesive forces between grains, dry granular material can, in many respects, be thought of as a fluid with zero surface tension. In the zero surface-tension limit, viscous fingering is known to possess singular behavior. We have studied the viscous fingering instability in such a granular ''fluid.'' In our experiment, we use a conventional radial Hele-Shaw cell consisting of two parallel glass plates separated by a gap. Gas with controlled pressures is blown through a hole at the center of one glass plate and displaces the surrounding dry granular material. We have systematically studied the fingering pattern as a function of gas pressure, gap thickness, and grain size. Two stages are observed during pattern growth. In the first stage, we find fluid-like fingering. However, as opposed to normal fluids, the pattern is more ramified at low pressure. In the second stage, we find several new behaviors in the system such as merging and pinching off of fingers and the existence of satellite bubbles.

**G33 3 The effect of packing density on self-assembled monolayer friction: Investigation of frictional contrast between OTS phase-separated regions** ERIN FLATER, *University of Wisconsin - Madison* Motivated by the lack of fundamental understanding of friction, and that friction and wear are major limiting factors for surface micromachined devices, we use atomic force microscopy (AFM) to determine the nanoscale frictional properties of alkylsilane monolayers commonly used in these microscale devices to reduce adhesion and friction. Quantitative nanoscale single asperity measurements of friction and contact stiffness are performed using monolayer-terminated AFM tips on monolayer-terminated silicon. By comparing the two structural phases present in octadecyltrichrolosilane (OTS) monolayers, we observe that friction depends on the local molecular packing density. The liquid condensed phase shows measurably lower friction at low loads than the liquid expanded phase, demonstrating that lower friction is associated with higher molecular packing density. However, the phases exhibit the same frictional response at higher loads, suggesting that compressed forms of both phases are structurally and tribologically equivalent. We discuss these results in terms of stress-induced molecular conformational changes in the confined interface. We acknowledge our collaborators: W. Robert Ashurst at Auburn University, who provided the OTS samples, and Maarten P. de Boer and Alex D. Corwin at Sandia National Laboratories.

**G33 4 Universal Impedance, Admittance and Scattering Fluctuations in Quantum-chaotic Systems** SAMEER HEMMADY, *University of Maryland* We experimentally investigate fluctuations in the eigenvalues of the impedance, admittance and scattering matrices of wave chaotic systems using a microwave analog of a quantum chaotic infinite square well potential. We consider a 2-D, time-reversal symmetric chaotic microwave resonator driven by two non-ideally coupled ports. The system-specific coupling effects are removed using the measured radiation impedance matrix ($\overleftrightarrow{Z}_{Rad}$) [1] of the two ports. A normalized impedance matrix ($\overleftrightarrow{z}$) is thus obtained, and the Probability Density Function (PDF) of its eigenvalues is predicted to be universal depending only on the cavity loss. We observe remarkable agreement between the statistical properties of $\overleftrightarrow{z}$ and $\overleftrightarrow{y} = \overleftrightarrow{z}^{-1}$ for all degrees of loss, which is in accordance with [1,2] and Random Matrix Theory (RMT). We compare the joint PDF of the eigenphases of the normalized scattering matrix ($\overleftrightarrow{s}$) with that obtained from RMT for varying degrees of loss. We study the joint PDF of the eigenvalues of $\overleftrightarrow{s} \leftrightarrow \overleftrightarrow{s}^{\dagger}$ and find good agreement with [3]. [1] X. **G33 5 Plastic Failure Events in 2D Sheared Granular Systems*** TRUSH MAJMUDAR, *Physics Department, Duke University* We present experimental measurements of plastic failure events in a two dimensional granular system consisting of polymer photoelastic disks, placed horizontally, and confined within a rectangular biaxial cell. The bi-refringence of these disks allows us to determine the normal and tangential components of contact forces. We image the system at various deformation states and measure the stress changes and displacements of the disks during one complete shear cycle. The stress changes are found by computing the stress tensor of each disk and the displacements are measured by particle tracking. We obtain bulk stress-strain curves by spatial averaging and find that the system exhibits regions of reversible deformation interrupted by irreversible plastic failure events. We also obtain the behavior of shear modulus of the system. The spatial distribution of reversible and plastic deformations found by studying the displacements of the disks show that in two corners, the disks move uniformly but in a central band aligned along a principal strain direction, we observe multiple vortices. Reversing the direction of shear causes maximum plastic deformation which results in disruption of the vortex structure. We compare our results to the shear transformation zone (STZ) theory.

**G33 6 Locally fluctuating elasticity of vulcanized solids** XIAOMING MAO, PAUL GOLDBART, *University of Illinois at Urbana-Champaign* XIANGJUN XING, *Syracuse University* ANNETTE ZIPPELIUS, *Universitaet Goettingen* The elastic properties of vulcanized solids, such as rubbery polymeric media, are characterized not only by their small mean shear moduli but also by the random spatial fluctuations of their local elasticity. These fluctuations originate in the randomness locked in, e.g., to a polymer network during the cross-linking process. We examine these fluctuations in the local elasticity of random solids via vulcanization theory, i.e., the replica field theory that describes cross-linking- driven random solidification transitions and their emergent rigidity. To do this we identify the Goldstone excitations of the random solid state as local shear deformations, and interpret their effective free energy in terms of a phenomenological model of inhomogeneous, nonlocal rubber elasticity. Thus, we arrive at predictions for the statistical properties of the fluctuating elasticity of vulcanized solids.

**G33 7 Rheological Fluids under Perturbation: Reconstruction and Relaxation Processes*** ELSA MARIA DE LA CALLEJA,[†] *Universidad Autonoma de Puebla* JOSE LUIS CARRILLO,[‡] *Universidad Autonoma de Puebla* We study the evolution of the structure of electro rheological as well as magneto rheological fluids in the presence of perturbation fields. We have previously shown that the fibrous structure acquired by these dispersions in the presence of a static, electric or magnetic, field has multifractal characteristics [1]. If in addition to the static field a perpendicular pulsed field is applied, under certain conditions it is possible to rearrange the structure into an ordered one [2]. Based on the measured mass fractal dimension and the radial distribution of mass, we discuss these processes and other structural characteristics of the system approaching these phenomena as a glass transition. **G33 8 Low temperature solution of the Sherrington-Kirkpatrick model** SERGEY PANKOV, *NHMFL, FSU, Tallahassee* We propose a simple scaling ansatz for the full replica symmetry breaking solution of the Sherrington-Kirkpatrick model in the low energy sector. This solution is argued to become exact in the limit $x \to 0$, $\beta x \to \infty$ of the Parisi replica symmetry breaking scheme parameter $x$. The distribution function $P(x,y)$ of the frozen fields $y$ has been known to develop a linear gap at zero temperature. We integrate the scaling equations to find an exact numerical value for the slope of the gap $\partial P(x,y)/\partial y|_{y\to 0} = 0.301046\ldots$ We also use the scaling solution to devise an inexpensive numerical procedure for computing finite timescale ($x = 1$) quantities. The entropy, the dynamical susceptibility at zero frequency and the local field distribution function are computed in the low temperature limit with high precision, barely achievable by other currently available methods.

**9:36**

**G33 9 Slowing dynamics of supercooled glycerol in the volume-temperature plane*** NARAYANAN MENON, K. WIN, *University of Massachusetts Amherst* We have measured[1] the dielectric susceptibility of supercooled glycerol from 0.01 Hz to 100 kHz at up to 900 MPa and close to the glass transition temperature. We find that the glass transition temperature and isobaric fragility increase with pressure. We separate the effects on the relaxation frequency of volume and temperature by studying the glass transition in the V-T plane. By introducing a generalized fragility we quantify these effects and show that V and T contribute almost equally to dynamic slowing-down. We exploit a connection between the generalized fragility and a recently discovered scaling exponent to show that these results are likely to hold for other fluids.

**G33 11 Relaxation Width and Ionic Conductivity of Supercooled Glycerol at High Pressure*** KYAW ZIN WIN, NARAYANAN MENON, *University of Massachusetts Amherst* We have measured the dielectric susceptibility of supercooled glycerol from 0.01 Hz to 100 kHz at up to 900 MPa and close to the glass transition temperature. We find that, at a fixed relaxation frequency, the relaxation width increases with pressure. We also establish a relation between isobaric fragility and the width of glycerol and compare it to a correlation[1] between these quantities at 1 atmosphere for a variety of liquids. We find that volume has a much bigger effect than temperature on the changes in the width. We are also for the first time able to study the ionic conductivity as a function of temperature and pressure, and study the Nernst-Einstein relation between the conductivity and the relaxation frequency.

**G33 12 Calculation of the configurational entropy for a binary Lennard-Jones fluid below the mode-coupling temperature using a hybrid Monte Carlo method** ELIJAH FLENNER, GRZEGORZ SZAMEL, *Dept. of Chemistry, Colorado State University* We developed a novel, hybrid Monte Carlo algorithm that combines configurational bias particle swaps with parallel tempering. We use this new method to simulate a standard model of a glass forming binary mixture above and below the so-called mode-coupling temperature, $T_{MCT}$. We find that an itansatz that was used previously to extrapolate thermodynamic quantities to temperatures below $T_{MCT}$ breaks down in the vicinity of the mode-coupling temperature. Thus, previous estimates of the so-called Kauzmann temperature need to be reexamined. Also, we find that the Adam-Gibbs relations $D \propto \exp(-a/TS_c)$ and $\tau \propto \exp(b/TS_c)$, which connect the diffusion coefficient $D$ and the relaxation time $\tau$ with the configurational entropy $S_c$, are valid for all temperatures for which the configurational and vibrational contributions to the free energy decouple.

**G33 13 Enhanced Elasticity and Soft Glassy Rheology of a Smectic Liquid Crystal in a Random Porous Environment** DENNIS LIANG, RANJINI BANDYOPADHYAY, *Johns Hopkins U.* RALPH COLBY, *Pennsylvania State U.* JAMES HARDEN, *University of Ottawa* ROBERT LEHENY, *Johns Hopkins U.* We present rheometry studies of the frequency dependent shear modulus, $G^*(\omega) = G'(\omega) + iG''(\omega)$, of the smectic liquid crystal octylcyanobiphenyl (8CB) confined by a colloidal silica gel. When the 8CB is in the isotropic or nematic phase, the shear modulus is independent of temperature and dominated by the elasticity of the gel. With the onset of smectic order, $G'$ grows approximately linearly with decreasing temperature and reaches values that can exceed by more than 3 orders of magnitude the values for pure 8CB. The modulus in the smectic phase possesses a weak power-law dependence on frequency, $G^*(\omega) \sim \omega^\alpha$, with the exponent $\alpha$ approaching zero with increasing gel density. Within the soft glassy rheology model, such a decreasing exponent

indicates an approach to a glass transition, which we correlate with the increasing random field coupling between the gel and smectic. We further interpret the enhanced elasticity and weak power law dependence of $G^*(\omega)$ as the result of a dense population of defects in the disordered smectic.

**10:36**
**G33 14 Concept of a Bond in Metallic Glasses. Bond's Lifetime in a Supercooled Liquid. MD Modeling.** VALENTIN A. LEVASHOV, TAKESHI EGAMI, *University of Tennessee, Knoxville, TN 37996* RACHEL S. AGA, JAMES R. MORRIS, *Oak Ridge National Laboratory, Oak Ridge, TN 37831-6115* We have done constant volume MD simulations of a one component system of particles interacting via modified Johnson pair potential previously developed for iron. Negative curvature of the potential at the distances beyond potential minimum leads to the clear differentiation between the first and second nearest neighbors observed in the pair distribution function. Therefore a concept of a bond could be introduced. We studied the distribution of bond lifetimes in a liquid state. At high temperatures probability to find a long living bond is very small. As temperature decreases there appear bonds whose lifetime is very long. At the same time, the number of bonds whose lifetime is relatively small remains significant. This could be considered as an indication of the separation of the system into solid-like and liquid-like regions. Obtained bond lifetime distributions will be analyzed from this point of view of the presence in supercooled liquids different kinetic regimes at different temperatures.

**G34 2 Direct measurement of the distinct part of van Hove correlation function $G_d(r, t)$ in colloidal gels and glasses** YONGXIANG GAO, MARIA KILFOIL, Great effort has been put into understanding the mechanism and dynamics of glass formation, and progress has been made. It is now known that the cage effect causes the dynamical arrest, and thus the observed glass transition. This has been proven by direct observation by microscopy, by light scattering and rheology experiments of hard sphere systems near the glass transition, and by computer simulation. However, no real-space direct three dimensional measurements of large-length-scale dynamics have been done in glass samples. The distinct part of the van Hove correlation function $G_d(r, t)$ provides direct access to the dynamics in glassy systems at all length scales. We use confocal microscopy to measure this function in both colloidal gels and glasses. Since both glass and gel formation are kinetic and not thermodynamic phenomena, we may expect that they share similarities. By looking at their dynamics, we may gain more insights into the unified jamming picture of liquid-to-disordered-solid transition.

**8:24**
**G34 3 Fluctuations of Structure and Dynamics in an Aging Colloidal Glass*** GIANGUIDO C. CIANCI, ERIC R. WEEKS, *Department of Physics, Emory University, Atlanta, GA 30322 USA* When a liquid is quenched to form a glass it becomes trapped in a non-equilibrium state. The non-ergodicity of the system is most clearly highlighted by the dependence of the glass' properties on the time elapsed since the quench. This phenomenon is known as aging. Dense colloidal suspensions have been shown to be a good model for the glassy state. We use fast laser scanning confocal microscopy to image sterically stabilized, micron-sized, PMMA spheres in three dimensions and track their positions over time with sub-pixel accuracy. While aging is most commonly detected by measuring the evolution of variables (such as the mean squared displacement or the intermediate scattering function) averaged over the entire system and over time these quantities cannot yield information about the detailed, structural changes that occur during aging. Confocal microscopy, on the other hand, allows us to intimately study the aging process with minimal or no averaging. We study the statistics of the fluctuations of geometrical and dynamical quantities over time as the sample ages. In particular, we find that the aging process is heterogeneous in time and space and compare the fluctuations of the aging process to intermittent, record induced dynamics models.

**G34 4 Dynamic correlations and correlation length in the aging of a simple structural glass** AZITA PARSAEIAN, *Department of Physics and Astronomy, Ohio University* HORACIO CASTILLO, *Department of Physics and Astronomy, Ohio University* We present the results of a detailed molecular dynamics simulation of the spatial correlations of fluctuations in a simple binary Lennard-Jones glass former in the aging regime. We study the 4-point generalized density susceptibility $\chi_4(t,t_w)$ and the dynamic correlation length $\xi_4(t,t_w)$ associated with it, where $t_w$ is the waiting time. We find that these data are consistent with the scalings $\chi_4(t,t_w) = F(t_w)\chi_4^0(C(t,t_w))$ and $\xi_4(t,t_w) = G(t_w)\xi_4^0(C(t,t_w))$, where $C(t,t_w)$ is the incoherent part of the intermediate scattering function. We also find that $F(t_w)$ can be fit as a power of the waiting time, and $G(t_w)$ can be fit as a logarithm of the waiting time. These differing time dependencies, plus the dramatically different behavior of the scaling functions $\chi_4^0(C)$ and $\xi_4^0(C)$ for small $C$ lead to the conclusion that the time evolution of $\chi_4(t,t_w)$ *is not* controlled by its associated dynamic correlation length $\xi_4(t,t_w)$.

**G34 5 Dynamic fluctuations of elastic lines in three-dimensional random enviroments** SEBASTIAN BUSTINGORRY, *Centro Atomico Bariloche, Argentina* LETICIA CUGLIANDOLO, *LPTHE-Jussieu and LPT-ENS, Paris* DANIEL DOMINGUEZ, *Centro Atomico Bariloche, Argentina* Elastic lines embedded in three-dimensional random environments present a low temperature glassy regime, with aging characterized by multiplicative scaling. We studied the scaling properties of the distribution functions of different dynamical observables: the roughness, the mean-squared-displacement and its associated response function. Following the multiplicative scaling hypothesis, we numerically show that the distribution functions depend only on the mean scaled value of the variables, and not on the different time scales involved. These results could be extended to the scaling of distribution functions in critical-like systems.

**G34 6 Microstructure of a polymer glass overaged by application of instantaneous shear strains*** BELA JOOS, *University of Ottawa* MATTHEW L. WALLACE, *Université Louis Pasteur, Strasbourg* When applying a transient shear on jammed colloidal suspensions, Viassnoff and Lequeux (*Phys. Rev. Lett.* **89**, 065701 (2002)) observed both rejuvenation and overaging in the system, as the relaxation times are altered in a non- trivial way. Application of instantaneous, one-time shear deformations on a polymer glass by molecular dynamics simulations produces a similar behavior (M.L. Wallace and B. Joós, *Phys. Rev. Lett.*, in press). Two regimes are observed corresponding to elastic and plastic strains. Of particular interest are deformations in the plastic regime, above the yield strain ($\epsilon > 0.1$), where the characteristic relaxation times $\tau_{1/2}$ increase exponentially with $\epsilon$, after a long waiting time $t_w$ following the deformation. We are in the process of understanding the nature of this state of the glass. There is a slight increase in the average energy of the inherent structures $< e_{IS} >$, in particular in the inter-chain component. The bond orientational order parameter appears to increase especially in the elastic regime. The shear modulus decreases. And there are significant changes in the distribution of relaxation times. The average shifts to larger times, and the distribution broadens and resembles more a Gaussian. These properties suggest that, above the yield strain, the system becomes more homogeneous, and possibly less jammed.

**G34 7 Observed Effects of Confinement on Colloidal Glasses*** CAROLYN NUGENT, HETAL PATEL, JOE SALDANA, ERIC R. WEEKS, *Department of Physics, Emory University* We used a binary colloidal suspension to model glass molecules. By increasing the concentration of colloids, a glass transition is induced. Previous studies of colloidal suspensions show that as the glass transition is approached, colloids tend to move in groups of increasing size. In order to examine this phenomenon more closely, a colloidal suspension was confined between two parallel glass plates with a narrow gap of the order of a few colloid diameters in thickness. Confocal microscopy was used to observe the particles and follow their motion over time. We observed that motion in confined regions was much slower than motion in non-confined regions of the same sample. In addition, the motion perpendicular to the walls was slower than motion parallel to the walls. The arrangement of colloids into layers was also observed, which further influenced the motion.

**G34 8 The effective temperature and the universal scaling behavior of aging colloidal glass system** PING WANG, CHAOMING SONG, HERNAN MAKSE, *City College of New York, New York, NY 10031* Mostly due to the enormous practical importance of glassy systems there has been a vast literature describing different theoretical frameworks for glasses, yet without a common theory applicable to the diverse range of systems undergoing a glass transition. Here we present experimental results on a simple glassy system pointing to a unifying view of out-of-equilibrium systems. We investigate correlation and response functions to external fields to monitor the aging of a colloidal glass composed of highly concentrated hard spherical particles suspended in an refraction index matched fluid for visualization. Our analysis reveals that even though the system is aging far from equilibrium, it behaves as it is equilibrated at a constant temperature, independent of the age. This temperature is larger than the bath, and can be rationalized by the cage dynamics in the system. Global and local fluctuations in the observables are also studied showing a common scaling behavior with the age of the system. While these results can be interpreted within the framework of unifying formulations of aging, the observed scaling forms of the correlation functions do not conform to the theoretical predictions.

**9:36**

**G34 9 Aging of Johari-Goldstein Relaxation in Structural Glasses** HASAN YARDIMCI, ROBERT L. LEHENY, *Department of Physics and Astronomy, Johns Hopkins University* Using frequency-dependent dielectric susceptibility measurements we characterize the aging in two supercooled liquids, sorbitol and xylitol, below their calorimetric glass transition temperatures, $T_g$. In addition to the alpha relaxation that tracks the structural dynamics, the susceptibilities of both liquids possess a secondary Johari-Goldstein relaxation at higher frequencies. Following a quench below $T_g$, the susceptibility slowly approaches equilibrium behavior. For both liquids, features of the Johari-Goldstein relaxation display a dependence on the time since the quench, or aging time, that is very similar to the age dependence of the alpha peak. However, one can not assign a single fictive temperature to both the alpha and Johari-Goldstein relaxations. For example, the peak frequency of the Johari-Goldstein relaxation remains constant during aging for sorbitol while it increases with age for xylitol, inconsistent with a decreasing fictive temperature. This behavior contrasts with that of the high frequency tail of the alpha peak whose shape and position track the aging of the main part of the peak.

**9:48**

**G34 10 Glassy Dynamics in Suspensions of Non-Spherical Colloids** GALINA YATSENKO, KENNETH SCHWEIZER, *University of Illinois, Urbana, IL 61801* Glassy dynamics of isotropic fluids of hard symmetric dumbbells (diatomics), rods, cylinders and disks are studied using a simple form of mode coupling theory and its generalization to predict barriers and activated hopping transport. Orientational degrees of freedom dynamically enter in a pre-averaged manner, and structural correlations are quantified based on a center-of-mass version of the site-site Reference Interaction Site Model. A length-to-diameter (aspect) ratio serves as a principal parameter describing shape anisotropy. The ideal glass

transition volume fraction of dumbbells is predicted to be a non-monotonic function of aspect ratio. For continuous cylinders, ellipsoids and disks power law dependencies of glass transition volume fraction and localization length on aspect ratio are found in the highly anisotropic limit. The consequences of discotic liquid crystalline order for infinitely thin disks have also been studied. Multiple scaling behaviors with volume fraction and aspect ratio are predicted for the localization length, barrier height, elastic shear modulus and yield stress.

**G34 11 Microrheology of an aging colloidal glass** S. JABBARI-FAROUJI, *Univ. of Amsterdam* D. MIZUNO, M. ATAKHORRAMI, *Free Univ. of Amsterdam* E. EISER, *Univ. of Amsterdam* C. SCHMIDT, F. MACKINTOSH, *Free Univ. of Amsterdam* G. WEGDAM, D. BONN, *Univ. of Amsterdam* Laponite is a synthetic clay which after mixing with water, spontaneously evolves from an initially liquid and ergodic state to a non-ergodic glassy state that exhibits elastic behavior. We provide a direct experimental test of the Stokes-Einstein relation as a special case of the fluctuation-dissipation theorem (FDT) in this aging colloidal glass. The use of combined active and passive microrheology allows us to independently measure both the correlation and response functions in this non-equilibrium situation. Contrary to previous reports, we find no deviations from the FDT over several decades in frequency (1 Hz-10 kHz) and for all the observed aging times. Our measurements also demonstrate the applicability of fluctuation-based (passive) microrheology in a non-equilibrium glassy system. This method allows obtaining the viscoelastic properties over a very wide frequency range. Our striking observation is that there is a cross over in frequency behavior of complex shear modulus of system from single power law at early stages of aging to two power laws at later stages. This suggests the existence of two distinct viscoelastic contributions in the aging glass: (i) a high-frequency viscoelastic response in which the shear modulus increases rapidly with frequency; and (ii) a predominantly elastic (weakly frequency-dependent) response at lower frequencies, which becomes increasingly important as the system ages.

**10:12**

**G34 12 Activated Hopping and Dynamic Heterogeneity in Glassy Colloidal Suspensions** ERICA SALTZMAN, KENNETH SCHWEIZER, *University of Illinois at Urbana-Champaign* A microscopic statistical dynamical theory of barriers and activated transport in dense colloidal suspensions has been developed by combining and extending methods of mode coupling, density functional and particle hopping theories. Quasi-analytic results for the mean relaxation time and ensemble-averaged transport coefficients agree well with experiment. However, a full determination of the dynamics requires numerical integration of the nonlinear overdamped stochastic equation of motion, i.e. Brownian dynamics simulation. This enables calculation of average quantities including the mean-square displacement, incoherent dynamic scattering function and alpha relaxation time, as well as trajectory-based quantities such as displacement and relaxation time distributions. Dynamic heterogeneity effects are explored by studying various decoupling factors, the non-gaussian parameter, the bimodality of the displacement distribution and the non-Fickian wavevector dependence of the structural relaxation time. Comparisons to mode-coupling theory, simulation and experimental results are performed.

**G34 13 Dependence of relaxation time on effective temperature in driven glasses*** THOMAS HAXTON, *Physics Dept., Univ. of Pennsylvania* AJAY GOPINATHAN, *Physics Dept., Univ. of California, Santa Barbara* ANDREA LIU, *Physics Dept, Univ. of Pennsylvania* Relaxation times of a class of driven glassy systems are shown to depend on a well-defined effective temperature in much the same way that they depend on temperature in quiescent systems. Molecular dynamics simulations were run for two-dimensional systems of bi-disperse spheres interacting via soft repulsive pair potentials. At high density the systems undergo a glass transition as temperature is lowered. We study low-temperature systems driven by an imposed shear gradient in steady state at a fixed high density. Effective temperatures can be defined from fluctuation-dissipation relations by the long-time limit of the ratio of correlation to response. Throughout a range of bath temperatures and shear rates, relaxation times are found to depend only on the bath temperature $T$ and the effective temperature $T_{\text{eff}}$. In particular, the relaxation time of the driven system as a function of $T_{\text{eff}}$ can be mapped on to the relaxation time of the quiescent system as a function of $T$, using a scale factor that varies only weakly with the ratio $T/T_{\text{eff}}$. This suggests that shear unjams the system because it gives rise to a $T_{\text{eff}}$ that is higher than the glass transition temperature.

**G35 1 Simulations of the Optical Properties of Silicon Nanoparticles Embedded in Silicon Nitride** SEBASTIEN HAMEL, *Lawrence Livermore National Laboratory* ANDREW WILLIAMSON, GIULIA GALLI, LUCA DAL NEGRO, *Massachusetts Institute of Technology* JAE HYUNG YI, VICTOR NGUYEN, YASHA YI, JURGEN MICHEL, LIONEL C. KIMERLING, There is currently a strong interest in the material science community in the optical properties of silicon nanoparticles embedded in silicon nitride. These nanostructures are CMOS-compatible materials which exhibit efficient and fast light emission. The optical properties of these embedded silicon nanoparticles are studied using first-principles Density Functional Theory simulations. We present simulations of the structural, electronic and optical properties of nitrogen-doped silicon nanoparticles both in the gas phase and embedded in a silicon nitride environment. These simulations point to the crucial role played by nitrogen atoms bonded to the surface of small ( $\sim$ 1nm) silicon nanoparticles in the light emission mechanism of $SiN_x$ films. We compare the calculated optical gaps and radiative lifetimes of the nanoparticles with recent experimental measurements of light-emitting silicon-rich silicon nitride films obtained by PE-CVD deposition followed by low tem-

perature (500-900 °C) thermal annealing. This work was performed under the auspices of the U.S. Dept. of Energy at the University of California/Lawrence Livermore National Laboratory under contract no. W-7405-Eng-48.

**G35 2 Multi-valued analog information storage using self-assembled nanoparticle films.** AL-AMIN DHIRANI, YOSHINORI SUGANUMA, *Department of Chemistry, University of Toronto* Digital computers use binary states, typically represented by 0 and 5 V, to store and process information at all stages of a calculation. If more states (ideally a continuum) were available in between, density of information could be dramatically increased. Here we show that self-assembled nanoparticle films can feature such continuous state or analog information storage. Nanoparticle films were prepared on gate oxides by alternate immersion in solutions of gold nanoparticle and dithiol linker molecules. These films afford microlithography-free fabrication bridging nanometer to micrometer length scales as well as a layer-by-layer assembly yielding three-dimensional functional structures. Information provided by an arbitrary gate voltage was 'written' by trapping charges in local, gate-modified potentials when films were cooled below 175 K. The information was 'read' using the film's built-in ability to sense charge via Coulomb blockade. Application of a time-dependent, multi-step writing gate voltage generates conductance maps corresponding to multi-valued analog information. As a proof of concept, we exploited this technique to store 'UT' in Morse code.

**G35 3 Using Accumulated Charge to Monitor Nanoparticle Deposition Rates Via Electrospray Ionization** JOEL THERRIEN, AMIR DINDAR, DAVID SMITH, *U. Massachusetts-Lowell, ECE Dept.* Electro-Spray Ionization (ESI) is a handy technique for depositing nanoparticles onto a substrate directly from a liquid suspension. ESI atomizes the suspension via high electric fields. The solvent in which the particles were suspended rapidly evaporates resulting in a stream of charged particles. This technique can be used to deposit a sub-monolayer dispersion of particles on any conducting substrate. AFM studies have been performed on ESI deposited samples to determine the correlation between the net charge deposited on the substrate via the deposition and the surface density of particles. This correlation may be used as a means of rate monitoring to assure higher reliability in achieving desired particle densities.

**G35 4 Enhanced optical luminescence in ZnO nanostructures following O 1s to $p_z$ excitation*** R.A. ROSENBERG, G.K. SHENOY, *Argonne National Laboratory* X.-T. ZHOU, T.K. SHAM, *University of Western Ontario* Room temperature ultraviolet ( $\sim$ 385 nm) lasing in ZnO nanostructures has recently been demonstrated.[1] This phenomenon is thought to arise from the natural cavity formed by the wurtzite nanostructure and its faceted ends. X-ray excited optical luminescence (XEOL) provides the capability to determine the nature of the sites responsible for producing low energy (1-6 eV) fluorescence. We will present XEOL excitation curves taken at the Zn L and O K edge obtained using both the defect ( $\sim$ 510 nm) and bandgap ( $\sim$ 370 nm) transitions as signals. Results obtained at the Zn L edge resemble the x-ray absorption curve of the nanostructure. However, striking differences are observed at the O K edge. Excitation to states of $p_z$ symmetry (along the c axis) leads to enhanced luminescence while excitation to $p_{x,y}$ states (lying in the basal plane) decreases the yield. We interpret this phenomenon as resulting from the lower probability of quenching by near surface defects for states excited along the c-axis as opposed to those excited perpendicular to it. 1. M.H. Huang, et al., Science **292**, 1897 (2001).

**G35 5 Silicon nanoporous pillar array: template for fabricating silicon-based nanocomposites with enhanced physical properties*** XIN JIAN LI, *Zhengzhou University, China* XIAO NAN FU, *Zhengzhou University, China* HAI JUN XU, *Zhengzhou University, China* WEI FENG JIANG, *Zhengzhou University, China* A triple hierarchical structure, silicon nanoporous pillar array (Si-NPA), was formed on silicon wafers by a hydrothermal method. The structure of Si-NPA is characterized by the regular array of micron-sized silicon pillars, quasi-identical nanopores densely distributing over each pillar, and silicon nanocrystalllites composing the walls of the nanopores. Utilizing the excellent structural regularity and high chemical reactivity of Si-NPA, patterned nanocomposites of CdS, carbon nanotubes (CNTs), Au, and Fe3O4/Si-NPA were fabricated. Their element compositions, morphologies and microstructures were characterized. Ideal physical properties of I-V curve in CdS/Si-NPA heterojunction, field emission in Si-NPA, CNTs/Si- NPA, Au/Si-NPA, and humidity/gas sensitivity in Fe3O4/Si-NPA were observed and the corresponding mechanisms were analyzed. These results indicate that Si-NPA could be employed as an ideal template to assembly silicon-based functional nanosystems, and might find multiple applications in fabricating novel electronic devices.

**G35 6 Excitons in Negative Band Gap Nanocrystals** JAMES SIMS, GARNETT W. BRYANT, HOWARD HUNG, *National Institute of Standards and Technology* Exploiting quantum confinement in nanocrystals made from materials with negative bulk band-gap will be critical for nanosensor applications in the far infrared. However, understanding quantum confinement, excitonic states and optical response in negative band-gap nanocrystals provides challenges not posed for usual nanocrystals with positive bulk band-gaps. We show that intrinsic surface states occur in nanocrystals made from negative gap semiconductors such as HgS. We use atomistic tight-binding theory that accounts for band mixing critical in negative-gap semiconductors but unimportant in positive-gap systems. Such band mixing makes effective mass theory inadequate for negative-gap nanocrystals. In small HgS dots, the lowest conduction band states are cation-derived and the band-edge valence states are anion-derived, as for finite-gap dots. However, in bigger HgS dots, the lowest conduction band state has a high density at the surface that slowly decays into the dot. As the dot size increases, this conduction state crosses the valence band edge, reaching a limit inside the bulk negative gap for very large dots. In this limit, the state is localized to the surface. The excitonic states and optical response of HgS dots are discussed to identify signatures for intrinsic surface states and to assess nanosensor applications with these systems.

**G35 7 Freely-Suspended Monolayers of Gold Nanocrystals: Fabrication and Elastic Properties*** KLARA ELTETO, *University of Chicago* XIAO-MIN LIN, *Argonne National Laboratory* SANG-KEE EAH, *Rensselaer Polytechnic Institute* HEINRICH M. JAEGER, *University of Chicago* We present a method to produce freely-suspended monolayers of 5.5nm-diameter gold nanocrystals, ligated with dodecanethiol, over holes with widths up to 2microns (about 250 particles). The holes are etched through a 120nm thick silicon nitride membrane. A water droplet initially covers the substrate. When nanocrystals suspended in toluene are added, they spread over the water-air interface, forming an extended, compact monolayer. As the water dries, the monolayer settles over the substrate and drapes itself over the holes. The resulting freely-suspended monolayers are stable in air and vacuum, as observed with optical, atomic force and transmission electron microscopy. No additional polymer or crosslinking of the ligands is required. Possible mechanisms for the stability of the monolayer include ligand interdigitation and van der Waals interaction between the gold cores. We report on measurements of the elastic properties of such monolayers, obtained by applying point forces to the suspended areas with an atomic force microscope and measuring the vertical elastic deformation.

**G35 8 Mapping Elastic Strain in Electrophoretically-Deposited CdSe Nanocrystal Films** IRVING HERMAN, SARBAJIT BANERJEE, SHENGGUO JIA, DAE-IN KIM, RICHARD ROBINSON, JEFFREY KYSAR, JOZE BEVK, *Materials Research Science and Engineering Center, Columbia University, New York, NY* The mechanical stability of nanocomponent films is critical for applications and yet is a largely unexplored area of research. Raman microprobe analysis has been used to probe elastic strain in the cores of thick, fractured electrophoretically-deposited CdSe nanocrystal films. Strain in these films arises from solvent evaporation and can be as much as 2.5% in the cores of CdSe nanocrystals for 3.2 $\mu$m thick films. The overall strain in these films, as determined by optical microscopy, is $\sim$ 11.7%. The in-plane stress developed in these films is $\sim$ 1.6 GPa. The biaxial modulus of the films is determined to be $\sim$ 13.8 GPa. Using micromechanics models, a value of $\sim$ 5.1 GPa is inferred for the biaxial modulus of the trioctylphosphine oxide ligand matrix. Since, solvent loss leads to strain in most ensembles of colloidal nanocrystals, this method has the potential for being broadly generalizable to other films made of nanocrystalline components. Support for this work was provided by the Materials Research Science and Engineering Center of the NSF under Grant No. DMR-0213574 and by NYSTAR.

**G35 9 White-Light Emission from Magic-Sized Cadmium Selenide Nanocrystals*** MICHAEL BOWERS, *Vanderbilt University* JAMES McBRIDE, *Vanderbilt University* SANDRA ROSENTHAL, *Vanderbilt University* Magic-sized cadmium selenide (CdSe) nanocrystals have been pyrolytically synthesized. These ultra-small nanocrystals exhibit broadband emission (420 -710 nm) that covers most of the visible spectrum while not suffering from self absorption. This behavior is a direct result of the extremely narrow size distribution and unusually large Stokes shift (40-50 nm). The intrinsic properties of these ultra-small nanocrystals make them an ideal material for applications in solid state lightingand also the perfect platform to study the molecule−to−nanocrystal transition.

**G35 12 Theory of plasmon excitations in coaxial cylindrical geometries: finite magnetic field** MANVIR KUSHWAHA, *Institute of Physics, University of Puebla, Mexico* BAHRAM DJAFARI-ROUHANI, *Department of Physics, University of Science and Technology of Lille, France* We report on a theoretical investigation of the plasmon propagation in the coaxial cylindrical geometries using Green's function (or response function) theory in the presence of an applied axial magnetic field ($\vec{B}\|\hat{z}$). Green's function theory generalized to be applicable to such quasi-one dimensional (1D) systems enables us to derive explicit expressions for the corresponding response functions (associated with EM fields), which can in turn be used to compute numerous physical properties of the system under consideration. As an application, we present several illustrative examples on the dispersion characteristics of the confined and extended magnetoplasmons in the single- and double-interface structures. These dispersive modes are also substantiated through the computation of local as well as total density of states (DOS). It is found that, unlike the zero-field

case, the magnetoplasma propagation is nonreciprocal with respect to the sign of the index *m* of the Bessel functions involved. We also briefly clarify some delusive traces of the edge magnetoplasmpons for a plasma shell embedded between two identical or unidentical dielectrics. Our theoretical framework can also serve as a powerful technique for studying the intrasubband plasmons and magnetoplasmons in the emerging multiwall carbon nanotubes.

**G37 2 Nucleation process on the 180° domain wall of $PbTiO_3$ by the external electric field** YOUNG-HAN SHIN, ILYA GRINBERG, I-WEI CHEN, ANDREW RAPPE, *University of Pennsylvania* Ferroelectric oxides are extremely useful as nonvolatile memory storage materials, and the speed at which polar domains can be reversed is a critical characteristic for future development of these materials. However, the size of the critical nucleus during the polarization reversal is still unknown experimentally. If we assume that the magnitudes of local polarizations are the same and their directions are along the external field, it will be triangular and the height of the nucleus along the external field should be much larger than its width following the Miller and Weinreich's study in 1960s. We made an atomic potential for perovskite ferroelectrics based on the first-principles calculation, and performed molecular-dynamics simulations to understand the nucleation and growth process of ferroelectric domains. We find that its shape is close to a square not a triangle and its size much smaller than Miller and Weinreich's. It stems from the small polarizations and the voltex-like flow around the nucleus. To increase the system size we used the stochastic study using the nucleation and growth rates which were obtained from the molecular dynamics simulations. The overall speed of the domain wall motion can be estimated from this stochastic calculation.

**8:24**
**G37 3 Critical Behaviors in $Pb(Zr,Ti)O_3$ Ultrathin films** EMAD ALMAHMOUD, IGOR KORNEV, LAURENT BELLAICHE, *Physics Department, University of Arkansas, Fayetteville, Arkansas 72701, USA* The first-principles-derived approach of Ref. [1] is used to determine the thickness dependency of Curie temperature and of the spontaneous polarization in $Pb(Zr,Ti)O_3$ (PZT) thin films that are under stress-free and open-circuit boundary conditions. It is found that, above a thickness of 7 (B-) monolayers (ML), the Curie temperature follows the finite-size relation of Ref. [2] with a critical exponent $\lambda = 1.04$. On the other hand, the Curie temperature deviates from this ''usual'' relationship for thickness of 6 monolayers and below, characterizing a crossover from a three- to a two-dimensional behavior. This striking crossover is also reflected in the critical exponent it $\beta$, that is associated with the power law describing the behavior of the polarization with thickness. As a matter of fact, such exponent decreases drastically from 0.14 to 0.1 between 7 and 4 ML. This work is supported by ONR grants N 00014-01-1-0365, N00014-04-1-0413 and 00014-01-1-0600, by NSF grants DMR-0404335 and DMR-9983678, and by DOE grant DE-FG02-05ER46188. [1] E. Almahmoud, Y. **G37 4 Phase transitions in ferroelectric superlattices.**
MATTHEW DAWBER, *DPMC, University of Geneva*

The construction of artificial ferroelectric superlattices with fine periodicity presents exciting possibilities for the development of new materials with extraordinary properties and furthermore a probe for understanding the fundamental physics of ferroelectric materials. Our superlattices of $PbTiO_3/SrTiO_3$ are prepared on conducting 0.5% Nb doped (001) $SrTiO_3$ substrates using off-axis RF magnetron sputtering. Cross-sectional TEM investigations were performed on several samples and reveal the coherent growth and artificial layering of the samples. Further structural characterization using standard $\theta$-$2\theta$ x-ray diffraction was performed on a series of 20 bilayer superlattices in which the $PbTiO_3$ thickness was varied from 54 to 1 unit cells while the $SrTiO_3$layer thickness was maintained at 3 unit cells. Intuitively one expects, as the thickness of the $PbTiO_3$ layers relative to the $SrTiO_3$ layers is reduced, a decrease of the ferroelectric polarization

which should result in a concomitant decrease of the average lattice parameter. This is indeed the behaviour we observe for superlattices $PbTiO_3/SrTiO_3$ n/3 where n is greater than 3. However, surprisingly, the 2/3 and 1/3 superlattices display larger average lattice parameters which indicate a recovery of ferroelectricity at very small $PbTiO_3$ layer thicknesses, a finding we confirmed using atomic force microscopy. The experimental finding thus stands in stark contrast to the intuitive expectation of a ferroelectric-paraelectric phase transition in this system as the ferroelectric component is reduced and we find further that the temperature of the ferroelectric-paraelectric phase transition is also greatly modified. Due to the excellent quality of the samples we are able to present the results of a number of detailed structural and electrical characterizations, along with the development of first principles based theoretical models, which cast further light on the fascinating phase transition behaviour of this system. Through this we can gain an insight into how we can understand and control the behaviour of ferroelectricity as the physical dimensions are reduced and the relevant boundary conditions are modified.

**G37 5 Generalized thermodynamics of solid surfaces applied to size effects on equilibrium** ROBERT CAMMARATA, *Johns Hopkins University* In his thermodynamics of liquid interfaces, Gibbs introduced the ''dividing surface'' and rigorously derived the general conditions for equilibrium, and showed how the size of phases can affect the equilibrium state. However, the case of systems with solid surfaces, he imposed certain restrictions, such as considering only single component solids, which limited the applicability of his approach. In the case of finite size and multicomponent solids, difficulties arise when defining the chemical potentials for the interface, which leads to difficulties in defining the surface energy. It will be shown how these difficulties can be overcome by using the concept of ''surface availability,'' analogous to the availability used in bulk thermodynamics. A generalized surface thermodynamics can be formulated consistent with Gibbs' analysis for liquid surfaces but that can be used for general multicomponent solid systems. Also, employing the surface availability allows one to dispense with the dividing surface construction and treat the interfacial region as a separate inhomogeneous phase. Applications to nanoscale materials will be discussed.

**G37 6 Theory of the Melting of Confined Nanocrystals** DARYL CHRZAN, Q. XU, I.D. SHARP, *Materials Science and Engineering, University of California, Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory* D.O. YI, *Applied Science and Technology, University of California, Berkeley* C.W. YUAN, C.Y. LIAO, A.M. GLAESER, *Materials Science and Engineering, University of California, Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory* J.W. AGER III, *Materials Sciences Division, Lawrence Berkeley National Laboratory* E.E. HALLER, *Materials Science and Engineering, University of California, Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory* Recent measurements of the melting point of Ge nanocrystals embedded within a silica matrix reveal that the nanocrystals can be heated approximately 200 K above the bulk melting point before melting, and cooled approximately 200 K below the bulk melting point before solidification. This behavior is in marked contrast to that observed for free standing nanocrystals. We have developed a classical, continuum thermodynamic model which demonstrates that the phenomenon is caused by kinetic barriers to the nucleation of the liquid phase. The kinetic barriers are associated with the density increase upon melting of Ge and the fact that liquid Ge does not wet silica. The model provides a quantitative description of the experimental observations. This research is supported by the U. S. Department of Energy under contract No. DE-AC02-05CH11231.

**9:36**

**G37 7 Theory of the Jahn-Teller Soliton** DENNIS CLOUGHERTY, *University of Vermont* It is demonstrated that under common conditions a molecular solid subject to Jahn-Teller interactions supports stable Q- ball-like non-topological solitons. Such solitons represent a localized lump of excess electric charge in periodic motion accompanied by a time-dependent shape distortion of a set of adjacent molecules. The motion of the distortion can correspond to a true rotation or to a pseudo-rotation about the symmetric shape configuration. These solitons are stable for Jahn-Teller coupling strengths below a critical value; however, as the Jahn- Teller coupling approaches this critical value, the size of the soliton diverges signaling an incipient structural phase transition. The soliton phase mimics features commonly attributed to phase separation in complex solids.

**G37 8 Finite-size scaling of the critical temperatures of magnetic thin films with variable range of interactions.** TIMOTHY BRAMFELD, *The Pennsylvania State University* ROY F. WILLIS, *The Pennsylvania State University* Finite-size scaling in magnetic (spin) systems with an arbitrary range of spin interactions was first discussed by Domb and Dalton [1]. These authors explored the effect on the various critical exponents of the thermodynamic quantities of a generalized Ising model in which each spin interacts equally strongly with neighbors within some finite interaction distance beyond which the interaction goes to zero. Such a model was used by Zhang & Willis [2] to explain the thickness dependence of the Curie temperatures of ferromagnetic nickel films. Specifically, they showed that Tc followed a power law, reduced temperature $t \sim L^{-\lambda}$down to a critical thickness Lo = Ro, at which point the critical temperature reduced linearly with further decreasing thickness L. In this talk, we show that the demarcation point Lo = Ro scales with the range of spin interactions in alloy films. This parameter Ro is a function of the changing dimensions of the Fermi surface i.e. related to the period of RKKY oscillations in these itinerant ferromagnets. We examine the ramifications of an increasing range of spin interactions Ro on the finite-size critical behavior of a magnetic system. [1] C. Domb & N.W. Dalton, Proc. Phys. Soc. 89, 859 (1966). **G37 9 Phase Diagrams, Crossovers and Charge-Spin Separation in Small Clusters** ARMEN KOCHARIAN, *California State University* GAYANATH FERNANDO, KALUM PALANDAGE, *University of Connecticut* JAMES DAVENPORT, *Brookhaven National Laboratory* The charge-spin separation effect and response thermodynamics in the presence of a magnetic field are calculated using exact analytical diagonalization and grand canonical ensemble method for small clusters. Rigorous criteria for the Mott-Hubbard, Néel and zero-magnetic field (spin) weak singularities (*saddle points*) in the thermodynamic charge and spin densities of states *versus* chemical potential and magnetic field are found in the exactly solvable two and four site Hubbard ($U \mp 0$) clusters. Large quantum spin fluctuations are signaled by the presence of spin and charge density peaks, pseudogaps and corresponding temperature driven crossovers. The numerically evaluated, exact expressions for the charge, spin susceptibilities and specific heat demonstrate separation of charge and spin degrees and presence of pseudogaps that disappear at the distinct critical temperatures of crossovers. The phase diagram in the ground state, when monitored as a function of doping, displays the presence of clearly identifiable quantum phase transitions and critical points (QCP). In overall, the obtained spin pseudogap, magnetic correlations with antiferromagnetic (spin) pseudogap structure and crossovers in small clusters at $U > 0$ closely resemble the pseudogap phenomena and the normal-state phase diagram in high $T_c$ superconductors.

**G37 10 Electron-Spin Resonance of Chromium-Doped Vanadium Dioxide** PATRICK BUNTON, D. BLANE BAKER, KENNETH MAYNES, KENNETH HARTMAN, *William Jewell College* ANDREJ HALABICA, RENE LOPEZ, RICHARD HAGLUND, *Vanderbilt University* We have investigated the metal insulator transition (MIT) in vanadium dioxide using the electron-spin resonance (ESR) response of a chromium probe. Our goal is to elucidate information regarding potential trigger mechanisms for the MIT such as extrinsic defects or thermal excursion associated with soft modes. A chromium-doped vanadium dioxide film was prepared on fused-silica by pulsed laser deposition in oxygen followed by annealing in an oxygen atmosphere. The chromium dopant proved to be sensitive to the MIT, exhibiting a hysteretic dependence of chromium intensity. A 140 nm-thick film exhibits a factor of four decrease in chromium line intensity as the temperature increases across the MIT. ESR can yield information regarding thermal excursions of lattice ions as well as symmetry information – typically through either linewidth or axial spin Hamiltonian parameter. In addition, decreases in ESR signal intensities are discussed in relation to changes in electron spin-lattice relaxation times. Extensions to two-dimensional films of contiguous nanoparticles and to nanoparticle arrays will be discussed.

**10:24**

**G37 11 Percolation effects in networks of vanadium dioxide nanocrystals*** JOHN ROZEN, RENÉ LOPEZ, RICHARD HAGLUND, LEONARD FELDMAN, *Department of Physics and Astronomy & Institute of Nanoscale Science and Engineering, Vanderbilt University, Nashville, Tennessee 37235* Bulk vanadium dioxide undergoes a phase transition from a semiconductor to a metal near 68 $^{o}$C upon heating. A unique aspect of $VO_2$ nanocrystals is that their small size leads to meta-stable states and to the widening of the hysteresis loop traced out by the semiconductor-to-metal phase transition. We report simultaneous measurements of the transmittance and of the resistance made on thin $VO_2$ nanocrystalline films. An offset between the effective electrical and optical switching temperatures is observed. Indeed, there is an intermediate state where the films are optically metallic but electrically semiconducting (opening the possibility of designing tri-state devices). This is explained in terms of current percolation through a network of nanometer-scale grains of different sizes undergoing the transition at distinct temperatures. An effective-medium approximation can model this behavior and proves to be an indirect method to calculate the surface coverage of the films. Also, the understanding of the collective properties of the nanocrystals leads to the reconstruction of the electrical hysteresis of the phase transition.

**G37 12 Transmission modulation through sub-wavelength hole arrays in metal-$VO_2$ double-layer nanostructures** J. Y. SUH, E. U. DONEV, R. LOPEZ, L. C. FELDMAN, R. F. HAGLUND JR., *Vanderbilt University* Nanoscale optical systems require active devices able to control light in sub-wavelength structures. We report the use of a unique double layer structure which provides this function. Enhanced transmission of near-infrared light through a subwavelength hole arrays patterned in Ag-$VO_2$and Au-$VO_2$ double-layer films shows that it is possible to modulate transmitted intensity by means of a semiconductor-to-metal phase transition in $VO_2$. The transmitted intensity in the near-infrared for the metallic phase of $VO_2$ is a factor of $\sim$ 10 greater than the intensity for the semiconducting phase. We explain this modulation in terms of the switchable permittivity difference of the $VO_2$ phases.

**10:48**

**G37 13 Optical diffraction in ordered $VO_2$ nanoparticle arrays** RENE LOPEZ, LEONARD FELDMAN, RICHARD HAGLUND, *Deparment of Physics and Astronomy & Institute of Nanoscale Science and Engineering, Vanderbilt University, Nashville, TN, 37235* The potential of oxide electronic materials as multifunctional building blocks is one of the driving concepts of the field. In this presentation, we show how nanostructured particle arrays with long-range order can be used to modulate an optical response through exploiting the metal-insulator transition of vanadium dioxide. Arrays of $VO_2$ nanoparticles with long-range order were fabricated by pulsed laser deposition in an arbitrary pattern defined by focused ion-beam lithography. The interaction of light with the nanoparticles is controlled by the nanoparticle size, spacing and geometrical arrangement and by switching between the metallic and semiconducting phases of $VO_2$. In addition to the near-infrared surface plasmon response observed in previous $VO_2$ studies, the $VO_2$ nanoparticle arrays exhibit size-dependent optical resonances in the visible region that likewise show an enhanced optical contrast between the semiconducting and metallic phases. The collective optical response as a function of temperature gives rise to an enhanced scattering state during the evolving phase transition, while the incoherent coupling between the nanoparticles produces an order-disorder-order transition.

**G38 1 Tuning the Superconducting Properties of $MgB_2$.**
RUDEGER H.T. WILKE, *University of Wollongong*

The relatively high superconducting transition temperature of 39 K in $MgB_2$ has garnered much interest over the past several years in both fundamental and applied research. $MgB_2$ is a conventional phonon mediated BCS superconductor with the unconventional property of two superconducting gaps. These gaps ($\sigma$ and $\pi$) arise from the coupling of boron phonons with two different orthogonal sheets of the Fermi surface. In a conventional single gap superconductor the upper critical field can be tuned by the introduction of nonmagnetic impurities. For $MgB_2$ the situation becomes more complex because there are 3 important scattering channels (inter and intra-band). Theoretical calculations predict different developments of the upper critical field and anisotropy ratio if the scattering can be selectively tuned to a specific channel. In this talk I will present data on two different types of perturbations to $MgB_2$: carbon doping and neutron irradiation. Low level carbon doping enhances the upper critical field with only a minor decrease in $T_c$. Whereas $T_c$ suppression is the result of carbon electron doping the system, the enhancement of $H_{c2}(T=0)$ is the result of an increase in scattering, with evidence to suggest carbon doping enhances intra-$\pi$-band scattering. In contrast, $H_{c2}(T=0)$ values tend to scale with $T_c$ in heavily neutron irradiated samples and the superconducting properties can be understood in terms of a decrease in the density of states at the Fermi surface and an increase in interband scattering.

**G38 2 Upper critical field and anisotropy in carbon alloyed $MgB_2$ thin films*** QI LI, VALERIA FERRANDO, JUN CHEN, ALEXEJ POGREBNYAKOV, JOAN REDWING, XIAOXING XI, *Penn State University* ALEX GUREVICH, DAVID LARBALESTIER, *University of Wisconsin - Madison* J. B. BETTS, C. H. MIELKE, *Los Alamos National Lab* We have studied the upper critical field and its anisotropy $\gamma$ of C-alloyed $MgB_2$ thin films grown on (0001) SiC single crystal substrates by hybrid physical-chemical vapor deposition (HPCVD). Different concentrations of C were introduced during the deposition, which increased the residual resistivity systematically but did not affect $T_c$ seriously. The upper critical field was found to increase to above 60 T for $H$ parallel to the ab plane and up to $\sim$ 40T for $H$ parallel to the $c$ axis with even moderate amounts of C doping. Moreover, we show that $H_{c2}$ stays at these levels in a wide range of C doping. The $H_{c2}$ anisotropy was found to decrease as the C concentration increases. The $H_{c2}(T)$ curves for both $H\|ab$ and $H\|c$ directions were explained by a theoretical model of dirty limit two band superconductivity, which takes into account different scattering rates in $\pi$ and $\sigma$ bands, as well as interband scattering. The differences in the $H_{c2}(T)$ and $\gamma(T)$ for different samples can be explained by the differences of the relative scattering rates in each band which make it possible to adjust the $\pi$ and $\sigma$ scattering such that $H_{c2}$ perpendicular to $ab$ can attain almost 20T at 20K.

**G38 3 Accentuated lattice parameters in carbon doped MgB2 thin films with enhanced upper critical fields** JONATHAN GIENCKE, *University of Wisconsin - Madison* ALEXEJ POGREBNYAKOV, *Penn State University* BEN SENKOWICZ, *University of Wisconsin - Madison* XIAOXING XI, *Penn State University* DAVID LARBALESTIER, CHANG BEOM EOM, *University of Wisconsin - Madison* We report a strong correlation between the accentuation of the a- and c-lattice parameters in carbon doped $MgB_2$ thin films grown via HPCVD and their enhanced upper critical fields. This phenomenon is in strong contrast to the behavior seen in carbon doped single crystals, where the a-lattice parameter is depressed while the c-lattice parameter remains unchanged. This has lead us to believe that the defects leading to the enhancement of the upper critical fields differ in single crystals and thin films, and is due to the non-thermodynamic equilibrium growth environment unique to thin film processes. In addition, the presence of secondary phases present only in thin films exhibiting the enhanced critical field will be discussed. Understanding the nature of these defects is essential to controlling the superconducting properties of $MgB_2$.

**G38 4 Carbon Inhomogeneity and Superconducting Properties of $Mg(B,C)_2$*** L. D. COOLEY, A. J. ZAMBANO,[†] A. R. MOODENBAUGH, *Condensed Matter Physics and Materials Science Department* R. F. KLIE, *Center for Functional Nanomaterials, BROOKHAVEN NATIONAL LABORATORY* Mg and $B_4C$ mixtures (molecular ratio of [1:2]) were reacted in a single step in stainless steel from 850[r]C to 1300[r]C to produce nominal $MgB_{1.8}C_{0.2}$ as estimated from unit cell volumes. Reactions from 850 to 1100°C produced an inhomogeneous superconducting phase despite the initial atomic $B_4C$ compound, suggesting that

carbon segregation is an important part of these reactions. For reactions above 1100°C, the critical temperature $T_c$ increased from 18 to 28 K as the strain (as estimated from x-ray diffraction peak broadening) decreased at nominally constant carbon content, suggesting that structural order is also important. These changes will be discussed with regard to the formation and coarsening of amorphous and crystalline impurity phases observed by electron microscopy, which affect electron scattering and connectivity. Since only scattering affects the upper critical field, whereas both scattering and connectivity affect the transport properties, optimization of these reactions is crucial to understanding the potential for $Mg(B,C)_2$ as a high-field superconductor.

**G38 5 Towards the development of a high quality doped boron precursor and the effect on the superconducting properties of $MgB_2$** JAMES MARZIK, *Specialty Materials, Inc.* ALBERT KUMNICK, *Specialty Materials, Inc.* Gas phase plasma synthesis techniques were used to produce nano-sized doped boron powder from vapor phase precursors. The powders were reacted with magnesium to make $MgB_2$. The measurement of the resultant superconducting properties suggests that boron made by this synthetic method may result in $MgB_2$ superconductors with enhanced critical currents and upper critical fields. The values of $J_c$ and $H_{c2}$ obtained using plasma synthesized boron precursors are compared with those values for $MgB_2$ obtained using crystalline and amorphous boron powder made by other techniques, as well as boron fiber made by chemical vapor deposition. The roles of processing temperature and time, particle and grain size, purity, dopant concentration, and chemical homogeneity are evaluated in terms of their relative effects on the critical current and upper critical field of $MgB_2$.

**9:24**

**G38 6 Boron powder purification and its effects on the microstructure and superconducting properties of $MgB_2$.** JIANYI JIANG, BEN SENKOWICZ, XUEYAN SONG, ERIC HELLSTROM, DAVID LARBALESTIER, *University of Wisconsin-Madison* APPLIED SUPERCONDUCTIVITY CENTER TEAM, $MgB_2$ wires can be easily fabricated by reacting Mg powder with amorphous boron powder. But commercial boron powder normally contains impurities such as $B_2O_3$. The presence of $B_2O_3$ could lead to the formation of oxides in $MgB_2$ wire, which may reduce the connectivity. In this work, $B_2O_3$ in amorphous boron powder was removed. $MgB_2$ samples were made both from purified and unpurified boron powders. X-ray diffraction showed that removing $B_2O_3$ in the boron powder resulted in a significant decrease in the content of MgO in the sample. The effects of boron powder purification on microstructure, critical temperature, critical field and connectivity will be presented.

**9:36**

**G38 7 Calorimetric transition widths, microstructure and magnetic relaxation of $MgB_2$ with and without additives** CARMINE SENATORE, *DPMC, University of Geneva, CH-1211, Switzerland* PAOLA LEZZA, *GAP, University of Geneva, CH-1211, Switzerland* GIUSEPPE CUSANELLI, *GAP, University of Geneva, CH-1211, Switzerland* SHI XUE DOU, *ISEM, University of Wollongong, NSW 2522, Australia* RENE FLUKIGER, *DPMC, University of Geneva, CH-1211, Switzerland* The addition of nanometric powders of SiC is known to improve the pinning properties of $MgB_2$. Nevertheless, the underlying physical mechanism remains yet unclear. In this frame we report on specific heat measurements of sintered polycrystalline samples of $MgB_2$ and itin situ $MgB_2$ wires, both pure and with SiC nano-additions. A comparison is made with results obtained from microstructural analysis (X-Ray diffraction, SEM, EDX). Specific heat has been measured as a function of temperature (2-45 K) at zero field and at 14 T. Our goal is to relate the broadening of the superconducting transition observed in the samples with additives to the variation in the lattice structure induced by the nano-additions. Furthermore, magnetic relaxation measurements have been performed in order to investigate the effect of the nano-additions on the pinning mechanism.

**9:48**

**G38 8 Critical Current Density and Connectivity Properties of High Jc Ex-situ $Mg(B_{1-X}C_X)_2$** B. J. SENKOWICZ, R. J. MUNGALL, J. R. MANTEI, E. E. HELLSTROM, D. C. LARBALESTIER, *University of Wisconsin - Madison, Applied Superconductivity Center* Using high-energy milling we have obtained $J_c$ (4.2K, 8T) $>$ $5*10^4$ A/cm$^2$ with H*(4.2K) $>$ 16T despite high normal state resistivity ($\rho$(40K) $>$ 100 $\mu\Omega$-cm). Analyzing resistivity curves by the Rowell method has led to the realization that as a result of overmilling and the presence of unincorporated carbon, our active cross section is only one tenth to one third of our total cross section. Therefore the potential exists to improve $J_c$ by a factor of several by increasing connectivity and decreasing grain boundary current obstruction. We examine the effect of composition and milling time on connectivity and superconducting properties. This research was performed under an appointment to the Fusion Energy Sciences Fellowship Program, administered by ORISE under contract between the U.S. DOE and the Oak Ridge Associated Universities. This work was supported by the NSF – FRG on $MgB_2$, and by DOE – Understanding and Development of High Field Superconductors for Fusion - DE-FG02-86ER52131.

**G38 9 Role of SiC Nanoparticles in the Electromagnetic Properties of SiC-doped $MgB_2$ Tapes*** PAUL VOYLES, YE ZHU, *University of Wisconsin* MATSUMOTO AKIYOSHI, *National Institute for Materials Science, Tsukuba* DAVID LARBALESTIER, *University of Wisconsin* $MgB_2$ tapes with $H_{c2}$(2.3K) = 42 T and $J_c$(4.2K) $\sim$ $4\times 10^5$ A/cm$^2$ have recently been demonstrated by Matsumoto et al. These tapes are synthesized by powder-in-tube-processing from $MgH_2$, B, and nanoparticle SiC precursors. TEM and scanning TEM analysis of samples as a function of SiC content and reaction temperature shows that the role of SiC is more complicated than simply providing a source of C to dope the

$MgB_2$. The sample with the highest $H_{c2}$ and $J_c$ contains unreacted SiC nanoparticles, which may act as pinning centers directly or may distort the adjoining $MgB_2$ lattice, increasing intraband scattering. Compared to pure $MgB_2$ samples, samples with SiC contain a significantly higher concentration of oxygen, leading to a higher density of second phases. SiC also tends to reduce the already small grain size of the pure $MgB_2$ from $\sim$ 50 nm to $\sim$ 20 nm, making grain boundaries another import source of pinning.

*This work is supported by the FRG on $MgB_2$ through the US National Science Foundation (DMR -0514592).

**10:12**

**G38 10 Enhancement of Critical Current Properties of $MgB_2$ Bulks by Controlling Microstructure and Crystallinity** JUNICHI SHIMOYAMA, *University of Tokyo* AKIYASU YAMAMOTO, YUKARI KATSURA, ISAO IWAYAMA, SHINYA UEDA, SHIGERU HORII, KOHJI KISHIO, Critical current properties of $MgB_2$ bulks with various grain size, crystallinity and bulk density were systematically studied. Samples with low crystallinity, which was achieved by the low temperature reaction and/or carbon substitution for boron, exhibited high $J_c$ in fields and high irreversibility fields, reflecting enhanced $H_{c2}$. In addition, a strong relationship was found between pinning force density and grain size controlled by changing starting particle size of boron, heating conditions and molar ratio between magnesium and boron. The highly dense $MgB_2$bulks prepared by a diffusion method showed excellent $J_c$ characteristics particularly in low fields. The carbon substitution for the dense bulk was effective for enhancement of $J_c$ under high fields. Essential pinning potential of the $MgB_2$was also evaluated using the dense bulks. Based on these results, a guiding principle to improve critical current properties of practical $MgB_2$ conductors will be discussed from various viewpoints.

**10:24**

**G38 11 Global and local flux jumps in $MgB_2$ films: Magneto-optical imaging and theory** D.V. SHANTSEV, D.V. DENISOV, Y.M. GALPERIN, T.H. JOHANSEN, *Department of Physics, University of Oslo, Norway* SUNG-IK LEE, *Pohang University of Science and Technology, Korea* A.L. RAKHMANOV, *Inst. for Theoretical and Applied Electrodynamics, Moscow* A.V. BOBYL, *Ioffe Physico-Technical Institute, St. Petersburg, Russia* $MgB_2$ is one of the most unstable superconducting materials, where flux jumps are commonly observed at low temperatures jeopardizing its potential for applications. We present a detailed MO imaging study of the jumps in $MgB_2$ films, where we observe large dendritic flux patterns as well as much smaller jumps down to 50 flux quanta. The large jumps destroy the critical state and dramatically suppress $\mathbf{J}_c$. The small jumps, instead, lead to a new type of the critical state where $\mathbf{J}_c$ is determined not only by the pinning, but also by the jump characteristics. A linear theory assuming a thermal origin of dendritic jumps gives the threshold fields for the instability to start and to form a dendritic pattern and reproduces its experimental temperature dependence. We also determine the size of flux jumps in the adiabatic approximation. Its field dependence as well as the flux density profiles after jumps, are in good agreement with the direct observations, see Denisov et al., cond-mat/0508679, and Shantsev et al. Phys. Rev. B 72, 024541 (2005).

**G38 12 Evolution of Anomalous Angular Dependence of $H_{c2}$ in $CaAl_{1-x}Ga_xSi$** TSUYOSHI TAMEGAI, KENTARO UOZATO, MASASHI TOKUNAGA, *Department of Applied Physics, The University of Tokyo* UNIV. OF TOKYO TEAM, In CaAlSi, the angular dependence of the upper critical field, $H_{c2}(\theta)$, shows an anomalous cusp when the field is applied parallel to the superconducting layer. $H_{c2}(\theta)$ can be reasonably well fitted by the Tinkham model for thin film superconductors. On the other hand, $H_{c2}(\theta)$ in CaGaSi does not show such an anomaly. Concomitant with these features, a lattice modulation along the *c*-axis exists only in CaAlSi. We have grown single crystals of the alloy $CaAl_{1-x}Ga_xSi$, and studied the evolution of the anomalous angular dependence of $H_{c2}$ and the superstructure. The superstructure.is sustained at least up to x = 0.2, although the period of the modulation changes from $\sim 6c$ to $\sim 3c$. On the other hand, the cusp-like feature in $H_{c2}(\theta)$ is strongly suppressed by the Ga substitution, and only evident at low temperatures. We have also investigated the homogeneity of the crystal by inspecting the vortex penetration using magneto-optical technique. We have found an inhomogeneous penetration of vortices along the superconducting plane in the itac plane, suggesting the presence of modulation of superconducting parameters. Based on these results, we will discuss the origin of the anomalous $H_{c2}(\theta)$.

**G38 13 Anisotropic s-wave superconductivity and peak effect in single crystals CaAlSi** R. PROZOROV, *Ames Laboratory and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011* T. OLHEISER, R.W. GIANNETTA, *Department of Physics, University of Illinois at Urbana-Champaign, 1110 W. Green Street, Urbana, IL 61801* K. UOZATO, T. TAMEGAI, *Department of Applied Physics, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113-8656, Japan* In- and out- of plane London penetration depths were measured in single crystals of CaAlSi by using radio-frequency resonant technique. The obtained temperature variation of the anisotropic superfluid density can be explained by an ellipsoidal s-wave gap with a weak-coupling BCS value in the ab-plane and larger gap amplitude in the c-direction. In a mixed state, similar measurements yield Campbell length, which was used to study the peak effect (PE) in the critical current. The position of the PE line on an H-T phase diagram, the influence of anisotropy and sample parameters are discussed.

**G39 1 d-wave Pairing in the Two-Dimensional Hubbard Model.***
DOUGLAS SCALAPINO

In this talk we will review numerical evidence showing that the 2D Hubbard model can exhibit antiferromagnetism, stripes, d(xx-yy) pairing and pseudogap behavior. These numerical studies show that the different phases are delicately balanced with respect to small changes in parameters, reminding one of the cuprate materials. We will then discuss the structure of the pairing mechanism in this model.

**G39 2 Andreev states in 2D finite size systems** LUCIAN COVACI, FRANK MARSIGLIO, *University of Alberta* Andreev reflection occurs at the interface between a normal metal and a superconductor. An electron with energy lower than the superconducting gap is reflected back as a hole while a pair enters the superconductor. In 1D systems, for energies smaller than the superconducting gap, the allowed states in the normal metal layer are quantized. For 2D systems these energies become continuous due to the extra degree of freedom in the direction parallel to the interface. With the use of a mean field extended Hubbard Hamiltonian to describe s-wave and d-wave superconductors, we employ a Lanczos recursion method to calculate the local density of states in these systems. Different shapes are considered, such as squares, triangles and circles. We observe the finite size properties of the Andreev bound states and present the different modes of the localized states. We also consider the effect of rough surfaces on the formation of the bound states.

**G39 3 *d*-wave Pairing Amplitude and Particle-hole Asymmetry of the $t - J$ type models: Implication from the Spectral Weight Analysis** CHUNG-PIN CHOU, *National Tsing-Hua University, Taiwan* TING-KUO LEE, *Academia Sinica, Taiwan* CHANG-MING HO, *Tam Kang University* By using the projected variational wave functions (VWF), we study the quasiparticle spectral weight (QPSW) of hole-doped cuprates in the $t - J$ type models. The QPSW $Z^+$ for adding an electron shows a pocket structure outside the Fermi surface that is related to the momentum distribution function $n_{\mathbf{k}}$. Based on our VWF, $Z^-$ for removing an electron can be proven to have a simple relation among the pairing amplitude and $Z^+$. In addition, we also find that strong correlations mainly causes the particle- hole asymmetry of the low-energy tunneling spectra.

**9:00**
**G39 4 The Structure of the Pairing Interaction in the 2D Hubbard Model** THOMAS MAIER, *Oak Ridge National Laboratory* MARK JARRELL, *University of Cincinnati* DOUGLAS SCALAPINO, *University of California* We present a detailed analysis of the effective pairing interaction in the doped two-dimensional Hubbard model. Using dynamical cluster Monte Carlo calculations we have studied the irreducible particle-particle vertex responsible for pairing in this model. The leading low temperature eigenvalue of the Bethe-Salpeter equation for the particle-particle channel is shown to have $d_{x^2-y^2}$-wave symmetry. The irreducible particle-particle vertex increases with increasing momentum transfer and decreases when the energy transfer exceeds a scale associated with the $Q = (\pi, \pi)$ spin susceptibility. Using an exact decomposition of this vertex into a fully irreducible two-fermion vertex and charge and magnetic exchange channels, the dominant contribution to the effective pairing interaction is found to come from the magnetic, spin $S = 1$ exchange channel.

**9:12**
**G39 5 Fluctuation exchange theory for superconductivity of *f*-electron systems with multipole degrees of freedom** KATSUNORI KUBO, TAKASHI HOTTA, *Advanced Science Research Center, Japan Atomic Energy Agency* Recently, an interesting possibility of superconductivity induced by multipole fluctuations has been discussed in some *f*-electron materials. In order to clarify such exotic superconductivity from a microscopic viewpoint, we apply fluctuation exchange (FLEX) approximation to an *f*-electron model with active orbital degree of freedom on the basis of a *j-j* coupling scheme. In this study, we consider a square lattice, for simplicity. First, we evaluate orbital dependent fluctuations and effective paring interactions within the FLEX approximation. Then, we determine the symmetry of the gap function among possible superconducting states by solving the Eliashberg equation. In particular, we pay our attention to the effect of crystalline electric field on the appearance of superconductivity. By further decomposing complex orbital dependent fluctuations into multipole components, we also discuss possible relevance of multipole fluctuations to exotic superconductivity.

**G39 6 New Phases, Superfluid Weights, Free Carrier Densities: RG Theory of Hubbard, tJ Models** A. NIHAT BERKER, *Koç U. and MIT* MICHAEL HINCZEWSKI, *F. Gürsey Res. Cent. and MIT* We have studied the Hubbard and tJ models in d=3 with renormalization-group theory, obtaining phase diagrams and thermodynamic properties for all temperatures, densities, and coupling strengths. In the Hubbard model, at low temperatures and around half filling, the antiferromagnetic phase is obtained. (1) At strong coupling and 30-35% doping from half filling, (2) at weak and intermediate coupling and 10-18% doping, two novel phases ($\tau$

phases) were found. In these phases, the hopping expectation value is non-zero at all length scales. The weak-intermediate coupling $\tau$ phase exhibits, as in BCS superconductivity, an excitation spectrum gap and, in the specific heat, a low-temperature exponential decay and a cusp phase transition singularity. The strong coupling $\tau$ phase exhibits, as in BEC superconductivity, in the specific heat, an $\alpha \sim -1$ phase transition singularity and a pair-formation peak above the phase transition temperature. In the tJ model, we find that the superfluid weight increases with hole doping, passes through a maximum within the $\tau$ phase at 32-37% doping, and decreases, and that the free carrier density also increases to a maximum value at 32-37% doping but remains at this value under further doping. Calculations with spatially anisotropic d=3 systems yield a chemical potential shift as a function of hole doping in good agreement with experiments. Recent results with magnetic and non-magnetic impurities will also be presented.

**9:36**

**G39 7 Pseudogap and antiferromagnetic correlations in the Hubbard model** ALEXANDRU MACRIDIN, *University of Cincinnati* MARK JARRELL, *University of Cincinnati* THOMAS MAIER, *Oak Ridge National Laboratory* PAUL KENT, *University of Tennessee* CARSTEN HONERKAMP, *University of Wurzburg* Using the dynamical cluster approximation we calculate the single-particle spectra of the Hubbard model with next-nearest neighbor hopping t' at small doping. We find that the pseudogap along the zone diagonal in the electron doped systems is due to long range antiferromagnetic correlations. The physics in the proximity of $(0,\pi)$ is dramatically influenced by t'and determined only by the short range correlations. The effect of t' on the low energy ARPES spectra is weak except close to the zone edge. The short range correlations are sufficient to yield a pseudogap in the magnetic susceptibility and produce occupied states in the second antiferromagnetic Brillouin zone which develop a gap with decreasing temperature. We compare our self-energy with the one obtained form renormalization group (RG) calculations. In order to analyze the importance of scattering in different channels we analyze the self energy using a simple ansatz motivated by RG calculations.

**9:48**

**G39 8 Nonmonotonic gap in the coexisting antiferromagnetic and superconducting state for electron-doped cuprates** QINGSHAN YUAN, FENG YUAN, CHIN-SEN TING, *Texas Center for Superconductivity, University of Houston, Houston, TX 77204* Recent measurements on the superconducting (SC) electron-doped cuprates $Nd_{1.85}Ce_{0.15}CuO_4$ and $Pr_{0.89}LaCe_{0.11}CuO_4$ (both at optimal doping) have revealed that the excitation gap does not fit the simplest commonly assumed *d*-wave function $\cos k_x - \cos k_y$, but exhibits a nonmonotonic behavior with the gap maxima locating midway between the Brillouin zone boundaries and the zone diagonals. This observed gap was naturally regarded as the SC gap and the previous theoretical explanations were limited to extending the SC gap out of the simplest *d* wave. Here we propose a new idea that the observed gap at optimal doping is the lowest quasiparticle excitation energy in the *coexisting* antiferromagnetic (AF) and SC state, which is not purely the SC gap. The idea is implemented by simply studying the coexistence of AF and SC orders within the slave-boson mean-field approach based on the $t$-$t'$-$t''$-$J$ model. Although the pairing gap itself is assumed to be the simplest *d* wave which is monotonic, we have found that the quasiparticle excitation gap in the coexisting state is nonmonotonic, with the maxima around the hot spots where the Fermi surface is missing due to the AF gap. Within the same coexisting state the spectral function is also calculated at optimal doping. The obtained results are all consistent with experiments.

**G39 9 Hole correlation in the $t - J$ model with four holes on a 32-site lattice*** P. W. LEUNG, *Hong Kong University of Science and Technology* We study the $t - J$ model with four holes on a 32-site square lattice using exact diagonalization. This system corresponds to doping level $x=1/8$. At the ''realistic'' parameter $J/t=0.3$, holes in the ground state of this system are unbound. They have short range repulsion due to lowering of kinetic energy. There is no antiferromagnetic spin order and the electron momentum distribution function resembles hole pockets. Furthermore, we show evidence that in case antiferromagnetic order exists, holes form *d*-wave bound pairs and there is mutual repulsion among hole pairs. This presumably will occur at low doping level. This scenario is compatible with a checkerboard-type charge density state proposed to explain the ''1/8 anomaly'' in the LSCO family, except that it is the ground state only when the system possesses strong antiferromagnetic order.

**10:12**

**G39 10 LDOS and Angle-Resolved Photoemission Spectral Function of An inhomogeneous Superconductor** MING CHENG, W.P. SU, *Texas Center for Superconductivity, University of Houston* Nanoscale inhomogeneity seems to be a central feature of the d-wave superconductivity in the cuprates. Such a feature can strongly affect the local density of states (LDOS) and the spectral weight functions. Within the Bogoliubov-de Gennes formalism we examine various inhomogeneous configurations of the superconducting order parameter to see which ones better agree with the experimental data. Nanoscale large amplitude oscillations in the order parameter seem to fit the LDOS data for the underdoped cuprates. The one-particle spectral function for a general inhomogeneous configuration exhibits a coherent peak in the nodal direction. In contrast, the spectral function in the antinodal region is easily rendered incoherent by the inhomogeneity. This throws new light on the dichotomy between the nodal and antinodal quasiparticles in the underdoped cuprates.

**10:24**

**G39 11 Distinguishing Patterns of Charge Order in 2 dimensions; Stripes or Checkerboards** JOHN ROBERTSON, STEVEN KIVELSON, AHARON KAPITULNIK, *Stanford University* EDUARDO FRADKIN, *University of Illinois at Urbana-Champaign* Charge ordered states are common in strongly correlated materials, including especially the cuprate high temperature superconductors. Identifying where such phases occur in the phase diagram, and where they occur as significant fluctuating orders is a critical step in understanding what role they play in the physics. However, the both the presence of quenched disorder, and the smallness of the charge modulations make the detection of such order difficult in experiments. We discuss strategies for identifying the nature of the underlying ''clean'' order (such as ''stripes'' or ''checkerboards'') in experiments, particularly in STM. We use a model of an effective Hamiltonian in the presence of quenched disorder to simulate experimental data, and further apply our techniques to real experimental data.

**10:36**

**G39 12 Inhomogeneous states with checkerboard order in the t-J Model** CHUNHUA LI, *Boston College* SEN ZHOU, ZIQIANG WANG, We study inhomogeneous states in the *t-J* model using an unrestricted Gutzwiller approximation. We find that $pa \times pa$ checkerboard order, where $p$ is a doping dependent number, emerges from Fermi surface instabilities of both the staggered flux phase and the Fermi liquid state with realistic band parameters. In both cases, the checkerboard order develops at wave vectors $(\pm 2\pi/pa,0)$, $(0, \pm 2\pi/pa)$ that are tied to the peaks of the wave-vector dependent susceptibility, and is of the Lomer-Rice-Scott type. The properties of such periodic, inhomogeneous states are discussed in connection to the checkerboard patterns in the local tunneling density of states discovered in underdoped cuprates.

**10:48**

**G39 13 Hidden D-Wave Checkerboard Order in Cuprates** JIANGPING HU, *Purdue University* KANGJUN SEO, *Purdue University* We propose a new hidden order, D-wave checkerboard order, to explain the local charge checkerboard ordering observed in STM studies of the High Tc superconductors. We show that even a weak D-wave checkerboard order can have a strong effect on the STM spectrum in superconducting states and can nicely explain experimental observations. The D-wave checkerboard order also generates a Fermi arc with little dispersion around nodal points, which are consistent with results from angle resolved photoemission spectroscopy measurements. Therefore, the D-wave checkerboard order can naturally connect the pseudo-gap physics with the checkerboard structure featured in STM measurements.

**G40 1 Single-Atom Indexing of Quantum State Superpositions*** CHRISTOPHER R. MOON, *Stanford University* C. P. LUTZ, *IBM Almaden* D. M. EIGLER, *IBM Almaden* H. C. MANOHARAN, *Stanford University* The ultimate miniaturization of electronic devices will likely require the local control of single-electron wavefunctions. One system where this may be accomplished consists of two-dimensional metallic electron states confined within atomically engineered nanostructures. Here we describe experiments showing that an individual atom inside a 44-atom quantum corral can index arbitrary coherent superpositions of spatial quantum states. We demonstrate how the quantum mirage effect can be harnessed to image the resulting quantum superposition. We also present a straightforward method for determining the appropriate atom location for any desired superposition. The atom provides a real-space handle for an abstract Hilbert space, providing a simple, novel technique for coherently manipulating quantum states.

**G40 2 Valley Splitting in a Silicon Two-Dimensional Electron Gas*** SRIJIT GOSWAMI, MARK FRIESEN, *University of Wisconsin-Madison* J.L. TRUITT, *Lincoln Laboratory, MIT* CHARLES TAHAN, *Cavendish Laboratory, Cambridge, U.K.* J.O. CHU, *IBM T. J. Watson Research Center* D.W. VAN DER WEIDE, S.N. COPPERSMITH, ROBERT JOYNT, M.A. ERIKSSON, *University of Wisconsin-Madison* We have performed low-temperature microwave transport spectroscopy of low-lying valley states in a silicon two-dimensional electron gas. The magnitude of this splitting determines whether the ground state is degenerate for purposes of quantum computing with spins. The valley splitting varies linearly with magnetic field from 0.3 to 3 T, reaching 75 $\mu$eV, with no sign of saturation. We unambiguously identify the observed resonance as a valley excitation by comparing with Shubnikov-de Haas oscillations. The origin of the splitting is the coupling of the two $z$ conduction valleys in the silicon band structure, due to quantum well confinement. Previous theory suggests that the valley splitting can be of order 1 meV. However, we present a theory incorporating atomic steps, which are present in experimental systems. The theory leads to small valley splittings at zero magnetic field, and a linearly increasing splitting at nonzero fields, as observed in experiments.

**G40 3 Valley Splitting Theory for Silicon 2DEGs Grown on a Vicinal Surface*** MARK FRIESEN, S. CHUTIA, SRIJIT GOSWAMI, M. A. ERIKSSON, S. N. COPPERSMITH, *University of Wisconsin-Madison, Madison WI 53706* We develop a theory for the energy splitting of the two-fold degenerate conduction valleys of a silicon 2DEG. We assume that the quantum well is not perfectly aligned with the crystallographic axes, as consistent with typical experimental conditions. Under these general conditions, the valley splitting can be suppressed by many orders of magnitude from its theoretical upper bound. However, the confined electrons are able to recover some of their valley splitting, and thus lower their total energy, by a variety of means. We discuss two recovery methods, which apply to the cases of zero and nonzero magnetic fields, respectively. The results show a linear dependence of the valley splitting on the magnetic field, as consistent with the experimental data.

**G40 4 Quantum theory of decoherence in solid-state spin quantum computing architectures*** WAYNE WITZEL, SANKAR DAS SARMA, *University of Maryland* Decoherence is the adversary of any proposed quantum computer. In order to overcome it, we must understand it. Nuclear induced spectral diffusion, a type of electron spin decoherence caused by interaction with a nuclear spin bath, is a predominant source of information loss for solid-state spin quantum computing architectures. All previous theories for this 50-year-old problem have used phenomenological, semi-classical models. This talk presents our cluster expansion method which provides the first fully microscopic and quantum mechanical solution to this problem. With our method it becomes possible to ascertain the effectiveness of pulse sequences designed to enhance spin coherence.

**G40 5 Effect of exchange interaction on spin dephasing in a double quantum dot*** EDWARD LAIRD, JASON PETTA, ALEX JOHNSON, *Harvard University* AMIR YACOBY, *Weizmann Institute of Science* CHARLES MARCUS, *Harvard University* MICAH HANSON, ART GOSSARD, *University of California, Santa Barbara* We use a pulsed-gate technique to study mixing of singlet and triplet spin states in a two-electron double quantum dot with a tunable exchange interaction. Spin dynamics in this system are governed by the interplay of exchange (which tends to preserve spin correlations) and hyperfine interaction with the lattice nuclei (which tends to destroy them.) When the two interaction strengths are comparable, we observe saturation of dephasing and damped temporal oscillations, persisting well beyond the hyperfine dephasing time, of the spin correlator. Both features of the data show good agreement with predictions from a quasistatic model of the hyperfine field.

**G40 6 Exchange in singlet-triplet qubits: spin funnel and magnetic field structure*** MICHAEL STOPA, *Harvard University* CHARLES MARCUS, *Harvard University* We employ density functional (DF) calculated eigenstates as a basis for exact diagonalization studies of lateral semiconductor double quantum dots through the transition from the symmetric bias regime to the regime where both electrons occupy the same dot. The DF basis allows us to maintain the geometric fidelity of the device in the calculation while still capturing all of the many-body effects. Recent experiments by Petta et al. [Science **309**, 2184 (2005)] have shown the existence of a ''spin funnel'' in the behavior of the singlet-triplet splitting (the exchange coupling) as a function of bias detuning J($\varepsilon$) in the vicinity of the crossover from the (1,1) to the (0,2) honeycomb stability cells. Here we calculate the spin funnel and explain its origin and functional form. For an applied magnetic field B we predict the existence of local minima where dJ($\varepsilon$,B)/d$\varepsilon$ =0, and suppression of voltage noise can be expected.

**G40 7 Competition between Coulomb localization and barrier modulation of the exchange energy in two-electron laterally coupled quantum dots** DMITRIY MELNIKOV, JEAN-PIERRE LEBURTON, *Beckman Institute for Advanced Science and Technology, University of Illinois at Urbana-Champaign, Urbana, IL 61801* We present calculations of the singlet-triplet energy separation (exchange energy) in the two-electron system confined in the double quantum dot system used in recent experiments on coherent manipulation of coupled electron qubits. The hybrid multiscale approach where the confined electrons are described by the direct diagonalization of the Schrödinger equation within the full quantum dot device environment was used to perform the calculations. We analyze the behavior of the exchange in the magnetic fields and find large changes from meV to sub-$\mu$eV value as the confinement gate biases (effective barrier) are varied, while the singlet-triplet transition magnetic field remains at about 1 T independently of the gate biases. The small values of the exchange in this structure are attributed to the large separation between the electrons leading to an almost classical description of the system due to the dominance of the Coulomb repulsion.

**9:24**

**G40 8 Entanglement of two strongly correlated electrons in a lateral quantum dot*** CONSTANTINE YANNOULEAS, UZI LANDMAN, *Georgia Institute of Technology* Exact-diagonalization calculations for two electrons in an elliptic lateral quantum dot show that the electrons can localize and form a molecular dimer even for screened interelectron repulsion. The calculated singlet-triplet splitting ($J$) as a function of the magnetic field ($B$) agrees with cotunneling measurements;[1] its behavior reflects the effective dissociation[2] of the electron dimer for large $B$. Knowledge of the dot shape and of $J(B)$ allows determination of two measures of entanglement (concurrence and von Neumann entropy for *indistinguishable* fermions), whose behavior correlates also with the dissociation of the dimer. The theoretical value for the concurrence at $B = 0$ agrees with the experimental estimates.

**G40 10 Engineering Double Quantum Dots in Si/SiGe using Shottky Top Gates** NAKUL SHAJI, *Electrical and Computer Engineering, University of Wisconsin-Madison* LEVENTE KLIEN, *Department of Physics, University of Wisconsin-Madison* DON SAVAGE, *Material Science and Engineering, University of Wisconsin-Madison* MARK ERIKSSON, *Department of Physics, University of Wisconsin-Madison* ROBERT BLICK, *Electrical and Computer Engineering, University of Wisconsin-Madison* Quantum information processing in silicon based semiconductors have gained importance lately due to its inherent advantages like low spin orbit coupling and thus very large spin coherence times, as compared to competing III-V devices. Previous work done on silicon based low dimensional devices include successful fabrication of etch defined quantum dots in Si/SiGe quantum wells, whose potentials are modulated by lateral side gates. Another way of forming quantum dots is by using shottky top gates to deplete the underlying two dimensional electron gas (2DEG) in selected areas. Quantum dots formed by shottky top gates are preferred over etched ones to achieve better control over the tuning of tunnel barriers and to minimize etch induced depletion of the 2DEG. Unlike III-V materials, shottky gates formed in SiGe/Si quantum wells have been found to be very leaky. In this talk we discuss the issues of gate leakage, formation of tunnel junctions and engineering double quantum dots (Qubits) in SiGe/Si quantum wells with the help of an additional back-gate.

**G40 11 Stability Diagram of a Few Electron Triatom** ANDREW SACHRAJDA, *IMS, NRC, Ottawa, Canada K1A 0R6* LOUIS GAUDREAU, *IMS/NRC and Sherbooke University, Quebec* STUDENIKIN SERGEI, ALICIA KAM, JEAN LAPOINTE, PIOTR ZAWADZKI, MAREK KORKUSINSKI, PAWEL HAWRYLAK, *IMS, NRC, Ottawa, Canada K1A 0R6* A lateral few electron triple quantum dot system has been studied and the stability diagram mapped out using charged detection techniques. All three quantum dots are coupled together. The device could be tuned to observe quadruple points including the fundamental ones for quantum information applications, associated with the confinement of one, two and three electrons. The stability diagram includes a series of novel elements, including the cloning of charge transfer lines. The main results are successfully modeled by both capacitive and Hubbard models.

**10:12**

**G40 12 External field control of donor electrons at the Si-$SiO_2$ interface*** MARIA J. CALDERON, *Condensed Matter Theory Center, Department of Physics, University of Maryland* BELITA KOILLER, *Instituto de Fisica, Universidade Federal do Rio de Janeiro, Brazil, and Condensed Matter Theory Center, Department of Physics, University of Maryland* XUEDONG HU, *Department of Physics, University at Buffalo, SUNY* SANKAR DAS SARMA, *Condensed Matter Theory Center, Department of Physics, University of Maryland* Prospects for the quantum control of electrons in the silicon quantum computer architecture are considered theoretically. In particular, we investigate the feasibility of shuttling donor-bound electrons forth and back between the impurity in the bulk and the Si-$SiO_2$ interface by tuning an external electric field. We calculate the shuttling time to range from subpicoseconds to nanoseconds depending on the distance ( $\sim$ 10-50 nm) of the donor from the interface. For a certain range of parameters, the state at the interface is localized in all three dimensions, which allows to take the electron back to the donor. The size of the wave-function at the interface can be manipulated by applying a perpendicular magnetic field. Our results establish that quantum control in such nanostructure architectures should be achievable.

**G40 13 Experimental Stark tuning the donor electron spin resonance in silicon*** FORREST BRADBURY, ALEXEI TYRYSHKIN, GUILLAUME SABOURET, *Princeton University* THOMAS SCHENKEL, *Lawrence Berkeley Nat'l Lab* STEPHEN LYON, *Princeton University* We measure the hyperfine and spin-orbit shifts due to electric fields applied to bound electrons in silicon. The ability to electrically tune resonances allows for selective single qubit operations on electron spins without localized magnetic fields. We study $^{31}$P donors in natural silicon epilayers and $^{121}$Sb donors implanted into isotopically purified $^{28}$Si. The E-fields ( $\sim$ kV/cm) are applied by lithographically-patterned, interdigitated metal top-gates. Small shifts in resonant energies are measured by pulsed electron spin resonance using a modified two-pulse (Hahn) spin echo experiment with an electrical pulse applied to the gates between microwave pulses. At $B_0 \approx 0.35$T, we find the $2^{nd}$ order hyperfine and spin-orbit Stark shifts to be comparable in magnitude. Though the literature has heretofore focused on the hyperfine Stark shift, we predict that the spin-orbit Stark shift will be the dominant tuning parameter at higher magnetic fields where a future quantum computer is likely to operate.

**G40 14 Nuclear Spin of Phosphorus Donors in Silicon: Spin Relaxation Times and Environmental Decoupling*** ALEXEI TYRYSHKIN, STEPHEN LYON, *Princeton University* JOHN MORTON, ARZHANG ARDAVAN, *Oxford University* All shallow donors in silicon (and their various isotopes) have non-zero nuclear spins and thus, both the electron and nuclear spins of neutral donors have been proposed for coding, manipulating and storing quantum information. We have recently demonstrated that the spin of electrons bound to donors have extremely long coherence times of at least $T_{2e} = 60$ms at liquid helium temperatures which permits $10^6$ single-qubit operations before the electron spin decoheres [1]. Here we extend this work and demonstrate that spin states of both the electron and nucleus of a $^{31}$P donor can be accurately controlled using resonant microwave and RF pulses in pulsed electron nuclear double resonance (ENDOR) experiments. We measure the spin relaxation times of the $^{31}$P nuclear spin and observe long longitudinal relaxation times $T_{1n} = 70$s at 6K, limited by hyperfine interaction with the electron spin residing on the donor. We implement a recently proposed bang-bang strategy which decouples the nuclear spin from a decohering environment, through repeated manipulation of the coupled electron spin [2]. This highlights the potential benefits of physical qubit systems beyond the simple 2-level structure. [1] A. M. Tyryshkin et al. PRB, 68, 193207 (2003); [2] J. J. L. Morton et al. **G40 15 Experimental realization of single electron confinement in an InAs quantum dot** G. M. JONES, *Department of Electrical and Computer Engineering, University of Maryland* B. H. HU, *Department of Electrical and Computer Engineering, University of Maryland* C. H. YANG, *Department of Electrical and Computer Engineering, University of Maryland* M. J. YANG, *Naval Research Laboratory* Y. B. LYANDA-GELLER, *Department of Physics, Purdue University* We demonstrate an enhancement-mode lateral single electron transistor (SET). In contrast to the depletion-mode SETs that reach one-electron regime by expelling electrons from multi-electron QDs, our SET structure uses a single top gate to create two symmetric tunnel barriers and make electrons tunnel into this empty quantum dot one at a time. The sample used in this work to demonstrate this novel SETs concept is an InAs/GaSb composite quantum well, whose bandgap is tunable by the thicknesses of the two QWs and is $\sim$ 100meV in our case. Using a gated Hall bar geometry, we show that the device can undergo a transition from hole accumulation to the inversion of electrons. As the widths of the conducting channel and the top gate are reduced to sub-micron, the conductance displays single electron tunneling. The data indicate a 15meV Coulomb charging energy and a 20meV orbital energy spacing, which imply a quantum dot of 20nm in diameter. Combining with the inherent advantage of a large electron g* factor in InAs, our demonstration is significant for solid state implementation of scalable quantum computing.

**G41 1 Bose-Glass to Superfluid Transition in the 3d Boson Hubbard Model: z=d** PETER HITCHCOCK, ERIK SORENSEN, *McMaster University* Recent experiments on cold atomic gases in disordered optical lattices (Schulte et al. PRL 95, 170411 (2005)) have renewed interest in the bose-glass to superfluid phase transition in the boson Hubbard model. The dynamical critical exponent z is of central importance to understanding this transition, yet its value at $d > 2$ remains unclear. We present a Monte Carlo study of this transition in the three dimensions. Simulations are performed on the classical $(3 + 1)$ dimensional link-current representation using the geometrical worm algorithm. Finite-size scaling analysis (on lattices as large as 16x16x16x512 sites) of the superfluid stiffness and the compressibility is consistent with the value $z = 3$ for the dynamical critical exponent, in agreement with existing scaling and renormalization group arguments that $z = d$. We calculate a value of $\nu = 0.66(2)$ for the correlation length exponent, satisfying the relation $\nu \geq 2/d$ as an equality.

**8:12**
**G41 2 Superfluid Glass of He-4** BORIS SVISTUNOV, *University of Massachusetts* MASSIMO BONINSEGNI, *University of Alberta* NIKOLAY PROKOF'EV, *University of Massachusetts* With a recently developed worm algorithm, we simulate 800 atoms of He-4 at the density corresponding to the zero-$T$ melting point of the hcp crystal. We find that low-$T$ properties of the system— in our case, at $T = 0.2$K—crucially depend on the initial state and cooling protocol. An ideal hcp crystal is a clear-cut insulator. But if we start with a high-$T$ liquid state and quench-cool the sample down to $T = 0.2$K, we end up with a new state of matter, 'superglass',—a metastable amorphous solid that features off-diagonal long-range order and superfluidity.

**8:24**
**G41 3 Dynamic Structure Function of a Model Supersolid** CHI-DEUK YOO, ALAN DORSEY, *Department of Physics, University of Florida* Second sound, which is a fingerprint of superfluid behavior, can be observed in light scattering through the splitting of the central Rayleigh peak of the thermal diffusion mode into an additional Brillouin doublet of the second sound [1,2]. Since a supersolid undergoes a similar transition as a superfluid, we expect that the Rayleigh peak due to the defect diffusion mode in a normal solid will split into a Brillouin doublet of propagating modes in the supersolid phase. In this work, we have derived the hydrodynamic equations of motion including defects, and obtained both the second sound mode and the dynamic structure function for an isotropic and isothermal supersolid. We find the splitting occurs not only in the transition from a normal fluid to a superfluid but also from a normal solid to a supersolid, which might be observable in light scattering. [1] G. Winterling, F. S. Holmes, and T. J. Greytak, Phys. Rev. Lett. **30**, 427 (1973). [2] J. A. Tarvin, F. Vidal, and T. J. Greytak, Phys. Rev. B **15**, 4193 (1977).

**G41 4 Landau Theory for the Normal Solid-Supersolid Transition** ALAN DORSEY, *University of Florida* PAUL GOLDBART, *University of Illinois at Urbana-Champaign* JOHN TONER, *University of Oregon* Kim and Chan [1,2] have reported an anomalous decoupling transition of solid $^4$He in a torsional oscillator measurement, and interpret their results as evidence for non-classical rotational inertia and a possible supersolid phase of $^4$He. Motivated by these results, we [3] have developed a phenomenological Landau theory of the normal-solid to supersolid (NS-SS) transition in which superfluidity is coupled to the elasticity of the crystalline $^4$He lattice. We find that the elasticity does not affect the universal properties of the superfluid transition, so that in an unstressed crystal the well-known $\lambda$-anomaly in the heat capacity of the superfluid transition should also appear at the NS-SS transition. We also find that the onset of supersolidity leads to anomalies in the elastic constants near the transition, that should be observable in sound speed measurements; conversely, inhomogeneous strains in the lattice can induce local variations of the superfluid transition temperature, leading to a broadened transition. [1] E. Kim and M. H. W. Chan, Nature (London) **427**, 225 (2004). [2] E. Kim and M. H. W. Chan, Science **305**, 1941 (2004). [3] A. T. Dorsey, P. M. Goldbart, and J. Toner, cond-mat/0508271.

**8:48**
**G41 5 Effect of Quantum Correlations on the Vibrational Spectrum of Bosonic Quantum Solids** JORGE SOFO, *Department of Physics, The Pennsylvania State University* We study the effects of quantum correlations on the vibrational spectrum of solids. In particular, we are interested on the description of delocalized zero point vacancies and systems of light atoms interacting through weak dispersion forces, like Helium. We write the interaction Hamiltonian in a basis set of localized oscillators. A decoupling similar to the Random Phase Approximation of the equations of motion exhibits the dependence on particle correlations of the dispersion relation for phonons and consequently the sound speed. The approximation recovers the normal phonon modes in the case of a system described by an uncorrelated wave function. We show that the onset of correlations, as the temperature is lowered, changes the speed of sound, and the vibrational response of the solid. Implications for recent experimental observations of the supersolid state are discussed.

**9:00**
**G41 6 Exploration of Vacancies in Solid 4He** BRYAN CLARK, DAVID CEPERLEY, *UIUC Physics Dept.* Experiments by Kim and Chan [1] have renewed interest in the understanding of supersolids and whether mechanisms exist in solid $^4He$ to allow for supersolid-like effects. Ground state vacancies would lead to bose condensation and superfluidity. Using Path Integral Monte Carlo we examine vacancy formation energies, vacancy-vacancy interactions and the effect of vacancies on supersolid behavior in solid $^4He$. [1] E. Kim and M. H. Chan, Science **305**, 1941 (2004).

**9:12**
**G41 7 Observation of Nonclassical Rotational Inertia in Bulk Solid $^4$He Confined to a Cylindrical Cavity*** KEIYA SHIRAHAMA, MOTOSHI KONDO, SHUNICHI TAKADA, YOSHIYUKI SHIBAYAMA, *Department of Physics, Keio University, Yokohama 223-8522, Japan* Recent observation of nonclassical rotational inertia (NCRI) in solid $^4$He by Kim and Chan has attracted great interest in physics of supersolid, and motivated

a number of theoretical studies. However, there have been surprisingly few experiments to pursuit the nature of their observation. Thus, we have begun a torsional oscillator experiment for bulk solid $^4$He. In order to study the effects of sample geometry and crystal quality, we employ a cylindrical cell, 8 mm high and 8 mm in diameter, which is mounted on an aluminum alloy torsion rod. The resonant torsion frequency is about 1750 Hz, which is 2 $\sim$ 5 times the frequencies in the Kim and Chan's experiments. In a preliminary experiment we have observed an increase in the frequency below about 250 mK, indicating the existence of NCRI. The frequency shift shows a substantial driving amplitude dependence, which is also consistent with the previous observation.

*This work is supprted by Grant-in-Aid for Scientific Research on Priority Area, MEXT, Japan

**9:24**

**G41 8 Effect of $^3$He impurity on the supersolid transition of $^4$He*** EUNSEONG KIM, MOSES H. W. CHAN, *The Pennsylvania State University* The supersolid phase of $^4$He was revealed by a series of torsional oscillator experiments. [1] One of the most intriguing features of the supersolid transition is the broadening of the transition and the enhancement of $T_c$ by the addition of extremely small amount of $^3$He impurity. This effect is very different from that in superfluid film and that in 'bulk' superfluid helium. We have investigated the influence of$^3$He on the supersolid transition by systematically diluting isotopically−pure 4He (3He impurity less than 0.3ppb) with 3He. [1] E. Kim and M. H. W. Chan, Science **305**, 1941 (2004); Nature **425**, 227 (2004); J. Low Temp. Phys. **138**, 859 (2005).

*This research is supported by NSF Grant DMR 0207071.

**9:36**

**G41 9 Ballistic Phonon Propagation in Solid $^4$He at Low Temperature*** YUKI AOKI, HARRY KOJIMA, Phonon propagations in hcp solid $^4$He are being studied down to 30 mK including the recently discovered supersolid phase range. Phonons are generated with 2 $\mu$s long heat pulses by applying current into a metal film resistor (of area 5.2 mm$^2$) deposited onto a planar silicon substrate. The power applied to the heater is varied between 20 and 200 $\mu$W/mm$^2$. The phonons travel through 4.3 mm of solid $^4$He and are detected by superconducting edge sensor of 60 nm thick titanium film. In agreement with earlier studies, the main propagation peak detected by the sensor is the transverse sound propagation. Crossover from second sound in normal solid to ballistic propagation is observed between 100 mK and 300 mK at 25 bars. Measurements of ballistic phonon propagation are extended up to 50 bars for the first time. The velocity of transverse phonon propagation increases from 220 m/s at 25 bars to 250 m/s at 50 bars. It is expected that supersolid transition modifies the velocity of transverse sound propagation. It is found, within $\pm$ 1.5 % scatter of data, the ballistic phonon propagation velocity (measured at 200 $\mu$W/mm$^2$) remains constant below 100 mK at both 25 and 50 bars. At 30 mK, the velocity is independent of heater power within $\pm$ 1 %.

*Supported by NSF.

**9:48**

**G41 10 Specific heat of solid helium** XI LIN, *Penn State University* ANTHONY CLARK, EUNSEONG KIM, MOSES CHAN, Recently superflow in solid $^4$He was found below 200mK via a torsional oscillator technique[1]. While there were a number of measurements on the specific heat of solid helium carried out down to 100mK, there is no evidence of a heat capacity signature related to the onset of the supersolid phase[2]. A serious experimental challenge is discerning the small specific heat of solid helium from that of the metallic cells which are typically used to confine the solid. We have recently begun a new measurement of the heat capacity of solid helium contained in a silicon cell. The heat capacity of the silicon cell below 300mK is always less than that of the solid helium sample. Results of the measurement will be presented. This work is supported by NSF under grant number 0207071. [1] E. Kim and M. H. W. Chan, Nature **427**, 225 (2004); E. Kim and M. H. W. Chan, Science **305**, 1941 (2004); E. Kim and M. H. W. Chan, J. Low Temp. Phys. **138**, 859 (2005). [2] S. H. Castles and E. D. Adams, J. Low Temp. Phys. **19**, 397 (1975); B. Hébral et al., Phonons in Condensed Matter, edited by H. J. ## SESSION G42: PHYSICS EDUCATION RESEARCH AND UNDERGRADUATE EDUCATION

**Tuesday Morning, 14 March 2006**
**345, Baltimore Convention Center at 8:00**
**Paula Heron, University of Washington, presiding**

**8:00**

**G42 1 Light Quanta and Photochemistry** M. BAUBLITZ, *Northeastern University & Boston University* M. HERSEK, *Northeastern University* N. A. GROSS, *Northeastern University* A. BANSIL, *Northeastern University* For many undergraduate students the photoelectric effect and quantum nature of light seem abstract because of their lack of first-hand experience with these phenomena. This is particularly true for non-science students taking general science courses. At Northeastern University through the Embedded Learning MOdules (ELMO) Project, developed with support from NSF and FIPSE, non-science students take part in experiments [1] related to the photoelectric effect that help them understand photochemical processes and the quantum nature of light. Photosensitive materials are produced by depositing thin layers of silver nitrate on paper, and various light sources and light filters are used that permit light from only a specific part of the spectrum to expose the photosensitive material. The dependence of the silver nitrate's photosensitivity on the color of the incident light provides students with an example that can be understood in terms of the quantum nature of light. [1] M. Hersek, N. A. Gross, E. J. Mason, and A. Bansil, J. College Sci. Teaching (in press); N. A. Gross, M. Hersek, and A. Bansil, Am. J. Phys. **73**, 986 (2005)

**8:12**

**G42 2 Generalizing the definition of buoyant force** CARL MUNGAN, *Physics Department, U.S. Naval Academy* I propose that buoyant force be defined as the negative of the weight of the displaced fluids, rather than as the net force exerted by fluid pressures on the surface of an object. In the case of a fully submerged

object, these two definitions are equivalent. However, if the object makes contact with a solid surface (such as the bottom of a beaker of liquid), only the first definition is well-defined, while the second depends on the ambiguous issue of how much fluid penetrates between the object and the solid surface.

**8:24**

**G42 3 Integrating computation and simulation into the undergraduate physics curriculum** GUS L. W. HART, *Northern Arizona University* At Northern Arizona University, we have been integrating computation and simulation into the curriculum at all levels. We hope to achieve a number of objectives: (i) increase student retention during the first three semesters of the program, (ii) train students in this ''third branch'' of science, (iii) provide students with scientific computing skills, (iv) expand the coverage of the upper-division course content. I will discuss two courses required during the freshman and sophomore years and how computation and simulation is integrated into the upper-division courses. The percieved successes and remaining shortcomings of the current curriculum will addressed.

**8:36**

**G42 4 Computational Physics in the Undergraduate Physics Curriculum** J.E. HASBUN, *University of West Georgia* Recent efforts to incorporate computational physics in the undergraduate physics curriculum have made use of Matlab, IDL, Maple, Mathematica, Fortran, and C[1] as well as Java.[2] The benefits of similar efforts in our undergraduate physics curriculum are that students learn ways to go beyond what they learn in the classroom and use computational techniques to explore realistic physics applications. In so doing students become better prepared to perform undergraduate research that will be useful throughout their scientific careers.[3] Our standard computational physics course uses some of the above tools.[1] More recently, we have developed a first draft of a textbook for the junior level mechanics physics course that incorporates computational techniques. The text being developed in addition to employing the invaluable traditional analytical approach to problem solving, it incorporates computational physics to build on those problems. In particular, the course makes use of students abilities to use programming to go beyond the analytical approach and complement their understanding. Selected examples of representative lecture problems will be presented. [1]''Computation and Problem Solving in Undergraduate Physics,'' David M. Cook, Lawrence University (2003), http://www.lawrence.edu/dept/physics/ccli. [2]''Simulations in Physics: Applications to Physical Systems,'' H. Gould, J. Tobochnik, and W Christian; see also, http://www.opensourcephysics.org. [3]R. Landau, APS Bull. Vol 50, No.1, 1069 (2005)

**8:48**

**G42 5 Using the Open Source Physics Java Library to do Computer Simulations*** HARVEY GOULD, *Clark University* JAN TOBOCHNIK, *Kalamazoo College* WOLFGANG CHRISTIAN, *Davidson College* Computation has become a common feature of many physics courses. However, the computation is usually an add-on and students do not learn how to write simulations in a way that is similar to how they are done in a research context. We describe how to teach students to learn physics by writing and modifying programs in Java using the objected oriented Open Source Physics library available at <www.opensourcephysics.org>.

*Supported in part by NSF DUE-0442481 and DUE-0127363.

**9:00**

**G42 6 Data Visualization in Physics I: Java applets for interactive demonstration of physics concepts** ELIZABETH M. CHERRY, *Cornell University* STEVEN J. EVANS, *Beth Israel Medical Center* HAROLD M. HASTINGS, *Hofstra University* FLAVIO F. FENTON, *Cornell University* As computing resources continue to develop toward increased flexibility and power, illustration of scientific concepts has become significantly easier. Java applets in particular form an especially appropriate medium through which simulations and animations can be shared easily across platforms. In this talk, we will show several Java applets that illustrate different concepts in physics, particularly in biophysics, complex systems, and excitable media. Various graphical interfaces will be shown for 0d to 2d systems. In addition, we will demonstrate how to incorporate Java applets into PowerPoint for easy presentation of results in classes and seminars.

**9:12**

**G42 7 Data Visualization in Physics II: VRML and Java for three-dimensional imaging and fully three-dimensional movies** FLAVIO H. FENTON, *Cornell University* STEVEN J. EVANS, *Beth Israel Medical Center* HAROLD M. HASTINGS, *Hofstra University* ELIZABETH M. CHERRY, *Cornell University* Presentation and analysis of large three-dimensional data sets is in general hard to do using only two-dimensional figures and plots. In this talk, we will demonstrate techniques for illustrating static and dynamic three-dimensional objects and data using Virtual Reality Modeling Language (VRML) as well as Java. The advantage of these two languages is that they are platform-independent, which allows for easy sharing of data and visualizations. In addition, manipulation of data is relatively easy as rotation, translation and zooming can be done in real- time for static objects as well as for data and objects that vary and deform in time. Examples of fully three-dimensional movies will be shown, including dendritic growth and propagation of electrical waves in cardiac tissue. In addition, we will show how to include VRML and Java viewers in PowerPoint for easy presentation of results in classes and seminars.

**9:24**

**G42 8 Advanced Lab Consortium ''Conspiracy''** JONATHAN F. REICHERT, *TeachSpin, Inc.* Advanced Laboratory instruction is a time-honored and essential element of an undergraduate physics education. But, from my vantage point, it has been neglected by the two major professional societies, APS and AAPT. At some schools, it has been replaced by ''research experiences,'' but I contend that very few of these experiences in the research lab, particularly in the junior year, deliver what they promise. It is time to focus the attention of APS, AAPT, and the NSF on the advanced lab. We need to create an Advanced Lab Consortium (ALC) of faculty and staff to share experiments, suppliers, materials, pedagogy, ideas, in short to build a professional network for those committed to advanced lab instruction. The AAPT is currently in serious discussions on this topic and my company stands ready with both financial and personnel resources to support the effort. This talk is a plea for co-conspirators.

**9:36**

**G42 9 Building and Sustaining a Successful Undergraduate Research Program** VIJENDRA AGARWAL, GUBBI SUDHAKARAN, *University of Wisconsin-La Crosse* The multidisciplinary Undergraduate Research (UR) program initiated about ten years ago continues to be one of the institutional priorities at the University of Wisconsin- La Crosse (UW-L). While, UR program has boosted overall student retention at UW-L, the physics program has very definitely experienced a phenomenal growth in the number of majors (from 5 to 130) and external grants (over a million dollars) in the last few years. In no uncertain terms, this kind of growth is attributed to the nurturing environment of the department and faculty mentored research with undergraduate students. This presentation will focus on various elements, shared responsibility, and resources that are critical to initiating and building a sustainable UR program in physics but even more importantly how to institutionalize it. We shall further discuss our overall experiences from the modest beginnings to our continuous growth.

**9:48**

**G42 10 Adaptations of the Physics By Inquiry Curriculum** LEON HSU, *University of Minnesota* KAREN CUMMINGS, *Southern Connecticut State University* JACK TAYLOR, *Baltimore City Community College* We report on the initial stages of a collaborative investigation into ways in which the Physics by Inquiry (PbI) curriculum (McDermott) can be implemented in larger enrollment courses using undergraduate peer instructors and cooperative grouping techniques. Typically, PbI is implemented in small classes with Physics graduate students as teaching assistants. However, many institutions, such as community colleges, do not have graduate students available. In other cases, there is a need for a larger enrollment class. We present three models we are investigating as responses to our local constraints. This work was partially supported by NSF DUE-0410804.

**10:00**

**G42 11 Science on the Table: Motivating Non-Science Majors to Learn Physical Science** MARTHA WELLER, JUDITH IRIARTE-GROSS, *Middle Tennessee State University* Most undergraduates in non-scientific fields view personal science knowledge as both irrelevant and unnecessary for their future well-being. Attempts by universities to address the problem of an increasingly scientifically illiterate citizenry through the incorporation of science requirements in the general education curriculum are viewed by students as one more obstacle in their quest for an undergraduate degree, not as an opportunity to develop the skills needed for personal and civic decision making related to scientific and technologic issues. We have modified the laboratory portion of our existing Physical Science course (previously a catch-all course intended to cover concepts in physics, chemistry, earth science, and astronomy in one semester) to incorporate activities that draw attention to the impact of science on society and individuals. These activities include classroom debates on current issues with scientific content as well as experiments that draw attention to the science of everyday materials and phenomena. We will discuss these activities and the skills students are expected to develop from them.

**10:12**

**G42 12 A Statistical Analysis of Activity-Based and Traditional Introductory Algebra Physics Using the Force and Motion Conceptual Evaluation*** CECELIA TRECIA MARKES, *University of Nebraska at Kearney* With a three-year FIPSE grant, it has been possible at the University of Nebraska at Kearney (UNK) to develop and implement activity- based introductory physics at the algebra level. It has generally been recognized that students enter physics classes with misconceptions about motion and force. Many of these misconceptions persist after instruction. Pretest and posttest responses on the ''Force and Motion Conceptual Evaluation'' (FMCE) are analyzed to determine the effectiveness of the activity- based method of instruction relative to the traditional (lecture/lab) method of instruction. Data were analyzed to determine the following: student understanding at the beginning of the course, student understanding at the end of the course, how student understanding is related to the type of class taken, student understanding based on gender and type of class. Some of the tests used are the t-test, the chi-squared test, and analysis of variance. The results of these tests will be presented, and their implications will be discussed.

*This work was supported by the US DOE's FIPSE Grant No. P116B51449.

**10:24**

**G42 13 To Hold A Class When You Can Not Be There** TARLOK AURORA, *Univ. of the Sciences in Philadelphia* Sometimes it is not possible for faculty to be physically present in class because of a need to participate in off-campus conferences or seminars. Due to scheduling conflicts, it may not be possible to find a substitute instructor. Under these conditions, one could cancel the class and make it up later on. Instead, it could also be productive for teaching and learning to make assignments that students could work on during the scheduled class time in the absence of the instructor. This would make learning student-centered and foster teamwork. To do this, students were instructed to meet in the classroom to work together on the specified day and an assignment was made visible on the Blackboard Learning Platform. The completed assignment was due no later than the next class period. The assignment involved reading selected pages from the physics textbook, answering questions and a quiz. It was found that on the specified day, thirteen (out of the fourteen) sophomore students got together and correctly completed the group assignment without supervision. This was not done for extra credit. Students liked working in a collaborative environment. This approach may be used in larger classes with multiple assignments made to small group of students. Details will be discussed.

**10:36**

**G42 14 Medical Physicists and AAPM** HOWARD AMOLS, *American Association of Physicists in Medicine* The American Association of Physicists in Medicine (AAPM), a member society of the AIP is the largest professional society of medical physicists in the world with nearly 5700 members. Members operate in medical centers, university and community hospitals, research laboratories, industry, and private practice. Medical physics specialties include radiation therapy physics, medical diagnostic and imaging physics, nuclear medicine physics, and medical radiation safety. The majority of AAPM members are based in hospital departments of radiation oncology or radiology and provide technical support for patient diagnosis and treatment in a clinical environment. Job functions include support of clinical care, calibration and quality assurance of medical devices such as linear accelerators for cancer therapy, CT, PET, MRI, and other diagnostic imaging devices, research, and teaching. Pathways into a career in medical physics require an advanced degree in medical

physics, physics, engineering, or closely related field, plus clinical training in one or more medical physics specialties (radiation therapy physics, imaging physics, or radiation safety). Most clinically based medical physicists also obtain certification from the American Board of Radiology, and some states require licensure as well.

**SESSION G44: CHARGE-DENSITY WAVES**
**Tuesday Morning, 14 March 2006**
**347, Baltimore Convention Center at 8:00**
**Robert Thorne, Cornell University, presiding**

**8:00**
**G44 1 Dynamics of the Electro-Optic Response of Blue Bronze** LUIS LADINO, MIRAJ UDDIN, MARIO FREAMAT, JOSEPH BRILL, *University of Kentucky* We have measured the frequency, voltage, and position dependence of the electro-transmittance and electro-reflectance of the charge-density-wave (CDW) conductor blue bronze at T $\sim$ 80 K when square-wave voltages are applied to the sample. The electro-optic response, assumed to be proportional to the local strain of the CDW, is characterized in terms of a relaxation time and a surprisingly long ( $>$ 0.1 ms) ''inertial'' delay for CDW repolarization. At a given position in the sample, the relaxation time increases with decreasing voltage, as expected. Both time constants increase away from the current contacts, indicating that the inertia is not due to barriers at the contacts. For one sample, the electro-optic response is also observed to decay for times $\sim$ 10 ms. This research was supported by NSF grants # DMR-0100572 and DMR-0400938.

**8:12**
**G44 2 Temperature Dependence of the Electro-Optic Relaxation Time of Blue Bronze** JOSEPH BRILL, LUIS LADINO, MARIO FREAMAT, MIRAJ UDDIN, *University of Kentucky* DAMIR DOMINKO, *University of Kentucky and Institute of Physics, Zagreb* We have measured the temperature dependence of the electro-transmittance of the quasi-one dimensional charge-density-wave (CDW) conductor blue bronze at temperatures between 55 K and 125 K when square-wave voltages are applied to the sample. For voltages well-above the threshold for nonlinear current, the characteristic electro-optic relaxation time, at a given position in the sample, depends primarily on the CDW current, whereas the magnitude of the relative change in transmittance decreases with decreasing temperature even for constant CDW current. At lower voltages, the frequency dependence of the response broadens, suggesting non-uniform and temperature dependent barriers to CDW repolarization. This research was supported by NSF grant # DMR-0400938.

**8:24**
**G44 3 Structure and Charge Density Waves of K0.3MoO3 (blue bronze) (20-1) Surfaces by Variable Temperature STM** MAXIM NIKIFOROV, *University of Pennsylvania* ABDEL ISAKOVIC, *Cornell University* ROBERT THORNE, *Cornell University* DAWN BONNELL, *University of Pennsylvania* Scanning Tunneling Microscopy has been used extensively in the study of charge density waves in hexagonal compounds such as NbSe2, $\alpha$-TaSe2, $\alpha$-TaS2, NbSe3 etc. A limited number of studies have been done of the surfaces of K0.3MoO3 (blue bronze), a monoclinic compound. To date, charge density waves on blue bronze have not been imaged by STM. In this work we demonstrate unit cell spatial resolution on the blue bronze (20-1) surface at room temperature and at 110K. The contrast in images obtained at room temperature is attributed to the surface atomic structure. The role of the tip atom in the contrast formation is demonstrated by comparison of three different images of the (20-1) surface of K0.3MoO3. At low temperatures charge density waves are superimposed on the unit cell resolution pattern. To the best of our knowledge this is the first observation of charge density waves on blue bronze by STM.

**8:36**
**G44 4 The Phase Diagram of Driven Density Waves*** ROBERT THORNE, *Cornell University* Despite nearly 30 years of study, the physics of the velocity-driving force relation of density wave (DW) conductors has remained controversial. Recent experiments indicate that at low temperatures collective DW motion begins at a threshold field $E_T$, but occurs via a new mechanism that we call coherent collective creep. A first-order transition from creep to high velocity sliding occurs when the DW reaches a critical velocity. As the temperature is increased, the transition vanishes at a critical point, and collective sliding begins immediately at $E_T$. This phase diagram is inconsistent with all existing models of driven elastic media in the presence of disorder, which assume a single length and energy scale associated with pinning. As emphasized by Larkin and Brazovskii, there are, in fact, two length and energy scales associated with local and collective pinning, respectively. This interpretation has broad consequences for our understanding of driven disordered systems.

*Supported by the NSF (DMR 04-05500)

**8:48**
**G44 5 Spatial and temporal correlations in CDW dynamics*** ZACHARY M. STUM, ABDEL F. ISAKOVIC, ROBERT E. THORNE, *Physics Department, LASSP, Cornell University, Ithaca, NY* Noise phenomena associated with the collective mode provide a powerful probe of charge-density-wave (CDW) dynamics. We have developed a setup to allow measurements of spatial and temporal correlations in the noise on length scales of hundreds of microns at frequencies of up to 1 GHz. Details of the electric field, temperature and sample quality dependence of these correlations will be discussed. Our goal is to observe long-sought evidence for critical dynamics as the depinning transition is approached from above.

*This work is supported through NSF DMR 04-05500

**9:00**
**G44 6 End current injection contacts for transport studies in CDW materials*** ABDEL F. ISAKOVIC, *Physics Dept., LASSP, Cornell University* KATARINA CICAK, *NIST, Boulder* ROBERT E. THORNE, *Physics Dept., LASSP, Cornell University* Current contacts to whisker- or rod-like crystals of quasi-one-dimensional conductors are generally applied to their sides. Effects associated with the resulting anisotropic current injection have long complicated interpretation of transport measurements. We have developed a method to microfabricate end current contacts. This method allows direct injection along the one-dimensional axis, greatly reduces spreading and contact resistances, and produces more uniform current densities. Using these contacts, we have been examining the physics of phase slip and

single-particle to collective current conversion in the CDW conductors $NbSe_3$ and $TaS_3$, and in particular how the excess voltage required for phase slip varies with current and temperature. End contacts also modify the magnitude and temperature dependence of the CDW's depinning threshold. Our analysis shows that the activation voltage for the nucleation of topological dislocations increases with decreasing temperature, and varies from typically 20 mV at 110 K to 80 mV at 80 K.

*Thsi work is supported through NSF DMR 04-05500

**9:12**

**G44 7 Electronic Structure of $LaTe_2$** DANIEL GARCIA, GEYHONG GWEON, *Department of Physics, University of California, Berkeley* SHUYUN ZHOU, *Department of Physics, University of California, Berkeley; Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley* JEFF GRAF, *Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley* CHRIS JOZWIAK, *Department of Physics, University of California, Berkeley* M.H. JUNG, *National Research Laboratory for Material Science, KBSI* Y.S. KWON, *Department of Physics, Sung Kyun Kwan University, Suwon* ALESSANDRA LANZARA, *Department of Physics, University of California, Berkeley; Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley* Current work on the charge density wave system $LaTe_2$ indicates the existence of near Fermi energy gapping due to $\mathbf{q}_{CDW}=\mathbf{a}^*/2$ and $\mathbf{b}^*/2$. We find this band gapping to be weaker than originally thought, particularly for the near $\Gamma$ point contour. In addition, we find evidence of gap anisotropy which maintains the expected four fold symmetry of the crystal. Finally, we observe evidence of non-negligible kz dependence, originally considered minor. This appears to alter the CDW nesting as well as the gap anisotropy and has considerable importance to future studies of Rare-Earth Dichalcogenides.

**9:24**

**G44 8 Effect of Pressure on the Competition between Charge Density Wave and Superconductivity in $ZrTe_3$ Single Crystal** Y. UWATOKO, M. ABLIZ, M. HEDO, *ISSP, Univ. of Tokyo, Kashiwa, Chiba 277-8581, Japan* R. YOMO, K. YAMAMYA, *Dept. of Appl. Phys., Hokkaido Univ., Sapporo 060-8628, Japan* Competition and coexistence of CDW and superconductivity are studied from ancient times by $NbSe_2$, $NbSe_3$, etc. The rivalry of CDW and superconductivity was changed with pressure and the method of investigating the situation has been used. We report on an intricate competition between charge density wave (CDW) formation and superconductivity under pressure up to 11 GPa in the low-dimensional conductor $ZrTe_3$. The electrical resistivity measurements up to 11 GPa in the temperature 2.4K to 300K were performed using a standard 4-probe method. Hydrostatic pressure was produced by using a cubic anvil pressure cell in the Teflon cell filled with a fluid pressure transmitting medium of mixture of Fluorinert. As pressure increases, the CDW transition temperature $T_{CDW}$ initially increases, then begins to decrease at 2 GPa and abruptly disappears near 5 GPa. On the other hand, while the superconducting transition temperature $T_C$ falls to below 1.2 K at $\sim$ 0.5 GPa and is not observed at up to 5 GPa above 2.5 K, a superconducting transition emerges beginning at $\sim$ 5 GPa and $T_C$ increases steeply up to 11 GPa. This is an observation of pressure-induced reentrant superconductivity. The results are discussed in terms of the change in the reduced area of the Fermi surface due to CDW formation.

**9:36**

**G44 9 Incommensurate lattice modulation in CDW compound $TbTe_3$** N. RU, A. FANG, A. KAPITULNIK, I. R. FISHER, *Dept. of Applied Physics, Stanford University* M. F. TONEY, *Stanford Synchrotron Radiation Laboratory, Stanford Linear Accelerator Center* The layered materials $RTe_3$ ($R$ = rare earth) are simple charge-density wave (CDW) compounds, for which large regions of the original quasi-2D Fermi surface are nested by a single incommensurate wavevector. We use high resolution x-ray diffraction and scanning tunneling microscopy (STM) to study how the lattice responds to the incommensurate ordering. The superlattice of $TbTe_3$ reveals a unidirectional lattice modulation characterized by $q_{CDW} = 0.296$ c*. Higher harmonics are several orders of magnitude lower in intensity, implying an almost sinusoidal lattice modulation. The CDW is well correlated within and between planes, with correlation lengths in excess of 1000 Å. STM measurements reveal the CDW gap and real-space lattice modulation.

**G44 10 Stripes in quasi 2D rare-earth tellurides** HONG YAO, *Department of Physics, Stanford University, Stanford, CA 94305* JOHN ROBERTSON, *Department of Physics, Stanford University, Stanford, CA 94305* EUN-AH KIM, *Department of Physics, Stanford University, Stanford, CA 94305* STEVEN KIVELSON, *Department of Physics, Stanford University, Stanford, CA 94305* Even though the rare-earth tellurides are tetragonal materials with quasi-2D band structure, they have a hidden 1D character. The consequent, near-perfect Fermi surface nesting results in the formation of a charge density wave (CDW) state. Interestingly, the CDW is unidirectional (?striped?), spontaneously breaking not only translational symmetry, but the discrete rotational symmetry, as well. We show that there are two possible ordered phases consistent with the band structure: A bidirectional ?checkerboard? state would occur if the CDW transition temperature is sufficiently low, whereas the observed striped state is favored when the transition temperature is larger. We comment, as well, on the implications of this finding for the issue of stripes vs. checkerboards in more strongly correlated systems, such as the cuprates.

**G44 11 The dimensionality of charge density waves in the presence of quenched disorder** ADRIAN DEL MAESTRO, *Department of Physics, Harvard University* BERND ROSENOW,* *Institut für Theoretische Physik, Universität zu Köln* SUBIR SACHDEV, *Department of Physics, Harvard University* We present the effects of quenched disorder on a model of charge density wave (CDW) ordering on the square lattice. Our model may be applicable to the cuprate superconductors, where a random electrostatic potential exists in the CuO planes as a result of the presence of charged dopants. We argue that the presence of a random potential can affect the uni-directionality of the CDW order. Coupling to a uni-directional CDW, the random potential can lead to the formation of domains with 90 degree relative orientation, thus tending to restore the rotational symmetry of the underlying lattice. For a checkerboard CDW on the other hand, disorder generates spatial anisotropies on short length scales and thus some degree of uni-directionality. Using both numerical and analytical techniques, we quantify these disorder effects. Contact will be made with different experimental approaches on various materials that seem to observe both stripe and checkerboard charge ordering.

**G44 12 Inhomogeneous and glassy electronic phases driven by competing orders** I. VEKHTER, *Louisiana State University* Z. NUSSINOV, *Washington University* A. V. BALATSKY, *Los Alamos National Laboratory* Emergence of inhomogeneous and glassy states in interacting systems has been a focus of much attention recently. It has been well established that such states may arise a) in the presence of disorder; b) in pure systems in the presence of interactions at competing length scales. Here we investigate the emergence of inhomogeneous states as a result of competing orders. We use a Ginzburg-Landau theory and find that, even if the theory is local, negative amplitude-gradient coupling leads to states of inhomogeneous coexistence of order parameters. Proliferation of low lying modes in such systems triggers slow dynamics and low critical temperatures.

**G44 13 Dynamic Compressibility and aging in Wigner crystals and quantum glasses*** THIERRY GIAMARCHI, *University of Geneva, DPMC, 24 Quai Ernest Ansermet, CH-1211 Geneva 4, Switzerland* LETICIA CUGLIANDOLO, *Laboratoire de Physique Theorique et Hautes Energies, 4 Place Jussieu, 75252 Paris Cedex 05, France* PIERRE LE DOUSSAL, *LPTENS CNRS UMR 8549 24, Rue Lhomond 75231 Paris Cedex 05, France* We study the non-equilibrium linear response of quantum elastic systems pinned by quenched disorder with Schwinger-Keldysh real-time techniques complemented by a mean-field variational approach. We find (i) a quasi-equilibrium regime in which the analytic continuation from the imaginary-time replica results holds provided the marginality condition is enforced; (ii) an aging regime. The conductivity and compressibility are computed. The latter is found to cross over from its dynamic to static value on a scale set by the waiting time after a quench, an effect which can be probed in experiments in e.g. Wigner glasses.

**G44 14 Wigner crystallization in $Na_3Cu_2O_4$ and $Na_8Cu_5O_{10}$ chain compounds.** P. HORSCH, *Max-Planck-Institute for Solid State Research, D-70569 Stuttgart, Germany* M. SOFIN, M. MAYR, M. JANSEN, We report the synthesis of novel doped edge-sharing chain compounds $Na_3Cu_2O_4$ and $Na_8Cu_5O_{10}$, which form insulating states with commensurate charge order [1]. We identify these systems as one-dimensional Wigner lattices, where the charge order is determined by the long-range Coulomb interaction and the number of holes in the d-shell of Cu. Our interpretation is supported by X-ray structure data as well as by an analysis of magnetic susceptibility and specific heat data. Remarkably, due to large second neighbor Cu-Cu hopping, these systems allow for an unambiguous distinction between the classical Wigner lattice and the $4k_F$ charge-density wave of quantum mechanical origin. Finally, we briefly discuss the domain-wall type charge excitations and the theoretical expectation for the optical conductivity of 1D Wigner lattices [2]. [1] P. Horsch, M. Sofin, M. Mayr, and M. Jansen, Phys. Rev. Lett. 94, 076403 (2005). [2] M. Mayr and P. Horsch, (unpublished).

**G44 15 Fermi surface nesting and the origin of the charge density wave in NbSe2** CHRISTOPHER HOWELLS, MICHELLE JOHANNES, IGOR MAZIN, *Naval Research Laboratory* The origin of a charge density wave (CDW) transition in $NbSe_2$ and related transition metal dichalcogenides has been studied and hypothesized about for the past four decades. The idea that CDW formation is the result of Fermi surface nesting was put forward as early as 1978 and continues to be suggested in current papers. Using highly accurate density functional calculations, we make a detailed study of the band structure and Fermi surfaces of equilibrium and pressurized $NbSe_2$. We calculate the real part of the non-interacting susceptibility, $\Re\chi_0(\mathbf{q})$, which is the relevant quantity for a CDW instability and the imaginary part,$\Im\chi_0(\mathbf{q})$, which directly shows Fermi surface (FS) nesting. We show that there are very weak peaks in $\Re\chi_0(\mathbf{q})$ near the CDW wave vector, but that no such peaks are visible in $\Im\chi_0(\mathbf{q})$, definitively eliminating FS nesting as a factor in CDW formation. We discuss the effects of pressure and provide calculated de Haas van Alphen frequencies and effective masses that can be compared to experiment.

**G45 1 Time-resolved Kerr effect in $SrRuO_3$: observation of oscillatory dynamics** M. LANGNER, C.L.S. KANTNER, C.P. WEBER, J. ORENSTEIN, L.W. MARTIN, R. RAMESH, *UC Berkeley and Lawrence Berkeley National Lab* We report measurements of magnetization dynamics in thin films of the perovskite transition metal oxide $SrRuO_3$, a metallic compound that is ferromagnetic below approximately 150 K. The dynamics of the magnetization vector, $\vec{M}$, were measured using the time-resolved magneto-optic Kerr effect. In this technique a pump laser pulse, at photon energy 1.5 eV, perturbs the magnet by reducing the magnitude of $\vec{M}$ and changing the direction of the anisotropy field. The subsequent dynamics of $\vec{M}$ are measured by detecting the rotation of the plane of polarization of a time-delayed probe beam that is reflected from the surface of the sample. Below $\sim$ 100 K, we observe a damped oscillation in the Kerr rotation with frequency 250 GHz. The damping decreases with decreasing temperature down to $\sim$ 50 K and remains constant below this temperature. We tentatively identify this oscillation as the q=0 magnon, or ferromagnetic resonance frequency (FMR), of SrRuO3. The rather large value of the FMR frequency is consistent with the known large magnetocrystalline anisotropy of this compound. We will report measurements of $\vec{M}$(t) as a function of film thickness, residual resistance, and orientation of crystalline axes.

**8:12**

**G45 2 Itinerant Ferromagnetism in Cr Doped Perovskite Ruthenates*** V. DURAIRAJ, E. ELHAMI, S. CHIKARA, X.N. LIN, A. DOUGLASS, G. CAO, *University of Kentucky* P. SCHLOTTMANN, E.S. CHOI, *National High Magnetic Field Lab* R.P. GUERTIN, *Tufts University* We report results of structural, magnetic and transport properties of single crystal $CaRu_{1-x}Cr_xO_3$ ($0 \leq x \leq 0.36$) and $SrRu_{1-x}Cr_xO_3$ ($0 \leq x \leq 0.20$). Cr substitution as low as $x=0.08$ drives $CaRu_{1-x}Cr_xO_3$ from paramagnetic state to an itinerant ferromagnetic state with an abrupt jump in isothermal magnetization leading to a sizeable saturation moment ( $\sim 0.4\mu_B$/f.u. within the ab plane). Ferromagnetism occurs abruptly and reaches as high as $T_C=123$ K for $x=0.22$. The Cr-driven ferromagnetism is highly anisotropic, suggesting an important role for spin-orbit coupling. Lattice constant and magnetic measurements strongly support the valence of the Cr to be tetravalent ($Cr^{4+}$, $3d^2$ configuration). The Cr substitution for Ru in $SrRuO_3$ ($T_C=165$ K) enhances the itinerant ferromagnetism, consistent with Cr-induced ferromagnetism in paramagnetic $CaRuO_3$, but without significant magnetic anisotropy. Preliminary pressure-dependent magnetization of $CaRu_{0.85}Cr_{0.15}O_3$ shows strong enhancement of the saturation magnetization (25% for P$\sim$ 0.7 GPa). All results indicate a coupling of Ru 4d and Cr 3d electrons that is unexpectedly favorable for itinerant ferromagnetism which often exists delicately in the ruthenates.

**G45 3 Borderline magnetism in $Sr_4Ru_3O_{10}$: Impact of dilute La and Ca doping on itinerant metamagntism and ferromagnetism*** SHALINEE CHIKARA, V. DURAIRAJ, W.H. SONG, Y.P. SUN, X.N. LIN, A. DOUGLASS, G. CAO, *University of Kentucky* The triple-layered $Sr_4Ru_3O_{10}$ features ferromagnetic behavior with Tc=105 K along the c-axis (interlayer) and a first-order metamagnetic transition below 50 K in the basal plane [1]. The coexistence of ferromagnetism and metamagnetism suggests $Sr_4Ru_3O_{10}$ be on the borderline that separates its closest neighbors: the itinerant ferromagnet $SrRuO_3$ and the enhanced paramagnet $Sr_3Ru_2O_7$. We report our results on $Sr_4Ru_3O_{10}$with Sr slightly substituted by La and Ca ions. The La doping drastically changes the magnetic and transport properties. In particular, it effectively suppresses Tc along the c-axis, but simultaneously induces ferromagnetic behavior in the basal plane with Tc=30 K, entirely different from that of the c-axis. Associated with these changes, the metamagnetism disappears in the basal plane but appears along the c-axis. In sharp contrast, the Ca doping significantly enhances the ferromagnetism along c-axis but drastically weakens the magnetic ordering in the basal plane where an unusual $T^{3/2}$-power law for the resisitivity is developed. The vastly different responses to the La and Ca doping, despite similar ionic radii of $La^{3+}$ and $Ca^{2+}$, highlight the role of the extra electron from the La ion added to the $t_{2g}$ orbitals. **G45 4 Infrared Hall effect in $SrRuO_3$ and $CaRuO_3$** M.-H. YANG, G. ACBAS, A. MARKELZ, J. CERNE,* *Physics Dept., Univ. at Buffalo, Buffalo, NY* I. OHKUBO, *Dept. of Applied Chemistry, Univ. of Tokyo, Tokyo, Japan* P. KHALIFAH, *Chemistry Dept., Univ. of Massachusetts, Amherst, MA* H. CHRISTEN, D. MANDRUS,† *Condensed Matter Sciences Div., Oak Ridge National Lab., Oak Ridge, TN* Z. FANG, *Inst. of Physics, Chinese Academy of Science, Beijing, China* The mid-infrared (MIR: 115-366 meV) Hall effect is studied in $SrRuO_3$ and $CaRuO_3$ films. In $SrRuO_3$, below 200 meV the MIR Hall response changes sign as a function of temperature near 120 K, similar to the dc Hall effect. Above 200 meV, no sign change occurs and the temperature dependence of the MIR Hall response is similar to the dc magnetization. On the other hand, in $CaRuO_3$, the MIR Hall effect is nearly independent of frequency above 100 meV, has a similar temperature dependence as the dc magnetic susceptibility, and does not change sign, unlike the dc Hall effect. In $SrRuO_3$, the complex Faraday and Kerr angles measured in the MIR at 10 K are in good qualitative and quantitative agreement with first-principles band calculations [Z. Fang et al., Science 2003].

**G45 5 Oscillatory magnetoresistance periodic in 1/$B$ and $B$ and specific heat of $Ca_3Ru_2O_7$*** X.N. LIN, V. DURAIRAJ, S. CHIKARA, A. DOUGLASS, G. CAO, V. VARADARAJAN, V.A. BONDARENKO, J.W. BRILL, *Univ. of Kentucky* Z.X. ZHOU, *ORNL* P. SCHLOTTMANN, *NHMFL* We report magnetoresistance oscillations in high magnetic fields, B, up to 45 T and over a wide range of temperature in the Mott-like system $Ca_3Ru_2O_7$ [1]. For B rotating within the itac-plane, slow and strong Shubnikov-de Haas (SdH) oscillations periodic in 1/B are observed for T$\leq$ 1.5 K in the presence of metamagnetism. These oscillations are highly angular dependent and intimately correlated with the spin-polarization of the ferromagnetic state. For B$||$ [110], oscillations are also observed itbut periodic in B (rather than 1/B)it which persist up to 15 K. While the SdH oscillations are a manifestation of the presence of small Fermi surface (FS) pockets in the Mott-like system, the B-periodic oscillations, an exotic quantum phenomenon, may be a result of anomalous coupling of the magnetic field to the $t_{2g}$-orbitals that makes the extremal cross-section of the FS field-dependent. In addition, measurements of the specific heat show sharp anomalies at 48 K and 56 K, the former with a strong frequency dependence consistent with a sluggish first-order transition. Much less entropy is removed at the upper, second-order transition. All results will be presented and discussed along with comparisons drawn from impurity doped $Ca_3Ru_2O_7$. **G45 6 ARPES study on $Ca_{1.8}Sr_{0.2}RuO_4$** MADHAB NEUPANE, *Department of Physics,Boston College, MA* A.K.P. SHEKHRAN, Z.-H. PAN, J. -H. MA, H. DING, *Department of Physics,Boston College, MA* R. JIN, D. MANDRUS, *Condensed Matter Science Division, Oak Ridge National Laboratory, Tennessee* Owing to the discovery of triplet superconductivity in $Sr_2RuO_4$, much effort has been devoted in the past few years to the understanding of the $Ca_{2-x}Sr_xRuO_4$ family. These compounds exhibit a rich phase diagram which connects the p-wave superconductor $Sr_2RuO_4$ to the Mott insulator $Ca_2RuO_4$. Particularly, the x = 0.2 compound is at the boundary between a magnetic metal and a canted antiferomagnetic insulator. It has been suggested recently that this compound

has d−electron heavy−fermion behavior due to modulations in the magnetic correlations induced by the structural distortion. For such behavior, flat electronic b and s are expected. However,our angle resolved photo emission measurements observed only highly dispersive b and s.

**G45 7 Investigation of the Competition between Structural and Ferromagnetic Transitions in $GdRu_2$ using the Mossbauer Effect*** DERMOT COFFEY, MICHAEL DEMARCO, RYAN HEARY, *Dept. of Physics, Buffalo State College, NY 14222* PEI-CHUN HO, TODD SAYLES, M. BRIAN MAPLE, *Dept. of Physics, University of California, San Diego, CA 92093* STEVE TOORONGIAN, MICHAEL HAKA, *Nuclear Medicine Department, State University of New York at Buffalo, NY 14260* We use the $^{99}$Ru Mossbauer Effect(ME) to investigate magnetism in the Laves phase $Ce_{1-x}Gd_xRu_2$ series. This series of compounds is superconducting for small $x$ and has been thought to be ferromagnetic for large $x$ on the basis of extrapolations of Curie-Weiss fits to the $\chi$(T) data. We have studied the temperature dependence of the ME spectra for a number of these compounds and found no evidence of a hyperfine magnetic field due to ferromagnetic order. In $GdRu_2$, a Curie-Weiss fit to the $\chi$(T) data above 120K yields a Curie-Weiss temperature of 93K. However, at $\sim 120K$, $\chi^{-1}$ deviates from a straight line fit. The ME spectra show that there is a qualitative change in the environment of the Ru nucleus in this temperature re gion pointing to a structural phase transition. Below this transition the width of the ME spectrum grows with decreasing temperature by 50% between 100K and 4.2K. We analyze this temperature dependence in terms of a slowing down of the fluctuations of the local field due to Gd moments.

**G45 8 Evidence for high temperature orbital fluctuations in $La_4Ru_2O_{10}$** PETER KHALIFAH, *University of Massachusetts - Amherst* BRIAN SALES, DAVID MANDRUS, *Oak Ridge National Laboratory* QINGZHEN HUANG, *National Institute of Standards and Technology* RAYMOND OSBORN, *Argonne National Laboratory* STEPHEN NAGLER, MARK LUMSDEN, *Oak Ridge National Laboratory* CHRISTOPHER KENDIZORA, *Naval Research Laboratory* EMIL BOZIN, SIMON BILLINGE, *Michigan State University* ROBERT CAVA, *Princeton University* Among ruthenates, the compound $La_4Ru_2O_{10}$ is unique in having a complete orbital ordering transition. Upon cooling below $T_{OO}$ = 160K, the magnetism of this compound is abruptly quenched. Initial crystallographic studies of this phase [1] showed that strong distortions in the Ru-O bond lengths appear only below $T_{OO}$. We have found distinctly different thermal conductivities of single-crystal $La_4Ru_2O_{10}$ above and below $T_{OO}$. At high temperatures, this material unexpectedly behaved as a thermal glass, providing strong evidence for dynamic orbital fluctuations in $La_4Ru_2O_{10}$. This is supported by a detailed analysis of the atomic displacement parameters (ADPs) of this material. We will discuss our current model for orbital ordering in $La_4Ru_2O_{10}$, the differences in the local and average structure of this material, and the reasons for the strong magnetoelastic coupling in this phase. [1] P. Khalifah, R. Osborn, Q. Huang, H. W. Zandbergen, R. Jin, Y. Liu, D. Mandrus, and R. J. Cava. ''Orbital ordering transition in $La_4Ru_2O_{10}$,'' Science, **297**, 2237-40 (2002).

**G45 9 Magnetic Field Induced Phases of $Ca_2RuO_4$ and $Ca_3Ru_2O_7$** J. F. KARPUS, R. GUPTA, H. BARATH, S. L. COOPER, *Department of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois Urbana-Champaign* G. CAO, *Department of Physics and Astronomy, University of Kentucky* We present a Raman scattering study of the magnetic field induced phases in the layered ruthenates $Ca_2RuO_4$ and $Ca_3Ru_2O_7$. Single-layer $Ca_2RuO_4$ has an antiferromagnetic ground state, is a paramagnetic (PM) insulator above $T_N$ = 113 K and is a PM metal above $T_{MI}$ = 357 K, while double-layer $Ca_3Ru_2O_7$ has an antiferromagnetic insulating ground state, is metallic above $T_{MI}$ = 48 K, and is paramagnetic above $T_N$ = 56 K. Applied fields oriented in the a-b planes of both these materials produce dramatic changes to both the magnetic and vibrational spectra; these changes are associated with field-induced changes in the Ru orbital populations of these materials. In this talk, we compare the field induced orbital, magnetic, and conducting phases observed in $Ca_2RuO_4$ and $Ca_3Ru_2O_7$. *Work supported by NSF DMR02-44502, NSF DMR02-40813, and DOE DEFG02-91ER45439.

**9:48**

**G45 10 Crystal structure, electronic and magnetic properties of $SrRuO_3$ under epitaxial strain*** ALEXEY ZAYAK, KARIN RABE, *Rutgers University, 136 Frelinghuysen Rd., Piscataway 08854, New Jersey* XIANGYANG HUANG, *RJ Mears, LLC 1100 Winter Street, Suite 4700, Waltham, MA 02451* JEFFREY NEATON, *The Molecular Foundry, Material Science Devision, Lawrence Berkeley National Laboratory, Berkeley CA 94720* Using density functional theory, properties of $SrRuO_3$ have been investigated. We focused both on general properies of the orthorhombic distortion in $SrRuO_3$ and the effects of applying epitaxial constraints, whereby the influence of large in-plane strain resulting from coherent epitaxy have been isolated and investigated. The overall pattern of the structural relaxations revealed coherent distortions of the oxygen octahedra network which are sensitive to the magnetic order. The magnetic parameters exhibit substantial changes allowing us to discuss possibilities of magneto-structural tuning of the $SrRuO_3$-based thin film structures.

**G45 11 Spectroscopic Investigation on the Electronic Structure of $Sr_2MO_4$ (M=Ru, Rh, and Ir)** S.J. MOON, M.W. KIM, K.W. KIM, T.W. NOH, *ReCOE & School of Physics, Seoul National University, Seoul 151-747, Korea* J.-Y. KIM, *PAL, Postech, Pohang, Korea* J.-H. PARK, *Department of Physics & Electron Spin Science Center, Postech, Pohang, Korea* I. NAGAI, S.I. IKEDA, *NeRI & AIST, Tsukuba, Japan* G. CAO, *Deparment of Physics and Astronomy, University of Kentucky, Lexington, Kentucky 40506, USA* We investigated the intriguing metal-insulator transition and the electronic structure change of the layered perovskite $Sr_2MO_4$ (M=Ru, Rh, and Ir) by optical and O 1s x-ray absorption (XAS) spectroscopy. $Sr_2RuO_4$ (four 4d electrons) is a superconductor. $Sr_2RhO_4$ (five 4d electrons) is a poor metal. $Sr_2IrO_4$ (five 5d electrons) is a small gap insulator. All the compounds have similar crystal structures, yet their unoccupied d-bands show intriguing change as the M is changed from Ru to Rh, and to Ir. In this presentation, we will discuss the possible origin of the electronic structure change in terms of the change in

local structural deformation, Coulomb energy, electron occupation, and the orbital degeneracy by comparing the optical conductivity with XAS spectra. We will also suggest a possible link between the electronic structure change and the metal (Sr2RuO4)-insulator (Sr2IrO4) transition.

**10:12**
**G45 12 Metamagnetism and domain formation in $Sr_3Ru_2O_7$** ANDREW MACKENZIE, RODOLFO BORZI, SANTIAGO GRIGERA, ROBIN PERRY, *University of St Andrews* YOSHITERU MAENO, *Kyoto University* The bilayer perovskite $Sr_3Ru_2O_7$ offers the possibility of creating a quantum critical point by tuning the end-point of a line of first-order metamagnetic transitions towards zero temperature[1,2]. In the purest samples, with residual resistivity less than 1 $\mu\Omega$cm, the quantum critical point is not reached, due to a bifurcation of the original first-order phase transition, possibly associated with the formation of a new phase [3,4]. Here we present the results of new measurements which give strong evidence for the existence of magnetic domains throughout the region of the phase diagram enclosed by the bifurcated transition lines. The effect of these domains on the electrical resistivity can be controlled by varying the relative directions of current and the in-plane component of the applied magnetic field. [1] S.A. Grigera et al., Science Science **294**, 329 (2001). [2] S.A. Grigera et al. Phys. Rev. B **67**, 214427 (2003). [3] S.A. Grigera et al. Science **306**, 1155 (2004). [4] A.G. Green et al. Phys. Rev. Lett. **95**, 086402 (2005).

**G45 13 Magnetic domain formation in the itinerant metamagnetic transition of $Sr_4Ru_3O_{10}$** ZHIQIANG MAO, MENG ZHOU, JOE HOOPER, *Tulane University* MINGHUI YU, CHARLES O'CONNOR, *University of New Orleans* We have performed systematic investigation on the electronic transport properties of the triple-layered ruthenate $Sr_4Ru_3O_{10}$. We observed surprising anomalous features near its itinerant metamagnetic transition, including ultrasharp magnetoresistivity steps and a non-metallic temperature dependence in resistivity for upward field sweeps. These features suggest that the metamagnetic transition of $Sr_4Ru_3O_{10}$ occurs via a phase separation process with magnetic domain formation. We have also identified the phase separated regime in the magnetic field-temperature phase diagram.

**10:36**
**G45 14 Modification of the Fermi Surface of a Ferromagnetic Metal at a Metamagnetic Transition: Shubnikov de Haas Effect in High Quality Single Crystals of $Sr_4Ru_3O_{10}$** YOUNJUNG JO, LUIS BALICAS, *National High Magnetic Field Lab* NAOKI KIKUGAWA, *School of Physics and Astronomy, University of St. Andrews, St. Andrews, Fife KY16 9SS, United Kingdom* KEVIN STORR, *Department of Physics, Prairie View A&M University, Prairie View, Texas 77446-0519, USA* ANDREW MACKENZIE, *School of Physics and Astronomy, University of St. Andrews, St. Andrews, Fife KY16 9SS, United Kingdom* ZHIQIANG MAO, *Department of Physics, Tulane University, New Orleans, Louisiana 70118, USA* We performed a detailed electrical transport study at low temperatures and high magnetic fields in high quality single crystals of the tri-layered ferromagnetic metal $Sr_4Ru_3O_{10}$. We observed Shubnikov de Haas oscillations for several frequencies. The most prominent orbits have two-dimensional character and display frequencies $F_\alpha = 9959$ T, $F_\beta = 3949$ T, $F_\gamma = 1877$ T corresponding respectively to 73.5, 29.2 and 13.9% of the area of the orthorhombic first Brillouin zone (FBZ). Several additional orbits, mostly with frequencies below 2 kT have also been identified, whose spectral weight and frequencies are shifted by a metamagnetic transition induced by an in-plane field component.

## SESSION G46: QHE, INCLUDING GRAPHENE

**G46 1 Edge States in Graphene*** NIKOLAI SINITSYN, *Department of Physics, The University of Texas, Austin* JASON HILL, HONGKI MIN, ALLAN H. MACDONALD, *Department of Physics, The University of Texas, Austin* We investigate edge states in graphene subject to both realistically described spin-orbit coupling and an external magnetic field. Localized edge states are responsible for the charge and spin transport when the electron chemical potential is in a gap of the bulk spectrum. We derive expressions for the edge state energy dispersions and wave functions both analytically and numerically and discuss specific features that distinguish them from conventional edge states due to magnetic field in electron gas. Finally we discuss the relationship between edge state characteristics and both spin and charge response functions.

**8:12**
**G46 2 Quantum Hall effect and edge states in graphene.** LUIS BREY, *CSIC-Madrid* The experimentally observed quantum Hall effect (QHE) in graphene has renewed the interest in the study of multivalley semiconductors in high magnetic fields. In this work we study some properties of graphene in presence of a high magnetic field. 1) We discuss the form of the quantization of the Hall conductivity. We argue that the Hall conductance can be understood in the general framework of the theory of the QHE in two-dimensional systems. 2) We study the properties of undoped graphene in the QHE regime. We find that the Zeeman coupling combined with the electron-electron interaction favors a spin-polarized ground state against a valley-polarized state. This ground state support low energy collective excitations that are combinations of spin and valley density waves. We discuss the possibility that spin texture excitations, Skyrmions, become the low energy charged excitations in the spin-polarized ground state. 3) Finally we analyze the properties of the edge states in the QHE regime. Due to the valley degeneracy occurring in graphene, electron-like and hole-like Landau levels with different spin and valley orientation cross at the edge of the sample. In the undoped samples Coulomb interaction produces repulsion between the states and forces the states to anti-cross, creating a valley and spin coherent stripe at the edge of the sample. We analyze the excitations occurring in this stripe and discuss their possible relevance in tunnelling experiments.

**G46 3 Quantum Hall Effect in Graphene*** ANTONIO H. CASTRO NETO, *Department of Physics, Boston University* FRANCISCO GUINEA, *Instituto de Ciencia de Materiales de Madrid, Spain* NUNO M.R. PERES, *Universidade do Minho, Portugal* We study the integer and fractional quantum Hall effect on a honeycomb lattice at half-filling (graphene) in the presence of disorder and electron-electron interactions. We show that the interactions between the delocalized chiral edge states (generated by the magnetic field) and Anderson-localized surface states (created by the presence of zig-zag edges) lead to edge reconstruction. As a consequence, the point contact tunneling on a graphene edge has a non-universal tunneling exponent, and the Hall conductivity is not perfectly quantized in units of $e^2/h$. We argue that the magneto-transport properties of graphene depend strongly on the strength of electron-electron interactions, the amount of disorder, and the details of the edges.

**G46 4 Band Collapse as Route to Odd-Integer Quantum Hall Effect In Graphene** B. ANDREI BERNEVIG, TAYLOR HUGHES, HANDONG CHEN, CONGJUN WU, SHOUCHENG ZHANG, *Stanford University* STANFORD/SPINAPPS TEAM, The recent Quantum Hall experiments in graphene have confirmed the theoretically well-understood picture of the quantum Hall (QH) conductance in fermion systems with continuum Dirac spectrum. In this paper we take into account the lattice, and perform an exact diagonalization of the Landau problem on the hexagonal lattice. At very large magnetic fields the Dirac argument fails completely and the Hall conductance, given by the number of edgestates present in the gaps of our spectrum, is dominated by lattice effects. As the field is lowered, the experimentally observed situation is recovered through a phenomenon which we call band collapse. As a corollary, for low magnetic field, graphene will exhibit two qualitatively different QHE's: at low filling, the QHE will be dominated by the ''relativistic'' Dirac spectrum and the Hall conductance will be odd-integer; above a certain filling, the QHE will be dominated by a non-relativistic spectrum, and the Hall conductance will span all integers, even and odd.

**G46 5 Quantum Hall Ferromagnetism in Graphene** ALLAN H. MACDONALD, JASON HILL, HONGKI MIN, NIKOLAI SINITSYN, *Department of Physics, The University of Texas, Austin* In a magnetic field non-interacting electrons with the graphene band structure have four nearly degenerate Landau levels close to the intrinsic Fermi level. The four levels are associated with different spin states and with the two different sites in the honeycomb lattice unit cell. In a single-particle theory weak spin-orbit coupling and Zeeman fields split the four levels by an amount that is small compared to the electronic self-energy. We discuss the quantum Hall effect in graphene using at integer filling factors $\nu = -1$, $\nu = 0$, and $\nu = 1$ in a picture where the ground state is a broken symmetry SU(4) ferromagnet and these weak single-particle terms act as symmetry breaking external fields. We also discuss the consequences of the difference in interaction strength beteween electrons on the same and different sublattice and sample quality criteria necessary to realize quantum Hall ferromagnetism in graphene.

**G46 6 Local defects and ferromagnetic interactions in 2D graphite*** M.P. LÓPEZ-SANCHO, *Ins. Ciencia de Materiales de Madrid (CSIC) Cantoblanco 28049-Madrid* M.A.H. VOZMEDIANO, *Unidad ASociada CSIC-UC3M E28911 Leganés Madrid* F. GUINEA, *Inst de Ciencia de Materiales de Madrid (CSIC) Cantoblanco 28049 MADRID* Recent experiments have shown unexpected properties in carbon-based materials. Ferromagnetic behavior enhanced by proton bombardment has been reported in graphite and, more recently, quantum Hall effect has been experimentally observed in graphene sheets. These results suggest that electronic correlations play an important role in these materials. The anomalous electronic and transport properties reported by the experiments agree with theoretical predictions of 2D models considering only $\pi$-electrons. The vanishing of the density of states at the Fermi energy and the absence of a true Fermi surface have important consequences in the electronic behavior of 2D graphite. Although at present there is not a microscopic explanation of the graphite ferromagnetic properties, they seem to be related to topological defects, as pointed out by AFM measurements. In this work we show that lattice defects and vacancies in the graphene structure give rise to localized states at the Fermi energy. Repulsive electron-electron interactions lead to the formation of local moments by polarization of local states. Due to the lack of a Fermi surface the RKKY-like interaction does not have oscillations instead it decays as $r^{-3}$, where $r$ is the distance between defects. The interaction is then ferromagnetic.

**G46 7 Disorder and the integer quantum Hall plateau-to-plateau transition** WANLI LI, D.C. TSUI, *Princeton University* J.S. XIA, *University of Florida and NHMFL* L.N. PFEIFFER, K.W. WEST, *Bell Labs* We have studied the temperature scaling of integer quantum Hall plateau-to-plateau transition in various disordered systems down to 10mK. The samples are $Al_xGa_{1-x}As$-$Al_{0.33}Ga_{0.67}As$ heterostructures with different Al concentration $x$. Previous work has shown a perfect power law $(dR_{xy}/dB)|_{Bc} \propto T^{-\kappa}$ with $\kappa=0.42$ over two decades of temperatures in the sample with $x=0.85\%$. In the sample of $x=0$, $\kappa=0.58$ was observed at high temperatures, while we have now found $\kappa=0.42$ restored below a crossover temperature $T_c=120$mK. $T_c$ increases to 250mK for $x=0.21\%$, and is not observable in the experimental temperature range in the sample of $x=0.85\%$. We propose that the quantum phase coherence length exceeds the disorder correlation length below $T_c$, shifting the nature of the disorder in the system from long-ranged to short-ranged. On the other end of the sample series with $x=4.1\%$, where alloy clustering is believed to be significant, $\kappa=0.58$ is found to persist down to the lowest temperature of the measurement limit, suggesting a different universal class of the transition in long-range disordered systems.

**G46 8 Resistively-Detected NMR in a 2DES near $\nu = 1$: Clues to the Origin of the Dispersive Lineshape** J.P. EISENSTEIN, L.A. TRACY, *Caltech* L.N. PFEIFFER, K.W. WEST, *Bell Labs* Resistively-detected NMR (RDNMR) measurements on 2D electron systems near the $\nu = 1$ quantum Hall state are reported. In agreement with previous RDNMR studies, we observe a dispersive lineshape, where $R_{XX}$ vs. frequency shows both negative and positive excursions from the equilibrium $R_{XX}$ value. However, in

contrast to recent results of Gervais, et al. [Phys. Rev. Lett. 94, 196803 (2005)], this dispersive lineshape is found at all RF powers, and a conventional, Korringa temperature dependence ($T_1T = const$) of the nuclear spin- lattice relaxation rate is observed. The shape of the unexplained dispersive lineshape is found to invert when then temperature derivative of the longitudinal resistance changes sign. This suggests that both Zeeman and thermal effects are important to RDNMR in this regime.

**9:36**

**G46 9 Anisotropic Electronic Transport in a Two-dimensional Hole System under a Tilted Magnetic Field** ZHIGANG JIANG, *Dept. of Physics, Columbia Univ. and National High Magnetic Field Lab* M.J. MANFRA, *Bell Labs, Lucent Technologies* Y.-W. TAN, H.L. STORMER, *Dept. of Physics, Columbia Univ.* D.C. TSUI, *Dept. of Electrical Engineering, Princeton Univ.* L.N. PFEIFFER, K.W. WEST, *Bell Labs, Lucent Technologies* We study the electrical transport properties of a high mobility two-dimensional hole system (2DHS) confined in a GaAs/AlGaAs quantum well grown on the (100) surface of GaAs. We observed a remarkable magnetotransport anisotropy in the $N = 1$ Landau level, different from the two-dimensional electron gas (2DEG), in which the anisotropy shows exclusively in the higher Landau levels ($N \geq 2$). Under a tilted magnetic field, we find that the anisotropy can be either reduced or enhanced by the in- plane magnetic field, depending on the direction of the field with respect to the lattice orientation of the sample. This behavior is again different from the previous reported results in 2DEG, where we expect the anisotropy will collapse precipitously as applying a much smaller in-plane magnetic field than what we have applied on the 2DHS. Particularly, at high tilting angles, we observed a ''spike'' like feature developed in the magnetoresistance ($R_{xx}$) at the filling factor $2 < \nu \leq 5/2$. However, unlike the resistance spike features associated with the first order magnetic transition between quantum Hall ferromagnets, no correlated spike has been observed in the Hall resistance ($R_{xy}$) of our sample.

**9:48**

**G46 10 Evidence for reentrant striped phases in a two-dimensional hole system** MICHAEL MANFRA, *Bell Laboratories* Z. JIANG, *NHMFL* HORST STORMER, *Dept. of Physics, Columbia University* D. C. TSUI, *Princeton University* LOREN PFEIFFER, K. W. WEST, A. M. SERGENT, *Bell Laboratories, Lucent Technologies* Anisotropic transport is observed at low temperatures in the N=1 and N=2 Landau levels of a very clean two-dimensional (2D) hole system. At $\nu = 7/2$ and $\nu = 11/2$, the longitudinal magnetoresistance develops strong anisotropies which depend on the direction of current flow and temperature. Interestingly, the transport at $\nu=9/2$ is *isotropic* for all temperatures. Our results for a two-dimensional hole system contrast sharply with 2D electron transport where no anisotropy has been observed in the N=1 Landau level, the strongest anisotropy occurs at $\nu=9/2$, and no reentrant behavior is evident.

**10:00**

**G46 11 Spin Transition in a 2DES at $\nu = 1/2$** L.A. TRACY, J.P. EISENSTEIN, *Caltech* L.N. PFEIFFER, K.W. WEST, *Bell Labs* The transition from partial to complete electron spin polarization as a function of density in a 2DES at $\nu = 1/2$ has been probed using a resistively-detected NMR (RDNMR) technique. Both the nuclear spin lattice relaxation time $T_1$ of $^{71}$Ga and the response in resistance to a change in the nuclear spin polarization appear to reflect this transition. At low densities, where the electron spin polarization is partial, the $T_1$ time is relatively short, due to the presence of both electron spin states at the Fermi level. In this regime $T_1$ is density independent and has a Korringa-like temperature dependence. Above a critical density $T_1$ increases and the RDNMR signal eventually vanishes, consistent with a transition to complete electron spin polarization. In the transition region we observe a non- Korringa $T_1$ temperature dependence and an unexpected enhancement of the RDNMR signal.

**10:12**

**G46 12 Spin polarization at fractional filling factors** JAVIER GROSHAUS,*P. PLOCHOCKA, M. RAPPAPORT, I. BAR-JOSEPH, *Weizmann Inst.* B. DENNIS, L. PFEIFFER, K. WEST, *Bell Labs* A. PINCZUK, *Columbia U. & Bell Labs* We measure the spin polarization of a two-dimensional electron system (2DES) in the Quantum Hall regime by photocurrent interband absorption spectroscopy. The sample is a single GaAs quantum well that is placed in a dilution fridge with optical windows at low temperatures down to 70 mK. The 2DES density is tuned by a back-gate. We illuminate with circularly polarized light. This allows us to discriminate optical transitions into each electronic spin level. We show that the spectra consist of many-body electron-hole complexes. The lowest in energy is a singlet trion-like transition *T* (J.G. Groshaus *et.al.*, *Phys. Rev. Lett.* **93**, 96802, 2004). In the *T*-absorption process, the photocreated electron- hole pair binds to an electron from the 2DES with spin that is opposite to that of the photocreated one. We model this process taking into account correlations and phase space considerations. Using this model and measurements of the *T*-absorption, we obtain the spin polarization of the 2DES. We find that at $\nu = 1/3$ the 2DES is fully polarized. As $\nu$ is increased there is loss of spin polarization. Around $\nu = 2/3$ the 2DES is half polarized. At this $\nu$, the 2DES remains half polarized for the relatively wide range of magnetic fields of 2 Tesla. This points to the existence of spatial magnetic domains, as proposed by G. Murthy (*Phys. Rev. Lett.* **84**, 350, 2000).

*Also Bell Labs.

**10:24**

**G46 13 Small length-scale probes of 2D electron conduction and correlations.** ROBERT WILLETT, KEN WEST, LOREN PFEIFFER, *Bell Laboratories, Lucent Technologies* An important approach to revealing correlation effects in high mobility 2D electron systems is through conduction measurements, and this is particularly true when a conduction measurement can be applied over small length-scales. Relevant but attainable significant length-scales include composite fermion mean-free-paths for the various composite particle constructions throughout the magnetic field spectrum. These length-scales are dependent upon the sample quality such that higher mobilities will typically allow a larger conductance probe to examine the correlation effects. The specific correlations will present different length-scales: composite fermion mean-free-path at filling factor 1/2 is substantially larger than the mean-free-path of the 5/2 state precursor particle at high temperatures. We will present here various probes recently used to try to access these small length scale effects. The various techniques will be reviewed and the complicating factors for these probes will be discussed, in addition to prospects for improved examination of relative small correlation energy states.

**10:36**
**G46 14 High Frequency Magneto Oscillations in low Electron Density GaAs/AlGaAs Quantum Wells** Y.-W. TAN, *Phys. Dept., Columbia Univ.* H. L. STORMER, *Phys. Dept., Appl. Phys. and Math. Dept., Columbia Univ., and Bell Labs* L. N. PFEIFFER, K. W. WEST, *Bell Labs* We have observed exceptional magneto oscillations in modulation doped GaAs/AlGaAs quantum well structures with low (10%) Al barriers. These reproducible, rapid oscillations appear in our low density samples ($n \sim 6.5 \times 10^{10}/cm^2$) after standard illumination and are robust against thermal cycling. They are periodic in itinverse magnetic field (1/B) and the amplitude increases with temperature up to $\sim 600mK$. With increasing temperature, these oscillations shift from the $\nu \sim 1/2$ range towards the $\nu \sim 1/3$ range of the underlying, low density 2DES. Some aspects are reminiscent of recent work by G. A. Csáthy et al. (PRL, **92**, 256804(2004)) Under tilt, these oscillations follow the standard $\cos\theta$ behavior of a 2D system. The period, if naively translates into density, yields $1.4 \times 10^{13}/cm^2$, which significantly outnumbers all countable carriers in the device. A backside gate affects the QHE in the 2DES as well as the rapid oscillations, although the density shifts for the latter are highly incompatible with dimensions and screening considerations.

**10:48**
**G46 15 Linear magnetoresistance in a high quality two-dimensional electron system** W. PAN, *Sandia National Labs* H.L. STORMER, *Columbia University and Bell Labs, Lucent Technologies* D.C. TSUI, *Princeeton University* L.N. PFEIFFER, K.W. BALDWIN, K.W. WEST, *Bell Labs, Lucent Technologies* In a high quality two-dimensional electron system of density $n \sim 1 \times 10^{11}$ cm$^{-2}$ and mobility $\mu \sim 10 \times 10^6$ cm$^2$/Vs, at the temperature ($T$) of 1.2K, the diagonal magnetoresistance, $R_{xx}$, shows a strictly linear magnetic ($B$) field dependence, except for sharp spikes at $B$- fields where the integer quantum Hall effect develops. As $T$ is lowered to $\sim$ 35 mK, the main feature of $R_{xx}$ is now dominated by multiple minima and peaks, due to the formation of integer and fractional quantum Hall states. However, when plotting $R_{xx}$ at the even-denominator fillings ($\nu = 1/4$, 1/2, 3/4, and 3/2) as a function of $B$ field, the same linear $B$ field dependence is recovered. Interestingly, this linear magnetoresistance cannot be understood under the composite fermion model. Rather, it can be explained in terms of a slight, unintentional electron density gradient in our sample: Practically all $R_{xx}$ features can be reproduced quantitatively through $R_{xy}$. We will discuss the implications of this finding.

**H1 1 Recent progress in trapped-ion quantum information processing.***
RAINER BLATT, *University of Innsbruck*

Trapped strings of cold ions provide an ideal system for quantum information processing. The quantum information can be stored in individual ions and these qubits can be individually prepared, the corresponding quantum states can be manipulated and measured with nearly 100% detection efficiency. With a small ion-trap quantum computer based on two and three trapped Ca+ ions as qubits we have generated in a pre-programmed way genuine quantum states. These states are of particular interest for the implementation of an ion quantum register: we have demonstrated selective read-out of single qubits and manipulation of single qubits of the register conditioned on the read-out results. Moreover, entangled states of up to eight particles were generated using an algorithmic procedure and the resulting states were analyzed using state tomography proving genuine multi-partite entanglement. With a new cavity QED setup we create an ion-qubit to photon-qubit interface for interconnecting ion-trap based quantum computers. With this device a source of deterministically generated single photons can be built and atom-photon entanglement can be investigated.

**11:51**
**H1 2 Quantum optics and quantum information processing with solid state systems.**
YOSHIHISA YAMAMOTO

A single semiconductor quantum dot embedded in a monolithic microcavity with a large spontaneous emission enhancement (Purcell) factor is capable of producing identical single photons on demand. Those single photons realize a multi-particle interference effect as quantum mechanically indistinguishable particles. Various quantum phenomena, such as violation of Bell's inequality and quantum teleportation, can be demonstrated with only such single photons and linear optics. An important challenge for quantum information system applications is to replace a man-made quantum dot by a natural substitutional donor impurity with suppressed inhomogeneous linewidth and electron/nuclear spin capability. In this talk we will discuss the recent experimental progress on this new quantum dot system.

**12:27**
**H1 3 Direct Observation of Atomic Number Squeezing in a Degenerate Bose Gas.**
MARK RAIZEN, *The University of Texas at Austin*

I will discuss recent work in my group on many-body quantum control towards the creation of atomic Fock states. In our rubidium experiment, a single Bose-Einstein condensate is optically trapped in crossed TEM01 modes, and we achieve confinement in two dimensions that is comparable to an optical lattice, but with single-atom addressability and detection. Using this system we have directly observed sub-Poissonian atom number statistics for a degenerate Bose gas with numbers as small as 20 atoms. The number squeezing was produced by starting with a Bose-Einstein condensate in an optical box trap and slowly lowering the walls in one dimension, a process we call quantum evaporation. The final atom number is determined by the energy of the N-body state in the box and can be precisely controlled. The observed squeezing is nearly a factor of two below the Poissonian (shot noise) limit. More importantly, known sources of noise can account for the residual fluctuations, so our results are consistent with the production of N-body Fock states. I will discuss the current limit to Fock state creation for even smaller numbers which we believe is due to many-body quantum tunneling. This effect can be controlled by the use of carefully tailored optical potentials and experiments are in progress. I will also discuss applications of our system to quantum computing and to the study of quantum critical phenomena.

**13:03**
**H1 4 General properties of Nonsignaling Theories.***
NICOLAS GISIN, *Geneva University*

We present a series of properties, usually associated to quantum physics, and show that they are common to all theories that do not allow for superluminal signalling and predict violation of Bell inequalities. These include intrinsic randomness, no cloning, monogamy of correlations, uncertainty relations, privacy of correlations, bounds on the shareability of some states. Finally, we emphasize that correlation data must violate some Bell inequality in order to contain distillable secrecy and introduce a new QKD protocol and prove its security against any individual attack by an adversary only limited by the no-signalling condition.

**H1 5 Quantum control and robust quantum information.**
BIRGITTA WHALEY, *Department of Chemistry, University of California, Berkeley*

Controlling the time evolution of quantum states and quantum logic operations in an optimal manner gives rise to various desiderata depending on the physical constraints. In addition to fidelity optimization with respect to systematic and environmental errors, there may be requirements to optimize with respect to time or energy. We describe several approaches to control of logic operations on quantum bits that illustrate these different aspects, including both analytic and numerical tools. Applications are made to high fidelity quantum operations on solid state quantum bits.

## SESSION H2: SPIN LIQUIDS IN 2D FRUSTRATED QUANTUM MAGNETS

**H2 1 Phase diagram of the 2D frustrated quantum magnet $Cs_2CuCl_4$ in applied field.**
RADU COLDEA, *University of Bristol, UK*

We use neutron scattering, magnetization and specific heat to probe how the ground state of the 2D spin-1/2 anisotropic triangular lattice antiferromagnet $Cs_2CuCl_4$ evolves as a function of applied magnetic field. We observe that the zero-field incommensurate spin spiral is suppressed by relatively small in-plane fields giving way to a commensurate 2D antiferromagnetic pattern stable over most of the intermediate field region, with incommensurate order appearing again for a narrow field range just below ferromagnetic saturation. The commensurate phase is not captured by a classical mean-field approach, suggesting that quantum fluctuations may be important in stabilizing this type of order.

**11:51**
**H2 2 Algebraic vortex liquid in spin-1/2 triangular antiferromagnets: Scenario for $Cs_2CuCl_4$.**
JASON ALICEA, *University of California, Santa Barbara*

Motivated by inelastic neutron scattering data on $Cs_2CuCl_4$, we explore spin-1/2 triangular lattice antiferromagnets with both spatial and easy-plane exchange anisotropies, the latter due to an observed Dzyaloshinskii-Moriya interaction. Exploiting a duality mapping followed by a fermionization of the dual vortex degrees of freedom, we find a novel ''critical'' spin-liquid phase described in terms of Dirac fermions with an emergent global SU(4) symmetry minimally coupled to a non-compact U(1) gauge field. This ''algebraic vortex liquid'' supports gapless spin excitations and universal power-law correlations in the dynamical spin structure factor which are consistent with those observed in $Cs_2CuCl_4$. We suggest future neutron scattering experiments that should help distinguish between the algebraic vortex liquid and other spin liquids and quantum critical points previously proposed in the context of $Cs_2CuCl_4$.

**12:27**
**H2 3 Spin liquid and Mott transition in organics with triangular lattice.**
KAZUSHI KANODA, *Department of Applied Physics, University of Tokyo*

The layered organics, k-(ET)2X, are model systems for the study of strongly correlated half-filled-band electrons. The Mott insulator k-(ET)2Cu2(CN)3 has a nearly isotropic triangular lattice and is a model system of frustrated quantum spins. The 1H and 13C NMR experiments show no indication of magnetic ordering down to 30 mK in spite of an exchange interaction of 250 K deduced from the susceptibility analysis. The spins are in the quantum liquid state. Under magnetic fields, an anomalous inhomogeneous spin state appears. Under pressure, it undergoes Mott transition to a Fermi liquid which shows superconductivity at low temperatures. The phase diagram and the nature of the superconductivity emerging from the spin liquid are also discussed.

**13:03**
**H2 4 Spinon Fermi sea state as a candidate spin liquid in $\kappa$-$(ET)_2Cu_2(CN)_3$.**
OLEXEI MOTRUNICH, *Kavli Institute for Theoretical Physics, University of California-Santa Barbara*

Experimental studies of the quasi-two-dimensional organic compound $\kappa$-$(ET)_2Cu_2(CN)_3$ strongly suggest a spin liquid state in the insulating phase at ambient pressure. This material is modelled as a half-filled triangular lattice Hubbard system close to the Mott transition. By applying trial wave function approach to an effective spin Hamiltonian with significant ring exchanges, it is proposed that a spin liquid state with spinon Fermi surface is realized in this system. Properties of this state are reviewed and compared with experiments. Further experiments find that an inhomogeneous spin state is induced by strong magnetic field. It is argued that the origin of this anomalous response is magneto-orbital effects, whereby spinons see significant orbital field and have strong back action on the internal gauge field. The spin liquid ground state itself is readjusting in the magnetic field, possibly in a discontinuous manner in an ideal system; this persists in a broad temperature range and may be responsible for the inhomogenuous state in the real system.

**13:39**
**H2 5 Spin excitations in frustrated Kagomé lattice systems.**
YOUNG LEE, *MIT, Department of Physics*

We present experimental results on the behavior of interacting spins on the two-dimensional frustrated Kagomé lattice. Basic concepts of geometrical frustration will be reviewed, and measurements on single crystal and powder samples of ideal Kagomé systems (both classical and quantum) will be described. For a system with S=5/2, our inelastic neutron scattering measurements of the spin wave excitations reveal a novel ''flat mode'' which is a direct consequence of the high degree of frustration. We observe interesting behavior related to spin chirality (both vector and scalar). Recently, we have performed measurements on a material with spin-1/2 ions in an ideal Kagomé lattice arrangement. We discuss our results in relation to the excitations proposed for novel quantum spin liquid states.

**H3 1 A few Landau-Levich films.**
DAVID QUERE, *College de France*

We describe a few situations which produce a Landau-Levich films, such as the withdrawal of a solid plate out of a bath of wetting liquid or the air withdrawal by a jet plunging in a bath of liquid. We show why such antagonist situations can be described by similar arguments. We also discuss the shape and the stability of the film, and the way it bursts, in particular when it is surrounded by a viscous environment. Other contributors to this work: Etienne Reyssat, Jens Eggers and Elise Lorenceau

**11:51**
**H3 2 Humps, Spouts & Tendrils: Topological Transition Driven by Viscous Flow.**
WENDY ZHANG, *University of Chicago*

Viscous flows with large-scale spatial gradients can create small-scale structure on a steady-state interface separating two liquids. Here we focus on how an axisymmetric large-scale withdrawal flow in one liquid can break the interface between two liquids and thereby entrain a second liquid. Above the entrainment transition, thin spouts or tendrils of entrained liquid that persist over time form. Below the entrainment transition, the interface is deflected upwards by the flow and can form a hump with a strongly curved tip. To understand what mechanism allows a large-scale withdrawal flow to create small-scale feature on an initially flat interface, we analyze two simple scenarios. First, we consider the hump formed on an interface separating immiscible liquids. As the entrainment transition is approached from below, the minimum radius of curvature at the hump tip is determined by the maximum interface deflection height. Second, we consider the steady-state tendril formed on an interface between two miscible liquids. Again, the tendril radius is determined by the zero-entrainment deflection height of the interface.

**12:27**
**H3 3 Surfactant mass transfer effects on drop detachment.***
KATHLEEN STEBE, *Chemical and Biomolecular Engineering Department, Johns Hopkins University*

When a buoyant viscous drop is injected into a viscous fluid, it evolves to form a distended shape that detaches via the rapid formation and pinching of a neck. The effects of surfactants in altering this process are studied numerically. In the absence of surfactants, surface contraction is fastest in the vicinity of the neck. When surfactants are present, they accumulate there and alter the ensuing dynamics by reducing the surface tension that drives the contraction. When surfactant adsorption-desorption is very slow, interfaces dilute significantly during drop expansion, and drops form necks which are only slightly perturbed in their dynamics from the surfactant-free case. When adsorption-desorption dynamics are comparable to rate of expansion, a family of drop necks are predicted. Drops break at the primary neck at low surfactant coverage, at both the primary and secondary necks at moderate coverages, only at the secondary neck at higher coverages, or fail to neck at elevated coverages. When adsorption-desorption kinetics are rapid, the surface remains in equilibrium with the surrounding solution, and drops break like surfactant-free drops with a uniform surface tension. A map of neck/no-neck thresholds is constructed as a function of surfactant coverage and sorption dynamics, suggesting that drop detachment can be used as a means of characterizing surfactant dynamics. **H3 4 Bubble microstreaming: Force focusing on lipid membranes.**
SASCHA HILGENFELDT, *ESAM and Mechanical Engineering, Northwestern University*

Ultrasound-driven oscillating microbubbles at container walls excite steady streaming flows of surprising speed that can be directed and controlled by patterning of the substrate. This new kind of microfluidics is simple to set up and does not need microchannels to guide flow transport. Hydrodynamic forces are locally focused around the oscillating bubbles and can be used to deform and rupture soft objects, such as the lipid membranes of vesicles and cells. We demonstrate these processes in experiment and quantify the stress exerted onto soft objects in the flow, investigating small and large deformations. We point out applications in bio-MEMS and biomedical studies of cellular response to hydrodynamic stimuli.

**H4 1 The Physics Force- Physics for ages 6 to 106.**
E. DAN DAHLBERG, *University of Minnesota, School of Physics and Astronomy, Minneapolis, MN 55455*

The Physics Force is a very successful and entertaining outreach program of the Institute of Technology in the University of Minnesota developed to make science exciting and fun for students of all ages, from 6 to 106. Although all attendees, including high school and college students and guests from retirement homes, praise our performances, the primary focus is on K-6 students. The original Force consists of six k-12 teachers, Hank Ryan, Jon Barber, Jack Netland, Fred Orsted, Aaron Pinski, and Jay Dornfeld and Dan Dahlberg of the University of Minnesota Physics Department. The Force performed variations of The Physics Circus, our most popular show, at Disney's Epcot Center, parts of it were shown on Newton's Apple and several of us have performed demonstrations on the Knoff-Hoff Show, a very successful German T.V. science program. The goal of The Physics Force is to show students and the public **Science is Fun, Science is Interesting, and Science is Understandable**. By all measures we have available, we are extremely successful in reaching our goals. In the last three year cycle of our University support almost 100,000 residents of Minnesota (or about 2% of the total population) saw a Physics Force performance; it appears we will surpass those numbers in the present cycle.

**H4 2 The Science of Optics; The History of Art.***
CHARLES FALCO, *University of Arizona*

Recently, renowned artist David Hockney observed that certain drawings and paintings from as early as the Renaissance seemed almost ''photographic'' in detail. Following an extensive visual investigation of western art of the past 1000 years, he made the revolutionary claim that artists even of the prominence of van Eyck and Bellini must have used optical aids. However, many art historians insisted there was no supporting evidence for such a remarkable assertion. I will show a wealth of optical evidence for his claim that Hockney and I subsequently discovered during an unusual, and remarkably productive, collaboration between an artist and a scientist. I also will discuss some of the implications this work has for the history of science as well as the history of art. These discoveries convincingly demonstrate optical instruments were in use – by artists, not scientists – nearly 200 years earlier than commonly thought possible, and account for the remarkable transformation in the reality of portraits that occurred early in the 15th century. http://www.optics.arizona.edu/ssd/FAQ.html.

*This work done in collaboration with David Hockney.

**H4 3 Science as Performance: A Proactive Strategy to Communicate and Educate Through Theater, Music and Dance.***
BRIAN SCHWARTZ, *The Graduate Center of the City University of New York*

Theater, music, dance, the literary and the visual arts can convey the joys and controversies of science. We describe a program at the Graduate Center entitled Science as Performance which is designed to communicate to the public the excitement and wonder of science, technology, engineering and mathematics. Over the past few years there have been major successes in communicating science to the public through the arts. This is especially evident in theater and film with such recent plays as Copenhagen and the Oscar winning film A Beautiful Mind. The performance series Science and the Arts has been developed and tested at the Graduate Center of the City University of New York (CUNY) in mid-Manhattan for more than four years, see http://web.gc.cuny.edu/sciart/. We have developed working relationships with actors, playwrights, dancers, choreographers, musicians, composers, artists and scientists who work at the intersection of science and the arts. In this presentation we will illustrate many of our collaborations in theater, dance, music and art. The response to the series has shown that the arts can make the sciences accessible, relevant, and exciting to diverse

audiences in ways that provide both scientific content and significant artistic and entertainment values. The National Science Foundation has awarded a grant to the Graduate Center to help replicate similar Science and the Arts programs on other campuses by involving both their science departments and their performing arts departments. Some results of campus visits will be described. The author will also describe his involvement with producing two musical versions of a play, Einsteins Dreams based on the novel by Alan Lightman. One production opened at the Teatro da Trindade in Lisbon, Portugal at on October 21, 2005 for a four month run and a second and different production opens at the Prince Music Theater in Philadelphia in March 2006.

**H4 4 Entropically Driven Helix Formation.**
YEHUDA SNIR, *University of Pennsylvania*

We model the folding of helices via the depletion interaction between a semi-flexible tube and hard spheres. We find that the lowest-entropy geometry of the tube depends on both the concentration and size of the spheres. In the limit of small spheres, the helix becomes optimally tight, that is, maximally thick for a fixed length. We discuss this effect when both the tube and spheres are confined in a cylinder, as a model of the ribosomal channel. The depletion interaction alone forces the tube to lie against the wall, as opposed to the tight helix. Hydrophobicity and electrostatics can stabilize the compact tube and we estimate the strength of these effects necessary to favor a tight helix.

**13:39**
**H4 5 Phase Behavior, Structure, and Assembly of Microsphere-Nanoparticle Mixtures.**
JENNIFER LEWIS, *University of Illinois*

The phase behavior, structure, and assembly of microsphere-nanoparticle mixtures have been investigated. A new mechanism for regulating the stability of colloidal particles, known as nanoparticle haloing, has been identified in binary mixtures that possess both high charge and size asymmetry. Negligibly charged colloidal microspheres, which flocculate when suspended alone in aqueous solution, undergo a remarkable stabilizing transition upon the addition of critical volume fraction of highly charged nanoparticle species. Using confocal microscopy, we have characterized the structural evolution of colloidal phases formed during sedimentation on patterned and non-patterned substrates as a function of varying composition. Through nanoparticle engineering, we have created robust colloidal crystals that can be harvested from solution without introducing drying related defects as well as colloidal gels whose structure and rheological properties vary dramatically.

## SESSION H5: FORUM: WHAT HAS ACTUALLY CHANGED IN PHYSICS DEPARTMENTS IN THE SITUATION FOR WOMEN, GRADUATE STUDENTS AND OTHER PEOPLE?

**Tuesday Morning, 14 March 2006; 309, Baltimore Convention Center at 11:15**
**Anthony Nero, Lawrence Berkeley National Laboratory, presiding**

**11:15–14:15**

The decade of the 90's was a period of intense scrutiny of climate issues in physics departments, e.g. the status of women, the job situation for new Ph.D.'s and postdocs, and the preparation of physicists for careers inside and outside of physics. There were many conference sessions on these topics, and both APS members and leadership instigated important efforts to focus on specific areas. These efforts included the program of visiting committees to departments to examine the situation for women by the Committee on the Status of Women in Physics, the AIP's various studies of a statistical nature, and the creation by the APS of a Committee on Careers and the Forum on Graduate Student Affairs, as well as the recent APS-AAPT task force on graduate education. This forum—patterned after similar sessions 10 years ago—will examine how physics departments have changed as a result of such efforts. It will begin with short (12-minute) talks by a panel of experts to describe what has happened in key areas. The greater part of the session will be a period of observations, questions, and discussion from the audience and the panel together. The purpose is to have an interchange

on these interrelated topics from which we can all learn.

Chair: Anthony Nero, Lawrence Berkeley National Laboratory.

**Patrick Mulvey**, AIP. Changes in graduate enrollment, composition, and subsequent jobs.

**Rachel Ivie**, AIP. Women in physics and astronomy departments 2005.

**H6 1 Orbital Magnetization in Periodic Insulators.***
TIMO THONHAUSER, *Rutgers University*

Recent years have seen a surge of interest in issues of charge and spin transport in magnetic materials and nanostructures, including anomalous Hall and spin Hall effects. In this context, it is quite surprising that the theory of orbital magnetization has remained in a condition similar to that of the polarization before the early 1990s, when the problem of computing finite polarization changes was solved by the introduction of the Berry-phase theory.[1] The essential difficulty, that the matrix elements of the position operator $\mathbf{r}$ are not well-defined in the Bloch representation, could be overcome by reformulating the problem in the Wannier representation. In order to derive an analogue theory for the orbital magnetization, we again work in the Wannier representation and assume a periodic insulator with broken time-reversal symmetry, vanishing (or commensurate) magnetic field, and zero Chern numbers. We show that by replacing the dipole operator $\mathbf{r}$ with the circulation operator $\mathbf{r} \times \mathbf{v}$, only one contribution to the magnetization is found, i.e., the magnetization associated with the internal circulation of bulk-like Wannier functions. The missing contribution arises from net currents carried by the Wannier functions at the boundary of the sample. We prove that both contributions can be expressed as bulk properties in terms of Bloch functions in a gauge-invariant way.[2] Our expression for the orbital magnetization is verified by comparing numerical tight-binding calculations for finite and periodic samples. Possible extensions to metals or insulators with non-zero Chern numbers will also be discussed.

**H6 4 Linear and Non-Linear Dielectric Response of Periodic Systems from Quantum Monte Carlo.**
PAOLO UMARI, *Department of Materials Science and Engineering, MIT, Cambridge, MA 02139, USA*

We present a novel approach that allows to calculate the dielectric response of periodic systems in the quantum Monte Carlo formalism. We employ a many-body generalization for the electric enthalpy functional, where the coupling with the field is expressed via the Berry-phase formulation for the macroscopic polarization. A self-consistent local Hamiltonian then determines the ground-state wavefunction, allowing for accurate diffusion quantum Monte Carlo calculations where the polarization's fixed point is estimated from the average on an iterative sequence. The polarization is sampled through forward-walking. This approach has been validated for the case of the polarizability of an isolated hydrogen atom, and then applied to a periodic system. We then calculate the linear susceptibility and second-order hyper-susceptibility of molecular-hydrogen chains whith different bond-length alternations, and assess the quality of nodal surfaces derived from density-functional theory or from Hartree-Fock. The results found are in excellent agreement with the best estimates obtained from the extrapolation of quantum-chemistry calculations. P. Umari, A.J. Williamson, G. Galli, and N. Marzari Phys. Rev. Lett. **95**, 207602 (2005).

**H6 5 Non-linear response of infinite periodic solids to homogenous electric fields and collective atomic displacements.**
PHILIPPE GHOSEZ, *Universite de Liege, Departement de Physique*

The non-linear response of infinite periodic solids to homogenous electric fields and cooperative atomic displacements will be discussed in the framework of density functional perturbation theory. The approach is based on the 2n + 1 theorem applied to an electric field dependent energy functional. We will focus on the non-linear optical susceptibilities, Raman scattering efficiencies and electrooptic coefficients. Different formulations of third-order energy derivatives will be examined and their convergence with respect to the k-point sampling will be discussed. The method will be applied to conventional semiconductors and to ferroelectric oxides. In the latter case, we will also describe how the first-principles results can be combined to an effective Hamiltonian approach in order to provide access to the temperature dependence of the optical properties. This work was done in collabration with M. Veithen and X. Gonze and was supported by the VolkwagenStiftung, FNRS-Belgium and the FAME-NoE.

## SESSION H7: NANOPORE BIOPHYSICS
**Tuesday Morning, 14 March 2006; 307, Baltimore Convention Center at 11:15**
**Xinsheng Sean Ling, Brown University, presiding**

**11:15**
**H7 1 Interaction of DNA and Proteins with Single Nanopores.***
J.J. KASIANOWICZ, *NIST, EEEL, Gaithersburg, MD 20899-8120*

The bacterial toxins Staphylococcus aureus alpha-hemolysin and itBacillus anthracis protective antigen kill cells in part by forming ion channels in target membranes. We are using electrophysiology, molecular biology/protein biochemistry and computer modeling to study how biopolymers (e.g., single-stranded DNA and proteins) bind to and transport through these nanometer-scale pores. The results provide insight into the mechanism by which these toxins work and are the basis for several potential nanobiotechnology applications including ultra-rapid DNA sequencing, the sensitive and selective detection of a wide range of analytes and high throughput screening of therapeutic agents against several anthrax toxins. In collaboration with V.M. Stanford, M. Misakian, B. Nablo, S.E. Henrickson, NIST, EEEL, Gaithersburg, MD; T. Nguyen, R. Gussio, NCI, Ft. Detrick, MD; and K.M. Halverson, S. Bavari, R.G. Panchal, USAMRIID, Ft. Detrick, MD.

**H7 2 Force measurements on a DNA molecule inserted into a solid-state nanopore.**
CEES DEKKER, *Delft University of Technology*

Single nanometer-sized pores (nanopores) in an insulating membrane are an exciting new class of nanosensors for rapid electrical detection of and actuation on single biomolecules. I will report (i) our fabrication of solid-state nanopores and translocation measurements of single dsDNA molecules through these pores, and (ii) our recent demonstration of measurements of the force acting on a single DNA molecule that is inserted in the nanopore. Ad (i): Siliconoxide nanopores are fabricated with single nanometer precision and direct visual TEM feedback. Translocation of double-strand

DNA is monitored in the conductance of a voltage-biased pore. We find that DNA molecules can pass the pore both in a straight linear fashion and in a folded state. On molecules with a length from 3,000-100,000 base pairs, we observe a power-law scaling of the translocation time versus length, which we attribute to an effect of the hydrodynamic drag on the section of the polymer outside the pore. Measurements of DNA translocation at various salt concentrations reveal a crossover from a high-salt regime where current dips are seen, to a low-salt regime where current enhancements are observed. Ad (ii) For force measurements during the voltage-driven translocation of DNA and RNA, we have added an optical tweezer to our setup. With the tweezer, we hold a bead with a DNA molecule attached. Upon insertion of the DNA into the nanopore, the induced bead deflection yields a measure of the local force that acts on the DNA in the pore. The magnitude of the force involved is of fundamental importance in understanding and exploiting the translocation mechanism, yet so far has remained unknown. We obtain a value of 0.24 +/- 0.02 pN/mV for the force on a single DNA molecule, independent of salt concentration. Our data allow the first direct quantitative determination of the effective DNA charge of 0.53 +/- 0.05 electrons per base pair, corresponding to a 73% reduction of the bare DNA charge. Our novel single-molecule technique for local force sensing and actuation bears great promise for biophysical studies, e.g. for the study of DNA-protein binding or unfolding of RNA.

**12:27**
**H7 3 Protein unraveling through a single protein nanopore.**
LIVIU MOVILEANU, *Syracuse University*

The ability to respond to an external stimulus is a fundamental process in living systems. Based on this principle, we were able to design an unusual temperature-responsive pore-based nanostructure with a single movable elastin-like-peptide (ELP). The peptide is placed within the cavity of the alpha-Hemolysin protein pore. The temperature-dependent properties of single engineered pores were monitored by single-channel current recording in planar lipid bilayers. If a voltage bias was applied, the engineered pores exhibited transient current blockades, the nature of which depended on the length and sequence of the inserted ELP. These blockades are associated with the peptide excursions into the narrowest region of the pore. At low temperatures, the ELP is fully expanded and blocks reversibly and completely the pore. At high temperatures, the ELP is dehydrated and structurally collapsed, thus enabling a substantial ionic flow. Potential applications of this nanostructure in several arenas will be discussed.

**13:03**
**H7 4 Detecting Single DNA and Proteins Using a Solid-state Nanopore Device.**
JIALI LI, *Physics Department, University of Arkansas, Fayetteville, AR72701*

Charged single proteins and DNA molecules can be detected as they are driven through a solid-state nanopore by an applied electric field. The solid-state nanopores are fabricated in a free standing silicon nitride membrane using low energy noble gas ion beams. We demonstrate the silicon nitride nanopore based sensor can measure the properties of single molecules of proteins, double stranded DNA, and single stranded DNA molecules at different temperature, pH, and ionic strength. This technique allows us to discriminate between different types of molecules, different conformations of the same molecules, and also determine the configuration of individual molecules as well as their configuration distribution. We demonstrate the silicon nitride nanopore sensing system is robust and capable of detecting structural information of protein and DNA at extreme conditions.

**13:39**
**H7 5 Microscopic Kinetics of DNA Translocation through Synthetic and Biological Nanopores.**
ALEKSEI AKSIMENTIEV, *University of Illinois at Urbana-Champaign*

Using highly focused electron beams, artificial pores of nanometer diameters can be manufactured in ultra-thin silicon membranes with a sub-nanometer precision. A trans-membrane voltage bias can drive DNA strands through such pores; the resulting electrical signals can be recorded. As the diameter of the pore as well as the thickness of the silicon membrane can be made to match precisely the dimensions of a DNA nucleotide, the electrical signals produced by the interaction of DNA with the pore were proposed to contain information about the DNA sequence. In order to relate the DNA sequence to the measured electrical signals we characterized DNA conformations inside the pore through molecular dynamics simulations. A typical simulated system included a patch of a silicon membrane dividing electrolyte solution into two compartments connected by the nanopore. External electrical fields induced capturing of the DNA molecules by the pore from the solution and subsequent translocation. To calibrate our methodology, we carried out MD simulations of DNA translocation through an $\alpha$-hemolysin channel suspended in a lipid bilayer. Our results suggest that the rate-limiting step for DNA translocation through narrow synthetic pores is not the actual transit of DNA, but rather the search for such initial conformation that facilitates subsequent translocation. At the same time, hydrophobic adhesion of DNA

bases to the pore walls may considerably slow down or halt DNA translocation. We observed a threshold electric field for translocation of double stranded DNA through pores smaller in diameter than a DNA double helix occurring due to the overstretching transition at load forces of $\sim$ 60 pN. In narrow pores, DNA bases were observed to tilt collectively towards the 5'-end of the strand, which explains experimentally observed directionality of single stranded DNA in the transmembrane pore of $\alpha$-hemolysin.

**SESSION H8: FOCUS SESSION: JAMMING IN GLASSES, GRAINS, AND GELS I**
**Tuesday Morning, 14 March 2006**

**11:15**
**H8 1 Random-Packing Dynamics in Dense Granular Flow** MARTIN Z. BAZANT, CHRIS H. RYCROFT, KENNETH KAMRIN, *Department of Mathematics, MIT* The jamming transition of disordered hard spheres has attracted much recent attention, but how do slightly less dense random packings flow? Here, we propose a simple mechanism based on diffusing ''spots'' of free volume, which cause correlated displacements of neighboring particles. A multiscale algorithm, alternating between coarse-grained spot dynamics and microscopic particle relaxation, can produce realistic flowing packings, and yet is also convenient for mathematical analysis of mean flow and diffusion. We apply the model to granular drainage from a silo and fit three basic parameters (spot size, volume, and diffusivity) to brute-force simulations by the discrete-element method. For a wide silo, we find that the spot simulations can largely reproduce the dynamics of 100,000 frictional, visco- elastic spheres in the DEM simulations, while running over 100 times faster, although a general model for the spot dynamics in different geometries is still lacking. This may come from a stochastic reformulation of Mohr-Coulomb plasticity, where spots undergo random walks along slip planes.

**11:27**
**H8 2 Contact Numbers in 2D Granular Systems*** MATTHIAS SPERL, TRUSHANT MAJMUDAR, ROBERT BEHRINGER, *Duke University* There exists a critical density below which a granular system is no longer mechanically stable. Above this threshold, the particles form stable contacts with each other, while below there are no permanent contacts. We introduce a method to determine the number of contacts per particle with high accuracy: Using stress induced birefringence to identify contact points, the critical density can be identified with an uncertainty of 0.5%. For a binary mixture of frictional disks we find a discontinuous transition in the number of contacts per particle from zero to a value around 2.5; the transition point is located at an area fraction of 0.845. For higher densities, the increase in the contact number is compatible with a square-root law; however, different exponents close to 0.5 cannot be ruled out yet. At the same transition point, the average force in the system increases linearly with density.

**11:39**
**H8 3 A hydrodynamic view on elasticity** ANAËL LEMAîTRE, *Institut Navier – France* LAURENTIU PASOL, *LadHyX – France* XAVIER CHATEAU, *Institut Navier – France* Considerable attention was drawn in the recent years on the non-affine displacement fields that accompany elastic deformation of non-crystalline materials. These non-affine displacements bring order unity corrections to the sound speed and Lamé constants that would be estimated using the traditional Born-Huang approximation. Bearing on standard homogenization tools and a compatibility theorem, we provide a simple analytical framework to write exact expressions for the elastic constants. We show that, in the thermodynamic limit, exact microscopic expressions reduce to integrals over the pair correlation function. We next show that the corrective terms may be further reduced to a simple integral involving the Green function of the disordered packing. This brings hope to be able to devise systematic procedures to estimate the real elastic constants of amorphous solids.

*Invited Papers*

**11:51**
**H8 4 Non-affine elasticity in jammed systems.**
CRAIG MALONEY, *Johns Hopkins University, Dept. of Physics and Astronomy; UC Santa Barbara, KITP*

Symmetry dictates that perfect crystals should deform homogeneously, or *affinely*, under external load, and computing the elastic moduli from the underlying interaction potential is then straightforward. For disordered materials no such simple procedure exists, and recent numerical works have demonstrated that non-affine corrections can dramatically reduce the naive expectation for the shear modulus in a broad class of disordered systems and may control rigidity loss in the zero pressure limit in purely repulsive systems, i.e. the unjamming transition (c.f. [O'Hern et al. PRE 68, 011306 (2003)]). We present numerical results and an analytical framework for the study of these non-affine corrections to the elastic response of disordered packings.

*Contributed Papers*

**12:27**

**H8 5 Effects of Nonaffinity on Jammed Materials*** DANIEL VERNON, ANDREA J. LIU, TOM LUBENSKY, *Department of Physics and Astronomy, University of Pennsylvania* If an amorphous solid such as a jammed particle system is subjected to an external stress, the induced displacements of internal particles are necessarily nonaffine. Using numerical minimization procedures, we investigate the response to stress of a disordered packing of purely repulsive spheres. We calculate the correlations of the nonaffine part of the displacements of individual particles just above the jamming threshold (point J)[1]. We find that these correlations are consistent with those predicted by a continuum theory and verified numerically in simple model random elastic systems[2].

**H8 6 Compactivity measurements for a bidimensional granular** FREDERIC LECHENAULT, *CEA* FREDERIC DACRUZ, OLIVIER DAUCHOT, *CEA SPEC* ERIC BERTIN, *Department of Theoretical Physics, University of Geneva* We investigate experimentally the statistical properties of the free volumes inside a bidimensional granular packing. Having in mind the more general issue of the measure of intensive thermodynamical parameters in out-of-equilibrium systems, we propose an experimental procedure to access the compactivity of the packing from the free volume distributions over clusters of grains, varying the size of the cluster. Our main result is that the logarithm of the probability to find a given free volume in a cluster scales in a nonextensive way. The compactivity of the packing is then extracted from the corresponding scaling function for two different kinds of grains, and two levels of compaction.

**12:51**

**H8 7 How does friction affect the distribution of mechanically stable disk packings?*** ERIK BROWN, *Department of Physics, Yale University* GUO-JIE GAO, JERZY BLAWZDZIEWICZ, *Department of Mechanical Engineering, Yale University* COREY O'HERN, *Departments of Mechanical Engineering and Physics, Yale University* In recent work (*Physical Review E* **71** (2005) 061306), we generated nearly all of the mechanically stable packings in small systems composed of up to 20 bidisperse frictionless disks that interact via normal forces. Complete enumeration allowed us to decompose the probability distribution $P(\phi)$, for obtaining a mechanically stable state at packing fraction $\phi$ into algorithm-dependent and independent contributions, $\beta(\phi)$ and $\rho(\phi)$. $\rho(\phi)$ is the probability density to obtain a distinct mechanically stable packing at $\phi$, while $\beta(\phi)$ is the frequency with which each distinct state occurs. In the present study, we add frictional interactions between grains that vanish when the particles are rest. We will compare distributions of mechanically stable packings in systems with and without friction. In particular, we will comment on whether a well-defined random loose-packed state exists in 2D.

**13:03**

**H8 8 Jamming as a critical phenomenon: A field theoretical approach** SILKE HENKES, BULBUL CHAKRABORTY, *Brandeis University* The proposed jamming diagram (Nature **396**, 21 (1998)) features a special point, termed point J, along the packing fraction axis where the jamming transition is sharp. Recent simulation work (PRE **68**, 011306 (2003)) has shown that point J has some features of a critical point. To model the jamming transition along the packing fraction axis, a field theory of frictionless, zero-temperature grain packings in two dimensions has been constructed (PRL **95**, 198002 (2005)). A mean-field theory involving two order parameters, $\langle\phi\rangle$, the average force per contact, and $\langle z\rangle$, the deviation of the average contact number from its isostatic value, predicts a transition from a jammed to an unjammed phase. The transition is of mixed order with a jump in $\langle\phi\rangle$ and divergent fluctuations. Current work focuses on application of this formalism to simulation data. This allows for the study of spatial fluctuations of $\phi$ and attempts are made to relate these to the concept of force chains. The $\phi$-field emerges as an excellent tool for data analysis and allows quantification of the structures seen in granular packings. Work supported by NSF-DMR 0403997.

**13:15**

**H8 9 Emergence of a critical scale in jamming of frictional grains** ELLAK SOMFAI, *University of Leiden and University of Oxford* MARTIN VAN HECKE, WOUTER ELLENBROEK, WIM VAN SAARLOOS, *University of Leiden* We probe the characteristic scale of two-dimensional frictional granular media close to the jamming transition by studying their vibrational properties as function of the applied pressure $P$ and friction coefficient $\mu$. The density of vibrational states exhibits a crossover from a plateau at frequencies $\omega > \omega^*(P,\mu)$ to a linear growth for $\omega < \omega^*(P,\mu)$. Both for large and for zero friction, this characteristic frequency $\omega^*$ vanishes when $P$ is lowered towards zero. For moderate friction, however, $\omega^*$ saturates at a finite value for $P \downarrow 0$. We show that $\omega^*$ is proportional with $\Delta z$, the excess number of contacts per grains relative to the minimally allowed, isostatic value, and that only for zero and infinitely large friction, systems at the jamming threshold have $\Delta z \to 0$ and hence are critical.

**13:27**

**H8 10 Granular dynamics in compaction and stress relaxation** PING WANG, *City College of New York* JASNA BRUJIC, *Schlumberger Doll Research* CHAOMING SONG, *City College of New York* DAVID JOHNSON, OLIVIER SINDT, *Schlumberger Doll Research* HERNAN MAKSE, *City College of New York* LEVICH INSTITUTE AND PHYSICS DEPARTMENT, CITY COLLEGE OF NEW YORK, NEW YORK, NY 10031 COLLABORATION, SCHLUMBERGER DOLL RESEARCH, OLD QUARRY ROAD, RIDGEFIELD, CT 06877 COLLABORATION, Elastic and dissipative properties of granular assemblies under uniaxial compression are studied both experimentally and by numerical simulations. Following a novel compaction procedure at varying oscillatory pressures, the stress response to a step-strain reveals an exponential relaxation followed by a slow logarithmic decay. Simulations indicate that the latter arises from the coupling between damping and collective grain motion predominantly through sliding. We characterize an analogous ''glass transition'' for packed grains, below which the system shows aging in time-dependent sliding correlation functions.

**13:39**
**H8 11 Jamming in Quasi-One Dimensional Systems** PRASANTA PAL, *Department of Applied Physics, Yale University* COREY O'HERN, *Department of Mechanical Engineering, Department of Physics, Yale University* We study the dynamics of hard rods undergoing Brownian motion in narrow channels. Our system is in the shape of a ''figure-8'' and composed of a horizontal and a vertical channel that intersect. In our preliminary studies, we allow the particles to switch at the ends of the channels, but not at the intersection. We calculate the mean-square displacement (msd), the residence time that a particle spends in the intersection, and other important dynamical quantities as a function of the density of rods and system size. In contrast to purely one-dimensional systems, we find that the figure-8 system jams (i.e. the msd possesses a plateau at long times) above a characteristic density that increases with system size. In addition, we have studied the effects of a biasing field on the dynamics and find that the jamming transition is pushed to much lower densities than at zero field. We also compare our results to those found in model glass-forming liquids in two and three dimensions.

**13:51**
**H8 12 Voronoi Volumes in Dense Granular Flow** CHRIS H. RYCROFT, MARTIN Z. BAZANT, *Department of Mathematics, MIT* The concept of free volume in amorphous materials has a long history, including void-based theories of viscous flow (Eyring 1936), the glass transition (Turnbull and Cohen 1957), and granular drainage (Mullins 1972), although it has become clear that particle displacements are highly correlated and not mediated by single-particle voids. Recently, we have shown that dense random packings can be made to flow cooperatively at nearly uniform density by diffusing ''spots'' of influence and find good agreement with discrete-element (DEM) simulations of frictional spheres in the case of granular drainage. Spots are presumed to carry a slight excess of interstitial volume, but verifying this would require tracking changes in local volume fraction of only a few percent. In flowing random packings, this is a significant computational challenge, which we address here by computing the evolving Voronoi tesselation with an efficient new algorithm. We study the distribution of local Voronoi volumes in simulations of granular drainage using the spot model and DEM and observe some intriguing differences. The Voronoi volume also provides a sensitive measure of whether a given region is ''liquid-like'' of ''solid-like'' in dense granular flow.

**H8 13 Correlated Dynamics in Dense Granular Flow** SHUBHA TEWARI, *Mount Holyoke College* ALLISON FERGUSON, BULBUL CHAKRABORTY, *Brandeis University* We report on studies of dense, gravity-driven granular flow via simulations of two-dimensional, inelastic, bidisperse hard disks in a vertical tube geometry. We analyze the flow in terms of coarse-grained velocity and stress fields. We find that as the flow rate decreases towards jamming, there is an increase in the timescale over which stress autocorrelations decay. While the spatial correlations of the stress do not increase significantly, there is a marked increase in the spatial correlation of the velocity, which is indicative of an increasing length scale that approaches the system size as the flow rate decreases. We further analyze the flow in terms of two different four-point correlation functions of the stress and the velocity analogous to those used to characterize dynamical heterogeneities in supercooled liquids. These allow us to extract a dynamical length scale as well as a relaxation time for this system.

**H10 1 A Revisit to Soliton Theory.**
XI LIN, *MIT*

Our recent studies on the soliton theory of conjugated polymers, via Hubbard model and first-principles computations, reveal two subtle points concerning electron-electron correlation and electron-phonon coupling. Significant three-dimensional conformational changes and a sequence of self-localized electronic states are identified and attributed to the presence of soliton. The soliton-induced conformational deformations provide an intrinsic high strain-rate actuation mechanism in optical excitation processes, while the sensitivity of new self-localized states to the presence of local fields provides a high-resolution sensing mechanism for ions and radicals.

**H10 2 Auxiliary field quantum Monte Carlo with a localized basis−applications to atoms and molecules*** WISSAM A. ALSAIDI, SHIWEI ZHANG, HENRY KRAKAUER, *College of William and Mary* We extended the recently introduced phaseless auxiliary field quantum Monte Carlo approach [1] to any single-particle basis, and applied it to study atoms and molecules using localized Gaussian basis. This method maps the interacting many-body problem into a linear combination of non-interacting problems using a complex Hubbard-Stratonovich transformation, and controls the phase/sign problem using a trial wave function. It employs a random walk approach in Slater determinant space to project the many-body ground state of the system. The computational cost scales as a low power of system size. In all of the presented results the trial wave function was from a Hartree-Fock calculation. The obtained total energies of the atoms and molecules agree to within a few milli Hartrees with the exact value from full configuration interaction or density matrix renormaliza-

tion group. The results are comparable in accuracy to those of CCSD(T) for equilibrium geometries but are superior for bond breaking. [1] S. Zhang and H. Krakauer, Phys. Rev. Lett. **90**, 136401 (2003).

**H10 3 Monte Carlo Studies of Soft Pentagonal Rotors and Polymer Self-Assembly** MICHAEL WINOKUR, *University of Wisconsin* MARCUS MUELLER, *Georg August Universitaet* Side chain substitution is widely used in $\pi$-conjugated polymers to promote processibility and reduce interchain aggregation. However this functionalization also creates diverse materials that self-organize at molecular length scales. Small modifications in the chemical architecture often produce large variations in the observed structures and phase behavior. An example of this is poly(9,9-bis(2-ethylhexyl)fluorene) (PF2/6) in which single chains form helices that subsequently undergo a supramolecular self-assembly to give a three chain unit cell or, equivalently, a $\sqrt{3} \times \sqrt{3}$ superlattice. Direct structure studies indicate that PF2/6 incorporates a heterogeneous sequence of conformational isomers approximating a 5-fold helix and this construction defines the overall shape of the chain. In terms of more conventional polymers we consider PF2/6 to be representative of a sparse brush with, on average, a columnar type structure. However PF2/6 structure studies already indicate that the potential is not uniformly cylindrical because of the 5-fold helix and the spontaneous formation of a 3 chain unit cell. Through construction of a representative ansatz Hamilton we have mimicked the interaction between soft pentagonal shaped rotors. Monte Carlo calculations employing this Hamiltonian identify a range of parameters that reproduce the experimentally observed $\sqrt{3} \times \sqrt{3}$ superlattice. Moreover we find that small changes in this orientational pair potential strongly alter the phase behavior.

**H10 4 Particle-Hole Corrections for Accurate DFT-based Charge Transfer Energetics** TUNNA BARUAH, *University of Texas at El Paso* M. PEDERSON, *Naval Research Laboratory* Density functional theory (DFT) is primarily a ground state theory because it lacks a rigorous prescription for the calculation of excited states. However, a formalism due to Theophilou showed that a Hohenberg-Kohn like theorem is extendable to an ensemble of ground and excited states provided the states are mutually orthogonality. This condition is also a necessary for a variational approach to individual excited states as shown by Levy. We present a way for obtaining accurate single-electron excitation energies from the ground-state Hamiltonian and orbitals. Our approach explicitly guarantees mutual orthogonality and removes spurious interactions between the electron and hole states. The method yields excellent results for inert gas atoms, closed-shell atoms and molecules, and to charge transfer systems such as the dissociated Na-Cl molecule and a 50 nm long organic molecule containing 200 atoms. Initial applications rely entirely upon standard GGA functionals but the approach is equally amenable to any mean-field method such as Hartree-Fock or DFT with SIC.

**12:27**

**H10 5 Low Energy Inelastic Helium Atom Scattering from Monolayers** L.W. BRUCH, *Department of Physics, University of Wisconsin-Madison* F.Y. HANSEN, *Department of Chemistry, Technical University of Denmark* A time-dependent wave packet calculation for inelastic low energy helium atom scattering (HAS) by a physisorbed monolayer[1] is extended to much longer propagation times by adding an absorbing potential at large distances. This enables a treatment of transiently trapped helium atoms for He/Xe/Pt(111) and shows that the lifetimes are in the range 10-30 ps. The scattering of the wave packet is essentially complete when the propagation is terminated. Systematic trends for an experiment on a Xe/Pt(111) monolayer[2] are discussed. The remarkable inelastic intensity for the shear horizontal (SH) monolayer branch is predicted to be strongly enhanced for incident energies in the range 4 to 6 meV, somewhat below the 8.2 meV energy used in most of that experiment.

**H10 6 A time-dependent density functional theory approach for the excited state dynamics of nanostructures and biomolecules.***

RUBIO ANGEL, *Dpto. Fisica de Materiales, Facultad de Quimicas, U. Pais Vasco, San Sebastian and European Theoretical Sepctroscopy Facility (ETSF)*

We will review the recent implementations of TDDFT to study the optical absoprtion of biological chromophores, one-dimensional polymers and layered materials. In particular we will show the effect of electron-hole attraction in those systems. We will folow two routes: one based on solving the Bethe-Salpeter equation and the other on an orbital-dependent OEP method on top of the GW approximation for the self-energy. Virtues and deficiencies of both methods will be illustrated.

*Work done in collaboration with A. Castro, M. Marques, L. Wirtz, A. Marini, M. Gruning, L. Wirtz and D. Varsano and supported by the NANOQUANTA network of excellence and the Humboldt Foundation under the Bessel research award (2005).

**H10 7 Energetic, structural and vibrational properties of carbon monoxide on transition-metal surfaces: a linear-response approach to the energy puzzle** ISMAILA DABO, *MIT* ANDRZEJ WIECKOWSI, *UIUC* NICOLA MARZARI, *MIT* We have studied the energetic, structural and vibrational properties of carbon monoxide adsorbed on platinum and platinum-ruthenium surfaces using density-functional theory within the generalized-gradient approximation (GGA) and its molecular U variant (GGA + molecular U) introduced by Kresse *et al. [Phys. Rev. B 68, 73401 (2003)]*. Our study puts in evidence that the GGA frequency predictions for the C-O stretching mode are in excellent agreement with spectroscopic measurements. This agreement is made more remarkable by the generally-poor performance of standard exchange-correlation functionals which fail even in predicting the most stable adsorption site for CO on platinum. It is also shown that the molecular U correction to the electronic hybridizations and adsorption energies does not affect the excellent accuracy of the GGA vibrational-property predictions. Based on the linear-response approach proposed by Cococcioni and de Gironcoli *[Phys. Rev. B 71, 35105 (2005)]*, we provide a theoretical justification for this observation. The accurary of density-functional theory in predicting accurate vibrational spectra while paradoxically failing in determining correct adsorption energies is also discussed.

**13:27**

**H10 8 y-induced chaotic Whispering Gallery modes** ARACELI GONGORA-TREVINO, *UNAM, Mexico and Northeastern USA* STUART SCHAFFNER, *Northeastern University* JORGE JOSE, *SUNY at Buffalo* A free particle inside a circular billiard bouncing elastically from the boundary produces classically bounded caustic orbits and Whispering Gallery (WG) modes in the quantum case. If a sector is taken out from the circle, forming a Pacman-like billiard, the classical caustic orbits remain. However, in the quantum case the WG modes have fractional quantum angular momentum described by Bessel functions of fractional order. In this work we have considered the case when the straight walls of the Pacman are not fixed in time but oscillate periodically or non-periodically. The structure of the WG modes changes; there are cases where the WG mode intensity increases significantly in certain spatial locations when compared with the situation in the Pacman stationary case. This intensity increase is analyzed in detail, and it may be implemented and tested in the type of micro-cavity used in quantum dot lasers.

**13:39**

**H10 9 A generalization of the charge equilibration method** RAZVAN A. NISTOR, JELIAZKO G. POLIHRONOV, MARTIN H. MUSER, NICK J. MOSEY, *Department of Applied Mathematics, University of Western Ontario* Charge-equilibration (C-Eq) methods are an efficient means of calculating the effective partial charges of the atoms in molecules. The aim of obtaining the partial charges is to reconstruct the electrostatic field of a molecule, which then may be used as an accurate replacement to *ab initio* interatomic potentials. However, the inability of the C-Eq method to consistently predict the correct charges for a wide range of molecular geometries has limited its potential use in molecular simulations. A generalization to a split charge (split-Q) formalism, where the semi-empirical fit parameters are defined not in terms of atom-type, but in terms of bond-type, greatly improves the quality, and more importantly, the transferability of the fits. The flexible formalism of the split-Q approach allows for a number of generalizations over traditional C-Eq methods at the cost of additional fit parameters in the model. However, the split-Q approach can reproduce the charges on a variety of different molecules containing H, C, O, and Si, up to three times more accurately than previous methods when comparing to *ab initio* calculations.

**H10 10 Atomization energies using analytic density functional theory*** RAJENDRA ZOPE, *George Washington University, Washington DC* BRETT DUNLAP, *US Naval Research Laboratory, Washington DC* Our recent formulation of analytic and variational Slater-Roothaan (SR) method uses Gaussian basis sets to express the molecular orbitals, electron density and the one-body effective potential of density functional theory. It allows arbitrary scaling of the exchange potential around each atom in heteroatomic systems. We examine the performance of the SR method for atomization energies using values of Slaters scaling parameters determined from the Hartree-Fock and the exact total atomic energies. We also present another set of scaling parameters for atomization energies. The performance of the computationally efficient SR method for the atomization energies of a set of 148 molecules using this third set of parameters is comparable to that of the Perdew-Burke-Ernzerhof generalized gradient approximation.

**H10 11 Comparison of two simple models for high frequency friction: Exponential vs. Gaussian wings** STEVEN ADELMAN, *Purdue University* We describe new methods for ruling out unphysical forms for the high frequency friction $\lim_{\omega\to\infty}\beta(\omega)$ needed to compute vibrational energy relaxation times. These are based on the fluctuating force autocorrelation function($faf$) $C(t) = \langle\tilde{\mathfrak{J}}^2\rangle_0^{-1}\langle\tilde{\mathfrak{J}}(t)\tilde{\mathfrak{J}}\rangle_0$, which is proportional to the Fourier transform of $\beta(\omega)$. Here we compare two model faf's $C_{se}(t) = \mathrm{sech}\,(t/\tau)$ and $C_{ga}(t) = \exp[-\frac{1}{2}(t/\tau)^2]$. These give respective high frequency frictions which have incompatible exponential and Gaussian forms. We apply our procedures to eliminate $C_{se}(t)$. We do this by showing from $\beta_{se}(\omega) \equiv \langle\mathfrak{J}^2\rangle_0/k_BT\int_0^\infty\cos\omega t C_{se}(t)dt$ that $\lim_{\omega\to\infty}\beta_{se}(\omega)$ derives from the long time ''tail'' of $C_{se}(t)$. We then note that $C_{se}(t)$ is built only from short time quantities, rendering the form of this ''tail'' artifactual. Thus the exponential form of $\lim_{\omega\to\infty}\beta(\omega)$, is also artifactual.

**H11 2 Ultrafast Vibrational Dynamics of Water Interfaces Probed by Sum-frequency Vibrational Spectroscopy*** JOHN A. McGUIRE, Y.R. SHEN, *Department of Physics, University of California and Material Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720* Using sum-frequency generation (SFG) as a surface-specific probe, we measured the ultrafast population and dephasing dynamics of excitations of OH-stretch modes of water at fused-silica/water interfaces. A tunable femtosecond IR pulse was used to pump the vibrational mode. Another independently tunable femtosecond IR pulse, after a time delay, was used to probe the vibrational excitation and then up-converted by SFG for detection. Experiments on the hydrophilic fused-silica/water interface reveal population relaxation of the hydrogen-bonded OH modes on time scales of 200-500 fs, more rapid on the red side than the blue side. The width of transient spectral holes produced by the IR pump pulse correspond to homogeneous dephasing times of $\sim$ 50 fs. Measurements of the dangling OH bonds at the hydrophobic silica/*n*-octadecyltrichlorosilane/water interface reveal a population relaxation time of about 1.2 ps.

**H11 3 Phase-sensitive sum-frequency vibrational spectroscopy on water/vapor interfaces*** VICTOR OSTROVERKHOV, NA JI, CHAO-YUAN CHEN, YUEN-RON SHEN, *Department of Physics, University of California, Berkeley* Water/vapor interfaces are ideal hydrophobic interfaces relevant to many important applications. They have been studied extensively by sum-frequency vibrational spectroscopy (SFVS) in recent years. Unfortunately, different interpretations of the spectra from different research groups have led to a great deal of confusion. The problem arises because in conventional SFVS, only the magnitude of the spectrum is recorded. We present here a phase-sensitive (PS) SFVS study of water/vapor interfaces that captures both the magnitude and the phase of an interfacial vibrational spectrum. The results allow us to decompose unequivocally the various OH stretch peaks in the spectrum and the net polar orientations of the water species contributing to the peaks.

**H11 4 Measuring solvation dynamics using sum-frequency cross-correlation frequency resolved optical gating (SF XFROG)*** NANCY LEVINGER, *Colorado State University* BENJAMIN LANGDON, *Colorado State University* Solvation dynamics has been used to measure the dynamical response of a solvent to an electronic perturbation. The response is typically followed through sum-frequency conversion of sample emission with short light pulses to time-resolve spectral shifting of a fluorescent probe molecule. In contrast to traditional fluorescence up-conversion techniques where the time resolved fluorescence signal is approximated from 10-15 different sum-frequency gated decays distributed across the fluorescence spectrum, sum-frequency cross-correlation frequency resolved optical gating offers the opportunity to determine the electric field of the sample fluorescence as a function of time. Dynamic quantities associated with changes in the sample emission, such as solvent relaxation, can then be obtained directly from the electric field without assumption of a particular spectral lineshape. We show that the time evolving phase of the SF XFROG signal corresponds to the solvent response function, $C(t)$, and that the technique also reveals details about vibrational modes associated with the relaxation.

**12:27**
**H11 5 Time- and Frequency-Domain Surface Spectroscopy of Polymers and Langmuir-Blodgett films** ANDREY BORDENYUK, HIMALI JAYATHILAKE, ALEXANDER BENDERSKII, *Wayne State University* We combine frequency- and femtosecond time-domain IR+visible Sum Frequency Generation (SFG) measurements for spectroscopic characterization of material surfaces. Vibrational quantum beats observed in Langmuir-Blodgett monolayers are demonstrated to be sensitive to the molecular order/disorder in the film, depending on the two-dimensional phase. Nearly vertical alignment of all-trans alkyl chains is observed in films transferred at high surface pressure, while at lower surface pressure, changes in chain tilt angle and onset of gauche-defects are observed. The time- and frequency-domain data are analyzed simultaneously based on optical Bloch equations, allowing to utilize the information redundancy for more

accurate determination of the spectral parameters. Polymer surfaces used as alignment layers in liquid crystal displays were investigated to elucidate how the mechanical rubbing affects the molecular orientation and conformation. Rubbing was found to induce pronounced azimuthal anisotropy of the alkyl side chain orientation, observed in the CH-stretch SFG spectra of the $CH_3$ and $CH_2$ groups. Orientational analysis of the SFG vibrational spectra as a function of azimuthal and tilt angles (in- and out-of-surface plane) of the polymer side chains shows their preferential tilt along the rubbing direction.

**H11 6 Small Molecules and Sum Frequency Generation Probes of Nanoparticulate $TiO_2$.**
MARY JANE SHULTZ, *Tufts University*

Anatase $TiO_2$ is known to photo catalytically mineralize a wide variety of pollutants and pathogens, both airborne and in aqueous solution. One of the major benefits of basing water treatment systems on $TiO_2$ is that it is environmentally benign and so non toxic that it is used as a colorant in creamy salad dressing. The primary impediment to wide spread implementation of a $TiO_2$ based system for water decontamination is that the quantum efficiency in contact with condense phase water is less than 5%. Since the quantum efficiency for destruction of airborne materials is greater than 80%, the potential for increased efficiency is very real. To convert the potential to practice, the oxidation mechanism needs to be more fully understood. We will report on the results of using a nonlinear optical spectroscopy, sum frequency generation (SFG) as an itin situ probe of interactions at the $TiO_2$ surface. Results suggest that the dominant oxidation mechanism converts from a direct to an indirect mechanism as the water content (vapor pressure) increases. This presentation will discuss the probe technique as well as the results.

**H11 7 Molecular Adsorption on Nano Colloidal Particles Probed by Second Harmonic Generation** SHIH-HUI JEN, HAI-LUNG DAI, *Department of Chemistry, University of Pennsylvania, Philadelphia, PA 19104-6323* It is shown that second-harmonic generation (SHG), detected at 90 degree angle from the fundamental beam propagation direction, can be used to probe molecular adsorption on spherical nano colloidal particles with diameter as small as 50 nm. Measurements done with the malachite green dye adsorbed on polystyrene particles with diameters ranging from 50 to 250 nm show that the SHG signal from these surface adsorbed molecules tilts toward larger scattering angles when the particle size becomes smaller. This phenomenon can be rigorously described by the nonlinear Rayleigh-Gans-Debye theory and used for measuring the density and adsorption free energy of molecules adsorbed on nanometer size colloidal particles.

**13:27**
**H11 8 Spectrally- and Time-Resolved Sum Frequency Generation (STiR-SFG): a new tool for ultrafast hydrogen bond dynamics at interfaces.** ALEXANDER BENDERSKII, ANDREY BORDENYUK, CHAMPIKA WEERAMAN, *Wayne State University* The recently developed spectrally- and time-resolved Sum Frequency Generation (STiR-SFG) is a surface-selective 3-wave mixing (IR+visible) spectroscopic technique capable of measuring ultrafast spectral evolution of vibrational coherences. A detailed description of this measurement will be presented, and a noniterative method or deconvolving the laser pulses will be introduced to obtain the molecular response function. STiR-SFG, combined with the frequency-domain SFG spectroscopy, was applied to study hydrogen bonding dynamics at aqueous interfaces ($D_2O/CaF_2$). Spectral dynamics of the OD-stretch on the 50-150 fs time scale provides real-time observation of ultrafast H-bond rearrangement. Tuning the IR wavelength to the blue or red side of the OD-stretch transition, we selectively monitor the dynamics of different sub-ensembles in the distribution of the H-bond structures. The blue-side excitation (weaker H-bonding) shows monotonic red-shift of the OD-frequency. In contrast, the red-side excitation (stronger H-bonding structures) produces a blue-shift and a recursion, which may indicate the presence of an underdamped intermolecular mode of interfacial water. Effect of electrolyte concentration on the H-bond dynamics will be discussed.

**H11 9 Non-linear vibrational spectroscopies for characterizing thin films of semi-conducting polymers** MARC GURAU, *National Institute of Standards and Technology* ZACHARY SCHULTZ, DEAN DELONGCHAMP, BRANDON VOGEL, JOSEPH KLINE, YOUNGSUK JUNG, ERIC LIN, LEE RICHTER, CHEMICAL SCIENCE AND TECHNOLOGY LAB, NATIONAL INSTITUTE OF STANDARDS AND TECHNOLOGY TEAM, MATERIALS SCIENCE AND ENGINEERING LAB, NATIONAL INSTITUTE OF STANDARDS AND TECHNOLOGY TEAM, The ongoing development of conjugated polymer electronic materials has shown that alterations of the structure of these materials and the means of processing can lead to large variations in the performance observed. Continued growth in this field requires the development of new metrologies suited to the examinations of thin polymeric films on a variety of substrates. Spectroscopic characterization of the vibrational structure of these systems provides a non-destructive means of monitoring such changes. The work presented in this talk demonstrates the use of nonlinear optical broadband coherent anti-stokes raman spectroscopy (CARS) and broadband sum frequency generation (SFG) to monitor both the bulk and interfaces of ultra-thin ( $<$ 50 nm) semiconducting polymer films. SFG provides insight into order at the critical buried polymer/dielectric interface of thin-film transistors while CARS provides insight into chemical degradation of the films.

**13:51**
**H11 10 Ferroelectric domains in dipolar liquids observed by hyper-Rayleigh scattering.** DAVID SHELTON, *U. Nevada Las Vegas* Hyper-Rayleigh scattering (HRS) is a sensitive probe of polar modes in isotropic media. For the dipolar liquids water, acetonitrile, nitromethane and nitrobenzene the depolarized HRS

spectrum is observed to contain a narrow spike at zero frequency shift due to a polar collective mode with a relaxation time greater than 30 ns. This spike in the HRS spectrum is attributed to ferroelectric domains in the liquid. The spike disappears when dilution of a dipolar liquid with a non-polar liquid reduces the dipole coupling strength of the solution below the predicted ferroelectric threshold. The size and dipole order parameter for the ferroelectric domains have been determined from HRS spectra for binary solutions of dipolar molecules.

**H11 11 Surfaces of alcohol-water mixtures studied by sum-frequency generation vibrational spectroscopy** JAEHO SUNG, KYUNGSU PARK, DOSEOK KIM, *Department of Physics and Interdisciplinary Program of Integrated Biotechnology, Sogang University, Seoul 121-742 Korea* Sum frequency generation vibrational spectroscopy in the $CH_x$ stretch vibration range used to investigate the surface of binary mixtures of water and short chain alcohols (methanol, ethanol, and propanol) at the air/liquid interface. It was found that the sum frequency signals from mixtures at low alcohol concentration are larger than that of pure alcohols. For example, the signal from a propanol mixture surface at 0.1 bulk mole fraction was $\sim$ 3 times larger than that from a pure propanol surface. On the other hand, the ratio between the sum-frequency signals taken at different polarization combinations was found to be constant within experimental errors as the bulk alcohol concentration was changed. This suggested that the orientation of surface alcohol molecules does not vary appreciably with the change of concentration, and that the origin of the signal enhancement is mainly due to the increase in the surface number density of alcohol molecules contributing to the sum-frequency signal for the alcohol/water mixture as compared to the pure alcohol surface.

**H12 1 Imaging of ALD Grown W Atoms on $\alpha$-TiO2(110) by X-ray Standing Wave Fourier Inversion** CHANG-YONG KIM, *Northwestern University* JEFFREY ELAM, MICHAEL PELLIN, *Argonne National Laboratory* DIPAK GOSWAMI, STEVEN CHRISTENSEN, MARK HERSAM, PETER STAIR, MICHAEL BEDZYK, *Northwestern University* Supported metal oxides are among the most important of catalytic materials systems. However, there is a lack of experimental atomic-scale structural information for describing the relevant interfaces. We combine atomic layer deposition (ALD) and x-ray standing wave (XSW) atomic-imaging to address this challenge. As a first case, we determine the precise registry of W atoms on a rutile TiO2(110) surface. The ALD W layer was formed by first exposing the $TiO_2$ surface to disilane ($Si_2H_6$) and then to tungsten hexafluoride ($WF_6$). The direct-space image reveals that W occupies the Ti-site that would be occupied by Ti if the bulk structure were extended above surface. The tungsten atoms are vertically shifted upward from the ideal Ti-site location by +0.23 Å. These XSW measurements of ALD heterolayer growth clearly show for the first time that ALD conformal layers can be highly coherent with the substrate lattice. The ALD method for supported catalyst material preparation provides a bridge over the ''materials preparation gap'' that typically separates practical, high-surface-area and single crystal model catalytic materials.

**11:27**

**H12 2 Beating Effects on X-ray Reflectivity for Pulsed Laser Deposition of TiN** YEN-RU LEE, *Dep. of Physics, University of Illinois at Urbana-Champaign* AARON GRAY, *Dep. of Physics, University of Illinois at Urbana-Champaign* PETER CZOSCHKE, JON TISCHLER, *Solid State Division, Oak Ridge National Laboratory* HAWOONG HONG, *Frederick-Seitz Material Research Laboratory, University of Illinois at Urbana-Champaign* TAI-CHANG CHIANG, *Dep. of Physics, University of Illinois at Urbana-Champaign* We grew TiN on sapphire (0001) substrates by pulsed laser deposition (PLD). The growth was monitored, in situ, in real time by x-ray diffraction at the $(0,0,\frac{1}{2})$ anti-Bragg position using a synchrotron beam. The experiment was carried out at the UNICAT undulator beamline at the Advanced Photon Source. The measured x-ray intensity shows atomic-layer-resolved oscillations superimposed on a beating pattern with changing wavelength. Numerical modeling shows that the results can be well described in terms of an evolving island height distribution. Implications in regard to film structure and morphology will be discussed.

**11:39**

**H12 3 Characterization of Graphene Films and Ribbons on Silicon Carbide** TIANBO LI, ASMEROM OGBAZGHI, XUEBIN LI, ZHIMIN SONG, CLAIRE BERGER, WALT DE HEER, PHILLIP FIRST, *Georgia Institute of Technology* Ultrathin graphite films, 1-6 graphene layers thick, were grown on both the Si-terminated (0001) and C-terminated $(000\bar{1})$ faces of 4H- and 6H-SiC via thermal desorption of silicon in UHV. Through investigations of the thinnest films (monolayer graphene) by LEED and STM, we show the existence of a complex $\sqrt{3} \times \sqrt{3}R30°$ reconstructed layer between the lowest graphene layer and the SiC substrate. The $6\sqrt{3} \times 6\sqrt{3}R30°$ LEED pattern obtained after annealing above $1250°C$ can be explained predominantly by kinematic scattering from the slightly $6 \times 6$ corrugated graphene, from the reconstruction, and from the SiC substrate. Low-order double-scattering is required to explain all of the diffraction features. LEED and STM on graphene ribbons patterned from these films (80-400 nm width) show that graphene layers remain intact after photolithography and plasma etching.

**H12 4 A new work function measurement technique allowing simultaneous material deposition, and reflectivity measurements.*** B. J. HINCH, A.V. ERMAKOV, E. Z. CIFTLIKLI, S. E. SYSOEV, I. G. SHUTTLEWORTH, *Dept. of Chemistry and Chemical Biology, Rutgers University, Piscataway, NJ 08854.* We report on the application of a novel technique for relative work function measurements, of single crystal surfaces, employing grazing incidence electron reflection. This technique cannot suffer from photo or e- beam induced surface damage effects, and yet does enable free access to the surfaces for simultaneous deposition/evaporation, and/or application of other surface characterization methods. We discuss the optimization of experi-

mental parameters in this method, and demonstrate its application in concurrent measurements of helium atom reflectivity and work function changes, taking place during oxygen exposure of a Cu(001) surface. Observed work function changes reproduce well the trends seen in earlier polycrystalline film measurements. In addition, the work function changes indicate structural changes that are not apparent in helium atom scattering at oxygen exposures in excess of ~ 50L.

**H12 5 Si/Cu Interface Structure and Adhesion** XIAO-GANG WANG, JOHN SMITH, *Delphi Research Labs* An *ab initio* investigation of the Si(111)/Cu(111) interfacial atomic structure and adhesion is reported [1]. Misfit dislocations appear naturally, as do hcp interfacial silicide phases that vary with temperature. The silicides form in the interface even at relatively low temperatures. These results are consistent with available experimental data. [1] Xiao-Gang Wang, John Smith, Physical Review Letters 95, 156102 (2005).

**12:15**

**H12 6 Modeling the formation of nanoscale pores in metal oxides during anodization** CHRISTINE SAMPLE, ALEXANDER GOLOVIN, *Northwestern University* A theory of the formation of nanoporous metal oxides grown by anodization is developed. Linear stability analysis of an oxide layer is performed for the case of field-dependent conductivity, and parameter regions are determined corresponding to the onset of instability and the growth of pores. It is shown that competition between the destabilizing effect of field-assisted dissolution and the stabilizing effect of surface energy provides the selection mechanism of the pore diameter. The weakly nonlinear evolution of the oxide layer is shown to be governed by the Kuramoto-Sivashinsky equation whose solutions exhibit spatio-temporal chaos. A system of strongly nonlinear long-wave equations describing the evolution far from the instability threshold is described. It's numerical solution illustrates the formation of deep pores.

**H12 7 Local field distribution near corrugated interfaces: Green function formalism versus effective medium theory** CHUN WING CHOY, JUN JUN XIAO, KIN WAH YU, *The Chinese University of Hong Kong* The Green function formalism (GFF) has been established recently [1,2] to study the local field electric field distribution near a periodic interface separating two homogeneous media of different dielectric constants. In GFF, the integral equations can be solved conveniently because of the existence of an analytic expression for the kernel (Greenian). However, due to a severe singularity in the kernel, the formalism was formerly applied to compute the electric fields away from the interface region [1,2]. In this work, we have been succeeded in extending GFF to compute the electric field inside the interface region, by taking advantage of a sum rule. To our surprise, the strengths of the electric fields are quite similar in both media across the interface, despite of the large difference in the dielectric constants. Moreover, we propose a simple effective medium approximation (EMA) to compute the electric field inside the interface region. We show that EMA can indeed give an excellent description of the electric field except near a geometric resonance. [1] K. W. Yu and Jones T. K. Wan, Comput. Phys. Commun. 142, 368 (2001). [2] H. F. Tam and K. W. Yu, Annual APS March Meeting, abstract Q31.009 (2002).

**H12 8 Textbook adsorption at non-textbook adsorption sites: alkali atoms on alkali halide surfaces** BO LI, ANGELOS MICHAELIDES, MATTHIAS SCHEFFLER, *Fritz-Haber-Institut der Max-Planck-Gesellschaft* Density-functional theory (DFT) and second order Møller-Plesset perturbation theory (MP2) calculations for F, Cl and Br adatoms on the (100) surfaces of NaF, NaCl and NaBr indicate that on these surfaces the halide adatoms adsorb preferentially above halide substrate sites, rather than above Na substrate sites as might be anticipated. Analysis of the electronic structures in each system reveals that this hitherto unheard of adsorption mode is stabilized by the formation of perfectly conventional covalent bonds between the halide adatoms and the halide substrate atoms. This finding has implications to, for example, alkali-halide crystal growth, atomic manipulation on insulator surfaces, and the design of accurate empirical potentials to describe insulator-adatom interactions.

**12:51**

**H12 9 Adsorption and desorption of hydrogen on Cu(111) and Xe-covered Cu(111).*** YIYAN FEI, XIANGDONG ZHU, *University of California at Davis* Using an optical ellipsometry technique to monitor adsorbate coverage in-situ, we studied activated adsorption of filament-heated molecular hydrogen on Cu(111) and the isothermal desorption of hydrogen adatoms from Cu(111). The adsorption follows a zeroth order kinetics such that the net sticking probability, though small, is independent of the hydrogen adatom coverage until a saturation coverage is reached. The desorption follows a second-order kinetics with an activation energy of 0.63 eV and a pre-exponential factor of $1 \times 10^9$/s. A pre-adsorbed monolayer of Xe atoms on Cu(111) prohibits subsequent adsorption of filament-heated molecular hydrogen, making physisorbed Xe useful templates for spatial patterning of hydrogen adatom density on Cu(111).

**13:03**

**H12 10 Pattern formation of hydrogen adatom density on Cu(111) using patterns of xenon adatoms as templates.*** XIANGDONG ZHU, YIYAN FEI, *University of California at Davis* We formed grating-like patterns of hydrogen adatom density on Cu(111) by using complementary patterns of xenon adatom density as the template. The template was pre-formed by laser-induced thermal desorption of a Xe monolayer on Cu(111) using the interference pattern of two coherent laser pulses. The ''patterned'' surface was subsequently exposed to hot hydrogen molecules which dissociate and adsorb preferentially on the uncovered part of the surface. We removed the Xe template by laser-induced thermal desorption which left behind a grating-like hydrogen density pattern intact on Cu(111). By following the evolution of hydrogen density gratings on Cu(111) from 153 to 183 K with linear

optical diffraction, we found that the diffusion of hydrogen atoms on Cu(111) in this temperature range was characterized by an activation energy barrier $E_{diff}$ = 6.4 kcal/mol (or 279 meV) and a pre-exponential factor $D_0 = 2.0 \times 10^{-3}$ cm$^2$/sec.

**H12 11 CRDS Detection of HS Radical in HFCVD Diamond Thin Film** MADALINA BUZAINAU, VLADIMIR MAKAROV, GERARDO MORELL, BRAD WEINER, *UPR* In the present study, the HS radical was detected using the Cavity Ring Down Spectroscopic (CRDS) method in hot filament diamond CVD for the $CH_4$(0.4%)/$H_2$ mixture doped by $H_2S$ (400 ppm). The HS radical was detected both by the 0 - 0(A —X) and 1 - 0(A — X) transitions. The absolute absorption density spectrum of the HS radical was obtained as well as the absolute HS concentration estimation. This study proofs that the HS radical is an intermediate produced during the diamond CVD synthesis.

**13:27**

**H12 12 The CRDS method application for study of the gas-phase processes in the hot CVD diamond thin film.** VLADIMIR BUZAIANUMAKAROV, ARTURO HIDALGO, GERARDO MORELL, BRAD WEINER, MADALINA BUZAIANU, *UPR* For detailed analysis of problem related to the hot CVD carbon-containing nano-material growing, we have to detect different intermediate species forming during the growing process as well as investigate dependences of concentrations of these species on different experimental parameters (concentrations of the $CJH_4$, $H_2S$ stable chemical compounds and distance from the filament system to the substrate surface). In the present study, the HS and CS radicals were detected using the Cavity Ring Down Spectroscopic (CRDS) method in the hot CVD diamond thin film for the $CH_4$(0.4 %) + $H_2$ mixture doped by $H_2S$ (400 ppm). The absolute absorption density spectra of the HS and CS radicals were obtained as a function of different experimental parameters. This study proofs that the HS and CS radicals are an intermediate, which forms during the hot filament CVD process. The kinetics approach was developed for detailed analysis of the experimental data obtained. The kinetics scheme includes homogenous and heterogenous processes as well as processes of the chemical species transport in the CVD chamber.

**H12 13 A Density Functional Study of the Americium (001) Surface*** DA GAO, ASOK KUMAR RAY, *University of Texas at Arlington* Electronic structure properties of the fcc americium (001) surface, modeled by periodically repeated fcc Am (001) surface slabs, have been studied with the full-potential linearized augmented plane wave (FP-LAPW) method. The alternative basis set APW+lo is used inside the atomic spheres for chemically important orbitals that are difficult to converge, whereas LAPW is used for others. The core states are treated fully relativistically and for valence states, two levels of treatments are implemented: (1) a scalar relativistic scheme including the mass-velocity correction and the Darwin s-shift and (2) a fully relativistic scheme with spin-orbit coupling included in a second variational treatment using the scalar-relativistic eigenfunctions as basis. Our results indicate that the ground state of Am (001) surface is antiferromagnetic. The quantum size effects in the surface energies and the work functions of the (001) fcc americium ultra thin films (UTF) have been examined up to seven layers. In addition, the Am (001) surface properties are compared with our earlier study of the Am (111) surface.

*This work is supported by the Chemical Sciences, Geosciences and Biosciences Division, Office of Basic Energy Sciences, Office of Science, U. S. Department of Energy (Grant No. DE-FG02-03ER15409) and the Welch Foundation, Houston, Texas (Grant No. Y-1525)

**13:51**

**H12 14 A Density Functional Study of Carbon Monoxide Adsorption on (100) Surface of $\gamma$-Uranium** ASOK RAY, PRATIK DHOLABHAI, *University of Texas at Arlington* Adsorption of the CO molecule on the $\gamma$-U (100) surface has been studied at both non-spin-polarized and spin-polarized levels using the generalized gradient approximation to density functional theory (GGA-DFT) with Perdew and Wang (PW) functionals. The bridge position with the vert2 approach is found to be most favorable site with a chemisorption energy of 2.93eV for the non-spin-polarized case, and 3.19eV for the spin-polarized case. The distances of the carbon atom from the uranium surface are found to be 1.59Å and 1.72Å for the non-spin-polarized and spin-polarized cases, respectively. The inter-atomic distances between the carbon and oxygen atoms for the most favorable position are found to be 1.13Å and 1.21Å for the non-spin-polarized and spin-polarized cases, respectively. The magnetic moment for the most favorable site is found to be 0.04$\mu_B$ per atom. A significant charge transfer from the first layer of the uranium surface to the carbon and oxygen atoms is found to occur, implying that the bonding is partly ionic. Significant hybridization between the U 5*f* and CO 2*p* orbitals are also observed. This work is supported by the Chemical Sciences, Geosciences and Biosciences Division, Office of Basic Energy Sciences, Office of Science, U. S. Department of Energy (Grant No. DE-FG02-03ER15409) and the Welch Foundation, Houston, Texas (Grant No. Y-1525).

**14:03**

**H12 15 A Density Functional Study of Atomic Oxygen and Carbon Adsorptions on the (100) Surface of $\gamma$-Uranium*** PRATIK DHOLABHAI, ASOK RAY, *University of Texas at Arlington* Atomic oxygen and carbon adsorptions on the $\gamma$-U (100) surface have been studied using the generalized gradient approximation to density functional theory (GGA-DFT) with Perdew and Wang (PW) functionals. Different chemisorption sites at both non-spin-polarized and spin-polarized levels of theory have been thoroughly investigated. For O adsorption, the bridge position is the most favorable site with chemisorption energies of 7.887eV and 7.965eV for the non-spin-polarized and spin-polarized cases, respectively. The distances of the O adatom from the U surface are found to be 1.19Å and 1.22Å, respectively. For C adsorption, the center position is the most favorable site with a chemisorption energy of 7.816eV for the non-spin-polarized case, and 7.895eV for the spin-polarized case. The distances of the C adatom from the U surface are 0.62Å for the non-spin-polarized and 0.52Å for the spin-polarized cases. A study of the density-of-states (DOS) for O and C adsorbed uranium surfaces shows that the hybridization between U 5*f* orbitals and the O and C 2*p* orbitals is weak and

the bonding is primarily ionic. Comparisons with published results will be presented.

*This work is supported by the Chemical Sciences, Geosciences and Biosciences Division, Office of Basic Energy Sciences, Office of Science, U.S. Department of Energy and the Welch Foundation, Houston, Texas.

**H13 1 Confinement-induced restructuring of colloidal particles** YINGXI ELAINE ZHU, CINDY LEI, YANGHAI YU, PRASAD SARANGAPANI, *Department of Chemical and Biomolecular Engineering, University of Notre Dame* Packing configuration of colloidal particles in the bulk suspension is determined by interparticle interaction and volume fraction. However, many modern technological applications of colloidal suspensions entail applications of surface confinement and significantly modify the packing structure of colloidal particles. The effect of surface confinement on particle packing is yet poorly understood. We have custom designed a compression apparatus that is well equipped with a confocal microscope, allowing us to vary the gap spacing between two flat solid substrates confining colloidal suspension and image the 3-D microstructure of colloidal particles simultaneously. We observe enhanced layering of confined colloidal particles and a well-ordered 2D crystal structure of each layer formed after quasi-static compression. Surprisingly, we have also observed disordered layers of colloidal particles and the jamming of multi-layers against one another after rapid quench. These observations suggest the intriguing confinement-induced restructuring of dense colloidal suspensions, and provide a unifying perspective from which to pack the particles more efficiently than in bulk. In preliminary experiments, we have also studied the effect of surface chemistry and topography on the packing configuration of confined colloidal particles.

**11:27**
**H13 2 Wetting Behavior of Nitrous Oxide Near its Critical Point** ROBERT WEILER, MORDECAI WAEGELL, RAFAEL GARCIA, *Worcester Polytechnic Institute* A liquid is said to ''not wet'' a surface if its beads on it and thus exhibits a nonzero contact angle. However, if the liquid spreads out uniformly on the surface, with a contact angle of zero, then it is said to ''wet'' the surface. Given any liquid whatsoever that initially does not wet a surface, the Cahn theory [1] predicts that the liquid will eventually wet the surface as we increase the temperature and follow along the liquid-vapor coexistence line. For liquids on solid surfaces, the wetting transition, from non-wetting to wetting, is predicted to be first order and occur sharply at a wetting temperature Tw [2]. Tw can be calculated from our knowledge of interatomic potentials that characterize the adatom-adatom attraction and the adatom-surface attraction. The Cahn theory has been verified for non-polar liquids on solid surfaces but so far there exist no experiments for polar liquids. Nitrous Oxide is polar and has a critical point slightly above room temperature. We will report on initial experiments to verify the Cahn theory for this system. [1] J. W. Cahn, J. Phys. Chem. 66, 3667 (1977). [2] M. Gatica, X. Zhao, J. K. Johnson and M. W. Cole, J. Phys. Chem. B 108, 11704 (2004) and References Therein.

**11:39**
**H13 3 Effects of contact line hysteresis and surface tension on contact line pinning of inclined droplets.** VIATCHESLAV BEREJNOV, ROBERT E. THORNE, *Physics Department, Cornell University, Ithaca, NY, 14853-2501* The stability and pinning of drops on inclined surfaces is of fundamental and technological interest. Contact line dynamics depends on the properties of the liquid, the solid surface and the manner in which line motion is driven. Achieving reproducible final contact line and drop shapes is important in biotechnology applications where drops are used as mini-reactors, such as in structural genomics where sessile drops are used for protein and virus crystallization. We will describe experiments investigating pinning and deformation of drops containing pure liquids, proteins and colloids, placed on substrates with a range of surface treatments. Proteins affect contact angle hysteresis at low concentrations, and surface tension at high concentration, leading to two different regimes of pinning. Theoretical approaches that can be useful in understanding our results will also be presented.

**11:51**
**H13 4 Contact Line Pinning by Microfabricated Patterns** YEVGENIY KALININ, VIATCHESLAV BEREJNOV, ROBERT THORNE, *Cornell University* Interactions of the liquid-solid contact line with micrometer-sized features on solid surfaces can provide a method for controlling contact line stability and shape. We have investigated how the size, shape and chemical properties of regular features affect the contact angle and its hysteresis. Microfabrication techniques are used to create 4-50 micrometer-size patterns on otherwise homogeneous flat surfaces, and the relative importance of geometric and chemical factors are determined. We discuss applications to protein crystallization, and in particular show that the volumes, shape stability and shape reproducibility of 10-100 microliter aqueous drops containing proteins and surfactants can be greatly increased. Surface patterning provides greater reproducibility in crystallization outcomes and greater flexibility in the design of crystallization experiments.

**12:03**
**H13 5 The kinetic coefficient of hard-sphere crystal-melt interfaces from molecular-dynamics simulations** MAJEED AMINI, *Department of Physics, University of Kansas, Lawrence, KS 66045 USA* BRIAN LAIRD, *Department of Chemistry, University of Kansas, Lawrence, Kansas 66045 USA* The kinetic coefficient for a crystal melt interface, $\mu$, is the ratio of the interface growth velocity to the undercooling $(T_M - T)$, where $T_M$ is the melting point. In this work we determine the kinetic coeffiecient for the hard-sphere system by analyzing capillary fluctuations in interface position using molecular dynamics (MD) simulation [Hoyt *et al*, Mat. Sci. Eng. **R41**, 121-163 (2003)]. We report the kinetic coefficient for the three interfaces: (100), (110), and (111). Our results for $\mu_{100}$, $\mu_{110}$, and $\mu_{111}$ are 1.15(4) $(k_B/(mT_M))^{1/2}$, 0.85(6) $(k_B/(mT_M))^{1/2}$, and 0.57(8) $(k_B/(mT_M))^{1/2}$, respectively, which gives the relation $\mu_{100} > \mu_{110} > \mu_{111}$. This ordering is consistent with the recent results of MD simulations for a variety

of metals. The anisotropy ratios $\mu_{100}/\mu_{110}$, and $\mu_{100}/\mu_{111}$ are 1.35(11), and 2.0(3), respectively. We compare our results to those of classical density functional theory (DFT) of [Mikheev and Chernov, J. Cryst. Growth **112**, 591-596 (1991)].

**12:15**

**H13 6 Quasielastic neutron scattering study of the dynamics of 1,3-diphenylpropane grafted to the pore surface of MCM-41** EDWARD KINTZEL, KENNETH HERWIG, MICHELLE KIDDER, A.C. BUCHANAN, PHILLIP BRITT, *Oak Ridge National Laboratory* ALAN CHAFFE, *Monash University* An initial study of the dynamics of 1,3-diphenylpropane (DPP, $\equiv$ Si-O-$C_6H_4(CH_2)_3C_6H_5$) attached to the surface of the mesoporous silica MCM-41 has been carried out using quasielastic neutron scattering. Measurements of the elastic intensity were carried out in the temperature range 50-380 K and indicate a trend in DPP dynamics with changing grafting density and pore size. Full quasielastic scans over an energy range of $\pm$ 17 $\mu$eV were carried out at temperatures of 240 K, 280 K, and 320 K. Initial analysis employed a stretched exponential to model the Fourier transformed data in the time domain. An average relaxation time, defined as $< \tau > = (\tau/\beta)\Gamma(1/\beta)$ where $\beta$ is the stretched exponent in the model, shows a dependence on temperature, pore size, and DPP grafting density. Molecular dynamics simulations using a model for DPP grafted onto the surface of MCM-41 was compared with the experimental results.

**12:27**

**H13 7 Experimental two-point microrheology of two-dimensional systems** VIKRAM PRASAD, ERIC WEEKS, *Emory University* Microrheology is often used to determine the bulk viscoelasticity of materials such as polymer solutions, by tracking the diffusion of tracer particles. For heterogeneous materials, where single particle microrheology breaks down, a modified technique known as two-point microrheology has been established where motions of particles with varying spatial separations are correlated. In 3-d systems, this correlated motion decays as 1/R, and can be used to identify the long wavelength modes in the system, and therefore the bulk viscoelasticity. For 2-d systems, theory has predicted a logarithmic decay, but to date, this prediction has gone untested. We look at the correlated motions of colloidal particles in two types of quasi 2-d systems (protein molecules at an air-water interface, and thin soap films), and observe a transition from 3-d to 2-d, by continuously varying the Boussinesq number, $B_0 = (\eta_s/\eta a)$ from 0 to $\infty$, where $\eta_s$ is the surface viscosity, $\eta$ is the bulk viscosity, and a is the size of the colloidal particle. The experimental results are compared to theory, and consequences for microrheology at interfaces are discussed.

**12:39**

**H13 8 Thermal response of polymer coated colloidal diffusion near surfaces** STEPHEN ANTHONY, HUILIN TU, LIANG HONG, PAUL BRAUN, STEVE GRANICK, *Departments of Chemistry and of Material Science, University of Illinois* Thermally responsive poly(/N/-isopropylacrylamide) (PNIPAAm) tethered silica particles represent a potential building block for new materials. For this research, Surface-initiated Atom Transfer Radical Polymerization (ATRP) was chosen for its ability to generate well defined, homogeneous polymer brushes on silica nanoparticles and surfaces. Phase contrast optical microscopy was used along with single particle tracking methods to characterize the motion of these particles in suspension as well as close to brush modified surfaces. Temperature dependence experiments reveal that increased temperature decreases the radius of the particles. Additionally, heating may trigger a transition from ''sticky'' surfaces to ''slippery'' surfaces. Below LCST, swelled PNIPAAm chains may interdigitate and slow down particle motion. Thermal hysteresis was also apparent; kinetic trapping of particles resulted in the retention of an immobilized population upon cooling. Furthermore, the analysis of the diffusion dynamics also implies interparticle interactions and particle-surface interactions. Understanding the kinetics of this complex fluid system facilitates the design and control of novel materials.

**12:51**

**H13 9 Surface patterns on co-assembled fibers from charged, amphiphilic molecules** KEVIN KOHLSTEDT, *Northwestern University* FRANCISCO SOLIS, *Arizona State University* MONICA OLVERA DE LA CRUZ, *Northwestern University* We analyze local segregation of species in charged multicomponent cylindrical micelles. In particular, we consider co-assemblies of cationic and anionic heterogeneous molecules such as lipids and peptide amphiphiles. Charge heterogeneities can develop at the surface of the fibers due to the competition between the short-range incompatibility of the co-assembled components and the electrostatic interactions. The system can be described by a line tension between domains $\gamma$, which favors growth of the domains of segregated components, and the electrostatic energy of the domains with charge density $\sigma$, which increases rapidly with the size of the segregated domain L. The competition results in the formation of domains with a characteristic size $L_o = (\gamma\varepsilon/\sigma^2)^{1/2}$. In stoichiometric mixtures the constraints of the geometry and the long range correlations lead to lamellar stripes of different pitch. We present results on the different orientations of the lamellar patterns as a function of the ratio between the lamellar size and the cylinder radius. We find the critical salt concentration, which is a function of radius and lamellar size, at which the patterns grow to macroscopic sizes due to the screening of the Coulomb interactions.

**13:03**

**H13 10 Ion and neutral particle emission from polytetrafluoroethyene under 157-nm irradiation** STEPHEN LANGFORD, SHARON JOHN, THOMAS DICKINSON, *Washington State University* Polytetrafluoroethylene (PFTE) is an important electronic material. Interactions with 157-nm laser radiation are of interest in the deposition and patterning of thin films of PTFE and similar materials. We have characterized the desorption of neutral and charged species from PTFE surfaces during 157-nm irradiation by time-resolved quadrupole mass spectroscopy. The principal neutral species are $(CF_2)_x$ units. The neutral time-of-flight signals have a fast component with kinetic energies on the order of an eV, consistent with direct photochemical emission. These energetic neutrals are presumably created by scission of the C-C backbone by UV excitation. Slower neutral emissions are consistent with thermal emission from the surface at temperatures of several hundred kelvin above ambient. Much of the slower emission is attributed to thermally activated unzipping of the polymer

backbone after photoelectronic scission. The principal positive and negative ions are $C^+$ and $F^-$. A large number of positive and negative charges are electrostatically coupled and travel together until separated by the electric fields of the mass filter.

**13:15**

**H13 11 Dual Syringe Electrospinning of FNfds-modified Hyaluronic Acid** YUAN JI, *Dept. of Materials Science, SUNY at Stony Brook* KAUSTABH GHOSH, *Dept. of Biomedical Engr., SUNY at Stony Brook* XIAOZHENG SHU, *Dept. of Medicinal Chemistry, the University of Utah* JONATHAN SOKOLOV, *Dept. of Materials Science, SUNY at Stony Brook* GLENN PRESTWICH, *Dept. of Medicinal Chemistry, the University of Utah* RICHARD CLARK, *Dept. of Biomedical Engr., SUNY at Stony Brook* MIRIAM RAFAILOVICH, *Dept. of Materials Science, SUNY at Stony Brook* We described the fabrication of a unique HA nanofibrous scaffold using dual syringe reactive electrospinning. 3′-dithiobis(propanoic dihydrazide)-modified HA (HA-DTPH) and Poly (ethylene glycol)-diacrylate (PEGDA) were selected as the cross-linking system. PEO was blended with HA-DTPH to facilitate the fiber formation. Fibronectin functional domains (FNfds) were incorporated with PEGDA and covalently linked to HA via conjugate addition to improve the cell attachment. The as-spun scaffold was soaked into DI water to remove PEO and yield an FNfds-modified HA-DTPH nanofibrous scaffold. Human dermal fibroblasts CF31 were seeded on FNfds-modified HA-DTPH scaffolds. The CF31 fibroblasts showed a unique extended dendritic morphology which is opposed to the typical flattened morphology of cells on regular 2D geometries. Supported by NSF-MRSEC.

**H13 12 Single Electron Tunneling to Individual Gold Nano-Particles** NING ZHENG, *Physics Dept* GANGLI WANG, *Chemistry Dept* EZRA BUSSMANN, *Physics Dept* LIN ZHAO, *Physics Dept* CLAYTON WILLIAMS, *Physics Dept, Univeristy of Utah* Single electron tunneling to naked gold clusters and monolayer protected gold clusters on a thermally grown silicon dioxide film has been performed by single-electron tunneling force microscopy (SETFM) at room temperature.[1,2] In this technique, single electron tunneling events are detected by electrostatic force measurement. We observe several abrupt steps in the smooth frequency shift curve as the tip approaches a cluster. These steps correspond to single or multiple electron tunneling events to the gold particle. Since the tunneling electron changes the charge on the particle, it is also detected as a change in surface potential. The electron can be manipulated to and from the gold particle by changing the voltage applied to the tip. These tunneling events can be used to determine the electronic structure and charging energy of the individual gold particle. The technique will be described and the single electron tunneling results will be discussed. A theoretical model of the tunneling measurements is in agreement with the measurements. [1] E. Bussmann, D. J. Kim, and C.C. Williamsit, Appl. Phys. Lett. **85**, 2538 (2004) [2] E. Bussmann, N. Zheng, and C.C. Williams, itAppl. Phys. Lett. **86**, 163109 (2005)

**H15 1 Angle Resolved Photoemission Spectroscopy of Single Crystal Uranium (001)*** C.P. OPEIL, R.K. SCHULZE, R.C. ALBERS, B. MIHAILA, K.B. BLAGOEV, M.E. MANLEY, J.C. LASHLEY, J.L. SMITH, *Los Alamos National Laboratory* P.B. LITTLEWOOD, *Cavendish Laboratory, University of Cambridge* Using Angle Resolved Photoemission Spectroscopy (ARPES) we measured the energy dispersion for binding energy (BE) $<$ 8 eV at 173 and 373 K on a high quality uranium single crystal (001) along the principle crystallographic directions $\Gamma$ to Y, $\Sigma$, and S. These measurements are compared with WIEN2K band structure calculations. We report significant correspondence between our band dispersion and theoretical calculations. Temperature and electron correlation effects will be discussed.

*Work performed under the auspices of the US Dept. of Energy.

**11:27**

**H15 2 Orbital-Resolved Soft X-ray Spectroscopy Measurnents of $Sr_2RuO_4$ Electronic Structure.** TIM SCHULER, *MPT Polymers* J. HOOPER, *Tulane University* ZHIQIANG MAO, *Tulane University* DAVID EDERER, *Tulane University* GUO-PING ZHANG, *Indiana State University* TOM CALLCOTT, *University of Tennessee* Strontium ruthenate ($Sr_2RuO_4$) is a spin-tripletsuperonductor[1] of the Ruddlesden-Popper (RP) series with n=1. We have studied the electronic structure of single crystals of this system by density functional theory (DFT) calculations and soft x-ray emission and absorption measurements at the oxygen K edge (530 eV) and find that DFT calculations provide an excellent model to characterize the molecular orbitals corresponding to the inequivalent O sites in this perovskite compound. The linearly polarized radiation excites primarily O [1] (planar) sites at almost normal incidence and O [2] (apical) sites at grazing incidence. Our results suggest a larger level of hybridization between the Ru d and the O p states in the $RuO^2$ planes than between the Ru and apical O atoms, which also implies more localized bonding along the apical direction than the planar direction. This work was supported by DOE grant No. DE−FG02−05ER−46183. 1)Y. Maeno, et al, Nature 372, 532 (1994).

**11:39**

**H15 3 Electronic Structure and Bulk Spin Valve Behavior in $Ca_3Ru_2O_7$** DAVID SINGH, *Oak Ridge National Laboratory* SUSHIL AULUCK, *IIT Roorkee, India* The perovskite based ruthenates show a remarkable range of electronic and magnetic properties, even though they are all based on $Ru^{4+}$ ions in octahedral environments with corner sharing bonding topologies. These behaviors include robust itinerant ferromagnetism, paramagnetic bad metal properties, unconventional superconductivity, Mott insulating properties and metamagnetic quantum critical behavior. The bilayer, so- called 327 compounds are of particular interest because of their borderline properties. We report density functional calculations of the magnetic properties and Fermiology of $Ca_3Ru_2O_7$. The ground state consists of ferromagnetic bilayers, stacked antiferromagnetically. The bilayers are almost but not exactly half-metallic. In the ferromagnetic state opposite spin polar-

izations are found for in-plane and out-of-plane transport. Relatively high out of plane conductivity is found for the majority spin, which is relatively weakly conductive in- plane. In the ground state in-plane quantities are essentially the same, but the out of plane transport is strongly reduced. This work was supported by the Department of Energy.

**11:51**

**H15 4 First Observation of MCD at O and Ru sites in $Sr_4Ru_3O_{10}$** YINWAN LI, ZHIQIANG MAO, MENG ZHOU, DAVID EDERER, *Tulane University* JOHN FREELAND, *Argonne National Laboratory* TOM CALLCOTT, *University of Tennessee* Perovskite strontium ruthenates of the Ruddlesden-Popper (RP) series $Sr_{n+1}Ru_nO_{3n+1}$show a variety of complex behavior including superconductivity and metamagnetism. $Sr_4Ru_3O_{10}$ is a trilayer member of the RP series with n=3 that is metamagnetic and shows an electronic phase separation[1]. We wanted to test if this material showed magnetic behavior at low fields and performed magnetic circular dichroism measurements (MCD) at the O K and Ru L edges. The measurements were carried out at the Sector 4 polarization beam line of the Advanced Photon Source at grazing (10°) and normal incidence angles at the characteristic temperature 50K below which metamagnetic behavior occurs[2] and above the ordering temperature (150K). We observed dichroic behavior at both temperatures although the dichroism was reduced by a factor of 10 at 150K relative to the measurements at 50K. It is significant to note that only the lowest unoccupied orbital (LUMO) associated with the planar O site showed dichroic behavior. This research was supported in part by DOE grant No. DE-FG02-05ER-46183, and the Advanced Photon Source is supported by DOE grant W-31-109-ENG-38.

**H15 5 Zero bias anomaly in the low-temperature scanning tunneling spectra of Sr3Ru2O7*** R. MATZDORF, B. NANSSEU, J. HAGER, *Institute of Physics, University of Kassel, 34109 Kassel, Germany* H. YAGUCHI, Y. MAENO, *Kyoto University, Japan* J. ZHANG, *Department of Physics, Florida International University, Miami, Florida 33199, USA* R. MOORE, E.W. PLUMMER, *Condensed Matter Science Division, Oak Ridge national Laboratory, Oak Ridge, Tennessee 37831, USA* We have studied a zero bias anomaly in scanning tunneling spectra of Sr3Ru2O7 as function of temperature. The dip-like feature in the dI/dV spectra is observed in an energy range of −20meV to +20meV around Fermi energy. The depth of the dip decreases with increasing temperature in a temperature range of 5 to 30 Kelvin. The temperature dependence of the dip is not due to the thermal broadening connected to the tunneling process. The results on Sr3Ru2O7 are compared with temperature dependent scanning tunneling spectra of Sr2RuO4. Finally, we discuss different effects as possible explanations for the zero bias anomaly.

**H15 6 Fermi-liquid-like quasiparticle excitations in $Sr_2RhO_4$** WILLIAM DUNKEL, FELIX BAUMBERGER, WORAWAT MEEVASANA, DONGHUI LU, *Stanford University* ROBIN PERRY, ANDY MACKENZIE, *St. Andrews University* ZHIXUN SHEN, *Stanford University* The layered 4d transition metal oxide $Sr_2RhO_4$ supports a highly anisotropic, well-defined Fermi-liquid-like electron fluid. Angle resolved photoemission spectroscopy shows a Fermi surface and quasiparticle effective masses in quantitative agreement with bulk de Haas-van Alphen data. Sr $_2RhO_4$ thus presents a prime opportunity to study the electronic self energy in a well-defined model system. To this end, we present a comprehensive spectral function analysis of high resolution angle resolved photoemission data from $Sr_2RhO_4$. Preliminary data at very low photon energies are presented and compared to state-of-the-art data taken at conventional UV photon energies.

**H15 7 Quantum oscillations in $RAgSb_2$ (R = La, Sm, Y) as seen via magnetostriction measurements** S.L. BUD'KO, S.A. LAW, P.C. CANFIELD, *Ames Laboratory and Dept. of Physics and Astronomy, Iowa State University* G.M. SCHMIEDESHOFF, *Dept. of Physics, Occidental College, Los Angeles* We present low temperature longitudinal magnetostriction measurements taken using a capacitance dilatometer in a PPMS-14 instrument for several $RAgSb_2$ (R = rare earth) compounds. The quantum oscillations in magnetostriction were observed up to temperatures as high as 25 K. These data are compared with the results of de Haas - van Alphen and Shubnikov - de Haas measurements. Using these data the uniaxial stress dependencies of the extremal Fermi surface orbits can be evaluated.

**H15 8 Local Flattening of the Fermi Surface and Quantum Oscillations in the Magnetoacoustic Response of a Metal** GREGORY ZIMBOVSKY, NATALYA ZIMBOVSKAYA, *University of Puerto Rico - Humacao* In the present work we theoretically analyze the effect of the Fermi surface local geometry on quantum oscillations in the velocity of an acoustic wave travelling in metal across a strong magnetic field. We show that local flattenings of the Fermi surface could cause significant amplification of quantum oscillations [1]. This occurs due to enhancement of commensurability oscillations modulating the quantum oscillations in the electron density of states on the Fermi surface. The amplification in the quantum oscillations could be revealed at fitting directions of the magnetic field. [1] N. A. Zimbovskaya, cond-mat/0505301.

**H15 9 Theory of the Cyclotron Resonance in Al,Pb,Zn and Cd** SHIGEJI FUJITA, ROHIT SINGH, ROBERT SIMION, *University of Buffalo* SEIICHI WATANABE, *Hokkaido University, Japan* SALVADOR GODOY, *UNAM, Mexico* A quantum theory of the cyclotron resonance is developed. For a face-centered-cubic (fcc) metal the obvious candidates for the Cyclotron Planes (CP) in which the conduction electron (''electron,'''hole'') circulates are the three families of planes {100}, {110} and {111}. Following Dresselhaus-Kip-Kittel (DKK,1955) we assume a quadratic energy-momentum ($\hbar k$) relation with the effective mass ($m_1, m_2, m_3$) and analyze the angle- dependent resonance peaks in terms of Shockley's formula (a generalization of the DKK formula).For aluminum Al (fcc) an ''electron'' ellipsoid with the major axes in [110] with ($m_1, m_2, m_3$) = (0.108,0.156,1.96)$m$ is obtained. For lead (Pb) (fcc) a hyperboloid in [110] with

$(m_1, m_2, m_3) = (1.18, 0.244, -8.71)m$ and an ''electron'' sphere with $m^* = 1.30m$ associated with the CP {100} are obtained. For a hexagonal- closed-pack (hcp) metal,the CP is the hexagonal base plane. The effective mass $m_b$ for the basal-plane motion and the mass $m_c$ along the c-axis for zinc (Zn) [cadmium (Cd)] (both hcp)are $(m_b, m_c) = (1.04, 0.212)$m [(1.14,0.217)m], which characterize the spheroids with the major axis along the c-axis.

**H15 10 Magnetic and Transport Properties of $RCoIn_5$(R=Pr,Nd) and $RCoGa_5$ (R=Tb-Tm)** JACOB HUDIS, *Department of Physics and Astronomy, Johns Hopkins University* RONGWEI HU, *Department of Physics, Brown University/ Brookhaven National Lab* COLLIN BROHOLM, *Department of Physics and Astronomy, Johns Hopkins University* V.F. MITROVIC, CEDOMIR PETROVIC, *Department of Physics, Brookhaven National Lab* We report on magnetic and transport properties of single crystals of the light rare earth containing series of compounds $RCoIn_5$ (R=Pr,Nd) and heavy rare earth con- taining series $RCoGa_5$ (R=Tb-Tm). All the compounds crystallize in the tetragonal $HoCoGa_5$ crystal structure and are very good metals with small defect scattering at low temperatures. $NdCoIn_5$ and members of the $RCoGa_5$ series with large de Gennes factors order antiferromagnetically.

**13:15**

**H15 11 Anomalous Nernst Effect in Ferromagnets** DI XIAO, QIAN NIU, *Department of Physics, The University of Texas, Austin, TX 78703* We study the intrinsic contribution to the anomalous Nernst effect in ferromagnets at low temperatures. It is shown that the anomalous Nernst conductivity is of topological nature and can be related to the Berry phase of occupied Bloch states. In ferromagnets, there may be nonzero magnetization current even in thermodynamic equilibrium. It can significantly change the thermoelectric transport coefficients. The Onsager relation is established for the charge and heat transport coefficients. Our theory well explains recent experimental result.

**13:27**

**H15 12 Giant Nernst effect in the Pr-filled skutterudite $PrFe_4P_{12}$** KAMRAN BEHNIA, ALEXANDRE POURRET, *ESPCI (Paris)* DAISUKE KIKUCHI, YUJI AOKI, HIDEYUKI SATO, *Tokyo Metropolitan University* The phase transition of $PrFe_4P_{12}$ at $T_O = 6.5$ K, probably associated with antiferroquadrupolar ordering, is explored by measuring thermal and thermoelectric transport coefficients. The transition leads to a drastic increase in lattice thermal conductivity pointing to a large drop in carrier concentration induced by the transition and a strong electron-phonon coupling. The low level of carrier density in the ordered state is confirmed by the anomalously large values of the Seebeck and Nernst coefficients. The latter attains a magnitude larger than what is reported for any metal. The results are reminiscent of the hidden-order state of $URu_2Si_2$. According to our analysis of the data, most carriers disappear at the transition, paving the way for an enhanced mean-free-path of both phonons and the residual quasi-particles. Thus, the ordered state of $PrFe_4P_{12}$ emerges as a heavy-fermion semi-metal.

**H15 13 Magnetoresistance and Hall Effect in cubic FeGe*** C. CAPAN, J.F. DITUSA, *Louisiana State University* H. LEE, L. PHAM, Z. FISK, *UC Davis* G. AEPPLI, *University College London* A. BANSKTON, E. THOMAS, J. CHAN, *Louisiana State University* An anomalous contribution to Hall Effect is observed in a variety of ferromagnetic systems ranging from simple metals and oxides to manganites, ruthenates and spinel compounds. Its nature (intrinsic or extrinsic) and microscopic mechanism is still an open issue and is being heavily investigated. It was originally attributed to skew or side jump scattering, which corresponds to an asymmetric scattering of conduction electrons by magnetic moments. More recent developments in the field seem to favor a scenario where an electron orbiting around the Fermi Surface at a finite field acquires a Berry phase when the direction of its moment is locked in presence of a strong spin-orbit interaction. FeGe is an itinerant helimagnet with a high Curie temperature of 280K. The lack of inversion symmetry of the crystal structure leads to helimagnetic order via Dzyaloshinskii-Moriya interaction, signature of a strong spin-orbit coupling in an otherwise cubic lattice. We will present new results of magnetoresistance, Hall Effect and magnetization in a single crystal of cubic FeGe and discuss the origin of the Anomalous Hall effect in this system.

**H15 14 Electrical conductivity of warm expanded aluminum** GERALD FAUSSURIER, CHRISTOPHE BLANCARD, PATRICK RENAUDIN, *CEA* PIER-LUIGI SILVESTRELLI, *Università di Padova* CEA COLLABORATION, UNIVERSITÀ DI PADOVA COLLABORATION, The electronic and ionic structures of warm expanded aluminum are determined self-consistently using an average-atom formalism based on density-functional theory and Gibbs-Bogolyubov inequality. Ion configurations are generated using a least-square fit of the pair distribution function deduced from the average-atom model calculations. The electrical conductivity is computed from the Kubo-Greenwood formula for the optical conductivity implemented in a molecular dynamics scheme based on density-functional theory. This method goes beyond the Ziman approach used in the average-atom formalism. Moreover, it is faster than performing quantum molecular dynamics simulations to obtain ion configurations for the conductivity calculation. Numerical results and comparisons with experiments are presented and discussed.

**H15 15 The Kondo effect in the presence of magnetic impurities** HUBERT B. HEERSCHE, ZEGER DE GROOT, JOSHUA A. FOLK, LEO P. K. KOUWENHOVEN, HERRE S. J. VAN DER ZANT, *Kavli Inst. of Nanoscience, Delft University of Technology, The Netherlands* ANDREW A. HOUCK, JAROSLAW LABAZIEWICZ, ISAAC L. CHUANG, *MIT Media Lab, Cambridge MA* We measure transport through gold grain quantum dots fabricated using electromigration, with magnetic impurities in the leads. A Kondo interaction is observed between dot and leads, but the presence of magnetic impurities results in a gate-dependent zero-bias conductance peak that is split due to an RKKY interaction (I) between the spin of the dot and the static spins of the impurities. Both ferromagnetic and anti- ferromagnetic interactions have been observed in different samples. A magnetic field restores the single Kondo peak in the case of an anti-ferromagnetic

RKKY interaction, whereas the splitting is enhanced in the case of ferromagnetic interaction. A gate electrode can change the relative interaction strength $T_K/I$. This system provides a new platform to study Kondo and RKKY interactions in metals at the level of a single spin.

**H16 1 Infrared Spectroscopy of Hydrogen in Fullerite and MOF-5 Hosts** STEPHEN FITZGERALD, HUGH CHURCHILL, PHIL KORNGUT, CHRISTIE SIMMONS, YORGOS STRANGAS, *Oberlin College* We present a novel use of diffuse reflectance infrared spectroscopy to study the quantum dynamics of hydrogen molecules trapped within a host material. This technique is particularly useful for the study of hydrogen storage materials since it provides detailed information about the intermolecular potential at the binding site. Because $H_2$ has no intrinsic infrared activity any observed features arise solely through interaction with the host material and as such are very sensitive to the symmetry of the binding site. The drawback is that the induced spectra are quite weak. However, a technique based on diffuse reflectance has been shown to produce a sufficiently large signal [1]. We have now constructed a cryogenic system that allows spectra to be obtained in this manner at pressures as high as 100 atm. and at temperatures as low as 10 K. Data will be presented for $H_2$ in both $C_{60}$ and MOF-5 showing a series of absorption features arising from the quantized vibrational, rotational, and translational motion of the trapped $H_2$. At the lowest temperature these peaks become quite sharp, FWHM less than 1 $cm^{-1}$, with a detailed fine structure arising from the $H_2$ host interactions. 1. S. A. FitzGerald et al., Phys. Rev. B **65**, 140302. (2002)

**H16 2 Hydrogen Adsorption and Its Displacement of Carbon Dioxide in Microporous Transition Metal Cyanides** SITTICHAI NATESAKHAWAT, JEFFREY CULP, CHRISTOPHER MATRANGA, BRADLEY BOCKRATH, *U. S. Dept. of Energy, National Energy Technology Laboratory* The adsorption properties of $H_2$ and $CO_2$ have been investigated in $M_3$ $[Co(CN)_6]$ (M = Cu, Zn) Prussian blue analogues and $M[Fe(CN)_5NO]$ (M= Co, Ni) metal nitroprussides. Adsorption isotherms show that both materials adsorb between 1.4 to 1.7 wt % of $H_2$ at 77 K and 1 atm. The isosteric heat of adsorption was between 6.5 to 7.5 kJ/mol. Kinetic measurements are conducted in a specially designed vacuum system which is coupled to a Fourier-Transform Infrared Spectrometer. In a typical experiment, an infrared active gas (i.e $CO_2$) is physisorbed in the transition metal cyanide and the system is later back-filled with $H_2$. The infrared intensity of the physisorbed $CO_2$ is monitored to deduce the kinetics and energetics associated with its displacement from the transition metal cyanide by $H_2$. We have identified several kinetic steps, measured the rate constants, and examined the temperature dependence of this displacement process.

**11:39**
**H16 3 Adsorption study of Hydrogen in Carbon based Materials as measured by Nuclear Magnetic Resonance*** ALFRED KLEINHAMMES, SHENGHUA MAO, MARCELO BEHAR, YUE WU, *Department of Physics and Astronomy and Curriculum in Applied and Materials Sciences, University of North Carolina at Chapel Hill, NC 27599-3255* Nuclear magnetic resonance is shown to be a sensitive tool to probe hydrogen adsorption. The technique distinguishes between adsorbed $H_2$, hydrogen in the gas phase and can discriminate against protons brought in through contaminants. NMR provides a quantitative measurement of the number of molecules adsorbed. An estimate of the adsorption energy can be obtained from the measured isotherm. Adsorption measurements of $H_2$ in several materials – metal organic frameworks, conducting polymers, and doped single walled carbon nanotubes – are reported. Boron doped SWNTs when loaded with $H_2$ produce intriguing $^1$Hspectra indicative of adsorption and possibly several adsorption sites

**H16 4 Hydrogen cryo-adsorption; comparing low pressure and isosteric heats.***
CHANNING AHN, *California Institute of Technology*

The two criteria for effective physisorbents for hydrogen storage are high surface area and high adsorption heats. There are two heats that can be determined readily from the sorption isotherm. At very low pressures corresponding to low surface coverages, we can consider the differential enthalpy at zero coverage, determined from the temperature dependence of the Henry's Law constant which is in turn determined by the low pressure isotherm slope. The differential enthalpy can also be determined from isosteric heat measurements from the same data, provided that data is taken over a higher pressure range that includes the saturation limit. We have found that the two quantities are of similar magnitude, and while the direct measurement of the differential enthalpy is the easiest to perform, the requirements necessary in determining the isosteric heat yield the most useful data. Ideally, the sorption heats are constant as a function of ad-atom/molecule coverage density. This is typically not the case due to sorption site heterogeneities that are typical of real surfaces, and due to hydrogen-hydrogen interactions that occur at higher pressures. Consequently, this value drops

as a function of pressure. The consequence of this is that materials that show initially high sorption values at low pressure, do not typically yield high gravimetric saturation values. We will discuss this behavior in metal organic frameworks, activated carbons and carbon aerogels. All of these materials can have high surface area but the adsorption heats are typically 4–7 kJ/mole. We have measured the highest gravimetric hydrogen sorption in an activated carbon.

**H16 5 Inelastic Neutron Scattering of $H_2$ Adsorbed on Boron Doped ( $\sim$ 1%) Single Walled Carbon Nanotubes** D. NAREHOOD, *Department of Physics, The Pennsylvania State University, University Park, PA 16802 USA* Y. LIU, C.M. BROWN, D.A. NEUMANN, *National Institute of Standards and Technology, NIST Center for Neutron Research, Gaithersburg, MD 208991, USA* PETER EKLUND, *Department of Physics, The Pennsylvania State University, University Park, PA 16802 USA* It is clear from this study that $H_2$ is preferentially adsorbed at boron sites in SWNTs and in these sites the $H_2$ experiences an orientational component in the potential. Thus, this study shows that the substitution of boron for carbon in the SWNT lattice produces higher energy binding sites for $H_2$ adsorption. We report here an inelastic neutron scattering investigation of $H_2$ adsorbed on $\sim$ 200 mg of purified boron doped ( $\leq$ 1%) SWNT bundles. At $H_2$ coverages $\leq$ 1 $H_2$/ B and at T = 3K, a clear splitting of $\sim$ 1.4 meV is observed for the sublevels of the J=1 state. As the $H_2$ coverage is increased, the rotational spectrum converges to that of the bulk like rotor observed for $H_2$adsorbed on undoped SWNTs with the appearance of a peak at 14.7 meV. As the temperature is increased from 3K, the bulk like peak decreases in intensity until only the split rotational peaks are present; the intensity of these peaks decreases with increasing temperature until about 75 K at which point no rotational peak is observable. Funding provided by the US DOE Office of Energy Efficiency and Renewable Energy within the Center of Excellence on Carbon-based Hydrogen Storage Materials.

**12:39**

**H16 6 Quantum Monte Carlo studies of the non-dissociative absorption of hydrogen to doped fullerenes** ANDREW WILLIAMSON, *Lawrence Livermore National Laboratory* YONGHYUN KIM, SHENGBAI ZHANG, *National Renewable Energy Laboratory* The reversible storage of hydrogen at room temperature requires an adsorption energy in the range of 0.2 to 0.6 eV per hydrogen molecule. However, there are currently no storage materials which have been shown to bind hydrogen with this energy. Typically, hydrogen either retains its molecular form, and binds only weakly via a van der Waals interaction, or it dissociates into atoms and forms strong covalent bonds. Here we present the results of first-principles density functional and Quantum Monte Carlo calculations of the non-dissociative absorption of hydrogen molecules to doped carbon fullerenes. These calculations reveal significantly enhanced binding of hydrogen to substitutional B and Be doped fullerenes. Our Quantum Monte Carlo and benchmark quantum chemistry calculations are used to evaluate the accuracy of different exchange correlation functionals for describing the hydrogen adsorption interaction. We find that the LDA functional significantly overestimates the binding energy of hydrogen, while GGA functionals underestimate the binding energy. This work was performed under the auspices of the US Department of Energy by the University of California, Lawrence Livermore National Laboratory under contract No. W-7405-Eng-48

**12:51**

**H16 7 Theoretical study of Hydrogen Storage in Nanotubes and Nanoscrolls.** GEORGE FROUDAKIS, *University of Crete* A combination of itab-initio and Molecular Dynamics methods is used for investigating the nature of atomic and molecular hydrogen interaction with C, SiC and BN Nanotubes and Nanoscrolls. The curvature of the tube wall together with the direction of the hydrogen approach is considered and evaluated. In addition the improvement of the storage capacity is tested under various conditions of doping, pressure and temperature.

**13:03**

**H16 8 The effect of metal clustering on hydrogen storage** PURU JENA, *Virginia Commonwealth University* QIAN WANG, *Virginia Commonwealth University* QIANG SUN, *Virginia Commonwealth University* YOSHIYUKI KAWAZOE, *IMS, Japan* Hydrogen has been recognized as an ideal energy carrier and has the potential to reduce our dependence on fossil fuels which are not only limited but also are harmful to the environment. The success of a new hydrogen economy, however, depends upon our ability to find materials that can store hydrogen reversibly with high gravimetric and volumetric density and operate under moderate temperatures and pressures. Although a great deal of effort has recently been devoted to searching of such materials, none are known to meet the above conditions. Nanostructures offer new possibilities for hydrogen storage due to the novel chemistry. It has been shown very recently that coating of carbon nanostructures with **isolated transition metal atoms** such as Sc and Ti can increase the binding energy of hydrogen and lead to high storage capacity up to 8 wt% hydrogen, However, this prediction depends on the assumption that the metal atoms coated on the fullerene surface will remain isolated. Using first principles calculations based on density functional theory, and we show that Ti atoms would prefer to cluster on the $C_{60}$ surface which can significantly alter the nature of hydrogen bonding, thus affecting not only the amount of stored hydrogen but also their thermodynamics and kinetics.

**13:15**

**H16 9 Storing hydrogen in graphene layers with tunable interlayer spacing*** YANG LEI, *Queen Mary, University of London* WENGUANG ZHU, *Harvard University* YAN SONG, *Queen Mary, University of London* ENGE WANG, *Institute of Physics, CAS* ZHENYU ZHANG, *University of Tennessee & ORNL* ZHENGXIAO GUO, *Queen Mary, University of London* Carbon nanostructures are being studied for hydrogen storage. However the nature of H-C interactions in such structures is unclear. We use first-principles simulation to model H adsorption between graphene layers. The adsorption of $H_2$ between layers is evaluated, particularly with respect to inter-layer variation thus simulating the effect of stressing the graphite for H storage. We note that $H_2$ dissociates when the inter-graphene distance is reduced (the graphite is compressed). When the ratio of H:C=1:1, the graphene changes from a planar to a diamond-like structure. The H-C interaction changes from weak physisorption to strong chemisorption. When the pressure is reduced, H atoms can recom-

bine to form $H_2$ by overcoming a small energy barrier. Based on this work, we propose a new scheme for H storage in C nanostructures: by way of altering the inter-graphene distance, the C structure can effectively ''inhale,'' store and release hydrogen in a controlled manner.

**H17 1 Modeling spintronic devices** IGOR ZUTIC, *SUNY Buffalo and Naval Research Laboratory* JAROSLAV FABIAN, *University of Regensburg, Germany* STEVEN ERWIN, *Naval Research Laboratory* Conventional spintronic devices are based on metallic magnetic multilayers which utilize the magnetic moment associated with the spin to read magnetically stored information, leading to a nonvolatility and a substantial improvement in the performance of computer hard drives and magnetic random access memories. However, these applications employ two-terminal spin valves which are of limited use for advanced functionalities appropriate for signal processing and digital logic. While semiconductor-based three-terminal devices are natural candidates for spin logic, they remain inadequately investigated and even a simple understanding of their integration with CMOS is still missing [1]. We illustrate here several basic elements for modeling spin transport in spintronic devices and propose schemes for spin injection and detection in silicon [2], as well as for spin-controlled gain [1,3]. Supported by the US ONR, DARPA, and the National Research Council. [1] I. Zutic, J. Fabian, S. Das Sarma, Rev. Mod. Phys. **76**, 323 (2004). [2] I. Zutic, J. Fabian, and S. C. **H17 2 Non-metal spintronics: study of spin-dependent transport in InSb- and InAs-based nanopatterned heterostructures** J.J. HEREMANS, HONG CHEN, *Department of Physics, Virginia Tech* J.A. PETERS, *Department of Physics and Astronomy, Ohio University* N. GOEL, S.J. CHUNG, M.B. SANTOS, *Department of Physics and Astronomy, University of Oklahoma* W. VAN ROY, G. BORGHS, *IMEC, Leuven, Belgium* Spin-orbit interaction in semiconductor heterostructures can lead to various spin-dependent electronic transport effects without the presence of magnetic materials. Mesoscopic samples were fabricated on InSb/InAlSb and InAs/AlGaSb two-dimensional electron systems, where spin-orbit interaction is strong. In mesoscopic devices, the effects of spin-orbit interaction are not averaged out over the geometry, and lead to observable electronic properties. We experimentally demonstrate spin-split ballistic transport and the creation of fully spin-polarized electron beams using spin-dependent reflection geometries and transverse magnetic focusing geometries. Spin-dependent transport properties in the semiconductor materials are also investigated using antidot lattices. Spin-orbit interaction effects in high-mobility semiconductor devices may be utilized toward the design of novel spintronics implementations. We acknowledge NSF DMR-0094055 (JJH), DMR-0080054, DMR-0209371 (MBS).

**H17 3 Novel nanopattern assisted Mn-implanted Ge for spintronic applications** JINGJING CHEN, *UCLA, Department of Electrical Engineer-Device Research Laboratory (DRL)* KOS GALATSIS, *UCLA-DRL* KANG WANG, *UCLA-DRL* UCLA-DRL TEAM, Mn-Ge is one of the most promising Diluted Magnetic Semiconductors (DMS) materials as reports indicate room temperature ferromagnetism. Our investigation focuses on fabricating Mn-Ge via novel diblock copolymer patterning methods to control Mn implantation within a Ge lattice. We foresee such methods could enable consistent tailoring of Mn-Ge magnetic properties by improving uniform solubility of Mn in Ge, along with decreasing defects. Sample fabrication is based on a 20nm-scale periodic nanodot patterning Ge substrate. Ion-implantation was performed with Mn at 40KeV and with a dose of $4.0 \times 10^{14}/cm^2$ then annealed at 400-700°C. Material characterization included XRD, SEM and TEM. XRD detected the presence of $Mn_5Ge_3$ and $Mn_{11}Ge_8$phase, which is theoretical known to have a Tc near room temperature. Ferromagnetic hysteresis loops were obtained at 5K using a SQUID magnetometer ranging from -5 to 5 kOe. Samples at various annealing temperatures showed the saturation magnetization reaches an optimum value at 450°C. The difference in the temperature-dependent remnant magnetization between the implanted n-type and p-type Ge is also observed.

**H17 5 Nanoscale Molecular-Electronic Device Fabrication enabling Complete Chemical and Physical Characterization** JASON J. BLACKSTOCK, *Quantum Science Research, HP Labs* DUNCAN T. STEWART, *Quantum Science Research, HP Labs* CARRIE L. DONLEY, *Quantum Science Research, HP Labs* R. STANLEY WILLIAMS, *Quantum Science Research, HP Labs* The limitation of most nanoscale molecular-electronic devices is the lack of physical/chemical characterization accompanying electrical data. Such characterization is typically impossible, because the critical layers and interfaces being inaccessibly buried in the final device structure. We present new fabrication techniques that enable a range of conventional characterization tools to be employed during and after nanoscale device fabrication. These techniques include: the fabrication of atomically-flat, patterned template-stripped bottom metal electrodes with well-defined atomic structure (elucidated by UHV-STM); and the formation of a new stencil-based nanopore device geometry enabling detailed characterization of the internal nanoscale physical/chemical properties of the final devices. The combination of these techniques allows for molecular-electronic devices with lateral sizes ranging from tens of nanometers to hundreds of microns. The fabrication, characterization and electrical properties of metal/molecular-monolayer/metal devices using these techniques (including UHV-STM, AFM, SEM, XPS and IR data) will be presented.

**H17 6 Carbon nanotube Y-junctions for Nanoscale Electronics** PRABHAKAR BANDARU, CHIARA DARAIO, SUNGHO JIN, *Univ. of California San Diego* APPARAO RAO, *Clemson University* Carbon Nanotube (CNT) based electronics offer significant potential, as a nanoscale alternative to silicon based devices, for novel molecular electronics technologies. To realize truly nanoelectronic architecture, it is desirable to have a fully integrated nanotube based technology, where both devices and interconnects are based on CNTs. With this aim in mind, we report on the electrical properties of CNT based Y-junctions. The carrier delocalization and the inevitable presence of catalyst particles, introduced during growth, at the junction region induce a net charge and scattering which can be exploited in constructing electronic devices. We have assembled and electrically characterized the DC resistance and the AC impedance of several Y-junction devices[2] with possibilities for switching and transistor related applications. These experiments alert us to the vast potentialities of Y-junction devices in the development of nanoelectronic components including inverters, logic gates, and frequency mixers. An electrical impedance model of a MWNT Y-junction will be presented which will help gain an understanding of the current transport mechanisms in these nanostructures. 1. P. **H17 7 Low Frequency Noise in Carbon Nanotube Field Effect Transistors*** FEI LIU, *UCLA* KANG L. WANG, DAIHUA ZHANG, *USC* CHONGWU ZHOU, UCLA TEAM, USC TEAM, It is critical to understand the noise performance of the carbon nanotube field effect transistors (CNT-FETs) due to their ultra-small diameters and large surface to volume ratios. In the abstract, we will describe the noise study of an ambipolar CNT-FET with a negative threshold of 5V and a positive threshold of 15V. The noise power spectra densities (PSDs) are obtained for frequencies from 0.0625Hz to 10.24kHz, showing $1/f^{\alpha}$ behavior. The exponential $\alpha$ of this $1/f^{\alpha}$ increases from about 0.6 to 1.2 for a gate bias from -6V to -15V at a small source-drain bias (-0.1V) and this exponential gate bias dependence comes from schottky contacts, where shot noise is the dominant noise component. We also observe a greater excess 1/f noise for electron conducting than that for hole conducting, suggesting higher defect density near the CNT conduction band. The characteristics of the CNT-FET noise are different from conventional MOSFET, and thus, additional studies are needed to understanding the noise in CNT-FETs.

**H17 8 Use of a Novel Fluidic Microplotter in Macroelectronics, Photonics, and Sensors** B. LARSON, D. LAGALLY, J. BAIER, *SonoPlot LLC, Madison, WI 53714* P. RUGHEIMER, B. TANTO, P. GOPALAN, M. G. LAGALLY, *University of Wisconsin-Madison, Madison WI 53706* Many future applications of microelectronics will focus not on computing but on broader uses in fast flexible electronics, imaging and displays, energy, and environmental and health monitoring. Such uses will require in many cases integration on the mesoscale, and the combination of the fast microelectronics with materials that provide other benefits. One need is the deposition of a wide range of materials from the fluid state. We describe a new fluidic microplotter that enables the deposition of a wide range of materials at the 1 $\mu$m and larger scale. The dispensing depends on a novel axial ultrasonic resonance of a fluid micropipette that allows a gentle noncontact deposition of spots, lines, curves, and 3D objects with high precision and very good CV values. We will demonstrate some of the capabilities of the plotter in 1) writing patterns on MEMS membranes, 2) writing a polymer LED, 3) writing parallel lines separated by 1 $\mu$m, 4) making bioarrays with very small spots, and 5) writing polymer waveguides, and writing on Si nanomembranes that serve as the basis for very fast flexible electronics. The physical basis for the unique dispensing action in this device, as well as broader features of the plotter will be described. Potential additional applications will be discussed.

**13:15**

**H17 9 Integration of top-down and bottom-up methods: generating templates for nanowire devices.** MATTHEW SHAW, *Intel / University College Cork* THOMAS FITZGERALD, *UCC* BARBARA KOSMALA, *UCC* MICK MORRIS, *UCC* Self-assembly can realize spatially controlled nanostructure arrays rivaling the lithography. However, self-assembled constructs to develop nano-circuitry on the macroscopic scale remains distant but combination of lithography and self-assembly might be used for sub-20 nm feature sizes. Spatially constrained block co-polymers can be used to generate these patterns and selective removal of one component can provide 'templates' to generate nanowire arrays. This work focuses on generating nm-size features across a real substrate. We use state of the art lithography to generate sub-$\mu$m features and within these generate nm sized co-polymer arrays. Spatial control is determined only by the block size of the co-polymers and not processing variables. Selective 'etching' and phase enhancement techniques were used to provide depth variations across the substrate and form the 'template' for nanowire

development. The results of sputtering and electrochemical deposition used to fill the templates are outlined. The results demonstrate an exciting nanofabrication technique for creating high density nanowire arrays for the nanoelectronic industry.

**H17 10 High Density Germanium Nanowire Assemblies: Contact Challenges, Electrical Characterization and Photoconductivity Dynamics** BRIAN DALY, *University College Cork* BORIS POLYAKOV, DONATS ERTS, *University of Latvia* MICHAEL MORRIS, JUSTIN HOLMES, *University College Cork* The conductivity and photoconductivity properties of vertically aligned germanium nanowires, within anodised aluminium oxide (AAO) templates have been characterized by C-AFM and macro-contact measurements. Contact resistance between the nanowires and metal macro-contacts was minimized by polishing and gradual etching of the AAO surface, to expose the nanowires, prior to deposition of the contacts. Conductivity data from C-AFM and macro-contact measurements were found to be comparable suggesting that both methods are inherently suitable for evaluating the electrical transport properties of encapsulated nanowires within a matrix. Photoconductivity measurements indicate a photocurrent/dark current ratio of up to 40% in the Ge nanowire matrix during illumination with an Ar laser between 457 – 514 nm. These results are significant as the ability to make good ohmic contacts to nanowires, within well defined arrays, is key for the future 'bottom-up' fabrication of multi-layered device architectures for future electronic and optoelectronic devices.

**H17 11 Excitonic states and carrier recombination in ZnO quantum dots** VLADIMIR A. FONOBEROV, ALEXANDER A. BALANDIN, *Nano-Device Laboratory (http://ndl.ee.ucr.edu), Dept. of Electrical Engineering, University of California, Riverside, CA 92521* ZnO quantum dots and related Mn-doped ZnO/ZnMgO nanostructures have recently attracted significant attention as a new nano-engineered functional material for spintronic and optoelectronic applications. We have studied the carrier recombination processes in ZnO-based quantum dots both theoretically and using the photoluminescence (PL) spectroscopy in the temperature range T=8.5 K - 300 K [1]. The obtained experimental data suggest that below T = 70 K, the ultraviolet PL in ZnO quantum dots originates from recombination of the donor-acceptor pairs, while above T = 70 K it is due to recombination of the acceptor-bound excitons. The latter is in agreement with our theoretical predictions [2]. No strong inhomogeneous broadening has been observed in ultraviolet PL from ZnO quantum dots. Our results shed new light on the carrier-recombination processes in ZnO quantum dots and can be used for the ZnO nanostructure optimization for the proposed applications. The authors acknowledge the support of MARCO and its Functional Engineered Nano Architectonics (FENA) Focus Center. [1] V.A. Fonoberov, K.A. Alim, A.A. Balandin et al., Phys. Rev. B, submitted (2005); [2] V.A. Fonoberov and A.A. Balandin, Phys. Rev. B 70, 195410 (2004); Appl. Phys. Lett. 85, 5971 (2004).

**H17 12 Mechanical Property Characterization for Nanowires** RUSTOM BHILADVALA, MINGWEI LI, THERESA MAYER, JAMES SIOSS, CHRISTINE KEATING, JOAN REDWING, *The Pennsylvania State University* Understanding and predicting the behavior of NEMS (nanoelectromechanical systems) resonators made by assembling template-grown nanowires requires characterization of the elastic modulus and intrinsic damping for such materials. In this work, we present results of resonance measurements using cantilevers made by electroplating clamps which fully enclose one end of nanowires (NWs) made from Si, Rh and Au. Data from 16 such Si NWs made by the VLS (Vapor-Liquid-Solid) technique reveal a typical Q-factor of 5000, a geometric scaling ( $\sim D/L^2$, diameter D, length L) of the frequency consistent with linear elastic beam theory, and a higher value of Young's modulus for single-crystal silicon than reported from experiments with thin-film Si resonators. The low scatter in the modulus data and the high value of Q are both indicative of low clamping losses. Similar-sized wires of polycrystalline Rh and Au made by electroplating, show net damping values (using Q-factor, mass and stiffness) for these materials to be close to each other and roughly 14 times that for silicon.

**H17 13 Selective epitaxy of III-V semiconductor on Si substrates patterned by diblock copolymer*** ZUOMING ZHAO, *Dept. of Electrical Engr., UCLA* TEA-SIK YOON, YA-HONG XIE, *Dept. of Materials Science and Engineering, UCLA* KANG L. WANG, *Dept. of Electrical Engr., UCLA* DUYEOL RYU, THOMAS P. RUSSELL, *Polymer Science and Engr. Dept., Univ. of Massachusetts, Amherst, MA, 01003* III-V semiconductors, GaAs and InAs, were grown on Si substrates using molecular beam epitaxy. Si substrates were patterned with $SiO_2$ using thin films of diblock copolymer, PS-*b*-PMMA. Using a thin film of a random P(S-r-MMA) copolymer to balance interfacial interactions, spin coated film of PS-b-PMMA, having cylindrical microdomains, were annealed 170$^o$C to orient the microdomais normal to the surface. [ P. Mansky et al, Science, 275, 1997 (1458)] After removal of the PMMA cylinders, RIE was used to transfer the copolymer template to the substrate yielding a hexagonal array of $\sim$ 20 nm pores in the substrate. GaAs and InAs were selectively filled in pores. Images from scanning electron microscopy show that GaAs and InAs quantum dots with density of $8\times 10^{10}$ cm$^{-2}$ and diameter of 30nm were achieved by selective epitaxy. This provides the possibility of patterning of nanostructures for integration of III-V materials on Si and offers new potentials for electronic and optoelectronic applications based on regular or homogeneous structures.

**H18 1 Two-photon photoluminescence and exciton binding energies in single-walled carbon nanotubes.**
CHRISTOPH LIENAU, *Max-Born-Institute, Berlin, Germany*

The optical properties of carbon nanotubes are thought to be dominated by excitonic effects. Exciton binding energies between 100 meV and 1 eV have been predicted, depending on diameter, chiral angle, and surrounding medium. Experimental proof for these large binding energies, however, has been missing so far. Here we present direct experimental evidence that the elementary optical excitations of carbon nanotubes are strongly Coulomb-correlated, quasi-one dimensionally confined electron-hole pairs, stable even at room temperature. By comparing one-photon and two-photon luminescence excitation spectra, we probe excitonic states with distinctly different wavefunction symmetry [1]. The energy splitting between one-photon active and two-photon active states is a distinct fingerprint of excitonic interactions in carbon nanotubes and binding energies between 300 and 500 meV are derived. Our results are strongly supported by itab initio calculations of two-photon absorption spectra [2]. We discover that for all the tubes studied, excitonic effects are very strong and are crucial for the one-photon as well as the two-photon spectra in both the peak shapes and positions. The implications of these results for the fluorescence yield and lifetime of single-walled carbon nanotubes [3] will be discussed. [1] J. Maultzsch et al., Phys. Rev. B 72, Rxxx (2005); cond-mat/0505150. [2] E. Chang, G. Bussi, A. Ruini, and E. Molinari, Phys. Rev. Lett. 92, 196401 (2004). [3] A. Hagen et al., Phys. Rev. Lett. 95, 197401 (2005).

**H18 2 Ab initio study of the optical properties of carbon nanotubes.**
ERIC CHANG, *CNR-INFM National Research Center S3 and Univ. of Modena and Reggio E., Italy*

We present an ab initio study of the optical properties of carbon nanotubes. We use state-of-the-art electronic structure methods based on many-body perturbation theory to compute the optical absorption and resonance Raman spectra of large tubes which have up to 200 atoms [1,2]. Our symmetry-based method makes the study of large tubes feasible within the many- body framework and also allows us to understand the symmetry properties of the excitons and selection rules. We include a study of the so-called dark excitons which are crucial for understanding luminescence efficiency in carbon nanotubes. The mechanism that explains the dark-bright splitting can be understood within our symmetry-based approach. Finally, we present an analysis of the two-photon spectra for several carbon nanotubes, a theoretical analysis which, in conjunction with combined one- and two-photon experiments, allows one to measure the binding energy of excitons. We find in all cases that the excitonic binding energy is large, ranging from 0.5 to 0.9 eV depending on the diameter of the tube, and that the excitonic wavefunction is Wannier-like and extended over many atoms. Our studies for the one- and two-photon absorption and resonance Raman spectra have been fruitful for understanding the corresponding experiments. In particular, our theoretical results are in good agreement with one- and two-photon absorption experiments [3-5]. The results for resonance Raman show that such a spectroscopic technique is a good alternative to optical absorption since it allows for the selection of tubes of a given diameter while probing the same excited states.

**H18 3 Structural Dependence of Excitonic Optical Transitions and Band-Gap Energies in Carbon Nanotubes** GORDANA DUKOVIC, FENG WANG, DAOHUA SONG, MATTHEW SFEIR, TONY HEINZ, LOUIS BRUS, *Columbia University* The optical transitions in semiconducting carbon nanotubes have recently been ascribed to excitons. We have used two-photon excitation spectroscopy to measure the energies of exciton states of different symmetries by taking advantage of the different selection rules for two-photon absorption and one-photon fluorescence in this quasi-one-dimensional molecule. The measured exciton binding energies are on the order of hundreds of meV. Here we report the investigation of structural dependence of the exciton energies for different nanotube species, ranging in diameter from 0.76 to 1.2 nm. The exciton binding energies vary inversely with nanotube diameter, ranging from 420 to 270 meV in this sample. This result is in agreement with theoretical predictions. In addition, we have found that the measured band-gap energies are significantly blue-shifted from those predicted by tight-binding calculations, which may have implications for the transport properties of semiconducting carbon nanotubes.

**H18 4 Ultrafast decay of $E_{22}$ subband excitons in semiconducting SWNTs** TOBIAS HERTEL, JARED J. CROCHET, ZIPENG ZHU, *Vanderbilt University* We use CW and time-resolved spectroscopy for an investigation of intra- and interband relaxation of excited states in micelle suspended SWNTs. We observe that the dynamics of $E_{22}$ subband exciton decay in SWNTs is surprisingly similar to the dynamics of photoexcited carriers in bulk graphite. Moreover we find a clear correlation of the $E_{22}$ exciton decay rate with the excited state energy. We compare these results with earlier theoretical studies of quasi-particle decay in graphite and discuss the role of electron-electron and electron-phonon coupling for the dynamics of higher excited states.

**12:51**

**H18 5 Real-time *ab initio* simulations of excited carrier dynamics in carbon nanotubes.*** YOSHIYUKI MIYAMOTO, *Fundamental and Environmental Res. Labs. NEC* ANGEL RUBIO SECADES, *Universita Pais Vasco* DAVID TOMANEK, *Michigan State University* Combining time-dependent density functional calculations for electrons with molecular dynamics simulations for ions, we investigate the dynamics of excited carriers in a (3,3) carbon nanotube at different temperatures. Following an $h\nu = 6.8$ eV photo-excitation, the carrier decay is initially dominated by efficient energy transfer to the electronic degrees of freedom. About 200 fs after the photoexcitation in a nanotube initially at room temperature, the electron-hole gap is reduced to nearly half its initial value and the decay mechanism becomes dominated by coupling to phonons. We show that the onset point and damping rate within the phonon regime change with the initial ion velocities, which is a manifestation of a temperature dependent electron-phonon coupling.

**H18 6 Pump-probe excitation spectroscopy of chirality enriched SWNT suspensions** ZIPENG ZHU, *Vanderbilt University* MICHAEL ARNOLD, *Northwestern University* JARED J. CROCHET, *Vanderbilt University* MARK HERSAM, *Northwestern University* CLAY McPHEETERS, *Rice University* DANIEL E. RESASCO, *University of Oklahoma* HENDRIK ULBRICHT, *University of Vienna* TOBIAS HERTEL, *Vanderbilt University* We study the transient optical response of chirality enriched SWNT samples by conventional pump-probe and pump-probe excitation spectroscopy using visible pump and white-light continuum probe pulses. Comocat starting material is suspended using either SDBS or DNA as surfactants. In addition, DNA suspended samples have been isopycnically fractionated. Transient spectra of these sample are significantly less congested than multi-disperse suspensions, which greatly simplifies the interpretation of photobleaching and photo-absorption transients. The newly developed technique of pump-probe excitation spectroscopy (PPES) also allows to study previously inaccessible aspects of the dynamics of the second subband $E_{22}$ exciton decay. Experiments indicate that $E_{22} \rightarrow E_{11}$ interband relaxation rates are higher than the decay of *G*-mode phonon sidebands seen not only in PPES but also in photoluminescence excitation spectra.

**13:15**

**H18 7 Intrinsic and extrinsic effects in the temperature dependent photoluminescence of semiconducting carbon nanotubes** DENIS KARAISKAJ, CHAIWAT ENGTRAKUL, TIMOTHY McDONALD, MICHAEL J. HEBEN, ANGELO MASCARENHAS, *Center for Basic Science, National Renewable Energy Laboratory, 1617 Cole Boulevard, Golden, Colorado 80401, USA* The temperature dependence of the band gap of semiconducting carbon nanotubes was measured for ten different nanotube species. The unprecedented effectiveness in avoiding the effect of external strain, or any other effects originating from the surrounding environment, lead to an accurate measurement of the band gap temperature dependence, giving fundamental insight into the nanotube electron-phonon interaction. Small but reproducible energy shifts of the emission lines with temperature were observed, showing a moderate chirality dependence, well in agreement with recent theoretical calculations [1]. In addition to the energy shift, a substantial narrowing of the emission lines was also observed. The removal of the temperature shift of the band gap, allows the precise measurement of the effect of external strain on carbon nanotubes in different environments. [1] Rodrigo B. Capaz, Catalin D. Spataru, Paul Tangney, Marvin L. Cohen, and Steven G. Louie, Phys. Rev. Lett. **94**, 036801 (2005).

**H18 8 Strong anisotropy in the THz absorption spectra of stretch-aligned single walled carbon nanotubes** Y. IWASA, N. AKIMA, H. MATSUI, N. TOYOTA, *Tohoku University* S. BROWN, A. M. BARBOUR, J. CAO, J. L. MUSFELDT, *University iof Tennessee* M. SHIRAISHI, *Osaka University* H. SHIMODA, O. ZHOU, *University of North Carolina* Polarized THz spectroscopy is crucial for understanding the low-energy electronic structure and carrier dynamics in single walled carbon nanotubes (SWNTs), as well as for exploring polarization-sensitive THz applications. We prepared stretch-aligned SWNT/polymer composites, and measured the polarized absorption spectra from the THz through the visible region. The low-frequency electronic excitations are predominantly polarized parallel to the tube direction. The peak centered near 100 $cm^{-1}$ is discussed in terms of a curvature-induced gap and a plasmon resonance due to a finite size/wavelength effects in the SWNTs. The broad middle infrared structure that is observed in unoriented films with spaghetti-like morphology disappears in stretch-aligned samples, suggesting that this middle infrared feature may be due to in-gap states in the semiconducting tubes caused by the highly disordered morphology of the unoriented films. Hole doping effects were also investigated, and conversion of semiconducting tubes to more conducting ones is demonstrated.

**13:39**

**H18 9 Ultrafast dynamics of the mid-infrared response of carbon nanotubes** CHRISTIAN FRISCHKORN, *Physics Department, Freie Universitat Berlin, Germany* TOBIAS KAMPFRATH, LUCA PERFETTI, MARTIN WOLF, We report on time-resolved measurements of low-energy excitations in carbon nanotubes and compare these with results obtained for graphite. The systems mid-infrared response has been obtained from time-resolved THz spectroscopy data in the 10 - 30 THz spectral range. We find essentially two processes governing an electronic current

dynamics in carbon nanotubes. First, strongly bound excitons are the main photoproduct in large-band gap tubes and thus prevent a typical free-carrier response, while in small-gap and metallic tubes carrier localization due to defects is observed as manifested in a substantial dichroism. In these measurements, the reduced polarizability perpendicular to the tube axis is exploited. In the case of graphite, our results show that strongly coupled optical phonons in the graphite layer dominate the ultrafast energy and transport relaxation dynamics after optical excitation [1]. These phonon modes heat up on a femtosecond time scale and cool down with a time constant of several picoseconds. Moreover, the observed pronounced increase in the Drude relaxation rate significantly originates from these few active lattice vibrations. - [1] PRL 95, 187403 (2005).

**H18 10 Photoluminescence excitation spectroscopy of individual single walled carbon nanotubes** JACQUES LEFEBVRE, *National Research Council* JEFFERY BOND, *University of Ottawa* YOSHIKAZU HOMMA, *NTT Basic Research Laboratories* PAUL FINNIE, *National Research Council* Photoluminescence excitation spectroscopy is an essential tool for understanding the optical properties of single walled carbon nanotubes. In many cases, such measurements are performed on large ensembles and, aside from the main spectral features, reliable assignment is most often difficult. In order to address the existence of additional emission and absorption levels/bands in PLE spectra, this work has focused on the study of individual and small ensembles of single walled carbon nanotubes. Such carbon nanotubes are grown by chemical vapor deposition on pre-patterned substrates allowing individual nanotubes to be suspended in free space. The measurements are performed in air, at room temperature, without post growth processing of the nanotubes.

**14:03**
**H18 11 Optical Spectroscopy of individual Single-Walled Carbon Nanotubes of Defined Chiral Structure** MATTHEW SFEIR, *Columbia University* TOBIAS BEETZ, *Brookhaven National Lab* FENG WANG, LIMIN HUANG, X.M. HENRY HUANG, JAMES HONE, STEPHEN O'BRIEN, *Columbia University* JAMES MISEWICH, *Brookhaven National Lab* TONY HEINZ, *Columbia University* YIMEI ZHU, *Brookhaven National Lab* LOUIS BRUS, *Columbia University* Single-walled carbon nanotubes (SWNTs) constitute of a family of nanostructures with over one hundred members. Each specific structure has distinct electronic and optical properties, varying from semiconducting to metallic. Here we study the correlation between electronic structure and physical structure in SWNTs by combing high-sensitivity Rayleigh spectroscopy and electron diffraction techniques. Simultaneous application of these experimental techniques on individual SWNTs allows for measurement of electronic transitions in tubes of fully and independently determined structure. In this manner, we directly verify the ''family behavior'' that has guided previous spectroscopic assignment of optical transitions in semiconducting SWNTs. We also demonstrate the previously unobserved, but theoretically predicted splitting of optical transitions in metallic SWNTs.

**H19 1 Optical Properties of Ferromagnetic Semiconductors.**
KENNETH BURCH, *University of California, San Diego*

Ferromagnetic semiconductors hold great promise for numerous magneto-optics applications. In this talk I detail recent optical spectroscopic studies of as grown and annealed thin films and digitally doped superlattices of $Ga_{1-x}Mn_xAs$, prepared in the group of D.D. Awschalom (UCSB) and annealed in the group of N.Samarth (PSU). Annealing induces a large strengthening of the optical conductivity ($\sigma_1(\omega)$), while the frequency dependence of $\sigma_1(\omega)$ remains unchanged. This indicates that the scattering rate and Fermi level have not been effected by annealing, despite the large increase in hole density. Our Infrared work on Digital Ferromagnetic Heterostructures reveals a unique ability to tune their optical properties as well as their intrinsic electronic structure without changing the doping/defect level. This work is in collaboration with D.B. Shrekenhamer, E.J. Singley, D.N. Basov (University of California, San Diego) J. Stephens, R.K. Kawakami, D.D. Awschalom (University of California, Santa Barbara), B.L. Sheu, and N. Samarth (Pennsylvania State University).

**H19 2 Faraday and Kerr effect studies in optimally annealed $Ga_{1-x}Mn_xAs$ random alloys.*** GHEOGHE ACBAS, A. MARKELZ, J. CERNE, *Physics Dept., Univ. at Buffalo, SUNY, Buffalo, NY* M. CUKR, V. NOVAK, *Institute of Physics, Acad. of Sciences of the Czech Republic, Prague, Czech Republic* J. SINOVA, *Physics Dept., Texas A&M Univ., College Station, TX* The mid-infrared (MIR: 115-366 meV) complex Faraday and Kerr effect are studied in $Ga_{1-x}Mn_xAs$ random alloy films (x = 0.05, and x = 0.07) as a function of frequency and temperature. The samples are optimally annealed with $T_C$ around 100K. The strong MIR magneto-optical response shows clear ferromagnetic behavior that is consistent with dc magnetization measurements. The real and imaginary parts of the measured Faraday and Kerr angles are in qualitative and quantitative agreement with the values predicted by an effective Hamiltonian model within a mean field treatment [E. M. Hankiewicz, J. Sinova et al., PRB 2004]. The Kerr and Faraday rotation peak at approximately 220 meV, which is consistent with theoretical predictions.

**H19 3 Ferromagnetic resonance (FMR) study of ultra-thin $Ga_{1-x}Mn_xAs$ films as a function of layer thickness*** YINGYUAN ZHOU, Y.J. CHO, Z. GE, X. LIU, M. DOBROWOLSKA, J.K. FURDYNA, *Department of Physics, University of Notre Dame, Notre Dame, IN 46556* We report a detailed study of ferromagnetic resonance (FMR) in a series of $Ga_{1-x}Mn_xAs$ (x = 0.05) thin films grown on (100)GaAs substrates by low-temperature MBE. The thicknesses of the specimens ranged from 10nm to 200nm. We measured angular and temperature dependences of FMR and fitted the data to obtain the cubic and the uniaxial anisotropy parameters and g- factors for each specimen. The quality of the theoretical fitting results clearly indicates that FMR data can be reliably used to determine magnetic anisotropy parameters of $Ga_{1-x}Mn_xAs$. Our experiment indicates a strong thickness dependence of the in-plane uniaxial anisotropy field; on the other hand, the cubic anisotropy field, perpendicular uniaxial anisotropy field, and the g-factors depend on the hole concentration, but show little if any dependence on the film thickness, at least for as-grown specimens. The measurements and analysis of annealed specimens are presently underway.

**H19 4 Ultrafast light-induced demagnetization in (III,Mn)V ferromagnetic semiconductors** L. CYWINSKI, L. J. SHAM, *University of California San Diego, Department of Physics* J. WANG, C. SUN, J. KONO, *Dept. of Elec. and Comp. Engineering, Rice University* A. OIWA, *University of Tokyo* H. MUNEKATA, *Tokyo Institute of Technology* An ultrafast (subpicosecond) demagnetization process induced by intense laser irradiation has been recently observed in InMnAs [1]. We propose a theoretical model of magnetization dynamics on such a timescale which is based on the sp-d exchange interaction between the delocalized carriers' spins and localized Mn spins. Light excitation heats up a population of holes, taking it out of equilibrium with the Mn spins. This triggers the process of energy and angular momentum exchange between the two spin systems. Fast spin relaxation of holes sustains the flow of spin polarization leading to the possibility of significant demagnetization of the Mn system. Ultrafast magnetization dynamics in GaMnAs will also be discussed. This work was supported by DARPA, NSF, ONR and MEXT. [1] J. Wang et al., Phys. Rev. Lett. 95, 167401 (2005).

**H19 5 Pressure Dependent Magnetotransport Properties of Dilute Magnetic Semiconductors** M. CSONTOS, G. MIHALY, *Department of Physics, Budapest University of Technology and Economics, 1111 Budapest, Hungary* T. WOJTOWICZ, *Institute of Physics, Polish Academy of Sciences, 02-668 Warsaw, Poland* B. JANKO, X. LIU, J. K. FURDYNA, *Department of Physics, University of Notre Dame, Notre Dame, Indiana 46556, USA* The $Mn^{2+}$ ions in (III,Mn)V ferromagnetic semiconductors provide magnetic moment and at the same time they act as a source of valence-band holes that mediate the $Mn^{2+}$-$Mn^{2+}$ interactions. This coupling results in the ferromagnetic phase. By using hydrostatic pressure to continuously tune the wavefunction overlap, one can control the strength of the ferromagnetic coupling resulting in a spectacular enhancement of the magnetization and the Curie-temperature [M. Csontos et al. Nature Materials **4**, 447 (2005)]. Magnetoresistance measurements on the magnetic semiconductor (In,Mn)Sb suggest that magnetic scattering in this material is dominated by isolated $Mn^{2+}$ ions located outside the ferromagnetically ordered regions [M. Csontos et al. Phys. Rev. Lett. **95**, 227203 (2005)]. The transport properties in presence of high magnetic field and hydrostatic pressure have also been investigated by Hall-effect and thermoelectric power measurements.

**12:39**

**H19 6 Magnetoresistance anomalies during hard axis magnetization reversal in (Ga,Mn)As epilayers.** MENG ZHU, GANG XIANG, BEN LI SHEU, XIA LI, PETER SCHIFFER, NITIN SAMARTH, *Physics Department, Penn State University, University Park PA 16802* The ferromagnetic semiconductor (Ga,Mn)As is known to display striking magnetoresistance (MR) during magnetization reversal. Here, we use temperature- and field-dependent MR measurements to probe hard axis magnetization switching processes in (Ga,Mn)As epilayers grown on (001) GaAs. MR is measured using Hall bars oriented along the three principal crystalline directions ([100], [$\bar{1}$10] and [110]) over a temperature range 0.35 mK $\leqslant T \leqslant$ 120 K, with the magnetic field normal to the sample plane. We find that the longitudinal MR exhibits distinct signatures corresponding to different types of magnetization reversal processes. While domain wall nucleation and propagation produce large MR anomalies ( $\sim 50\Omega - 100\Omega$), coherent domain rotation is accompanied by surprisingly weak MR. We discuss our experimental measurements using analytical simulations that incorporate SQUID magnetization data as additional input. Supported by DARPA/ONR and NSF.

**H19 7 Magnetotransport studies of $Ga_{1-x}Mn_xSb$ Random Alloys.** M. EGINLIGIL, G.B. KIM, S. WANG, H. LUO, B.D. MCCOMBE, *Department of Physics, University at Buffalo, SUNY* We report magnetotransport and magnetization measurements from two sets of well-characterized $Ga_{1-x}Mn_xSb$ samples grown by molecular beam epitaxy: set 1 - varying Sb/Ga flux ratios and constant nominal Mn concentration of 2.3%; set 2 - constant flux ratio (Sb/Ga=5.7) and varying nominal Mn content. Plots of $R_{sheet}$vs. temperature show both metallic and thermally activated

behavior. Two samples (one from each set) having the highest effective Mn content (as determined from measurements of saturation magnetization at low temperatures) but different flux ratios, exhibited thermally activated transport. Hole densities in the range $2.6x10^{19}cm^{-3}$ to $1.3x10^{20}cm^{-3}$ were extracted from plots of $R_{Hall}/ R^{\alpha}_{Sheet}$ vs. $B/ R^{\alpha}_{Sheet}$ at high fields and low temperatures; for the metallic samples $1 < \alpha < 2$ and for the samples showing thermally activated behavior $\alpha < 1$. The two samples that showed thermally activated transport, although they had the highest measured Mn content, have hole densities at the low end of the measured range. Both of these samples also exhibit extrema in the remnant hall resistance vs. temperature, with the sample from set 1 also showing very complex behavior of the anomalous Hall coefficient (a change of sign) vs temperature. This complex behavior is attributed to movement of the chemical potential through a region of non-monotonic behavior of the density of states vs. energy. Supported in part by DARPA ONR SpinS and NSF ECS0224206.

**H19 8 Transport Properties of $Ga_xCr_{1-x}N$ thin films synthesized by MBE** STEPHEN WU, HONGXUE LIU, RAKESH SINGH, NATHAN NEWMAN, *Arizona State University* The electrical transport properties of ferromagnetic single phase Cr-doped gallium nitride films grown by reactive molecular beam epitaxy were investigated by performing Hall and resistivity measurements as a function of temperature over a wide range of dopant concentrations. For Cr concentrations at 3%, the films are highly resistive and the thermally activated electron transport follows the exponential law, $R=R_o\exp[(T_o/T)]^{-1/4}$, characteristic of variable range hopping between localized states in an impurity band [1]. This relationship does not explicitly hold over a significant temperature range for other Cr concentrations. The physical mechanism responsible for the differences in the electrical properties of these films will be elucidated by comparing the transport processes involved with the fraction of Cr atoms situated on Ga substitutional sites as measured by RBS ion channeling and the ferromagnetic properties determined using a variable temperature vibrating sample magnetometer. [1] N.F. Mott, Philos. Mag., **19**, 835 (1969).

**H19 9 Controlling ferromagnetism in GaMnAs by arsenic defect engineering*** R. C. MYERS, A. W. JACKSON, A. C. GOSSARD, D. D. AWSCHALOM, *Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106* B. L. SHEU, P. SCHIFFER, N. SAMARTH, *Department of Physics, The Pennsylvania State University, University Park, PA 16802* We manipulate the Curie temperature and hole density of $Ga_{1-x}Mn_xAs$ for $x = 0.75\%$ to 3% by systematically varying the arsenic compensation by As-flux control. The As:Ga flux ratio is varied using a new technique of non-rotated GaMnAs growth, where the geometry of the molecular beam epitaxy system provides a continuous variation in As-flux across a wafer. In this manner, As-stoichiometry can be calibrated in a single growth run for any Mn doping density. The hole density and Curie temperature are maximized at the same position on each wafer suggesting that minimizing As-defect compensation improves magnetic properties. Surprisingly, changes in the arsenic flux of as little as 10% can quench ferromagnetism in the low Mn-doped material causing an apparent shift in the paramagnetic to ferromagnetic cross over transition toward higher Mn concentrations. The results suggest that proper control of arsenic compensation is critical for optimizing Curie temperatures in the low Mn-doping regime.

**13:27**

**H19 10 Evidence of MnAs precipitates in a diluted magnetic semiconductor (Ga,Mn)As** TAESOON HWANG, SOONCHIL LEE, *Dept of physics, Korea Advanced Institute of Science and Technology, Daejeon Korea* S. H. CHUN, *Dept of Physics, Sejong University, Seoul Korea* H.K. CHOI, Y.S. KIM, Y.D. PARK, *School of Physics, Seoul National University, Seoul Korea* Local magnetic field in (Ga,Mn)As epilayers with 500 nm thickness having 3.6% and 5.8% Mn was studied by zero field nuclear magnetic resonance (NMR) at liquid helium temperatures. The macroscopic magnetic and transport properties of the epilayers are quite similar to other previously reported low temperature molecular beam epitaxy prepared samples. We carefully searched for NMR signal from 20 MHz to 250 MHz, but only the spectrum of MnAs precipitations of hexagonal NiAs structure was observed. No evidence for the magnetism due to the substituted Mn ions was observed by NMR within the frequency range investigated. About 1/7 of Mn atoms incorporated into the sample participates in the formation of precipitates whose size is as small as to favor formation of single magnetic domains. Temperature dependence of magnetic moment of MnAs precipitations estimated by NMR frequency below 12 K indicates that its Tc should be much lower than that of bulk. The magnetization of MnAs precipitations decreases faster with increasing temperature for samples with a lower transition temperature. The origin of this correlation between the critical temperatures of MnAs precipitates and the single phase (Ga,Mn)As is not fully understood at this moment.

**13:39**

**H19 11 Magnetic Properties of Ferromagnetic (Ga,Mn)As Grown on (511) GaAs Substrates** CHONG XIE, Y. J. CHO, R. CHAKARVORTY, Y. Y. ZHOU, Z. GE, W. L. LIM, X. LIU, J. K. FURDYNA, M. DOBROWOLSKA, *Department of Physics, University of Notre Dame, Notre Dame, IN 46556* Ferromagnetic (Ga,Mn)As films were successfully grown on SI GaAs (511)A and (511)B substrates by LT-MBE. We have performed SQUID, magnetotransport, ferromagnetic resonance (FMR), and Magneto-Optic Kerr Effect (MOKE) measurements to characterize the magnetic properties of these samples. A conspicuous feature observed on these samples is an asymmetric shift of the Hall resistance caused by the superposition of the Planar Hall Effect (PHE) and the Anomalous Hall Effect (AHE), in agreement with our earlier studies of (Ga,Mn)As grown on vicinal GaAs (001) substrates. This asymmetric shift is a direct manifestation of the strength of the magnetocrystalline anisotropy, which confines the magnetization to the preferred crystalline plane, thus resulting in a non-zero component of the magnetization normal to the (Ga,Mn)As layer. The results are also compared with the magnetic properties measured in (Ga,Mn)As films grown on GaAs substrates with other orientations, e.g., (001) and (311). Supported by NSF Grant DMR02-10519.

**13:51**

**H19 12 Large spin polarization in $Ga_{1-x}Mn_xP$ synthesized by ion implantation and pulsed-laser melting** M.A. SCARPULLA, P.R. STONE, R. FARSHCHI, I.D. SHARP, E.E. HALLER, O.D. DUBON, *Dept. of Materials Science and Engineering, University of California and Lawrence Berkeley National Laboratory, Berkeley CA 94720* J.W. BEEMAN, *Lawrence Berkeley National Laboratory, Berkeley, CA 94720* E. ARENHOLZ, *Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA 94720* We have recently demonstrated that the mediating holes in $Ga_{1-x}Mn_xP$ reside in an impurity band separated from the valence band by a gap [Scarpulla et al., Phys. Rev. Lett. **95** 207204 (2005)]. For samples with x≈ 0.06 and Curie temperature 60 K, this gap is approximately 25 meV. In this work, we demonstrate a very large spin polarization of states near the Fermi level across a range of Mn compositions using Mn $L_{3,2}$ X-ray magnetic circular dichroism (XMCD). We find that the X-ray absorption spectrum at the Mn $L_{3,2}$ edge is very similar to that observed in $Ga_{1-x}Mn_xAs$ [Edmonds et al., Appl. Phys. Lett. **84** 4065 (2004)], indicating that the Mn bonding environment is similar between $Ga_{1-x}Mn_xAs$ and $Ga_{1-x}Mn_xP$. The magnitude of the X-ray fluorescence XMCD signal reaches approximately 70% at the Mn $L_3$ edge across the range of compositions, indicating a large spin asymmetry in the density of states. This is consistent with (but not exclusive to) the existence of a spin-polarized impurity band near the Fermi level.

**14:03**

**H19 13 Evidence of room temperature itsp-d exchange in InMnAs epitaxial films** PHILIP CHIU, BRUCE WESSELS, *Northwestern University* InMnAs grown by metal organic vapor phase epitaxy (MOVPE) is a promising ferromagnetic semiconductor due to its high Curie temperature ($T_c$) of 330 K. However, the nature of itsp-d exchange in this material is not well understood. Since enhancement of magnetic circular dichroism (MCD) at band structure critical points is indicative of sp-d exchange, the reflection MCD of MOVPE InMnAs was measured. At room temperature and an applied field 0.5 T, the MCD spectrum is composed of two types of transitions: a negative peak centered between 2.60-2.68 eV and a broad featureless negative response from 1.6-3.0 eV. At both transitions, ferromagnetic hysteresis and saturation are observed in the MCD field dependence. The negative peak occurs between the *L*-point critical transitions of InMnAs, at 2.53 and 2.79 eV respectively. The single negative peak is also similar to that observed in MBE InMnAs in both the peak energy and width. The MCD enhancement at the *L*-point is consistent with room temperature itsp-d exchange splitting in MOVPE grown InMnAs. The itsp-d exchange is tentatively attributed to the presence of Mn dimers and trimers in the InMnAs that result in a $T_c$ of 326-327 K. The assignment of the broad spectral response is currently under way.

**H20 1 Spin-nematic order in the frustrated pyrochlore-lattice quantum rotor model*** KAROL GREGOR, DAVID A. HUSE, S.L. SONDHI, *Princeton University* As an example of ordering due to quantum fluctuations, we examine the nearest-neighbor antiferromagnetic quantum $O(N)$ rotor model on the pyrochlore lattice. Classically, this system remains disordered even at zero temperature; we find that adding quantum fluctuations induces an ordered phase that survives to positive temperature, and we determine how its phase diagram scales with the coupling constant and the number of spin components. We demonstrate, using quantum Monte Carlo simulations, that this phase has long-range spin-nematic order, and that the phase transition into it appears to be first order.

**11:27**

**H20 2 Engineering order−from−disorder** YUKITOSHI MOTOME, *RIKEN (The Institute of Physical and Chemical Research)* KARLO PENC, *Research Institute for Solid State Physics and Optics* NIC SHANNON, *H. H. Wills Physics Laboratory, University of Bristol* One of the most intriguing features of frustrated magnetism is the prevalence of *order–from–disorder* effects, where fluctuations conspire to select a unique state from a disordered manifold of degenerate classical ground states. Quite generally, order−from−disorder effects favour collinear spin configurations, and therefore lead to magnetization plateaux in many two−dimensional frustrated spin systems. Much less is known about order from disorder in three dimensions. Here we use classical Monte Carlo and low−T expansion techniques to show how thermal fluctuations stabilize a half−magnetization plateau in a Heisenberg model on the highly frustrated, three−dimensional Pyrochlore lattice if — and only if — they are given a ''helping hand'' by additional longer−ranged interactions. Our results provide the first example of fluctuation−driven magnetization plateau which can be tuned at will between different ordered states.

**H20 3 Inelastic Neutron Scattering Studies of $GeCo_2O_4$** M.K. CRAWFORD, R.L. HARLOW, *DuPont Company, Wilmington, DE* Y. CHEN, Q. HUANG, J.W. LYNN, Y. QUI, J.R.D. COPLEY, *NCNR, NIST, Gaithersburg, MD* S. HARA, Y. YOSHIDA, S.I. IKEDA, *AIST, Tsukuba, Japan* D.T. ADROJA, *ISIS, United Kingdom* R.W. STEVENS, B.F. WOODFIELD, J. BOERIO-GOATES, *Brigham Young University, Provo, UT* P.L. LEE, Y. ZHANG, *APS, ANL, Argonne, IL* R.A. FISHER, *LBNL, Berkeley, CA* $GeCo_2O_4$ is a normal spinel in which the magnetic spin- 3/2 $Co^{2+}$ ions are located on the crystallographic *B*-sites. $GeCo_2O_4$has a Néel transition ($T_N$ = 20.6 K) that coincides closely with a cubic-to-tetragonal structural phase transition, below which $c/a > 1$. Inelastic neutron scattering measurements show that there is an energy gap in the Néel state of magnitude 3 meV. We have measured the dispersion of the lowest energy spin wave branch along the (100), (110) and (111) directions for single crystals grown by the floating zone technique. In addition, inelastic neutron powder diffraction data have been obtained to study the higher energy crystal field levels of $Co^{2+}$. These data will be described and compared with results for other *B*-site spinels.

**11:51**

**H20 4 Suppressing magnetic order in $GeNi_2O_4$ and $GeCo_2O_4$** M. JAIME, A.V. SILHANEK, *LANL, Los Alamos, NM* P GODDARD, S.J. BLUNDELL, *Clarendon Lab, Oxford, UK* J.C. LASHLEY, *LANL, Los Alamos, NM* R.A. FISHER, *LBNL, Berkeley, CA* M.K. CRAWFORD, *DuPont, Willmington, DL* Spin S = 3/2 $GeCo_2O_4$ and spin S = 1 $GeNi_2O_4$ are both frustrated spinels, but they nevertheless order magnetically a low temperatures. $GeCo_2O_4$ achieves this by undergoing a structural phase

transition, but the mechanism adopted by $GeNi_2O_4$ is still an open question. We measured the magnetization, specific heat and magnetocaloric effect in polycrystalline samples of the title materials in high fields up to 45 T, and obtained detailed H,T phase diagrams. In the case of $GeNi_2O_4$ an almost degenerate double phase transition in zero field splits into two transitions separated by a wide magnetic field gap. The possibility of a spin-flop transition driven by single-ion anisotropy that also relieves the frustration in the Ni compound will be discussed.

**12:03**

**H20 5 Spin singlet state due to heptamer formation in $AlV_2O_4$** KEISUKE MATSUDA, NOBUO FURUKAWA, *Aoyama Gakuin University* YUKITOSHI MOTOME, *RIKEN* Spinel $AlV_2O_4$ is a mixed-valent system, where V ions construct a pyrochlore lattice with an average valence of 2.5+. This compound shows a phase transition at $T_c \sim$ 700K, and a doubling of the unit cell along the [111] direction is observed below $T_c$. A 3-1 type ''valence-skipping'' charge-ordering (CO) due to the strong correlation has been proposed to describe this transition. [1] Recently, a more careful analysis reported a trimer formation on [111] Kagomé layers. [2] It is also pointed out that the temperature dependence of the magnetic susceptibility can be decomposed into the Curie-Weiss contribution from $S = 1$ local moments on 1/8 of V sites and a spin-gap contribution from the rest V sites. [2] In the present study, instead of the CO scenario, we focus on the pairing of the Kagomé layers which leads to seven V-sites clusters (heptamers) by two trimers and a V site between the trimers. On the basis of the exact diagonalization study, we found that this model explains well the magnetic susceptibility in experiments. Hence, the heptamer formation appears to be the origin of the phase transition in this compound rather than the CO due to the electron correlation. [1] K. Matsuno *et al.*, J. Phys. Soc. Jpn. **70**, 1456 (2001) [2] Y. Horibe, *et al.*, unpublished

**12:15**

**H20 6 Entropy and susceptibility of ''stuffed'' spin ice – $Ho_2(Ho_xTi_{2-x})O_{7-x/2}$** B.G. UELAND, R.S. FREITAS, P. SCHIFFER, *Department of Physics and Materials Research Institute, Pennsylvania State University* G.C. LAU, B.D. MUEGGE, E.L. DUNCAN, R.J. CAVA, *Department of Chemistry, Princeton University* The spin ice material $Ho_2Ti_2O_7$ has been studied extensively due to its apparent residual ground state entropy, which is similar to that seen in water ice. This material has a pyrochlore structure in which the $Ho^{3+}$ and $Ti^{4+}$ cations form two interpenetrating sets of corner sharing tetrahedra. Here we present thermodynamic measurements on $Ho_2(Ho_xTi_{2-x})O_{7-x/2}$, with $0 \leqslant x \leqslant 0.67$, where we have replaced some Ti with Ho – effectively stuffing the lattice with more magnetic ions. We find that the zero field magnetic entropy remains essentially unchanged with stuffing. AC susceptibility measurements show the $T = 2$ K peak associated with the spin ice freezing decreases in magnitude with increasing $x$, indicating that spin freezing has been suppressed. While the residual entropy in $Ho_2Ti_2O_7$ is reduced with the application of a magnetic field, our measurements show that the entropy becomes less sensitive to applied field as $x$ is increased. This work is supported by the NSF.

**12:27**

**H20 7 Spin dynamics in the kagomé ice state** YOSHIKAZU TABATA, *Osaka University, Japan* HIROAKI KADOWAKI, *Tokyo Metropolitan University, Japan* KAZUYUKI MATSUHIRA, *Kyushu Institute of Technology, Japan* ZENJI HIROI, NAOFUMI ASO, *ISSP, University of Tokyo, Japan* BJÖRN FÅK, *CEA-Grenoble, France* Macroscopic degeneracy of the spin ice state in the geometrically frustrated pyrochlore oxide $Dy_2Ti_2O_7$ is partly or fully released under magnetic fields. For field along a [111] axis, it was proposed that another macroscopic degeneracy with a finite zero- temperature entropy occurs in the frustrated kagomé layers, which are built in the pyrochlore lattice. We have investigated this kagomé ice state using single-crystalline neutron scattering experiments. Spin correlations, i.e. scattering intensity maps, will be discussed based on Monte-Calro simulations of the spin-ice model with the dipolar interatction.

**12:39**

**H20 8 Spontaneous Strains in the Ground State of the Frustrated Pyrochlore $Tb_2Ti_2O_7$** JACOB RUFF, KIRRILY RULE, PATRICK CLANCY, JOHN PAUL CASTELLAN, JOSE RODRIGUEZ, BRUCE GAULIN, *McMaster University* The geometrically frustrated pyrochlore antiferromagnet $Tb_2Ti_2O_7$ has been the focus of much recent attention due to the spin liquid physics it displays at low temperatures. We have carried out high resolution x-ray scattering measurements of the principal Bragg peaks of $Tb_2Ti_2O_7$ which show substantial longitudinal broadening below approximately 20 K. Measurements on the non-magnetic pyrochlore $Y_2Ti_2O_7$ show no such broadening, suggesting this effect is driven by strong magnetoelastic coupling, as had been concluded from earlier anomolous low temperature Young's modulus measurements [Mamsurova et.al, JETP Letters, 1986]. We compare our x-ray scattering results to similar measurements in $TbVO_4$, which undergoes a cooperative Jahn-Teller phase transition near 34 K, and conclude that the longitundinal broadening is due to cubic-tetragonal fluctuations near a zero temperature phase transition, which acts to relieve the magnetic frustration.

**12:51**

**H20 9 Crystal Field Fluctuations in a Frustrated Pyrochlore Antiferromagnet $Tb_2Ti_2O_7$.** HAMID R. MOLAVIAN, MICHEL J. P. GINGRAS, *Department of physics, University of Waterloo* The antiferromagnetic pyrochlore $Tb_2Ti_2O_7$ presents a challenging puzzle to experimentalists and theorists studying frustrated magnets. Results from muon spin resonance and neutron scattering experiments for $Tb_2Ti_2O_7$ reveal a paramagnetic structure down to 50mK despite an antiferromagnetic Curie-Weiss temperature, $\theta_{CW} = -20$K. Crystal field calculations show that the $Tb^{3+}$ ion in $Tb_2Ti_2O_7$ is a ground state doublet with local $\langle 111 \rangle$ anisotropy and is separated from the first excited doublet state by a gap of 20K. We apply the Rayleigh-Schrodinger method to map the four states problem with exchange and dipole-dipole interactions onto an effective Hamiltonian with two states per ion. We give some properties of this effective Hamiltonian and discuss the possible classical and quantum phases of $Tb_2Ti_2O_7$.

**13:03**

**H20 10 Nematic order in square lattice frustrated ferromagnets** TSUTOMU MOMOI, *Condensed Matter Theory Laboratory, RIKEN* NIC SHANNON, *H. H. Wills Physics Laboratory, University of Bristol* PHILIPPE SINDZINGRE, *LPTMC, UMR 7600 of CNRS, Universite P. et M. Curie* We present a new scenario for the breakdown of ferromagnetic order in a two–dimensional quantum magnet with competing ferromagnetic and antiferromagnetic

interactions. In this, dynamical effects lead to the formation of two–magnon bound states, which undergo Bose–Einstein condensation, giving rise to bond–centered nematic order. This scenario is explored in some detail for an extended Heisenberg model on a square lattice. In particular, we present numerical evidence confirming the existence of a state with d– wave nematic correlations but no long range magnetic order, lying between the saturated ferromagnetic and collinear antiferromagnetic phases of the ferromagnetic $J_1$–$J_2$ model. We argue by continuity of spectra that this phase is also present in a model with 4–spin cyclic exchange. The case of the multiple spin exchange model on a triangular lattice, relevant to magnetism of solid $^3$He films, is also discussed.

**13:15**
**H20 11 A metamagnetic critical point in a three dimensional frustrated antiferromagnet** NIC SHANNON, *University of Bristol (UK)* KARLO PENC, *KFKI (Hungary)* YUKITOSHI MOTOME, *RIKEN (Japan)* The competition between different forms of order is central to the problem of strong correlation. This is particularly true of frustrated systems, which frequently exist at or near to a zero–temperature critical point. Here we show that a state with a half–magnetization plateau but no long range order can arise when a three dimensional frustrated antiferromagnet is tuned to a critical point bordering a metamagnetic state. We use classical Monte Carlo simulation and low–temperature expansion techniques to accurately characterize this ''spin pseudogap'' state, and show how its properties relate to those of the critical point. Our results provide an example of three dimensional spin model which can be used to study the relationship between gap and ''pseudogap'' — i.e. long range and preformed local order — near a metamagnetic critical point.

**13:27**
**H20 12 Transverse susceptibility of Ising spins** D. M. SILEVITCH, C. ANCONA-TORRES, T. F. ROSENBAUM, *James Frank Institute/University of Chicago* G. AEPPLI, *University College, London* The ac vector magnetic susceptibility of the Ising magnet $LiHo_xY_{1-x}F_4$ is studied as a function of frequency, excitation amplitude, transverse field and temperature. In the spin liquid ($x = 4.5\%$), application of a dc magnetic field projects the linear susceptibility transverse to the Ising axis. In addition, pumping the system along the Ising axis produces non-linear excitations in the transverse plane; these excitations can encode information and are potentially useful for quantum computation. In the ferromagnet ($x = 65\%$), measurements of the transverse susceptibility are used to probe the dynamics of domain wall tunneling and to estimate the mass of the domain walls.

**13:39**
**H20 13 $LiHo_xY_{1-x}F_4$ and the quantum Ising spin glass** MOSHE SCHECHTER, *Department of Physics and Astronomy, University of British Columbia* PHILIP STAMP, NICOLAS LAFLORENCIE, $LiHo_xY_{1-x}F_4$ in transverse field is considered to be the experimental realization of the transverse field Ising model, and a main tool in the study of quantum magnetism. For different values of $x$, ranging from 1 to $10^-3$, the system exhibits ferromagnetism, spin glass order, single large spin tunneling and various other interesting phenomena. Here we consider the spin glass regime, and in particular address two long standing puzzles posed by the experiments, i.e. the large disordering transverse field and the diminishing of the cusp in the nonlinear susceptibility as temperature is decreased. The solution of these puzzles emphasizes the significance of the hyperfine and offdiagonal dipolar interactions in this system. We then show that the latter destroys the spin glass order at any finite transverse field in this system, as well as in a general dipolar Ising spin glass. The nature of the disordering of the spin glass phase by quantum fluctuations will be discussed.

**13:51**
**H20 14 Random Field Effects in the Transverse Field Ising Spin-Glass $LiHo_xY_{1-x}F_4$ Magnetic Material.** S.M. ALI TABEI, MICHEL J.P. GINGRAS, *Department of Physics, University of Waterloo* Magnetic $LiHo_xY_{1-x}F_4$ in a transverse field has attracted a lot of attention recently because it is an ideal system to study quantum effects in disordered systems. When a magnetic field is applied transversely to the Ising magnetic moments in $LiHo_xY_{1-x}F_4$, the field-induced transition behaves quite differently from theoretical expectations. For $x = 0.167$ a paramagnet to spin glass transition has been studied experimentally in some detail. In particular,experiments find that the cusp in the nonlinear susceptibility signaling the glass state decreases in size as the temperature is lowered and the critical transverse field increases. We will show that the combination of applied transverse field and random off-diagonal dipolar interactions lead to random longitudinal field in $LiHo_xY_{1-x}F_4$. Using a simple model, we will show how this random field phenomenology accounts semi-quantitatively for the behavior of the nonlinear susceptibility in $LiHo_xY_{1-x}F_4$.

**H21 1 Experimental Studies of the Effects of Mixing on Reacting Systems.***
MATTHEW PAOLETTI, *University of Maryland at College Park*

Experimental studies of the effects of mixing on reacting systems are presented. The experiments can be divided into two classifications: (1) the effects of chaotic mixing on front propagation and (2) synchronization via superdiffusive mixing in an extended, fluid system. The front propagation studies are conducted in an oscillating vortex chain flow. The velocities of the propagating fronts are measured as a function of the frequency and amplitude of the external forcing. In the absence of mixing the Fisher-Kolmogorov result correctly predicts the front velocity; however these experiments show that this result is not extendable to chaotically mixed systems. Instead, the fronts are shown to mode-lock onto the

external forcing, propagating an integer number of vortices in an integer number of drive periods. The flow used in the synchronization studies is an oscillating/drifting vortex chain, which may be used to produce both enhanced diffusion and superdiffusion. We show that the key to synchronization in an extended, fluid system is superdiffusive transport produced by Lévy flights, where tracers undergo rapid jumps between distant regions of the flow.

**H21 2 Electrophoresis of Large DNA Molecules in Microcontractions** PATRICK DOYLE, GREG RANDALL, JU MIN KIM, *MIT* The ability to controllably position and stretch large DNA molecules in a microfluidic format is important for gene mapping technologies such as Direct Linear Analysis (DLA). Current technologies developed for DLA use controlled hydrodynamic flows created in a microfluidic device. The downside to this approach is that the imposition of the no-slip condition at the channel walls generates vorticity which can lead to DNA chain tumbling and incomplete stretching. We have recently shown that electric field gradients can be readily generated in a microfluidic device and the resulting field is purely elongational. We present here single molecule studies of DNA molecules driven by an electric field through a microfabricated contraction. Analogous to the hydrodynamic deformation of DNA, we can define an electrophoretic Deborah number (De) for our problem. We will discuss the effectiveness of the device to fully stretch DNA as a function of De and compare to stretching achieved in hydrodynamic flows. A detailed analysis of molecular stretching and the role of a non-homogeneous electric field will be discussed.

**12:03**

**H21 3 Measuring Streaming Current/Potential in Microchannel Arrays** ALI MANSOURI, AYDIN JAFARNEJAD, *U of Alberta* DANIEL KWOK, *U of Calgary* LARRY KOSTIUK, *U of Alberta* Streaming current/potential measurements have been commonly used to estimate interfacial properties. This paper explores challenges in conducting these measurements in an array of parallel microchannels, which is akin to flow through porous media. The issue that arise with these arrays is that increasing the number of channels subsequently increases the total conductance across an array. In situations with a large number of channels this array conductance can become comparable to the conductance in the bulk fluid in the reservoirs where electrodes are placed. In these cases, current drawn through an external electrical circuit connecting the two reservoirs (i.e. streaming current) become highly dependent on the location, material and surface area of the electrodes. However, with fewer channels the relative magnitude of conductances can be made such that this externally measured current is independent of these parameters and more representative of the streaming current. Streaming potential measurement, since they do not involve external current flow, also do not show these dependencies. In this study variations in the electrode materials (bright platinum, platinized platinum, silver and stain steel), size of electrodes, placement of the electrodes and electrolyte concentration ($10^{-3}$M KCL, $10^{-4}$M KCL and 0 M KCL) were used to affect the relative conductance in the system and to highlight these characteristics.

**H21 4 Electrophoretic extraction of ions from a pressure-driven flow*** HAO LUO, BOYD EDWARDS, SCOTT MILLER, BRENT RESCHKE, AARON TIMPERMAN, WVU TEAM, Coupling pressure-driven and electrokinetically driven flow streams in microfluidics is a critical issue for developing multi-dimensional separations systems. A promising method of coupling these flows is to electrokinetically extract the charged components from the pressure driven flow stream while minimizing the hydrodynamic flow in the electrokinetically driven channel. To model this extraction process we calculate the fraction f of ions in a pressure-driven microchannel that are diverted electrophoretically to a perpendicular side channel. The channel cross sections are rectangular, with aspect ratio $\gamma$. In the main channel, we use truncations of an exact series solution to describe the laminar velocity profile of the aqueous solution. The aqueous solution in the side channel is stationary; individual ions move through this channel in response to a uniform applied electric field at an electrophoretic velocity that is proportional to this field. We calculate f as a function of $\gamma$ and the ratio R between the flow rate in the main stream and that in the side stream. We find that f decreases with increasing R, as expected, and is nearly independent of $\gamma$.

**H21 5 The effect of fluid density on the transport of particles in nanochannels** ZHIGANG LI, GERMAN DRAZER, *Department of Chemical and Biomolecular Engineering, Johns Hopkins University* Understanding particle transport in nanochannels is crucial for the development of micro and nanofluidic devices. In this work, we investigate the effect of fluid number density on the transport of particles in nanochannels, by means of molecular dynamics simulations. Specifically, we examine the motion of a Lennard-Jones nanoparticle, under the action of a constant external force, in a Platinum nanochannel that contains a Lennard-Jones fluid. In the limiting case of a nanochannel free of fluid molecules the particle adsorbs to the surface of the nanochannel and moves at a very low velocity, due to dry friction with the wall. As the number density of the fluid increases the mobility of the nanoparticle is greatly enhanced, due to the formation of adsorbed fluid layers on the surface of both the nanochannel and the particle, which substantially reduce friction between the particle and the wall. Then, if the number density of the fluid is increased further the particle mobility drops, due to viscous drag. In fact, there is an optimal value at low fluid densities, at which the particle mobility can be significantly enhanced. We also examine the existence of a second peak at higher densities, when the fluid density is high enough to prevent the adsorption of the nanoparticles, and how these phenomena depend on the fluid-solid molecular interactions.

**12:39**

**H21 6 Molecular Dynamics simulations of polymers in Brownian ratchets.** MARTIN KENWARD, GARY W. SLATER, *University of Ottawa* Brownian ratchets rely on a combination of thermal *noise* and an asymmetry in a system to induce directed transport of particles (e.g., pumping in ion channels). This is

somewhat counter intuitive since thermal motion is often a detriment to transport mechanisms. In particular a Brownian ratchet can be used to manipulate polymers, for example in separation systems. We present a Molecular Dynamics study (with explicit hydrodynamic interactions) of short polymer chains in a fluid subjected to a periodic, asymmetric, saw-tooth potential (with zero net force) which is switched on and off for given time intervals, $\tau_{on}$ and $\tau_{off}$ repectively. We examine how variations of $\tau_{on}$ and $\tau_{off}$ affect the net migration of the polymer chains. We also examine how the width of the trapping potential and the degree of asymmetry affects the dynamics of the molecules.

**12:51**
**H21 7 Self-Assembly of Paramagnetic Beads in Rotating Magnetic Fields*** ERIC KEAVENY, *Division of Applied Mathematics, Brown University* MARTIN MAXEY, *Division of Applied Mathematics, Brown University* Paramagnetic beads, about 1 $\mu m$ in diameter, suspended in a liquid will aggregate to form chains when an initially random dispersion is subject to a uniform, static magnetic field. In a rotating field, the chains deform and, depending on the rotation rate, form S-shaped chains or aggregate clusters. A correct determination of the final shape requires an accurate calculation of the interparticle forces. We developed new methods to efficiently and accurately calculate the far-field and near-field magnetic interactions. Hydrodynamic interactions are resolved through the force-coupling method. We study the dynamics of single chains and suspensions of beads in rotating fields using these models and compare results from our simulations with recent experiments by Melle et al. (Phys. Rev. E **68**, 041503). At high rotations rates, the observed particle oscillations provide information on the particle properties affecting near-contact hydrodynamic forces.

**13:03**
**H21 8 Semiflexible magnetic filaments** ANDREJS CEBERS, *Institute of Physics, Salaspils, LV-2169* Extension of the Kirchhoff model of an elastic rod by taking into account the long-range magnetic interactions allows one to describe the semiflexible filaments with body couples. Their behaviour in some aspects is similar to the flagellas of different microorganisms driven by internal torques due to molecular motors. Basing on the model different new phenomena are described - buckling instability due to the action of body torques, selfpropulsion of the filament in an ac field, a periodic regime of the magnetic filament motion under the action of the shear flow and the field and others. Taking into account the thermal noise the crossover from $t^{3/4}$ to $t^{1/2}$ for the time dependence of the mean square displacement of the filament at magnetic field increase is predicted. The characteristics of semiflexible magnetic filaments can be studied by measuring their magnetic susceptibility in small ac magnetic field for which in the high- frequency range the scaling law $\omega^{-3/4}$ is obtained. Application of these results for the study of the properties of magnetotactic bacteria is discussed.

**13:15**
**H21 9 Using nanowires to perform in-vivo measurements of elastic and viscous properties of an anisotropic fluid** CHRIS SMITH, *University of Western Ontario* COLIN DENNISTON, *University of Western Ontario* The immersion of a small wire within an anisotropic fluid is studied using a lattice Boltzmann algorithm. A magnetic field is used to manipulate and rotate the wire. The field and the anisotropic fluid each impose a torque on the wire. Our simulations agree well with experiments on the dynamics of high aspect ratio wires within a liquid crystal. In addition, our simulations are able to extend the range of predictive measurements to low aspect ratio wires, more suitable for use in biological environments. We are able to predict elastic and viscous properties of the anisotropic fluid environment based on the torque response of the rotating wire.

**H21 10 Experimental and theoretical study of mixing and transport due to the motion of a slender body sweeping out a cone.*** TERRY JO LEITERMAN, *University of North Carolina at Chapel Hill* RICHARD M. MCLAUGHLIN, ROBERTO CAMASSA, UNC RTG FLUIDS GROUP TEAM, We have used singularity theory to construct an exact solution for the fluid motion induced by a spheriod spinning about its center sweeping out a double cone in a low Reynolds number flow. We have additionally used slender body theory to construct an asymptotic solution for a slender cylinder attached to a no-slip plane spinning about its base sweeping out an upright cone. These time-varying, three-dimensional hydrodynamic solutions have been used to benchmark micro-fluidic experiments which have immediate consequences to understanding transport and mixing in ciliated tissues. A similar macro-scale experiment that is absent of thermal flucutations has been designed which validates the theory.

**H21 11 Field Effect Modulation of Ion Transport in Single Nanotubes** RONG FAN, PEIDONG YANG, *Department of Chemistry, University of California at Berkeley* Field effect control in metal-oxide semiconductor field effect transistors (MOSFETs) has revolutionized how information is processed and stored, and created the modern digital age. Introducing field effect in fluidic systems would enable the manipulation of ionic and molecular species at a similar level and even logic operation. Due to strong Debye screening, field effect control in ionic solutions has to be occurring in nanoscale. Here we present the integration of chemically synthesized inorganic nanotubes into metal-oxide-solution field effect transistors (MOSolFETs), and demonstrated a rapid field effect modulation of ionic conductance. Surface modification, functioning as doping in semiconductors, alters the nanofluidic transistors from p-type field effect transistors, to ambipolar FETs, and n-type field effect transistors. Ambipolar behavior is of special interests in this gapless transport system. Possion-Boltzmann model has been employed to extract two key physical parameters – zeta potential and surface charge density. Furthermore, transient study was conducted, leading to the first kinetic model of field effect in ionic solutions. Nanofluidic FETs would be the key elements in sub-femtoliter analytical techniques and the integration of large-scale nanofluidic circuits.

**H21 12 Performance based applications of the Ultrasound Contrast Agents in the bio-medical field** PANKAJ JAIN, *University of Delaware* KAUSIK SARKAR, *University of Delaware* Ultrasound Contrast Agents are micron size bubbles encapsulated by nanometer-thick layer of surface active materials such as proteins and lipids. They are injected to patients to improve the quality of ultrasound images. They are also being used for drug delivery and arteriogenesis. We present results of itin-vitro ultrasound investigation on two such contrast agents, Definity and Optison.

We measure attenuation and scattering of ultrasound through emulsion of these agents. We investigate destruction of contrast agents and measure sub- and super-harmonic contents in their scattered response. Optison has a much lower threshold excitation level compared to Definity. Definity has a persistent sub-harmonic generation compared to Optison, for which the sub-harmonics go down above a certain pressure level. Both agents experiences transient bubble growth at lower excitation pressures due to increased permeability of the membrane to dissolved air outside. The results along with their implications on the applications such as drug delivery and imaging will be discussed.

**14:03**
**H21 13 Tuning the orbital angular momentum in optical vortices** CHRISTIAN SCHMITZ, KAI UHRIG, JOACHIM SPATZ, JENNIFER CURTIS, *Max-Planck-Institute for Metals Research, Dept. of New Materials and Biosystems, D-70569 Stuttgart, Germany* Optically-driven micromachines rely upon the precise definition of the intensity distribution and the angular momentum content of the controlling light fields. One such manipulation tool is the optical vortex (OV), which employs orbital angular momentum to spin particles around a ring of light. The orbital angular momentum of an OV is tuned by changing the helicity of its electric field's wavefronts or by tuning the input power. However, changing wavefront helicity has the undesirable effect of altering the vortex diameter. Thus, making complex patterns of OVs with fixed sizes but adjustable rotational frequencies is difficult. We introduce a new class of OVs with an additional independent tuning parameter to overcome these limitations. With these OVs, it is possible to smoothly increase particles' rotational frequency without changing the radius or power. We show that this tunability can be extended to groups of OVs with similar or different radii, allowing for complete flexibility to construct optical micromachines, or large arrays of OVs for parallel assays of biomolecules and cells.

**H22 1 Magnetocaloric Effect in Nanoparticle Systems and Clathrates** D.J. REBAR, J. GASS, S. SRINATH, H. SRIKANTH, *Functional Materials Laboratory, Physics Department, University of South Florida, Tampa, FL 33620 USA* G.S. NOLAS, *Department of Physics, University of South Florida, Tampa, FL 33620* We report the magnetocaloric effect (MCE) in cobalt ferrite, manganese ferrite, and nickel ferrite nanoparticle systems and also the first observation of a large MCE in $Eu_8Ga_{16}Ge_{30}$ clathrate compounds. The ferrite nanoparticles were synthesized using organometallic precursors in a wet chemical technique and characterized by XPS and XRD. Change in entropy ($\Delta S^{mag}$) was calculated using the Maxwell relation from the family of M-H curves at different temperatures. The maximum entropy change in these nanoparticle systems is influenced by the particle size, overall distribution in anisotropy, and moments. Even though the entropy change for these nanoparticles is reasonably large in comparison to previous reports, it is much smaller in comparison to the bulk systems exhibiting giant MCE. We also investigated MCE in a bulk clathrate system and observed large entropy changes of 6 and 9.3 J/kg-K for the Type I and Type VIII clathrate phases, respectively. These results indicate that the clathrates known to possess excellent thermoelectric properties are also promising candidates as magnetic refrigerant materials. HS acknowledges support from NSF grant CTS-0408933.

**H22 2 Magnetotransport properties and microwave experiments on Co nanoparticles embedded in a Ag matrix*** NEUS DOMINGO, JOAN MANEL HERNÁNDEZ, ANTONIO FERNÁNDEZ, *Universitat de Barcelona* ALBERTO MARIA TESTA, *Istituto di Struttura della Materia - CNR* CHRIS BINNS, *University of Leicester* DINO FIORANI, *Istituto di Struttura della Materia - CNR* JAVIER TEJADA, *Universitat de Barcelona* The magnetic and magnetotransport properties of Co nanoparticles (1.6 nm diameter) embedded in Ag matrix with different volume fraction have been investigated. Magnetic measurements give evidence of blocking temperatures $T_B$ = 10 K (1.5% volume fraction) and $T_b$ = 15 K (9.8 % volume fraction). Such values, quite high for so small particle sizes, reveal an important surface contribution to the total anisotropy energy. From magnetoresistance measurements we have obtained typical values of GMR of the order of 10 %. The data were analyzed with respect to the relationship $\Delta R / R \sim [M(H)]^{\wedge 2}$. Then we have also studied the response of the samples with microwave radiation measuring the absorption properties of these nanoparticles as a function of the applied magnetic field at different temperatures. The relationship between magnetic and transport measurements is discussed.

**H22 3 Examination of Giant Magnetoresistance in Cu-Co Granular Films with Two-Particle Size Distribution** JIANQING WANG, *Binghamton University* NAM KIM, JORDAN PECK, Giant Magnetoresistance (GMR) effect and magnetization curves above the blocking temperature were studied for Cu80Co20 granular thin films. The attempt was to understand the relationship between the GMR effect, magnetization, and the degree of interface contribution to the spin-dependent scattering in a unified scheme. When the magnetization curve is fitted to the Langevin function using an averaged single particle size, the average size of the estimated Co particles is 2.8 nm.1 However, when the magnetization curve is used to fit the GMR curve, there is a lack of agreement between the experimental data and the fitting. The discrepancies were resolved by assuming that there are two size distributions in the Co nano-particle population. Under such assumptions, good fittings can be achieved with the experimental curves for both the GMR and the magnetization, using the same set of parameters. The obtained average particle sizes for the smaller and the larger particles, and their respective populations, are 1.1 nm and 2.7 nm, and 0.35 and 0.65, respectively. The smaller particles are responsible for the high field GMR effect while the large ones are for the low field. The study has revealed that a certain degree of magnetic bulk scattering is present in the spin-dependent scattering in this system. 1. L.M. Malkinski, J.-Q. Wang, et al, Appl. Phys. Lett. 75, 844 (1999).

**H22 4 Understanding the Role of Oxygen in $CoFeO_x$ Superparamagnetic Nanoparticles** PAMELA JEPPSON, TONY CARUSO, DOUG SCHULZ, ROB SAILER, SUPERPARAMAGNETISM TEAM, There is a present need for materials which provide both magnetic flux isolation and concentration. The primary application of such materials regards coatings for very sensitive (picotesla) magnetic field measurement or applied magnetic fields. The coatings help reduce 1/f noise and provide a means of controlling wanted or unwanted, internal and/or external magnetic fields. For the high permeability superparamagnetic materials that are presently in use, severe thin film limitations are keeping picotesla resolution from being realized. An example of such present limitations is the strain encountered in thin permalloy films. Beyond strain, there is also brittleness which impedes many inorganic, metallic films. The original goal of this research was to develop flexible and insulating superparamagnetic materials to help fulfill the present thin film limitations and to provide new applications, which utilize the insulating and/or flexible nature of the composite films. However, after optimizing the magnetic properties, we found an extreme saturation moment for some parameters of the transition metal oxide based films. The extreme saturation moments are attributed to the oxygen ratio and termination at the surface of the nanoparticle. This talk will focus on the surface magnetic structure and how it can enhance or suppress the soft properties of transition metal based oxide superparamagnetic nanoparticles.

**H22 5 Magnetic Properties of Fe-alloy Catalyst Nanoparticles for Carbon Nanofiber Synthesis*** K. D. SORGE, TH. LEVENTOURI, C. FINKEL, O. MALKINA, *Florida Atlantic University* P. D. RACK, *University of Tennessee* A. V. MELECHKO, J. D. FOWLKES, K. L. KLEIN, M. L. SIMPSON, *University of Tennessee and Oak Ridge National Lab* The magnetic properties of Fe-alloy nanoparticles, used as catalysts in vertically-aligned carbon nanofiber (VACNF) growth, has been investigated. First, Fe and Co or Ni were co-sputtered onto Si substrates in order to make a catalyst alloy film. These substrates were then placed in a plasma-enhanced CVD chamber with a substrate temperature of 700°C and a flowing mixture of acetylene ($C_2H_2$) and ammonia ($NH_3$) gas. During the PECVD, the catalyst film breaks into nanoparticles of 50–200 nm and VACNFs are grown. EDX shows that the catalyst nanoparticles nominally have the deposited alloy ratio. In addition, the nanoparticles are still magnetic and have a non-negligible remanence and hysteresis. Their magnetic properties are investigated by SQUID magnetometry in applied field of $|H| \leqslant 50$ kOe and temperatures of 5–400 K. In addition, AC susceptibility studies give energy loss characteristics of the co-synthesized VACNF system.

*Part of this research was conducted at the Center for Nanophase Materials Sciences, which is sponsored at Oak Ridge National Laboratory by the Division of Scientific User Facilities, U.S. Department of Energy.

**H22 6 Size Effects in Nanostructured MnBi*** LAURA H. LEWIS, KYONGHA KANG, ARNOLD MOODENBA, *Brookhaven National Laboratory* In addition to variations in temperature, pressure and magnetic field, nanostructuring can tailor the magnetostructural transition; in particular, transition temperatures and anisotropies may change as the material expresses large surface:volume ratios. Compositions near the Mn-Bi eutectic (Mn5Bi95, Mn10Bi90) were rapidly solidified to produce the ferromagnetic low-temperature phase (LTP) NiAs-type MnBi embedded in a Bi matrix. High-resolution TEM reveals that the two compositions have different microstructures: the Mn5Bi95 composition consists of isolated nanorods (10 nm $x$ 30 nm) self-assembled along the major hexagonal symmetry directions of the Bi matrix. In contrast, the Mn10Bi90 composition exhibits regions of equiaxed clustered MnBi precipitates (50 100 nm) in addition to regions of isolated nanorods. SQUID magnetometry shows that the Mn5Bi95 composition has an abrupt magnetization decrease for $T > 520$ K associated with a first- order hysteretic magnetostructural transformation from LTP MnBi to high-temperature phase (HTP) MnBi. This transition temperature is 100 degrees lower than that of the Mn5Bi95 composition, which exhibits the bulk MnBi transition temperature of 633 K with second-order character.

**H22 7 Phase and Heterostructure Controlled Fabrication of Freestanding Magnetic Nanocrystals.*** JIAN-PING WANG,

Magnetism at the nanoscale is still not fully understood. One of the major issues involved is the lack of precise experimental results. For nanoparticles, as their size shrinks the importance of surface atoms increases to such a level that they may dominate the overall magnetic performance. Clean and well defined surfaces on nanocrystals are therefore desirable to understand the surface effect with sufficient accuracy. Unfortunately, conventional fabrication techniques usually require specific surfactants or surface passivation agents, which may conceal the role of surface atoms. Here we report a unique technique that can prepare freestanding nanocrystals with controlled crystalline phase as well as desirous heterostructures. As an example, uniform $L1_0$ FePt nanoparticles with room temperature coercivity of 8.25 kOe were achieved. HRTEM analysis shows that these particles have perfect octahedron shape with only {111} surfaces exposed UHV compatible gas phase aggregation technique was used for the generation of nanoparticles. Atoms were generated from metal targets by using a magnetron sputtering gun, in which the plasma can be manipulated to provide certain circumstances for particle nucleation and growth. The materials were carried on by carrier gas from source to substrate

so the nucleation and growth stages were separated in space. Monodispersity is therefore achieved together with controlled phase and structure.

**H22 8 Synthesis and characterization of functional magnetic nanocomposites** J. GASS, J. SANDERS, S. SRINATH, H. SRIKANTH, *Functional Materials Laboratory, Physics Department, University of South Florida, Tampa, FL 33620, USA* Magnetic nanoparticles and carbon nanotubes have been excellent functional materials that could be dispersed in polymer matrices for various applications. However, uniform dispersion of particles in polymers without agglomeration is quite challenging. We have fabricated PMMA/polypyrrole bilayer structures embedded with $Fe_3O_4$ magnetite nanoparticles synthesized using wet chemical synthesis. Agglomeration-free dispersion of nanoparticles was achieved by coating the particles with surfactants and by dissolving both the particles and PMMA in chlorobenzene. Structural characterization was done using XRD and TEM. Magnetic properties of the bilayer structures indicated superparamagnetic behavior that is desirable for RF applications as the magnetic losses are reduced. Our polymer nanocomposite bilayer films with conducting polymer coatings are potential candidates for tunable RF applications with integrated EMI suppression. We will also report on our studies of pumped ferrofluids flowing past carbon nanotubes that are arranged in microchannel arrays. Magnetization under various flow conditions is investigated and correlated with the hydrodynamic properties. This scheme provides a novel method of energy conversion and storage using nanocomposite materials.

**13:15**

**H22 9 Iron nanoparticles embedded in $SrTiO_3$ via ion implantation1*** P.V. WADEKAR, Q.Y. CHEN, X.M. WANG, H.W. SEO, O. LOZANO, D.H. KIM, Z.H. ZHANG, J.R. LIU, Y.Y. XUE, WEI-KAN CHU, *Dept. of Physics & Texas Center for Superconductivity, University of Houston, Texas, USA*. Magnetic nanoparticles are interesting because of their possible applications ranging from biomedicine to data storage. Syntheses of iron nanoparticles embedded in YSZ and $Al_2O_3$ matrices by ion implantation have already been reported in literature. It is thus natural to ask if $SrTiO_3$ would be a good alternative matrix material because of its compatibility with silicon and the unique dielectric behaviors. In this work, 60 keV $Fe^+$ ions were implanted at room temperature into single-crystalline substrates of $SrTiO_3$ to a dosage of $5x10^{16}$ ions/cm$^2$. The specimens were then annealed at different temperatures in various ambient to bring about the nanoprecipitation. Spectrophotometry, SQUID magnetometry, X-ray diffraction, electron microscopy, and electrical measurements were conducted to understand the magnetic and electrical properties in relation to the structures of the nano-composites formed under various conditions of ion implantation and post-annealing.

*Supported by NSF grant DMR-0404542 and by DOE grant DE-FG02-05ER46208. Partial support by the Welch Foundation and the State of Texas through TcSUH are also acknowledged.

**H22 10 $^1$H NMR Spectra vs. the Bulk Magnetization of Magnetically Heterogeneous Systems with Nano- and Micro-scale Magnetic Inclusions** E.M. LEVIN, *Ames Laboratory and Department of Physics, Iowa State University (ISU), Ames, IA* A. RAWAL, *Ames Laboratory and Department of Chemistry, ISU, Ames, IA* S.L. BUD'KO, *Ames Laboratory and Department of Physics, ISU, Ames, IA* K. SCHMIDT-ROHR, *Ames Laboratory and Department of Chemistry, ISU, Ames, IA* The bulk magnetization of magnetically heterogeneous systems, where magnetic nano- and micro-particles are dispersed in a diamagnetic matrix, is correlated with their $^1$H static and magic angle spinning (MAS) NMR spectra. Mixtures containing magnetic $Fe_2O_3$ nano- and micro-particles varying from 0.5 to 8 mass % in a matrix of diamagnetic laponite layered silicate were studied as model systems. Laponite has two characteristic centerbands in $^1$H NMR, which allow us to exclude contributions that can arise from protons possibly associated with the iron oxide particles. An increase in the concentration of magnetic particles results in an increase of the width of static $^1$H NMR spectra. In contrast, all $^1$H MAS spectra show a very narrow centerband and a clear sideband pattern, which is due to magnetic dipole-dipole interactions and depends on the concentration of the $Fe_2O_3$ particles. Unexpectedly, $^1$H MAS NMR spectra are observed even if the materials have a very large magnetization of 4.8 emu/g. The width of the NMR signal increases linearly with the total bulk magnetization, which can be explained by a scaling model.

**H22 12 Magnetic Properties of Hetrostructured Layered Thin Films Based on Prussian Blue Derivatives[1]** J.-H. PARK, M.W. MEISEL, *Department of Physics, University of Florida* F. FRYE, D. R. TALHAM, *Department of Chemistry, University of Florida* By utilizing a sequential deposition method and controlling the chemical composition of each layer, a series of hetrostructured layered thin films of different Prussian blue derivatives were fabricated. As a starting material, a thin film of 20 cycles of sequentially deposited $Rb_jNi_k\ [Cr(CN)_6]_l \cdot nH_2O$ film was generated, and the magnetization studies showed a ferromagnetic ordering at $T_C \sim$ 84 K and a frequency dependent susceptibility. A similar film of $Rb_jCo_k\ [Fe(CN)_6]_l \cdot nH_2O$ is known to show anisotropic photoinduced magnetism.[2] A hetrostructured film was also prepared with $Rb_jNi_k\ [Cr(CN)_6]_l \cdot nH_2O$ and $Rb_jCo_k\ [Fe(CN)_6]_l$

$\cdot\ n\mathrm{H_2O}$ alternately deposited for 10 cycles. The preliminary magnetooptical study of the hetrostructured film shows the presence of magnetic interactions between the layers of the two different Prussian blue derivatives. [1]This work was supported, in part, by the National Science Foundation DMR-0305371 (MWM) and NSF DMR-0543362 (DRT). [2]J.-H. Park, E. Čižmár, M. W. Meisel, Y. D. Huh, F. Frye, S. Lane, and D. R. Talham, Appl. Phys. Lett. 85, 3797 (2004).

**14:03**

**H22 13 Photoinduced Magnetism in Nanoparticles of Prussian Blue Derivatives*** N. E. ANDERSON, J.-H. PARK, M. W. MEISEL, *Department of Physics, University of Florida* F. FRYE, D. R. TALHAM, *Department of Chemistry, University of Florida* Nanoparticles of the Prussian blue family are of great interest due to the possibility for applications in magnetic memory, biosensing, and magnetic filtering. Nanoparticles also serve to better investigate fascinating phenomena, such as the anisotropic photomagnetic properties seen in thin films of Prussian blue derivatives.[1] Here, we present results on $\mathrm{Rb}_j\mathrm{Co}_k\ [\mathrm{Fe(CN)_6}]_l\ \cdot\ n\mathrm{H_2O}$ Prussian blue analog nanoparticles, which exhibit photoinduced magnetism. The nanoparticles are synthesized in a controlled manner, which allows for particle growth in the range of 5-50 nm. Early experiments show that upon irradiation with light at 5 K for a period of 2 hours, the final magnetization increases on the order of 10-100% compared to the initial dark state value. This increase is comparable in magnitude with the results reported for bulk materials. The change in magnetization is also accompanied by an increase in $T_c$. Furthermore, the effect of the dispersing agent on the photomagnetism, the size effect on characteristic magnetic properties, and ac susceptibility data will be presented.

*This work was supported, in part, by the National Science Foundation DMR-0305371 (MWM) and NSF DMR-0543362 (DRT).

**H23 1 Magnetoresistance of atomic-scale electromigrated nickel nanocontacts** ZACHARY KEANE, LAM YU, DOUGLAS NATELSON, *Rice University* We report measurements of the electron transport through atomic-scale constrictions and tunnel junctions between ferromagnetic electrodes. Structures are fabricated using a combination of e-beam lithography and controlled electromigration. Sample geometries are chosen to allow independent control of electrode bulk magnetizations. As junction size is decreased to the single channel limit, conventional anisotropic magnetoresistance (AMR) increases in magnitude, approaching the size expected for tunneling magnetoresistance (TMR) upon tunnel junction formation. Significant mesoscopic variations are seen in the magnitude and sign of the magnetoresistance, and no evidence is found of large ballistic magnetoresistance effects.

**11:27**

**H23 2 Retention of Giant Magnetoresistance in Thin Films on Very Rough Substrates** S.M. WATSON, A.C. REILLY, D.M. VLASSAREV, K. SMITH,* *College of William and Mary* B.C. HOLLOWAY,† *College of William and Mary* W.F. EGELHOFF, JR, *National Institute of Standards of Technology* Interfacial roughness is known to affect GMR. Past studies have measured increases, decreases or negligible changes in GMR produced by increasing interfacial roughness. Most studies have explored small scale interfacial roughness induced by changes in growth parameters or annealing[1]. We present a study of the effects of large scale roughness ($\sigma_{rms} > 5$ nm) on the properties of GMR multilayers. GMR thin films were deposited on glass substrates chemically etched for different lengths of time producing a range of lateral and vertical roughness. We found that this long length scale does not have a significant detrimental effect suggesting that viable GMR multilayers can be deposited on a wide variety of surfaces, even with large roughness. **H23 3 Electrical Resistance of Sputtered Chromium Thin Films** Z. BOEKELHEIDE, D. COOKE, F. HELLMAN, *University of California - Berkeley* D. J. SMITH, *Arizona State University* M. J. CAREY, *Hitachi Global Storage Technologies* We have measured a large variation in the electrical resistivity of magnetron sputtered chromium thin films. The resistivity ranges from anomalously high (up to 20 times the bulk value) to comparable with the bulk value, and depends strongly on the deposition parameters, in particular the sputtering gas pressure. The range of sputtering gas pressure was 0.75 mTorr to 8 mTorr, with the resistivity increasing with pressure. We have also measured the structure and composition of the films, and the high resistivity does not appear to be caused by exotic structural phases, gross impurities, or grain size effects. The impact on the antiferromagnetism of sputtered chromium films and their role in magnetic multilayers will be discussed.

**11:51**

**H23 4 Non-saturating Magnetoresistance of Inhomogeneous Conductors** JINGSHI HU, *University of Chicago* T. F. ROSENBAUM, *University of Chicago* MEERA M. PARISH, *Cavendish Laboratory, Cambridge, UK* J. B. BETTS, *NHMFL Los Alamos* The inhomogeneous distribution of excess/deficient silver atoms, introducing spatial conductivity fluctuations with length scales independent of the cyclotron radius, lies behind the large, positive and linear transverse magnetoresistance displayed by $\mathrm{Ag}_{2\pm\delta}\mathrm{Se}$ and $\mathrm{Ag}_{2\pm\delta}\mathrm{Te}$. We report here a systematic measurement of the $\rho_{xx}(\mathrm{H})$, $\rho_{xy}(\mathrm{H})$ and $\rho_{xz}(\mathrm{H})$ components of the resistivity tensor with various sample geometries, showing clear evidence of distorted current paths as seen in theoretical simulations. Comparison of the (positive) transverse and (negative) longitudinal magnetoresistance for different sample thicknesses and electrical contact separations points to a characteristic length scale set by the spatial inhomogeneity that is as large as ten microns.

**12:03**

**H23 5 Electronic and Magnetic Structure of $CrO_2$ and $CrO_2$-$RuO_2$ Interfaces*** W. H. BUTLER, *MINT Center, University of Alabama* HUNTER SIMS, *Department of Physics, Tulane University* KRISHNA CHETRY, ZHIHONG LU, SANJOY SARKER, *MINT Center, University of Alabama* $CrO_2$ and $RuO_2$ share the same (rutile) crystal structure and have similar lattice constants. We have used Density Functional Theory within both the generalized gradient and LDA+U approximations to calculate the electronic and magnetic structure of $CrO_2$, $RuO_2$ and their interfaces. Consistent with previous calculations and experiment we find (for both GGA and LDA+U) that the $CrO_2$ Fermi energy lies in a band gap for the minority channel. $RuO_2$, in agreement with experiment, is predicted to be a metal by both types of calculations. We find relatively good matching between the majority energy bands of $CrO_2$ and either channel of $RuO_2$ in the (100), (110) and (001) directions. The nearest neighbor exchange interaction in $CrO_2$ is calculated and used to estimate a Curie temperature of 411K. For (100) interfaces of $CrO_2$ and $RuO_2$, we find that the $CrO_2$ moments remain collinear if the interfaces are abrupt, but our models of intermixed interfaces yielded non-collinear moment configurations with neighboring Cr moments making an angle of approximately 150° and a small induced Ru moment oriented opposite to that of the sum of the Cr moments. We speculate that non-collinear spins at interfaces may be a common problem in oxides that may be a challenge to overcome to achieve large GMR and TMR effects in some of these materials.

**12:15**

**H23 6 Spin-Orbital Coupling Effects on Magnetoresistance in Organic Materials** YUE WU, ZHIHUA XU, BIN HU, *University of Tennessee* We report the studies on magnetoresistance of organic materials based on the light-emitting diode of phosphorescent iridium complex $Ir(ppy)_3$ molecules dispersed in fluorescent poly(N-vinylcarbazole) (PVK). The magnetic field-dependent injection current indicates that the PVK of weak spin-orbital coupling exhibits a significant magnetoresistance while the resistance of $Ir(ppy)_3$ of super-strong spin-orbital coupling shows an independence of magnetic field up to 3000 Gauss. We find that the magnetoresistance from the $Ir(ppy)_3$/PVK composite displays a gradual decrease with increasing the concentration of $Ir(ppy)_3$. The magnetic field-dependent electroluminescence confirms that the dispersed $Ir(ppy)_3$ molecules account for the change of magnetorsistance in the $Ir(ppy)_3$/PVK composite. From the uniform dispersion of $Ir(ppy)_3$ molecules observed from transmission electron microscope, we suggest that the spin-orbital coupling is modified by the interface interaction and consequently varies the magnetoresistance in the $Ir(ppy)_3$/PVK composite.

**H23 7 Single domain ferromagnet/superconductor nanoscale heterostructures** ANDREI URSACHE, JAMES GOLDBACH, THOMAS RUSSELL, MARK TUOMINEN, *University of Massachusetts Amherst* Nanoscopic single-domain ferromagnetic elements promise simple model behavior for future generations of spintronic devices. In this work, ferromagnetic/superconductor (Co/Pb) multilayer nanowire devices with point contact interfaces are fabricated by electrodeposition in P(S-b-MMA) diblock copolymer derived nanoporous templates, which can produce lateral dimensions as small as 10 nm. Using a single two ion species electrolyte, selective electrodeposition of Co and Pb is achieved by electrode potential control, and the process is characterized in situ by an electrochemical quartz crystal microbalance technique. This fabrication scheme provides the possibility of probing the transport spin polarization of a a single domain ferromagnetic nanowire by means of point contact Andreev reflection (PCAR) spectroscopy. Preliminary electron transport measurements will be presented. This work is supported by NSF grants DMR-0306951, DMI-0103024 and MRSEC.

**H23 8 Inverse proximity effect in Ferromagnet/ Superconductor composite*** JIYEONG GU, *Department of Physics and Astronomy, California State University, Long Beach, 1250 Bellflower Blvd. Long Beach, CA 90840-3901* Recently, a theoretical study of spin-screening effect in ferromagnet ($F$)/superconductor ($S$) heterojunctions has been reported [1]. From the physics involved in $F/S$ junctions it is clear that the inverse proximity effect (the magnetization of the system changes due to the presence of the superconducting correlations) is related to the properties of the conducting electron. Either bi-layer or granular ($F$ particles embedded in $S$ matrix, for example, Co particles embedded in Nb matrix) types of $F/S$ thin films have been made using co-sputtering method. We measured the magnetization as a function of temperature, especially above and below the superconducting critical temperature, to determine the screening or antiscreening effect in $F/S$ hybrid system. This experiment is useful to examine the electronic properties at the Fermi level and the distribution of magnetic moments of ferromagnetic metals. Not only inverse proximity effect but also other properties such as regular proximity effect have been investigated. [1] F. S. Bergeret and N. Garcia, Phys. Rev. B 70, 052507 (2004)

*Characterization of the thin films at low temperature and high magnetic field was carried out in the Molecular Materials Research Center at the Beckman Institute of the California Institute of Technology.

**H23 9 Proximity effect in four-layered ferromagnet/ superconductor nanostructures: decoupled superconductivity and hierarchy of critical temperatures** NAIL G. FAZLEEV, *University of Texas at Arlington, Arlington, Texas, USA* YURII N. PROSHIN, *Kazan State University, Kazan, Russia* MANSUR G. KHUSAINOV, *Vostok branch, Kazan State Technical University, Chistopol, Russia* The four-layered nanostructure consisting of rather dirty superconducting (S) and ferromagnetic (F) metals is studied within the theory of the proximity effect taking detailed account of the boundary conditions. The F/S nanostructures with four and more F and S layers are shown to have considerably richer physics than the F/S/F trilayer and F/S superlattices. The dependence of the critical temperatures versus the F layers thicknesses is investigated. It is shown that the F/S/F′/S′ nanostructure can experience decoupled superconductivity. The latter manifests itself through a hierarchy of the critical temperature Tc, which can be different for different S and S′ layers. An optimal set of parameters is determined, for which the difference between the critical temperatures becomes significant, and the corresponding phase diagrams are constructed. A conceptual scheme of a new control device based on the F/S/F′/S′ nanostructure with superconducting and magnetic recording channels that can be controlled separately using a weak external magnetic field is proposed.

**13:03**

**H23 10 Giant Magneto-Refractive Effect in Pseudo-Valve Thin Films** JARED D. ROKITOWSKI, NAM H. KIM, JIAN-QING WANG, *Binghamton University* Magnetic-field-induced changes in infrared transmission of Co/Cu/Co pseudo spin-valve (PSV's) thin films are studied for the Magnetorefractive Effect (MRE). Samples are deposited on a Si (100) wafer under a high vacuum using magnetron sputtering, followed by annealing at various temperatures up to 6000C to enhance the GMR effect. A Thermo Electron Nexus 670 FT-IR spectrometer is used to measure a mid-IR spectrum with wavelengths ranging from 2.5$\mu$m to 30$\mu$m. The transmitted spectra through the thin films, placed in a magnetic field, were measured by a KBr detector at room temperature. The measured GMR value for a sample made up of several layers, Fe(5nm)/Co(5nm)/Cu(3nm)/Co(2nm), that has been annealed at 2500C is about 2% at room temperature. This sample exhibits a sharp low switching field at about 20G and a gradual high field switching at half peak height, approximately 400G. Variations of about 1.0% in the intensity of the transmitted IR spectrum are observed for a range of magnetic field strengths up to $\pm$ 1300G with special attention focused in the low field response (roughly -100 to 100 Gauss). The MRE is analyzed for a particular wavelength of 4m. The results of this graph produce a typical GMR curve. Earlier studies of Spin-vales have yielded comparable MRE results. Detailed experimental results (1) and possible explanations will be discussed. 1. S. Uran et al., Phys. Rev. B 57, 2705 (1998).

**13:15**

**H23 11 Tunneling Magnetoresistance in Magnetic Tunnel Junctions with a (Zn,Cr)Te electrode.*** WEIGANG WANG, *Physics and Astronomy, University of Delaware* CHAOYING NI, *Materials Science and Engineering, University of Delaware* TA-KAHIRO MORIYAMA, JUN WAN, ED NOWAK, JOHN XIAO, *Physics and Astronomy, University of Delaware* Tunnel magnetoresistance (TMR) of 21% is observed at low temperature in hybrid magnetic tunnel junctions composed of a magnetic semiconductor (Zn,Cr)Te and Co electrodes separated by a Al2O3 barrier. The MTJs were deposited in a magnetron sputter system with structure as Si / (Zn,Cr)Te(50)/ Al (0.75 – 2.75)+oxidation / Co (15) / Cu (70), where the numbers in parentheses are layer thickness in nanometers. The Cr atomic concentration in the (Zn-,Cr)Te layer is controlled to be at 20%. The TMR value decreases with increasing temperature but sustains up to 250K, which is a considerable improvement over the MTJs with semiconductor electrodes in previous studies. The temperature and bias dependence of TMR are understood in the context of spin polarized tunneling and spin independent hopping through impurity states. The observed zero bias anomaly in the dI/dV curve is correlated to the existing of a soft coulomb gap at the $E_F$ in the (Zn,Cr)Te electrode which leads to $T^{-1/2}$ dependence of logarithmic resistance, logR, at low temperature. The TMR characteristic can be significantly improved by optimizing the interface and barrier quality.

**13:27**

**H23 12 Giant electroresistance and giant magnetoresistance of Fe-doped amorphous carbon film on Si substrate** XIAOZHONG ZHANG, PENG TIAN, QINGZHONG XUE, *Dept of Materials Science and Engineering, Tsinghua University, PR China* Amorphous $Fe_x$-$C_{1-x}$ films are deposited on Si substrates at different temperatures using pulsed laser deposition (PLD). It is found that the resistance of $Fe_x$-$C_{1-x}$ films on Si (100) substrates are controlled by the measuring current within a given temperature range. Correspondingly, giant electroresistance (ER) and giant magnetoresistance (MR) were found in this material. For example, $Fe_{0.011}$-$C_{0.989}$ film has a positive MR of 138% at temperature of 300K and magnetic field of 5T. It is found that the switching of the conducting channel from the $Fe_x$-$C_{1-x}$ film to the Si substrate plays an important role in the current-dependent resistance of $Fe_x$-$C_{1-x}$ films. The multilayer of $Fe_x$-$C_{1-x}$ films on Si (100) substrate was also prepared by PLD. This multiplayer material has a positive MR of over 30% at low magnetic filed, and the MR sensitivity is comparable to the spin-vale structure of traditional GMR materials. However, this material has a novel MR mechanism. It is believed that this multiplayer material can find application in magnetic information storage such as magnetic sensors, magnetic recording head and magnetic random access memory.

**H23 13 Orbitronics: The Intrinsic Orbital Hall Effect in p-doped Silicon** TAYLOR HUGHES, *Stanford University* ANDREI BERNEVIG, SHOU-CHENG ZHANG, The spin Hall effect depends crucially on the intrinsic spin-orbit coupling of the energy bands in semiconductors. However materials with small spin-orbit coupling such as silicon will only exhibit a much reduced spin Hall effect. We show that the electric field in p-doped silicon will induce a dissipationless orbital current in a fashion reminiscent of the spin Hall effect. The effect is robust against disorder because the vertex correction due to impurity scattering vanishes due to symmetry. This orbital Hall effect can lead to the accumulation of local orbital angular momentum at the edge of the sample, and can be detected by the Kerr effect.

**H24 1 Adsorption-induced fracture of branched macromolecules.*** SERGEI SHEIKO, FRANK SUN, DAVID SHIRVANYANTS, MICHAEL RUBINSTEIN,[†]HYUNG-IL LEE, KRZYSZTOF MATYJASZEWSKI, *Carnegie Mellon University* Recently, we have discovered the remarkable phenomenon that brush-like macromolecules with long side chains undergo scission of the backbone bonds as a result of adsorption onto a substrate. The macromolecule's self-destruction occurs because its side chains stretch the polymer backbone as the macromolecule struggles to reconfigure and maximize the number of contacts with the substrate. We show that the tension imposed by the surface attraction is unevenly distributed over the covalent bonds of the molecular skeleton. Along the brush axis, a major fraction of the tensile force is carried by the backbone, while in the perpendicular

direction the tension is distributed over many side chains. Using molecular visualization and computer simulation, we confirmed the first order kinetics and measured the corresponding rate constant, which revealed strong dependence on the attraction to the substrate.

**H24 2 The swelling and dissolution kinetics of polymer thin films** ARINDAM KUNDAGRAMI, M. MUTHUKUMAR, *Polymer Science & Engineering, University of Massachusetts, Amherst* We consider a theoretical analysis of the swelling and dissolution phenomena in polymer thin films. To determine the overall kinetics, we first consider the swelling process in a two-component system(solvent and polymer) and then apply this theory in conjunction with the theory of diffusive penetration of the solvent into the thin film. We also consider the dissolution of a pre-formed swelled gel of cross-linked polymers. Both analyses involve multiple moving boundaries. A comparison of our theoretical results with experimental data will be presented.

**H24 3 Sum-Frequency Vibrational Spectroscopy on Rubbed Poly(vinyl cinnamate) films for Liquid Crystal Alignment.** PASQUALE PAGLIUSI, *University of Calabria* ERIC C.Y. CHEN, *University of California at Berkeley* Y. R. SHEN, *University of California at Berkeley* Rubbing or uv-irradiation of poly-(vinyl cinnamate) (PVCi)-coated substrates can effectively align liquid crystal (LC) films deposited on them. We report here the use of surface-specific sum-frequency vibrational spectroscopy (SFVS) to investigate how rubbing affects the interfacial molecular structure of PVCi. The stretch modes of the pendant side-chain phenyl groups dominate the spectra, from which the average orientation of the phenyl groups is deduced. The results show that rubbing aligns the main chains of PVCi along the rubbing direction. While hard rubbing also aligns the phenyl rings toward the rubbing direction, soft rubbing preferentially aligns them perpendicular to the rubbing direction. The observations are correlated with the fact that hard-rubbed substrates induce LC alignment along the rubbing direction, and soft-rubbed substrates induce LC alignment perpendicular to the rubbing direction. This work was supported by NSF.

**11:51**

**H24 4 Structure of Confined Fluid between an Elastomer and a Flat Surface*** KUMAR NANJUNDIAH, *The University of Akron* ALI DHINOJWALA, The behavior of simple fluids under spatial restrictions is of considerable technological and fundamental interest. Experiments using force measurements have indicated that viscosity of confined fluids is different from that in the bulk. We have studied the confinement of linear alkanes between a poly (dimethyl siloxane) and a sapphire surface using surface sensitive infrared sum frequency generation spectroscopy (SFG). The results indicate ordering of the alkane molecules upon confinement above their bulk melting temperature. The SFG spectra of confined alkanes cooled below the bulk melting temperature shows a structure that is very different from the crystal structure of unconfined alkanes. A simple model will be presented that shows the alkane molecules crystallizing with the chains lying flat next to the sapphire surface.

**H24 5 Resonant Soft X-ray Reflectivity of Polymer Thin Films** CHENG WANG, TOHRU ARAKI, HARALD ADE, *NC State University* Resonant Soft x-ray reflectivity [1], a new method for low Z materials that combines aspects of neutron reflectivity and x-ray reflectivity, is presented and its usefulness delineated. Resonant reflectivity provides enhanced and selective sensitivity to specific chemical moieties near the absorption edges of constituent elements and was demonstrated through the characterization of a bilayer polymer thin film. The relative reflectivity of a particular interface could be tuned by adjusting the incident photon energy. Using photons in the 270-320 eV energy range, measurements were performed on thin film bilayers of polystyrene on top of poly(methyl methacrylate). Large changes in reflectivity at an interface and the resulting interference in thin films and multilayers were observed as the complex index of refraction, $n = 1\text{-}\delta\text{-}i\beta$, changed rapidly as a function of photon energy. Through the use of specific energies, the sensitivity to the polymer-polymer or polymer-vacuum interface can be selectively enhanced. The resulting chemical specificity is analogous to using deuteration as a marker in neutron reflectivity, but without requiring special sample preparation. The interfacial width determined with resonant reflectivity is virtually identical to that measured previously by XR and NR confirming that RXR is an excellent, complementary tool for the study of low-Z material thin films. [1] C. Wang, T. Araki, and H. Ade, Appl. Phys. Lett. 87, 214109 (2005).

**12:15**

**H24 6 Possible explanation of polymer surface diffusion anomaly** DEBASHISH MUKHERJI, *Department of Physics and Astronomy, The University of Western Ontario, London, Ontario N6A 3K7, Canada* MARTIN H. MUSER, *Department of Applied Mathematics, The University of Western Ontario, London, Ontario N6A 5B7, Canada* Surface diffusion of polymer is studied with molecular dymanics simulation. Our simulation result shows the non-monotonic behavior of the polymer surface-diffusion coefficient D as a function of surface coverage. D first increased with increasing polymer surface concentration, then suddenly drops at a critical value. This finding shows striking similarities with the experimental result [1]. We found that the strong reduction of D above the threshold concentration is related to the spontaneous formation of double-layered structures, whose bottom layers manage to lock into the registry of the substrate much better than the single-layer pancakes that form at smaller concentration. This increases the barriers for lateral diffusion and is thus consistent with small values of D at larger concentration. [1] J. Zhao and S. Granick, J. Am. Chem. Soc. 126, 6242 (2004).

**12:27**

**H24 7 Unconventional Spinodal Surface Fluctuations on Polymer Films*** YONG JIAN WANG, OPHELIA K. C. TSUI, *Department of Physics and Institute of Nano Science and Technology, Hong Kong University of Science and Technology* We study the temporal growth pattern of surface fluctuations on a series of spinodally unstable polymer films where the instability is adjustable by the film thickness, $h_0$. For the most unstable film studied (whose $|h_0 - h_{sp}/h_{sp}| = 0.988$; $h_{sp}$ is the thickness where the second derivative of the interfacial potential of the film equals to zero), the growth rate function of the surface modes as a function

of the wavevector fits well to the mean-field theory. As the film thickness is increased such that $|h_0 - h_{sp}/h_{sp}| \leq 0.977$, the mean-field theory demonstrates marked disagreement with experiment, notwithstanding provision of the known corrections from high-order terms and thermal noises. We show that the deviations arise from large-amplitude fluctuations induced by homogeneous nucleation, which is not accounted for in the conventional treatments.

**H24 8 Interfacial Characterization of Contact in Aqueous Environments with a Quartz Crystal Microbalance** DAVID A. BRASS, KENNETH R. SHULL, *Northwestern University* Adhesion of a material to a surface in an aqueous environment requires the removal of a water layer coating the surface. The evolution of this water layer between a micron thick polymer membrane and a quartz crystal microbalance has been investigated. This quartz crystal microbalance is highly surface sensitive, allowing determination of the water thickness during membrane contact. To improve this sensitivity, the thin, polymer membrane is backed by an ambient air environment. The surface of the quartz crystal is coated with a gold layer that acts as an electrode. This same surface allows for surface modification through the grafting of thiol terminated poly(ethylene oxide) brushes. These brushes can also by established with a coating of poly(ethylene oxide-b-styrene) diblock copolymer micelles.

**12:51**

**H24 9 Humidity influence on atomic force microscopy electrostatic nanolithography** SERGEI LYUKSYUTOV, *The University of Akron, OH* SHANE JUHL, RICHARD VAIA, *AF Research Laboratory, WPAFB OH* The formation and sustainability of water menisci and bridges between solid dielectric surface and nanoasperity under external electrostatic potential is a mystery, which must be adequately explained. The goal of our study is twofold: (i) To address the influence of an ambient humidity through the water meniscus formation on the nanostructure formation in soften polymeric surfaces; (ii) Estimate an electric charge generation and transport inside the water meniscus in vicinity of nanoscale asperity taking into consideration an induced water ionization in strong non-uniform electric field of magnitude up to $10^{10}$ $Vm^{-1}$. It is suspected that strong electric field inside a polymer matrix activates the hoping mechanism of conductivity. The electrons are supplied by tunneling of conductive tip, and also through water ionization. Electric current associated with these free carriers produces Jule heating of a small volume of polymer film heating it above the glass transition temperature. Nanostructures are created by mass transport of visco-elastic polymer melt enabling high structure densities on polymer film.

**13:03**

**H24 10 Comparison of thermal and chemical treatments of ultrathin chitosan films** CHRIS MURRAY, JOHN DUTCHER, *University of Guelph* Chitosan is a biodegradable polysaccharide derived from seashell waste products. The high water absorbency and biocompatibility of chitosan have enabled its use as a hydrogel in specialty biomedical applications. Chitosan can be dissolved in weakly acidic solutions enabling its use in applications such as films and gels, which can be converted into chitin by a chemical process known as acetylation. We present the results of several experiments in which changes in the thickness, index of refraction and molecular environment in response to changes in relative humidity for ultrathin films of chitosan are examined as a function of exposure to temperatures above 150 degrees Celsius. Measurements made by ellipsometry and FTIR spectroscopy indicate that changes in the thickness and index of refraction of the films are accompanied by a change in the infrared absorption spectra similar to that associated with acetylation, which is typically accomplished by exposure of chitosan to acetic anhydride. We believe that these changes are responsible for reduced equilibrium water content in the films at all relative humidity values studied, and may offer a simple method for converting chitosan into a chitin-like material.

**13:15**

**H24 11 Glucose/galactose binding protein changes its mechanical properties: Novel AFM method of detection in-situ.** VENKATESH SUBBA RAO, LINDA LUCK, IGOR SOKOLOV, *Clarkson University* Recently a periplasmic glucose/galactose binding protein, GGRQ26C, immobilized on gold surface has been used as an active part of a glucose biosensor based on quartz microbalance technique (QCM). However the nature of the glucose detection was not clear. Here we have found that the receptor protein film immobilized on the gold surface increases its rigidity when glucose is added, which explains the unexpected detection signal. To study the rigidity change, we developed a new fast and simple method based on using atomic force microscopy (AFM) in tapping mode. The method was verified by explicit measurements of the Young's modulus of the protein film by conventional AFM methods. Since there are a host of receptors that undergo structural change when activated by ligand, AFM can play a key role in the development and/or optimization of biosensors based on rigidity changes in biomolecules. From fundamental point of view, the developed method can be used for study of mechanics of proteins in different environments. This can be compared with molecular simulations to get additional information about the protein structure.

**13:27**

**H24 12 Modifying Surfaces with Light.** JEFF KOBERSTEIN, *Columbia University* GREG CARROL, FENG PAN, PENG WANG, NICHOLAS TURRO, The ability to locate particular functional groups at surfaces is an enabling aspect of many important technologies. Unfortunately, high energy functional groups are not thermodynamically stable at the surface of polymers and other low surface tension materials. We show that this difficulty can be overcome through the synthesis of surface active block copolymers and self-assembled monolayers that contain photoactive functional groups. Photoactive functional groups are protected during the synthesis step, but can be deprotected upon exposure to light. To accomplish this task we borrow from photoresist technology and employ photoacid generators to deprotect carboxylic acid groups delivered to a surface upon exposure to light. Since all modifications are accomplished with light, direct micropatterning of surface functional groups is possible simply by exposure through a mask. The technique is thus a simple, direct alternative to other patterning techniques such as stamping. We also demonstrate that polymers and carbohydrates can be photografted to a surface using photoactive groups that are capable of hydrogen abstraction. Applications that are demonstrated include prevention of thin film dewetting, general surface functionalization, micropat-

terning of functional groups, polymers and biopolymers, and the creation of the first covalently bound carbohydrate microarrays. This work is funded by grants from the Polymer Program of the National Science Foundation Division of Materials Research and the U.S. Army Research Office.

**13:39**

**H24 13 Dynamical simulations of rheology and phase behavior of ternary polymer blend systems.** BHARADWAJ NARAYANAN, VENKAT GANESAN, VICTOR PRYAMITSYN, *Department of Chemical Engineering, The University of Texas at Austin* We present the results of a multiscale simulation approach which combines Brownian dynamics simulations with polymer self-consistent field theory to study flow induced phase transitions in microemulsion phases of ternary polymer blends with homopolymers A and B with added copolymer AB. The results match qualitatively with the experimental observations and suggest flow transition of microemulsion phases into a three-phase coexistence followed by macrophase separation at stronger shears. We explore the effect of viscoelastic asymmetry (by varying polymer mobilities) and the copolymer (AB) to homopolymer length ratio ($\alpha$) on flow induced phase transitions. Though the series of phase transitions remain unchanged, quantitative differences arise as a function of viscoelastic asymmetry and $\alpha$. These transitions are also accompanied by a strong shear-thinning behavior in the rheological response. The results suggest significant differences between ternary polymeric systems and oil-water-surfactant systems. We rationalize the above results from a molecular viewpoint.

**13:51**

**H24 14 Orientation competition of lamellar phases in sheared block copolymers via hydrodynamic instability** ZHI-FENG HUANG, JORGE VINALS, *McGill University* We study the shear alignment of three dimensional lamellar diblock copolymers for achieving macroscopic order in defected, multidomain systems. We find that the competition between differently oriented microdomains, and thus the orientation selection between lamellar phases, is determined by the domain viscosity contrast which originates from different uniaxial domain symmetries relative to the imposed shear. This variation of domain viscosity causes hydrodynamic instability at high enough shear frequencies, breaking the degeneracy between parallel and perpendicular orientations in the system. The instability is found to obey a thin layer effect, inducing a size dependence of perpendicular domain expansion. Our calculations also suggest that the effective boundary of the experimentally observable regime with predominant perpendicular alignment follows a power law behavior between shear amplitude and frequency, with an exponent equal to 3/4.

**14:03**

**H24 15 Defects in a Noncentrosymmetric Lamellar Block Copolymer Blend** SHUJUN CHEN, SAMUEL P. GIDO, *Dept. of Polymer Sci. and Eng., Univ. of Massachusetts, Amherst, MA 01003* THODORIS TSOUKATOS, APOSTOLOS AVGEROPOULOS, NIKOS HADJICHRISTIDIS, *Dept. of Chemistry, Univ. of Athens, Panepistimiopolis, Zografou, 15771 Athens, Greece* KUNLUN HONG, JIMMY W. MAYS, *Dept. of Chemistry, Univ. of Tennessee, Knoxville, TN 37996, and Chem. Sci. Div., Oak Ridge National Lab, Oak Ridge, TN 37831* Here we report results from a defect study on the noncentrosymmetric (NCS) lamellar blend of an ABCD tetrablock copolymer and an AD diblock copolymer. The block copolymers used were polystyrene-block-polybutadiene-block-polyisoprene-block-polycyclohexadiene and polystyrene-block-polycyclohexadiene. Coexisting tetrablock-rich mixed centrosymmetric (CS) and NCS lamellar morphologies were seen in TEM, as predicted by the mean-field theory. NCS grain boundary defects similar to those in CS lamellar systems were observed as well as new defects unique to NCS layered systems, such as chain polarity reversals and kink bands with dilation or compression of the layers. In addition to morphology observations, geometrical and energetic calculations were performed on several new NCS defects, which are in good agreement with experimental results.

**H25 1 Noncontinuum Effects in Dynamics of Nanoparticles in Polymer Matrices** GANESAN VENKATRAGHAVAN, VICTOR PRYAMITSYN, *The University of Texas at Austin* The dynamics and rheology of particulate suspensions have long been well-understood in a continuum fluid-mechanical framework dating back to Stokes and Einstein. These theories predict that the mobility of the particles decreases with an increase in the viscosity of the fluid and that the addition of particles increases the overall viscosity of the suspension. However, in many recent applications such as polymer-nanoparticle composites, the particle size is comparable to or smaller than the structural scale of the solvent and the dynamics exhibits many ''non-continuum'' effects, such as the mobility becoming independent of the molecular weight (and viscosity) of the polymer, a decrease in the suspension viscosity due to the addition of nanoparticles etc. Here we propose a new theoretical formulation for the dynamics of particulate suspensions, which within a single framework encompasses for the first time both the ''macroparticle'' limit of particles larger than the structural scale of solvent and the ''nanoparticle'' limit where the particles are smaller than such scales. We present theoretical predictions for the case of polymer-nanoparticle suspensions which quantitatively explain the preceding observations and also delineates the size scales at which the particles cross-over from behaving dynamically as a ''particle suspension in polymers'' to a ''solvent for the polymers.''

**11:27**

**H25 2 Mechanisms of Steady State Rheological Behavior of Polymer Nanoparticle Composites** VICTOR PRYAMITSYN, VENKAT GANESAN, *University of Texas at Austin* We use a mesoscale computer simulation framework to delineate the the mechanisms behind the linear and nonlinear dynamical properties of polymer-nanoparticle composites. Our studies specifically focus on the regimes where the particle sizes and the interparticle distances become comparable to the polymer sizes. Our results indicate that the zero shear viscosities of the composite can be described in a manner similar to colloidal suspensions in a simple fluid when both the particle-induced changes in the polymer relaxation spectra and the polymer slip effects are accounted. The

nonlinear shear rheology and the first normal stresses of the composite exhibits a subtle interplay between the shear thinning arising from the polymer and particle stresses. Overall, at dilute and semidilute nanoparticle concentrations, the composite shear rheology is dominated by the shear thinning of the polymer chains which in turn is modified by the presence of the particles. For higher particle loads, especially in regimes where particle jamming manifests, the polymeric contribution to the rheology becomes much less important and the shear thinning is dominated by the particles stresses. These competing efffects lead to intriguing polymer molecular weight, particle loading dependencies for the steady shear rheological behavior. Our results and mechanistic explanations are in excellent agreement with associated experimental observations.

**H25 3 Surface Modification of Plate-Like Nanoparticles and Their Assembly into Nematic Organogels** BANI CIPRIANO, SRINIVASA RAGHAVAN, *Department of Chemical and Biomolecular Engineering, University of Maryland, College Park, MD 20742* Plate-like clay nanoparticles (e.g., laponite) form gels in water at sufficiently high concentration. A remarkable feature of these gels is the appearance of birefringent textures characteristic of nematic liquid crystals. Here we report the counterpart of this phenomenon in organic solvents, i.e., the formation of nematic textures by adding organically modified clay nanoparticles into non-polar liquids such as toluene and chloroform. We present the phase diagram (isotropic/nematic phases) for these gels. The viscoleastic properties of the resulting gels are characterized by use of rheological methods. The quality of the dispersions and the birefringent textures are evaluated using optical microscopy and x-ray scattering techniques. The finding that organoclays self assemble into a nematic phase in non-polar mediums may well provide a route for in-situ formation of nematic polymer nanocomposites. We also describe preliminary efforts towards achieving nematic ordering of particles in polymers.

**11:51**

**H25 4 Gelation and structural characteristics of nanoparticles in solutions of adsorbing polymers** MEGHA SURVE, VICTOR PRYAMITSYN, VENKAT GANESAN, *University of Texas at Austin, TX* In the present talk, we examine the gelation, clustering behavior and structural characteristics of nanoparticles in presence of adsorbing polymers. We implement a polymer self consistent field theory to obtain the structural conformations of the polymer chains between two spherical particles. By solving the self-consistent field theory equations numerically in bispherical coordinates we account for size disparities between the particles and polymers. We present the effect of different molecular parameters such as adsorption strength, particle size, polymer concentration on the size, number and probability distribution of polymer bridges and anchors. The structure of polymer-nanoparticle mixtures is examined using Monte Carlo simulations. By incorporating the microscopic bridging statistics into the simulation framework, we predict the structure and clustering statistics of polymer-nanoparticle gels formed in mixtures of nanoparticles and adsorbing polymers. We further extend our formalism to predict the elastic and mechanical properties of the polymer-nanoparticle mixtures. Our analysis provides a molecular insight into the nanoscale phenomena such as prevalent gelation and significant lowering of percolation thresholds observed in nanoparticle regime and quantifies the role played by various nanoscale parameters such as particle curvature and strength of polymer-particle interactions in determining the macroscopic properties of polymer nanocomposites.

**12:03**

**H25 5 Shear induced alignment in thin bilayer films: a simulation study** JOERG ROTTLER, *Dept. of Physics and Astronomy, University of British Columbia, 6224 Agricultural Road, Vancouver, BC V6T 1Z1* DAVID J. SROLOVITZ, *Dept. of Mechanical and Aerospace Engineering, Princeton University, Princeton, NJ 08544* PAUL CHAIKIN, *Physics Dept., New York University, 4 Washingon Place, New York, NY 10003* Motivated by recent experimental progress, we study ordering mechanisms in confined bilayer systems under shear via Brownian dynamics simulations. In sphere-forming thin block copolymer films, spherical nanodomains arrange in grains of local hexagonal symmetry, but random orientation. If the film has precisely the bilayer thickness, the application of simple shear leads to global, macroscopic alignment in a triangular lattice (D. Angelescu et al., Adv. Mat. 17, 1878 (2005)). By representing each nanodomain a as purely repulsive sphere on a coarse-grained level (therefore making the model also applicable to colloidal assemblies), our simulations reveal that the long range order can develop through the shear induced motion of grain boundaries rather than global melting and recrystallization. The time dependence of this process may be described by Avrami growth laws. In order to gain further insight into the microscopic mechanism of shear induced ordering, we study the motion of single domain walls in simplified geometries and determine the dependence of the grain boundary migration velocity on geometry, shearing conditions and the resulting local stress gradients.

**12:15**

**H25 6 Field-theoretic nanocomposite simulations: preliminary results of hybrid particle/SCFT simulations** SCOTT SIDES, *Tech-X Corporation* GLENN FREDRICKSON, *University of California at Santa Barbara* Using block copolymers as mesoscale templates for organic/inorganic nanoparticles has the potential to create patterned particle aggregates that could be used as magnetic storage media and semiconductor materials. More generally, polymer nanocomposites such as these are being investigated for the potential to develop materials with specifically tailored optical, electrochemical, thermal and mechanical properties. The overall behavior of the nanocomposite system depends on the morphology of the polymer chains as well as the arrangement of the particles in the polymer matrix. Self-consistent field theory (SCFT) for dense polymer melts has been highly successful in describing complex morphologies in block copolymers. Field-theoretic simulations such as these are able to access large length and time scales that are difficult or impossible for particle-based simulations such as molecular dynamics, while still incorporating more realistic polymer models than many macroscopic, continuum simulations. In this talk I will outline the SCFT method, discuss some efficient methods of numerically solving the SCFT equations and present results for spherical nanoparticles embedded in an AB diblock copolymer melt. These results have been obtained using a hybrid particle/SCFT approach that treats the polymer in a field theory framework while explicitly retaining the individual nanoparticle coordinates as degrees of freedom.

**12:27**

**H25 7 Distributed Polymeric Stickers and their Role in Colloidal Interactions and Selective Adhesion Dynamics.** MARIA SANTORE, NATALIA KOZLOVA, *Department of Polymer Science and Engineering University of Massachusetts Amherst* BING MEI, *Department of Chemical Engineering University of Massachusetts Amherst* Polyelectrolytes are frequently added to colloidal dispersions as flocculants. When they are high in molecular weight and low in backbone charge, as they adsorb to particles they extend (at least temporarily) into solution from the surface of a first particle to trap a second. This is the basis for bridging flocculation, which is often reversible to the extent that backbone relaxation ultimately causes the chain to release the second particle and more completely coat and stabilize the first. By contrast, addition of small amounts of densely-charged low molecular weight chains produces irreversible flocculation via a patchwise mechanism: A localized region on a first particle is charge-overcompensated by an adsorbing chain, and adheres to a bare spot on an approaching particle. We show here, with a model system, how the dynamics of patchwise flocculation depend on fluctuations in the distribution of adsorbing chains, and gives rise to a curvature-based selectivity for particle destabilization.

**12:39**

**H25 8 Barrier Hopping, Viscous Flow and Kinetic Gelation in Nanoparticle-Polymer Suspensions** KENNETH SCHWEIZER, YENG-LONG CHEN, VLADIMIR KOBELEV, *University of Illinois at Urbana-Champaign* Ideal mode coupling theory is combined with the polymer reference interaction site model theory of structural correlations to predict depletion-induced physical gelation and elasticity of suspensions of nonadsorbing polymers and hard particles. The approach has been extended to treat the alpha relaxation process in the ultra-slow activated barrier hopping regime. The dynamic barrier is a rich function of polymer concentration, polymer-particle size asymmetry ratio and particle volume fraction. All these dependences can be collapsed on to a single master curve that is an effective power law function of a composite variable. Over a range of material parameters commonly studied experimentally the alpha relaxation time is an exponential function of colloid volume fraction and reduced polymer concentration. The theory has been applied to compute kinetic gel boundaries and the shear viscosity, and also to address the phenomenon of delayed sedimentation.

**12:51**

**H25 9 Soft X-ray Resonant Scattering of Structured Polymer Nanoparticles** HARALD ADE, T. ARAKI, *NCSU* G. MITCHELL, *Dow Chemical* J. STUBBS, D. SUNDBERG, *U. New Hampshire* J. KORTRIGHT, A.L.D. KILCOYNE, *LBNL* We present the development and application of resonant soft x-ray scattering (RXS) to chemically heterogeneous, i.e. structured, soft condensed matter materials. Polymer composite latex particles $\sim$ 200 nm in diameter were utilized to determine the potential utility of this technique. Two styrene-acrylic polymer latex systems were prepared on silicon nitride membranes. Scattering measurements were performed in transmission. Angular scans at photon energies corresponding to strong scattering contrast between specific chemical moieties made it possible to infer the relative effective radii corresponding to the two polymer phases in the structured latex particles. The results show that resonant soft x-ray scattering should be a powerful complementary tool to neutron- and hard x-ray scattering and NEXAFS spectromicroscopy for the characterization of structured soft condensed matter nanomaterials.

**13:03**

**H25 10 Studies of the formation of microporous polymer films in 'breath figure' condensation processes** MOHAN SRINIVASARAO, JUNG PARK, *School of Polymer, Fiber and Textile Engineering, Georgia Institute of Technology, Atlanta, GA* MATTHEW BARROW, RICHARD JONES, CHRIS WRIGHT, P. RHODRI WILLIAMS, *Center for Complex Fluids Processing, University of Wales, Swansea* We report studies of the formation of ordered microporous polymer films by the evaporation of polymer solutions following exposure to a humid atmosphere. High speed microphotographic (HSMP) studies of the formation process reveal that near the surface of the polymer solution, vapor condensation produces near monodisperse water droplets which form a close-packed monolayer (or 'breath figure'). Following the evaporation of the solvent, characterization of the solid by Atomic Force Microscopy confocal microscopy and white light interferometry reveals that the surface of the polymer film features extensive regions of hexagonally close-packed microscopic pores, whose spatial arrangement replicates that of the initial droplet monolayer. Defects recorded by HSMP in the packing of the colloidal monolayer of liquid droplets formed above the surface of the polymer solution are found to correspond to those transferred into the eventual solid film, providing the first direct evidence of the structure templating role of the droplet monolayer.

**13:15**

**H25 11 Filling Small Pores With Polymer Melts** PRIYANKA DOBRIYAL, MINGFU ZHANG, JIUN TAI CHEN, THOMAS RUSSELL, *Department of Polymer Science and Engineering, University of Massachusetts, Amherst* Wetting of nanoporous inorganic templates by polymer melts is a well known and convenient way to generate polymeric nanostructures. In this work, we carried out a systematic study of wetting of nanoporous aluminum oxide membranes by polystyrene melts and obtained very different polymeric nanostructures (rods or tubes) under different conditions. When the annealing of polystyrene was done at temperature slightly above its glass transition temperature ($T_g$), nanorods were generated. When the annealing temperature was well above $T_g$, the resultant nanostructure depended on polymer molecular weight: for low molecular weight polystyrenes, nanotubes were obtained; for polystyrenes with very high molecular weights, however, nanorods formed. Thus, the viscosity of polymer melt controlled the nanostructure formation. When the viscosity of polymer melt was high, the capillary force was the dominant driving force which gave rise to the formation of nanorods; but when the melt viscosity was low, nanotubes formed and the wetting of the nanopores was achieved through the formation of precursor film.

**13:27**

**H25 12 Shear Rate Dependent Structure of Polymer Stabilized $TiO_2$ Dispersions - 1. $TiO_2$ Structure** ALAN NAKATANI, *Rohm and Haas Company* ANTONY VANDYK, LIONEL PORCAR, *NIST* JOHN BARKER, We measured the shear rate dependent structure of $TiO_2$ dispersions (37% volume fraction) stabilized with commercial polymer dispersants in water. The $TiO_2$ is a commercial grade $TiO_2$ with a particle diameter of approximately 400 nm (when the dispersions were diluted and measured

by Nanotrac 150). The solvent compositions were adjusted to the contrast match point of each dispersant to isolate the behavior of the $TiO_2$. Two different molecular weight poly acid dispersants (Referred to as ''low MW acrylate polymer salt'' and ''high MW acrylate polymer salt'') and two different molecular weight alkali soluble acrylate copolymers (Referred to as ''low MW hydrophobic acrylate copolymer salt'' and ''high MW hydrophobic acrylate copolymer salt'') were used in this study. The experiments were conducted at the NIST Center for Neutron Research (NCNR) on the perfect crystal diffractometer (PCD) for ultra-high resolution small-angle neutron scattering (USANS) measurements. The results for the $TiO_2$ scattering show that shear induced agglomeration occurs for certain dispersants and shear induced breakup of $TiO_2$ aggregates is observed for other dispersants. The results suggest new ways to consider dispersion of particles.

**H27 1 Coarse Molecular Dynamics Applied to the Study of Structural Transitions in Condensed Matter** MIGUEL A. AMAT, *Department of Chemical Engineering, University of Massachusetts, Amherst, MA* IOANNIS G. KEVREKIDIS, *Department of Chemical Engineering, Princeton University, Princeton, NJ* DIMITRIOS MAROUDAS, *Department of Chemical Engineering, University of Massachusetts, Amherst, MA* We report results from application of two coarse molecular-dynamics (MD) methods to determining the onset of structural transitions in condensed matter focusing on the melting of crystalline silicon. The two techniques require properly defined coarse variables that are slow and attracting. The first method is coarse projective integration. It allows wrapping a coarse time stepper around an MD simulator to extract the corresponding itcoarse-level description resulting from short MD bursts, which is used to extrapolate forward over coarse time steps. The second method is used to construct the underlying effective free energy landscape. Proper multi-system initialization at representative points in coarse-variable space along with analysis of the coarse-variable trajectories yields the effective free energy landscape upon integration of the reconstructed Fokker-Planck equation. Subsequent application of a coexistence criterion yields the thermodynamic melting point.

**11:27**
**H27 2 Adaptive Resolution Molecular Dynamics Scheme** LUIGI DELLE SITE, MATEJ PRAPROTNIK, KURT PRAPROTNIK, *Max Planck Institute for Polym.Res.* A new adaptive resolution scheme for efficient particle-based multiscale molecular dynamics (MD) simulations is presented. The key feature of the method is that it allows for a dynamical change of the number of molecular degrees of freedom during the course of the MD simulation by an on-the-fly switching between the atomistic and coarse-grained levels of detail. The new approach is tested on a model system of a liquid of tetrahedral molecules. The simulation box is divided into two regions: one containing only atomistically resolved tetrahedral molecules, and the other containing only one particle coarse-grained spherical molecules. The molecules can freely move between the two regions while changing their level of resolution accordingly. The hybrid and the corresponding all-atom systems have the same statistical properties.

**11:39**
**H27 3 A Multiscale Field Theory for Atomistic Multi-element Systems*** YOUPING CHEN, JAMES LEE, Formulas for local densities of fundamental physical properties, including stress and heat flux fields, are derived for atomistic systems with many-body potentials. The obtained formulas are then generalized to multi-element systems and the field representation of the corresponding conservation equations is obtained. The resulting formulas are calculable within an atomistic simulation, in consistent with the conservation laws of the thermodynamics continuum, and can be applied to single- and multi-element systems involving general two- and three-body interaction forces. It is found that, for multi-element systems, fluxes are composed of homogeneous and inhomogeneous parts and the energy conservation equation takes a different form from single-element systems. At atomic level, stress is nonlinear and nonlocal in displacements and consists of higher order strain gradients, and heat flux is a function of both strain and temperature gradients. With the derived balance equations and constitutive relations, it is shown that the atomistic formulation is able to completely define a field theory that exactly represents the classical many-body dynamics and is able to work as an alternative to, but computationally more efficient than, atomic-level molecular dynamics simulations in studying statistical and finite temperature properties of finite size multi-element materials. Numerical examples will be presented. Potential applications of the obtained field theory will be discussed.

**11:51**
**H27 4 Wavelet-based Multiresolution Particle Methods** MICHAEL BERGDORF, *ETH Zurich* PETROS KOUMOUTSAKOS, *ETH Zurich* Particle methods offer a robust numerical tool for solving transport problems across disciplines, such as fluid dynamics, quantitative biology or computer graphics. Their strength lies in their stability, as they do not discretize the convection operator, and appealing numerical properties, such as small dissipation and dispersion errors. Many problems of interest are inherently multiscale, and their efficient solution requires either multiscale modeling approaches or spatially adaptive numerical schemes. We present a hybrid particle method that employs a multiresolution analysis to identify and adapt to small scales in the solution. The method combines the versatility and efficiency of grid-based Wavelet collocation methods while retaining the numerical properties and stability of particle methods. The accuracy and efficiency of this method is then assessed for transport and interface capturing problems in two and three dimensions, illustrating the capabilities and limitations of our approach.

**12:03**
**H27 5 Multiscale model for the study of phase separation in alloys with elastic misfit*** DANNY PEREZ, LAURENT LEWIS, *Université de Montréal* We present a multiscale model developed for the study of phase separation and microstructure evolution in

binary alloys. The model is based on the classical time-dependent DFT formalism for lattice systems generalized so that elastic effects are taken into account. A multi-scale implementation of this formalism is then performed using the finite volume method to obtain the evolution of the diffusive degrees of freedom while the quasicontinuum method is used to relax the elastic degrees of freedom. The combination of these two methods allows for a seamless coupling between different length-scales using a single formalism, while reducing exactly to the original TDDFT model as the mesh size is reduced to atomic dimensions. As a first application of this model, we study the effect of elastic heterogeneity on the chemical potential of inclusions as a result of inclusion-matrix and inclusion-inclusion interactions, and infer the consequences on the coarsening behaviour of a collection of inclusions.

**H27 6 Multiscale Modeling of Polymer Rheology** SUBHRANIL DE, JACOB FISH, MARK SHEPHARD, PAWEL KEBLINSKI, SANAT KUMAR, We propose a novel simulation method which can be used to readily parallelizesimulations on systems with a large spatial extent. We simulate small parts of thesystem with independent molecular dynamics simulations, and only occasionally passinformation between these simulations through a constitutive model free continuumapproach. We illustrate the power of this method in the case of a polymeric fluidundergoing rapid one dimensional shear flow. Since we show that this flow problemcannot be modeled by using a steady-state constitutive model, this method offers the unique capability for accessing the non-linear viscoelasticity of complex fluids.

**12:27**

**H27 7 PUPIL: A New Concept of Software Integration in Multi-scale Simulations.** JUAN TORRAS-COSTA, ERIK DEUMENS, SAMUEL TRICKEY, *QTP, University of Florida* We present a relatively straightforward way to incorporate existing software packages systematically into a fully automated multi-scale simulation framework. The **PUPIL** (itProgram for User Package Interfacing and Linking) architectural concept is to provide a simulation manager, enabled by small, minimally intrusive wrapper routines installed within each software package. Thus prepared, the different packages (''Calculation Units'') are plugged into the **PUPIL** system which one then operates as a software driver. A protocol is defined to communicate between the different Calculation Units and the **PUPIL** system to exchange information. The system has been designed using the OO paradigm and implemented in Java as a fast prototyping language. A test has been carried out joining three different packages to do a MD calculation with pattern recognition to identify the QM region and an external QM force calculation. The results show the ease of operation and maintenance of this software system with little overhead. Work supported by NSF ITR award DMR-0325553.

**H27 8 Multi-scale Simulation of Ferroelectric Properties in Perovskite Solid** YAJIE LEI, *George Washington University* JAMES LEE, YOUPING CHEN, LIMING XIONG, The first principles calculations provide us with the fundamental information for the study of ferroelectric materials, including the atomic structures of morphotropic phases, ferroelectric double-well potentials, dynamical effective charges and phonon spectra. Building on such information obtained from the electronic-structure calculations by density functional theory, we developed a multi-scale approach with parameterization of the classical Buckingham potential. Applying the empirical potentials to the atomistic modeling method and a newly developed continuum theory, the ferroelectric behaviors of BiScO3 are investigated through dynamical simulations. This approach illustrates the capability to study ferroelectric materials with finite temperature and external electromechanical loadings, with no limitation to a small system with zero temperature as being imposed in the first principles calculations.

**H27 9 Anisotropy of Step Stiffness and Its Implications*** T. L. EINSTEIN, T. J. STASEVICH, F. SZALMA, *U. of Maryland, College Park* Based on a lattice gas viewpoint, we have derived[1] a simple expression for the [in-plane] orientation dependence of step stiffness which is accurate for, e.g., noble metals at room temperature except near orientations with close-packed steps. We have extended our result to deal with this narrow but important range of angles. In addition to previous applications to Cu (001) and (111), we consider, e.g., simulations of fluctuations of island edges on Pb (111) in conjunction with experimental data.[2] We find that the numerical data in an Arrhenius plot is dominated by the contributions from highly kinked regions of the step edge. We emphasize that our expression is far superior to the standard phenomenological forms and is continuous and differentiable, so well suited to continuum models and finite-element calculations.

**H27 10 Grain Boundary Cohesive Laws as a Function of Geometry** VALERIE COFFMAN, *Cornell University* JAMES SETHNA, *Cornell University* Cohesive laws are stress-strain curves used in finite element calculations to describe the debonding of interfaces such as grain boundaries. It would be convenient to describe cohesive laws as a function of the parameters needed to describe the grain boundary geometry; two parameters in 2D and 5 parameters in 3D. However, we find that the cohesive law is not a smooth function of these parameters. In fact, it is discontinuous at all geometries for which the two grains have repeat distances that are rational with respect to one another. Using atomistic simulations, we extract cohesive laws of grain boundary fracture in 2D with a Lennard-Jones potential for all possible geometries which can be simulated within periodic boundary conditions with a maximum box size. We connect the atomistic result to analytic calculations of fracture toughness as a function of dislocation density.

**13:15**

**H27 11 Water-Silica Interactions from Quantum Calculations and Non-Markovian Meta-Dynamics*** YINGXIA WAN, HAIPING CHENG, *University of Florida* The interaction of silica clusters and water molecules has been investigated using first-principles Born-Oppenheimer molecular dynamics (BOMD)

method. A small silica nano-rod that contains 108 atoms is chosen to illustrate the effects of external stress. Our results show clearly that the hydration energy between the nano-rod and water increases as a function of strain, which suggests that the water is more reactive under stress. Further simulations have been performed in which the nano-rod is twisted or squashed. We have also implemented a meta-dynamics based on the ideas of the extended Lagrangian and coarse-grained Non-Markovian dynamics. Hopefully, the method can be used to explore free energy barriers of chemical reactions.

**H27 12 POP-ART: thermodynamically correct activated event sampling in complex materials*** M.V. CHUBYNSKY, *Université de Montréal, Montréal, QC, Canada* HENK VOCKS, *Universiteit Utrecht, Utrecht, The Netherlands* NORMAND MOUSSEAU, *Université de Montréal* G.T. BARKEMA, *Universiteit Utrecht* Dynamics of complex systems with a rugged energy landscape can be represented as a sequence of rare activated events during which the system jumps between different potential energy minima. The activation-relaxation technique (ART) [1] is an efficient method of sampling such events; however, because of an unknown bias in selecting these events it cannot easily provide thermodynamical information. We present a modification of ART, the properly obeying probability ART (POP-ART) [2]. POP-ART combines short molecular dynamics runs with ART-like activated moves, with an additional accept/reject step designed to satisfy detailed balance and thus reproduce correct thermodynamics. Both correctness and efficiency of the method have been tested using a variety of systems. We mention briefly some ways of extending the approach to obtain correct dynamics as well. [1] G.T. Barkema and N. Mousseau, Phys. Rev. Lett. 77, 4358 (1996) [2] H. Vocks, M.V. Chubynsky, G.T. Barkema and N. Mousseau, J. Chem. Phys., accepted

**H27 13 Microstructural Effects in a Fully-Resolved Simulation of 1,024 Sedimenting Spheres*** LORENZO BOTTO, ZHONGZHEN ZHANG, ANDREA PROSPERETTI,† *Johns Hopkins University* The results of a fully-resolved simulation of 1,024 particles settling under gravity in a periodic domain are described and analyzed. The particle volume fraction is about 13% and the single-particle terminal Reynolds number about 10. Single and two-particle diffusivities are explored in the vertical and horizontal directions and their values related to the anisotropy of the system. Examination of the microstructure reveals that that the formation of nearly-horizontal particle pairs is an important phenomenon affecting the mean settling velocity as well as the velocity fluctuations.

**H27 15 Information-Based Examination of Variable Hierarchy in Radiation Detection** KIM FERRIS, BOBBIE-JO WEBB-ROBERTSON, *Pacific Northwest National Laboratory* DUMONT JONES, *Proximate Technologies, LLC* Of considerable importance in the development of a general program of information-based materials design is the manner in which materials data are stored, retrieved and analyzed. In the area of radiation detection materials, the variable spaces tend to be large and property measurements (and computations) of candidate materials are not abundant. Moreover, measurements and calculations of the same nominal quantity (e.g. bandgap) are typically based on differing and incompletely defined environments, and may not be directly comparable. The identification of parameter degeneracies, reduced spaces and transferability within the information hierarchy have become critical issues for the development of effective structure mappings for making inferences on these systems. As the initial framework for a materials-informatics approach to radiation detection materials, we have explored the use of both supervised (Support Vector Machines (SVM); Linear Discriminant (LDA)) and unsupervised (Principal Component (PCA)) learning methods for the development of structural signature models. Application of these methods yields complementary results, both of which are necessary to reduce parameter space and variable degeneracy. Using a crystal structure classification test, nonlinear SVM significantly increases predictive performance, suggesting trade-offs between smaller descriptor spaces and simpler linear models.

**H28 1 Exciton Trapping at Heterojunctions in Polymer Blends.***
CARLOS SILVA, *University of Montreal*

Optoelectronic devices made from semiconductor polymers often employ partially phase-separated binary polymer blends with 'distributed heterojunctions' in the polymer film and the migration of bulk excitons towards these heterojunctions crucially influences the device performance. Here, we investigate exciton migration in blend films of two polyfluorene derivatives. Localized exciplex states form in electron-hole capture at the heterojunction between the two polymers and these can be thermally excited to transfer to bulk excitons. Rapid radiative emission from these excitons can then allow efficient light-emitting diode operation. We show here that when these excitons migrate to another heterojunction site within their lifetime they are re-trapped at the interface and again form exciplex states or dissociate completely. We demonstrate that in polymer blend light-emitting diodes this can reduce the exciton population by more than 54% and strongly influences the emission spectrum. We then analyze exciton re-trapping in detail using time-resolved photoluminescence spectroscopy on blends with different morphologies and find that for nm-scale phases exciton emission is completely suppressed. We show that the data agrees well with a simple kinetic model which confirms the importance of the blend morphology for the exciton trapping efficiency.

**H28 2 Narrow Band Tails in Organic Semiconductor Crystals** C. KRELLNER, S. HAAS, D. J. GUNDLACH, B. BATLOGG, *ETH Zurich, Switzerland* In order to study the electronic states in the bulk of high quality organic semiconductor crystals, we have applied the technique of temperature-dependent SCLC measurements. The result is a quantitative density of states curve extending from typically 0.5 eV to (0.05–0.1) eV above the valence band mobility edge. We have studied dozens of crystals of pentacene, rubrene and related compounds, and find in the purest samples a very low DOS in the range of $10^{15}\mathrm{cm}^{-3}\mathrm{eV}^{-1}$ and a characteristic exponential distribution parameter of $\sim$ 180 meV. Close to the mobility edge, a rapidly rising DOS is found with a narrow typical energy of $\sim$ 10 meV. Extrapolated to the mobility edge, these curves meet the DOS derived from electronic structure calculations. The band tails are significantly narrower than in amorphous Si:H, or derived for pentacene in previous measurements, where surface or interface effects might play a significant role.

**H28 3 Hückle $\pi$-electron theory of self-assembled metalloporphyrin films** W. SCHWALM, J. MORENO, *University of North Dakota* A. BRANDT, *Moorhead State Univ.* Porphyrin-based thin films including transition metal ions can be formed by self-assembly (Y. Ni and Q. Huo, J. of Porphyrins and Phthalocyanines **9**, 275 (2005)). They have significant magnetic and optical properties. Assuming that the structures are planar and two-dimensionally periodic, the $\pi$-electron theory, though highly approximate, may give some rough insight into their electronic properties. We model the two-dimensional array of metalloporphyrin molecules using a double-exchange Hamiltonian, that couples the local moments on the metal ions with the metal-like extended $\pi$-orbitals. Within a parametrized Local Combination of Atomic Orbitals (LCAO) approximation the electronic wavefunction is treated in a minimal basis of states odd in reflection through the plane of the molecule. Local Density of States and other simple properties are computed by Green function methods. The support surface interaction breaks the reflection symmetry and contributes self energy. This effect is included through a simple model approximation.

**H28 4 Triplet exciton formation and decay in polyfluorene light emitting diode** H.H. LIAO, H.F. MENG, S.F. HORNG, J.T. SHY, K CHEN, C.S. HSU, We study the triplet excitons in poly (9,9-dioctylfluorene-2,7-diyl) (PFO) light emitting diode using infrared induced absorption. The infrared absorption is exclusively due to the triplet excitons and there is no spectral overlap with any other species. A strong suppression of the triplet exciton density relative to the singlet by voltage is observed. Through an unique independent measurement on the triplet exciton lifetime it is shown that the suppression solely comes from triplet exciton quenching by current injection. The triplet-to-singlet exciton formation ratio is independent of voltage as well as temperature, implying a spin-independent exciton formation.

**12:27**
**H28 5 Estimating the electronic conductivity of size-expanded DNA: a complex bandstructure study** MIGUEL FUENTES-CABRERA, JACK C. WELLS, *Oak Ridge National Laboratory* OSCAR HUERTAS, F. JAVIER LUQUE, *Facultat de Farmacia, Universitat de Barcelona* HAO WANG, JAMES P. LEWIS, *Department of Physics and Astronomy, Brigham Young University* MODESTO OROZCO, *Institut de Recerca Biomedica and Facultat de Quimica, Universitat de Barcelona* OTTO F. SANKEY, *Department of Physics and Astronomy, Arizona State University* xDNA is a new class of synthetic nucleic acid with one of the bases larger than the natural congeners. The larger bases, called x-bases, can be viewed as a synthesis of benzene and a natural base. We recently have found that the x-bases have HOMO-

LUMO gaps smaller than their natural congeners, and that size-expanded duplexes have stronger $\pi$-$\pi$ stacking interactions than B-DNA duplexes. These findings suggest that xDNA is likely to have a smaller band gap than B-DNA, which could make xDNA a candidate for molecular wire applications. Here we use the complex band-structure method to estimate the conductive properties of polyxG.polyC and polyxG.polyxC. These results are compared to those we obtained previously on polyG.polyC. In this manner, we systematically probe how changes in the $\pi$-$\pi$ stacking interactions affect the conductivity of DNA-like molecules.

**12:39**

**H28 6 Excitonic effects in molecular crystals built up by small organic molecules** PETER PUSCHNIG, CLAUDIA AMBROSCH-DRAXL, *University Leoben, Chair of Atomistic Modelling and Design of Materials* KERSTIN HUMMER, *University of Vienna, Institute of Materials Physics* STEPHAN SAGMEISTER, *University of Graz, Institute of Physics* The excitonic effects of biphenyl and 2,2'-bithiophene are investigated within an ab-initio framework. For this purpose the Bethe-Salpeter equation for the two-particle Greens function is solved. Therefrom the imaginary part of the dielectric function is derived, which includes the electron-hole interaction in the absorption process. It turns out that these organic molecular crystals, which are built by small molecules, give rise to sizeable exciton binding energies, which are between 0.7 and 0.8 eV. To study the influence of the intermolecular interaction, the exciton binding energy of crystalline biphenyl is calculated as a function of pressure. The decrease of both, the band gap and the exciton binding energy, results in a slight red-shift of the lowest optically active singlet exciton.

**12:51**

**H28 7 Doping Induced Energy Level Shift in Organic Semiconductors** HUANJUN DING, *University of Rochester* KATE GREEN, *University of Michigan (REU student)* YONGLI GAO, *University of Rochester* Using photoemission and inverse photoemission spectroscopy (UPS, XPS and IPES), we investigated the electronic structure of alkali metal (Cs and Na) doped copper phthalocyanine (CuPc) and tris(8-hydroxyquinoline) aluminum (Alq) films. We found that doping induces energy level shift, which can be seen as in two different stages. The first stage is predominantly due to the Fermi level moving in the energy gap as a result of the doping of electrons from the alkaline metal to the organic, and the second stage is characterized by the significant modification of organic energy levels such as the introduction of a new gap state and new core level components. In addition, we observed that the energy level shift in the first stage depended in a semi-logarithmic fashion on the doping concentration, whose slope could not be explained by the conventional model used in inorganic semiconductors. Furthermore, we also observed a reversal shift by depositing Au on alkali metal doped Alq film. The initial Au deposition quenches the Alq gap state, as well as the new component in N 1s core level, caused by the alkali metal doping. Further Au depositions shift gradually the energy levels opposite to that induced by doping. The results indicate that the gap state and energy level positions can be decoupled in the organic semiconductors, and that it's possible to fine tune the electronic structure by selective doping in the interface region.

**H28 8 Optical Studies of Excited States in Polyfluorene*** MINGHONG TONG, CHUANXIANG SHENG, Z. VALY VARDENY, *Physics Department, University of Utah* Polyfluorene is an attractive $\pi$-conjugated polymer for display applications owing to efficient blue emission and relatively large hole mobility with trap free transport. The understanding of its photophysics is important for improving its applications. We have applied a variety of ps transient and cw optical techniques to study the optical properties of poly(9,9-dioctyl) fluorene (PFO). These spectroscopies include absorption, photoluminescence, electroabsorption (EA), two-photon absorption (TPA), and ps transient photoinduced absorption. Using these techniques we probed odd- and even-parity excited states that are complementary to each other. We fitted the EA and TPA spectra by calculating the imaginary part of the third order optical susceptibility using a summation over states model, which include the effects of strongly coupled vibrations and distribution of conjugation lengths.

*Supported in part by the DOE.

**H28 9 On the Charge transport regime of crystalline organic semiconductors: diffusion limited by thermal off-diagonal electronic disorder** ALESSANDRO TROISI, *University of Warwick* In organic crystalline semiconductor molecular components are held together by very weak interactions and the transfer integrals between neighboring molecular orbitals are extremely sensitive to small nuclear displacements. We used a mixed quantum chemical and molecular dynamic methodology to assess the effect of thermal structural fluctuations on the modulation of the transfer integrals between close molecules. We have found that the fluctuations of the transfer integrals are of the same order of magnitude of their average value for pentacene and anthracene. This condition makes the band description inadequate because a dynamic localization takes place and the translational symmetry is completely broken for the electronic states. We also present a simple one-dimensional semiclassical model that incorporates the effects of dynamical localization and allows the numerical computation of the charge mobility for ordered organic semiconductors. These results explain several contrasting experimental observations pointing sometimes to a delocalized ''band-like'' transport and sometimes to the existence of strongly localized charge carriers.

**13:27**

**H28 10 Charge Transport Simulations for Amorphous Organic Thin Film Devices** CONOR MADIGAN, VLADIMIR BULOVIC, *EECS, MIT, Cambridge, MA* We employ Monte Carlo simulations to analyze charge transport through amorphous organic thin films using the well-established ''Miller-Abrahams'' hopping model within a disordered manifold of molecular energies. Whereas most existing studies calculate non-dispersive, equilibrium mobilities at low carrier concentrations, in this work we instead calculate current densities for film thicknesses (i.e. 10 to

100 nm) and applied voltages (i.e. 0.1 to 100 V) typical of common thin film devices (e.g. organic light emitting devices and photovoltaics). We find that at these thicknesses one can not assume the non-dispersive, equilibrium condition. Also, since conduction typically occurs at high carrier concentrations and is space charge limited, we must employ simulations which treat both conditions. We compare our results with those predicted by existing analytic theories, and find that the analytic theories are often highly inaccurate, mainly due to faulty use of Fermi statistics and improper calculation of backward hopping.

**H29 1 From Genes to Morphogenetic Movements: How Cell-level Modeling Makes such Connections Possible.**
G. WAYNE BRODLAND, *University of Waterloo*

New understanding provided by computational modeling makes it possible to identify, in detail, the sequence of events by which gene expression gives rise to specific morphogenetic movements. Convergent extension (CE), an important developmental process in which embryonic tissues undergo self-driven narrowing in one in-plane direction and expansion in the other, is one such example. CE is triggered by gene expression and, in amphibian gastrulae, involves cephalocaudal (CC) gradients of the morphogens Xbra and Chordin and signalling molecules that include planar cell polarity (PCP) and Wnt/Ca2+ (Nature 2004, 430: 305-306). When these pathways have established suitable biochemical conditions, cellular protrusions called lamellipodia, which previously arose with random orientations, form preferentially in the mediolateral (ML) direction. To investigate whether lamellipodium action has the mechanical capacity to drive cell intercalation and its attendant cell reshaping, the cell-level finite element model of Chen and Brodland (ASME J. Biomech. Eng., 2000, 122: 394-401) was modified so that lamellipodia could originate from randomly selected cells, connect to next-neighboring cells in the ML direction and then contract. The simulations show that lamellipodia with these characteristics can, indeed, drive CE and that adjacent tissue must resist ML narrowing in order for characteristically elongated cells to result, predictions that have been confirmed experimentally. When these meso-scale findings are integrated with tissue- and whole-embryo mechanics, multi-scale ''mechanical pathways'' become evident. These pathways, in turn, interface directly with known biochemical pathways to produce an unbroken causal sequence from gene expression to specific morphogentic movements.

**H29 2 Myxobacteria Fruiting Body Formation.***
YI JIANG, *Los Alamos National Laboratory*

Myxobacteria are social bacteria that swarm and glide on surfaces, and feed cooperatively. When starved, tens of thousands of cells change their movement pattern from outward spreading to inward concentration; they form aggregates that become fruiting bodies, inside which cells differentiate into nonmotile, environmentally resistant spores. Traditionally, cell aggregation has been considered to imply chemotaxis, a long-range cell interaction mediated by diffusing chemicals. However, myxobacteria aggregation is the consequence of direct cell-contact interactions. I will review our recent efforts in modeling the fruiting body formation of Myxobacteria, using lattice gas cellular automata models that are based on local cell-cell contact signaling. These models have reproduced the individual phases in Myxobacteria development such as the rippling, streaming, early aggregation and the final sporulation; the models can be unified to simulate the whole developmental process of Myxobacteria.

**H29 3 Quantifying the Intercellular Forces during Drosophila Morphogenesis** XIAOYAN MA, M. SHANE HUTSON, *Dept of Physics and Astronomy, Vanderbilt University; and VIIBRE - Vanderbilt Institute for Integrative Biosystem Research and Education* In many models of morphogenesis, cellular movements are driven by differences in interfacial tension along cell-cell boundaries. We have developed a microsurgical method to determine these tensions in living fruit fly (Drosophila) embryos. Cell edges in these embryos are labeled with green fluorescent protein chimeras; and line scan images that intersect several cell edges are recorded with a laser-scanning confocal microscope at a time resolution of 2 ms. While recording these scans, a Q-switched Nd:YAG laser is used to cut a single cell edge. The recoil of adjacent cell edges is evident in the line scans and the time-dependent cell edge positions are extracted using custom ImageJ plugins based on the Lucas-Kanade algorithm. The post-incision recoil velocities of cell edges are determined by fitting the cell edge positions to a double exponential function. In addition, a power spectrum analysis of cell-edge position fluctuations is used to determine the viscous damping constant. In the regime of low

Reynolds number, the tension along a cell-cell boundary is well-approximated by the product of the viscous damping constant and the initial recoil velocity of adjacent cell edges. We will present initial results from two stages of Drosophila development – germ band retraction and early dorsal closure.

**H29 5 Upregulation of Tissue Dynamics in Response to UV Laser Perturbations** XOMALIN G. PERALTA, Y. TOYAMA, *Department of Physics* S. VENAKIDES, *Department of Mathematics* D. P. KIEHART, *Department of Biology* G. S. EDWARDS, *Department of Physics, Duke University* We investigate tissue dynamics *in vivo* using a steerable UV-laser microbeam coupled to a scanning laser confocal microscope. We follow a stage in the morphogenesis of the fruit fly known as dorsal closure, which largely occurs in 2D. Dorsal closure is a consequence of four biological processes that are coordinated in space and are synchronized in time. During dorsal closure, two advancing flanks of epidermal tissue demarcate an eye-shaped opening on the dorsal side of the embryo, exposing the underlying amnioserosa tissue. As closure progresses, the two flanks of epidermal tissue approach each other and, via an adhesion mediated process, ''zip'' to form seams at the two canthi, i.e. the corners of the opening. In our studies, we target the microbeam to selectively remove specific tissues and track the resulting dynamics. We account for the results with a quantitative model. When we inhibit zipping by repeatedly targeting the microbeam to one canthus, we find evidence for an increase in the zipping rate of the seam at the other, unperturbed canthus. The upregulation occurs in a region remote from the tissue targeted by the microbeam and involves many cells. This upregulation of zipping is an example of a compensatory mechanism that ensures successful closure and highlights the resiliency of dorsal closure to perturbations. Supported by the NIH (GM33830 and GM61240).

**H29 6 Pattern Scaling Achieved by Oppositely Directed Morphogen Gradients** PETER McHALE, *UCSD* WOUTER-JAN RAPPEL, *UCSD* HERBERT LEVINE, *UCSD* Morphogens are proteins, often produced in a localised region, whose concentrations spatially demarcate regions of differing gene expression in developing embryos. The boundaries of expression must be set accurately and in proportion to the size $L$ of the developing field; this cannot be accomplished by a single one-dimensional gradient. Here, we show how a pair of morphogens produced at opposite ends of a developing field can solve the pattern-scaling problem. In the most promising scenario, two morphogens interact according to $A + B \rightarrow \varnothing$ and the switch occurs according to the absolute concentration of the first gradient. In this case scaling occurs in a window of developing-field sizes centred at a few times the morphogen decay length.

**H29 7 Shape and Size of the Fission Yeast Nucleus are governed by Equilibrium Mechanics** GERALD LIM, *Baylor College of Medicine (BCM)* GREG HUBER, *University of Connecticut Health Center* JONATHAN MILLER, *BCM* SHELLEY SAZER, *BCM* Nuclear morphogenesis in the asexual reproduction of itSchizosaccharomyces pombe (fission yeast) consists of two stages: (i) volume-doubling growth, in which a round nucleus inflates uniformly, and (ii) division, in which the nucleus undergoes shape changes from round to oblong to peanut to dumbbell before it resolves into two smaller, round daughter nuclei, driven by the formation and elongation of a microtubule-based spindle within the nucleus. The combined volume of the daughter nuclei immediately after division is the same as the volume of the single nucleus at the onset of division. Consequently, the nuclear envelope (NE) area must increase by 26% during division. We are developing a model in order to determine the mechanics governing these shape and size changes. It is based on current knowledge of the nuclear structure, insight from normal and abnormal nuclei, and concepts from the mechanics governing lipid-bilayer membranes. We predict that (a) the NE prefers to be flat, (b) the NE is under tension, (c) the nucleus has an internal pressure, (d) nuclear growth is governed by the Law of Laplace, and (e) some abnormal nuclei behave like vesicles with encapsulated microtubules.

**H29 8 A surprising answer in the search for a comprehensive health protection exposure metric for radiofrequency (RF) fields** MARJORIE LUNDQUIST,* *The Bioelectromagnetic Hygiene Institute* Matter can interact with light in 3 different ways (known by 1910): by absorption of energy [*thermal* hazard] or by absorption of linear momentum (radiation pressure) or of angular momentum (torque) or of both [*nonthermal* hazards].[1,2] The same is true for RF fields; indeed, microwave wattmeters may operate on a momentum absorption principle.[3,4] But most RF health protection standards today are based solely on *thermal* effects, ignoring nonthermal effects. Formal expressions for scientifically valid exposure metrics will be presented. It will be shown that nonthermal effects depend on field frequency, polarization and spatial configuration as well as on field strength, so a *general* metric valid for *all* fields may not exist. But with some approximations, the *magnetic induction current* may constitute an adequate *practical* exposure metric for RF fields. [1]M. Lundquist, BAPS **50** (1):620(2005). [2]M. Lundquist, BAPS **50** (1):1178(2005). [3]A. L. Cullen, Proc. IEE **99** Pt4(2):100-110(Apr 1952). [4]A. L. Cullen & I. M. Stephenson, Proc. IEE **99** Pt4(4):294-301 (Dec 1952).

**H29 9 Nonlinear Analysis of Electromyography Time Series of Low Back Muscles** ULRICH ZURCHER, KAUFMAN MIRON, PAUL SUNG, *Cleveland State University* We have calculated the mean-square displacement $\Delta(t)$ from the EMG time series and have found that increases diffusively, $\Delta(t) \sim t$, for short times $t < 10$ms, and shows a plateau-like behavior, $\Delta(t) \sim t^0$, for interintermediate times $10\,\text{ms} < t < 0.5,\text{s}$. The plateau-like behavior implies the presence of correlations in the signal. We characterize these correlations and relate them to properties of the power spectrum of the signal.

**H30 1 Electrochemically Controlled Self-Assembly of an Organometallic Block Copolymer** HANY EITOUNI, NITASH BALSARA, *U.C. Berkeley, LBNL* We have established a technique for exerting localized reversible control over the formation of block copolymer microphases. The application of electrical fields as low as 2 V/cm across a 17 weight % solution of a disordered, partially oxidized poly(isoprene-itblock-ferrocenyldimethylsilane) copolymer in dichlorobenzene results in the formation of ordered domains near the positive electrode. Spatially- and temporally-resolved small-angle neutron scattering (SANS) and birefringence measurements on the sample in the presence of the electric field were used to follow the order formation process. After reversal of the electrical bias on the system, the ordered regions underwent order-to-disorder transitions and new ordered regions were formed at the opposite electrode. Optical birefringence measurements indicated that the ordered regions possessed significant long-range orientational order.

**H30 2 Anomalous Segregation of Deuterium Labeled PS at hPS:dPS/hPMMA Interfaces as Characterized by SIMS and Mean-Field Theory*** SHANE HARTON, FRED STEVIE, HARALD ADE, *North Carolina State University* Secondary ion mass spectrometry (SIMS) was used to measure real- space depth profiles of deuterium labeled polystyrene (dPS) in hPS:dPS/poly(methyl methacrylate) (hPMMA) bilayers, with the hPS:dPS blend being well within the single-phase region of the phase diagram. Profound changes in the thermodynamic behavior of this system at the polymer/polymer interface are observed in the form of significant segregation of dPS to the hPS:dPS/hPMMA interface. Furthermore, a depletion hole was observed during the early stages of formation of an equilibrium excess of dPS, implying that the energetic gain at the interface per dPS chain has to be $>$ kT. The observed interfacial excess is quantified by generating theoretical profiles, using self-consistent mean- field theory (SCMF), and fitting an effective interaction energy parameter $\Delta\chi$ as a function of temperature. The temperature dependency of $\Delta\chi$ was found to be a factor of $3 - 4$ greater than any of those reported for $\chi$ of PS/PMMA. It was also found that SCMF accurately describes the concentration dependency of dPS segregation at a constant dPS molecular weight using a concentration independent $\Delta\chi$, however $\Delta\chi$ was found to be dependent on dPS molecular weight. A novel method of using carbon-13 labeling is demonstrated as an alternative to deuterium labeling, providing a true tracer for investigations of such phenomena as polymer chain mobility near surfaces and interfaces and reactive coupling at polymer/polymer heterogeneous interfaces.

**H30 3 Toward Single-Chain Crystallisation Kinetics** MICHAEL V. MASSA, KARI DALNOKI-VERESS, *Physics and Astronomy, McMaster University* By dewetting a thin film of a crystallisable polymer on an unfavourable substrate, one can create an ensemble of isolated and impurity-free droplets, in which homogeneous crystal nucleation can occur. Previously we have demonstrated (PRL, 92, 255509, 2004) that for bulk-like droplets (containing on the order of 10 [9] chains) the homogenous nucleation rate scales with the itvolume of the droplet. However, as the domain size is reduced far below these length scales, the confinement of polymer chains to dimensions less than the radius of gyration, the increase in the ratio of surface area to volume, and the decrease in the number of neighbouring chains can all potentially lead to changes in the crystallisation kinetics. With the same sample geometry, we extend our study of homogeneous nucleation to smaller droplet length scales. Crystallisation is monitored using ellipsometry, which offers a very sensitive probe to changes in the sample density, even for extremely small quantities of material. With complimentary results from atomic force microscopy, we follow the homogeneous crystallisation of a supercooled melt, from bulk length scales down to single-chain dimensions.

**11:51**
**H30 4 Fabrication of Three-Dimensional Nanostructures from Self-Assembling Block Copolymers on Two-Dimensional Chemically Patterned Templates with Mismatched Symmetry** MARK STOYKOVICH, *University of Wisconsin* KOSTAS DAOULAS, *University of Goettingen* HARUN SOLAK, *Paul Scherrer Institute* SANG-MIN PARK, YIORYOS PAPAKONSTANTOPOULOS, JUAN DE PABLO, *University of Wisconsin* MARCUS MUELLER, *University of Goettingen* PAUL NEALEY, *University of Wisconsin* A combined experimental and theoretical approach is used to examine the direct fabrication of complex three-dimensional (3D) nanostructures by the self-assembly of block copolymer materials on two-dimensional templated surfaces. Here a lamella-forming ternary block copolymer – homopolymer blend is considered on periodically patterned substrates consisting of square arrays of spots. The blend follows the substrate pattern and forms a quadratically perforated lamella (QPL). At intermediate film thicknesses necks connect this QPL to the film surface, resulting in a bicontinuous morphology. For thicker films bicontinuous morphologies are observed that consist of a sequence of parallel lamellae with disordered perforations. The principal concept of this work extends beyond this initial demonstration and can be generalized to the fabrication of complex 3D structures that have potential applications in nanoelectronics, separation membranes, and catalysis.

**H30 5 Slaved Diffusion in Phospholipid Bilayers** LIANGFANG ZHANG, *Department of Chemical & Biomolecular Engineering, UIUC* STEVE GRANICK, *Department of Materials Science & Engineering, of Chemistry, of Physics, and of Chemical & Biomolecular Engineering, UIUC* Dual-color fluorescence correlation spectroscopy (FCS) was employed to simultaneously investigate the translational diffusion of phospholipids in supported fluid bilayers and polymers which adsorb on these bilayers at incomplete surface coverage. It was found that the translational diffusion of phospholipids split into two populations due to polymer adsorption. A slow mode, whose magnitude was the same as that of adsorbed polymers, coexisted with a fast mode characteristic of naked lipid diffusion. Using 2-color fluorescence, cross-

correlation between the diffusion of phospholipids and polymers suggested the plausible interpretation that polymer adsorption created nanodomains of lipid whose mobility was determined by the occluded area of the adsorbed polymer. That is, those lipids inside the nanodomains were enslaved by the adsorbed polymers and diffused collectively. Variations of the polymer molar mass showed that the slow mode of phospholipid diffusion varied inversely with molar mass of the adsorbate, as predicted by our notion of slaved diffusion. This work offers a new mechanism to explain how naonsized domains with reduced mobility arise in lipid membranes.

**H31 1 Persistent Current and Drude Weight in Mesoscopic Rings** F. CARVALHO DIAS, I.R. PIMENTEL, *University of Lisbon, Portugal* M. HENKEL, *Universite Henri Poincare, Nancy I, France* We study the persistent current and the Drude weight of a system of spinless fermions, with repulsive interactions and a hopping impurity, on a mesoscopic ring pierced by a magnetic flux, using a DMRG algorithm for complex fields. We find that the persistent current changes from an algebraic to an exponential decay with the system size, as the system crosses from the Luttinger Liquid (LL) to the Charge Density Wave (CDW) phase with increasing interaction $U$. We also find that in the interacting system the persistent current is invariant under the impurity transformation $\rho \rightarrow 1/\rho$, for large system sizes, where $\rho$ is the defect strength. In the LL phase the Drude weight decreases algebraically with the number of lattice sites $N$, due to the interplay of the electron interaction with the impurity, while in the CDW phase it decreases exponentially, defining a localization length which decreases with increasing interaction and impurity strength. Our results show that the impurity and the interactions always decrease the persistent current, and imply that the Drude weight vanishes in the limit $N \rightarrow \infty$, in both phases.

**H31 2 Applying Time-dependent DMRG to Calculate the Conductance of Nanostructures** KHALED AL-HASSANIEH, *Oak Ridge National Laboratory, Oak Ridge TN, and University of Tennessee, Knoxville TN 37831* A. E. FEIGUIN, *Kavli Institute for Theoretical Physics, University of California, Santa Barbara, CA 93106* J. A. RIERA, *Universidad Nacional de Rosario, Avenida Pellegrini 250,2000-Rosario, Argentina* C. A. BÜSSER, *Ohio University, Athens, OH 45701* E. DAGOTTO, *Oak Ridge National Laboratory, Oak Ridge TN, and University of Tennessee, Knoxville TN 37831* DMRG provides a powerful tool to study quantum 1D systems. We present a detailed procedure for applying the recently developed time-dependent DMRG to calculate the conductance of nanostructures, such as quantum dots (QD's). The leads are modelled using tight-binding Hamiltonians. The ground state at time zero is calculated at zero bias. Then a small bias is applied between the two leads, the wave-function is evolved in time and the current is measured as a function of time. Typically, the current saturates at a steady state after a short period of time. The conductance is obtained from the steady-state current. To test this approach We study several cases of interacting and non-interacting systems. Our results show excellent agreement with the exact results in the non-interacting case. We also reproduce quantitatively the well-established results in the case of one interacting QD and two coupled interacting QD's. [1] K. A. Al-Hassanieh *et al*, in preparation. [2] Steven R. White and Adrian E. Feiguin, Phys. Rev. Lett. **93**, 076041 (2004).

**H31 3 Structural and electronic properties of solvated benzene and hexafluorobenzene from itab initio simulations** MARKUS ALLESCH, *Department of Theoretical and Computational Physics, Graz University of Technology, Austria, and Lawrence Livermore National Laboratory, Livermore, CA* ERIC SCHWEGLER, *Lawrence Livermore National Laboratory, Livermore, CA 94550* GIULIA GALLI, *Lawrence Livermore National Laboratory, Livermore, CA 94550 and University of California at Davis, Davis, CA 95616* We have studied the aqueous solvation of benzene and hexafluorobenzene using extensive first principles molecular dynamics simulations. By employing a rigid water approximation [1], we have been able to efficiently address long time-scale simulations ( $\sim$ 100 ps) within a first-principles context. Our analysis of radial, spatial and tilt angle distribution functions of first shell water molecules reveals structural details in the axial and equatorial regions of the solute. In particular, we have identified strong orientational ordering near the faces of the rings and cage-like spacial structures in the equatorial regions. The structural properties of the first solvation shell lead to subtle changes in the electronic structure of water, e.g. changes in dipole moments. [1] M. Allesch, et al. J. Chem. Phys. 120, 5192 (2004) This work was performed under the auspices of the U.S. Dept. of Energy at the University of California/Lawrence Livermore National Laboratory under contract no. W-7405-Eng-48.

**H31 4 Boron: do we know the ground state structure?***
TADASHI OGITSU, *Lawrence Livermore National Laboratory*

Boron is only the fifth element in the periodic table, having a simple electronic configuration, yet, it is known to form one of the most complicated crystal structures, $\beta$-rhombohedral structure. Up to date, the best estimate on the number of atoms in its hexagonal unit cell is 320.1, not even an integer number. The key concept to understand its complexity is

covalency and electron deficiency: It does not have enough valence electrons to form a simple covalent crystal, like carbon or silicon. Instead it forms a complicated packing of icosahedrons. The structural model of $\beta$-boron was developed in the 1960s based on X-ray experiment. Although this model structure captures the most of the structural characteristics of $\beta$-boron, it has a crucial pitfall; the number of atoms per cell estimated by X-ray experiment does not agree with the number of atoms estimated by the pycnometric density. In 1988, Slack et al. discovered four more POS, by which the discrepancy in the number of atoms is reconciled [J. of Solid State Chem. 76, 52 (1988)]. There still remains an unanswered question; how are these POS atoms configured? Is it completely random? Or there is some kind of order as it has been suggested in Slacks paper? A major challenge here is the astronomical number of possible configurations, roughly 150 million even for the irreducible cell. We tackle this problem using *ab-initio* simulated annealing coupled with a Lattice Model Monte Carlo simulated annealing. Our results reveal that the stable structure, indeed, has a certain type of correlation in its POS configuration. More detail on the structural property and its impact on electronic property of $\beta$-boron will be discussed at the presentation. This work was performed under the auspices of the U.S. Dept. of Energy at the University of California/ LLNL under contract no. W-7405-Eng-48.

**H31 5 First principles thermodynamics studies on the surface structures of Pt-alloy catalyst as a function of the surface segregation, co-adsorption and particle size** BYUNGCHAN HAN, GERBRAND CEDER, *Massachusetts Institute of Technology* Segregation in alloy catalysts can be significantly affected by the chemical environments. Using density functional theory coupled to the cluster expansion technique we study how adsorption of chemical species and bulk alloying change the surface structures and hence reactivity of Pt. We find that chemical adsorbates (O, OH, CO and water etc,) can change surface segregation energy of alloy elements dramatically in both bulk and nano-sized Pt. It implies that the interactions between adsorbates and surface atoms are important to understand the surface morphology and catalyst activities. We also find that Pt oxide (Pt-O or Pt-OH) has a higher reactivity to CO oxidation than pure Pt. On the other hands, Ru alloying on the Pt surface without adsorbates enhances the CO adsorption on Pt. We also investigate the effect of nanoparticle size of the on surface segregation and CO oxidation.

**H31 6 Structural and Vibrational Properties of Boron Nitride Analogues of Diamondoids** STEVEN L. RICHARDSON, *Howard University* KYUNGWHA PARK, *Virginia Polytechnic Institute and State University* TUNNA BARUAH, MARK R. PEDERSON, *Naval Research Laboratory* Diamondoids are stable cage-like hydrocabon molecules that possess a structure that is superimposable upon the diamond crystal. These highly symmetric structures have a generic structural formula $C_{4n+6}H_{4n+12}$, and they have been isolated from petroleum oil. Because of their various shapes and sizes, there has been speculation in the literature that diamondoids might be suitable building blocks for possible applications in nanotechnology. One could ask whether boron nitride (BN) analogues of diamondoids might exist. It is known experimentally that cyclotriborazane ($B_3N_3H_{12}$), the BN-analogue of the smallest diamondoid molecule adamantane exists, but there is no experimental evidence for the existence of higher-order BN-diamondoids at the present time. In this work we perform accurate all-electron density-functional theory (DFT) calculations to study the structural and vibrational properties of a small set of lower order BN-diamondoids (e.g. BN-adamantane ($B_6N_4H_{16}$), BN-diamantane ($B_7N_7H_{20}$), BN-triamantane ($B_{10}N_8H_{24}$), and BN-itanti-tetramantane ($B_{11}N_{11}H_{24}$)). We discuss the relative stability of each of these representative BN-diamondoid molecules and provide theoretical infrared and Raman spectra for future identification of this novel class of molecules. *This work was supported by the National Science Foundation and the Office of Naval Research.

**H31 7 High quality molecular dynamics simulation of carbon nanotubes in** DEYU LU, YAN LI, UMBERTO RAVAIOLI, *Beckman Institute, University of Illinois at Urbana-Champaign* GIANCARLO CICERO, *Istituto Superiore Mario Boella, Italy* GIULIA GALLI, *Chemistry department, University of California, Davis* KLAUS SCHULTEN, *Beckman Institute, University of Illinois at Urbana-Champaign* Biological applications of carbon nanotubes (CNTs) rely on mechanical, electrical, and chemical interactions between CNTs and biomolecules in water. Efficient computational methods for such nanoscale disordered systems have been developed that take into account the electronic degree of freedom of the CNTs interacting with biological media with thousands of atoms. For this purpose we combined in a molecular dynamics program an empirical CNT model employing a tight-binding CNT Hamiltonian with a classical description of the biological medium (water, ions, protein, DNA). The first application of this new method [1,2] described a potassium ion-CNT complex [3] and revealed a terahertz frequency oscillation of the ion inside a 16 angstrom long CNT segment. At a greatly reduced computational expense, our result showed good agreement with a Car-Parrinello molecular dynamics simulation. [1] D. Lu, Y. Li, U. Ravaioli, and K. Schulten. J. Phys. Chem. B, 109 (2005)11461. [2] D. Lu, Y. Li, S. V. Rotkin, U. Ravaioli, and K. Schulten. Nano Lett., 4 (2004) 2383. [3] D. Lu, Y. Li, U. Ravaioli, and K. Schulten. Phys. Rev. Lett., (2005) in press.

**H31 8 Realistic, quantitative descriptions of electron-transfer reactions: diabatic free-energy surfaces from first-principles molecular dynamics** P. H.-L. SIT, *Department of Physics, Massachusetts Institute of Technology* M. COCOCCIONI, *Department of Materials Science and Engineering, Massachusetts Institute of Technology* NICOLA MARZARI, *Department of Materials Science and Engineering, Massachusetts Institute of Technology* A general approach to calculate the diabatic surfaces for electron-transfer reactions is presented, based on first-principles molecular dynamics of the active centers and their surrounding medium. The excitation energy corresponding to the transfer of an electron at any given ionic configuration (the Marcus energy gap) is accurately assessed within ground-state density-functional theory via a

novel penalty functional for oxidation-reduction reactions that appropriately acts on the electronic degrees of freedom alone. The self-interaction error intrinsic to most exchange-correlation functionals is also corrected using the same penalty functional. The free-energy diabatic surfaces are then constructed with umbrella sampling on large ensembles of configurations. As a paradigmatic case study, the self-exchange reaction between ferrous and ferric ions in water is studied in detail.

**H31 9 Role of Interfaces and Effect of Impurities in Nitride-based Superhard Nanocomposites** HAO SHIQIANG, *The University of Sydney* BERNARD DELLEY, *Paul-Scherrer-Institut* CATHERINE STAMPFL, *The University of Sydney* Recently, a hardness similar to that of diamond has been reported for the ternary nitride-based nanocomposite, *nc*-TiN/ *a*-$Si_3N_4$/*a*- and *nc*-$TiSi_2$ [1]. The reproducibility, however, has proved difficult, as has the superhardness of the related, prototypical, binary nanocomposite *nc*-TiN/*a*-$Si_3N_4$. Extensive density- functional theory calculations indicate that the hardness enhancement in the latter system is due to the preferential formation of TiN(111) polar interfaces with a thin Si-layer which is N-coordinated and tetrahedrally bonded [2]. The tensile strength of TiN in the [111] direction is very similar to the weakest bonding direction in diamond. Oxygen impurities cause a significant reduction of the interface strength which could partly explain the conflicting results, and signals the importance of avoiding such contaminants for achieving super- and ultra-hard nanocomposites. [1] S. Veprek et al. Surf. Coat. Technol. 133-134, 152 (2000). [2] S. Hao, B. Delley, and C. Stampfl, to be published.

**H31 10 Spectral functions of fullerene molecules and solids** FEI LIN, ERIK SORENSEN, CATHERINE KALLIN, JOHN BERLINSKY, *McMaster University* There have been lots of interests in producing and engineering the fullerene materials, either because of their highly symmetric molecular geometry, the discovery of superconductivity in doped C60 materials, or their potential applications in nano devices. In this talk I will report some Quantum Monte Carlo/exact diagonalization calculations of the single-particle spectral properties on the Hubbard C20 molecule and its possible lattices. Similar calculations on the C36 and C60 materials may also be presented.

**13:39**

**H31 11 Static Polarizabilities of Nanoclusters** HYE-YOUNG KIM, JORGE SOFO, *Physics Department, The Pennsylvania State University, University Park, PA* DARRELL VELEGOL, *Chemical Engineering Department, The Pennsylvania State University, University Park, PA* MILTON COLE, *Physics Department, The Pennsylvania State University, University Park, PA* GAUTAM MUKHOPADHYAY, *Physics Department, Indian Institute of Technology-Bombay, India* In the present work, we evaluate the static polarizability of a cluster using a microscopic method that is exact within the linear and dipolar approximations. Numerical examples are presented for various shapes and sizes of clusters composed of identical atoms, where the term ''atom'' actually refers to a generic constituent, which could be any polarizable entity. The results for the clusters' polarizabilities are compared with those obtained by assuming simple additivity of the constituents' atomic polarizabilities; in many cases, the difference is large, demonstrating the inadequacy of the additivity approximation. Comparison is made (for symmetrical geometries) with results obtained from continuum models of the polarizability. Also, the surface effects due to the nonuniform local field near a surface or edge are shown to be significant.

**H32 1 First-Principles Study of Atomistically Engineered 2D-Boron Sheets** KAH CHUN LAU, RAVINDRA PANDEY, *Department of Physics, Michigan Technological University, Houghton, MI* Based on density functional theory with a planewave basis set, the stability, morphology and electronic properties of 2D boron sheets are studied. We suggest that a 2D boron sheet can be stable, and can posses metallic, half-metallic and semiconducting properties, depends on their distinct configurations. In contrast to previous studies, we predict the stability of a new novel 2D reconstructed {1221} boron sheet over the idealized {1212} triangular plane, together with their corresponding buckled configurations. Despite the high stability in cohesive energy, the unique features in geometry and electronic properties found in both configurations, suggest strong variations in electronic and mechanical properties, which might occur when the plane is rolled into different chiral structures of single-wall boron nanotubes.

**11:27**

**H32 2 Density Functional Investigation of Surface Stress-Induced Phase Transformations in FCC Metallic Nanowires** MICHAEL HAFTEL, *Naval Research Laboratory* KEN GALL, *Georgia Institute of Technology* We use density functional theory (DFT) to study the relaxation of narrow Cu, Ni, Au, Pt and Ag nanowires originally oriented in the $< 001 >$ direction with a FCC structure. For a small enough diameter ($D < 2$ nm) each nanowire, under the compressive influence of its own surface stress, spontaneously relaxes to either a $< 110 >$ orientation (Cu, Ni, Ag) or to a BCT $< 001 >$ (Au, Pt) orientation, both of which are characterized by a compression of the wire axis of at least 30%. To analyze the stability of BCT structures, we calculate the elastic constants for the BCT phases of these metals under bulk, slab, and nanowire conditions. We find that the surface contribution to the elastic constant for shear, $C_{66}$, helps stabilize the BCT phase in Au which would otherwise be unstable under bulk conditions. A large stabilization contribution from the surface also occurs in Ni and Cu, but not enough to overcome the shear instability in the bulk, and these nanowires do not transform to BCT. We discuss the implications of these results on the superelastic shape-memory effect for FCC metals.

**11:39**
**H32 3 First principles investigation of polymer-ceramic interfaces and composites** V. RANJAN, L. YU, M. BUONGIORNO NARDELLI, J. BERNHOLC, *North Carolina State University* Composite structures with high-k dielectrics are important future technologies for high-performance capacitors. We perform generalized-gradient approximation calculations to study interfacial properties of ceramic-polymer composites, focusing in particular on the strength of polymer adhesion to ceramic surfaces. Our results show that several polymers of interest do not bind directly to the ceramic. However, it is possible to functionalize the surface so that polymer attachment occurs. We present various possibilities for attachment to ceramic surfaces, which should lead to the formation of stable composites.

**H32 4 Inverse Design of Surface-Based Magnetic Nanostructures.***
ZHENYU ZHANG, *Oak Ridge National Lab*

Multiscale modeling is gaining an increasingly important role in guiding the fabrication of artificially structured nanomaterials with atomic-scale precision and desirable physical properties. In this talk, two recent examples will be presented to illustrate its predictive power in modern materials research. The modeling approaches range from electronic-scale calculations based on first principles to mesoscopic-scale continuum elasticity theory. Specific examples include: (a) fabrication of ordered magnetic atom wires on non-magnetic metal substrates; (b) optimal dopant control in dilute magnetic semiconductors via ''Subsurfactant Epitaxy.'' Emphasis will be made on the substantially improved structure-property relationships achieved through such synergetic efforts between theory and experiment, including in the second example the striking observation of magnetic ordering temperatures well above 300 K.

**H32 5 Design of Nano-Ears for Surface Enhanced Raman Scattering*** FERNANDO A. REBOREDO,† CHAD E. TALLEY, STEPHEN M. LANE, *Lawrence Livermore National Laboratory* Metallic structures optimized for surface enhanced Raman scattering (SERS) must combine i) large dipole moments, for stronger coupling with the external field E, and ii) highly localized plasmon modes, which increase Raman Scattering cross sections (proportional to E4) and improve spatial resolution. Since typical molecules are much smaller than the visible wave lengths, the design of nanostructured surfaces for SERS involves an electrodynamical problem analogous to the one solved with ear shapes in acoustics. In this limit, retardation effects can be ignored, which reduces the problem to the response at the metal surface. We have developed a finite element computational tool that allows the calculation of surface plasmons on arbitrary metallic shapes. We have found that an accurate description of the surface curvature is crucial. Our numerical results agree with exact analytical solutions for the quasi-static model known for spheres and spherical shells. Using this method, we have compared several shapes, where analytical results are not available, and uncover ear-shaped structures that are 12 orders of magnitude more efficient than spheres.

**H32 6 Tip-based simulations of nanotribology of self-assembled monolayers** MICHAEL CHANDROSS, CHRISTIAN D. LORENZ, MARK J. STEVENS, GARY S. GREST, *Sandia National Laboratories* While nanotribological simulations are generally performed for two opposing parallel surfaces, the Atomic Force Microscopy (AFM) experiments to which they are often compared measure the interactions between a curved probe tip and a sample. The parallel plate geometry cannot capture many effects seen in experiments, including load-dependent contact areas and molecular transfer of material from the substrate to the tip. We present the results of true dynamical nanotribological simulations of alkylsilane self-assembled monolayers (SAMs) with realistic tip/substrate geometries. Tips matching experimental dimensions (up to $\sim$ 30 nm radius of curvature) were cut out of an amorphous silica substrate (a-$SiO_2$) and either coated with SAMs or annealed for uncoated tips. The adhesion and friction of the tip in contact with a SAM-coated amorphous a-$SiO_2$ substrate were studied with massively parallel molecular dynamics simulations. The effects of load-dependent contact areas are compared to previous simulations with flat plate geometries, and to AFM measurments. Conditions leading to tip fouling, and the effects on nanotribological measurements will also be discussed. Sandia is a multiprogram laboratory operated by Sandia Corp., a Lockheed Martin Company, for the United States Departme nt of Energy's National Nuclear Security Administration under Contract DE-AC04-94AL85000.

**H32 7 Defects Assisted Growth Carbon-Based Nanomaterials*** M.N. YOON, ZHENYU ZHANG, DOUG LOWDNES, *Oak Ridge National Laboratory* A multiscale approach has been applied to study the growth mechanism of carbon-based nanomaterials such as graphite flakes, fullerenes, nanotubes, and nanohorns. Especially, the role of defects during the growth of different morphologies will be discussed. At high temperatures, interesting structural transitions among given morphologies are observed when defects are introduced. The transitions are driven by entropy which plays a crucial role in determining the structural stability at these temperatures. The stability of large structures is also studied

using molecular dynamics simulations and analytical calculations based on ab initio density functional techniques. We will further discuss the role of catalytic particles in determining the structural stabilities of experimentally observed nanomaterials.

**H32 8 Ab-Initio Simulations of the Growth of Short Carbon Nanobells** G.L. ZHAO, *Southern University and A&M College; Visiting Fellow, Princeton University* D. BAGAYOKO, *Southern University and A&M College* We performed ab-initio density functional simulations to study the structural and growth properties of short carbon nanobells. We used a real space approach and the linear combination of atomic orbitals (LCAO) formalism. In the nitrogen-doped carbon nanobells, the nitrogen atoms that are attracted to the open-edge sites of the carbon nanobells play an important role in the growth of the short carbon nanostructures. We also present the calculated electronic structure of the short nanobells. The calculated local density of states of the nanobells revealed field emission characteristics that agree with experimental observations. Acknowledgments: this work was funded in part by NASA (Award No. NCC 2-1344), NSF (Award No. 0508245), and ONR (Grant No: N00014-05-1-0009).

**H32 9 Modeling the catalytic action of supersaturated Ni droplets for the initial stage of growth of single-walled nanotubes*** I. CHAUDHURI, M. YU, C.S. JAYANTHI, S. Y. WU, *University of Louisville* Transition metal nanoparticles are the catalysis of choice for the growth of single-walled carbon nanotubes because of the high miscibility of carbon atoms with their supersaturated liquid droplets. This suggests that, at least for modeling the initial stage of growth, the droplets may be represented by the jellium medium and catalytic action of the droplets may be modeled by the electron redistribution for carbon atoms mediated by the medium. We have tested this scenario by comparing stable configurations of cage-structured C clusters in vacuum with those in jellium, with an average charge transfer from the jellium to C atoms $n_{av} \approx$ 0.2e to model the effect of nickel atoms. The structural optimization was carried out using the semi-empirical self-consistent and environment- dependent Hamiltonian in the framework of linear combination of atomic orbitals developed by our group [1]. Our results showed that the pentagons are more stable with substantial charge transfer occurrence in the defects in the vicinity of pentagons, consistent with previous results [2]. We also found that for a cage-structured cluster of a given size, increasing $n_{av}$ tends to elongate the hexagonal rings. Thus it appears that the catalytic action provided by Ni-droplet may be modeled by the charge fluctuations on C atoms mediated by the jellium. [1] S. Y. Wu et.al. Handbook of Material Modeling Vol. I, p.2935 (2005). [2] X. Fan et. al. Phys. Rev. Lett. **90**, 145501 (2003).

**H32 10 Molecular Functionalization Mechanism of Hydrogenated Si Surfaces** YOSUKE KANAI, *Princeton University* ANNABELLA SELLONI, *Princeton University* NOBORU TAKEUCHI, *Universidad Nacional Autonoma de Mexico* ROBERTO CAR, *Princeton University* Within the current effort to understand and develop the organic functionalization of silicon surfaces, recent experiments have identified the radical chain reaction of unsaturated organic molecules with H-terminated silicon surfaces as a particularly promising route for controlled formation of such functionalized surfaces. Using periodic Density Functional Theory calculations, we theoretically study and characterize the basic steps of the radical chain reaction mechanism for different (conjugated and unconjugated) aldehyde molecules reacting with the H-Si(111) surface, under the assumption that a Si dangling bond is initially present on the surface. Molecular conjugation is found to play a crucial role in the viability of the reaction, by controlling the delocalization of the spin density at the reaction intermediate. Interesting differences are observed and discussed between our present results for aldehydes and our previous study for the reactions of alkene/alkyne molecules with H-Si(111) [Takeuchi, et al *J. Am. Chem. Soc.* **2004**, *126*, 15890.]

**13:39**

**H32 11 Density Functional Calculation of Hydrogen Storage in a $C_{60}$ Molecule*** CHIH-KAI YANG, *Chang Gung University* Storage of hydrogen molecules is a research topic that has deep scientific interests and enormous applications in providing a clean type of energy for the future. Recent experimental breakthrough in encapsulating hydrogen molecules in fullerene $C_{60}$ promises a wider role for the versatile carbon cage in this regard. Probing further, we use density functional theory to study how the enclosed hydrogen molecules interact with the carbon cage. The calculations show that quite a few molecules can be exothermically inserted into the cage and as many as 35 hydrogen molecules can be stored inside without rupturing the cage structure.

**11:15**

**H33 1 Effect of Counterface Roughness on Sliding Friction of Alkane Monolayers** KEVIN VAN WORKUM, *United States Naval Academy* GINGER CHATEAUNEUF, GUANGTU GAO, DAVID SCHALL, JUDITH HARRISON, Classical molecular dynamics simulations of carbon-based counterfaces sliding against a monolayer of alkane chains are presented. The tribological behavior three carbon-based counterfaces of varying roughness are compared. The distribution of contact forces between individual monolayer chain groups and the counterface shows a strong dependence on the surface roughness of the counterface. Distinctions between contact forces which oppose and those which assist the counterface motion are made and are related to the net friction. A perfectly smooth counterface shows a realitively narrow distribution

of contact forces. The width of the distribution of contact forces increases with increasing counterface roughness. The local motion of the alkane chain end-groups is also discussed in terms of the roughness of the sliding counterface.

**11:27**
**H33 2 Molecular dynamic simulations of the contact between elastic solids and fractal substrates** CARLOS E. CAMPANA, MARTIN H. MÜSER, *University of Western Ontario* The contact mechanics and friction between unlubricated, elastic solids with fractal surfaces is studied using molecular dynamics. Large interfaces could be studied, owing to the use of elastic Green's functions for semi-infinite, elastic lattices. Our simulations confirm the emerging picture that friction and pressure distribution depend mainly on the mean slope of the walls in contacts (unlubricated and chemically passivated solids). Besides, the level of discreteness of the description plays an essential role. This supports another emerging picture, namely that the detailed structure of the very last layer is crucial for friction between two solids.

**11:39**
**H33 3 Friction and plasticity between self-affine surfaces*** BINQUAN LUAN, MARK ROBBINS, *Johns Hopkins University* JUDITH HARRISON, *U.S. Naval Academy* Simulations are used to study the contact area and adhesion between two amorphous solids with self-affine fractal surfaces, and the results are compared to continuum calculations. The friction between non-adhesive surfaces is proportional to load, but the coefficient of friction increases with roughness. The friction is much higher than expected for elasticallly deforming surfaces,* and substantial plastic deformation is observed. Indeed, friction forces for different surface roughness collapse when plotted against the number of plastic rearrangements per unit sliding distance. Including adhesion leads to an increase in both friction and plasticity.* M. H. Müser, L. Wenning, and M. O. Robbins, Phys. Rev. Lett. **86**, 1295 (2001).

**H33 4 Superlubricity and atomic-scale energy dissipation in ultrahigh vacuum.***
ENRICO GNECCO, *University of Basel*

''Superlubricity'' has been recently achieved on ionic crystals in ultra-high vacuum in two different ways. First, the normal load exerted by a sharp AFM tip on the crystal surface has been reduced below a critical threshold under extremely low noise conditions, and kept constant while scanning in the usual way. The transition from the stick-slip motion commonly observed on the atomic scale to the superlubricated regime occurs in a continuous way, and can be theoretically described introducing a parameter $\eta$, which is, respectively, larger or smaller than 1 in the two regimes. A comparison with the Tomlinson model allowed us to carefully estimate the contact stiffness and the interaction between tip and surface down to the superlubricated regime [1]. The ''static'' superlubricity obtained in such way cannot be easily extended to systems of practical interest, like micro- and nano-electromechanical devices. The main problem is the smallness of the applied loads (below 1 nN), which must be maintained for a long time. This obstacle is removed if superlubricity is achieved in a different ''dynamic'' way. When an $ac$ voltage is applied between the tip and a counterelectrode on the other side of the crystal sample, and the actuation frequency corresponds to a normal resonance of the system, a sistematic decrease of friction to negligible values is also observed. In such case the magnitude of the applied load is not subject to upper limitations. This effect is probably due to a delicate interplay between thermal activation and the fast variation of the tip-surface interaction, as suggested by recent computer simulations. [1] A. Socoliuc, R. Bennewitz, E. Gnecco, and E. Meyer, Phys. Rev. Lett. 92 (2004) 134301.

**H33 5 Study of nano-scale kinetic friction using vortices in superconductors and charge-density waves** A. MAEDA, Y. INOUE, H. KITANO, *Department of Basic Sciences, University of Tokyo* S. SAVELEV, F. NORI,* *Frontier Reserach System, RIKEN* I. TSKADA, *Central Research Institute of Electric Power Insdustry* S. OKAYASU, *Japan Atomic Research Institute* In analogy with the standard macroscopic friction in massive blocks, we present a comparative study of the friction force felt by moving quantized vortices in high-$T_c$ superconductors and charge-density waves (CDWs). Using $I - V$ characteristic measurement and a model for this data, our observations: (1) provide a link between friction at the micro- and macroscopic scales; (2) explain the roundness of the static-kinetic friction transition in terms of system sizes (critical-phenomena view) and thermal fluctuations; and (3) explain the crossing of the kinetic friction $F_k$ versus velocity $v$ for our pristine (high density of very weak defects) and our columnar-defect-irradiated samples (with lower density of deeper pinning defects). We will also investigate any possibilities of the observation of the scaling relation between the velocity dependence of the kinetic friction and the waiting time dependence of the static friction in these systems.

**12:39**
**H33 6 Friction Measurements With Dewetted Polymer Droplets: Bridging the Gap in Contact Area Between Lateral Force Microscopy and the Surface Forces Apparatus** ANDREW B. CROLL, KARI DALNOKI-VERESS, *Physics and Astronomy, McMaster University* Lateral Force Microscopy (LFM) is an important tool that essentially created the field of nano-tribology some 20 years ago. The interest in this technique stems from its ability to measure true single asperity surface contact. Although

tremendously successful, LFM lacks the ability to vary contact area without complicated tip modifications, most of which require modeling to determine contact area. At the other end of the contact area length scale is the Surface Forces Apparatus (SFA). This technique allows for extremely high precision friction measurements, but only on macroscopic lateral length scales. Here we present a simple technique that uses dewetted polystyrene droplets (spherical caps) to overcome these obstacles. Droplets are reversibly attached to conventional atomic force microscope tips, and scanning takes place much as in LFM. The dewetted droplets have the advantage of very flat, well-defined, rigid contact with the substrate, over several orders of magnitude in area ( $\sim 10\ \mu m^2$ – $10000\ \mu m^2$). Measurements on an extremely thin poly(dimethyl siloxane) layer yield insight into the complex interplay between viscosity and elasticity in thin polymer lubricants.

**H33 7 Formation of nanoscale water bridges*** ELISA RIEDO, *Team 1* ROBERT SZOSZKIEWICZ, *Team 1* TAI-DE LI, *Team 1* JIANPING GAO, *Team 2* UZI LANDMAN, *Team 2* SCHOOL OF PHYSICS, GEORGIA INSTITUTE OF TECHNOLOGY TEAM, The water bridges provide stability to sand castles, act as transport channels for dip-pen nanolitography and increase adhesion and friction in micro- and nano- devices such as MEMS. The kinetics of capillary condensation and growth at the nanoscale is studied here using friction force microscopy and molecular dynamics calculations. At 40% relative humidity we find that the meniscus nucleation times increase from 0.7 ms up to 4.2 ms when the temperature decreases from 332 K to 299 K. The nucleation times grow exponentially with the inverse temperature 1/T obeying an Arrhenius law. We obtain a nucleation energy barrier of 7.8*10{-20}$\sim$ J and an attempt frequency ranging between 4-250 $\sim$ GHz, in excellent agreement with theoretical predictions. These results provide direct experimental evidence that capillary condensation is a thermally activated phenomenon.

**13:03**

**H33 8 The effect of packing density on self-assembled monolayer friction: Investigation of frictional contrast between OTS phase-separated regions** ERIN FLATER, ROBERT CARPICK, *Univ. of Wisconsin-Madison* Motivated by the lack of fundamental understanding of friction, and that friction and wear are major limiting factors for surface micromachined devices, we use atomic force microscopy (AFM) to determine the nanoscale frictional properties of alkylsilane monolayers commonly used in these microscale devices to reduce adhesion and friction. Quantitative nanoscale single asperity measurements of friction and contact stiffness are performed using monolayer-terminated AFM tips on monolayer-terminated silicon. By comparing the two structural phases present in octadecyltrichrolosilane (OTS) monolayers, we observe that friction depends on the local molecular packing density. The liquid condensed phase shows measurably lower friction at low loads than the liquid expanded phase, demonstrating that lower friction is associated with higher molecular packing density. However, the phases exhibit the same frictional response at higher loads, suggesting that compressed forms of both phases are structurally and tribologically equivalent. We discuss these results in terms of stress-induced molecular conformational changes in the confined interface. We acknowledge our collaborators: W. Robert Ashurst at Auburn University, who provided the OTS samples, and Maarten P. de Boer and Alex D. Corwin at Sandia National Laboratories.

**13:15**

**H33 9 Coverage dependence of 1-propanol adsorption on the Si(001) surface and fragmentation dynamics** JIAN-GE ZHOU, FRANK HAGELBERG, *Jackson State University* The chemisorption of organic molecules on silicon surfaces is a highly topical subject of current research, both experimental and computational. This interest may be ascribed to both the fundamental nature of this problem, involving the interaction between finite units and periodic substrates, but also to its relevance to various areas of recent technology, such as insulator films, nanolithography, chemical and biological sensors, and molecular electronics. The organic layers are formed by depositing organic compounds on the semiconductor surface. In order to optimize this process, the understanding of the interaction between the surface and the organic species is crucial. The geometric, electronic, energetic, and dynamic properties of 1-propanol absorbed on the Si(001)-(2x1) surface are studied from first principles by use of a slab approach. The 1-propanol molecule initially interacts with the Si surface through formation of a dative bond, subsequently the physisorbed 1-propanol molecule reacts with the surface by cleavage of the O-H bond, and the Si(001)-(2x1) surface undergoes further reconstruction as a result of the adsorption of the organic species. The band structure and density of states (DOS) are first analyzed for this system. The band gap of the Si-1-propanol film increases as the coverage level is enhanced. Good agreement is found with available experimental data.

**H33 10 Buckling Instability In Bilayer Membranes** A. CONCHA, J. McIVER, P. MELLADO, R.L. LEHENY, *Johns Hopkins University* We have analyzed the patterns generated when a stress field is introduced to the inner layer of a cylindrically symmetric bilayer membrane through a combination of analytic calculations, numerical simulations, and experiments. A wrinkled structure forms that we explain in terms of a competition between bending and stretching energies under a suitable geometrical constraint. The wavelength, $\lambda$, at the onset of the instability is found theoretically and experimentally to be $\lambda = \pi\sqrt{8B/T_c}$, where $T_c$ is the critical tension of the inner layer marking the onset of the instability, and $B$ is the bending modulus of the membrane. We have also investigated the formation of pseudo-fractal structures that emerge beyond the onset of the instability. We further explain the existence of defects in the regular pattern as a consequence of multiple metastable states in the effective potential that describes this system.

**H35 1 Improving optical performance of W-structured type-II superlattices by adjusting $As_2$ and In flux** J.C. KIM, J.G. TISCHLER, I. VURGAFTMAN, J.R. MEYER, E.H. AIFER, L.J. WHITMAN, *Naval Research Laboratory* C.L. CANEDY, E.M. JACKSON, *SFA Inc.* We are investigating ''W-structured'' type-II superlattices (W-SLs) for use in IR photodiodes. A typical W-SL period consists of a hole quantum well (QW) sandwiched by two electron QWs, which are in turn bounded by barrier layers (*e.g.*, InAs/InGaSb/InAs/AlGaInSb), such that the bulk band-edges form a ''W'' pattern. The mini-band straddles the GaSb valence and InAs conduction bands, with a direct gap that can be varied from mid- to very long-wave IR. Photoluminescence (PL) has proven to be a sensitive indicator of photodiode performance, and here we present results correlating the PL intensity of W-SL's grown under varying conditions with their structure. X-ray diffraction is used to measure overall strain and periodicity, and cross-sectional STM (XSTM) is used to directly image the atomic-scale structure. We have discovered that roughness at InAs-on-InGaSb interfaces can be controlled by adjusting the $As_2$:In flux ratio and thereby reducing Sb cross-incorporation in the InAs. The smoother interfaces and reduced strain correlate with stronger PL. By independently adjusting the $As_2$ and In flux, W-SLs with low strain can be fabricated across a range of wavelengths with PL up to 20% greater than we have previously achieved. We discuss our analysis using XSTM to correlate the PL spectra with the structure of the W-SLs as a function of $As_2$ and In flux.

**11:27**
**H35 2 Equilibration of Two-dimensional Excitons in an In-Plane Harmonic Potential** ZOLTAN VOROS, DAVID SNOKE, *University of Pittsburgh* LOREN PFEIFFER, KEN WEST, *Bell Labs, Lucent Technologies* We report on the equilibration dynamics of a 2D gas of long-lifetime (10 $\mu$s), high-mobility excitons trapped in an in-plane harmonic potential produced by inhomogeneous external stress. Spatially indirect excitons are created in a GaAs/AlGaAs double quantum well structure by a quasi-continuous laser pulse. After excitation, the excitons approach equilibrium with a well-defined volume and constant temperature. When the system is far from quantum degeneracy, the effective temperature can be deduced from the spatial profile of the exciton cloud. We show that at the lowest temperatures, the disorder prevents the excitons from reaching the lattice temperature and that the external confining potential is greatly reduced by exciton-exciton repulsion. We discuss the implications of these two phenomena on the possibility of Bose-Einstein condensation of quantum well excitons.

**11:39**
**H35 3 Quantum well structure for a test of intersubband plasma instability** P. BAKSHI, C. DU, K. KEMPA, *Boston College* T. ROCHELEAU, M. SHERWIN, A. GOSSARD, *UCSB* We have shown theoretically that a resonant interaction of an intersubband plasmon emission mode with an absorption mode creates a plasma instability [1]. This can be tested experimentally in an asymmetric double quantum well where the lowest three levels, with appropriate occupancy, provide near resonant emission and absorption modes. The third level is to be partially populated by THz laser pumping from the first level. An applied bias tunes the second level in relation to the other two. The two modes attract each other to form a pair of complex conjugate modes, thus creating a plasma instability. Such a structure has been designed, grown and characterized through absorption measurements without pumping. The results are in good agreement with theory calculations. Narrow Lorentzian lineshapes are observed, indicating a low level of collisions. A realistic pumping fraction can produce sufficiently strong instability to overcome the collisional damping. Characteristic instability criteria, including a modified lineshape are predicted, to be tested with pumping in the next phase of the program. [1] P. Bakshi and K. Kempa, Cond. Matter Theories, 12, 399 (1997); 20, 45 (2005); Physica E7, 63 (2000).Work supported by ARO and NSF.

**H35 4 Mapping the Copper energy band using the quantum well states** J. WU, J. CHOI, T. OWENS, Z. Q. QIU, *Dept. of Phys., UC-Berkeley, Berkeley* E. ROTENBERG, N. V. SMITH, *Advanced Light Source, LBNL, Berkeley, CA 94720* Quantum well states (QWS) of copper electrons in Cu/Co/Cu(100) system are investigated using Angle Resolved Photoemission Electron Spectroscopy (ARPES). The samples were grown epitaxially at room temperature and measured in situ at beamlime 7 of the Advanced Light Source (ALS). Photoemission intensity oscillates with both the electron energy and the Cu film thickness. By counting the thickness oscillation periodicity at a given energy, we can determine the out-of-plane electron momentum without the need of the phase value in the phase accumulation model. This allows the experimental determination of the E-k relation (energy band) for the Cu film. We here report the Cu energy band determined in this way at different in-plane momentum. In addition, by fitting the oscillation as a function of the Cu thickness, we also determined the phase value of the quantization condition as a function of the energy and in-plane momentum.

**H35 5 Coulomb drag in coupled quantum wells: effects of bandstructure and q-dependent scattering*** RICHARD W. DENEEN III, *University of Akron* BEN YU-KUANG HU, *University of Akron* We study the effects of non-parabolicity of the bandstructure and wavevector-dependent scattering rates on the Coulomb drag in coupled quantum wells, using a theoretical formulation that takes these effects into account [K. Flensberg and B. Y.-K. Hu, Phys. Rev. B **52**, 14796 (1995)]. We examine the conditions in which this formulation reduces to the result given by von Oppen *et al.* [F. von Oppen, S. Simon and A. Stern, Phys. Rev. Lett. **87**, 106803 (2001)], in which the effects of band-structure are included through the terms $d\hat{\sigma}_i/dn_i$, where $\hat{\sigma}$ is the (single-layer) conductivity tensor and $n$ is the (single-layer) density and $i$ is the

layer index. The effect of scattering that is strongly wavevector-dependent will also be discussed.

**H35 6 Dependence of current switching dynamics on contact conductivity in semiconductor superlattices** STEPHEN W. TEITSWORTH, HUIDONG XU, *Duke University* Numerical simulation results are presented for a discrete drift-diffusion electronic transport model appropriate to weakly-coupled semiconductor superlattices [1]. Sequential resonant tunneling between adjacent quantum wells is the primary conduction mechanism for this model which also incorporates an effective contact conductivity $\sigma_c$. We study the dependence on $\sigma_c$ of time-averaged current-voltage characteristics and transient current response to abrupt steps in applied voltage. For intermediate values of $\sigma_c$, three qualitatively distinct transient responses – each associated with a different mechanism for the itrelocation of a static charge accumulation layer [1] - are observed for different values of voltage step $V_{step}$; these involve, respectively, 1) the motion of a single charge accumulation layer, 2) the simultaneous motion of one depletion and two accumulation layers [2], and 3) the simultaneous motion of two accumulation layers. The range of $V_{step}$ values for each mechanism and the relocation times associated with each are studied as a function of $\sigma_c$; a critical value of $\sigma_c$ is identified above which the second relocation mechanism is not observed for any value of $V_{step}$. Relocation times are found to depend sensitively on specific values of $\sigma_c$ and $V_{step}$. [1] L. L. Bonilla and H. T. Grahn, Rep. Prog. Phys. **68**, pp. 577-683 (2005), and Refs. therein. **H35 7 Scanning probe study of dopant charging in a semiconductor heterostructure*** IRMA KULJANISHVILI, CEMIL KAYIS, JAMES HARRISON, CARLO PIERMAROCCHI, THOMAS KAPLAN, STUART TESSMER, *Michigan State University* LOREN PFEIFFER, KEN WEST, *Bell Laboratories, Lucent Technologies* The smallest possible semiconductor nano device is a single dopant atom. The properties of such a structure are most prominent at low temperature, where multiple electrons or holes can be localized at the parent donor or acceptor. Using a scanning probe method, we study dopant atom charging in an AlGaAs/GaAs heterostructure with a delta-doped Si layer. The method is based on the Scanning Charge Accumulation (SCA) imaging technique that allows for studying a subsurface electronic system. Here we report on our results resolving the single-electron addition spectra of small numbers of dopant atoms. These highly localized capacitance measurements are contrasted to gated capacitance measurements. The SCA data are compared to a simple model based on a donor-molecule picture.

**H35 8 Theoretical Carrier Mobilities in $\delta$-doped AlInSb/InSb Hereterostructures*** Y. SHAO, S. A. SOLIN, *Washington University in St. Louis* L. R. RAM-MOHAN, *Worcester Polytechnic Institute* Ultrathin films with thicknesses ( $<$ 100 nm) and very high ( $>$ 1 $m^2$/Vs) room temperature carrier mobility are of immense practical importance in a number of magnetic sensor applications.[1] The electron transport mobilities in $\delta$-doped AlInSb/InSb heterostructures had been studied. The sub-band electron occupation and the energy levels were numerically obtained by solving the Schrödinger and Poisson equations self-consistently as a function of spacer layer thickness, well width and temperature. The quantum energy levels were found within the quasi-classical approximation. The electron mobilities were calculated by combining ionized impurity, background impurity, deformation potential acoustic phonon and polar optic phonon scattering. The dependencies of the electron mobility on temperature, spacer layer thickness and quantum well thickness were simultaneously obtained. At 0K and room temperature, mobilities as high as $1.3x10^3$ and 10 $m^2$/V s, respectively, were obtained at larger spacer layer (400nm) and well widths (400nm). In contrast to privious work, for the application of device design, the product of electron density and mobility was studied to maximize the transconductance. The model we used can be adaped to study other heterostructure.

**H35 9 Three novel effects in nanostructures** GAGIK SHMAVONYAN, *State Engineering University of Armenia* To achieve the broadband characteristics, a sequence of non-identical multiple quantum well (MQWs) were designed. When designing a broadband semiconductor optical amplifier (SOA) using a non-identical MQW structure, factors such as QW transition energy, number and sequence of different QWs, the thickness of the separate confinement heterostructure (SCH) layer, the selection of the dominant carrier, the ability of the QW to trap the 2D carrier, the uniformity of the 2D carrier within the QWs, etc. must be taken into account. For SOAs fabricated on the substrate with five 6 nm InGaAsP quantum wells and two 150 nm InGaAsP quantum wells, a very broad emission spectrum is obtained. The spectral width is 400 nm, covering range from 1250 to 1650 nm. The broadest bandwidth for SOA ( $\sim$ 400 nm) allows us to observe three novel effects: Bi-directional guided effect of lasing mode in a bending waveguide of SOA. An optical switching effect in one SOA The SCH layer thickness effect.

**H35 10 Mesoscopic Anisotropic Magnetoconductance Fluctuations in Ferromagnets** SHAFFIQUE ADAM, MARKUS KINDERMANN, SAAR RAHAV, PIET W. BROUWER, *Laboratory of Atomic and Solid State Physics, Cornell University, Ithaca, NY 14853-2501* The conductance of a ferromagnetic particle depends on the relative orientation of the magnetization with respect to the direction of current flow. This phenomenon is known as ''anisotropic magnetoresistance.'' Quantum interference leads to an additional, random dependence of the conductance on the magnetization direction. These ''anisotropic magnetorestance fluctuations'' are caused by spin-orbit scattering, which couples the electron motion to the exchange field in the ferromagnet. We report a calculation of the dependence of the conductance autocorrelation function on the rotation angle of the magnetization direction.

**13:15**

**H35 11 Minigap plasmons in a periodically modulated two-dimensional electron gas: single-particle necktie spectra** HIROYUKI SAKAKI, *Institute of Industrial Science, University of Tokyo, Japan* MANVIR KUSHWAHA, *Institute of Physics, University of Puebla, Mexico* We investigate the plasmon excitations in a two-dimensional electron gas (2DEG) subjected to a one-dimensional (1D) weak periodic potential. We derive and discuss the dispersion relations for both intrasubband and intersubband excitations within the framework of Bohm-Pines' random-phase approximation (RPA). For such an anisotropic system with spatially modulated charge density, we observe a splitting of the 2D plasmon dispersion. The splitting is caused by the superlattice effect of the charge-density modulation on the collective excitation spectrum. In addition, We observe how the energy-tunneling allows the intersubband single-particle excitations (SPE) to attain a finite width at the zone center and to contain the gaps inside. The resulting gaps inside the intersubband SPE give rise to an intriguing structures of *neckties* appearing at the zone boundaries in the excitation spectra illustrating plasmon energy versus Bloch vector. We discuss how the tunneling and the potential amplitude affect such a *necktie* spectrum.

**13:27**

**H35 12 Work function oscillations of atomic-layer-resolved Pb films** JINFENG JIA, *Institute of Physics, The Chinese Academy of Sciences, Beijing 100080, China* YUN QI, XUCUN MA, SHUAIHUA JI, YINGSHUANG FU, QIKUN XUE, By scanning tunneling microscopy, the local work function (LWF) dependance on thickness was studied on Pb quantum wedges with flattop grown on stepped Si(111) substrate. The oscillatory behavior of LWF was observed due to the quantum well state formation induced by the electrons confined in the [111] direction of Pb wedges. The electronic density of state, which is believed to play an important role in such physical property as LWF, was also obtained by scanning tunneling spectroscopy. It is found that the highest occupied quantum well state near Fermi level presented by dI/dV curve has great relationship with the LWF oscillating. Our results show good agreement with the theoretical predictions. This work directly proves that the local work function and the related physical properties are also modulated by quantum well state.

**13:39**

**H35 13 The classical limit of coherent transport properties** SAAR RAHAV, PIET BROUWER, *Laboratory of Atomic and Solid State Physics, Cornell University* We investigate the behavior of weak localization, conductance fluctuations, and shot noise of a chaotic scatterer in the semiclassical limit. Time resolved numerical results, obtained by truncating the time-evolution of a kicked quantum map after a certain number of iterations, are compared to semiclassical theory. Considering how the appearance of quantum effects is delayed as a function of the Ehrenfest time gives a new method to compare theory and numerical simulations. We find that both weak localization and shot noise agree with semiclassical theory, which predicts exponential suppression with increasing Ehrenfest time. However, conductance fluctuations exhibit different behavior, with only a slight dependence on the Ehrenfest time.

**13:51**

**H35 14 Composite-fermion antiparticle description of the hole excitation in the maximum-density droplet** ALEV DEVRIM GUCLU, *Cornell University* GUN SANG JEON, *Pennsylvania State University* CYRUS J. UMRIGAR, *Cornell University* JAINENDRA K. JAIN, *Pennsylvania State University* The maximum-density droplet of quantum dots is a finite-size realization of the state at filling factor one. For a sufficiently small number of electrons, it becomes unstable to the creation of a central hole as the magnetic field is increased or the strength of the confinement potential reduced. The simplest model for the hole is a vortex at the center, which, however, is renormalized by edge excitations. We show that a remarkably accurate description of the actual hole state is achieved in terms of a ''composite-fermion antiparticle,'' which is surprising in view of the fact that composite fermions are thought to be relevant only in the fractional Hall regime. The composite-fermion antiparticle description also allows us to study the effect of Landau level mixing through variational and diffusion Monte Carlo calculations in a very efficient manner. Generalizations to systems containing several holes, as well as to the quasiholes of fractional quantum Hall states are presented.

**14:03**

**H35 15 Giant piezoresistance in AlAs 2D electron systems with antidot lattice** O. GUNAWAN, Y.P. SHKOLNIKOV, K. VAKILI, E.P.D. POORTERE, M. SHAYEGAN, *Princeton University* We report a novel giant piezoresistance effect in AlAs wide quantum well 2D electron system, patterned with an antidot lattice of about 1.0 $\mu$m period. At a low density of $\sim$ $3.5\times 10^{11}/\mathrm{cm}^2$ and at T=0.3 K, the piezoresistance exhibits a strain gauge factor as large as 20,000, the largest value reported so far without magnetic field. Compared to the region without the antidot pattern, this antidot region represents $\sim$ $3.5\times$ larger gauge factor and $\sim$ $5\times$ wider dynamic range in piezoresistance. Such device may find important applications for super sensitive strain detection in mechanical microstructures.

**H36 1 Probing molecular electronics with mechanical break junctions.**
HEIKO WEBER, *University of Erlangen*

We will report on experiments with single molecule junctions, performed with the mechanically controlled break-junction technique. A review is given on the capabilities of the technique and the results obtained so far. The importance of the

molecular structure, the local environment, the contacts, and of the electronic polarizability will be elucidated. As a particular example, we will present an experiment with a molecule that was designed to form a single-molecule diode when contacted from two sides. The concept is closely related to Aviram-Ratner's Gedankenexperiment. Indeed, the IVs show a pronounced asymmetry, whereas a blind experiment with symmetric molecules resulted in symmetric IVs. A closer analysis of the data, involving theoretical models, suggests that the bias-dependent charge reconfiguration of the electronic structure is responsible for the diode-like characteristics.

**H36 2 Pulling gold nanowires with a hydrogen clamp** SZABOLCS CSONKA, *Budapest University of Technology and Economics* ANDRAS HALBRITTER, GEORGE MIHALY, ELECTRON TRANSPORT RESEARCH GROUP OF THE HUNGARIAN ACADEMY OF SCIENCES AND DEPARTMENT OF PHYSICS TEAM, Gold nanojunctions were found to be perfect candidates for studying the quantum nature of the conductance. It was shown that monoatomic gold contacts have a single conductance channel with perfect transmission. During the elongation of a single-atom gold contact stable atomic chain can be formed [2]. We have performed an experimentally study of the interaction of gold nanowires with hydrogen molecules by the Mechanically Controllable Break Junction technique [1]. Our results show, that in hydrogen environment the conductance of the chain is strongly reduced compared to the perfect transmission of pure Au chains. The comparison of the experiments with recent theoretical prediction for the hydrogen welding of Au nanowires [3] implies that a hydrogen molecule can even be incorporated in the gold nanocontact, and this hydrogen clamp is strong enough to pull a chain of gold atoms. [1] Csonka et al., to be published in Phys. Rev. B, cond-mat/0502421 (2005). [2] Agrait et al., Phys. Rep. **377**, 81 (2003). [3] Barnett, Nano Letters **4**, 1845 (2004).

**12:03**

**H36 3 Gold point-contact measurements of molecular junctions** LATHA VENKATARAMAN, JENNIFER KLARE, IRIS TAM, COLIN NUCKOLLS, MARK HYBERTSEN, MICHAEL STEIGERWALD, *Columbia University* The conductance of molecular junctions, formed by breaking gold point-contacts dressed with various thiol-functionalized organic molecules, is measured at 293 K and at 30 K. In the presence of molecules, individual conductance traces measured as a function of increasing gold electrode displacement show clear steps below the quantum conductance steps of the gold contact. These steps are distributed over a wide range of molecule-dependent conductance values. Histograms constructed from all conductance traces therefore do not show clear peaks either at room and low temperatures. Filtering of the data sets by an objective automated procedure does only marginally improve the visibility of such features. We conclude that the geometrical junction to junction variations dominate the conductance measurements.

**12:15**

**H36 4 Theoretical Exploration of the Impact of Link Chemistry on Single Molecule Junction Conductance*** MARK S. HYBERTSEN, *Applied Physics and Applied Math. Dept, Columbia University* MICHAEL STEIGEWALD, *Chemistry Dept., Columbia University* LATHA VENKATARAMAN, *Physics Dept., Columbia University* JENNIFER E. KLARE, IRIS W. TAM, COLIN NUCKOLLS, *Chemistry Dept., Columbia University* Measurement of molecular conductance by repeatedly breaking an Au point contact in an environment of molecules allows for the study of a large number of fresh junctions and presents a statistical picture of the junction conductance. However, there is no direct control or knowledge of the atomic scale structure in each individual junction. It is important to distinguish effects on the conductance related to the structure of the metal-molecule link from those that are intrinsic to the backbone of the molecule in the junction. To that end, we examine the energetics and frontier electronic states of various link groups such as thiolate and isonitrile coupled to candidate Au structures using DFT based calculations. We discuss systematic trends in comparison with experiments.

**H36 5 Charge Storage Based Hysteretic Negative-Differential-Resistance in Metal-Molecule-Metal Junctions** RICHARD KIEHL, *University of Minnesota* JOHN LE, *University ofo Minnesota* PANGLIJEN CANDRA, *University ofo Minnesota* REBECCA HOYE, *University ofo Minnesota* THOMAS HOYE, *University ofo Minnesota* Experimental results on the electrical characteristics of Hg-alkanethiol//arenethiol-Au molecular junctions are used to develop a physical model for the hysteretic negative differential resistance observed for these, and possibly other, metal-molecule-metal junctions. The dependence of the current-voltage characteristic on sweep direction and rate are examined together with the voltage dependence of the junction's ac conductance. Based on several specific electronic properties, it is concluded that the observed behavior is caused by a slow charge storage process. The implications of this model on potential electronic applications are discussed.

**12:39**

**H36 6 Kondo resonances and anomalous gate dependence of electronic conduction in single-molecule transistors** D. NATELSON, L.H. YU, Z.K. KEANE, *Rice University, Dept. of Physics and Astronomy* J.W. CISZEK, L. CHENG, J.M. TOUR, *Rice University, Dept. of Chemistry* T. BARUAH, M.R. PEDERSON, *Naval Research Laboratory* We report Kondo resonances in the conduction of single-molecule transistors based on transition metal coordination complexes. We find Kondo temperatures in excess of 50 K, comparable to those in purely metallic systems. The observed gate dependence of the Kondo temperature is inconsistent with observations in semiconductor quantum dots and a simple single-dot-level model. We discuss possible explanations of this effect, in light of electronic structure calculations.

**12:51**

**H36 7 Self-aligned lithography and in-situ assembly of chemically responsive single-molecule transistors*** JINYAO TANG, JENNIFER KLARE, YILIANG WANG, ETIENNE DE POORTERE, COLIN NUCKOLLS, SHALOM WIND, *Columbia University* We report the fabrication and assembly of single-molecule transistors comprising ultrathin metal electrodes separated by a nanoscale gap, which is bridged by a single molecule or a small number of molecules. The electrodes sit upon a conductive sub-

strate, which serves as a gate, separated by a thin gate dielectric, and the gap is defined by a completely self-aligned process involving the lateral oxidation of a sacrificial thin film of Al. Devices with gaps ranging from $\sim$ 2 - 10 nm are fabricated with yields approaching 80%. Highly conjugated bis-oxazole molecules are assembled within the gaps in a sequential fashion, relying upon individually designed end-group chemistry to control the attachment of molecular units to the metal electrodes and the modular assembly of the bis-oxazole units, respectively. In addition, metal ion complexes are used to reversibly attach and detach terpyridyl molecular units from one another. Fully assembled devices display distinctive electrical response, which is strongly modulated by the molecular assembly and attachment.

**13:03**

**H36 8 Prevalence of Coulomb blockade in conjugated and non-conjugated molecules on gold versus palladium electromigrated junctions*** ARTUR ERBE, LARUE DUNKLEBERGER, KIRK BALDWIN, ROBERT WILLETT, *Bell Laboratories, Lucent Technologies* ANAT DE PICCIOTTO, JENNIFER KLARE, KENJI SUGO, COLIN NUCKOLLS, *Department of Chemistry and The Nanoscience Center, Columbia University* The conduction properties of electro-migration gap junctions made with Au or Pd and with various organic molecules incorporated in the gaps are studied to expose the full range of possible transport processes, and their prevalence. Primarily comparisons are made between molecules with an electron delocalized vs. electron-localized backbone, between molecules with one vs. two thiol end groups, and between molecules with and without large side chains on the Au junctions. Within these junctions Coulomb blockade can be observed in all molecular species tested, including bare junctions and those coated by molecules with no electron-accepting properties, but at significantly lower prevalence than molecules with delocalized electron backbones. Importantly, Coulomb blockade with high charging energy values is seen almost exclusively on junctions with molecules possessing the delocalized electrons. An overall lower prevalence of Coulomb blockade is observed in the Pd junctions, but with the same relative molecular dependence. These results indicate the scope of variation in transport possible for molecules on electro-migrated junctions of various metals.

*Under NSF Award Number CHE-0117752.

**13:15**

**H36 9 Control of topography, stress and diffusion at molecule-metal interface** NIKOLAI ZHITENEV, DONALD TENNANT, RAYMOND CIRELLI, *Bell Labs.* WEIRONG JIANG, ERIC GARFUNKEL, *Rutgers* ARTUR ERBE, *U. Konstanz* ZHENAN BAO, *Stanford* The electronic properties of molecular devices that are just a few atomic layers thick are determined not solely by the properties of the molecules but are equally dependent on dopants, defects and electronic states at the interfaces. We study the phenomena affecting the conductance of molecular devices by systematically varying the growth conditions at the metal-molecule interface. Transport properties of metal-molecule-metal junctions containing monolayer of conjugated and saturated molecules with characteristic dimensions in the range of 30-300 nm are correlated with microscopic topography, stress and chemical bonding at metal-molecule interfaces. Small shadow masks defined within a stack of $Si/SiO_2/SiN_x/SiO_2$ layers are used to obtain features below the usual lithographic limits. We demonstrate that the defects/interfaces can be rationally controlled and that their properties are often more important than the electronic properties of molecules in determining the device conductance. The density of defects caused by metal penetration into monolayers is significantly reduced yielding $>$ 95% of non-shorted devices. Our statistically significant dataset allows us to conclude that the conductivity of organic molecules $\sim$ 1.5 nm long is at least 4 orders of magnitude lower than is commonly believed.

**13:27**

**H36 10 Electronic Transport through Organic Monolayer Devices** DUNCAN STEWART, JASON BLACKSTOCK, CARRIE DONLEY, ZHIYONG LI, DOUGLAS OHLBERG, R. STANLEY WILLIAMS, *Hewlett-Packard Laboratories, Palo Alto, CA USA* SEHUN KIM, *KAIST, Daejeon, Korea* REGINA RAGAN, *UC Irvine, Irvine, CA, USA* We report experimental studies of electronic transport through molecular monolayers. Particular emphasis is placed on combining detailed chemical, physical and electronic characterization in a single test structure, and to whatever degree possible, fabricating well-defined interfaces that enable quantitative chemical and physical analysis. To this end, we describe physical characterization of ultra-flat template-stripped Au and Pt metal electrodes including UHV-STM imaging and incorporation into a new stencil-based nanopore structure. In-situ XPS and IR spectroscopy are used to characterize the organic monolayers and the buried inorganic/organic interfaces. Using this well-characterized device structure, we present detailed I-V characterization including temperature dependence and IETS spectroscopy of several alkane self-assembled and Langmuir-Blodgett monolayers, correlating both electrical switching behavior and IETS spectral responses to the measured chemical and physical structure of the device.

**13:39**

**H36 11 Structural Characterization of a Molecular Junction by X-ray Reflectivity** JULIAN BAUMERT, *Brookhaven National Laboratory* MICHAEL LEFENFELD, *Columbia University* ELI SLOUTSKIN, *Bar-Ilan University* PETER PERSHAN, *Harvard University* MOSHE DEUTSCH, *Bar-Ilan University* COLLIN NUCKOLLS, *Columbia University* BEN OCKO, *Brookhaven National Laboratory* In the field of molecular electronics, the nature and pathways of charge transfer through molecules is among the most intensely studied open questions. Experimental studies, employing both single molecules and self-assembled monolayers attached to the electrodes, have demonstrated that the electronic characteristic of these junctions is difficult to reproduce. We report x-ray reflectivity studies of the structure of organic mono- and bi-layers self-assembled between two conducting electrodes: silicon and mercury. At high molecular coverage, the Angstrom resolution high-energy synchrotron x-ray measurements reveal densely-packed layers of roughly interface-normal molecules. The interface normal structure is stable and relatively insensitive to electric fields when a voltage is applied across the junction. Furthermore, our x-ray studies reveal that variation of the molecular coverage of the electrodes influences the structure and quality of the molecular junctions.

**13:51**

**H36 12 Charge addition effects in phenylene ethynylene oligomers: the effect of -$NO_2$ substitution** S. W. ROBEY, C. D. ZANGMEISTER, R. D. VAN ZEE, *NIST-Gaithersburg* Interest in aromatic systems based on phenylene ethynylene oligomers (OPE) has been spurred by reports of interesting negative differential resistance/hysteretic behavior in metal-molecule-metal junctions. Theoretical work has invoked the importance of charge addition effects on conformation and electronic structure and polaronic effects to provide potential explanations for this behavior. We have investigated the influence of charge addition, via ''doping'' with K, in pristine versus nitro-substituted OPE using photoelectron spectroscopies. Sequential addition of K in unsubstituted OPE produces a gradual shift to higher binding energy, reminiscent of ''rigid band'' behavior, with relative shifts of $\pi$ levels suggesting some distortion/conformation change. For a nitro-substituted oligomer, a markedly different behavior is observed with K addition. After an initial shift, the electronic levels are pinned for subsequent K addition before a final shift brings the spectrum to near coincidence with that for the pristine oligomer. Potential explanations for this behavior are provided based on model calculations of the effects of charge addition on the molecular electronic structure. We have also investigated differences in the reorganization energy that accompanies charge addition/removal in these systems by a combination of photoelectron and optical spectroscopies and theoretical calculation.

**H37 1 Electronic Transport in Molecularly-Linked Gold Nanoparticle Films Near the Metal-Insulator Transition.** AL-AMIN DHIRANI, JEFFREY DUNFORD, YOSHINORI SUGANUMA, *Department of Chemistry, University of Toronto* We have investigated the temperature ($T$) dependence of the conductance ($g$) of 1,4-butane dithiol linked Au nanoparticle films. Over a wide range of temperatures (20 K to 300 K), the conductance behaves as $g = g_0 \exp(-(T_0/T)^{1/2}))$. Such a temperature dependence is predicted by an Efros-Shklovskii variable-range hopping model based on a competition between Coulombic and intercluster tunneling processes. However, we find that hopping distances are too large (62 nm to 720 nm at 100 K) to be consistent with tunneling between clusters, and tend to scale with cluster size. We propose a modified ''quasi-localized hopping'' model based on competition between single-electron cluster charging and intra-cluster electron backscattering to explain this temperature dependence.

**11:27**

**H37 2 Plasticity and energy absorption at the nanoscale: kinetics and chemical control** MATTEO COCOCCIONI, GERBRAND CEDER, NICOLA MARZARI, *Department of Materials Science and Engineering and Institute for Soldier Nanotechnologies, MIT* Shock-induced phase transitions of group-IV nanoparticles are investigated using first-principles molecular dynamics in the electronic-enthalpy formalism [1]. In some of these systems a shock compression can induce plastic deformations, leading to the absorption of the mechanical energy coming from the impact. Kinetic factors greatly affect phase transformations, and so only some of the thermodynamically stable structures are explored. Still, transitions are always nucleated in the core of the nanoparticles, and are accompanied by the formation of small close-packed clusters of characteristic shape. Also, as the particle's size grows, amorphization remains confined in the core region. Finally, we highlight how chemical doping can be used to affect nucleation, and to tune pressure thresholds; this could be relevant e.g. for target applications such as the design of novel impact-absorbing nanostructured materials. **H37 3 Magnetic response and enhanced Tc in the 1D to 2D crossover regime of mesoscopic superconducting aluminum rings.** NICHOLAS C. KOSHNICK, HENDRIK BLUHM, *Stanford University* MARTIN E. HUBER, *University of Colorado, Denver* KATHRYN A. MOLER, *Stanford University* We have studied more than 40 mesoscopic Aluminum rings by positioning a scannable SQUID susceptometer over each ring individually, and have found a striking non-monotonic dependence of Tc on linewidth. By measuring the magnetic response, or current in the ring, as a function of applied flux and temperature, it is possible to extract $\lambda(T)$ and $\xi(T)$. The rings vary in width (40-350nm) and diameter (1-4um) with a nominal thickness of 35nm. For rings with linewidths above 150nm ( $\approx 2\xi(T = 0)$), the extracted superfluid density shows a high-temperature tail up to temperatures as high as 15% above the 1D and bulk thin film critical temperatures. In this regime, we also find evidence for the saturation of $\xi(T)$ on the order of the ring's linewidth. We speculate that these results indicate the particular importance of Tc disorder in the crossover from quasi-1D to 2D superconductivity.

**11:51**

**H37 4 Fluctuation diamagnetism in mesoscopic Aluminum rings** HENDRIK BLUHM, NICHOLAS C. KOSHNICK, *Stanford University* MARTIN E. HUBER, *University of Colorado, Denver* KATHRYN A. MOLER, *Stanford University* We have measured the magnetic response of mesoscopic, superconducting Al rings using a high sensitivity scanning SQUID microscope. We find that for sufficiently small, quasi one- dimensional rings, the rounding of the superconducting transition due to thermal fluctuations is in good agreement with theoretical preditctions. The main effects are a fluctuation tail in the amplitude of the response near $T_c$ and a suppression of the apparent $T_c$ as determined from the temperature dependence of the superfluid density below the fluctuation tail compared to the extracted mean field $T_c$ by several mK. In larger rings, the tail is less pronounced due to the lack of phase coherence.

**12:03**
**H37 5 Magnon characterization in magnetic quantum dots**
MOHAMMAD-REZA MOZAFFARI, KEIVAN ESFARJANI, *Dept. of Physics, Sharif University of Technology, Tehran, Iran*
The spin structure in a magnetic dot is studied as a function of exchange coupling strength or dot size, within the semiclassical approximation on a discrete lattice. In addition to the exchange term, the dipole interaction has also been included in our calculations. As the exchange coupling is decreased or the size is increased, the ground state undergoes a phase change from a single domain ferromagnet to a spin vortex. The line separating these two phases has been calculated numerically for small system sizes. Magnon frequencies in such a dot have also been calculated in both phases by the linearized equation of motion method. These calculations have also been checked by comparing them to the spin autocorrelation function spectrum. Furthermore, the modes have been characterized for both the ferromagnetic and the vortex phase. The modes responsible for the instability of the vortex and the ferromagntic phases have been identified, and can provide the mechanism for spin reorientation in these phases.

**H37 6 Magnetic multilayers on nanospheres.**
MANFRED ALBRECHT, *University of Konstanz*

In modern magnetic recording materials the 'superparamagnetic effect' [1] has become increasingly important as new magnetic hard disk drive products are designed for higher storage densities. In this regard, nanoparticle media [2], where two-dimensional arrays of monodisperse nanoparticles with high magnetic anisotropy are used, is assumed to be the ideal future magnetic recording material. In this presentation a novel magnetic gradient nanomaterial, which has been created by depositing Co/Pd multilayers onto two-dimensional arrays of self-assembled nanoparticles [3] will be introduced. The magnetic nanostructures formed on top of the particles are in a magnetically exchange-isolated quasi-single-domain state. This nanoscale system is quite distinct from the classical geometries: Neither extrinsic properties nor the intrinsic properties are uniform in space. The film is extended over a wide region of the sphere and thus shows substantial curvature. The film thickness varies and so do the intrinsic magnetic properties most notable the magneto-crystalline anisotropy, which is a key factor affecting the fundamental nature of the reversal process. The specific magnetic characteristics of such a gradient nanomaterial and in particular its impact on the reversal mechanism will be discussed. Angle-dependent reversal studies were performed for different particle sizes and the experimental results were interpreted using micromagnetic simulations. The simulations account for the angular dependence of the hysteresis loops and provide a detailed picture of how the local magnetization evolves during reversal, offering new opportunities in the functionalization of magnetic nanostructures for storage applications. **H37 7 Coulomb effects and hopping transport in granular metals** ANDREI LOPATIN, IGOR BELOBORODOV, VALERII VINOKUR, *Argonne National Laboratory* We investigate effects of Coulomb interaction and hopping transport in the insulator phase of granular metals and quantum dot arrays considering both spatially periodic as well as irregular grain/dot arraignments. We study the Mott transition between the insulating and metallic phases in a strictly periodic system and find the dependence of the Mott gap on the intergranular coupling. In this case the conductivity of the insulating state has the activation form with the Mott gap entering the exponent. In the irregular arrays the electrostatic disorder induces the finite density of states near the Fermi level giving rise to the variable range hopping conductivity. We derive the transport properties of the irregular array in the dielectric, low coupling limit and show that the conductivity follows the Efros-Shklovskii law. We develop a theory of tunneling through a chain of grains and discuss in detail both elastic and inelastic cotunneling mechanisms; the former dominates at very low temperatures and very low applied electric fields, while the inelastic mechanism controls tunneling at high temperature/fields.

**13:03**
**H37 8 Distinguishing Magnetic Behavior on the Slater-Pauling Curve applied to nanoscale thin films.** K.R. PODOLAK, M.G. BIRKE, *Penn State Univ.* N. JANKE-GILMAN, *Latrobe Univ. (present affiliation)* R.F. WILLIS, *Penn State Univ.* The Slater-Pauling curve is a plot of the stoichiometric mean saturation magnetization per atom as a function of the electron filling of the d-bands in the transition metals and their alloys. When the elemental magnetic moments are aligned, the volcano-shape curve plots the variation of the mean magnetic moment. It has been predicted that a narrowing of the d-bands in nanostructured magnetic materials will influence both the magnitude of the magnetic moments as well as the overall magnetic alignment through increased spin-orbit coupling [1]. In this paper, we report dichroism in the core-level x-ray photoemission spectra of the elements which reveals and distinguishes the changing magnitudes of the magnetic moments and the changing alignment of these moments with changing composition. The 3p core-level spectral densities of multiplet spin-ordered states show a width W proportional to the local Zeeman splitting of levels, and a magnetic dichroism amplitude A sensitive to the non-local magnetic order (anisotropy). In nanoscale epitaxial layers, small deviations from the bulk Slater-Pauling curve are observed due to enhanced moments due to d-band narrowing [2]. It is predicted that a plot of the spectral parameters W, A will show a different dependence of temperature approaching Tc, the critical ordering temperature. [1] S. Handschuh & S. Blügel, Solid State Communications. 105, 633 (1998). [2] R.F. Willis & N. Janke-Gilman, Europhysics Letters. 69, 411 (2005).

**H37 9 Localization of coupled plasmon modes in graded plasmonic chains*** JUN JUN XIAO, *Chinese Univ. of Hong Kong* K. YAKUBO, *Hokkaido Univ., Japan* K. W. YU, *Chinese Univ. of Hong Kong* Electromagnetic energy propagation and localization in plasmonics offer the potential for integrated nanophotonics. Plasmonic waves occur naturally inside the subwavelength scale with lateral confinement below the diffraction limit. However, controlling their localization/delocalization behavior in the propagating (longitudinal) direction is also desirable. We present results of longitudinal localization-delocalization tuning of coupled plasmon modes in graded chains of metallic nanodots. Two graded models will be studied: incremental spacing between the nanoparticles and graded index of refraction in the host medium. The coupled plasmons in these systems exhibit strong localization when detuned from the Mie plasmon frequency, showing a tunable passband in finite size system. To understand the localization mechanism, we map the problem onto an equivalent system of one-dimensional chain of coupled harmonic oscillators, whose coupling strength is gradually varied from one end to the other, with additional on-site potentials. The results can be applied to analogous graded systems. Confining and transmitting electromagnetic energy in these structures may pave new way for many fruitful applications in plasmonics.

**H37 10 A study of Co thin films grown on Si(111) with Al buffer layer** ZI Q. QIU, J. WU, J. CHOI, J. LI, *Dept. of Phys., UC-Berkeley, Berkeley, CA 94720* A. SCHOLL, A. DORAN, *Advanced Light Source, LBNL, Berkeley, CA 94720* Growth and magnetic properties of Co/Si(111) and Co/Al/Si(111) were investigated using Scanning Tunneling Microscopy (STM), Surface Magneto-Optic Kerr Effect (SMOKE), and Photoemission Electron Spectroscopy (PEEM). For Co film grown directly on Si(111), silicide is formed at the interface which leads to a loss of magnetization for ultrathin Co film. By growing an Al buffer layer at the Co/Si interface, we found that the Al buffer layer effectively reduces the silicide formation and SMOKE signal was detected at a much thinner Co thickness as compared with Co film directly deposited on Si(111). Magnetic domain imaging using PEEM confirms the SMOKE measurement. STM measurements were also performed to study morphology change after inserting the Al buffer layer.

**H37 11 Experimental Evidence for a Dynamic Phase Transition in Ultra-thin Magnetic Films*** D.T. ROBB, *Florida State University* Y.H. XU, *University of Minnesota* O. HELLWIG, *Hitachi Global Storage Technologies* A. BERGER, *Hitachi Global Storage Technologies* M.A. NOVOTNY, *Mississippi State University* P.A. RIKVOLD, *Florida State University* We present the first convincing evidence for an experimental observation of a Dynamic Phase Transition (DPT) in a magnetic system: an ultrathin $[Co(0.4nm)/Pt(0.7nm)]_3$ multilayer, which is well modeled by a two-dimensional kinetic Ising system. This DPT, as a function of the period $P$ of an applied alternating magnetic field, has been observed previously in simulations of magnetic systems [1]. For several values of $P$ and bias field $H_b$, the magnetization was measured for 50 cycles of the field [2]. The order parameter, which was identified in simulations as the magnetization averaged over the $i$th cycle, $Q_i$, was obtained from the experimental data as a time series. Kinetic Monte Carlo simulations produced close agreement with the experimental data for the order parameter averaged over the final 30 cycles, $< Q_i >$, as a function of $P$ and $H_b$. The experimental fluctuations in the order parameter are also consistent with a DPT. [1] S.W. Sides, P.A. Rikvold, and M.A. Novotny, Phys. Rev. Lett. **59**, 2710 (1999). [2] D.T. Robb, Y.H. Xu, O. **H37 12 Structural and Magnetic Phase Diagrams of Co and Mn Doped Ge (100) Epitaxial Films** BRIAN COLLINS, LIANG HE, FRANK TSUI, *University of North Carolina* YUNCHENG ZHONG, STEFAN VOGT, YONG CHU, *Advanced Photon Source* We present studies of structural and magnetic properties of epitaxial films of $Co_xMn_yGe_{1-x-y}$ magnetic semiconductors, grown by combinatorial MBE on Ge (100) substrates. Structural effects were examined in-situ by reflection high energy electron diffraction and ex-situ by microbeam x-ray diffraction. A ternary epitaxial phase diagram has been determined for doping concentrations (x and y for Co and Mn respectively) up to 30 at %, where regions of coherent epitaxy and associated strain states, and regions of rough disordered growth and the nature of the disorders have been examined and identified. Specifically, within a narrow range of compositions around the atomic ratio between Co and Mn (x/y) of 3, the observed epitaxial strain is low ( $< 0.1\%$) and coherent epitaxial growth is most stable, where the thin film lattice constants obey Vegard's law and they match those of the Ge at x/y $=3$. Within this region of compositions, high quality epitaxial films of p-type magnetic semiconductors can be stabilized for total doping concentration of transition metal dopants as high as 13 at % and with $T_C$ as high as 300 K. A ternary magnetic phase diagram has been measured using magnetooptic Kerr effect. The interplays between structural effects and magnetism have been investigated.

## SESSION H38: SUPERCONDUCTIVITY-DISORDERED THIN FILMS AND QUANTUM PHENOMENA

**H38 1 Quantum Superconductor-Insulator transition and Nernst effect in NbxSi1-x** HERVE AUBIN, ALEXANDRE POURRET, KAMRAN BEHNIA, JEROME LESUEUR, *CNRS-ESPCI; 10 rue Vauquelin, Paris, France* CLAIRE MARRACHE-KIKUCHI, LAURENT BERGÉ, LOUIS DUMOULIN, *CSNSM-IN2P3, Orsay, France* We show that the nature of magnetic-field tuned superconductor- insulator transitions in amorphous $Nb_{0.15}Si_{0.85}$ thin films depends on the orientation of the magnetic with respect to the film. In perperndicular magnetic field, the transition is driven by quantum fluctuations, characterized by an isobestic point (Bc,Rc) in the resistance measurements, and a kink

in the temperature profile of the critical magnetic field – that indicates a temperature scale below which quantum fluctuations control the dynamics of the system. The isobestic point and the kink are not found when the magnetic field is applied parallel to the films, where the transition is classical, driven by the breaking of Cooper pairs at the temperature dependent critical field $H_{c2}$. In addition, we will present the first study of Nernst coefficient in such a disordered superconductor. As previous studies on the cuprates have suggested, we show that the Nernst signal is particularly sensitive to superconducting fluctuations, where a sizable signal is observed in a large temperature (T>Tc) and magnetic field range.

**11:27**

**H38 2 The interplay between localization and superconductivity in ultrathin amorphous beryllium films*** WENHAO WU, *Texas A&M University* E. BIELEJEC, *Sandia National Laboratories* Near the superconductor-insulator transition (SIT), quench-condensed ultrathin Be films show a highly anisotropic magnetoconductance (MC). The conductance can drop orders of magnitude in a weak perpendicular field ( $<$ 1 T). In the high field regime, 2 $\sim$ 10 T, the MC in a perpendicular field is positive and can vary orders of magnitude with increasing field. These features disappears when a small amount of Mn impurities are introduced. Our results indicate that superconductivity is the origin of the observed MC. We have carried out simultaneous electron transport and tunneling measurements across the SIT, which allow us to determine, itindependently and up to a constant on the order of unity, the localization length, $\xi_L$, and the dielectric constant, $\kappa$, for the films. We have found that, as the normal-state sheet resistance of the films at 20 K is reduced with increasing film thickness, $\xi_L$ increases exponentially. The SIT occurs when $\xi_L$ crosses the Ginzburg-Landau coherence length, $\xi_S$.

*Supported by NSF Grant No. DMR-0551813.

**11:39**

**H38 3 Field-Induced Superconductor to Metal and Superconductor to Insulator Transitions in Thin Indium Oxide Films** K. H. SARWA B. TAN, KEVIN A. PARENDO, ALLEN M. GOLDMAN, *School of Physics and Astronomy, University of Minnesota* Z. OVADYAHU, *The Racah Institute of Physics, The Hebrew University* The application of magnetic fields to ultra-thin superconducting films is believed to bring about superconductor-insulator transitions which are quantum phase transitions. We will present measurements in perpendicular and parallel magnetic fields of R(T) of amorphous indium oxide films. In contrast with what has been reported for films with similar $T_c$'s, scaling, although successful for the superconducting curves, fails for the insulating ones. For a 150 Angstrom thick film with a zero-field $T_c$ = 2.8K, the high-field behavior is governed by a $T^{1/3}$ law suggestive of a 3D dirty metal. For a 100 Angstrom film with $T_c$ =1.8K the high-field regime is governed by Efros-Shklovskii hopping. This suggests that the former is superconductor-metal transition, whereas the latter is a superconductor-insulator transition. Further studies related to quantum corrections and film morphology are still in progress. This work was supported in part by the National Science Foundation under grant NSF/DMR-0455121.

**11:51**

**H38 4 Vortices and quasiparticles near the ''superconductor-insulator'' transition in thin films.** VICTOR GALITSKI, *University of Virginia* GIL REFAEL, *Caltech* MATTHEW P. A. FISHER, *KITP, UCSB* T. SENTHIL, *IISc* We consider the low temperature behavior of an amorphous superconducting film driven normal by a perpendicular magnetic field. We introduce a new two-fluid formulation consisting of fermionized field-induced vortices and electrically neutralized Bogoliubov quasiparticles interacting via a long-ranged statistical interaction. This approach allows us to access a novel non-Fermi liquid phase which naturally interpolates between the low field superconductor and the high field normal metal. We also discuss the transport, thermodynamics, and tunneling properties of the resulting ''vortex metal'' phase.

**12:03**

**H38 5 Anomalous Insulating State Induced by Application of Parallel Magnetic Fields to 2D Superconducting Films** KEVIN A. PARENDO, K. H. SARWA B. TAN, ALLEN M. GOLDMAN, *School of Physics and Astronomy, University of Minnesota* Superconductor-insulator transitions in ultrathin films of amorphous Bi have been investigated by electrostatic electron doping, incrementing film thickness, and applying parallel magnetic fields. When superconductivity was induced in an insulating film by electrostatic tuning, a quantum phase transition was observed down to 60 mK. When superconductivity was quenched by parallel magnetic fields, above $\sim$ 150 mK, R(T) was best described by 2D Mott variable range hopping at the highest fields and scaling was successful. However, an anomalous insulating state was induced by the field below $\sim$ 150 mK in which the resistance becomes larger than expected from extrapolation of R(T) from higher temperatures, causing scaling to break down. This anomalous state has not been observed in zero field thickness- or electrostatic-tuned transitions in bismuth. It has also been observed in amorphous $In_2O_3$films in parallel fields, but not in perpendicular fields. This work is supported in part by the National Science Foundation under grant NSF/DMR-0455121.

**12:15**

**H38 6 Insulating State of Granular Superconductors in a Strong Coupling Regime** IGOR BELOBORODOV, *Argonne National Laboratory* YASHA FOMINOV, *Landau Institute for Theoretical Physics* ANDREI LOPATIN, VALERII VINOKUR, *Argonne National Laboratory* We analyze the possibly of the formation of a magnetic field induced insulating state in a two-dimensional granular superconductor with relatively strong intergranular coupling and show that such a state appears in a model with spatial variations of the single grain critical magnetic field. This model well describes realistic granular samples with the dispersion in grain sizes and explains qualitatively the recent experimental observation of a giant peak in the magnetoresistance of dirty superconducting films.

**12:27**

**H38 7 The effect of 3*d* paramagnetic impurities on superconductivity in quench-condensed amorphous Pb films** ASHWANI KUMAR, DAN E. READ, JEFFREY S. PARKER, H JEFFREY GARDNER, PENG XIONG, *Department of Physics and MARTECH, Florida State University* A modified dilution refrigerator equipped with Sb, Pb and NiCr sources is used to carry out an itin situ study of the effect of magnetic impurities (MI) on the same quench-condensed Pb films. Si substrate with pre-deposited

Au contacts is mounted in dilution unit and cool down to 5K. To ensure the electrical and possibly structural homogeneity down to monolayer thickness, we deposit a thin layer of Sb prior to the Pb evaporation. At a thickness above 8 ? the film exhibits superconductivity with well-defined resistive transition and $T_c$ controlled by the film thickness. When a film of desired $T_c$ is obtained we incrementally evaporate itMI onto the film by heating a NiCr wire at constant current and perform itin situ measurements. We observe that $T_c$ is continuously suppressed with increasing itMI density while the resistive transitions remain sharp, although the itMI induces significant filling of states inside the gap. The $T_c$ as a function of itMI density is well described by the Abrikosov-Gorkov theory regardless of the starting $T_c$ and the pair-breaking strength of the itMI appears to be independent of the degree of disorder.

**12:39**

**H38 8 Confirmation of the discrepancy between experiment and theory in the superconducting proximity effect** MANJIANG ZHANG, *Dept. of Physics and Astronomy, Univ of Southern California* GO TATEISHI, GERD BERGMANN, The transition temperature $T_c$ of a superconducting film S is reduced when it is covered with a normal metal N. Recently we investigated the superconducting proximity effect in double layers of Pb and alkali metals and found the initial slope $dT_c/dd_n$ of $T_c$ as a function of the thickness of the normal metal $d_n$ was smaller than the theoretical value by a factor of 2. The theory shows that the \QTR normalized initial slope $S_{sn} = (d_s/T_s)|dT_c/dd_n| = \Gamma^*_{sn}(N_n/N_s)$ depends only on the density of states ratio of the two metals, $N_n/N_s$, but not on the mean free paths or the interface. A literature search showed that this initial slope is rarely measured. The few experiments in the literature where the initial slope can be derived yield the same disagreement with the theory. In the present work we investigated systematically the initial slope of S/N sandwiches (S for Pb and N for the normal conductor) and also extended the investigation to $S_1/S_2$ sandwiches ($S_1$=Pb, $S_2$= Cd, Zn, Al, In, Sn). The normalized initial slope $S_{sn}$ is confirmed to be independent of the Pb thickness. Again for S/N sandwiches the value of $\Gamma_{sn}$ is more than a factor 2 smaller than the theoretical value. For the $S_1/S_2$ sandwiches this discrepancy decreases with increasing $T_c$ of $S_2$.

**12:51**

**H38 9 Vortex Glass is a Metal*** JIANSHENG WU, *University of Illinois* PHILIP PHILLIPS, *University of Illinois* We consider the disordered quantum rotor model in the presence of a magnetic field. We analyze the transport properties in the vicinity of the multicritical point between the superconductor, phase glass and paramagnetic phases. We find that the magnetic field leaves metallic transport of bosons in the glassy phase in tact. In the vicinity of the superconductivity to the intervening metallic state transition, the resistivity turns on as $(H - H_c)^2$ with $H_c$. This functional form is in excellent agreement with the experimentally observed turn-on of the resistivity in the metallic state in MoGe, namely $R \approx R_c(H - H_c)^\mu$, $1 < \mu < 3$. The metallic state is also shown to presist in three spatial dimensions. As the phase glass in $d = 3$ is identical to the vortex glass, we conclude that the vortex glass is, in actuality, a metal rather than a superconductor at $T = 0$.

**13:03**

**H38 10 Quantum phase transition and possible phase separation in ultrathin doubly-connected superconducting cylinders of Al** HAOHUA WANG, NEAL STALEY, BENJAMIN CLOUSER, YING LIU, *Department of Physics, Penn State University* Fluxoid quantization demands that the superfluid velocity, $v_s$, of a doubly-connected superconducting cylinder increase as its diameter, $d$, decreases, leading to a destructive regime and a quantum phase transition (QPT) in one dimension (1D) - Superconductivity is suppressed around half-integer flux quanta even at zero temperature for cylinders with a $d$ less than the zero-temperature superconducting coherence length, $\xi(0)$. We have fabricated ultrathin doubly-connected superconducting cylinders of Al over a wide range of $d/\xi(0)$ ratios, with the smallest cylinder down to 100 nm in diameter. Electrical transport measurements revealed the presence of robust step-like features in resistance $vs.$ temperature curves as the destructive regime is approached. These field-induced step-like features, present only in the smallest cylinders with $d/\xi(0)$ close to or less than 1, are unrelated to sample inhomogeneity or phase slip centers, and are most likely resulted from a phase separation close to the QPT. We have also found that the normal state in the destructive regime becomes less stable as the $d/\xi(0)$ ratio increases, with the resistances at the half-flux quantum suppressed continuously from its full normal-state value. Resistance $vs.$ magnetic field measurements show that the field tuned QPT is very sharp (less than 1G) with little evidence for hysteretic behavior.

**13:15**

**H38 11 Hysteresis and Noise from Electronic Nematicity** ERICA CARLSON, *Purdue University* KARIN DAHMEN, EDUARDO FRADKIN, *University of Illinois at Urbana-Champaign* STEVEN KIVELSON, *Stanford University* An electron nematic is a translationally invariant state which spontaneously breaks the discrete rotational symmetry of a host crystal. In a clean square lattice, the electron nematic has two preferred orientations, while dopant disorder favors one or the other orientations locally. In this way, the electron nematic in a host crystal maps to the random field Ising model (RFIM). Since the electron nematic has anisotropic conductivity, we associate each Ising configuration with a resistor network, and use what is known about the RFIM to predict new ways to test for electron nematicity using noise and hysteresis. In particular, we have uncovered a remarkably robust linear relation between the orientational order and the resistance anisotropy which holds over a wide range of circumstances. We discuss the consequences of this for noise and hysteresis in transport anisotropy, as well as possible extensions to other experimental probes such as neutron scattering and STM.

**13:27**

**H38 12 Enhancement of superconductivity by local inhomogeneities** IVAR MARTIN, *Los Alamos National Laboratory* DANIEL PODOLSKY, *University of California, Berkeley* STEVEN KIVELSON, *Stanford University* We study the effect of inhomogeneity of the pairing interaction or the background potential on the superconducting transition temperature, $T_c$. In the weak coupling BCS regime, we find that inhomogeneity, which is incommensurate with the Fermi surface nesting vectors, enhances $T_c$ relative to its value for the uniform system. For a fixed modulation strength we find that the highest $T_c$ is reached when the characteristic modulation length scale is of the order of the superconducting coherence length.

**13:39**
**H38 13 Nanosecond, Transient Resistive State in Two-Dimensional Superconducting Stripes** JENNIFER KITAYGORSKY, I. KOMISSAROV, A. JUKNA, ROMAN SOBOLEWSKI, *University of Rochester* O. MINAEVA, N. KAUROVA, A. KORNEEV, B. VORONOV, I. MILOSTNAYA, GREGORY GOL'TSMAN, *Moscow State Pedagogical University* We have observed, nanosecond-in-duration, transient voltage pulses, generated across two-dimensional (2-D) NbN stripes (width: 100–500 nm; thickness: 3.5–10 nm) of various lengths (1–500 $\mu$m), when the wires were completely isolated from the outside world, biased at currents close to the critical current, and kept at temperatures below the mean-field critical temperature $T_{co}$. In 2-D superconducting films, at temperatures below the Kosterlitz-Thouless transition, all vortices are bound and the resistance is zero. However, these vortices can get unbound when a large enough transport current is applied. The latter results in a transient resistive state, which manifests itself as spontaneous, 2.5–8-ns-long voltage pulses with the amplitude corresponding to the unbinding potential of a vortex pair. In our 100-nm-wide stripes, we have also observed the formation of phase slip centers (PSCs) at temperatures close to $T_{co}$, and a mixture of PSCs and unbound vortex-antivortex pairs at low temperatures.

**H39 1 Tunneling spectroscopy studies of the interplay between *s*- and *p*-wave pairings in a Ru microdomain embedded in bulk single-crystal $Sr_2RuO_4$** ZHENYI LONG, CHRYSAFIS ANDREOUS, ZHIQIANG MAO, YOSHITERU MAENO, YING LIU, *Department of Physics, Penn State University* We have performed detailed tunneling spectroscopy measurements on In-Ru/$Sr_2RuO_4$ junctions prepared by pressing freshly cut pure In wire onto $Sr_2RuO_4$ single crystals containing Ru microdomains (the 3-K phase). We have observed a superconducting transition with a $T_c = 0.5$ K and an energy gap of 0.08 meV, both of which correspond to those of the bulk Ru. We have also observed a Josephson coupling between In and Ru, suggesting that conventional *s*-wave pairing is present in the Ru microdomains. On the other hand, a zero bias conductance peak (ZBCP) in the tunneling spectrum and an enhanced critical magnetic field over the bulk value for Ru were observed as well, indicating that *p*-wave pairing exists simultaneously in the Ru microdomain. The temperature and the magnetic field dependences of the tunneling spectrum suggest a non-trivial interplay of the *s*- and *p*-wave pairings and a novel phase modulation of the order parameter at the boundary of the Ru microdomain. We observed an oscillation of the Ru energy gap as the magnetic field is applied along the c axis of the $Sr_2RuO_4$ crystal. Such oscillation was not observed with the field applied along the ab plane. We will discuss the implication of the above observations in this unique superconducting system.

**11:27**
**H39 2 Probing the configuration and dynamics of order parameter domains in $Sr_2RuO_4$ by Josephson interferometry** FRANCOISE KIDWINGIRA, JOEL STRAND, DALE VAN HARLINGEN, *University of Illinois at Urbana-Champaign* YOSHITERU MAENO, *Kyoto University, Kyoto, Japan* We observe anomalous features in the magnetic field dependence of the critical current of Josephson junctions formed between conventional superconductors and the ruthenate superconductor $Sr_2RuO_4$, including magnetic hysteresis, switching noise, and a wide variation of qualitatively different diffraction pattern shapes. All of this behavior can be explained by assuming a complex p-wave order parameter of the form $p_x+ip_y$ that supports a dynamical structure of domains of different chirality and orientation. To test this hypothesis, we are studying the effects of magnetic field cooling on the junction critical current. We find a substantial enhancement of the critical current in field cooled samples, consistent with chiral domains that couple to an applied magnetic field.

**11:39**
**H39 3 Phase-sensitive tests of the pairing state symmetry in $Sr_2RuO_4$** IGOR ZUTIC, *State University of New York at Buffalo* IGOR MAZIN, *Naval Research Laboratory* Exotic superconducting properties of $Sr_2RuO_4$ have provided strong support for an unconventional pairing symmetry. However, the extensive efforts over the past decade have not yet unambiguously resolved the controversy about the pairing symmetry in this material. While recent phase-sensitive experiments using flux modulation in Josephson junctions consisting of $Sr_2RuO_4$ and a conventional superconductor have been interpreted as conclusive evidence for a chiral spin- triplet pairing [1], we propose here an alternative interpretation [2]. We show that an overlooked chiral spin- singlet pairing is also compatible with the observed phase shifts in Josephson junctions and propose further experiments which would distinguish it from its spin-triplet counterpart. **H39 4 The Phase-sensitive *c*-Axis Twist Experiments on $Bi_2Sr_2CaCu_2O_{8+\delta}$ and Their Implications.** RICHARD KLEMM, *Kansas State University*

There are presently three sets of *c*-axis twist experiments on $Bi_2Sr_2CaCu_2O_{8+\delta}$ (Bi2212)[1]: the bicrystal experiments of Li *et al.*[2], the artificial cross-whisker experiments of Takano *et al.*[3], and the natural cross-whisker experiments of Latyshev *et al.*[4] We summarize these experiments and the extensive theoretical analyses of their possible implications, so

that reliable conclusions can be inferred. The theoretical discussion includes the allowable order parameter symmetries, the twist theorem for the *c*-axis critical current of *d*-wave superconductors across a 45° twist junction, treatments of weak, first-order *c*-axis tunneling with coherent and incoherent components, and effects of the Fermi surface, strong coherent tunneling, orthorhombicity, nanoscale disorder, and OP twisting near the physical twist junction. As a minimum, all three experiments can only be understood in terms of a substantial *s*-wave superconducting order parameter component in Bi2212 for $T \leqslant T_c$. An anisotropic *s*-wave order parameter can fit all three experiments quantitatively. The bicrystal and natural cross-whisker experiments are also consistent with the preponderance of other data that the *c*- axis tunneling in Bi2212 is strongly incoherent, so that all of the *c*-axis critical current arises from the *s*-wave order parameter component. These three sets of experiments appear to rule out a purely repulsive pairing interaction.

**H39 5 Josephson effect with d+ip superconductors** BRIGITTE LERIDON, *CNRS/ESPCI, 10 rue Vauquelin, 75005 Paris* TAI-KAI NG, *Physics Department, HKUST, Hong-Kong* C. M. VARMA, *Department of Physics, University of Riverside, CA 92521* Two different experiments, namely ARPES with circularly polarized photons and neutron diffraction have observed a time-reversal and inversion symmetry breaking in the pseudogap state of the cuprates. This phase had actually been predicted in the framework of a general model for the normal and superconducting state of high-Tc superconductors. This symmetry breaking should also affect the superconductive symmetry and lead to the admixture of a p-wave component to the dominant d-wave order parameter. We show here that this allows to make specific predictions for the Josephson effect between a ''d+ip'' superconductor and an ordinary s-wave superconductor, or between two ''d+ip'' superconductors, according to the orientation of the surface. We propose a set of experiments where, for some particular orientations, an anomalous Josephson effect should be observed whenever a pseudogap is present.

**12:39**

**H39 6 Direct test of pairing fluctuations in the pseudogap phase of an underdoped cuprate** NICOLAS BERGEAL, JEROME LESUEUR, MARCO APRILI, BRIGITTE LERIDON, *LPQ ESPCI/UPR5-CNRS, 10 rue Vauquelin 75005 Paris (France)* GIANCARLO FAINI, *LPN-CNRS, Route de Nozay, 91460 Marcoussis (France)* JEAN-PIERRE CONTOUR, *UMR 137 CNRS/ THALES, Route departementale 128, 91767 Palaiseau Cedex (France)* In underdoped cuprates, many experiments have provided evidence for the presence of a gap-like structure in the electronic excitations spectrum, in a region above the critical temperature and below a characteristic temperature T*. The origin of this so-called pseudogap is still hardly debated and the answer to this question turns out to be essential for the understanding of high-$T_c$ superconductivity. One doesn't know if the pseudogap is related to superconductivity or to an order in competition. In the former case, it has been suggested that superconducting pairing fluctuations may be responsible for the partial suppression of electronic excitations. This remains to be tested experimentally, but most of the probes used to investigate the pseudogap are not sensitive to pairs and therefore cannot provide such a test. Here, we report for the first time on a direct test of pairing fluctuations in the pseudogap regime using a Josephson-like experiment. Our results shows that fluctuations survive only in a restricted range of temperature close to $T_c$ ($T-T_c < 15K$), well below T*, and therefore cannot be responsible for the opening of the pseudogap at high temperature.

**12:51**

**H39 7 Josephson (001) tilt grain boundary junctions of high temperature superconductors** GERALD ARNOLD, *University of Notre Dame* RICHARD KLEMM, *Kansas State University* We calculate the Josephson critical current $I_c$ across in- plane (001) tilt grain boundary junctions of high temperature superconductors. We solve for the electronic states corresponding to the electron-doped cuprates, two slightly different hole-doped cuprates, and an extremely underdoped hole- doped cuprate in each half-space, and weakly connect the two half-spaces by either specular or random Josephson tunnelling. We treat symmetric, straight, and fully asymmetric junctions with *s*-, extended-*s*, or $d_{x^2-y^2}$-wave order parameters. For symmetric junctions with random grain boundary tunnelling, our results are generally in agreement with the Sigrist-Rice form for ideal junctions that has been used to interpret ''phase-sensitive'' experiments consisting of such in- plane grain boundary junctions. For specular grain boundary tunnelling across symmetric junctions, our results depend upon the Fermi surface topology, but are usually rather consistent with the random facet model of Tsuei *et al.* [Phys. Rev. Lett. **73** 593(1994)]. Our results for asymmetric junctions of electron-doped cuprates are in agreement with the Sigrist- Rice form. However, our results for asymmetric junctions of hole- doped cuprates show that the details of the Fermi surface topology and of the tunnelling processes are both very important, so that the ''phase-sensitive'' experiments based upon in-plane Josephson junctions are less definitive than has generally been thought.

**13:03**

**H39 8 Josephson junctions and arrays fabricated via nanolithography and ion damage** SHANE CYBART, JOHN CLARKE, ROBERT DYNES, *University of California Berkeley* KE CHEN, YI CUI, QI LI, XIAOXING XI, *Penn State University* In the years to come, the size and cost of cryo-coolers will get smaller and the demand for a VLSI Josephson junction technology will increase. One possible candidate to fill this need is the ''ion-damage'' Josephson junction. These junctions are fabricated by using ion bombardment to create localized narrow regions of defects in the plane of a thin film of superconductor. These regions have a superconducting transition temperature lower than that of the bulk film and act as hysteretic Josephson junctions. The advantage of these junctions over other technologies is that they have

no interfaces between different materials, and can be placed over 10 times closer to each other in comparison to competing techniques. Individual junctions and series arrays were fabricated from YBCO and magnesium diboride. Junction current-voltage characteristics near the critical temperature follow the resistively shunted junction model however at lower temperatures the barrier becomes strongly coupled and flux flow behavior is evident. Series arrays of up to 20 junctions have been fabricated with sufficient parameter uniformity to achieve giant Shapiro steps under microwave radiation.

**13:15**

**H39 9 Quantum dynamics of a d-wave YBCO Josephson junction** FLORIANA LOMBARDI, *Chalmers University of Technology* THILO BAUCH, TOBIAS LINDSTRÖM, FRANCESCO TAFURI, GIACOMO ROTOLI, TORD CLAESON, We present direct observation of macroscopic quantum properties in an all high critical temperature superconductor d-wave Josephson junction. Although dissipation caused by low energy excitations is expected to strongly suppress macroscopic quantum effects we demonstrate macroscopic quantum tunneling [1] and energy level quantization [2] in our d-wave Josephson junction. We have investigated specific YBCO grain boundary Josephson junction's geometry, where tunneling in the node of the order parameter sensibly contributes to the transport properties. In such a case the Josephson current-phase relation is significantly modified and we have found that the fundamental state of the junction is doubly degenerate. The results indicate that the role of dissipation mechanisms in high temperature superconductors has to be revised, and may also have consequences for the class of solid state ''quiet'' quantum bit with superior coherence time. [1] T. Bauch et al., Phys. Rev. Lett. **94**, 087003 (2005). [2] accepted for publication in Science.

**H39 10 Biot-Savart correlations in anisotropic superconductors** KUMAR RAMAN, *University of Illinois at Urbana-Champaign* VADIM OGANESYAN, *Yale University* SHIVAJI SONDHI, *Princeton University* We study the normal-superconducting phase transition of layered type II superconductors in the limit of very weak Josephson coupling. By extending previous renormalization grouptreatments we investigate the importance of interlayer Biot-Savart interactionsfor three dimensional correlations near the transition and the recent weak-field magnetization experiments in BSSCO.

**13:39**

**H39 11 Electromagnetic wave generation by mesoscopic intrinsic Josephson junctions of single crystal $Bi_2Sr_2CaCu_2O_{8+\delta}$** KAZUO KADOWAKI, TAKUYA YAMAZAKI, ITSUHIRO KAKEYA, TAKASHI YAMAMOTO, UNIV. OF TSUKUBA TEAM, It is known that the junction resistance $R_c$ of mesoscopic intrinsic Josephson junctions of single crystal $Bi_2Sr_2CaCu_2O_{8+\delta}$ in a sweeping magnetic field parallel to the $ab$-plane exhibits a strong quantum oscillating behavior with periods of a unit of magnetic quantum flux $\phi_0$ or $\phi_0/2$, which penetrate through each insulating layer between superconducting $CuO_2$ layers of $Bi_2Sr_2CaCu_2O_{8+\delta}$ above or below a certain magnetic field $H^*$, respectively. This happens only at low level of currents, whereas at high currents this oscilating behavior fades away and $R_c$ becomes rather smooth saturation behavior. In such a condition it is expected that the collective motion of Josephson vortices would generate Josephson plasma in a junction, which may continuously emit the coherent THz electromagnetic waves. In reaching a current levels at $\sim$ 0.3-0.7$J_c$ in rather low fields, we were indeed able to detect electromagnetic radiation emitted from the junctions by a bolometer detecter located near the junction. The power observed is very large, reaching a few 100 W/cm$^2$, and is extremely efficient, showing 3-7% of the total input current energies. This is compared with the other methds such as cascade lasers using quantum dots and parametric oscillators using laser mixing in a non-linear optical materials.

**13:51**

**H39 12 Magnetic oscillations of critical current in Josephson-junction stacks** ALEXEI KOSHELEV, *Argonne National Laboratory* We consider magnetic oscillations of critical current in stacks of Josephson junctions, which are realized in mesas fabricated from layered high-temperature superconductors. Depending on the stack lateral size and magnetic field, oscillations may have either period of half flux quantum per junction (large-size regime) or one flux quantum per junction (small-size regime). We study in detail the crossover between these two regimes. In the small-size regime the lattice structure experiences periodic series of phase transitions between aligned rectangular configuration and triangular configuration. Triangular configurations in this regime realize only in narrow regions near magnetic-field values corresponding to integer number of flux quanta per junction. This work was supported by the U. S. DOE, Office of Science, under contract # W-31-109-ENG-38.

**14:03**

**H39 13 Effects of topological excitations in Josephson junction arrays.** SAID SAKHI, *American University of Sharjah* We study the zero-temperature physics of planar Josephson junction arrays in the self-dual approximation in the presence of external offset charges and magnetic fluxes. We introduce a new Landau-Ginzburg formulation to describe both types of topological excitations (electric and magnetic) that determine the quantum phase structure of the model. Through the condensation of the boson fields, this approach captures with ease various phases of Josephson junction arrays including the superconducting phase, the insulating phase, in addition to a novel quantum Hall phase that results from the condensation of composites formed by electric and magnetic topological excitations.

**H40 1 Microwave absorption by electrons on helium in a tilted magnetic field** SOLOMON DUKI, H. MATHUR, *Case Western Reserve University* Microwaves can be used to drive transitions between the ground and low-lying excited states of electrons bound to the surface of liquid helium. Such microwave absorption

has been observed since the 1970s and is the basis of quantum computing schemes that use electrons on helium. We study theoretically the effect of a tilted magnetic field on the microwave absorption. It is found that the absorption lineshape will change from a symmetric Lorentzian to an asymmetric Fano lineshape as the tilted field is increased. Thus application of the tilted field permits control of the lineshape.

**11:27**
**H40 2 Measurement of the charge transfer efficiency of electrons on liquid helium in a CCD-like architecture*** GUILLAUME SABOURET, E. A. SHANER, S. A. LYON, *Princeton University* Electrons floating on the surface of liquid helium are possible qubits in quantum computing; the necessary two quantum levels can either be the charge states or the spin states of the electrons. Varying electric potentials do not modify spin states, which allows the transport of qubits on the surface of liquid helium using a CCD-like array of underlying gates. A quantum computer will require the controlled movement of single electrons and the reliability of this scheme depends on how readily an electron can be transferred from one gate to another and on the absence of electron traps along the way. We will present a measurement of the charge transfer efficiency (CTE) of electrons clocked back and forth above a short CCD-like structure submerged under liquid helium. This was achieved by using a special clocking sequence that ejects any electrons left above a chosen gate at the end of each clock cycle. The CTE obtained at low clocking frequencies is very high with an electron density of about 0.3 electrons/cm$^2$, comparable to the CTE of silicon CCD's with much higher electron densities. We find no evidence for deep electron trapping in our system.

*Supported in part by ARO and ARDA.

**11:39**
**H40 3 A photoelectron source for electrons on liquid helium*** SHYAM SHANKAR, GUILLAUME SABOURET, WEI ZHAO, FABRICE AMY, ANTOINE KAHN, S. A. LYON, *Princeton University* Manipulation of the spins of electrons on the surface of liquid helium is a promising method to implement a quantum computer. One of the challenges in this method is to generate electrons on the helium surface in a reliable and controlled manner. The traditional approach is to use thermionic emission from a tungsten filament. This approach generates many electrons in an uncontrolled manner and heats the low temperature system. An electron source relying on photoemission from a zinc film has been previously described [1] using a high power light source coupled to a fiber. This work has been reproduced in a more compact manner by using a small modular lamp and proximity focussing. However, zinc films tend to oxidize rather quickly. We are studying the use of alternative low work function materials such as samarium that promise better stability. [1] L. A. Wilen and R. W. Gianetta, Rev. Sci. Instrum. 56(11), November 1985.

**H40 4 Oxygen Instabilities and the Electronic Properties of Oxide Tunnel Barrier Layers.**
ROBERT BUHRMAN, *Cornell University*

Very thin $AlO_x$ layers, usually formed by the controlled dose, RT oxidation of the surface of Al thin films, have long been the most successful and most reproducible approach for the fabrication of high-quality superconducting Josephson junctions, as well as for the formation of the gate-insulator for myriad non-conventional electronics studies. $AlO_x$ has also been widely employed as the barrier in magnetic tunnel junctions (MTJs). In recent years, however, it has become clear that for demanding applications, most notably Josephson junction qubit devices, the performance of the $AlO_x$ barrier layer is far below what is needed, particularly with respect to 1/f noise behavior; a determination that has given new urgency to the task of better understanding and significantly improving the properties of this barrier layer material, or of developing a better alternative. I will describe the results of a series of scanning tunneling spectroscopy, XPS and electronic transport studies on ultra-thin AlOx layers, in both half-formed and fully-formed junction configurations. These results demonstrate the inherently unstable nature of a significant portion of the oxygen component of the oxide. As the result of this instability, the process that forms a completed AlOx tunnel junction is much more complex than the reproducibility of the process might otherwise suggest. I will compare this character of amorphous AlOx barrier layers with the oxygen stability in crystalline MgO layers such as are currently being employed in MTJs, and on the basis of these findings discuss some approaches that might lead to more stable, lower noise Josephson junctions. Finally I will discuss some preliminary results that suggest that a low T tunnel-junction 1/f noise level that is much more than 10x less than the best that has been reported to date may indeed be achievable.

**H40 5 Eliminating Junction Fluctuators using Epitaxial Barrier in Josephson Qubit** SEONGSHIK OH, K. CICAK, M. S. ALLMAN, JEFFREY S. KLINE, K. D. OSBORN, G. PROKOPENKO, M. A. SILLANPAA, A. J. SIROIS, J. A. STRONG, J. D. WHITTAKER, R. W. SIMMONDS, D. P. PAPPAS, *NIST, Boulder* R. MCDERMOTT, JOHN M. MARTINIS, *UC, Santa Barbara* Before a multi-qubit solid-state quantum computer is realized, many obstacles need to be overcome. The most significant problem with any solid- state qubit implementation is strong coupling to sources of decoherence in the environment. Accordingly, identifying and removing these sources is an important prerequisite for construction of a solid-state quantum computer. Among other things, all the present-day superconducting qubits use amorphous $AlO_x$ as a tunnel barrier. However, there is growing evidence that the amorphous $AlO_x$ tunnel barriers have undesirable two-level fluctuators that adversely affect the qubit. Along this line, we have fabricated the first epitaxial Josephson phase qubit with single-crystal $Al_2O_3$ barrier and observed substantially reduced density of two-level fluctuators in this new type of qubit. This is the first clear evidence showing the relationship between crystallinity of the tunnel barrier and the two-level fluctuators. With this new epitaxial Josephson qubit technology, we are one-step closer to realization of a practical multi-qubit solid-state quantum computer. This talk will be focused more on the fabrication side of the epitaxial qubit and the following talk will discuss the details of its measurement.

**12:39**

**H40 6 Improved Phase Qubits with Re-$Al_2O_3$-Al Junctions with Epitaxial Barriers.*** K. CICAK, M.S. ALLMAN, JEFFREY S. KLINE, SEONGSHIK OH, K.D. OSBORN, G. PROKOPENKO, M.A. SILLANPAA, A.J. SIROIS, J.A. STRONG, J.D. WHITTAKER, *National Inst. of Standards and Tech. - Boulder* JOHN M. MARTINIS, *UC Santa Barbara, Dept. of Physics* D.P. PAPPAS, R.W. SIMMONDS, *National Inst. of Standards and Tech. - Boulder* In our efforts to identify and eliminate sources of decoherence in our qubits we have established that dielectric loss, both from substrate and from insulating layers in the device, can compromise qubit coherence. This has lead to significant improvements of our phase qubits. Now we show that the structural quality of the Josephson junction barrier itself can significantly improve qubit performance in a specific way. As compared to qubits with amorphous barriers, our latest measurements using qubits fabricated with epitaxial Josephson tunnel barriers show a significant decrease in density and coupling strength of individual spurious resonator defects.

**12:51**

**H40 7 Epitaxial growth of Mo/$Al_2O_3$/Mo trilayers for Josephson junction qubits** JEFFREY S. KLINE, KRISTINE M. LANG, SEONGSHIK OH, KEVIN D. OSBORN, RAYMOND W. SIMMONDS, *National Institute of Standards and Technology* ROBERT MCDERMOTT, JOHN M. MARTINIS, *University of California-Santa Barbara* DAVID P. PAPPAS, *National Institute of Standards and Technology* The growth of ultrathin epitaxial $Al_2O_3$ tunnel barriers on Re has been proven to reduce the number of spurious resonators in Josephson phase qubits when compared to qubits fabricated with amorphous tunnel barriers. Other refractory metals might also be used as base layers for epitaxial $Al_2O_3$ growth. In this work, Mo films were deposited onto $Al_2O_3(11\bar{2}0)$ substrates by UHV magnetron sputtering. To achieve epitaxy, the substrate was held at elevated temperature during the deposition. Post-deposition high temperature anneals increase the terrace size and occurrence of step-bunching as observed by STM. Ultrathin films of $Al_2O_3$ were then deposited at room temperature onto the Mo base layer by reactive evaporation of Al in a controlled oxygen background. A high temperature anneal in an oxygen background crystallizes the amorphous $Al_2O_3$ layer. Finally, the structure is capped with polycrystalline Mo by sputter deposition at room temperature. Dielectric loss measurements on LC oscillators fabricated from these structures will be reported.

**13:03**

**H40 8 Josephson Tunnel-Junctions Fabricated From Epitaxial Niobium-Based Multi-Layers** PAUL B. WELANDER, TIM J. MCARDLE, JAMES N. ECKSTEIN, *Department of Physics, Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, Urbana, Illinois 61801* We report on the investigation of Josephson tunnel-junctions fabricated from epitaxial multi-layers. The foundation of these devices is the growth of a single-crystal niobium base electrode on sapphire. Niobium films grown near 800 °C typically have critical temperatures around 9.4 K and residual resistance ratios above 100. Diffraction measurements show excellent crystallinity, and microscopy reveals surfaces with mono-layer step-edges and rms roughness less than 0.2 nm. Tunnel barriers are formed using a range of methods. On one hand, epitaxial alumina is grown on niobium above 700 °C by evaporating aluminum metal in an oxygen gas background of about 1 microtorr. On the other hand, an aluminum single- crystal film about 20 nm thick is deposited on niobium at room temperature and then oxidized in 10-100 torr oxygen gas for about one hour. The counter-electrode in both cases is amorphous niobium deposited at ambient temperature. The latter method of barrier formation produces tunnel-junctions with critical current densities around 100 A/cm$^2$.

**13:15**

**H40 9 Enhanced Macroscopic Quantum Tunneling in $Bi_2Sr_2CaCu_2O_{8+\delta}$ Intrinsic Josephson Junction Stacks** X.Y. JIN, J. LISENFELD, Y. KOVAL, A. LUKASHENKO, A.V. USTINOV, P. MÜLLER, *Physikalisches Institut III, Universität Erlangen-Nürnberg* We have investigated macroscopic quantum tunneling in $Bi_2Sr_2CaCu_2O_{8+\delta}$ intrinsic Josephson junctions and performed microwave absorption experiments. Classical-to- quantum crossover temperatures of up to 700mK were found. Plasma frequencies of up to 1.13 THz have been observed. In uniformly switching intrinsic Josephson stacks, the escape rate from zero-voltage state is enhanced by several orders of magnitude in comparison to single intrinsic junctions having comparable junction parameters. This enhancement is due to the unique stacking structure of intrinsic Josephson junctions.

**13:27**

**H40 10 Coupled Quantum Dots in the Kondo regime: interference and filtering effects.** LUIS DIAS DA SILVA, NANCY SANDLER, *Department of Physics and Astronomy, Ohio University* KEVIN INGERSENT, *Department of Physics, University of Florida* SERGIO ULLOA, *Department of Physics and Astronomy, Ohio University* Double quantum-dot systems (DQDs) provide a vast array of possibilities for both theoretical and experimental investigations of the Kondo regime. In this work, we propose

DQDs as a possible experimental realization of a Kondo impurity coupled to an effective structured (non-constant) density of states (DoS). We consider a DQD in parallel configuration coupled to metallic leads. By changing the lead-dot and dot-dot couplings, the effective hybridization function for an individual dot displays sharp resonances and/or pseudogaps, allowing for an experimental probe into the transition between both regimes. Using numerical renormalization group methods, we calculate the dot's spectral function in different regimes. For a dot weakly coupled to the leads and strongly coupled to the second dot, the effective DoS has a sharp resonance with width $\Delta$ and the spectral density shows a splitting in the Kondo resonance for $T_K > \Delta$, although the Kondo singlet is itpreserved. Furthermore, for small inter-dot coupling, second order dot-dot interactions through the conduction electrons lead to the formation of a pseudo-gap. The spectral density goes to zero as a power-law $|\epsilon - \epsilon_F|^2$ and the Kondo screening is suppressed. Supported by NFS-NIRT.

**13:39**

**H40 11 Spin polarized current in a double quantum dot with time-dependent interdot tunneling*** ERNESTO COTA, FRANCISCO MIRELES, FERNANDO ROJAS, *CCMC-UNAM* SERGIO E. ULLOA, *Ohio University* A bipolar spin filter has been proposed using a few-electron double quantum dot (DQD) in a 'hanging-dot' configuration [1], and tunable by controlling the molecular hybridization (interdot tunneling) between dots. The bipolar nature of the electron spin current arises from a singlet-triplet transition in the ground state of the two-electron DQD. The transition occurs due to the competition among Zeeman energy, exchange interaction and interdot coupling, favoring a lower (higher) energy for the triplet (singlet) configuration in the weak (large) interdot tunneling regime. In this work we use a density matrix equation to study the dynamical behavior of the DQD, by considering the adiabatic variation of the interdot tunneling in time. We report on the spin-polarized current through the DQD as a function of the relevant physical parameters. A bipolar spin filtering effect in the time domain is observed to arise on time scales smaller than the relevant coherent and spin relaxation times in typical QDs. Spin-orbit coupling is included in our approach but found to not significantly affect our results. [1] F. Mireles, E. Cota, F. Rojas and S.E. Ulloa, submitted.

**H40 12 Charge sensing in Si/SiGe quantum dots using single electron transistors** FENG PAN, TIM GILHEART, ALEXANDER RIMBERG, *Dartmouth College* KEITH SLINKER, LISA MCGUIRE, MARK ERIKSSON, *University of Wisconsin-Madison* J. O. CHU, *IBM Research Division, T. J. Watson Research Center* Qubit schemes based on silicon technology have obvious economic appeal as well as compelling physical motivations, such as a long spin-spin dephasing time. Proposed silicon solid-state qubit schemes include quantum dots coupled to fast readout devices, such as a quantum point contact or single electron transistor (SET). Recently, Si/SiGe quantum dots defined by Schottky gates deposited on a Si/SiGe heterostructure containing a high mobility two-dimensional electron gas have been fabricated. [1] Here we report the integration of a SET with such a Si/SiGe quantum dot. Several such devices have been produced, and recent measurements, including transport and sensing of the dot charge with the SET, will be discussed. [1] K A Slinker et al 2005 New J. Phys. **7** 246.

**H40 13 Few Electron Si/SiGe Quantum Dots** LEVENTE KLEIN, *University of Wisconsin* SRIJIT GOSWAMI, DON SAVAGE, KEITH SLINKER, LISA MCGUIRE, MAX LAGALLY, MARK ERIKSSON, Fully top-gated silicon/silicon-germanium quantum dots have been fabricated and characterized at low temperatures. For the quantum dots with few electron occupation, by varying the gate voltages two regimes may be accessed: at large negative voltages sharp Coulomb diamonds and classical Coulomb blockade is observed with a charging energy of 3.8 meV. At more positive gate voltage, co-tunneling features appear and a zero-bias conductance anomaly is observed with a behavior closely resembling the quantum dot Kondo effect. The increased zero-bias conductance vanishes with increasing temperature, and this peak splits into two peaks at finite drain-source voltage with increasing perpendicular magnetic field. The peak splitting increases linearly with increasing magnetic field. We discuss the various conductance regimes and the application of these types of quantum dots for quantum information processing.

**H41 1 Constrained polarization study of ferroelectric $KNO_3$*** OSWALDO DIÉGUEZ, DAVID VANDERBILT, *Rutgers University* Potassium nitrate has an interesting phase diagram that includes a reentrant ferroelectric phase (phase III, *R3m*), and it has been proposed as a promising material to be used in random-access memory devices.[1] Recently, we have developed a method to compute the ground-state of an insulator under a fixed value of its polarization[2] that can be used to gain insight into the properties of polar materials. In this talk we show the results of applying this method to study the structural behavior of potassium nitrate under polarization reversal, describing an unusual mechanism in which the reversal is accompanied by a rotation of the $NO_3$ unit by 60°. We also use our calculations as a basis for constructing first-principles based models that can be used to gain a deeper understanding of the switching behavior of this material.

**H41 2 Surface passivation of III-V compound semiconductors using atomic-layer-deposition grown Al2O3** M.L. HUANG, M. HONG, Y.C. CHANG, C.H. CHANG, Y.J. LEE, P. CHANG, T.B. WU, J. KWO, DEP. OF MAT. SCI. & ENG., TSING HUA U., HSINCHU, TAIWAN TEAM, DEP. OF PHYS., TSING HUA U., HSINCHU, TAIWAN TEAM, Al2O3 was deposited on In0.15Ga0.85As/GaAs using atomic layer deposition (ALD). Without any surface preparation or post thermal treatment, excellent electrical properties of Al2O3/InGaAs/GaAs heterostructures

were obtained, in terms of low electrical leakage current density (10-8 to 10-9 A/cm2) and low interfacial density of states (Dit) in the range of 1012 cm-2eV-1. The interfacial reaction and structural properties studied by HRXPS and HRTEM. The depth profile of HRXPS, using synchrotron radiation beam and low energy Ar+ sputtering, exhibited no residual arsenic oxides and elemental arsenic at interface. The removal of the arsenic oxides from Al2O3/InGaAs heterostructures during ALD process ensures the Fermi level unpinning, which was observed in the C-V measurements. The HRTEM shows sharp transition from amorphous oxide to single crystalline semiconductor. The bandgap of ALD grown Al2O3 was measured by O 1s core level loss spectra as 6.55 eV, and valence band offset was 3.78 eV between Al2O3 and In0.15Ga0.85As layers.

**11:39**

**H41 3 Electronic and vibrational properties of tungsten-bronze niobates** MARCO FORNARI, *Dept. of Physics, Central Michigan University* We investigated the electronic and vibrational properties of complex niobates with tetragonal tungsten-bronze structure. Our first principles results show that, in $PbNb_2O_6$, the largest contribution to the polarization is from the four 15-coordinates Pb sites ($A^{XV}$). The interaction between these sites favors the orthorhombic ground-state. The substitution of Ba on the $A^{XV}$ site drives the system to a tetragonal phase forming a morphotropic phase boundary. Replacing Ba with Pb breaks the cooperative behavior a the origin of the orthorhombic phase. Octahedral rotations do not seem to play a significant role even if they influence the energetic of the position of Pb in the $A^{XV}$ cage. Chemical substitutions are tried to explore novel ferroelectric materials.

**H41 4 Cubic HfO2 Doped with Y2O3 for Advanced Gate Dielectrics by MBE.** ZHIKAI YANG, W.C. LEE, PEN CHANG, MOLIN HUANG, YI LIN HUANG, MINGHWEI HONG, *Dept. of MSE NTHU Taiwan* C.M. HUANG, C.H. HSU, *NSRRC Taiwan* RAYNIEN KWO, *Dept. of Phys. NTHU Taiwan* NATL SYNCHROTRON RAD. RES. CTR.TAIWAN COLLABORATION, High $\kappa$ $HfO_2$ ($\kappa$ =20) is currently employed as an alternative gate dielectric replacing $SiO_2$ in CMOS scaling. There are three known crystal structures of $HfO_2$, monoclinic, cubic, and tetragonal with varying dielectric constants [1]. Recently we showed $HfO_2$ films epitaxially grown on GaAs(100) formed the stable monoclinic phase ($\alpha = \gamma = 90$ and $\beta \sim 99$) with the *a* and *b* axes aligned with the in-plane GaAs{100} axes resulting in four equivalent domains. This work demonstrates the successful alteration of the crystal structure of $HfO_2$from the lower $\kappa$ monoclinic phase to the higher $\kappa$ ($\kappa$ =30) cubic phase stabilized through epitaxy on GaAs(100) and Si(100) with the aid of $Y_2O_3$ doping ( $\sim$ 20% based on XPS). X-ray diffraction scans on these films clearly indicated the cubic symmetry. Doping $Y_2O_3$ is also to enhance the thermal stability of amorphous $HfO_2$. $Y_2O_3$doping was shown to help raise the re-crystallization temperature of $HfO_2$to be compatible with high temperature processing.[1] X. Zhaoetal, PRB **65**, 233106 (2002).

**H41 5 Hydrogen bistability in non-magnetic oxides** JACOB GAVARTIN, ALEXANDER SHLUGER, MARSHALL STONEHAM, *University College London, U.K.* STEVE COX, *ISIS Facility, Rutherford Appleton Lab, U.K.* Recent extensive muonium spectroscopy measurements ($\mu$SR) [1] suggest a general correlation between stable muonium (Mu) forms in non magnetic oxides and their band gap, $E_g$ : in the materials with Eg$<$ 4 eV, Mu is, as a rule, fully ionized; in the oxides with Eg$>$ 7 eV, most of the Mu exists in the atomic form, while both ionized and atomic forms of Mu coexist in the oxides with the band gap in the interval 4$<$ Eg $<$ 7 eV. Based on the analogy between muonium and hydrogen, we propose a general model which may explain such a correlation and makes important predictions about hydrogen behavior in non-magnetic oxides. As an example, we use ab initio calculations to extract the parameters for this model to explain difference in hydrogen behavior in $HfO_2$, $ZrO_2$ films and in their silicates at low hydrogen concentrations [2]. We further discuss the role of hydrogen in mechanisms of tetragonal to a monoclinic phase transformations in $ZrO_2$ and $HfO_2$. 1. S.F.J. Cox, J.L. Gavartin, J.S. Lord et al. J. Phys. : Condens. Matter, 2006 (in press). 2. R.P. Pezzi, L. Miotti, K.P. Bastos et al. Appl. Phys. Lett. **85** 3540 (2004).

**H41 6 Growth of highly oriented monoclinic $HfO_2$ thin films after Co and Fe doping by pulsed laser deposition** S. DHAR, M.S.R. RAO, S.B. OGALE, D.C. KUNDALIYA, S.R. SHINDE, T. VENKATESAN, *Center for Superconductivity Research, Department of Physics, University of Maryland, College Park, MD 20742, USA* S.J. WELZ, R. ERNI, N.D. BROWNING, *Lawrence Berkeley National Laboratory, NCEM, One Cyclotron Road, Berkeley, CA 94720, USA* Above room-temperature ferromagnetism in undoped and Co doped high-k dielectric $HfO_2$thin films opens up the possibility for using spin functionality in various new electronic devices. In the present work, we report on the growth of high quality epitaxial $HfO_2$ thin films stabilized in monoclinic phase after 5% Co or Fe doping at 700-800$^o$C in an oxygen partial pressure of $10^{-4}$ torr on (001) yttria stabilized zirconia and (001) Si substrates by pulsed laser deposition. On the one hand, pure $HfO_2$ film did not grow epitaxally under various deposition conditions. On the other hand, the formation of single crystalline phase after Co or Fe doping was confirmed by X-ray analysis. Ion channeling analysis in Co and Fe doped films showed 8-24% minimum yield indicating highly oriented film growth, whereas, a very poor minimum yield was observed in the undoped case. Angular scans showed the $HfO_2$ to grow in a monoclinic phase with a 9.1 degree tilt with respect to the substrate. High resolution transmission electron microscopy showed very sharp interface while Electron energy loss spectroscopy revealed that Co is in 2+ state indicating the substitution of Co in ionic form into the $HfO_2$lattice.

**12:27**

**H41 7 Anomalous behavior of the dielectric constant of hafnium silicates** CARLO ANTONIO PIGNEDOLI, ALESSANDRO CURIONI, WANDA ANDREONI, *IBM Research, Zurich Research Laboratory, 8803 Rueschlikon (Switzerland)* Hafnium silicates (HfSiO) are among the materials most frequently investigated in the search for a replacement of silicon dioxide as gate dielectric in CMOS devices. Measurements of the dielectric constant as a function of the relative concentration of the two binary oxides exhibit an anomalous behavior. Large-scale DFT-based calculations reveal that this is due to the change of the relative stability of different structures with composition and their strong

influence on the permittivity. These results also help to rationalize the wide scatter in the experimental data for the dielectric constant for some concentrations and suggest ways to optimize the integration of these materials in the device.

**12:39**

**H41 8 Nucleation and Growth of ALD Hafnium Oxide High-k Dielectric Films by GISAXS.** ANDREW ALLEN, *NIST* MARTIN GREEN, *NIST* Atomic layer deposition (ALD) is an important film growth technique that enables accurate growth of ultrathin layers for high-k gate dielectrics. Results will be presented of grazing incidence small angle x-ray scattering (GISAXS) studies of the nucleation and growth of ALD hafnium oxide films. The scattering is related to surface roughness and internal interfaces within the films, resulting from film coalescence of the nuclei. Films grown on H-terminated Si are rough and nonplanar, exhibit greater scattering, and have greater internal surface area than films grown on chemically oxidized Si. These films have 5 times the internal surface area of films grown on chemically oxidized Si, and may be significantly porous. The characteristic scattering features are the film nuclei, which coalesce and become inherited features of the films. The nuclei size is about 2 nm, consistent with TEM observations. Films grown on chemically oxidized Si reach coalescence at about 25 cycles, or 1.3 nm thickness, consistent with electrical data. Implications arising from the different film morphologies discussed.

**H41 9 Self-interaction corrected extrinsic levels of oxygen vacancies in hafnia** GIORGIA M. LOPEZ, VINCENZO FIORENTINI, ALESSIO FILIPPETTI, *SLACS-CNR and University of Cagliari, Italy* To identify fixed-charge (generally negative) centers in thin hafnia layers on silicon, the position and nature of the electronic levels of candidate defects should be known accurately. Due to the DFT gap problem, this is still a controversial issue in ab initio calculations, especially for high-gap insulators and near-conduction states. Here we apply a self-interaction corrected DFT method, which dealt successfully with a variety of systems dominated by localized and correlated states, to study the electronic structure of oxygen vacancies in monoclinic hafnium oxide in various charge states. We set the position of the extrinsic levels within the gap, and relative to the Si gap position as determined by interface band offsets. In the positive states, the partially filled levels are well below the Si gap, hence the Fermi level, and play a minor role. For the neutral vacancy, a filled extrinsic state sits within the Si gap and may tend to pin the Fermi level. A negative center may be realized upon occupation of a near-conduction shallow state, which would occur under typical device operation bias. While a conclusive identification of fixed-charge centers remains an open issue, the nature of this level is compatible with the experimentally observed kinetics of trapping and detrapping.

**13:03**

**H41 10 A Novel Template Approach by MBE for ALD Growth of High k Dielectrics** K.Y. LEE, *Dept. of Mat. Sci. and Eng., National Tsing Hua Univ., Taiwan,* W.C. LEE, M.L. HUNG, Y.C. LEE, C.H. CHANG, Y.K. CHIOU, M. HONG, J. KWO, *Dept. of Phys., National Tsing Hua Univ., Taiwan.* Although growth of high k dielectrics by ALD on H-Si is feasible, it undergoes an incubation period during which the formation of SiO2 layer seems inevitable. Recently we showed the MBE growth of HfO2 on Si produced atomically abrupt interfaces, and achieved excellent electrical performance. Here we employed the MBE-grown high k dielectrics thin film as a template to suppress the interfacial layer formation during the ALD growth, and to improve the electrical properties of ALD films. The first demonstration is a bi-layer composite made of a lower HfO2 (MBE) layer 2.5nm thick, and an upper Al2O3 (ALD) film 4.0nm thick. The electrical properties are consistent with the two capacitors in series from two individual dielectric layers. The second demonstration is an MBE and ALD composite Al2O3 6.6nm thick. Studies are underway for the third structure of Al2O3 (MBE) and HfO2 (ALD) composite, which offers dual advantages of interfacial layer suppression and leakage current reduction during HfO2 recrystalization.

**13:15**

**H41 11 Dielectric Relaxation of $CaCu_3Ti_4O_{12}$ synthesized from a pyrolysis method*** JIANJUN LIU, W. N. MEI, *Department of Physics, University of Nebraska at Omaha, Omaha, Nebraska 68182-0266* R. W. SMITH, *Department of Chemistry, University of Nebraska at Omaha, Omaha, Nebraska 68182-0109* J. R. HARDY, *Department of Physics and Center for Electro-Optics, University of Nebraska, Lincoln, Nebraska 68588-0111* Giant dielectric constant material $CaCu_3Ti_4O_{12}$ has been synthesized by using a pyrolysis method. A stable solution was made by dissolving calcium nitrate, copper nitrate, and titanium isopropoxide in 2-methoxyethanol; the solution was then heated at 500 and 700 $^oC$ for 2 hours to obtain a pure phase of $CaCu_3Ti_4O_{12}$. The frequency and temperature dependences of dielectric permittivity were examined in the ranges of $10^{-1} \sim 10^6$ Hz and -150 $\sim$ 200 $^oC$. We found that the dielectric properties of the sample were the same as those made from solid state reaction. Specifically, there is a Debye-like relaxation at low temperature and its giant dielectric constant about 11000 is independent of the temperature and frequency over a wide range.

**H41 12 Cathodoluminescence Studies of Rare Earth Ions in $LiNbO_3$ and GaN*** S. TAFON PENN, ZACK FLEISCHMANN, *Dept. of Physics, Lehigh University* G.S. CARGILL, *Dept. of Material Sciences, Lehigh University* V. DIEROLF, *Dept. of Physics, Lehigh University* In most host materials, rare earth ions have intra-atomic transitions that exhibit a sensitivity to the local environment through the crystal field splitting of their Stark sub-levels and the modification of the free ion parameters (e.g.: Slater parameters). Moreover, in crystals that lack inversions symmetry the transitions exhibit linear Stark shifts that makes them good probes for local electric fields that are created for instance by local charging and a ferroelectric domain inversion. We present cathodoluminescence emission spectra of $Eu^{3+}$ ions and $Er^{3+}$ in two host materials ($LiNbO_3$ and GaN) for a temperature range between 12 and 300K using the electron beam in JEOL JSM-6400 SEM with a voltage of 10keV, various beam currents and beam scanning modes. We observe a pronounced saturation effect in the emission of the rare earth ions that depends on details of the scan mode, the electron beam deflection frequency, and magnification. The saturation effect is absent in the intrinsic emission of GaN that is recorded simultaneously. We will present an interpretation of the effect that takes into account charging effects and the excitation and relaxation dynamics of the free carriers and the rare earth ions.

**H41 13 Electronic Structure Calculations of BiFeO3*** DAVID SULOCK, LUCAS K. WAGNER, LUBOS MITAS, *North Carolina State University* Bismuth Ferrite (BiFeO3) is a potentially useful material because it exhibits both ferroelectricity and antiferromagnetism, providing a link between magnetic and ferroelectric action in the same material. Experimentally BiFeO3 has been reported to have a spontaneous polarization ranging from.06 C/m2 to 1.50 C/m2, possibly indicating a large dependence on experimental setup. Theoretical efforts thus far within Density Functional Theory in the LDA approximation have settled on a value of around 0.95 C/m2; however, it is not clear that LDA provides a sufficient description of the material as it predicts a lattice constant in error by .2 angstroms and zero band gap for some parts of the ferroelectric distortion. To check the results provided by LDA we use Quantum Monte Carlo (QMC), which allows us to treat the system in a fully correlated way. We use the Reptation Monte Carlo algorithm of Moroni and Baroni to calculate the polarization and other properties, allowing us to then evaluate the accuracy of QMC versus LDA.

**H41 14 Calculated polarizations and piezoelectric constants of wurtzite ZnO, CdO and MgO** PRIYA GOPAL, *UCSB* The macroscopic polarization in wurtzite crystal structures such as GaN and ZnO has a strong influence on the electrical and optical properties. This property has been exploited in GaN/AlGaN heterostructures, where the difference in the polarizations between layers induces an electric field at the interface forming a high mobility two-dimensional electron gas (2DEG)[1]. Here we calculate the polarization and the piezoelectric properties of the corresponding wurtzite-structure binary oxides ZnO, MgO and CdO. The knowledge of these properties is essential to explore the possibility of creating similar high mobility polarization induced 2DEGs in the ZnO-based material system. However, since wurtzite-structure MgO and CdO are not experimentally accessible, the values can be obtained computationally. We use the recently developed self-interaction corrected pseudopotential (pseudo-SIC) implementation[2] of the density functional theory and the widely used Berry phase method[3] for obtaining the polarization and piezoelectric constants. We find that the polarization gradients between the end-point compounds in the MgO-ZnO-CdO are larger[4] than in the GaN analogues.

**H41 15 A More Accurate Generalized Gradient Approximation for Solids*** ZHIGANG WU, RONALD E. COHEN, *Carnegie Institution of Washington* We present a new nonempirical density functional generalized gradient approximation (GGA) based on a diffuse radial cutoff for the exchange-hole in real space and the analytic gradient expansion of the exchange energy for small gradients. There are no adjustable parameters, the constraining conditions of PBE are maintained, and the functional is easily implemented in existing codes. For the 18 testing solids including simple and transition metals, and ionic and covelent crystals, the new functional improves equilibrium lattice constants and bulk moduli significantly over the most popular Perdew-Burke-Ernzerhof (PBE) GGA and the local density approximation (LDA), and its accuracy for cohesive energies is similar to PBE. It also predicts highly accurate ground states of ferroelectrics, better metal surface energies and sublimation energy of ice than PBE and LDA, and correct ground states of magnetic iron and alpha quartz.

**H42 1 Analyzing Isentropic Compression Wave Experiments.**
DENNIS HAYES, *Sandia National Laboratories*

Some common assumptions that are used to analyze shock wave experiments are inadequate for analyzing ramp wave compression experiments. Analysis of a Doppler shift through a window usually assumes a steady wave in the window, a condition that is violated when a ramp compression wave steepens as it propagates, requiring separate consideration during the analysis (LiF to 20GPa). Introduction of a free or windowed interface produces large perturbations to the flow in the sample that must be reconciled to achieve required timing accuracy: when the specimen has a unique stress-strain compression relation, the equations of motion are hyperbolic so that stress-strain relation can be directly deduced from measurements on two samples. If the sample is hysteretic like an elastic plastic material, there is not a unique solution to the flow and a separate drive measurement is needed. Time-dependent plasticity (spall in aluminum or twinning in U6Nb) has parabolic equations and backward solutions are unstable. Analyses that compare experiment and simulation have very broad minima in the parameters used to model stress-strain; unconstrained polynomial stress-strain expansions can wander and converge to unreasonable results. Better convergence is achieved with constrained models like certain forms of the Mie-Gruneisen EOS (copper to 18GPa) but those poorly represent materials with large changes in com-

pressibility with strain (HMX to 50GPa). Maintaining small sample thickness to eliminate shock-up while maximizing thickness for accurate wave velocity measurement produces problems for designing high stress experiments and leads to hybrid experimental designs. Sandia is a multi-program laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**H42 2 From solitons to shocks: entropy generation and quasi-isentropic compression.**
ROGER MINICH, *LLNL*

Recently a number of experimental platforms have demonstrated the ability to produce stress waves that have thermodynamic paths intermediate between an ideal isentrope and the Hugoniot. It is of interest to quantify the entropy generated for a given path in order to accurately determine the equation of state. Stationary propagating structures known as solitons have recently been observed in particle velocity time histories and provide insight as to how entropy is generated in quasi-isentropic flows. The origin of the structures is discussed in terms of dispersion and dissipation and a metric for quantifying the entropy generated is derived. A generalization of Lagrangian analysis is presented that allows an experimental determination of the relative contributions of nonlinear steepening, dispersion and dissipation. Finally, wavelet analysis is introduced as a powerful tool for the quantification of nonlinear wave dispersion and energy dissipation.

**H42 3 Application of Ellipsometry to Shock-Compressed Materials*** J. REED PATTERSON, JEFFREY H. NGUYEN, NEIL C. HOLMES, *Lawrence Livermore National Laboratory* Measurements of optical properties, such as the dielectric tensor, along the shock Hugoniot can be achieved in real time and *in-situ* via ellipsometry. Since standard Hugoniot-EOS and sound speed experiments do not provide crystal structure information, our knowledge of the phase diagrams of high-pressure high-temperature materials is limited. Complementary to x-ray diffraction techniques, ellipsometry of dynamically compressed materials provides data that can be coupled with calculations, yielding information on phase transitions and crystal structures. Single-wavelength ellipsometry experiments demonstrate our ability to observe solid-solid ($\alpha - Fe \rightarrow \epsilon - Fe$) and solid-liquid (e.g. Sn) phase transitions. In addition, changes in the complex index of refraction are related to changes in the strain state of a material, as observed in preliminary experiments on LiF, which demonstrated stress-incduced birefringence. Time-resolved ellipsometric measurements have the potential to provide insight into dynamic phenomena such as elastic/plastic deformation/relaxation and phase transition kinetics. We will also discuss our efforts to extend the applicability of ellipsometry of dynamically compressed materials by incorporating multiple wavelengths.

**H42 4 Experimental Measurement of Compression Isentropes to Multimegabar Pressures*** JEAN-PAUL DAVIS, *Sandia National Laboratories* Isentropic ramp-wave loading of condensed matter has been hailed as a potential means to obtain accurate equation-of-state (EOS) data in the solid phase at relatively low temperatures and multimegabar pressures. In this range of pressure, isothermal diamond-anvil techniques have limited accuracy due to reliance on theoretical EOS of calibration standards; accurate isentropic compression data would help immensely in constraining EOS models. An isentropic compression technique developed using the Z Machine at Sandia as a magnetic drive has been extended to the multimegabar regime. Diagnostics typically consist of time-resolved velocity interferometry to monitor the back surfaces of samples having different thickness but subjected to the same magnetic loading. A number of design and analysis issues arise when attempting to extract a stress-density curve from such data. Following a brief discussion of these issues, recent results will be presented for quasi-isentropic compression of several materials to greater than 200 GPa.

**H42 5 Recent Advances in Tailored Dynamic Compression*** JEFFREY H. NGUYEN, JEREMY R. PATTERSON, DANIEL ORLIKOWSKI, LOUIS P. MARTIN, P. ASOKA-KUMAR, KLAUS WIDMANN, NEIL C. HOLMES, *Lawrence Livermore National Laboratory* In the past few years, the functionally graded density impactor has been used in dynamic compression experiments that are tailored to reach previously inaccessible dynamic thermodynamic states beyond the principal Hugoniot and isentrope. These experiments demonstrated complex loading paths that included a combination of shocks, quasi-isentropic compressions, and controlled releases. The quasi-isentropic compression experiments last microseconds, and are capable of bridging the timescales of static experiments and current dynamic compression experiments. Some of the interesting experiments that were carried out included phase transition and equation of state studies. Our recent efforts have been concentrated on improving reproducibility and planarity of the impactors. Here, we will report the efforts and progresses on impactor manufacturing as well as experiments characterizing these impactors. We employed both line-VISAR and multi-PDV probes to characterize the planarity of the impactor as the target undergoes tailored dynamic compression.

**H42 6 Dynamic Response of Shock-Loaded Multi-Component Glasses*** C.S. ALEXANDER, W.D. REINHART, T.J. VOGLER, D.E. GRADY, L.C. CHHABILDAS, *Sandia National Laboratories* Glass, in various formulations, may be useful as a transparent armor material. Fused quartz ($SiO_2$), modified with either $B_2O_3$ (13 % wt.) or $Na_2O$ (15 % wt.), was studied to determine the effect on the dynamic response of the material. Utilizing powder and two-stage light gas guns, plate impact experiments were conducted to determine the effect on strength properties, including the elastic limits and plastic deformation response. Further, the effect of glass modification on known transitions to higher density phases in fused quartz was evaluated. Results of these experiments will be presented and discussed.

**H42 7 Coherent optical photons from shock waves in polarizable crystals** EVAN REED, *Lawrence Livermore National Laboratory* MARIN SOLJACIC, *Massachusetts Institute of Technology* RICHARD GEE, *Lawrence Livermore National Laboratory* JOHN JOANNOPOULOS, *Massachusetts Institute of Technology* We predict that coherent electromagnetic radiation can be generated in polarizable crystalline materials when subject to a shock wave or soliton-like propagating excitation. To our knowledge, this phenomenon represents a new source of coherent optical radiation source in the 1-100 THz frequency range that is distinct from lasers and free-electron lasers. The radiation is generated by the synchronized motion of large numbers of atoms when a shock wave propagates through a crystal. Analytical theory, finite-difference time-domain simulations of Maxwell's equations, and molecular dynamics simulations demonstrate coherence lengths on the order of mm (at 16 THz) and potentially greater.

**13:27**

**H42 8 kinetics of solid to solid phase transitions in bismuth** RICKY CHAU, FREDERICK STREITZ, *Lawrence Livermore National Laboratory* The role of kinetics in determining the time scale for transition from one phase to another is not known, but has been cited as contributing to the often observed discrepancy between phase boundaries determined in dynamic versus static pressure experiments. In this study, we demonstrate the use of real-time electrical conductivity as a phase diagnostic by presenting preliminary measurements of the conductivity of Bi under dynamic loading conditions. By exploiting the drastic variation in electrical conductivies among the low pressure phases, we are able to correlate changes in measured conductivity with phase changes in the sample. We will discuss the observed timescale for the phase transitions as well as possible effects due to the competition of phases. In addition, we will present results from experiments where both the electrical conductivity and particle velocity profiles are measured simultaneously, allowing observation of both the bulk and the local response of the system. This work was performed under the auspices of the U.S. Department of Energy by University of California, Lawrence Livermore National Laboratory under Contract W-7405-Eng-48.

**H42 9 Pressure Induced Metallization of Light Group IV Hydrides** AITOR BERGARA, MIGUEL MARTINEZ-CANALES, *University of the Basque Country (UPV/EHU) and Donostia International Physics Center (DIPC)* JI FENG, *Department of Chemistry and Chemical Biology, Cornell University.* WOJCIECH GROCHALA, *Department of Chemistry, University of Warsaw.* ROALD HOFFMANN, *Department of Chemistry and Chemical Biology, Cornell University.* N.W. ASHCROFT, *Laboratory of Atomic and Solid State Physics and Department of Physics, Cornell University.* Recently reported superconductivity in lithium under pressure has renewed the interest on hydrogen and hydrogen-rich systems in the long standing conquest of room temperature superconductivity. Although the required metallization of pure hydrogen cannot be achieved within current experimental capabilities, chemical precompression exerted by heavier atoms in compounds with a large hydrogen content is expected to imply that lower pressures might be required to attain the metallic transition in these alloys. In this work we present an itab initio analysis of pressure induced metallization of methane, silane and germane, as light group IVa hydrides. According to our calculations, although metallization in methane cannot be reached at pressures lower than 400 GPa, silane and germane are predicted to become metallic at experimentally accessible pressures of around 90 GPa and 70 GPa, respectively. Possible superconducting transitions of these compounds will be also analyzed.

**H42 10 Core/Shell Nanocrystalline Clusters in a Glass Matrix: A High Pressure Synchrotron X-Ray Diffraction Study*** PATRICIA E. KALITA, *High Pressure Science and Engineering Center, Dept. of Physics, UNLV* GINO MARIOTTO, *Dipartimento di Fisica, Università di Trento, Italy* YOSHIMICHI OHKI, *Dept. of Electrical Eng. and Bioscience, Waseda University, Tokyo, Japan* KRISTINA E. LIPINSKA-KALITA, *Center for Nanoscale Device Research, Dept. of Electrical and Computer Eng. University of Nevada Las Vegas* Synchrotron x-ray diffraction studies up to 50 GPa were performed on an optically transparent composite with nanometer-sized $ZrTiO_4/LiAlSi_2O_6$ core/shell clusters embedded in a host glass. In the low-pressure range the shift and broadening of the x-ray diffraction lines was consistent with the densification of the $LiAlSi_2O_6$ shell phase. At higher pressures, the considerable diffraction line broadening pointed to a partial amorphization of the nanocrystalline phase. With pressure increase the x-ray patterns progressively revealed the presence of the $ZrTiO_4$ core phase. Upon decompression from 50 GPa to ambient conditions the pressure-induced changes were not fully reversible, however the diffraction pattern of the pressure-quenched material suggested that the decompressed structure carries the signature of the initial ambient $LiAlSi_2O_6$ phase.

**H43 1 Understanding the Superfluid phase diagram in trapped Fermi gases*** KATHY LEVIN, QIJIN CHEN, *University of Chicago* We address previous experimental observations of the condensation of fermionic atom pairs involving trapped Fermi gases which can be tuned from the BCS to BEC regime, with the application of magnetic fields. In the intermediate regime, condensation is demonstrated experimentally by a sweep technique that pairwise projects fermionic atoms onto molecules. While the condensate fraction is measured after a fast sweep to BEC, the temperature is measured by a slow adiabatic sweep to the Fermi gas regime. In this paper we compare the normal-superfluid phase boundary in this temperature-magnetic field plane as obtained in this way for $^{40}$K and computed theoretically. We demonstrate good agreement between the two. References: arXiv:cond-mat/0411090; Phys. Rev. Lett., in production.

**H43 2 Critical Temperature and Thermodynamic Properties of Attractive Fermions** EVGENI BUROVSKI, NIKOLAY PROKOF'EV, BORIS SVISTUNOV, *University of Massachusetts, Amherst* MATTHIAS TROYER, *ETH, Zurich* The unitarity regime of the BCS-BEC crossover can be realized by diluting a system of two-component lattice fermions with an on-site attractive interaction. We perform a systematic-error- free finite-temperature simulations of this system by diagrammatic determinant Monte Carlo. We report the data obtained on the Cray X1E ''Phoenix'' of the Oak Ridge National Laboratory. The critical temperature in units of Fermi energy is found to be $T_c/E_F = 0.152(7)$. We also report the behaviour of the thermodynamic functions, and discuss the issues of thermomentry of ultracold Fermi gases.

**11:39**
**H43 3 Dynamical Mean-Field Equations for Strongly Interacting Fermi Gas in a Trap** WEI YI, LUMING DUAN, *University of Michigan* FOCUS TEAM, We derive the time evolution equations at zero temperature for the wavefunctions of the molecular bosons and the fermion pairs in a trapped Fermi gas near a wide Feshbach resonance. The derivation of the equations is based on the variational principle and the BCS-like ansatz state: $|\Phi\rangle = \mathcal{N} e^{\int \phi_b(\mathbf{r}) \Psi_b^\dagger(\mathbf{r}) d^3\mathbf{r}} e^{\int \rho(\mathbf{r},\mathbf{r}') \Psi_\uparrow^\dagger(\mathbf{r}) \Psi_\downarrow^\dagger(\mathbf{r}') d^3\mathbf{r} d^3\mathbf{r}'} |0\rangle$. In deriving the equations, we have assumed that the external trapping potential and the wavefunction of the molecular bosons are spatially slow-varying on the length scale of the size of the fermionic atom pairs, which should be valid over a wide range on the BEC side of resonance, including the resonance point. In the bosonic region ($\mu \leqslant 0$, where $\mu$ is the chemical potential), the equations will reduce to one that resembles a Gross- Pitaevskii (GP) equation. We solve the the stationary ground state of the system at different detunings near the crossover region and self-consistently checked our assumptions. The time evolution equations provide macroscopic description for the wavefunctions of the molecular bosons and of the fermion pairs near the interesting BCS-BEC crossover region. In future studies, these equations can be used to analyze the interesting physics of vortices or the excitation spectrum in the Fermi condensate.

**H43 4 Studying the BCS-BEC crossover regime with a Fermi gas of $^{40}$K atoms.**
CINDY REGAL, *JILA: NIST and the University of Colorado and Department of Physics, University of Colorado*

Recent years have seen the emergence of an intriguing Fermi system achieved with ultracold atomic gases. With these systems it is possible to widely tune the s-wave interatomic interaction strength using a Feshbach resonance. Of particular interest is the strongly interacting regime ($-1 < 1/k_F a < 1$) where a crossover between BCS theory of superconductivity and Bose-Einstein condensation (BEC) of molecules occurs. Recently experiments with $^6$Li and $^{40}$K have succeeded in studying many aspects of this superfluid Fermi system. In my talk I will discuss recent experiments performed at JILA on this Fermi system using $^{40}$K.

**H43 5 Counting Statistics of Density Fluctuations in a Quantum Gas** WOLFGANG BELZIG, *University of Konstanz, Theoretical Solid State Physics, Department of Physics, D-78457 Konstanz, Germany* CHRISTIAN SCHROLL, CHRISTOPH BRUDER, *Dept. of Physics and Astronomy, University of Basel, Klingelbergstr. 82, CH-4056 Basel, Switzerland* We investigate the statistics of density fluctuations in a coherent ensemble of interacting fermionic atoms around the BEC-BCS crossover. Adapting the concept of full counting statistics, well-known from quantum optics and mesoscopic electron transport, we study second-order as well as higher-order correlators of density fluctuations. This method is applied to the crossover from a molecular BEC state to a fermionic BCS state and yields a transition from Poissonian statistics to binomial statistics. The large Poissonian fluctuations confirm the picture of independent molecules on the BEC side of the transition. Strongly suppressed fluctuations on the BCS side reflect the correlation among Cooper pairs and the in-

ertness of a Fermi sea. In the transition region the third cumulant is a measure of the particle hole symmetry of the distribution function. The statistics can thus be used as an experimental tool to gain information on the many-body ground states.

**12:39**

**H43 6 A mean-field model for condensates in the BEC-BCS crossover regime** CHENG CHIN, *The University of Chicago* We present a new mean-field model to describe Fermionic condensates in the BEC-BCS crossover regime. By introducing an effective mean-field potential, this approach allows us to analytically evaluate the chemical potential, the equation of states, and the pair wave function. The results agree surprisingly well with recent quantum Monte Carlo calculations. Density profiles and the collective mode frequencies of a trapped gas can thus be analytically determined. In particular, the pair wave function can be expressed in terms of Airy function. We show that this wave function naturally approaches molecular wave function in the BEC limit. In the presence of strong interaction, the wave function is compressed to a smaller size, which implies an upshift of the pairing energy. This effect can be understood based on the repulsive interaction between two pairs (Petrov et al.) and has been observed in rf spectroscopy experiment. Although the mean-field approach does not explicitly include anti-symmetric fermionic correlations, it does provide a complementary picture to view the crossover physics. The validity of this approach is based on the fact that a degenerate Fermi gas constitutes the same quantum phase as that of a condensate of pairs. Both descriptions should therefore be similarly effective in the crossover. One advantage of the bosonic approach is that the molecular mean-field term can conveniently capsulate four-fermion interactions. It is, however, more difficult to do so in the BCS-type calculation.

**H43 7 FFLO State in a Rotating Cold Fermionic Atom System** YUN-PIL SHIM, REMBERT DUINE, ALLAN H. MACDONALD, *University of Texas at Austin* Superconductors with a large Zeeman splitting are expected to have an inhomogeneous order parameter. This Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state was proposed in the early 1960's, and recent experiments in various solid state systems have shown some progress in realizing this state. We study the FFLO state for rotating fermionic atom systems consisting of two hyperfine species with different populations. The fermi surface mismatch due to the population imbalance effectively plays the role of Zeeman splitting. In recent experiments [1,2], vortex structures were observed in rotating cold fermion systems over the whole range of the BEC-BCS crossover, but the exotic vortex structures expected for the FFLO state have yet to be observed. We use a fully quantum mechanical approach to include the Landau level quantization effect due to the rotation and present a phase diagram for superconducting phase transition with center of mass (COM) motion of the paring atoms in different Landau levels. The FFLO state is expected over small range of parameters and as the population imbalance increases, the paring condensation occurs at higher COM Landau level. [1] M. W. Zwierlein et al, Nature 435, 1047 (2005) [2] M. W. Zwierlein et al, cond-mat/0511197.

**H43 8 Spin-polarized fermionic superfluidity in a trap** DANIEL E. SHEEHY, LEO RADZIHOVSKY, *University of Colorado* Recent research on Feshbach resonantly paired superfluids has focused on the fate of such superfluidity upon changing the relative population of the two hyperfine states undergoing pairing. I will discuss recent work [1] showing that such imposed spin polarization frustrates pairing and leads to a rich phase diagram consisting of a polarized superfluid, phase separation, and Fulde-Ferrell-Larkin-Ovchinnikov phases. In the spatially inhomogeneous environment of a trap, the local spin polarization (magnetization) is also inhomogeneous, providing a direct signature of these phases. I will discuss this and other signatures of such phases in degenerate atom experiments. This work was supported by NSF DMR-0321848 and the Packard Foundation. [1] D.E. Sheehy and L. Radzihovsky, cond-mat/0508430.

**H43 9 Density profile and collective modes of the unpolarized and partially polarized trapped Fermi gas in the BCS-BEC crossover region.** THEJA DE SILVA, ERICH MUELLER, *LASSP, Cornell University* We study the zero temperature BCS-BEC crossover physics of both the unpolarized and partially polarized 2-component trapped Fermi gas near a Feshbach resonance. We investigate the spatial distribution of the partially polarized atomic system; studying superfluid and normal fluid phase separation and coexistence within a local density approximation. We calculate collective mode frequencies as a function of the interaction strength, finding quantitative agreements with experiments.

**13:27**

**H43 10 Pairing in Feshbach-resonant trapped fermionic atom gases with unequal species populations** MASUDUL HAQUE, HENK STOOF, *Utrecht University, the Netherlands* Interest in BCS-like pairing with unequal Fermi surfaces has recently been revived due to the possibility of its realization in ultracold atomic gases, and the first experimental measurements have appeared in the past few months. We briefly review zero-momentum pairing with unequal chemical potentials for the two species. We then describe effects of an external trapping potential on the pairing process, and the resulting shell structure of different phases in the trap.

**13:39**

**H43 11 Strong coupling theory for the superfluidity of Bose-Fermi mixtures** DAW-WEI WANG, *Physics Department, National Tsing-Hua University, Hsinchu, Taiwan, ROC* We develop the strong coupling theory for the superfluidity of fermion *s*-wave pairing state in a Bose-Fermi mixture. Dynamical screening, self-energy renormalization, and pairing gap function are included self-consistently in the regime where the phonon velocity is smaller than the Fermi velocity. Analytical form for the transition temperature ($T_c$) is derived within reasonable approximations. In typical $^{40}$K-$^{87}$Rb mixtures, the obtained $T_c$ is several times larger than that in the weak coupling theory and can be as high as several percents of Fermi temperature.

**SESSION H44: QUANTUM PHASE TRANSITIONS**

**H44 1 Quantum Phase Transition in Hard-Core Bosons Due to Background Potentials** ANAND PRIYADARSHEE, JI-WOO LEE, SHAILESH CHANDRASEKHARAN, HAROLD BARANGER, *Duke University* We study the zero temperature phase diagram of hard-core bosons hopping on a two dimensional lattice under the influence of three types of background potentials: (1) staggered, (2) uniform, and (3) random (on-site disorder). Using the directed-loop quantum Monte Carlo algorithm on large square lattices, we examine the susceptibility, superfluid density, compressibility, and particle-particle correlation length. For all three types of potentials, the system undergoes a quantum phase transition from a superfluid phase at small potential to a normal phase when the applied potential is large. For a staggered or uniform potential, the transition is to an insulating phase; as expected, the staggered case shows XY universality, while the uniform case belongs to the mean field universality class with dynamic exponent z=2. In contrast, the disorder driven transition is clearly different from either of these. We find a transtion to a phase with non-zero compressibility with critical exponents $\nu \sim 1$, $\beta \sim 0.6$ and $z \sim 1.4$

**11:27**
**H44 2 Thermal Transport at the Superfluid–Insulator Transition** MIRACULOUS BHASEEN, *Oxford University* ANDREW GREEN, *University of St Andrews* SHIVAJI SONDHI, *Princeton University* We investigate the finite temperature thermoelectric response in the vicinity of the Superfluid–Insulator quantum phase transition. We present results for the Nernst coefficient in the disorder free Bose–Hubbard model.

**11:39**
**H44 3 The quasi-particle gap in a disordered boson Hubbard model in two dimensions** JI-WOO LEE, *School of Physics, Korea Institute for Advanced Study, Dongdaemun-gu, Seoul 130-722, Korea* MIN-CHUL CHA, *Department of Applied Physics, Hanyang University, Ansan, Kyunggi-do 426-791, Korea* We investigate the behavior of the quasi-particle energy gap near quantum phase transitions in a two-dimensional disordered boson Hubbard model at a commensurate filling. Via Monte Carlo simulations of ensembles with fixed numbers of particles, we observe the behavior of the gap as a function of the tuning parameter for various strength of diagonal disorder. For weak disorder, we find that gapped Mott insulating phase is sustained up to the transition point and disappears only in a superfluid, strongly supporting a direct Mott-insulator-to-superfluid transition. Bose glass behavior, insulating with vanishing gap, appears only when the strength of disorder is bigger than a critical value.

**11:51**
**H44 4 Current noise near to the 2D superconductor-insulator quantum critical point** ANDREW G. GREEN, *University of St Andrews* JOEL E. MOORE, ASHVIN VISHWANATH, *UC Berkeley* SHIVAJI L. SONDHI, *Princeton University* We consider current fluctuations near to the two-dimensional superconductor-insulator transition described by a quantum XY model. This model displays metallic conductivity at criticality. We consider the system both in thermal equilibrium and when a large electric field drives it far from thermodynamic equilibrium. As the strength of the electric field is increased, we find a crossover from thermal, Johnson-Nyquist noise (whose form is demanded by the fluctuation dissipation relation) to a high-field non-linear ''shot noise'' or Schwinger regime, where the current noise is proportional to $\sqrt{E}$. Comparison with noise in diffusive electronic systems and the possible relevance of using noise measurements in experiments on S-I systems will be discussed.

**12:03**
**H44 5 Quantum Monte Carlo studies of charged monolayer Bose fluids** EFSTRATIOS MANOUSAKIS, *MARTECH, Physics Department, Florida State University and University of Athens, Greece* KEOLA WIERSCHEM, *MARTECH, Physics Department, Florida State University* Computational studies of phase separation due to competing forces are implemented on monolayers of charged bosons above a smooth substrate (effectively a two dimensional Bose fluid). Hard-core bosons with van der Waals attraction are modeled with a Lennard-Jones potential, and to this is added a Coulomb repulsion of variable strength. The long range interparticle repulsion induces the Bose fluid to phase separate into ordered clumps of equilibrium liquid and low density gas, instead of a single domain of equilibrium liquid surrounded by its vapors. The ''clumps'' form bubbles or stripes (or a combination of these states), depending on the particle density as well as the repulsion strength. A Bose fluid with weak van der Waals attraction and large quantum fluctuations will become superfluid at low temperatures (as is the case with helium). The possibility of superfluidity in the microscopically phase separated state is also investigated. Path integral Monte Carlo is employed to include the effects of quantum fluctuations and particle permutations.

**12:15**
**H44 6 Phases, RK Points and Possible Deconfined Transitions in a Model of Bosons on the Honeycomb Lattice** ASHVIN VISHWANATH, CENKE XU, JOEL MOORE, *UC Berkeley* We consider a model of hard-core bosons (or S=1/2 spins) on the sites of the honeycomb lattice with an interaction that favors exactly three bosons per hexagon. A rich phase diagram of insulating states is obtained, which includes a solvable point of the Rokhsar-Kivelson type where the ground-state wavefunction is related to a constrained version of the three-color model. On introducing charge fluctuations a superfluid phase obtains. We study transitions between the different insulating phases and between the superfluid and insulating states utilizing a duality due to Motrunich. The unusual aspect of these transitions is that when continuous, they lead to 1/3 charged fractional excitations and an emergent U(1)xU(1) gauge structure in the vicinity of the critical point. The phase diagram of this model makes it a promising candidate for numerically studying 'deconfined' quantum criticality using Quantum Monte Carlo techiniques.

**12:27**
**H44 7 Comparison of the Superconductor to Insulator Transition in Nano-Perforated and Conventional Homogeneous Films*** M.D. STEWART, JR., JAMES M. VALLES, JR., *Dept. of Physics, Brown University* AIJUN YIN, J.M. XU, *Division of Engineering, Brown University* Near a critical resistance of 6.5 kOhms a quantum Superconductor to Insulator Transition (SIT) occurs in homogeneous ultra-thin films. We have measured this transition at dilution refrigerator temperatures in conventional

Bi/Sb films as well as Bi/Sb films that are perforated by a regular array of holes. The perforations are separated by an amount ( $\sim$ 100nm) that is much less than the penetration depth but on the same scale as the coherence length. We will compare these transitions to determine whether the macroscopic normal state sheet resistance (measured over many perforations) or the microscopic (characteristic of the links between holes) normal state sheet resistance determines whether a film is on the insulating or superconducting side of the transition. We will discuss how the results provide insight into the relative influences of vortex and quasiparticle fermionic degrees of freedom on the SIT.

*This work has been supported by the NSF through DMR-0203608, AFRL, and ONR.

**12:39**

**H44 8 Continuous Phase Transition of the Fully Frustrated 3D XY Model with a Magnetic Field in the [111] Direction*** KWANGMOO KIM, DAVID STROUD, *The Ohio State University* We study the fully frustrated three-dimensional XY model on a simple cubic lattice. This model describes a 3D array of superconducting grains in an applied magnetic field $\mathbf{H} = (\Phi_0/a^2) \times(1/2,1/2,1/2)$. Using standard Metropolis Monte Carlo simulations with periodic boundary conditions, we obtain the internal energy $U$, the specific heat $C_V$, and the helicity modulus $\gamma$ of our system. Our results support the conclusion that our system has a continuous phase transition between two liquid-like phases. Disorder in the low-temperature phase is suggested by the behavior of the vortex density-density correlation function at a very low temperature, $T = 0.01J/k_B$. By contrast, previous results for $\mathbf{H} = (\Phi_0/a^2)(1/3,1/3,1/3)$ indicate a first-order phase transition. Mean-field theory suggests a possible explanation for the liquid-like low-temperature phase: there are four degenerate unstable modes at the mean-field transition temperature $T_c^{\mathrm{MF}}$. We also use finite-size scaling and two renormalization group methods to determine the critical exponents $\alpha$, $\upsilon$, and $\nu$ for $C_V$, $\gamma$, and the correlation length $\xi$. We compare our values of these critical exponents with those for other phase transitions.

*This work was supported by NSF Grant DMR04-13395. All calculations were carried out on the P4 Cluster at the Ohio Supercomputer Center.

**12:51**

**H44 9 Noise and Phase Transitions** ZHI CHEN, CLARE C. YU, *University of California, Irvine* Noise is present in many physical systems and is often viewed as a nuisance. Yet it can also be a probe of microscopic fluctuations. There have been indications recently that the noise in the resistivity increases in the vicinity of the metal-insulator transition. But what are the characteristics of the noise associated with well-understood first and second order phase transitions? It is well known that critical fluctuations are associated with second order phase transitions, but do these fluctuations lead to enhanced noise? We have addressed these questions using Monte Carlo simulations to study the noise in the 2D Ising model which undergoes a second order phase transition, and in the 5-state Potts model which undergoes a first order phase transition. We monitor these systems as the temperature drops below the critical temperature. At each temperature, after equilibration is established, we obtain the time series of quantities characterizing the properties of the system, i.e., the energy and magnetization per site. We apply different methods, such as the noise power spectrum, the Detrended Fluctuation Analysis (DFA) and the second spectrum of the noise, to analyze the fluctuations in these quantities.

**13:03**

**H44 10 Percolation quantum phase transitions in diluted magnets** THOMAS VOJTA, *Department of Physics, University of Missouri-Rolla* JOERG SCHMALIAN, *Department of Physics and Astronomy and Ames Laboratory, Iowa State University* We show that the interplay of geometric criticality and quantum fluctuations leads to a novel universality class for the percolation quantum phase transition in diluted magnets. All critical exponents involving dynamical correlations are different from the classical percolation values, but in two dimensions they can nonetheless be determined exactly. We develop a complete scaling theory of this transition, and we relate it to recent experiments in $La_2Cu_{1-p}(Zn,Mg)_pO_4$. Our results are also relevant for disordered interacting boson systems.

**13:15**

**H44 11 Competing order in a 3D antiferromaget** KEVIN BEACH, *Boston University* It has long been believed that systems of interacting spins can support, in addition to the usual collinear Néel state, a variety of paramagnetic ground states with resonating or static valence bond order. Confirmation of their existence in candidate models has been complicated by the fact that the frustrating interactions that might support these exotic phases are generally sign problematic and not amenable to exact numerical simulation. Recent advances in projector valence bond Monte Carlo [A. W. Sandvik, Phys. Rev. Lett. **95**, 207203 (2005)], however, have expanded the limited class of models that can be simulated. This algorithm is compatible with a class of SU(2) invariant interactions that suppress antiferromagnetism. In particular, a continuous transition (a candidate for a deconfined quantum-critical point) between an antiferromagnetic and columnar bond phase in 2D can be engineered by tuning the strength of a four-spin interaction. We consider a generalization of this interaction in a 3D antiferromagnet, where it is suspected that the Néel and bond-ordered phases are separated not by a single quantum critical point but by an extended spin liquid phase. New developments for the valence bond basis allow us to calculate higher-order spin correlations, Binder cumulants, and the spin stiffness.

**13:27**

**H44 12 Néel and disordered phases of coupled Heisenberg chains*** SAMUEL MOUKOURI, *University of Michigan* We use the recently proposed two-step density-matrix renormalization group method to study the effects of frustration in Heisenberg models with $S=\frac{1}{2}$ to $S=4$ in a two- dimensional spatially anisotropic lattice. We find that the system is made of nearly disconnected chains at the maximally frustrated point, $J_d/J_\perp = 0.5$, i.e., the transverse spin-spin correlations decay exponentially. This leads to the following consequences: (i) all half-integer spins systems are gapless, behaving like a sliding Luttinger liquid; (ii) for integer spins, there is an intermediate disordered phase with a spin gap, with the width of the disordered state is roughly proportional to the 1D Haldane gap.

*This work was supported by the NSF grant No DMR-0426775

**13:39**

**H44 13 Relevance of Disorder to Critical Behavior of Antiferromagnets** OMID NOHADANI, *University of Southern California* STEFAN WESSEL, *University Stuttgart, Germany* STEPHAN HAAS, *University of Southern California* We study the magnetic-field-induced antiferromagnetic order in cubic dimer systems with bond disorder. The critical exponents, in absence of randomness, were reported to be mean-field-like in 3D. Using stochastic series expansion quantum Monte Carlo simulations at ultra-low temperatures, we investigate the relevance of disorder to the critical behavior in the vicinity of a quantum critical point. Furthermore, we demonstrate that in the presence of bond disorder, a new Bose-glass phase separates the dimer spin liquid regime from the antiferromagnetically ordered phase. Since most of the experimentally probed compounds reveal traces of disorder, our results are significant for quantum phase transition studies.

**13:51**

**H44 14 Quantum disordered phase in bond-diluted two-dimensional Heisenberg antiferromagnets** RONG YU, TOMMASO ROSCILDE,*STEPHAN HAAS, *Department of Physics and Astronomy, University of Southern California* We investigate quantum phase transitions in the spin-1/2 Heisenberg antiferromagnet on square lattices with *inhomogeneous* bond dilution. It is shown that quantum fluctuations can be continuously tuned by inhomogeneous bond dilution, eventually leading to the destruction of long-range magnetic order on the percolating cluster. We find two multicritical points at which the magnetic transition separates from the percolation transition, taking a quantum nature. Beyond these multicritical points a quantum-disordered phase appears, characterized by an infinite percolating cluster with short ranged antiferromagnetic order. In this phase, the low-temperature uniform susceptibility diverges algebraically with non-universal exponents. This is a signature that the novel quantum-disordered phase is a *quantum Griffiths phase*, as also directly confirmed by the statistical distribution of local gaps. This study thus presents evidence of a genuine quantum Griffiths phenomenon in a two-dimensional Heisenberg antiferromagnet.

**14:03**

**H44 15 Universal adiabatic dynamics in the vicinity of a quantum critical point** ANATOLI POLKOVNIKOV, *Boston University* I will discuss temporal behavior of a quantum system under a slow external perturbation, which drives the system across a second order quantum phase transition. Despite the conventional adiabaticity conditions are always violated near the critical point, the number of created excitations still goes to zero in the limit of infinitesimally slow variation of the tuning parameter. It scales with the adiabaticity parameter as a power related to the critical exponents $z$ and $\nu$ characterizing the phase transition. I will support general arguments by direct calculations for the Boson Hubbard and the transverse field Ising models.

## SESSION H45: THEORETICAL METHODS IN STRONGLY CORRELATED ELECTRON SYSTEMS

**Tuesday Morning, 14 March 2006**
**348, Baltimore Convention Center at 11:15**
**A.J. Millis, Columbia University, presiding**

**11:15**

**H45 1 Analytic derivation of the equivalence between the Gutzwiller-projected BCS Hamiltonian and the t-J model at half filling** KWON PARK, *Korea Institute for Advanced Study* A connection between quantum antiferromagnetism and high $T_C$ superconductivity is theoretically investigated by analyzing the *t-J* model and its relationships to the Gutzwiller- projected BCS Hamiltonian. In particular, it is analytically shown that the ground state of the *t-J* model at half filling (i.e., the 2D antiferromagnetic Heisenberg model) is entirely equivalent to the ground state of the Gutzwiller- projected BCS Hamiltonian with strong pairing. The relationship between the ground state of the projected BCS Hamiltonian and Anderson's resonating valence bond state (i.e., the projected BCS ground state) is discussed.

**11:27**

**H45 2 Implications of the Low-Temperature Instability of Dynamical Mean Theory for Double Exchange Systems** CHUNGWEI LIN, ANDREW MILLIS, *Department of Physics, Columbia University* The single-site dynamical mean field theory approximation to the double exchange model is found to exhibit a previously unnoticed instability, in which a well-defined ground state which is stable against small perturbations is found to be unstable to large-amplitude but purely local fluctuations. The instability is shown to arise either from phase separation or, in a narrow parameter regime, from the presence of a competing phase. The instability is therefore suggested as a computationally inexpensive means of locating regimes of parameter space in which phase separation occurs.

**11:39**

**H45 3 A continuous-time impurity solver for dynamical mean field theory*** PHILIPP WERNER, ANDREW J. MILLIS, *Department of Physics, Columbia University* MATTHIAS TROYER, *Theoretical Physics, ETH Zurich* We present a new continuous-time impurity solver for dynamical mean field theory. The method is based on a diagramatic expansion in the quadratic part of the effective action, in contrast to a previous approach [A. N. Rubtsov et al., cond-mat/0411344], which uses an expansion in the interaction part. Interactions and chemical potentials are taken into account during the Monte Carlo sampling of certain collections of diagrams. Comparison to Hirsch-Fye QMC simulations shows that the new approach allows an efficient calculation of the Greens function even at very low temperatures.

*PW and AJM acknowledge support from NSF DMR 0431350

**11:51**

**H45 4 Correlated hybridization in transition metal complexes*** ARND HUBSCH, *Max-Planck-Institut für Physik komplexer Systeme, Nöthnitzer Str. 38, 01187 Dresden, Germany* JONG-CHIN LIN, JIANPING PAN, DANIEL L. COX, *Department of Physics, University of California, Davis, CA 95616* We apply local orbital basis density functional theory (using SIESTA) coupled with a mapping to the Anderson impurity model to estimate the Coulomb assisted or correlated hybridization between transition metal

d-orbitals and ligand sp-orbitals for a number of molecular complexes. We find remarkably high values which can have several physical implications including: (i) renormalization of effective single band or multiband Hubbard model parameters for the cuprates and, potentially, elemental iron, and (ii) spin polarizing molecular transistors.

**H45 5 Exactly solvable Hamiltonian for the chiral spin liquid** DARRELL SCHROETER, *Occidental College* ELIOT KAPIT, *Reed College* An exact spin Hamiltonian for the chiral spin liquid will be presented. The model starts with the quantum Hall wave function on a lattice of N sites in a toroidal geometry, a state that describes a spin liquid that violates the symmetries of parity and time reversal. A parent Hamiltonian for which the state is the exact ground state is constructed out of vector operators that annihilate the ground state. This model avoids the subtle error that has been identified [D. F. Schroeter, Ann. Phys. **310**, 155 (2004)] in Laughlin's original solution to the problem [R. B. Laughlin, Ann. Phys. **191**, 163 (1989)]. The construction of the model and its numerical verification will be presented.

**12:15**

**H45 6 Spin Glass Solution to the Double-Exchange Model in Infinite Dimensions** RANDY FISHMAN, *Oak Ridge National Lab* JUANA MORENO, *University of North Dakota* THOMAS MAIER, GONZALO ALVAREZ, *Oak Ridge National Lab* FLORENTIN POPESCU, *Florida State University* Using dynamical mean-field theory, we have evaluated the magnetic instabilities and T=0 phase diagram of the double-exchange model on a Bethe lattice in infinite dimensions. In addition to ferromagnetic (FM) and antiferromagnetic (AF) phases, we also study a broad class of spin-glass (SG) solutions with extensive entropy and short-range magnetic order. In the weak-coupling limit, a SG has a higher transition temperature than the AF phase for all fillings p below 1 and can even have a higher transition temperature than the FM phase. At T=0 and for small Hund's coupling, a SG has lower energy than either the FM or AF phases for $0.26 < p < 1$. Phase separation is absent as the Hund's coupling vanishes but appears for any non-zero value. Our T=0 phase diagram agrees remarkably well with Monte-Carlo results in two and three dimensions. The stability of a SG at T=0 can be understood by examining the interacting density-of-states, which is gapped for any nonzero Hund's coupling in an AF but only when the Hund's coupling exceeds a critical value in a SG.

**H45 7 Bound states, symmetry breaking, and memory effects in doped $t - J$ $Y$-junctions** JURIJ SMAKOV, SASHA CHERNYSHEV, STEVE WHITE, *UC Irvine* The effect of strong electronic correlations on the properties of the weakly doped $Y$-junctions is studied within the $t - J$ and $t - J_z$ models using an analytical Green's function approach and DMRG. It is shown that the bound state at the junction depends counter-intuitively on the strength of the correlation: the bound state exists for the range of $0 < J/t < J/t|_c$, where at $J = 0$ ($U \to \infty$) the problem maps on the free-electron one, while the bound state disappears above the critical value of $J/t|_c \approx 0.47$ as the correlations weaken. Such a bound state also shows a dynamic symmetry breaking between the legs of the junction: the charge density is distributed unevenly among the legs. It is also demonstrated that the $Y$-junction with the Ising anisotropy can exhibit peculiar type of memory effects for charge transport.

**H45 8 Quasiparticle self-consistent GW method applied to f systems** MARK VAN SCHILFGAARDE, ATHANASIOS CHANTIS, TAKAO KOTANI, *Arizona State University* ANDRE PETUKHOV, *South Dakota Tech* We have applied the recently-developed quasi-particle self-consistent $GW$ method (QPsc$GW$) to several f systems, Gd, GdN, GdAs, ErAs, and CeO2. The QPsc $GW$ is desigened to determine the best independent particle picture; it can cover rather wide-range of materials, semiconductor to transion metal oxides with acceptable accuracy [1] [2] without any parameters. We found that QPsc$GW$ gives reasonable description of the f level positions and exchange splitting, though it predicts unoccupied f levels a little too high. In addition, the Fermi surface analysis shows that SdH frequencies and carrier concentration are in good agreement with available experimental data. [1] Mark van Schilfgaarde, Takao Kotani, and Sergey V. Faleev, cond-mat/0510408 [2] A. N. Chantis, Mark van Schilfgaarde, Takao Kotani, cond-mat/0508274.

**H45 9 Fermi arcs and hidden zeros of the Green function in the pseudogap state** TUDOR STANESCU, *University of Illinois at Urbana Champaign* GABRIEL KOTLIAR, *Rutgers University* We investigate the evolution of the low energy properties of a correlated metal in the proximity of a Mott insulator within the planar Hubbard model. We use a generalized version of the Cellular Dynamical Mean Field Theory having cumulants as the basic irreducible objects for re-constructing the lattice quantities from their cluster counterparts. We find that the zero temperature one particle Green function is characterized by the appearance of lines of zeros, in addition to a Fermi surface which changes topology as a function of doping. We show that these features are directly related to the opening of a pseudogap in the one particle spectrum and provide a simple picture for the appearance of Fermi arcs.

**13:03**

**H45 10 Incompressible Quantum Liquids and New Conservation Laws** ALEXANDER SEIDEL, HENRY FU, DUNG-HAI LEE, JOEL MOORE, *Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720* JON MAGNE LEINAAS, *Department of Physics, University of Oslo, P.O. Box 1048 Blindern, 0316 Oslo, Norway* We discuss a class of Hamiltonians which, in addition to the usual center-of-mass (CM) momentum conservation, also have center-of-mass position conservation. We find that regardless of the particle statistics, the energy spectrum is at least $q$-fold degenerate when the filling factor is $p/q$, where $p$ and $q$ are coprime integers. Interestingly, the simplest form of Hamiltonian respecting this type of symmetry encapsulates two prominent examples of novel states of matter, namely the fractional quantum Hall liquid and the quantum dimer liquid. We explore the connection to the Hall liquid in some detail, and also discuss the possible relevance of this class of Hamiltonian to the search for featureless Mott insulators.

**13:15**

**H45 11 High-Temperature Criticality in Strongly Constrained Quantum Systems*** CLAUDIO CASTELNOVO, CLAUDIO CHAMON, *Boston University Physics Department* CHRISTOPHER MUDRY, *Paul Scherrer Institut* PIERRE PUJOL, *Ecole Normale Superieure de Lyon* The exotic nature of many strongly correlated materials at reasonably high temperatures, for instance cuprate superconductors in their normal state, has lead to the suggestion that such behavior occurs within a quantum critical region where the physics is controlled by the influence of a phase transition down at zero temperature. Such a scenario can be thought of as a bottom-up approach, with the zero temperature mechanisms finding a way to manifest critical behavior at high temperatures. Here we propose an alternative, top-down, mechanism by which strong kinematic constraints that can only be broken at extremely high temperatures are responsible for critical behavior at intermediate but still high temperatures. This critical behavior may extend all the way down to zero temperature, but this outcome is not one of necessity, and the system may actually order at low temperatures. We provide explicit examples of such high-temperature criticality when extra strong interactions are added to quantum Heisenberg, transverse field Ising, and some lattice bosonic models.

**H45 12 Search for ferromagnetism in a generalized Hubbard model with disorder** ERIK NIELSEN, R.N. BHATT, *Dept. of Electrical Engineering, Princeton University* While the Hubbard model on a hypercubic lattice in two and three dimensions is believed to have a ferromagnetic phase away from half filling, its extent and precise location has remained controversial. With the introduction of positional disorder, a random singlet/valence-bond glass state is stabilized at half filling over the conventional antiferromagnetic phase, which could lead to a considerable reduction in the regime of ferromagnetism. In this study, we have used a variety of numerical techniques, including exact diagonalization of small systems and numerical mean field methods to search for the possibility of ferromagnetism in a generalized Hubbard model with and without positional disorder, aimed at the system of hydrogenic centers in semiconductors. We will present our results showing the effects of positional disorder, of electron-hole asymmetry, and other properties applicable to real experimental systems of doped semiconductors. The possibility of setting up a renormalization scheme as for the half-filled case will be discussed.

**H45 13 Quantum Phase Transitions of Hard-Core Bosons on the Kagome Lattice** S. V. ISAKOV, *University of Toronto* R. G. MELKO, *Oak Ridge National Laboratory* K. SENGUPTA, *Saha Institute of Nuclear Physics* S. WESSEL, *University of Stuttgart* YONG BAEK KIM, *University of Toronto* We study hard-core bosons with nearest-neighbor repulsion on the kagome lattice at different filling factors using quantum Monte Carlo simulations and a dual vortex theory. At half-filling, the ground state of the system is always a uniform superfluid in contrast to the case of the triangular lattice. There exists a quantum phase transition from a superfluid to a valence bond solid phase away from half-filling. The possibility of unusual quantum criticality is investigated.

**H46 1 Gallium Nitride-Based Nanowire Radial Heterostructures for Nanophotonics.**
FANG QIAN, *Harvard University*

Semiconductor nanowires are attractive building blocks for the assembly of active photonics devices, providing a unique and flexible pathway for creating multicolor integrated nanophotonic systems beyond the limit of conventional planar structures. Realizing this potential will require novel electrically driven and interconnected nanowire building blocks with emission wavelengths that can be rationally tuned. To achieve this goal, we have exploited the controlled growth of well-defined GaN-based nanowire radial heterostructures, and their application as efficient and synthetically tunable multicolor light sources. Prepared by metal-organic chemical vapor deposition, these nanowire heterostructures consist of an n-GaN core and diverse multishells, including n-GaN/InGaN/p-GaN double heterostructures, n-GaN/InGaN/GaN/p-AlGaN/p-GaN single quantum well, and n-GaN/(InGaN/GaN)m/p-AlGaN/p-GaN multi-quantum well structures, where variation of indium mole fraction is used to tune emission wavelength. Transmission electron microscopy analysis shows that these nanowires are dislocation-free single crystals with triangular cross-sections and chemically distinct shells, while composition and thickness of individual shells are well controlled during synthesis. Under optical excitation, they exhibit strong photoluminescence consistent with bandgap emission of InGaN inner shell, and behave as freestanding Febry-Pérot optical cavities. Moreover, by contacting simultaneously n-GaN core and p-GaN shell, electroluminescence results demonstrate that in forward bias they function as high-brightness light-emitting diodes with tunable emission from 365 to 600 nm and high quantum efficiencies. The ability to synthesize rationally GaN-based nanowire radial heterostructures as electrically-driven, efficient and color-tunable light sources should open up significant potential for integrated photonics.

**H46 2 GaN nanorods grown on Si(111) substrates by plasma-assisted molecular beam epitaxy** CHING-LIEN HSIAO, LI-WEI TU, TONG-WEI CHI, MIN CHEN, *Department of Physics and Center for Nanoscience and Nanotechnology, National Sun Yat-Sen University, Kaohsuing 80424, Taiwan, Republic of China* Various GaN nanorod structures grown on Si(111) substrate are realized by plasma-assisted molecular-beam epitaxy. Evolution of the nanorod structure from isolated regular nanorods, to isolated non-regular nanorods, and to dense nanorods is well controlled by the GaN buffer structure. Adding the parameter of beam-equivalent pressure of N/Ga ratio to the nanorod growth, the density of the regular nanorod becomes also a controllable item. There are several combinations of rod density and diameter in the nanorod growth. High density-small diameter and low density-large diameter can be grown directly on the surface without buffer layer. Low density-small diameter, low density-large diameter, and high density-large diameter can be achieved by inserting a GaN buffer. Nanorod of single crystal wurtzite structure without dislocation was characterized by high-resolution transmission electron microscopy. Only Ga and N signals were detected by energy-dispersion x-ray spectroscopy analysis. Single freestanding nanorod was prepared to perform micro-Raman spectroscopy. Wurtzite-type Raman modes at different scattering configurations have small line width and indicate the high crystalline quality of the nanorod. Frölich interaction and the surface vibrational modes are observed at high laser power densities which will be discussed in detail.

**H46 3 GaN Overgrowth on GaN Nanocolumns by Molecular Beam Epitaxy*** K. L. AVERETT, J. E. VAN NOSTRAND, J. BOECKL, *Materials and Manufacturing Directorate* R. CORTEZ, J. D. ALBRECHT, *Sensors Directorate, Air Force Research Laboratory, Wright-Patterson Air Force Base, OH* GaN nanocolumns grown by plasma-assisted molecular beam epitaxy are explored as host structures for overgrowth of bulk-like GaN films. We investigate the layers of vertical GaN nanocolumns 90 $\pm$ 10nm in width which were grown on sapphire and alternate substrates. We present photoluminescence, x-ray diffraction, and microscopy data that indicates that the columns are unstrained, low-defect wurtzite GaN nanostructures. The nanocolumns form discontinuous layers with areal densities controlled by grown conditions. The nanocolumn layers are subsequently overgrown with thick GaN films and compared with commercial GaN template materials used for device fabrication. The overgrowth of GaN is studied as a function Ga flux and growth temperature. We present photoluminescence and Hall effect characterization of the overgrown layers. The microstructure and morphology are probed by atomic force, scanning and transmission electron microscopy, as well as x-ray diffraction.

**12:15**

**H46 4 Growth of ZnO Nanotube without catalyst and templates** YOKE KHIN YAP, *Michigan Tech University* SAMUEL MENSAH, *Michigan Tech University* VIJAYA KAYSTHA, *Michigan Tech University* Nanotubular structures of oxides materials have recently gained attention for their hydrophilic properties. These oxide nanotubes are attracting interest for biological applications including nanofuidic devices for single DNA molecule sensing, rapid disease diagnosis and DNA sequencing. Here we show that tubular cavities of ZnO can be directly grown on substrates without the use of catalyst and templates. This is obtained by the evaporation and the condensation of a mixture of ZnO and graphite powders in a double-tube vapor-phase transport system. Field-emission scanning electron microscopy (FESEM), high-resolution transmission electron microscopy (HRTEM), X-ray powder diffraction, Raman spectroscopy and photoluminescence (PL) were employed to study and characterize the tubular structures. Results show that these tubular structures were single crystals of pure hexagonal Wurtzite structure. Our results show that rapid cooling rate and deficiency of oxygen during cooling contributed to the tubular ZnO nanostructures. A growth model and possible reasons for the growth of ZnO nanotubes will be discussed at the meeting.

**12:27**

**H46 5 Growth of ZnO Nanowires without the mixture of other ZnO nanostructures** SAMUEL MENSAH, *Michigan Tech University* VIJAYA KAYSTHA, *Michigan Tech University* YOKE KHIN YAP, *Michigan Tech University* We describe a new procedure to grow pure ZnO nanowires without the mixture of other ZnO nanostructures like nanobelts and nanocombs. A variety of ZnO nanostructures have been grown on oxidized Si substrates by a vapor phase transport process at temperatures ranging from 900 –500 deg. C. A mixture of ZnO and graphite powders are used as raw materials and result in the growth of nanobelts, nanocombs, and nanorods at various temperature zones when Au catalysts are used. We found that pure ZnO nanowires can be grown on catalyst free substrates. This is obtained at the temperature zone 500 to 600 deg. C, a region beyond those for growing nanobelts and nanorods. The crucial step is the need of an Au-coated substrate adjacent to the plain substrates. Long nanowires with uniform diameter less than 50 nm were obtained. Field-emission scanning electron microscopy (FESEM) analysis shows that the gold vapor from the adjacent substrates creates the nucleation sites on the catalyst free substrates to initiate the nanowire growth. Characterization of these ZnO nanostructures was conducted by X-ray powder diffraction (XRD), high-resolution transmission electron microscopy (HRTEM), Raman spectroscopy and photoluminescence (PL). Details of these will be discussed in the meeting.

**12:39**

**H46 6 Exceptionally Bright Visible-wavelength Luminescence from Sulfur-doped ZnO Nanowires** JOHN V. FOREMAN, *U.S. Army Aviation and Missile RDEC, Redstone Arsenal, Alabama 35898 and Department of Physics, Duke University, Durham, North Carolina 27708* HONGYING PENG, *Department of Physics, Duke University* JIANYE LI, *Department of Chemistry, Duke University* SOOJEONG CHOI, *Department of Physics, Duke University* HENRY O. EVERITT, *U.S. Army Aviation and Missile RDEC and Department of Physics, Duke University* JIE LIU, *Department of Chemistry, Duke University* Sulfur-doped ZnO nanowires have been grown by the vapor-liquid-solid technique using ZnS and carbon as starting materials. The broadband, visible-wavelength emission of unprecedented brightness from these nanowires is characterized by steady-state and time-resolved spectroscopy. Energy transfer is explored by simultaneously studying the fast ( $<$ 50 ps) decay of band edge emission and the slow ( $>$ 5 ns) decay of the visible-wavelength emission as a function of temperature and excitation intensity. The contributions of sulfur doping and nanostructuring to the generation of this intense visible-wavelength emission are clarified by characterizing

ZnO nanowires and micropowders of different morphologies and dopant concentrations. The results can be understood in terms of a physically motivated rate equation model, for which several of the key parameters are experimentally constrained.

**12:51**

**H46 7 Optical properties of AlGaN/AlGaN microcavities containing GaN quantum wells** OLEG MITROFANOV, STEFAN SCHMULT, MICHAEL MANFRA, MICHAEL SERGENT, *Bell Labs, Lucent Technologies* RICHARD MOLNAR, *Lincoln Lab, MIT* The large oscillator strength and binding energy of excitons in GaN make GaN based microcavities attractive for studies of light-matter coupling. Lattice mismatch within the family of Nitride alloys, however, results in formation of many extended defects, which degrade optical quality of heterostructures and substantially increase inhomogeneous broadening of excitons. We will discuss optical properties of AlGaN/AlGaN microcavities for the spectral region around 350 nm grown by molecular beam epitaxy on thick GaN templates. The structural quality of the microcavities is maintained by compensating the compressive and tensile strains in the layers of the distributed Bragg reflectors (DBR). This approach results in the lowest elastic strain energy and allows the growth of thick coherently strained DBRs with reflectivity higher than 99%. We will present photoluminescence studies on GaN quantum wells incorporated inside microcavities and discuss exciton-photon coupling.

**13:03**

**H46 8 Studies of Enhanced Internal Quantum Efficiency of Photoluminescence from $Al_xGa_{1-x}N$ Alloys Displaying Nanoscale Compositional Inhomogeneities** GREGORY A. GARRETT, A. V. SAMPATH, C. J. COLLINS, W. L. SARNEY, H. SHEN, M. WRABACK, *US Army Research Lab, Sensors and Electron Devices Directorate, Adelphi, MD* AlGaN epilayers, grown by plasma-assisted molecular beam epitaxy, show internal quantum efficiency (IQE) for photoluminescence (PL) much higher than expected for growth on sapphire where high defect densities ( $> 10^{10}$ $cm^{-2}$) are generated. Results are similar to earlier successes seen in blue- green light emitting diodes (LEDs) incorporating InGaN active regions where carrier localization is seen due to indium segregation. With no predicted immiscibility gap for aluminum in GaN and no observed aluminum segregation, the IQE increase in our AlGaN layers is attributed to localization of carriers to regions of nanoscale compositional inhomogeneities (NCI) that inhibit movement of carriers to nonradiative sites. Subpicosecond time-resolved PL, using gated downconversion in a nonlinear optical crystal, is used to measure carrier capture dynamics from the bulk epilayers into these NCI regions. Rate equation modeling is used to estimate the density of NCI regions and to help understand the observed changes in IQE for NCI AlGaN epilayers grown under different conditions.

**13:15**

**H46 9 Wide bandgap semiconductor nanoclusters: Magnetism and UV photoluminescence** JIJI ANTONY, *University of Idaho* DAVID E. McCREADY, MARK ENGELHARD, CHONGMIN WANG, *Pacific Northwest National Laboratory* AMIT SHARMA, JOSEPH NUTTING, DANIEL MEYER, YOU QIANG, *University of Idaho* PACIFIC NORTHWEST NATIONAL LABORATORY COLLABORATION, Transition metal-doped ZnO is of great interest to current research due to its wide variety of applications in spintronic materials. We prepared 5% Ti, V, Co or Ni-doped ZnO nanoclusters using a third generation nanocluster source. TEM images show that the nanoclusters are monodispersive with a nanocrystalline size $<$ 10 nm. XRD patterns are identical to the bulk ZnO wurtzite structure. XPS detected the dopant elements in clusters and showed Ti in +4 oxidation state, V in +4 and +5, Co in +2, and Ni in +2 and +3. These analyses indicate that dopant elements do not exist as independent aggregates but are incorporated into the ZnO structure. All the doped ZnO nanoclusters are ferromagnetic above room temperature. Magnetic moments of Ni or V-doped ZnO are much larger than Ti or Co doped ZnO clusters at 300K. Double exchange interactions due to the mixed valance states can be the reason that Ni or V-doped ZnO clusters a better magnetic moment than the Ti or Co-doped clusters. UV-photoluminescence is observed at pure and low dopant concentration ZnO nanoclusters.

**13:27**

**H46 10 Microbeam High Resolution X-ray Diffraction and Reciprocal Space Mapping Characterization of Selective Area Grown InGaN/GaN Waveguides** A.A. SIRENKO, *New Jersey Institute of Technology* A. KAZIMIROV, S. CORNABY, D. H. BILDERBACK, *Cornell High Energy Synchrotron Source, CU* A. OUGAZZADEN, *Georgia Institute of Technology, GTL/Metz, France* B. NEUBERT, F. SCHOLZ, *Universitaet Ulm, Germany* We present microbeam high-resolution x-ray diffraction (HRXRD) and Reciprocal Space Mapping (RSM) analysis of InGaN/GaN-based MQW ridge-waveguide arrays for monolithically integrated optoelectronic devices. InGaN/GaN waveguides were produced by the MOVPE technique in the Selective Area Growth (SAG) regime with the width of 6 microns and the oxide mask widths varied between 2 and 14 microns. Synchrotron Radiation-based triple- axis HRXRD measurements with the angular resolution of 13 arcsec were carried out at CHESS with the x-ray beamsize of 10 microns. Strain, thickness, and Indium composition variation in the active region of the ridge waveguides have been measured for different configurations of the SAG mask. Gas-phase diffusion coefficients have been determined for In and Ga precursors. Strain-induced relaxation effects in the active regions have been studied using RSM analysis.

**13:39**

**H46 11 Magnetotransport investigation of spin-orbit interactions in high-mobility GaN/AlGaN heterostructures.** STEFAN SCHMULT, MICHAEL MANFRA, ALEX PUNNOOSE, MICHAEL SERGENT, *Bell Laboratories, Lucent Technologies* RICHARD MOLNAR, *MIT, Lincoln Laboratory* Spin-splitting in the conduction band of a two-dimensional electron gas (2DEG) in GaN/AlGaN single interface heterostructures with mobilities of $\sim$ 80.000$cm^2$/Vs is investigated utilizing low field magnetoconductivity measurements. The observation of a distinct antilocalization feature near zero magnetic field signals the presence of significant spin-orbit coupling. A spin-orbit coupling value in the Rashba formalism of $6x10^{-13}$eVÅ is extracted. For a typical 2DEG density of $\sim 10^{12}cm^{-2}$ this value of the coupling strength corresponds to a spin-splitting energy of 0.3meV at the Fermi edge. The observed value is unexpectedly high for a wide-bandgap semiconductor. This talk summarizes our studies of the carrier density, mobility, and temperature dependence of the magnetoresistance data.

**13:51**

**H46 12 Low-temperature peculiarities of AlGaN/GaN heterostructure transport.*** ANDRIY KURAKIN, SVETLANA VITUSEVICH, SERHIY DANYLYUK, NORBERT KLEIN, *Forschungszentrum Juelich, ISG 2, Germany* ALEXANDER BELYAEV, *Institute of semiconductor physics, Kiev, Ukraine* At present, AlGaN/GaN heterostructures are attracting a lot of scientific interest in semiconductor research and are extensively studied. Despite this there are a number of open questions concerning the low temperature properties of such systems with two-dimensional electron gas (2DEG). We report here our recent results on transmission-line model (TLM) patterns and high electron mobility transistor (HEMT) measurements in the temperature range of 0.3-10.0 K. A set of samples with different Al fractions of the barrier layer, wide bandgap spacer and different substrates were tested. It is important that accurate information on 2DEG systems becomes available with the systematic analysis of current-voltage characteristics of TLM patterns. The latter enables channel resistance to be extracted from total device resistance. It was found that channel conductance in low electric field shows metal-like temperature dependence. The peculiarities observed in low-temperature characteristics of AlGaN/GaN heterostructures are analyzed.

*The research is supported by Deutsche Forschungsgemeinschaft (Project KL 1342)

**J1 2 Mechanical Spectral Hole Burning – A Technique to Characterize Dynamic Heterogeneity*** XIANGFU SHI, QIAN QIN, GREGORY MCKENNA, *Texas Tech University* The Mechanical Spectral Hole Burning (MSHB) technique was developed and initially used to qualitatively characterize dynamic heterogeneity of polymer melts and solutions. Here we attempt to develop a quantitative relationship between the heterogeneity and the length scale, by developing a ''calibration'' for the dynamic heterogeneity, i.e. the frequency and magnitude of the burned hole and the size or length scale. Here we consider the local heterogeneity and well characterized structures of macroscopically homogeneous systems, such as miscible polymer blends and block copolymers in the disordered state, but approaching the phase boundary. We interrogate these materials using the MSHB method at different temperatures going through the phase boundary. Presently and for a styrene-isoprene-styrene triblock copolymer, we find that the hole amplitudes increase as the phase boundary is approached from the one-phase region, i.e., as the order-disorder transition is approached. Further work is ongoing to use miscible blends and other block copolymer systems to determine if the MSHB response can be related quantitatively to the known heterogeneities of the systems.

*Thanks to the ACS-PRF grant # 40615-AC7 for support of this project.

**J1 3 Ferromagnetic single-electron transistors fabricated by atomic force microscopy*** RUISHENG LIU, HAKAN PETTERSSON, *Center for Applied Matematics and Physics, Halmstad University, Sweden* LUKASZ MICHALAK, CARLO CANALI, *Div. of Physics Dept of Chemistry and Bimedical Sciences, Kalmar University, Sweden* LARS SAMUELSON, *Solid State Physics/Nanometer Consortium, Lund University, Sweden* We report on the fabrication and magneto-transport measurements of Ni/Au/Ni ferromagnetic single-electron transistors (F-SETs), fabricated by atomic force microscopy. By positioning a single Au disc (30 nm in diameter) into the gap between the Ni drain and source electrodes (of width 220 nm and 80 nm, respectively) step-by-step with Angstrom precision, and using plasma-processed $NiO_x$ as tunneling barriers, we can successfully fabricate F-SETs of high quality and substantial stability. The characteristic time interval of the device between two successive tunneling events is $\sim$ 10ps. The absence of any clear features in the transport related to the applied external magnetic field indicates that no spin-accumulation is maintained in the central Au disc. This interesting result indicates that the spin-relaxation time inside the central island should be shorter than 10ps. Based on these findings, we will discuss possible mechanisms of spin-relaxation in metal nanostructures triggered by spin-orbit interaction.

*This work is supported by the SSF as well as by VR in Sweden.

**J1 4 Molecular dynamics simulations of equilibrium and undercooled liquid Ni*** ALVARO POSADA-AMARILLAS, EFRAÍN URRUTIA-BAÑUELOS, ROBERTO NÚÑEZ-GONZALEZ, *Universidad de Sonora* I.L. GARZÓN, *Universidad Autonoma de México* Molecular dynamics computer simulations were performed for equilibrium and undercooled liquid Ni. The Gupta potential was used to mimic the interatomic metallic interaction for different thermodynamic states. The inherent structures formalism is used to explore the potential energy landscape, showing a competition between periodic crystalline order (fcc, rhcp and bcc) and regular and distorted icosahedral order. For undercooled liquid Ni, a correlation between the entropy and the change in the crystalline (fcc) and icosahedral order is shown. This is the first simulation study which shows an interplay between the

microstructural ordering in undercooled liquid metals and the entropy of the system.

*Acknowledge to POMEP for support and Dirección de Investigación y Posgrado, UNISON for computational resources on ACARUS

**J1 5 Elastic properties and phase stability of AgCl under external pressure*** ALEJANDRO BAUTISTA-HERNÁNDEZ, PEDRO H. HERNÁNDEZ, GREGORIO HERNÁNDEZ-COCOLETZI, J. FRANCISCO RIVAS-SILVA, *Universidad Autónoma de Puebla* Ab initio total energy calculations have been performed to study AgCl phase stabilities. Our calculations are done using the density functional theory within the local density approximation, for the exchange and correlation energies. The ion-electron interactions are treated with the Troullier-Martins pseudopotentials. We determine the equation of state and free energy in the B1 (NaCl) and B2 (CsCl) phases. To obtain the elastic constants, we take the second derivative of the total energy respect to the applied deformations in both B1 and B2 phases. Our calculated structural parameters of the phases B1 and B2 of AgCl are compared with those available experimental data and theoretical calculations based on the local density approximation. The stability analysis based on elastic coefficients yields a critical pressure of 6 GPa at which the ideal lattice of B1 structure becomes unstable against homogeneous tetragonal shear deformation. The B2 structure is unstable in the interval of pressures 0-25 GPa. Therefore, a pressure induced phase transition between the structures B1 and B2 is not allowed elastically. We also explore the atomic structure of AgCl in the KOH phase.

**J1 6 Single-Wall Gold Nanotubes** R. TUGRUL SENGER, *Bilkent University, Turkey* SEFA DAG, *Oak Ridge National Laboratory, USA* SALIM CIRACI, *Bilkent University, Turkey* In recent ultra-high-vacuum transmission-electron-microscopy experiments evidence is found for the formation of suspended single-wall nanotubes (SWNTs) of gold. Similar to carbon nanotubes, the (n,m) notation defines the structure of the gold SWNTs. Experimentally, only the (5,3) tube has been observed to form among several other possible alternatives. Using first-principles calculations we demonstrate that gold atoms can form both freestanding and tip-suspended, chiral, single-wall nanotubes. Although freestanding, infinite (5,5) tube is found to be energetically the most favorable, the experimentally observed suspended (5,3) tube corresponds to a local minimum in the variation of wire-tension with the radius of the structure, which explains the experimental finding. Similarly, we predict the (4,3) tube as a favorable structure yet to be observed experimentally. Analysis of band structure, charge density, and quantum ballistic conductance suggests that the current on these nanotubes is less chiral than expected, and there is no direct correlation between the numbers of conduction channels and helical strands. [1] R.T. Senger, S. Dag, and S. Ciraci, Phys. Rev. Lett. **93**, 196807 (2004).

**J1 7 Role of relativity in electron impact ionization** BIDHAN C. SAHA, *Florida A&M University, Florida-32307* ARUN K. BASAK, *University of Rajshahi, Rajshahi, Bangladesh* M. ALFAZ UDDIN, *University of Rajshahi, Rajshahi, Bangladesh* The recently modified MBELL parameters [1] are generalized in terms of nl quantum numbers and applied to few selective systems. We intend to describe the procedure and to report the excellent predictive role of this simple procedure [2]. [1] A. K. F. Haque, M. A. Uddin, A.K. Basak, K. R. Karim and B. C. Saha, Phys. Rev. A 76 (in press) [2] A. K. F. Haque, M. A. Uddin, A.K. Basak, K. R. Karim, B. C. Saha, and F. B. Malik, Phys. Rev. Lett (under consideration).

**J1 8 Density-Functional Calculation for the Junction between Metal and Semimetal** CHIN-SHENG WU, *Center for General Education, Yuan-Ze University, Nei-Li, Taiwan* . We apply the density-functional theory to calculate the junction characteristics between the metal and semimetal. We obtain the self-consistent solution of the charge distribution both when Fermi levels of the metal and semimetal are set equal and when they are set unequal. The differential junction capacitance is obtained by differentiating the areal charge density with respect to the shift of Fermi levels. The electronic structure, potential, differential junction capacitance for the interface are reported. Our calculations for the metal with the conduction electron densities r=2, 6, and 12 a.u., and the semimetal with r=24 a.u.

**J1 9 Asymmetric confinement of an electron in a double-well potential and its relation with molecular lasers** IVAN MARIN-ENRIQUEZ, JOSE LUIS MARIN-FLORES, GERMAN CAMPOY-GUERENA, RAUL RIERA-AROCHE, *Departamento de Investigacion en Fisica, Universidad de Sonora* The confinement of an electron in an asymmetric double-well is proposed as an alternative system in which transitions and tunneling between bound states can have a similar behavior as in double-square well structures, regarding lasing properties. We show that this system would be more reliable than actual devices, since the relevant factor related to its efficiency is sharper and can be shifted in wavelength in a wide range as compared with, namely, its closest partner, the square double-well potential. Since nowadays technology allows the deposition of atom by atom (or molecule by molecule) layers of active materials, we think that such a device is feasible of construction, and represents a very attractive subject for research at both experimental and theoretical physics.

**J1 10 Wannier-Like Functions of Cesium Under High Pressure** EVA ZUREK, *Max Planck Institute for Solid State Research* OVE JEPSEN, *Max Planck Institute for Solid State Research* OLE KROGH ANDERSEN, *Max Planck Institute for Solid State Research* At ambient pressures cesium metal is found in the body centered cubic structure. At higher pressures, it undergoes a series of phase transitions which are accompanied by an electronic transition of the valence *s* electron to *d*-like states. We first of all propose a procedure which may be used to obtain Wannier-like functions for metallic systems using the newly developed NMTO (Muffin Tin Orbitals of order *N*) method. Wannier-like orbitals for a subset of the experimentally determined crystal structures of cesium are calculated. The electron density obtained from these orbitals is compared with that obtained from standard LMTO calculations. These orbitals give clear evidence of the electronic transition: they are primarily *s*-like at ambient volumes and display an increasing amount of *d*-character for structures found at higher pressures.

**J1 11 The effect of M (M=Ti, Cr, V, Nb) on transport and elastic properties of nanolayered ternary carbides $M_2AlC$** JEFF HETTINGER, PETER FINKEL, SAM LOFLAND, *Rowan University* MICHEL BARSOUM, ADRISH GUPTA, *Drexel University* We report on a systematic investigation of the electronic, magneto-transport, thermal and elastic properties of the family of materials $M_2AlC$ where M is Ti, V, Cr or Nb in the temperature

range 4 to 300K. The elastic constants were measured for all compounds ultrasonic technique. The bulk moduli and anisotropic Young's moduli found to be varied in these compounds for various transition metal M. The Debye temperatures were high in the 640-710 K range and quite insensitive to composition. The Seebeck coefficient was a non-monotonic function of a temperature: at the lowest temperatures is small but increases with increasing temperature and saturates at 60-80 K and goes through zero again manifesting change in the dominating charge carrier type. The electrical conductivity, Hall coefficient and magnetoresistances are analyzed within a two-band framework assuming a temperature-independent charge carrier concentration. We concluded that there is little correlation between the Seebeck voltage and Hall number. As with other MAX-phase materials, all these materials are nearly compensated. Comparisons of these results will be presented. Results will be discussed in relation to theoretical work and recent measurements on related systems.

**J1 12 Vacancy Scanning Tunneling Spectroscopy of Ag (111)** DANDA P. ACHARYA, *Ohio University* KAI-F. BRAUN, *Ohiu University* SAW-WAI HLA, *Ohio university* We investigate the vacancy electronic structures on a Ag(111) surface at 4.6 K by using scanning-tunneling-microscopy (STM) manipulation and spectroscopy in an ultra-high-vacuum environment. The vacancies with single atom to over a hundred-atom sizes are created on atomically cleaned Ag(111) surface by controlled tip-sample contact and single atom manipulation. Conductance tunneling spectroscopy data are then acquired by using a lock-in amplifier attached to the STM. The shift of the on-set of Ag(111) surface state is observed in few-atom vacancies. For the larger vacancies, we are able to probe the bulk silver unoccupied s-p band using tunneling spectroscopy. This experiment demonstrates a unique capability of a combined STM manipulation and spectroscopy to probe bulk and surface properties of materials through engineered atom and nanoscale cavities. This work is financially supported by a US-DOE grant, DE-FG02-02ER46012, and a NSF-NIRT grant, DMR-0304314.

**J1 13 Analytic treatment of metallic multilayer strength at all length scales** LAWRENCE FRIEDMAN, LEI FANG, *Pennsylvania State University, Dept. of Engineering Science and Mechanics* Metallic multilayers can be used as ultra-high strength coatings. They exhibit a very pronounced size-effect where the mechanical strength depends on the layer thickness. Traditionally, the Hall-Petch Relation is used to describe the size effect. The Hall-Petch Relation is based on dislocation pileup theory, which states that the macroscopically observable strength is determined by dislocation obstacles and stress multiplication from pileups. However, more rigorous application of dislocation pileup theory as applied to multilayers predicts significant deviation from the Hall-Petch Relation due to elastic inhomogeneity, discreteness of dislocations and dislocation source operation. The necessary modifications to the Hall-Petch Relation are presented. An analytic formula accounting for these effects can only be obtained in a piecewise fashion. The variation of strength with layer thickness must be broken down into four length-scale regimes, and a simple analytic formula is obtained for each regime. This formulation allows one to bridge the length scales and predict multilayer strength from microscopic parameters (interface strength and dislocation source characteristics) and fundamental material parameters (elastic moduli, layer thickness and crystal structure). Finally, the theory is applied to Cu/Ni multilayers and theory prediction is compared with experimental data.

**J1 14 Low-temperature Superplasticity of Dual-phase $Ti_3Al$ Based Alloy** KAI-LIN YANG, CHIH-CHING HUANG, To date, the $Ti_3Al$ based alloys have been widely reported their admirable superplasticity within the temperature ranges of 900-1000$^o$C. However, the superplastic behavior of temperature lower than 900$^o$C was seldom reported. The current paper will be aimed on the superplastic behavior at lower temperatures (700-900$^o$C). The phase transformation of $\beta \rightarrow \alpha_2$ in the two-phase ($\alpha_2 + \beta$) region during static annealing and superplastic straining at 700-1000$^o$C was occurred in this ($\alpha_2 + \beta$) dual-phase alloy. In addition, the misorientation angle distributions and texture characteristics of the $\beta$ and $\alpha_2$ phases were examined by the electron backscattered diffraction (EBSD) to complete the deformation behavior. Under the optimum LTSP condition at 850$^o$C and the strain rate of $5x10^{-4}$ $s^{-1}$, texture evolution is also investigated. From the texture characteristics associated with microstructure, the transformation behavior related to the deformation behavior could be demonstrated more clearly. In this current study, the texture characteristics, phase transformation phenomena, and the deformation mechanism at lower temperatures (below 900$^o$C) will be related and discussed.

**J1 15 Abstract Withdrawn**

**J1 16 Designing Laser Pulses to Control Molecular Motion** QINGHUA REN, GABRIEL BALINT-KURTI, FREDERICK MANBY, *School of Chemistry, University of Bristol, Bristol, BS8 1TS, UK* MAXIM ARTAMONOV, TAK-SAN HO, HERSCHEL RABITZ, *Department of Chemistry, Princeton University, Princeton, New Jersey 08544* A new method for incorporating polarization effects of the strong electric field into optimal control calculations is presented. An Electric-Nuclear Born-Oppenheimer approximation is introduced in which both the nuclear motion and the fluctuations of the external electric field are assumed to be slow compared with the speed at which the electronic wavefunction responds to these changes, which permits the generation of a potential energy surface that depends not only on the geometry of the nuclei, but also on the electric field strength and on the orientation of the molecule with respect to the electric field. As an illustration, it is firstly applied to the optimal control of the vibrational excitation of a hydrogen molecule aligned along with the field direction.[1] And then it is extended to full three dimensions by allowing the $H_2$ molecules to rotate as well as vibrate.[2] All calculation results show that it is possible to design shaped laser pulses that can excite $H_2$ either vibrationally, rotationally or both with a probability higher than 90%. [1] G. G. Balint-kurti, F. R. Manby, Q. Ren, M. Artamonov, T. Ho, and H. Rabitz, J. Chem. Phys. 122, 084110 (2005). [2] Q. Ren, G. G. Balint-kurti, F. R. Manby, M. Artamonov, T. Ho, and H. Rabitz, J. Chem. Phys. (in press).

**J1 17 Auger Parameter of Aluminum in aluminum compounds*** A. CHOURASIA, R. MILLER, G. NIXON, *Texas A&M University-Commerce* X-ray photoelectron spectroscopy has been employed to study 1s core level of aluminum in elemental aluminum, and in various aluminum compounds. The XPS spectra in the various regions have been recorded in the high resolution mode. The zirconium anode (energy = 2042 eV) has been used to access the 1s core level of aluminum. The energy difference between the 1s core level and the x-ray excited Auger line of aluminum in the XPS spectrum has been used to calculate the Auger

parameter. Wagner plot has been constructed from these data. In this plot the insulating materials appear lower on the grid as compared to those showing metallic nature. The points do not lie on the same line with slope +1, distinctly indicating that aluminum exists in different chemical states in these materials. The estimation of bonding characteristics from this plot will be discussed.

*Faculty Enhancement Grant, TAMU-Commerce

**J1 18 Electronic Structure of $Sr_2RhO_4$ investigated by ARPES** SEUNGHYEOK LEE, BUM-JOON KIM, JAEJUN YU, SE-JUNG OH, *School of Physics and Center for Strongly Correlated Materials Research, Seoul National University, Seoul, Korea* CHANGYUNG KIM, *Institute of Physics and Applied Physics, Yonsei University, Seoul, Korea* I. NAGAI, S.I. IKEDA, *National Institute of Advanced Industrial Science and Technology, Tsukuba, Ibaraki 305-8568, Japan* We investigated the electronic structure of 4d-transition metal oxides $Sr_2RhO_4$by high-resolution ARPES(angle-resolved photoemission spectroscopy) and compared the results with density-functional electronic structure calculation. $Sr_2RhO_4$has the same crystal structure with $Sr_2RuO_4$and just one more electron than $Sr_2RuO_4$ in 4d orbitals. But ARPES data reveal very different Fermi surface from that expected in the simple rigid-band picture, and especially the electronic structure related to the $d_{xy}$ band-the full occupation and missing at Fermi surface of the $d_{xy}$ band- is qualitatively different from $Sr_2RuO_4$. This turns out to be due to the fact that $RhO_6$ octahedra are rotated about the c-axis. We will discuss how the rotation of octahedra change the electronic structure by comparing the ARPES experimental results with density-functional electronic structure calculation in real crystal structure of $Sr_2RhO_4$.

**J1 19 A Generalized Model for Dielectric Relaxation and Resonance** JAMES BAKER-JARVIS, MICHAEL JANEZIC, PAVEL KABOS, *NIST* In this paper we develop a very general model from our previously developed statistical mechanical theory that describes relaxation, resonance, with temperature dependence. We also analyze the model in terms of entropy and a generalized Lyddane-Sachs-Teller relationship. The model is based on a correlation function approach and complex relaxation time from our previously developed theory. The commonly used Cole-Cole, Cole-Davidson and other models are related to this model as a special case. Using a fluctuation-dissipation theorem, we develop an algorithm for extraction of the loss properties of nanowires.

## J1 20 SEMICONDUCTORS POSTER SESSION

**J1 21 HgSe Semiconductor Nanoclusters in Zeolite*** A.M.M. ABEYKOON, *University of Houston* E.A. ANOKHINA, MIGUEL CASTRO-COLIN, W. DONNER, A.J. JACOBSON, SIMON C. MOSS, Our primary challenge has been to produce HgSe semiconductor nanoclusters with a precise, controllable and narrow size distribution. Since a zeolite framework constrains the size and shape of species encapsulated within a pore, we use zeolite pores to contain our nanoclusters. Two different zeolite frameworks, Linde type L (tubular pore) and Faujesite (nearly spherical pore) are used in our study. Elemental Hg and Se are embedded into dehydrated zeolite cavities via vapor phase deposition. The AXS (Anomalous X-ray Scattering) technique is used in combination with the PDF (atomic Pair Distribution Function) technique to solve for the structure of the nanocluster. Optical absorption measurements are used to determine the band gap of the cluster. We intend to perform Raman Spectroscopy to complement our determination of local structure and to probe the electronic properties of the semiconductor nanoclusters. AXS and PDF data sets were collected at X7A beam line at the NSLS. Optical measurements were carried out in the UH Chemistry Department. Currently we are analysing our x-ray data sets to yield a successful model for the nanoclusters.

*DOE

**J1 22 Crystallographic analysis on growth process of GaAs nanocrystals deposited onto Si(100) surface** HIROYUKI USUI, *Venture Business Laboratory, Kobe University, Nada, Kobe 657-8501, Japan* KENSUKE YAMADA, *Department of Mechanical Engineering, Kobe University, Nada, Kobe 657-8501, Japan* HIDEHIRO YASUDA, *Department of Mechanical Engineering, Kobe University, Nada, Kobe 657-8501, Japan* HIROTARO MORI, *Research Center for Ultra-High Voltage Electron Microscopy, Osaka University, Yamadaoka, Suita, 565-0871, Japan* Crystallographic analysis on growth process was carried out for GaAs nanocrystals deposited onto Si(100) by molecular beam epitaxy. Equilibrium crystal shapes of the GaAs nanocrystals at each growth stage were observed by cross-sectional transmission electron microscopy. At the initial growth stage, Stranski-Krastanov wetting layer and facetted nanocrystals with lower aspect ratio were formed. The GaAs nanocrystals at the middle growth stage formed regular pyramids consisting of {111} planes. At the later stage, the shape of GaAs nanocrystals was changed to dome structure consisting of {111} and {311} planes which has lower aspect ratio. This indicates that the GaAs nanocrystals introduced {311} facets to minimize the total surface free energy at the later stage because the surface free energy of {311} facets is smaller than that of {111} facets.

**J1 23 Study of Interfacial Water Layer during Pentacene Monolayer Deposition** SONGTAO WO, BINRAN WANG, YIPING WANG, RANDALL HEADRICK, *University of Vermont* ALEXANDER KAZIMIROV, *Cornell High Energy Synchrotron Source, Cornell University* This study includes the formation of pentacene monolayer on SiO2 substrate. itIn situ synchrotron x-ray scattering was used to probe the early stages of pentacene growth in real time and under conditions relevant to the fabrication of Organic Thin Film Transistors (OTFTs). Reflectivity measurements reveal that there is interfacial water layer between the pentacene monolayer and SiO2, which initially present on the substrate, and is trapped at the interface when the pentacene film is deposited. Anti-Bragg oscillations, observed for the first time during organic film growth, reveal that the first monolayer of pentacene completes fully before the second one nucleates.

**J1 24 3D Simulation of Phonon Modes in Semiconductor Nanocrystals*** NICHOLAS JURASEK, SHANG-FEN REN, WEI CHENG, *Illinois State University* The goal of this current research is the visualization of different phonon modes of NCs with 3D simulation to help in the understanding of their behavior. In order to realize this goal, the numeric data output from the previous atomistic model calculations is used that provides a list of

positions of atoms in NCs, the vibration frequencies and the displacement vectors of atoms in each phonon mode. These phonon modes are organized in different symmetries. Methods of visualizing the movement of these atoms are searched, and VMD from the University of Illinois is chosen as the best method to carry out it. VMD can create a 3-D image based on the positions and displacements of atoms, and it allows the user to rotate the structure around and to also ''fly'' through the structure. To use VMD, a program to convert the output of the simulation program into something that VMD can read is created. In this presentation, how VMD is used to carry out the 3D simulation of phonons in NCs will be discussed, and some interesting simulation results will be presented. These simulations can be used to understand more about the phonons and their related properties of NCs.

*This research is supported by an award from the Research Corporation (CC6274).

**J1 25 Determination of electron penetration depth and stopping power of amorphous AlN using luminescence of Tm and Ho ions** MUHAMMAD MAQBOOL, *Mount Olive College* MARTIN KORDESCH, *Ohio University* Electron penetration depth and stopping power of amorphous AlN is determined using luminescence of $Tm^{+3}$ and $Ho^{+3}$ ions. Thin film bilayers of AlN:Ho and AlN:Tm are deposited on flat Silicon substrates by RF Magnetron sputtering at liquid nitrogen temperatures. In making a bilayer, 15.3 nm thick AlN:Ho film is first deposited on a flat Si(111) substrate of $2\times$ 2 $cm^2$ surface area. On the top of this AlN:Ho film 37.8 nm thick AlN:Tm film is deposited to make it a bilayer. Electron beam of different energies, obtained from electron gun of the CL apparatus, is allowed to penetrate in the AlN:Tm/AlN:Ho bilayer film. Blue emission from $Tm^{+3}$ as a result from $^1D_2 \rightarrow {}^3F_4$ transition and green emission from $Ho^{+3}$ as a result from $^5S_2 \rightarrow {}^5I_8$ transition were used to track the electron beam penetrating in the bilayer. Energy of the beam just crossing 37.8 nm AlN:Tm film is recorded to obtain the stopping power experimentally. Experimental results are compared to the theoretical value using the established mathematical equations for stopping power. A percent deviation of 6.6% is found in the experimental and theoretical results.

**J1 26 Diffusion doping and Infrared Optical Properties of Transition Metal Ions in ZnSe windows and $Cd_{0.55}Mn_{0.45}Te$ crystals** EI NYEIN, UWE HOMMERICH, IVY JONES, MONIQUE CALHOUN, ERICA HAYNES, *Hampton University* SUDHIR TRIVEDI, *Brimrose Corporation of America* Transition metal (TM) doped II-VI semiconductors are of current interest for tunable solid state lasers in the mid-infrared (IR) spectral region as well as passive optical Q-switches. Laser action has been demonstrated at $\sim$ 2.3 $\mu$m from Cr: ZnSe, Cr: ZnS, Cr: CdSe, Cr: CdTe, Cr: Cr: CdMnTe, and at $\sim$ 4 $\mu$m from Fe: ZnSe. In this work, we report on the material preparation and IR optical properties of diffusion-doped TM ions ($Cr^{2+}$, $Fe^{2+}$, $Co^{2+}$) in polycrystalline ZnSe windows and $Cd_{0.55}Mn_{0.45}Te$ crystals. Different dopant sources were employed in thermal diffusion experiments including TM chloride compounds, TM selenides, and elemental TM powders. The characteristic IR absorption bands from $Cr^{2+}$, $Co^{2+}$, and $Fe^{2+}$ doped II-VI hosts were observed in all samples, independent of the dopant source. Details of the absorption and luminescence properties of these TM: ZnSe and TM: CdMnTe samples will be presented at the conference.

**J1 27 On the transfer matrix method and WKB approximation for systems with spatial-dependent effective mass** CHUN-FENG HUANG, *National Measurement Laboratory, Center for Measurement Standards, Industrial Technology Research Institute, Hsinchu 200, Taiwan, R. O. C.* S.D. CHAO, *Institute of Applied Mechanics, National Taiwan University, Taipei, Taiwan, R. O. C.* D.R. HANG, *Department of Materials Science and Optoelectronic Engineering, National Sun Yat-sen University, Kaohsiung 804, Taiwan, R. O. C.* Y.C. LEE, *Institute of Materials Science and Engineering, National Sun Yat-sen University, Kaohsiung 804, Taiwan, R. O. C.* A set of coupled differential equations is derived by considering the continuous limit of the transfer matrix method, which is a numerical approach for the one-dimensional structures such as the semiconductor heterostructures. By decoupling such a set of equations, an extension to the Wentzel-Kramers-Brillouin (WKB) method is obtained to incorporate effects due to the spatial-dependent effective mass. For a traveling wave, the decoupling is to ignore the reflection resulting from the variations of both the potential and effective mass. By considering a solvable fully-quantized system, it is shown that the extended WKB method provides good approximation for the states with the high eigenenergies.

**J1 28 Unusual excitation spectra of magnesium-related donor impurities in silicon** L.T. HO, *Institute of Physics, Academia Sinica, Taipei, Taiwan* It is well known that the group-II magnesium, when diffused into silicon, enters the silicon lattice interstitially and behaves as a helium-like double donor. Magnesium has also been found to be able to pair with dispersed oxygen in silicon to form magnesium-oxygen complex impurity, which is an interstitial double donor as well. Previous studies on the excitation spectra of these helium-like impurities indicate that the excited states of neutral magnesium donor or neutral magnesium-oxygen complex donor are all similar to those of hydrogen-like group-V donor impurities in silicon. Recently, however, from further study of the excited spectra of these magnesium-related donor impurities, we have observed some very unusual result totally unexpected and clearly different from a typical donor spectrum in silicon.

**J1 29 LDA density functional study of lithium intercalated compounds in grephite** JUAN SALVADOR ARELLANO, *Area de Fisica Atomica Molecular Aplicada, UAM Azcapotzalco, 02200, Mexico D.F.* PABLO DE LA MORA, *Depto. de Fisica, Fac. de Ciencias, UNAM, Mexico* M. J. LOPEZ, L. M. MOLINA, J. A. ALONSO, *Departamento de Fisica Teorica, Universidad de Valladolid, 47011, Valladolid, Spain* Local Density Functional (LDA) calculations have been done for different lithium intercalated graphite compounds. We have explored the most common ones namely $LiC_6$, and $LiC_2$. Also the $LiC_3$ has been studied. To explain some details about the structural and electronic properties of the last one, we have used two computer codes, FHI98MD and WIEN2k. This was motivated by a recent work for the $LiC_3$compound, where it is said that lithium atoms positions are not in the middle plane between the graphene layers formed by the carbon atoms. Discussion of the three mentioned lithium intercalated compounds and somewhat about the superconductivity will be given during the presentation.

**J1 30 Electronic structure of V-doped TiO2** YUSHAN WANG, *University of Delaware* First-principles calculations using the full-potential linearized augmented plane-wave method have been performed to investigate the electronic structure of V-doped TiO2 in the anatase modification. In calculations with local density approximation (LDA) plus U ( Hubbard coefficient) approach, V 3d states were found to be completely spin- polarized with net magnetic moment generated.

**J1 31 Structural deformation and instability of strong covalent solids*** CHANGFENG CHEN, *University of Nevada, Las Vegas* HONG SUN, *Shanghai Jiaotong University* We employ first principles total-energy calculations to study the structural deformation modes at large strains and the lattice instabilities beyond the elastic limit for several strong covalent solids. We examine the atomistic bonding changes to elucidate the microscopic mechanism for the stress response and the orientational dependence of the peak stresses along different crystallographic directions and the bond breaking modes. Implications for the mechanical properties will be discussed.

*This work was supported in part by the Department of Energy

**J1 32 The 4x4 spin 1/2 representation in electron polarization in a magnetic field** KESHAV SHRIVASTAVA, *University of Hyderabad* We introduce a 4x4 spin representation for spin 1/2. There are two spin orientations for a given value of $g_+$ and two for $g_-$ which arise for two signs of spin. This theory produces factors which affect the product m*g* so that if these factors are not taken into account, much larger values of the electron mass than those of the electron mass in a band arise. This predicted phenomenon is in accord with the experimental data. Similarly we find that factors arise in cyclotron frequency which affect the magnetoresistance and hence the g values. Accordingly, large g values are measured in the experimental data. When our factors are taken into account, the g values compare well with band values. The $g^* = g_\pm - \delta$ describes the shift due to many-body interactions.

**J1 33 An alternative model of the integer quantum Hall effect** TOBIAS KRAMER, *Physics Department Harvard University* Contrary to common belief, the current emitted by a contact embedded in a two-dimensional electron gas (2DEG) is quantized in the presence of electric and magnetic fields. This observation suggests a simple, clearly defined model for the quantum current through a Hall device that does not invoke disorder or interactions as the cause of the integer quantum Hall effect (QHE), but is based on a proper quantization of the classical electron drift motion. The theory yields a quantitative description of the breakdown of the QHE at high current densities that is in agreement with experimental data. Furthermore, several of its key points are in line with recent findings of experiments that address the dependency of the QHE on the 2DEG bias voltage, results that are not easily explained within the framework of conventional QHE models. For additional information, see also http://arxiv.org/abs/cond-mat/0509451 (accepted by IJMPB) and the article references on http://people.deas.harvard.edu/~tkramer.

**J1 34 Determination of the structure of ZnS:$ErF_3$ TFEL phosphors using XAFS** STANISLAV STOUPIN, *Illinois Institute of Technology* CARLO SEGRE, *Illinois Institute of Technology* MARK DAVIDSON, *University of Florida* PAUL HOLLOWAY, *University of Florida* Many phosphor systems that provide useful levels of IR emission have a poor match between dopant atom and the host structure. An example of such a system is ZnS doped with rare-earth elements incorporated into the host as trivalent ions. For example, the size of Er is quite large compared to Zn and it does not easily substitute into the same crystallographic site. We have prepared a number of $ErF_3$ 1 mol% doped ZnS thin film electroluminescent (TFEL) phosphors using RF magnetron sputtering followed by annealing at various temperatures. The intensity of the IR emission is found to be very sensitive to the post-deposition annealing. As the local chemical and structural environment of the dopant atom is very important to the performance of the phosphor we have used x-ray absorption fine structure spectroscopy (XAFS) to provide detailed information on the local environment surrounding the Er atom. The XAFS spectra are consistent with Er-F complex substitution into the Zn site accompanied by creation of S vacancies. The ZnS host lattice reveals significant disorder effects in the first Zn-S coordination shell. These structural features change with annealing temperature and are likely responsible for the observed changes in intensity of the various Er emission lines.

**J1 35 Surface modification of InP wafers by pulsed UV laser radiation below ablation threshold** OMAR MUSAEV, *UMKC* O.-S. KWON, *UMKC* D.-M. ZHU, *UMKC* D. WIELICZKA, *UMKC* J. WROBEL, *UMKC* SURFACXE SCIENCE TEAM, Under multi-pulse laser irradiation below the threshold of ablation modification of surface layer of semiconductor can happen. The creation of point defects may lead to their subsequent aggregation and cause macroscopic damage of the irradiated surface if the number of pulses is large enough despite that the fluency is lower than ablation threshold. Low energy pulsed laser irradiation may also cause different structural changes in the surface layer of a compound semiconductor which manifests itself in changes of physical and chemical parameters of the surface. The surface of InP wafer irradiated by different numbers of pulses with different fluences below ablation threshold was analyzed with AFM and XPS. Mechanisms of defect creation and aggregation in InP surface under low intensity laser irradiation are discussed.

**J1 36 Capacitance Dispersion in GaN Grown by Molecular Beam Epitaxy** MO AHOUJJA, REX BERNEY, SAID ELHAMRI, *University of Dayton, Dayton OH* YUNG KEE YEO, *ENP/AFIT, W-PAFB OH* UNIVERSITY OF DAYTON, DAYTON OH TEAM, GaN semiconductors are of great interest for applications in high-temperature and high-frequency electronic devices as well as blue to UV light emitting and detecting devices. However, an understanding of the role of dopants and defects in these semiconductors is essential for the realization of high performance devices. Si doped GaN samples grown by radio-frequency plasma activated molecular beam epitaxy on sapphire substrates were characterized by capacitance-voltage (C-V) measurements. The C-V measurements were performed with an LCR meter in series mode with an AC modulation level of 50 mV in the frequency range of 500 Hz to 1MHz. The junction capacitance of the Schottky diodes varied with both temperature and frequency. The variation of capacitance with frequency is known as capacitance dispersion. This dispersion is generally attributed to the slow response of deep levels to the high frequency AC signals. Consequently, it is suggested that native defects in GaN play a role in the observed capacitance dispersion.

**J1 37 Intervalley Transitions in GaN Single Crystals** S. WU, D. WANG, R. SOBOLEWSKI, *University of Rochester, Rochester, NY 14627* P. GEISER, J. JUN, J. KARPINSKI, *ETH, CH-8093 Zurich, Switzerland* We present the direct observation of the intervalley transition of electrons between the conduction band $\Gamma$ valley and the L valley in GaN single crystals, using the two-color

(ultraviolet-near infrared), femtosecond, pump-probe spectroscopy technique. We have found that scattering of electrons from the Γ to L valley is faster than the optical phonon emission time, while the return process of electrons from L to Γ is measurably slower. The developed model based on three-state rate equations fitted very well our experimental results. The fitting parameters showed that the Γ– L scattering time is ~ 250 fs, while the L–Γ return time is ~ 1 ps. The optical phonon emission time was found to be equal to ~ 500 fs. The characteristic scattering times obtained in our experiments demonstrate that the dynamics of the intervalley transition process in GaN is substantially slower than the similar transitions earlier observed for GaAs.

**J1 38 Positron annihilation induced Auger electron emission from silicon carbide surfaces** S. MUKHERJEE, M. NADESALINGAM, *University of Texas at Arlington* G. BRAUER, *Institut für Ionenstrahlphysik und Materialforschung, Forschungszentrum Rossendorf* T. NOZAWA, A. KOHYAMA, *Institute of Advanced Energy, Kyoto University* A.H. WEISS, *University of Texas at Arlington* Silicon carbide (SiC) in monocrystalline, hexagonal polytype form is a very interesting material for a wide class of novel applications in electronics. SiC fiber-reinforced SiC matrix composite materials (SiC/SiC) are considered to be the attractive candidates as materials for advanced energy systems, such as high performance combustion systems, fuel-flexible gasification systems, fuel cell / turbine hybrid systems, nuclear fusion reactors, and high temperature gas-cooled fission reactors. Positron Annihilation induced Auger Electron Spectroscopy (PAES) is an established tool to characterize the top most atomic surface layer of solids. Here, PAES has been used to study the surface of 6H-SiC after annealing under different thermal and ambient conditions. In addition, results of investigating the surface of a composite consisting of sintered SiC Nanopowder and fibres of pyrolytic carbon are presented and discussed. This research supported by the Welch Foundation under Y-1100.

**J1 39 Anisotropy in the Amplitude of Shubnikov-de Haas Oscillations in AlGaN/GaN Heterostructures** S. ELHAMRI, R. BERNEY, M. AHOUJJA, G. LANDIS, *University of Dayton* W. MITCHEL, W. MITCHELL, *Wright Patterson Air Force Base* Variable temperature resistivity and Hall effect measurements were performed on several AlGaN/GaN heterostructures. The temperature dependence of the mobility and carrier density extracted from these measurements indicated the presence of a good quality two dimensional electron gas. At liquid helium temperatures, the carrier density and mobility in these samples ranged from about 2 x $10^{12}$ to roughly 1 x $10^{13}$ $cm^{-2}$ and from about 4000 to more than 50000 $cm^2$/Vs respectively. Variable field magnetoresistance studied were also conducted on several of these van der Pauw shaped samples at 1.2 K in fields up to 8 T. These measurements revealed the presence of Shubnikov-de Haas oscillations in the longitudinal magnetoresistance. However, the amplitude of the Shubnikov-de Haas oscillations originating from perpendicular van der Pauw positions were not isotropic. This anisotropy varied with the carrier density which was changed by illumination. The results of this study suggest that the anisotropy is either a manifestation of spatial carrier density inhomogeneities and/or an indication of a nonuniform scattering mechanism arising from an anisotropic interface roughness.

**J1 40 Spin-Orbit Interaction for Cylindrical Nanotubes** GODFREY GUMBS, *Hunter College of CUNY* YONATAN ABRANYOS, *Hunter College of CUNY* When a gate voltage is applied perpendicular to the axis of nanotubes, this can lead to spin-orbit interaction (SOI) effects. This is of the same nature as the Rashba-Bychkov SOI at the interface of an asymmetric semiconductor heterojunction. We use a continuum model to obtain analytical expressions for the spin-split energy eigenstates for electrons on the surface of nanotubes in the presence of SOI. Each energy level could then be used to accommodate the two types of spin. For qubit functionality, one can use either one nanotube or a pair of coupled nanotubes. We investigate this scheme by calculating the exchange interaction energy and subsequently the entanglement of electron spins as they occupy allowed subbands. We also calculate the effect which SOI has on the plasma excitations since the exchange interaction can be mediated by long-range collective excitations.

**J1 41 Conductivity for a Spin-Split 2D Electron System** GODFREY GUMBS, *Hunter College of CUNY* Recent research on spintronic systems has examined a wide variety of their transport and optical properties from both a theoretical and experimental perspective. By including spin-orbit interaction (SOI) in a model Hamiltonian, we calculate the low-frequency local conductivity, starting with Kubo's formula. For long mean-free paths, we obtain a closed-form analytical result which is a generalization of the Drude conductivity. By adding vertex corrections using maximally crossed Feynman diagrams to our result, we also obtain, to lowest order in the scattering parameter, the non-local conductivity is given in terms of function which shows that there is an ''interference'' effect due to the SOI. This means that the electrons do not diffuse through the sample when the SOI is neglected, as it demonstrated several years ago.

**J1 42 Effect of SOI on the Acoustoelectric Current** YONATAN ABRANYOS, GODFREY GUMBS, *Hunter College of CUNY* With a need to increase the accuracy of the measured acoustoelectric current for metrological applications, we investigate the role played by the Rashba spin-orbit (SO) coupling. With a model Hamiltonian which takes into account the confinement of electrons within a narrow channel between split metal gates, we demonstrate that the SO interaction increases the confinement of a captured electron in a moving quantum dot and may consequently improve the quenching of the quantized acoustoelectric current.

**J1 43 A kinetic equation approach to the spin Hall effect in *p*-type bulk semiconductors** S. Y. LIU, *Stevens Institute of Technology and Shanghai Jiaotong University, China* NORMAN J. M. HORING, *Stevens Institute of Technology* X. L. LEI, *Shanghai Jiaotong University, China* V. FESSATIDIS, *Fordham University* A two-band kinetic equation method is employed here to investigate the spin-Hall effect (SHE) in a *p*-type Luttinger semiconductor. We find that the previously predicted solely intrinsic SHE arises from a dc-field induced polarization directly, or in other words, a stationary Rabi process, associated with all hole states below the Fermi surface. The total SHE, encompassing a mix of both extrinsic and intrinsic features, results essentially from a related polarization process involving electric field excitations between heavy- and light-hole bands, both directly and indirectly through scattering. In particular, we examine effects of long-range disorder on spin-Hall current (SHC) within the self-consistent

Born approximation. In contrast to the vanishing SHC contribution due to short-range disorder, we show that long-range impurity scattering produces a nonvanishing SHC, independent of impurity density, having its sign opposite to that of the intrinsic SHC contribution and leading to a significant reduction of the total SHC. This disorder-generated SHE arises from a disorder-mediated interband polarization, related only to hole states near the Fermi surface. We analyze the hole density dependencies of SHC and spin mobility numerically: with increasing hole density, the SHC first increases and then decreases, while the spin mobility decreases monotonically.

**J1 44 Kane model for the spin-splitting of holes in semiconductor heterostructures*** ARTURO WONG, FRANCISCO MIRELES, *Centro de Ciencias de la Materia Condensada, UNAM* We present a theoretical study of the Rashba-like spin-orbit coupling in two dimensional hole systems formed in zincblende semiconductor heterostructures. Using an 8X8 band Kane model within the envelope function approximation we derive exact analytical expressions for the Rashba-like Hamiltonians of the heavy, light and split-off holes [1]. The linear and cubic dependence in the wave vector of such Hamiltonians will be discussed. Simple analytical expressions for the spin-orbit coupling parameters can be also extracted from our model. A variational approach has been used in order to estimate the hole spin-splitting energies in typical III-V semiconductor quantum wells. Our preliminary results indicate that the magnitude of the spin-splitting energies for heavy holes is generically larger than their counterparts for electrons. This results could be of relevance for the design and implementation of novel (hole) transport spintronic devices. [1] A. Wong and F. Mireles (in preparation).

*This work has been supported in part by CONACYT/México, projects No. J40521F and 43673.

**J1 45 Structural, Magnetic and Transport Properties of Cobalt doped ZnO Epitaxial Thin Films** HYOJIN LEE, SUNGHO LEE, FIKRET YILDIZ, YOON HEE JEONG, *Dept. of Physics, POSTECH* Semiconductors with ferromagnetism at room temperature has been actively searched for in recent years; a prospect of spintronic devices using both charge and spin continuously gives impetus to the activities. Co substituted ZnO thin films, for example, were reported to show ferromagnetic properties at room temperature. However, various subsequent studies including ours do not seem to converge on a definite picture and controversy continues. What is needed is well synthesized and thoroughly characterized samples. A series of $Zn_{1-x}Co_xO$ ($0 = x = 0.2$) thin films on sapphire (0001) substrates were epitaxially grown by using Laser MBE deposition technique, controlling laser fluence, substrate temperatures and oxygen partial pressures. In-situ RHEED pattern showed that the films grew in the layer by layer growth mode. We performed high resolution X-ray diffraction (XRD), SEM, TEM, and AFM measurements to confirm the structure and morphology of the films. XRD figures showed that the films were of single phase with the pure ZnO wurtzite structure. AFM measurements showed that the RMS values of roughness of the films were about 2Å. Magnetization, resistivity, and Hall coefficient measurements were also carried out systematically as a function of $x$. These measurements revealed that Co doping brings about self-curing of oxygen vacancies. These results will be presented in detail.

**J1 46 Magnetic and transport properties of cobalt doped ZnO Epitaxial thin films.** HYO-JIN LEE, *Department of Physics & Electron Spin Science Center, Pohang University of Science and Technology, Pohang 790-784, S. Korea* FIKRET YILDIZ, S.-H LEE, YOON-HEE JEONG, *Department of Physics & Electron Spin Science Center, Pohang University of Science and Technology, Pohang 790-784, S. Korea* Transition metal doped ZnO has become an important topic of scientific interest in view of diluted magnetic semiconductor (DMS) at room temperature. A series of $Zn_{1-x}Co_xO$ ($0 \leq x \leq 0.2$) thin films on sapphire (0001) substrates were epitaxially grown by using Laser MBE deposition technique, controlling laser fluence, substrate temperatures and oxygen partial pressures. RHEED, X-ray diffraction (XRD), Atomic force microscope (AFM) scanning, magnetization and transport measurements were performed to investigate their structural, morphological, transport and magnetic properties. During the film growth, layer by layer growth mode were seen on RHEED pattern. XRD measurements showed that the films have the single phase of the pure ZnO wurtzite structure, there was not any secondary phase. The RMS values of roughness of the films were determined about 2Å range from AFM images. The electric and magnetic properties will be presented.

**J1 47 Investigations of the magnetocrystalline anisotropy by the Planar Hall Effect in (Ga,Mn)As epilayers grown on vicinal GaAs substrates*** W. L. LIM, X. LIU, K. DZIATKOWSKI,† Z. GE, S. SHEN, J. K. FURDYNA, M. DOBROWOLSKA, *Department of Physics, University of Notre Dame, IN 46556 USA* An asymmetric shift of the Planar Hall resistance is observed in the ferromagnetic (Ga,Mn)As epilayers grown on vicinal GaAs substrates, due to the superposition of both the in-plane Planar Hall Effect (PHE) and the out-of-plane Anormalous Hall Effect (AHE). The asymmetric shift reveals the direct manifestation of the strong magnetocrystalline anisotropy that confined the magnetization to the crystalline plane, providing a non-zero normal component of the magnetization with respect to the sample plane at low fields. This shift allows one to measure both components of AHE and PHE simultaneously in these (Ga,Mn)As thin films. We found that the ratio of the AHE resistance to the average PHE resistance change is independent of the vicinal angles. The asymmetry shift is found to be reduced with the increase of the temperature. At the temperature around 30K, the anisotropic magnetoresistance obtained by the PHE measurements shows a significant different profile near the switching fields during the magnetization reversal processes, indicating a complex competition between the cubic magnetocrystalline anisotropiy and the uniaxial anisotropy in these samples grown on vicinal GaAs substrates.

**J1 48 Hydrostatic pressure enhancement of the Curie temperature and anomalous Hall effect in $Sb_{2-x}Cr_xTe_3$*** JEFFREY S. DYCK, ANDREW J. LUCIANA, *Department of Physics, John Carroll University* CESTMIR DRASAR, PETR LOSTAK, *Faculty of Chemical Technology, University of Pardubice, Czech Republic* The narrow band gap tetradymite-type semiconductors with the form $A_2^VB_3^{VI}$ (A = Sb, Bi and B = Se, Te) are normally associated with thermoelectric cooling devices. However, $Sb_2Te_3$ doped with V or Cr and $Bi_2Te_3$ doped with Fe display a ferromagnetic transition at low temperatures. We have investigated electrical transport properties of bulk single crystals of

the ferromagnetic diluted magnetic semiconductor $Sb_{2-x}Cr_xTe_3$ under varying pressure (0 GPa to 1.5 GPa), temperature (2 K to 300 K), and magnetic fields (0 T to 6 T). High pressure measurements afford a reversible way to tune both the electronic structure and magnetic interactions of these materials. The behavior of the Curie temperature $T_C$ can be monitored via the position of the peak in the resistance data associated with the ferromagnetic transition. We observe that $T_C$ increases with increasing pressure in this compound. The anomalous Hall effect with clear hysteresis is also observed below $T_C$, and trends with pressure will be discussed.

*C.D. and P.L. thank the Ministry of Education of the Czech Republic for the support under the project No. MSM 0021627501 and J.D. and A.L. gratefully acknowledge support from the Research Corporation.

## J1 49 INSULATORS AND DIELECTRICS POSTER SESSION SION

**J1 50 Polarizing and phase-shifting properties of multilayered X-ray mirrors with fluctuating parameters** ARKADY SATANIN, *Institute for Physics of Microstructures RAS* MARIA BARYSHEVA, NIKOLAY CHKHALO, It is well known that the multilayered periodical structures (MS) may be used for different X-ray optics applications: dispersion elements, mirrors, polarimeters etc. At the present the polarizing and phase-shifting properties of the MS attract much attention. It was found an intriguing behavior of the MS when the structures having almost the same reflection coefficients demonstrate the strong variations of the polarizing and phase-shifting characteristics. To understand this phenomenon we have investigated the distribution functions of polarization and phase-shift fluctuations for an array of identical MS depending on layer thickness fluctuations. It was shown both analytically and numerically that the relative small fluctuations of layer thickness and the deterministic (systematic) local period deviations may change dramatically the polarization and phase-shift of the MS. In our work we have shown that the polarization and phase-shift of the MS may be found from the reflection measurements.

**J1 51 Crystal Structure, Magnetism, and Infrared Reflectivity of Double Perovskites$Sr_2B\ UO^6$ and Sr2B $UO_{6-d}$, B =Mn,Fe,Co,Ni,Zn** R. M. PINACCA, M. DELC. VIOLA, J. C. PEDREGOSA, *FQBF, UNSL, SanLuis, Argentina* R. E. CARBONIO, *INFIQC, UNC, Córdoba, Argentina* M. J. MARTINEZ−LOPE, J. A. ALONSO, *ICMM, CSIC, Cantoblanco, Madrid, Spain* F. P. DELACRUZ, N. E. MASSA, *LANAISEFO−CEQUINOR, U.N.L.P., C.C. 962, (1900) LaPlata, Argentina* Double perovskites$Sr^2B\ UO_6$ where B'=Mn, Fe, Co, Ni, Zn have been prepared as a polycrystalline powder by solid-state reaction. and studied by X-ray diffraction and magnetic measurements. At 300K, they present the same monoclinic distorted crystal structure, space group $P2_1$ /n. The perovskite lattice consists of a completely ordered array of B $O^6$ and $UO^6$ octahedra exhibiting a slight tilting of the type a − b + a − . Magnetic measurements show antiferromagnetism for the phases with B =Co, Ni and Mn at low temperature. The effective magnetic moment at T ⩾ $T_{Neel}$ (5.22l B/f.u. for Co phase and 3.26 B/f.u. for Ni phase) suggests an unquenched orbital contribution. The value for the Mn phase (5.74 B/f.u.) is consistent with that expected for high-spin $Mn^{2+}$ (5.91 B/f.u.). The topotactic reduction of the stoichiometric sample leads to oxygen deficient disordered perovskites, SrB0.5U0.5O3 − d having an orthorhombic distorted structure, space group Pbnm, at 300K. We will also comment on the temperature dependent infrared reflectivity of Sr2CoUO6 and isomorphous compounds.

**J1 52 Epitaxial Thin Films of the Oxynitride $BaTaO_2N$ Grown by Pulsed-laser Deposition** WEIDONG SI, SANGMOON PARK, ELI SUTTER, THOMAS VOGT, *Brookhaven National Laboratory* YOUNG-IL KIM, PATRICK WOODWARD, *Department of Chemistry, The Ohio State University* Pulsed-laser deposition has been used to grow epitaxial thin films of the oxynitride $BaTaO_2N$ on MgO substrates and $SrTiO_3$ substrates with and without $SrRuO_3$ buffer layers. The thin films have a relatively high dielectric constant in the order of 200 - 250 from room temperature down to 4.2K with no significant frequency dependence. This special property, which has not been found before in other materials, potentially makes it a good candidate for many dielectric applications. We argue that a new mechanism is required to understand the dielectric properties of $BaTaO_2N$.

**J1 53 Time-dependent space-charge-limited conduction** HOKEI CHAN, *School of Physics and Astronomy, University of Manchester, Manchester (U. K.)* YAN ZHOU, CHI-HANG LAM, F.G. SHIN, *Department of Applied Physics, Hong Kong Polytechnic University, Hong Kong* The concept of time-dependent space-charge-limited conduction (TDSCLC) was introduced in 2004 to account for the well-known observation of polarization offsets in compositionally graded ferroelectric films [1]. It is a generalization of Mott's steady-state SCLC model ($J \sim V^2$) [2] to include two carrier types ($p$ and $n$) and time dependence. Subsequently it was found to have a wider applicability in explaining the imprint phenomenon commonly observed in homogeneous ferroelectric films [3]. Here we would like to review the derivation of the TDSCLC formula and its relation to the steady-state SCLC model, and discuss its applicability to other electrical insulators. [1] H. K. Chan, C. H. Lam, and F. G. Shin, J. Appl. Phys. 95, 2665 (2004) [2] R. Coelho, Physics of Dielectrics for the Engineer (Elsevier Scientific, New York, 1979), pp. 123-125 [3] Y. Zhou, H. K. Chan, C. H. Lam, and F. G. Shin, J. Appl. Phys. 98, 024111 (2005).

**J1 54 Mossbauer studies of mixed Fe-Mo oxides** H.H. HAMDEH, H. AL-GHANEM, J.C. HO, *Wichita State University* R.J. WILLEY, E. MARCHESE, W. JABLONSKI, *Northeastern University* Mossbauer spectroscopy was carried out in conjunction with a catalytic study on mixed Fe-Mo oxides, among which $Fe_2(MoO_4)_3$ has been widely used in selective oxidation of certain hydrocarbons. With the specific activity being sensitive to the catalyst particle size and morphology, an aerogel process was employed to prepare the samples covering Fe/Mo ratios from 1/2 to 2/1. Each set of Mossbauer data were well fitted to reflect one Fe3+ and two or three non-equivalent Fe2+ sites. Their isomer shift, quadruple splitting and molar fraction are analyzed in terms of temperature and Fe/Mo-ratio dependence. The Fe-rich samples exhibit magnetic ordering at low temperatures.

**J1 55 Mid-infrared spectroscopy of Praseodymium doped $KPb_2Br_5$ and $KPb_2Cl_5$** PETER AMEDZAKE, EI NYEIN, UWE HOMMERICH, *Hampton University* SUDHIR TRIVEDI, *Brimrose Corporation of America* JOHN ZAVADA, *US Army Research Office* Rare-earth doped low phonon energy hosts are promising materials for mid-infrared (MIR) solid-state laser applications. Room temperature laser activity has been demonstrated at 7.2 $\mu$m, 5.2 $\mu$m and 1.6 $\mu$m from Pr: $LaCl_3$. In this work, we report on the material preparation and optical properties of Pr doped $KPb_2Br_5$ (KPB) and $KPb_2Cl_5$ (KPC). KPB and KPC are both non-hygroscopic and have low maximum phonon energies of 140cm$^{-1}$ and 200cm$^{-1}$, respectively. The small phonon energies lead to reduced non-radiative decay rates due to multiphonon relaxation. The preparation of Pr: KPB and Pr: KPC was based on a careful purification of the host materials followed by self-seeded Bridgman crystal growth. The characteristic absorption bands were obtained in the visible and IR spectral region. Under 1907 nm and 1550 nm excitations, both crystals exhibited broad MIR emission spectra centered $\sim$ 4.7 $\mu$m with a room-temperature lifetime of 4.5 ms. Results of temperature dependent and time-resolved emission spectroscopy of Pr: KPB and Pr: KPC will be presented at the conference.

**J1 56 Planar faults in metastably retained hexagonal $BaTiO_3$.** YU-CHUAN WU, HONG-YANG LU, Hot-pressed $BaTiO_3$ ceramic samples contain predominantly h-$BaTiO_3$ as determined by XRD, and with a trace amount of t-$BaTiO_3$ as revealed by TEM. Extended planar stacking faults (EPSF's) found ubiquitously in hot-pressed samples having the eligible fault vectors $\mathbf{R}_{F(I)} = (1/2)\mathbf{c} + \mathbf{p}_{(I)}$ and $\mathbf{R}_{F(II)} = (n/6)\mathbf{c} + \mathbf{p}'_{(II)}$, containing both $\mathbf{p}_{(I)} = 1/3\langle 2110\rangle$, $\mathbf{p}'_{(II)} = 1/3\langle 1010\rangle$, n = 1, 2, 4, and 5, and $\mathbf{c} = [0001]$, have been determined by contrast analysis using the $2\pi\mathbf{g}\cdot\mathbf{R}_F = 0$ or $2n\pi$ criteria crystallographically, and the number of layers along **c** confirmed by high-resolution imaging uniquely. Two general types of EPSF's are found; one group with only three vectors of the six degeneracies of the **p**-component $\langle 1010\rangle$ eligible and the other with all six degeneracies of the **p**-component $\langle 2110\rangle$ eligible for the fault vector. The latter is analogously a $\pi$-rotation fault (as in $DO_{19}$ intermetallics) that a rotation about [0001] by 180$^o$ (or 60$^o$) arrives at another eligible fault vector. The metastable retention of the high-temperature h-$BaTiO_3$ phase is discussed in favour of oxygen deficiency.

**J1 57 PIMC simulation of Ps in a dielectric solid** ZACHARY WOLFSON, *Swarthmore College* AMY BUG, *Swarthmore College* Positronium (Ps) is commonly used to probe the pore space in insulating materials like polymers and low-k dielectrics. Such studies require an accurate model relating the lifetime to the size of the pore. The standard Tao-Eldrup approach models Ps as one quantum particle in the ground state of a spherical box. We go beyond Tao-Eldrup by modeling Ps exactly as two quantum particles at arbitrary temperature, using Path Integral Monte Carlo (PIMC) to simulate the electron and positron each as a classical polymer. As a further correction, we also include the dielectric response of the surrounding material. The total annihilation rate, which is the inverse of the lifetime, may be calculated from the pickoff and self annihilation rates via $\Gamma = \Gamma_{p.o.} + \kappa\Gamma_{self}$ We find that the material's polarization causes the Ps to be more attracted to the wall, decreasing its pickoff lifetime. The internal contact density, $\kappa$, decreases with increasing dielectric constant. The combination of using the two particle model as well as polarizable walls yields a lifetime close to the Tao-Eldrup result.

**J1 58 Scaling laws In PZT/Si(001) Thin Films** JUAN RAMÍREZ, ALEXANDER CORTES, WILSON LOPERA, MARIA ELENA GÓMEZ, PEDRO PRIETO, *Universidad del Valle, Physics Department* THIN FLIM GROUP TEAM, Self-affine scaling behavior of ferroelectric $Pb(Zr_{1-x}Ti_x)O_3$ (PZT) thin films grown on Si(001) substrates has been investigated by AFM Atomic Force Microscope. PZT thin films were grown via Rf-sputtering technique at high oxygen pressures and at substrate temperatures 600 $^o$C varying the deposition time and keeping all parameters. growth constant. The $\alpha$-global rough-exponent was founded close to 0.7 indicating a correlated growth. Anomalous scaling behavior was founded in all PZT/Si surfaces. A value of 0.5 for the $\alpha$-local value was founded. The local value of the roughness exponent is associated to the diffusional process on the first stage growth. Saturation roughness showed oscillation dependence with the PZT-thickness. This dependence can be explained by the mismatch between Si substrate and PZT thin film. These results are corroborated calculating the grain size for all samples. This work was supported by COLCIENCIAS under the Excellence Center for Novel Materials Contract no 0043-2005.

**J1 59 Crystal Structure and Relaxor-Type Transition In Praseodymium Doped SBT** JORGE MATA*, ALEJANDRO DURAN*, RAUL ESCAMILLA, *IIM-UNAM Mexico* EDUARDO MARTINEZ*, JESUS HEIRAS*, JESUS SIQUEIROS*, **Centro de Ciencias de la Materia Condensada-UNAM, MEXICO* The effects of Pr substitution and ferroelectric response for the $Sr_{1-x}Pr_xBi_2Ta_2O_9$ ceramic system were studied. Rietveld refined X-ray diffraction indicates that Pr ion progressively replaces Sr in the $A2_1$itam space group structure. The solubility of Pr in the solid solution is around 15 %. The replacement induces change in the crystal structure and as consequence dielectric properties are affected. The displacement of $TiO_6$ octahedra with respect to $Bi_2O_2$ along the polarization axis decreases as Pr is increased. A notable decrease in the transition temperature (Tm) is observed. With Pr substitution the Tm shifts gradually from $\sim$ 305 $^o$C to $\sim$ 120 $^o$C. Apparently, the rotation at the ab-plane ($\beta$) as well the octahedral distortion observed are strongly related to the coupling between Tm and x. However, the tilt angle ($\alpha$) associated to the c-axis don't play an important role as it remains essentially constant. Relaxor type transition is observed as Pr increases due to polar microregions above the nominal ferroelectric transition. Local disorder induced by Pr ion is confirmed by the continuous increase in the diffuseness coefficient according to Isupov's model. Thanks to DGAPA-UNAM and CONACYT for funds through Proj. No. 40604-F, 47714-F, IN116703, IN100903 and to P. Casillas, J. Peralta, M. Sainz.

**J1 60 Thermal stability and interfacial properties of $ZrAl_xSi_yO_z$ films prepared by pulse-laser deposition in high vacuum** XIAOYAN QIU, *Nanjing National Laboratory of Microstructures, Nanjing University & Institute of Physics, Southwest University* HONGWEI LIU, JUNMING LIU,* *Nanjing National Laboratory of Microstructures, Nanjing University* The thermal stability and interfacial properties of $ZrAl_xSi_yO_z$ film prepared by pulse-laser deposition (PLD) in high vacuum have been investigated. X-ray diffraction (XRD) and differential scanning calorimeter (DSC) investigation show that the crystallization temperature of $ZrAl_xSi_yO_z$ film is above 900°C. A dielectric constant of 12.9 (at 1MHz) is obtained by measuring a Pt/$ZrAl_xSi_yO_z$/Pt structure. High-resolution transmission electron microscopy (HRTEM) and X-ray photon spectroscopy (XPS) analyses reveal that an amor-

phous Zr-silicide interfacial layer is formed at 700°C, but $Pt/ZrAl_xSi_yO_z$/Zr-silicide/Si capacitors still have good electrical properties, such as small equivalent oxide thickness of 0.5nm, flat band voltage of 0.43V and low leakage current density of 2.76mA/cm2 at 1V gate voltage.

**J1 61 Fatigue endurance property of PZT thin films enhanced by Sr and Ba doping.** YANG WANG, ZHENYU LI, QIYUE SHAO, *Nanjing National Laboratory of Microstructures, Nanjing University* JUNMING LIU,* *Nanjing National Laboratory of Microstructures, Nanjing University & International Center for Materials physics, Chinese Academy of Sciences* PZT thin films with Sr and Ba doping at A site, deposited by sol-gel and PLD method respectively, were investigated in our work. The enhancement of fatigue resistance property with increasing doping content were both observed in two kinds of samples. The experiments of dc conductivity vs temperature reveal that this behavior can be attributed to the reduction of oxygen vacancies, due to the stronger chemical bonding of Sr-O and Ba-O bonds compared to that of Pb-O bond suppressing the volatility of Pb ions and intensifying the stability of the metal-oxygen octahedron, since the defect chemistry is believed to play a key role in the fatigue of perovskite ferroelectrics.

**J1 62 Trends in behavior for tunable ferroelectric material** DANIEL POTREPKA, *US Army Research Laboratory* Measurements in an environmental chamber pose problems in effectively coupling to rf- and microwave-tunable, ferroelectric devices. Capacitance can be measured but true device loss is shrouded by losses due to calibration error, impedance matching error from cables and packaging, and vibration interference. In this study, the true device losses of pulsed-laser deposited Barium Strontium Titanate films, at rf frequencies under DC bias are sought using a probe station, calibrated for matching. Breakdown of the device at the higher end of applied voltage and thin film material structure are characterized. Resulting losses and tunability versus temperature are commented upon.

**J1 63 Thermal analysis and evidence of structural transition induced by praseodymium in $SrTiO_3$** *ALEJANDRO DURAN, **FRANCISCO MORALES, *IIM-UNAM* ***LUIS FUENTES, +JAVIER CASTRO, *JESUS SIQUEIROS, **Centro de Ciencias de la Materia Condensada-UNAM, **IIM-UNAM, ***CIMAV-Chihuahua, Chih. MEXICO, +UACJ-Ciudad Juarez, Chih. MEXICO* To explore the nature of ferroelectric behavior induced by Pr ion in the $SrTiO_3$ ceramic, we brought together a combination of Synchrotron x-ray powder diffraction and thermal analysis. Rietveld analysis shows a clear peak splitting strongly suggesting a cubic-tetragonal structural transition when 15 % Pr substitutes the Sr site. To determine the temperature of the structural instability differential thermal analysis at high temperatures (30-900 °C) and specific heat at low temperatures (2-300 K) were performed. The difference in the heat capacity for Pr doped and undoped samples is very small. A plateau in Cp/T-T at 110 K is a clear evidence of the competing effect of two kinds of order parameters, one represented by the polarization and the other by the rotation of the oxygen octahedral in the perovskite structure. Upon heating, DTA analysis shows an unexpected single endothermal broad anomaly at about 118 °C. The occurrence of this thermal anomaly could be related to displacive structural contributions providing unambiguous evidence of diffuse phase transition and of the ferroelectric behavior observed at room temperature. Thanks are due to CONACYT P. 47714-F, DGAPA P. IN100903 and to P. Casillas for technical help.

**J1 64 Structural and Dielectric Characterization of $SrBi_2Ta_2O_9$ Doped with Gadolinium** JORGE MATA, ALEJANDRO DURAN, RAUL ESCAMILLA*, EDUARDO MARTINEZ, JESUS SIQUEIROS, *Centro de Ciencias de la Materia Condensada, UNAM. Apdo. Postal 2681, Ensenada, B.C., Mexico.*IIM-UNAM, Apartado Postal 70-360, Mexico, D. F. 04510.* The results of the study of polycrystalline samples of $SrBi_2Ta_2O_9$ (SBT) doped with Gd, Sr-vacancies and a Bi-excess are presented. XRD structural characterization using Rietveld refinement revealed that the Gd-doped SBT with Sr-vacancies and Bi-excess ($Sr_{0.70}?_{0.15}Gd_{0.15}Bi_2Ta_2O_9$) is single phase. Furthermore, cationic disorder on the $Bi^{3+}$ and $Sr^{2+}$ crystallographic sites is promoted by the addition of the $Gd^{3+}$ ions. Replacement of Gd ions for Sr and vacancies in the SBT structure produces a shift toward lower values of the Curie Temperature (Tc) from 400 to 200 $^o$C in contrast with previous reports in the literature where a notable increase in Tc and the dielectric permittivity are found when the Sr- site is replaced with vacancies. Bi and Gd substitution and the cation vacancies at the Sr site in the $Sr_{0.70}?_{0.15}Gd_{0.15}Bi_2Ta_2O_9$ compound, enhance the structural distortion in the $TaO_6$ octahedra and leads to a larger ferroelectric spontaneous polarization. Acknowledgments: This work was partially supported by DGAPA-UNAM Project N$^o$ IN100903 and CONACYT No. 47714-F and 40604-F. The authors thank Pedro Casillas, M. Sainz, J. Peralta for their technical assistance.

**J1 65 Thermo-Electromechanical Coupling Effects on Ferroelectric Perovskites** XIAOWEI ZENG, *George Washington University* JAMES LEE, *George Washington University* YOUPING CHEN, *George Washington University* We are investigating the thermo-electromechanical coupling effects on ferroelectric perovskite materials. This work is based on a shell model potential with parameters obtained from first-principles calculation. Molecular dynamics simulations are performed to investigate the dynamic response of the ferroelectric perovskites under thermal, mechanical and electric loadings. The phenomena of finite temperature phase transitions and polarization reorientation are observed. The temperature-pressure phase diagram is also obtained.

## J1 66 SUPERCONDUCTIVITY POSTER SESSION

**J1 67 Effects of triplet pairing amplitudes in hybrid junctions of superconductor, ferromagnet, and normal metal.** NA YOUNG LEE, HAN-YONG CHOI, HYEONJIN DOH, We calculate the critical temperature Tc and pairing amplitude of the hybrid junctions of superconductor (S), ferromagnet (F), and normal metal (N) by solving the Usadel equation in the dirty limit. S is a conventional singlet s-wave supercondcutor like Nb. The interface between S and N is modeled in terms of the interface

resistance without the spin flips, while the interface between F and S or F and N is modeled by both the interface resistance and spin flip scatterings, parameterized by, respectively, $\gamma_b$ and $\gamma_m$. The spin flip scatterings induce the triplet pairing components from the singlet component. The Tc of the junction is determined by the critical order parameter, ie., the singlet pairing component. The $\gamma_b$ or $\gamma_m$ changes the Tc of the junctions indirectly by altering the singlet component by modifying the boundary conditions at the interfaces. We calculate the Tc and pairing amplitudes of S/N/F and F/S/F trilayers including $\gamma_b$ and $\gamma_m$ and investigate the effects of the triplet pairing components on the Tc and pairing amplitudes of the trilayers.

**J1 68 Domain patterns in type-I superconducting films.** ANDREJS CEBERS, *Institute of Physics, Salaspils, LV-2169, Latvia* CATHERINE GOURDON, VINCENT JEUDY, TAKANORI OKADA, *Institut des Nanosciences de Paris, CNRS UMR 7588, Universities Paris 6 and 7, France* INSTITUTE OF PHYSICS, UNIVERSITY OF LATVIA TEAM, INSTITUT DES NANOSCIENCES DE PARIS,CNRS UMR 7588, UNIVERSITIES PARIS 6 AND 7 TEAM, Like many other systems (magnetic fluids, Langmuir polarized layers . . . ) type-I superconducting (SC) films exhibit a phase modulation known as the intermediate state (IS). It consists of coexisting domains of the normal state (NS) and SC phases. The striking similarity of the domain patterns for various systems has stimulated the development of general models [1] based on the competition between the interface energy and the long-range interaction between domains. However, for superconductors, the long-range magnetic interaction between domains has to be modified to take properly into account screening currents [2]. This leads to substantial improvement of the description of the IS as it will be illustrated through 3 examples: (i) the impeded growth of NS circular domains, (ii) the stability limit of the circular shape, (iii) the nucleation and collapse of SC domains in the NS phase. [1] A.T. Dorsey and R.E. Goldstein, Phys. Rev. B 57, 3058 (1998) [2] A. Cebers et al, Phys. Rev. B 72, 014513 (2005).

**J1 69 Specific heat of bosons among periodical layers*** MIGUEL A. SOLÍS, *Instituto de Física, UNAM, Apartado Postal 20-364, 01000 México, D.F., MEXICO* MARCELA GRETHER, *Facultad de Ciencias, UNAM, Apartado Postal 70-542, 04510 México, D.F., MEXICO* It is well known that the specific heat of a 3D ideal boson gas shows continuity as a function of the temperature. However, interactionless bosons among periodic plane layers with variable penetrability, show a specific heat jump at the critical temperature, which increases as a function of the layer impenetrability. The jump resembles that of a conventional superconductor instead of that of a laminar cuprate. We expect that inclusion of inter-boson interaction leads to a more realistic specific heat.

*We thank PAPIIT IN111405 and CONACyT 43234-F

**J1 70 Thermodynamic properties of $Ca_{1.82}Na_{0.18}CuO_2Cl_2$ single crystals** KYUNG-HEE KIM, HEON-JUNG KIM, JUNG-DEA KIM, H.-G LEE, SUNG-IK LEE, *POSTECH* NATIONAL CREATIVE RESEARCH INITIATIVE CENTER FOR SUPERCONDUCTIVITY AND DEPARTMENT OF PHYSICS, POHANG TEAM, We report the experimental results on the reversible magnetization of high quality $Ca_{1.82}Na_{0.18}CuO_2Cl_2$ single crystals in the high-pressure condition of about 5.2 GPa. The superconducting transition temperature $T_c$ ( $\sim$ 27 K) of this single crystal is the highest reported in this family. The magnetizations are analyzed using the Hao-Clem model and the high-field scaling law. From these analysis, we have obtained various thermodynamic parameters such as the penetration depth and the critical fields, and clarified the dimensional nature of the superconductors. Even though the doping content between $Ca_{1.82}Na_{0.18}CuO_2Cl_2$ and $La_{1.82}Sr_{0.18}CuO_4$ is same, the physical properties of these materials are quite different. For example, $\lambda_{ab}(0)$ is estimated to be 440 nm, which is larger than that of $La_{1.82}Sr_{0.18}CuO_4$. These changes are totally unexpected in this iso-structural superconductor.

**J1 71 Linear Temperature Dependence of the Resistivity in the Pseudogap State** A.A. ABRIKOSOV, *Materials Science Division, Argonne National Laboratory, USA* A concept is proposed, explaining the characteristic features of the in-plane resistivity of high-$T_c$ layered cuprates above$T_c$: quasi-linear temperature dependence and absence of the residual resistance in the extrapolation of the curve $\rho(T)$ from $T > T_c$ to $T = 0$. This concept is based on the idea of the pseudogap state structure described in previous works by the present author. This work was supported by the Department of Energy under the contracts # W-31-109- ENG-38.

**J1 72 Changes in the superconducting temperature by pressure in $Nb_3Sn$ and its influence in the martensitic transition.** RICHART FALCONI, *UJAT* FRANCISCO MORALES, ROBERTO ESCUDERO, *IIMUNAM* R. WEBB, *UCSD* High pressure experiments performed in a $Nb_3Sn$ single crystal shows changes on the superconducting temperature and in the martensitic transition. Specific heat measurements performed in this crystal shows an anomaly at about 50 K associated to the martensitic transition. At ambient pressure, the electrical resistivity as a function of temperature shows a $T_C$ of 18.7 K with a transition width $\Delta T_C$ (10 to 90 %) of 0.7 K. At low temperatures the R vs T curve show a $T^2$ behavior, specifically in the temperature range from 52 down to 23 K. The superconducting transition temperature decreases in linear form with a rate dTc/dP = - 0.79 K/GPa. The results are discussed in terms of the pressure effects on the martensitic transition via changes in the density of electronic states.

**J1 73 Generating spin current by AC magnetic field** MINHUI SHANGGUAN, *Center of theoretical and computational physics and Department of Physics, The University of Hong Kong, Pokfulam Road, Hong Kong, China* QINGFENG SUN, *Institute of Physics, Chinese Academy of Sciences, Beijing, P.R. China* JIAN WANG, *Center of theoretical and computational physics and Department of Physics, The University of Hong Kong, Pokfulam Road, Hong Kong, China* HONG GUO, *Department of Physics, McGill University, Montreal, Quebec, Canada* We report a theoretical investigation on the possibility of generating pure spin current without an accompanying charge current, by applying a train of magnetic field pulses on the leads of a tunnel junction. When the duration of on-state of the pulse is shorter than the spin relaxation time while the off-state is longer than it, a spin current is driven through the two-probe device coherently. The time averaged spin current is found to be almost a periodic function of the pulse strength. A negative spin current can also be produced for a positive spin chemical potential, due to quantum interference among the Fourier modes of the photon assisted tunneling.

**J1 74 Effect of Electron-Electron Scattering on the Conductance of a Single Quantum Wire*** DANHONG HUANG, *USAF Research Lab* KEN LYO, *Sandia National Labs* Electron-electron scattering conserves momentum and does not dissipate momentum in a low-density system where the Umklapp process becomes forbidden. However, it can still affect the conductance through the energy relaxation of carriers. We show that this effect can be studied with an arbitrary accuracy in a multi-level single quantum wire system with impurity and phonon scattering using a formally exact solution of the Boltzman transport equation. We study the effect of electron-electron scattering on the temperature and density dependence of the conductance at low temperatures. Some unique features in the calculated conductance as functions of the temperature and the density are predicted and physically explained.

*Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the U.S. DOE under Contract No.DE-AC04-94AL85000.

**J1 75 Density-matrix renormalization group study of pairing in Holstein-Hubbard model: effect of electronic band structure*** MASAKI TEZUKA, *University of Tokyo* RYOTARO ARITA, *Max-Planck Institute Stuttgart and University of Tokyo* HIDEO AOKI, *University of Tokyo* The density-matrix renormalization group, with a modification [1], is used to directly obtain correlation functions [2] when both electron-electron and electron-phonon interactions are strong with the Holstein-Hubbard model in a region intermediate between the adiabatic (Migdal's) and antiadiabatic limits. We found that the pairing correlation for a one-dimensional system at half-filling does not dominate over the charge density- wave (CDW) correlation, even when the phonon-induced attraction is comparable with the electron-electron repulsion. However, the pairing is shown to become dominant in a trestle lattice where the electron-hole symmetry is absent, which indicates that superconductivity can appear in a manner dependent on the lattice (hence the electronic band) structure even for the Holstein-Hubbard model with on-site interactions. Band- filling dependence is also discussed. [1] M. Tezuka, R. Arita, and H. Aoki, Physica 359B-361B, 708 (2005). [2] M. Tezuka, R. Arita, and H. Aoki, Phys. Rev. Lett. 95, 226401 (2005).

*This work is in part supported by a Grant-in-Aid for Science Research on Priority Area from the Japanese Ministry of Education.

**J1 76 Dynamics of magnetic flux jumps in highly dense $MgB_2$ samples** C. ROMERO, O.A. HERNANDEZ, *IF-UAP* F. MORALES, *IIM-UNAM* A. DURAN, D.H. GALVAN, *CCMC-UNAM* R. ESCUDERO, *IIM-UNAM* Flux jumps in magnetization curves were investigated experimental and theoretically in a polycrystalline $MgB_2$ dense sample. We performed magnetization cycles of M-H at different temperatures. Theoretical calculation were performed using an adiabatic critical-state model, that considers the heating effects due to the motion of flux lines, the instability process that originates flux jumps, and the flux redistribution towards a new metastable critical state. The flux jump and temperature dependence in the final state were successfully reproduced from experimental M-H curves. The number of the flux jumps and the jump size increase as the temperature is decreased corroborating the typical flux jump in hard type-II superconductor.

**J1 77 Flux jumps in irradiated $MgB_2$ dense samples** E. VERDIN, *DF-UNISON* C. ROMERO, *IF-UAP* F. MORALES, *IIM-UNAM* E. ADEM, J. RICKARDS, *IF-UNAM* A. DURAN, D.H. GALVAN, M.B. MAPLE, *UCSD* R. ESCUDERO, *IIM-UNAM* This work shows magnetic flux jumps and changes in specific heat measurements studied in $MgB_2$ dense bulk samples irradiated: with $^{60}Co$ (500 mrad), electrons (500 mrad), and protons ($1x10^6$ $cm^2$). Magnetic susceptibility measurements $\chi(T)$ show that the Tc ( $\sim$ 38.5 K) is independent of irradiation doses. M vs H data display flux jumps strongly dependent of the temperature. Specific heat measurements show an increase in the magnitude of Cp/T vs T curves just in the transition temperature for the irradiated protons, suggesting enhanced local disorder. The behavior of specific heat data at low temperature is analyzed using a two band model in order to clarify the effect of local disorder with the gap superconducting structure.

**J1 78 Vortex nucleation in a Layered Superconductor*** PATRICIA SALAS, *Posgrado en Ciencia e Ingenieria de Materiales, UNAM, MEXICO* MIGUEL A. SOLIS, *Instituto de Fisica, UNAM, Apartado Postal 20-364, 01000 Mexico, D.F., MEXICO* We propose that the paired fermions (electrons) in a layered superconductor, such as cuprates, be treated as interacting bosons in the Bose-Einstein regime. We solve the time dependent Gross-Pitaevskii equation for these bosons inside a rotating layered superconductor which is simulated by an external periodical potential of the Kronig-Penney type perpendicular to the planes while bosons are allowed to be free in the other two directions [1]. Among the several numerical methods that exist to solve the Gross-Pitaevskii Equation, we use a time iteration procedure, based on the discretization of time and space [2]. We annalize the vortex nucleation and its influence in the thermodynamic properties of the superconductor. [1] See M.A. Solis and M. Grether, ''Specific heat of bosons among periodical layers,'' in this proceedings. [2] S. K. Adhikari and P. Muruganandam, J. Phys. B **35**, 2831 (2002).

**J1 79 Gap Distributions in Cuprate Superconductors*** ASHOT MELIKYAN, *University of Florida* BRIAN M. ANDERSEN, *University of Florida* TAMARA S. NUNNER, *Institute of Theoretical Physics, Berlin* P. J. HIRSCHFELD, *University of Florida* Recent Scanning Tunneling Microscopy (STM) data on $Bi_2Sr_2CaCu_2O_{8+x}$ impose stringent restrictions on the spatial distribution of the superconducting order parameter and scalar potential due to impurities. In Ref. [1] it was shown that these distributions are inconsistent with a conventional mean-field approach where the inhomogeneities in the LDOS are driven by a scalar impurity potential. It was further demonstrated that the salient experimental features of the LDOS spatial modulations can be obtained if the pairing coefficient itself is assumed to be enhanced by the dopant atoms. Here, we report additional features of the LDOS that support the conclusions of Ref. [1]. [1] T. S. Nunner, B. M. Andersen, A. Melikyan, and P. J. Hirschfeld, Phys. Rev. Lett. 95, 177003 (2005).

**J1 80 Holonomic quantum computation using rf superconducting quantum interference devices coupled through a mi-**

**crowave cavity** JIADA SUN, PENG ZHANG, ZIDAN WANG, CHANGPU SUN, We propose a different scheme to realize holonomic quantum computation with rf superconducting quantum interference device (SQUID) qubits in a microwave cavity. In this scheme associated with the non-Abelian holonomies, the single-qubit gates and a two-qubit controlled-PHASE gate as well as a controlled-NOT gate can be easily constructed by tuning adiabatically the Rabi frequencies of classical microwave pulses coupled to the SQUIDs. The fidelity of these gates is estimated to be possibly higher than 90% with the current technology.

**J1 81 An improved system for SQUID-detected MRI at microtesla fields** S. BARRIGA, P. KOO, A. HUNT, S. BUSCH, D. KINION, M. HATRIDGE, W. MYERS, M. MÖßLE, A. PINES, JOHN CLARKE, *UC Berkeley and LBNL* M. MÜCK, *U. of Giessen* We perform magnetic resonance imaging (MRI) by detecting protons precessing at 5.6 kHz in a 132-$\mu$T field with a superconducting gradiometer coupled to a superconducting quantum interference device (SQUID). We have designed, built, and tested an improved system with an increased signal to noise ratio, intended to reduce data acquisition time and/or increase spatial resolution. By using a SQUID with a lower noise and an input coil inductance optimally matched to that of the gradiometer we have reduced the intrinsic magnetic field noise referred to one pickup loop by a factor of four to 0.4 fT $Hz^{-1/2}$. To take advantage of this reduced noise we have enclosed the entire system in a 6-mm thick aluminum shield that attenuates 5.6-kHz magnetic noise by a factor of about 60. Our new coils provide more homogeneous imaging fields and field gradients and are more compact than those employed in our prototype. Finally, we align the precession field perpendicular to the fields generated by the building elevator to minimize shifts in the precession frequency. We present images obtained in our new system. This work was supported by the USDOE.

**J1 82 Pulsed Tera-hertz Radition from Femto-second Laser Excited Superconductive $YBa_2Cu_3O_{7-\delta}$ Antenna** SHYH-SHII PAI, CHENG-CHUNG CHI, *Department of Physics, National Tsing Hua University, Hsinchu, Taiwan, R. O. C.* We have observed the ultrashort electromagnetic pulse radiation from a current-biased bow-tie structure of $YBa_2Cu_3O_{7-\delta}$ thin film dipole antenna on MgO using 100 fs, 750 nm laser pulses. With the electro-optic detection, we obtained the THz pulses with 1.0 ps full width at half maximum, containing frequency components up to 1.0 THz. The THz peak amplitude dependence shows the saturation and a nonlinear behavior with a higher excitation pumping power and with the applied bias currents. The saturation on the dependence with the excitation powers exhibits the bolometric heating in nature. However, the nonlinear characterization of the THz radiation from the superconductive thin film antenna revealed that the inadequacy of pure supercarrier approximation on a two-fluid model. The ultrashort transient response and the deviation from the classical theory are discussed in relation to the quasiparticle dynamics of the nonequilibrium mechanism.

**J1 83 Vortex avalanche in gold-coated and finite-sized $MgB_2$ thin films.** EUN-MI CHOI, HYUN-SOOK LEE, SUNG-IK LEE, *POSTECH* Å. A. F. OLSEN, D.V. SHANTSEV, T.H. JOHANSEN, *University of Oslo* The vortex avalanches in carbon-free $MgB_2$ thin films were studied using magneto-optical imaging. The main focus of this study was the effect of a gold coating and the sample size on the occurrence of the dendritic flux avalanches. For this purpose, we prepared two different sets of $MgB_2$ films. In the first, the films had gold coatings of various thicknesses, and in the second set bare $MgB_2$ films were patterned into long strips of different widths. The dendritic flux avalanches essentially disappeared for gold coatings thicker than 2.5 $\mu$m. Also for strip widths less than 0.33 $mm^2$ the formation of flux dendrites are suppressed. The results are consistent with a thermomagnetic origin of the dendritic instability.

**J1 84 Effect of disorder in neutron irradiated $MgB_2$ thin films investigated by transport measurements in high magnetic field** VALERIA FERRANDO, *CNR-INFM-LAMIA, University of Genova* ILARIA PALLECCHI, *CNR-INFM-LAMIA* CHIARA TARANTINI, MARINA PUTTI, *CNR-INFM-LAMIA, University of Genova* XIAOXING XI, *The Pennsylvania State University* CARLO FERDEGHINI, *CNR-INFM-LAMIA* We analyse a series of $MgB_2$ thin films grown by Hybrid Physical Chemical Vapor Deposition (HPCVD), where disorder is introduced by neutron irradiation. Increasing progressively the neutron fluence, $T_c$ monotonously decreases down to 2K and $\rho_0$ increases by one order of magnitude. A complete characterization of this series of samples is presented. In particular, we propose high field magnetoresistivity and critical field as a method to study the effect of disorder in the two bands. Differently from polycrystalline samples, $H_{c2}$, after a first increase at the lowest neutrons fluences, only weakly depends on the irradiation level. This suggests that in thin films $H_{c2}$ and resistivity are affected by different mechanisms induced by irradiation. From a quantitative analysis of the magnetoresistivity curves as a function of the angle between the field and the crystalline axes, we extract the scattering times in $\pi$- and $\sigma$-bands. We find that the unirradiated films have less mobile $\pi$ − bands than $\sigma$ − ones; upon irradiation, the scattering rates of both bands progressively increase, allowing to estimate resistivity values consistent with the measured ones.

**J1 85 Tuning inter-band scattering mechanism in $MgB_2$ through ion irradiation*** S. PATNAIK, S.D. KAUSHIK, *School of Physical Sciences, Jawaharlal Nehru University, New Delhi 110067, India* The effect of light and heavy ion irradiation on Magnesium Diboride thin films is studied. $MgB_2$ is a two-band superconductor and its electromagnetic response is determined by the relative strength of scattering between the isotropic $\pi$ band vis á vis the planar $\sigma$ band. Our results indicate that by suitably choosing the type of ion, fluence, and energy we can control the inter and intra band scattering and thereby alter the physical properties of this intermetallic superconductor. For example, we find that while the anisotropy in upper critical field can be increased with point defects created by $Si^{+8}$ ions, it can only be decreased by extended defects formed by heavy ion $Au^{+15}$ at same fluence. Similarly while the upper critical field in the direction parallel to c-axis of the film shows enhancement post irradiation with heavy ions, it exhibits some decrease with light ion irradiation. The curvature in H-T phase diagram is also dependent on the defect type. We understand these phenomena within the framework of disorder in multiband superconductivity.

*This work was funded by DST & CSIR, India

**J1 86 Study of $MgB_2$ Films on Niobium Substrate*** CHENGGANG ZHUANG, DAN YAO, FEN LI, KAICHENG ZHANG, QINGRONG FENG, ZIZHAO GAN, *School of Physics and State Key laboratory for Artificial Microstructure and Mesoscopic*

*Physics, Peking University, Beijing 100871, P. R. China* We have successfully fabricated polycrystalline $MgB_2$ films on metal niobium by using the hybrid physical-chemical vapor deposition technique. $T_C$ (onset) of these samples ranged from 38.5 K to 39.4 K, with $\Delta T$, 0.1 K $\sim$ 0.3 K. The observed $T_C$ was the highest among all the $MgB_2$ films over metal substrates reported to date. Thicknesses of the films were about 1.0 $\mu$m. XRD indicated that lattice constants approached the values of the bulk. The film surface was visible with hexagonal plate-shaped $MgB_2$ crystallites but not dense enough, shown by SEM observation. A line scanning spectra of EDX on the cutting cross section exhibited that there was an oxygen-rich region at the interface. Also, the diffusion of the Mg atoms deeply into the film has resulted in the tenacity and adherence of the film to the substrate. TEM investigation proved the existence of this buffer layer, $\sim$ 100 nm. Estimated using magnetic hysteresis loops and Bean model, $J_C$ was above $2.30 \times 10^4$ A/cm$^2$ at 10 K in zero field. The synthesis of $MgB_2$/Nb films with thickness above one micron, showing certain tenacity, is an important and significant step towards the application of the $2^{nd}$ generation $MgB_2$ superconductor wires or tapes.

*This work is supported by NSFC under contract No. 50572001

**J1 87 Nonequilibrium Photoresponse of Current-Biased, Epitaxial $MgB_2$ Microbridges** M. KHAFIZOV, D. WANG, X. LI, R. SOBOLEWSKI, *University of Rochester, Rochester, NY 14627* Y. CUI, X. X. XI, *Pennsylvania State University, University Park, PA 16802* We report nonequilibrium, subnanosecond-wide voltage transients generated by current-biased $MgB_2$ microbridges excited by 100-fs optical pulses. Our epitaxial $MgB_2$ films were grown by the HPCVD technique and the microbridge structures, embedded into coplanar waveguides, were patterned by a conventional photolithography and ion milling. The electrical photoresponse transients, measured in the superconducting state, could be decomposed into two elements: the fast, $\sim$ 100-ps-wide, dominating pulse attributed to the kinetic inductive response, and the slow, several-ns-long signal representing the thermal resistive response. The characteristics of the fast response follow the Rothwarf-Taylor model, although in order to explain the peculiar features of this nonequilibrium signal one needs to incorporate into the model the two distinct superconducting gaps. The nonequilibrium photoresponse of $MgB_2$ microbridges makes them attractive as fast photodetectors.

**J1 88 The loss of the anisotropy in the electrical conductivity in $MgB_2$ under pressure** ULISES ESTEVEZ, PABLO DE LA MORA, *Depto. de Fisica, Fac. de Ciencias, UNAM, Mexico* $MgB_2$ is a multiple band superconductor, with two $\sigma$-bands and two $\pi$-bands. The $\sigma$-bands that are highly anisotropic are the responsible of the superconductivity in this compound. It has been shown that with Sc, C and Al doping the $\sigma$-bands reduce their anisotropy, but for the case of Al and C doping the bands fill up and as consequence the number of $\sigma$-carriers reduce and disappear which leads to $T_c$ reduction. In this work it is shown that pressure reducing the $MgB_2$-cell parameters which leads to an increase of the interplane $\sigma$-orbitals overlap. This leads to an increase of the $\sigma$-bands electrical conductivity in the c-direction, in other words, a reduction of the anisotropy of the $\sigma$-bands, on the other hand there is no band filling therefore no reduction of $\sigma$-carriers. This reduction as function of pressure follows a similar trend as $T_c$, thus showing that the anisotropy in the $\sigma$-bands could be an important factor of the high $T_c$ in $MgB_2$.

## J1 89 MAGNETISM POSTER SESSION

**J1 90 Research on Dynamic Model Building of Active Magnetic Bearing** JIAN SHI, GUO-ZHENG YAN, KUN-DONG WANG, *820 Institute, School of Electron, Information and Electrical Engineering, Shanghai Jiao Tong University, Shanghai, 200240, China* As for AMB(active magnetic bearing), many researchers and engineers use theoretical method presented by G. Schweitzer to get the dynamic model. But the model built in this way can not suspend the magnetic system effectively sometimes. Furthermore if any original physical parameter is changed or lost, the theoretical method will be out of work at all. This paper presents a simple and convenient experimental method to build the primary dynamic model of AMB. There is a special advantage that this process has no relation to any original parameter except the mass of rotor which can be obtained easily however. Base on the dynamic model, feedback control system is designed which can make AMB system suspended stably. Through online identifying with frequency method we get the so-called precise model. Finally three models from experiment, theoretical method and online identification respectively, are compared. Result shows that the model from experiment is much closer than that from theoretical method to the precise model.

**J1 91 Spin liquids of a frustrated SU(3) quantum magnets on a triangular lattice** PENG LI, SHUN-QING SHEN, *Dept. of Phys., The Univ. of Hong Kong, Pokfulam Road, Hong Kong, China* The spin disorder state of the bilinear-biquadratic model near the edge of antiferromagnetic region on a triangular lattice is studied in a point of view of frustrated SU(3) quantum magnets. A mean field theory in the quasi-particle representation is established. From the quasi-particle spectra, we show that the density-of-states rise linearly from zero in the region where the SU(3) symmetry is broken. As a consequence, the specific heat at low-temperature in this region exhibits the power law, $C \propto T^2$, which may give an explanation for a recent experiment on NiGa2S4. A finite susceptibility is also obtained in the zero temperature limit, which is also in agreement with the experiment.

**J1 92 Linear and nonlinear magneto-optical properties of Fe/Au multilayered films and Fe-Au alloy films** Y. H. HYUN, Y. P. LEE, *q-Psi and Dept. of Physics, Hanyang Univ., Seoul, Korea* K. W. KIM, *Dept. of Physics, Sunmoon Univ., Asan, Korea* R. YANG, Q. Y. JIN, *Dept. of Optical Science & Engineering, Fudan Univ., Shanghai, China* In this study, the magnetic and the magneto-optical properties of Fe/Au multilayered films (MLF) and Fe-Au alloy films were comparatively studied to elucidate the peculiar magneto-optical properties of Fe/Au MLF. (3.0 nm Fe / $t_{Au}$)$_{20}$ MLF (where $t_{Au}$ = 1.0, 2.0, 2.5 and 3.0 nm) and $Au_{1-x}Fe_x$ ($0 < x < 1$) alloy films of about 100 - 150 nm in thickness were prepared by rf-sputtering onto glass substrates at room temperature. The structures of these films were studied by

x-ray diffraction. The magnetic properties were investigated by using a vibrating sample magnetometer. The magneto-optical properties of Fe-Au alloys and Fe/Au MLF were measured by using magneto-optical Kerr effect (MOKE) and magnetization-induced second-harmonic generation (MSHG). The MOKE was obtained in the equatorial mode, and the MSHG measurements were performed in the longitudinal mode. The MSHG results were analyzed in connection with the MOKE and the VSM results.

**J1 93 Magnetic Properties and Electronic Structure in Transition Metal Doped $La_{0.5}Ca_{0.5}MnO_3$** K.K. YU, S.J. JUN, J.S. PARK, J.Y. KIM, Y.P. LEE, *q-Psi and Dept. of Physics, Hanyang University, Seoul, Korea* K.H. HAN, *Proton Engineering Frontier Project, Korea Atomic Energy Research Institute, Dejeon, Korea* Y.S. LEE, *Division of information Communication and Computer Engineering, Hanbat National University, Daejeon, Korea* J.-H. KANG, *Department Nano and Electronic Physics, Kookmin University, Korea* The magnetic properties of $La_{0.5}Ca_{0.5}Mn_{0.98}TM_{0.02}O_3$ (TM = Cr, Ti) perovskites were studied by using the temperature dependences of magnetization and coercive field. The transition-metal doping like $La_{0.5}Ca_{0.5}Mn_{1-y}TM_yO_3$ (TM = transition metal) can alter the $Mn^{3+}/Mn^{4+}$ ratio, and lead to significant modifications in the magnetic properties. The observed reductions of Curie temperature and magnetization are interpreted with the calculated ratio of $Mn^{3+}/Mn^{4+}$ according to the Curie- Wiess law. The value is determined to be 0.48 for the TM-doped samples. The Mn L- and O K-edge were also measured by x-ray absorption fine-structure spectroscopy. The domain- wall pinning was investigated, as well, with the temperature dependence on coercivity at a constant field.

**J1 94 Magnetic behaviour of $Sr_{2-x}La_xIrO_4$** CARLOS COSIO, GUSTAVO TAVIZON, *Depto. de Fis. y Quimica Teorica, Fac. de Quimica, UNAM, Mexico* PABLO DE LA MORA, *Depto. de Fis., Fac. de Ciencias, UNAM, Mexico* ROBERTO ESCUDERO, *Inst. de Inv. en Materiales, UNAM, Mexico* Magnetic properties of $Sr_2IrO_4$ are an interesting topic because the anisotropic behaviour showed in the single crystal case, as well to the variable valence states of iridium. By solid state reaction we have obtained polycrystalline samples of the solid solution $Sr_{2-x}La_xIrO_4$ and performed structural refinements based on the X-ray powder pattern. We have observed that, as a consequence of distortions in the [IrO6] octahedra, the symmetry of the compounds in the solid solution $Sr_{2-x}La_xIrO_4$ goes from the $K_2NiF_4$ (SG 139) type to $I4_1/acd$ (SG 142). This explanation also is supported by internal parameters optimization with electronic structure calculations using the Wien2K code. On the other hand, magnetic and electrical behaviour characterization of samples in the range of 2-300 K shows that this system can be thought as a weak ferromagnet in all the solubility range. For the high temperature regime the observed effective magnetic moment of iridium ion diverges from the free ion case.

**J1 95 Field dependence of RF susceptibility in the vicinity of a ferromagnetic transition in single crystals $CeAgSb_2$** R. PROZOROV, M.D. VANNETTE, S.A. LAW, S.L. BUD'KO, P.C. CANFIELD, *Ames Laboratory and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011* A 10 MHz resonant technique was used to study ferromagnetic transition in single crystals $CeAgSb_2$. Detailed measurements of field and temperature dependencies of the dynamic susceptibility in the vicinity of the ordering temperature were performed. It was found that a sharp peak in zero-field response rapidly smears out in a weak ( $\sim$ 100 Oe) magnetic field. Obtained results are compared to DC magnetic susceptibility and resistivity, - both showing no similar effect. The possible relation our measurements to study dynamics of a ferromagnetic transition is discussed.

**J1 96 Determination of complex magnetism in a homologous series of compounds.*** R.W. MCCALLUM, Y. JANSSEN, TA. LOGRASSO, K.A. GSCHNEIDNER, JR., V.K. PECHARSKY, B.N. HARMON, *Ames Laboratory, Iowa State University, Ames IA 50011* $Pr_{(n+1)(n+2)}Ni_{n(n-1)+2}Si_{n(n+1)}$, where n = 2, 3, and 4, forms a homologous series of hexagonal compounds whose basic structural unit is a trigonal prism of Pr atoms with its axis parallel to the c-axis. Between 100 and 400 K, their dc susceptibility, $\chi$s measured with H$||$c and H$\perp$ c on a single crystal follows a Curie-Weiss law. In all compounds, the component of M$||$c orders ferromagnetically with T*c* increases with n. For H$\perp$ c, a peak is observed in the low−field M vs T plots below Tc suggesting antiferromagnetic order. For H$\perp$ c at 5 K, all three compounds exhibit a metamagnetic transition between 2 T and 3 T. Based on the systematics of the properties of the members of the series, a model for site specific interactions has been developed for comparison with first principles calculations.

*Ames Laboratory is operated for the US Department of Energy by Iowa State University under contract number W−7405−ENG−82.

**J1 97 The spin structure of maghemite investigated by $^{57}Fe$ NMR** SEONG-JOO LEE, SOONCHIL LEE, *Korea Advanced Institute of Science and Technology* Maghemite( $\gamma$-$Fe_2O_3$) is a ferrimagnetic material known for a long time but its detailed spin structure is not fully understood yet. Interpretation of the hyperfine field measured by the Mössbauer study, which has been the main tool to study local spin structure of this material, has been controversial. Maghemite has an inverse spinel structure where magnetic Fe ions can occupy either the octahedral or the tetrahedral sites. The NMR spectrum shows two separate peaks in zero external field. We split these peaks clearly by applying external magnetic field and compared the peak intensities. The result shows that the hyperfine field at the nuclear spins in the octahedral site is larger than that in the tetrahedral site. The field dependence of the resonance frequency shows that the spins at the octahedral site are antiparallel with external field while those at the tetrahedral site are canted and parallel to external field.

**J1 98 Spin structure of NiFe/FeMn/NiFe trilayers** A.M. ALSMADI, *Physics Department, Hashemite University, 13115 Zarqa, Jordan and Intense Pulse Neutron Source, Argonne National Laboratoy, Argonne IL 60439* S.G.E. TE VELTHUIS, G.P. FELCHER, *Material Science Division, Argonne National Laboratory, Argonne, IL 60439* H.G. YOON, C.G. KIM, *Department of Material Science and Engineering, Chungnam National University, Daejon 305-764, South Korea* Using polarized neutron reflectometry we studied the layer-by-layer spin structure of NiFe(t)/FeMn(15nm)/NiFe(5nm) trilayers with, t = 3.8, and 12 nm in. For both samples the hysteresis curves show two clearly separated loops, each corresponding to the magnetization reversal of one of the two NiFe layers. For the first sample of t = 3.8 nm the neutrons were reflected without undergoing a spin inversion, indicating that at all fields the magnetization of both NiFe layers are

either parallel or antiparallel to the field. However for the second sample of t = 12 nm, at the field where the magnetization of the top NiFe layer starts being hysteretical, the presence of non-zero neutron spin-flip reflectivities signals that some component of the magnetization is perpendicular to the applied field at some depth in the film. The data are consistent with a magnetic configuration where the NiFe layer magnetizations are canted with respect to each other. The polarized neutron results are discussed in terms of the detail FM/AF/FM interactions.

**J1 99 Superlattice effects on spin precession in lateral ferromagnetic heterostructures*** NIKOLAY POLUSHKIN, STEVEN MICHALSKI, ROGER KIRBY, *Department of Physics and Astronomy, University of Nebraska-Lincoln, 68588-0111, Lincoln, NE* FAST MAGNETIZATION DYNAMICS LABORATORY TEAM, Wang and Tilley have developed a model to describe spin wave behavior in systems of magnetic stripes separated by non-magnetic spacers.[1] A key parameter defining spin-wave excitation features in periodic systems is the QD product, where Q is the wavenumber of excited magnons and D the superlattice period. In the long-wavelength limit when QD$<<$1, spin-wave frequencies can be calculated analytically. We have extended the Wang and Tilley model to describe spin-wave behavior in striped media with stripes of two different magnetizations. The analysis reveals the existence of a basic difference in the spectra for different geometries of the applied magnetic field. For instance, two dominating modes occurring under parallel field orientation reduce to a single mode if the field is oriented in the transverse direction. This crossover reflects the different arrangement of the effective medium permeability tensor, which depends on the geometry of the field. This analysis is applied to our pump-probe studies of patterned heterostructures of submicron-width Fe-V stripes. [1]X.Z. Wang and D.R. Tilley, Phys. Rev. B 50, 13472 (1994).

**J1 100 Spin-state Transition Associated with the Magnetization Jump on $Y_{1-x}Sr_xCoO_{3-\delta}$ Compounds (x=0.67, 0.75)** M. IZUMI, Y.F. ZHANG, S. SASAKI, *Tokyo University of Marine Science and Technology* O. YANAGISAWA, *Yuge National College of Maritime Technology* Perovskite-type compounds $Y_{1-x}Sr_xCoO_3$ (x=0.67, 0.75) were prepared by the conventional solid state method and sintered under air and $O_2$ flow. There is a DC magnetization jump during the field cooling at 0.01 T and then it comes normally back to high temperature in the specimens, which is called as magnetic memory effect. The $Co^{3+}$ ions spin state transition from low to intermediate state results in the magnetization jump. The jump temperature ($T_J$) and magnetization increase with the x increases. With increasing the magnetic field, the magnetization jump disappears. Air-processed samples exhibit higher $T_J$ and larger magnetization than $O_2$-processed samples. The main reason is the different content of $Co^{3+}$ ions due to the oxygen deficiency under the different prepared conditions. Samples with x=0.75 show the higher Curie temperature ($T_C$) and at almost the same temperature the cusp appears in the zero-field curve. At the same time, there is another small cusp in the zero-field curve in x = 0.75 samples.

**J1 101 Scaling of hysteresis in phenomenological models of thin ferromagnetic films** ESHEL FARAGGI, *Physics Department, Florida International University, Miami, Florida 33199* Explicit solutions are derived for several phenomenological models of magnetization reversal in thin ferromagnetic films driven by a saw-tooth magnetic field. For a domain wall velocity that is linear in the magnetic field it is found that the dynamic coercive field, and hence the scaling of hysteresis, follows a square-root power-law in the slope of the magnetic field, shifted by the depinning field. For a more general domain wall velocity different power-law exponents are found, yet the overall form for the scaling of the area of the hysteresis loop remains a power-law shifted by the depinning field. This shifted power-law could be interpreted to be a crossover between adiabatic and dynamic regimes.

**J1 102 Magnetic Properties and Magnetization Dynamics in Amorphous Ferromagnetic Microwires*** JOÃO PAULO SINNECKER, RAFAEL NOVAK, *Instituto de Física - Universidade Federal do Rio de Janeiro - CP 68528 - 21941-972 - Rio de Janeiro - BRAZIL* The dynamics of the domain walls during magnetization reversal processes in amorphous ferromagnetic microwires is studied. The studies have been based in measurements made in bmagnetic bistable $Fe_{77.5}Si_{7.5}B_{15}$ microwires. In bistable microwires the magnetization reversal process generally happens through the propagation of a single domain wall along the axial direction, i.e., a large Barkhausen jump. This reversal process is initiated at the wire ends, where a complex domain structure, characterized by the presence of closure domains, is found. Samples with diameters between 20 and 40 $\mu$m, and lengths between 7 and 12 centimeters have been studied. The dynamics has been investigated through the analysis of the signal induced in search coils by the domain walls movement. The influence of externally applied magnetic fields in the dynamics of domain wall propagation has been investigated. Through these studies it was possible to distinguish the different magnetization processes taking place at the extremities and the central part of the microwires.

**J1 103 Dissipative dynamics of vortices in a spiral state and transport in the spin-glass phase of $La_{2-x}Sr_xCuO_4$** V. JURICIC, *Institute for Theoretical Physics, Univ. of Utrecht* L. BENFATTO, *Dept. of Physics, Univ. of Rome ''La Sapienza,'' Italy* A.O. CALDEIRA, *Inst. of Physics, Univ. of Campinas, Brazil* C. MORAIS SMITH, *Institute for Theoretical Physics, Univ. of Utrecht* Doping of an antiferromagnet with holes may lead to a spiral rearrangement of the spins, as it has been argued by Shraiman and Siggia. The formation of a spiral is consistent with the incommensurate magnetic order observed by the neutron scattering experiments in the spin-glass phase of $La_{2-x}Sr_xCuO_4$. The spiral state has a chiral degeneracy that leads to the formation of topologically nontrivial vortex-like defects. We propose that the dissipative dynamics of these defects is responsible for the transport properties in the spin-glass phase of cuprates [1]. Using the collective-coordinate method, we show that the defects are coupled to a bath of magnons. The resulting effective action, after the magnons have been integrated out, indicates that the motion of the defects is damped due to the scattering by the magnons. Assuming that the holes are attached to the vortices, we have calculated the corresponding in-plane resistivity, which exhibits an anisotropy and linear temperature dependence in agreement with experimental data. References: [1] V. Juricic, L. Benfatto, A. O. Caldeira, and C. Morais Smith, Phys. Rev. B **71**, 064421 (2005).

**J1 104 Spin fluctuations and quantum criticality in a CePt ferromagnetic Kondo lattice** JULIO LARREA J., M.B. FONTES, E. BAGGIO-SAITOVITCH, *Centro Brasileiro de Pesquisas Físicas, Brazil* A. EICHER, *Technical University of Braunschwaig, Germany* M. CONTINENTINO, *Instituto de Física, Universidade Federal Fluminense, Brazil* We report on an study of the quantum critical behavior of a ferromagnetic (FM) CePt Kondo lattice using ac susceptibility ($\chi_{ac}$) and electrical resistance ($R(T)$) measurements under high pressures ($P \leqslant 15$ GPa). Our results shows that the FM ordering disappears at the critical pressure $P_C \sim 12.1$ GPa, which is seen as a vanishing of the Curie temperature ($T_C$) and the anisotropic FM magnons ($\Delta$). This $P_C$ is taken as a quantum critical point (QCP) and separates the FM ordering from paramagnetic (PM) state at zero temperature. In the vicinity of $P_C$, a non Fermi liquid behavior (NFL) is observed in the $R(T)$ data as a temperature dependence $T^{1.3}$, which is ascribed to the FM-QCP transition. Beyond the QCP, the system recovers the truly Fermi liquid (FL) behavior. For our knowledge, CePt is the only Ce Kondo lattice that shows a direct FM-QCP transition [1]. Our analysis of the $R(T)$ data, using scaling relations and a spin wave scenario, suggest that the two dimensional FM spin fluctuations is the mechanism to accounts for this ferromagnetic instability. [1] J. Larrea J. et al, Phys. Rev. B 72, 035129 (2005).

**J1 105 Magnetism and hybridization effects in UCuSn** SAMI EL-KHATIB, ANNA LLOBET, *LANSCE-LC, Los Alamos National Laboratory, Los Alamos* AGUS PURWANTO, *Neutron Scattering Laboratory, BATAN, Serpong, Tangerang 15314, Indonesia* A. ALSMADI, *Physics Department, Hashemite University, 13115 Zarqa, Jordan* HEINZ NAKOTTE, *Physics Department, New Mexico State University, Las Cruces NM 88003* UCuSn crystallizes in an orthombically-distorted structure that is closely related to the hexagonal GaGeLi structure. Bulk studies reveal that UCuSn undergoes two magnetic transitions at about 60 and 25 K. Here, we present more detailed neutron-diffraction studies that performed on the High-Intensity Powder Diffractometer (HIPD) at the Manuel Lujan, Jr. Neutron Scattering Center at Los Alamos. Neutron-diffraction studies provide clear evidence for a non-collinear configuration of the magnetic moments in both magnetic phases. We propose a simultaneous existence of two magnetic allowed-symmetry structures as one possible explanation to fit the observed magnetic intensities below 25 K. We will discuss the relationship between magnetic and structural properties in UCuSn. We observe regular thermal contraction with decreasing temperature down to 60 K, below which we observe discontinuities for the interatomic spacings, $d_{U-U}$, $d_{U-Cu}$ and the cell parameters, which provides a measure of the hybridization effects in UCuSn. We were able to correlate the structural changes with the magnetism in UCuSn.

**J1 106 Hartree-Fock calculations of the frustrated 2D Hubbard model*** MATTHEW ENJALRAN, *Southern CT State University* Motivated by recent work on the materials $Na_xCoO_2 \cdot yH^2O$ and a class of organic conductors ($\kappa-(BEDT-TTF)^2X$), where strongly correlated electrons are confined to a geometrically frustrated triangular lattice, we investigate the frustrated Hubbard model via mean−field theory. Were port preliminary results from Hartree−Fock calculations of the charge and magnetic properties of our model on the triangular and square lattices. We also discuss the potential application of the constrained path quantum Monte Carlo (CPQMC) method to the study of frustrated 2D Fermi systems.

**J1 107 Colossal resistivity change besides magnetoresistance: an extended theoretical framework for electronic transport of manganites** SHUAI DONG, KEFENG WANG, *Nanjing National Laboratory of Microstructures, Nanjing University* HAN ZHU, *Department of Physics, Princeton University, Princeton* XIAOYAN YAO, *Nanjing National Laboratory of Microstructures, Nanjing University* JUNMING LIU,* *Nanjing National Laboratory of Microstructures, Nanjing University & International Center for Materials physics, Chinese Academy of Sciences* Current theoretical approaches to manganites mainly stem from magnetic framework, in which the electronic transport is thought to be spin-dependent. However, quite a number of experimental observations can yet not be reasonably explained. An extended framework for electronic transport of manganites has been proposed, in which the total resistivity has been partitioned into two parts: $\rho_s$ and $\rho_c$ in terms of two different mechanisms: spin-dependent and charge-dependent. Correspondingly, the colossal magnetoresistance (CMR) classification inherited from Aliaga et al has been extended as: CMR2 and XR, where CMR2 is the classical spin-dependent process while XR is spin-independent. We emphasize the important role of XR which helps to understand the true mechanism of CMR.

**J1 108 The enhanced magnetoresistant effects and cluster-glass state induced by A-site cational size disorder** KEFENG WANG, LIFENG WANG, *Nanjing National Laboratory of Microstructures, Nanjing University* JUNMING LIU,* *Nanjing National Laboratory of Microstructures, Nanjing University & International Center for Materials Physics, Chinese Academy of Sciences* In pervoskite-structure oxides, not only the A-site cational mean radii, but also the variance of the A-site cational radii, controls the physical properties of the sample. The disorder effects induced by A-site cational size mismatch in large band-width manganite $La_{0.55}Sr_{0.45}MnO_3$ have been carefully studied by preparing a series of samples which have the same $< r_A > = 1.25$Å with different variance of the A-site ionic radii. The ground state of the system changed from a ferromagnetic metal to a cluster-glass insulator with increasing of the variance of the A-site ionic radii. Moreover, the magnetoresistant effects is enhanced significantly in the sample with intermediate disorder. We argued that the A-site disorder enhanced the fluctuation between the competing ordered states and then induced the cluster-glass state and the enhanced magentoresistant effects.

**J1 109 Resistor-network study of tunneling magnetoresistance in ordered arrays of magnetic nanoparticles** DIMITRIS KECHRAKOS, KALLIOPI TROHIDOU, *Institute of Materials Science, NCSR Demokritos, 15310 Athens, GR* The tunneling magnetoresistance (TMR) of a hexagonal array of dipolar interacting magnetic nanoparticles is studied using a resistor network model and micromagnetic configurations obtained from Monte Carlo simulations. Analysis of the field-dependent TMR and the corresponding magnetization curve shows that dipolar interparticle

interactions suppress the maximum TMR effect, increase or decrease the field-sensitivity depending on the direction of applied field and produce strong dependence of TMR on the direction of applied magnetic field. The peak in TMR for a unipolar sweep of the magnetic field is associated with the critical field for irreversible rotation of the magnetization, rather than the coercive field as commonly interpreted. This behavior is evident in strongly interacting arrays with the magnetic field at a nearly right angle to the array. Under these conditions the difference between the coercive and critical field is maximized. The relation of our simulations to recent TMR measurements in self-assembled Co nanoparticle arrays is discussed.

**J1 110 Epitaxial half metallic/oxide semiconductor schottky contacts** J. JHAVERI, *Department of Physics, University of Florida, Gainesville, FL* A. VENIMADHAV, QI LI, *Department of Physics, Pennsylvania State University, PA16801* Half metallic/semiconductor junctions are useful for spintronic devices. With such an interface, one can potentially inject a large percentage of spin polarized electrons into the semiconductor in a active spintronic device. We fabricated half-metallic $Sr_2FeMoO_6$ (SFMO) and 0.1% Nb doped $SrTiO_3$(Nb: STO) schottky contacts using Pulsed Laser Deposition (PLD). $Sr_2FeMoO_6$films were grown epitaxially on Nb-$SrTiO_3$ with Ar and small amounts of $O_2$ (0.02%) while the substrate was kept at $800^o$ C. The current versus voltage characteristics of the junction were measured on 1 $mm^2$ contact area. The I-V curves were measured at several temperatures and in each case, the junction exhibited a clear rectifying behavior. A strong rectifying behavior was observed at room temperature with a small activation voltage of 0.2 V. Temperature dependence of I-V characteristics shows a clear schottky nature of the contacts. The barrier height and ideality factor of the junction were calculated using the thermionic model given by $I = I_s(e^{V/nkT} - 1)$. Here, $I_s = AA^* T^2 e^{q\phi/kT}$, where $A$ is the active area, $A^*$ is the effective Richardson constant, $\phi$ is the Schottky barrier height, and $n$is the ideality factor. We found that the ideality factor was approximately constant as the temperature was varied with small deviations, and the barrier height decreased with temperature and more abruptly below 100K.

**J1 111 Spin-polarized sources for Si-based spin injection-detection devices** SEBASTIAAN VAN DIJKEN, *Trinity College Dublin* C. BOOTHMAN, *Trinity College Dublin* M. THIEBAULT, *Trinity College Dublin* C. MURRAY, *Trinity College Dublin* G. FENG, *Trinity College Dublin* J.M.D. COEY, *Trinity College Dublin* We have explored magnetite/Si and Fe/MgO/Si contacts as possible sources of highly spin-polarized currents. Reactive sputtering of magnetite from a pure Fe target results in the growth of single crystal films with a (111) texture on both Si(001) and Si(111) substrates. The evolution of the film magnetization with temperature exhibits a sudden decrease around 120 K, which is characteristic for the Verwey transition in magnetite and indicates high quality film growth. Electrical transport across the magnetite/Si interface is dominated by tunneling through (at low temperatures) and thermionic emission across (at elevated temperatures) a Schottky barrier. The Schottky barrier height is 0.52 eV and 0.65 eV for magnetite films on Si(111) and Si(001), respectively. Direct rf magnetron deposition of MgO on Si(001) results in tunnel barriers with a weak (001) film texture. The injector current (at fixed bias voltages) varies non-monotonically with tunnel barrier thickness. This dependence is qualitatively explained by a competition between a reduction in current due to a thicker tunnel barrier and an increase in current due to a reduction of the Schottky barrier height and Si depletion width.

**J1 112 High coercive cobalt ferrite $Co_xFe(3\text{-}x)O4$ nano−composite thin films prepared by spin−on process' *** P. TALAGALA, R. NAIK, *Wayne State University* G.M. TSOI, L.E. WENGER, *University of Alabama at Birmingham* R. SURYANARAYANAN, *Universite of Paris−Sud* V.M. NAIK, *University of Michigan−Dearborn* Spin coating technique have been employed to synthesize $CO_xFe_{3-x}O_4$ ($0.5 \leqslant x \leqslant 1.9$) nano−composite thin films of $\sim$ 10nm crystalline size on sapphire, glass, and aluminum substrates. The films were annealed invarious environments such as air, H2/Ar, and vacuum. The structural properties were characterized by XRD and Raman Spectroscopy. The magnetic hysteresis measurements of the films exhibit a large coercivity HsC (15−17kOe) at 5K. Low temperature processed films demonstrate super magnetic characteristics with HC=$\sim$ 150 Oe and reduced remanence $M_{rs}/M_s = \sim 0.05 at 300$ K.These films show a spin−glass behavior with the blocking temperature $T_B \propto H^2$ for low fields and $T_B \propto H^{2/3}$ for high fields. High temperature processed films with various annealing conditions demonstrate $H_C$ as high as 1.8kOe at 300K. Estimated magnetic anisotropy value of the films is in the range of $0.8-2.4x10^6$ erg/$cm^3$. Optical absorption spectra exhibit band gaps in the visible range of 1.4−1.7eV and in the I Rrange (1.0eV and 0.7eV). Annealing in hydrogen shows are duction of resistivity. Further details of the structural, electrical and magnetic properties of the films will be presented.

*This Work is supported by NSF−REU grant No. EEE0097736

**J1 113 Structural and Magnetic Ordering of the Interface of Fe/Gd Multilayers** ATAUR CHOWDHURY, *University of Alaska Fairbanks* ANDREA FREITAG, *Brookhaven National Laboratories* Multilayers of Fe/Gd were fabricated with magnetron sputtering to study the magnetic and structural ordering of the interfaces of these multilayers. Two groups of samples, one with fixed Gd layer thickness and one with fixed Fe layer thickness, were prepared to study the effect of layer thickness on the structural properties of these multilayers. The samples were investigated using x-ray diffraction and Mossbauer spectroscopy. Two major structures were identified with x-ray diffraction, and two more minor structures were identified from Mossbauer measuremnt. The composition and the thickness of the interface was found to change with both Fe and Gd layer thicknesses. Results of Mossbauer measurement also show that an amorphous Gd-Fe component at the interface with an average composition close to that of the intermetallic compound $GdFe_2$ is likely to be the origin of perpendicular magnetic anisotropy (PMA) of Fe/Gd multilayers. Experimental results clearly suggest that PMA in Fe/Gd multilayers and amorphous Gd-Fe films may have the same origin.

**J1 114 Properties of magnetoelectric susceptibility*** JUNYI ZHAI, JIEFANG LI, DWIGHT VIEHLAND, *Virginia Tech* M.I. BICHURIN, *Novgorod State University, Russia* VIRGINIA TECH TEAM, NOVGOROD STATE UNIVERSITY TEAM, The magnetoelectric (ME) susceptibility is the principle property of ME materials, determining the connection between polarization (or electric induction) and an external magnetic field. Since measurement of the ME susceptibility over a wide frequency range [1]

and the design of new ME devices require more information about the ME susceptibility, the present work has focused on this property in detail. First, we consider the ME susceptibility as a complex parameter with both real and the imaginary parts, advancing a methodology for measurement of these values. Second, we have analyzed the ME susceptibility, for example a trilayer laminate composite of Terfenol-D/PZT, Terfenol-D, and found a maximum value of $\sim$ 3.5x10-7s/m in the electromechanical resonance range. In addition, we have studied the internal structure of the ME susceptibility: i.e., its dependencies on phase volume fractions, layer thickness, and choice of materials couple. Our results for the ME susceptibility will allow it to be more correctly used both as a fundamental materials property and also in potential ME device applications. [1] M.I. Bichurin, V.M. Petrov, Yu.V. Kiliba, and G. Srinivasan. Phys. Rev. B 66, 134404 (2002).

**J1 115 Domain wall phase diagram and wall widths** M. KLAUI, M. LAUFENBERG, D. BACKES, U. RUDIGER, *Fachbereich Physik, University of Konstanz* C. A. F. VAZ, J. A. C. BLAND, *Cavendish Laboratory, University of Cambridge* L. J. HEYDERMAN, F. NOLTING, *PSI, Villigen* SPELEEM GROUP, ELETTRA TRIESTE COLLABORATION, The details of the spin structure of domain walls have recently become the focus of intense research due to the fundamental physical questions associated with domain walls (wall width, magnetoresistance, current-induced domain wall propagation). Using photoemission electron microscopy (XMCDPEEM) we have obtained high-resolution images of the spin structure of the domain walls, which allows us to determine the wall type and the wall width for different Co [1] and NiFe wire and ring geometries. We determine the phase transition between the different domain wall types as a function of the geometrical parameters (width, thickness) [1]. Comparison with theoretical calculations [2] and micromagnetic simulations reveals the importance of local energy minima and the geometry-dependent height of the energy barriers separating the two wall types can be derived. The energy barrier height is then directly measured by high-temperature (up to 600 K) imaging of thermally activated transitions from transverse to vortex walls. By varying the spacing between domain walls, we determine the coupling strength that leads to a shift in the phase boundary. [1] M. Klaui et al., APL **85**, 5637 (2004); [2] R.D. McMichael and M.J. Donahue, IEEE Trans. Magn. **33**, 4167 (1997).

**J1 116 Electric Dipole Transitions at Magnetoacoustic Resonance** M.I. BICHURIN, V.M. PETROV, O.V. RYABKOV, A.V. FILIPPOV, A.A. IVANOV, *Novgorod State University, Russia* G. SRINIVASAN, *Oakland University* Ferromagnetic-ferroelectric composites show giant magnetoelectric (ME) effects that are facilitated by the sample response to electric, magnetic, and elastic forces. Composites consisting of magnetostrictive ferrites and piezoelectric lead zirconate titanate (PZT) or lead magnesium niobate-lead titanate (PMN-PT) are found to show strong ME coupling. Such materials also provide us with unique opportunities for theoretical and experimental studies on ME coupling when the magnetic and/or electric subsystems show resonance behavior. Two types of resonances are of importance: electromechanical resonance (EMR) for the piezoelectric component and ferromagnetic resonance (FMR) for the magnetic component. At the coincidence of EMR and FMR, i.e., at the magneto-acoustic resonance (MAR) ME interaction becomes stronger [1]. This work focuses on electric dipole transitions in multilayer ferromagnetic-ferroelectric composites, such as yttrium iron garnet (YIG) and PZT, at MAR. Expressions have been obtained for ME susceptibility and the ME coefficient. The results indicate the potential for novel microwave devices based on ME interactions at MAR. Supported by grants from the ARO, ONR and NSF. [1] M.I. Bichurin, V.M. Petrov, O.V. Ryabkov, S.V. Averkin and G. Srinivasan, Phys. Rev. B. **72**, 060408(R) (2005).

**J1 117 Enhancement in Magnetoelectric Effects at Thickness Modes of Layered Ferromagnets and Ferroelectrics** D.A. FILIPPOV, M.I. BICHURIN, V.M. PETROV, *Novgorod State University, Russia* V.M. LALETSIN, *Inst. Tech. Acoustics, Belarus* G. SRINIVASAN, *Oakland University* C.W. NAN, *Tsinghua University, China* Magnetoelectric (ME) effects in magnetic - piezoelectric heterostructures are caused by mechanical coupling between magnetic and piezoelectric layers. We reported earlier on the theory and observation of a resonant enhancement in the ME effects when the electrical subsystem is driven to resonance, i.e., electromechanical resonance (EMR) associated with radial acoustic modes [1]. Here we discuss the theory and data for ME effects associated with thickness EMR modes. Profiles of ME voltage coefficients versus frequency were estimated for trilayers based lead zirconate titanate and the following ferromagnetic phases: cobalt ferrite, nickel ferrite and lithium ferrite and Fe, Co and Ni. The results are compared with data on samples 10 mm in diameter and 2 mm in thickness. An enhancement in the ME voltage due to radial modes is observed at 350 kHz. A similar behavior due to the thickness mode is observed at 1.5-2 MHz, in agreement with the theory. Calculated ME voltage coefficients versus frequency profiles are in excellent agreement with data. - supported by an NSF grant. [1] D. A. Filippov, M. I. Bichurin, V. M. Petrov, V. M. Laletin, G. Srinivasan, Phys. Solid State **46**, 1674, (2004).

**J1 118 Nonextensivity in Magnetic Nanocluster Ensembles*** CHRISTIAN BINEK, *Dept. of Physics and Astronomy* SRINIVAS POLISETTY, XI HE, TATHAGATA MUKHERJEE, RAJESH RAJASEKERAN, *Dept. of Chemistry* JODY REDEPENNING, *University of Nebraska-Lincoln* We study the scaling behavior of dipolar interacting nanoparticles in 3D samples of various sizes but constant particle density. Ferromagnetic $\gamma$-$Fe_2O_3$ clusters embedded in a polystyrene matrix are fabricated by thermal decomposition of metal carbonyls. Transmission electron microscopy reveals a narrow size distribution of 12 nm clusters. They are randomly dispersed in the matrix with an average separation of 80 nm. Magnetization isotherms of these single domain particle ensembles are measured by SQUID magnetometry above the blocking temperature $T_B$ =115K where non-equilibrium effects are avoided. After demagnetization corrections which convert the applied magnetic fields into internal fields, H, a data collapse is achieved when scaling the magnetic moment, m, and H by appropriate factors. The latter are theoretically predicted functions of the number of particles and determined here numerically. Scaling of H takes into account the nonextensive (NE) behavior of dipolar interacting particles. In the case of long range interactions a scaling schema has been proposed by Tsallis and confirmed by simulations. The controversial field of NE thermodynamics requires however experimental evidence provided here.

**J1 119 Magnetic and magneto-optical properties of $Co_2MnSi$ magnetic grating** J.B. KIM, G.J. LEE, Y.P. LEE, *q-Psi and Dept. of Physics, Hanyang Univ., Seoul, Korea* C.S. YOON, *Dept. of Materials Science and Engineering, Hanyang Univ., Seoul, Korea*

J.Y. RHEE, *Dept. of Physics, Sungkyunkwan Univ., Suwon, Korea* K.W. KIM, *Dept. of Physics, Sunmoon Univ., Asan, Korea* The magnetic and the magneto-optical properties of periodic magnetic structure, produced by the femtosecond-laser induced crystallization of amorphous $Co_2MnSi$ films, were elucidated. The amorphous $Co_2MnSi$ films have been prepared by rf-magnetron sputtering on a glass substrate at room temperature. In order to form a grating structure, two-beam interference of femtosecond laser pulses was employed. The atomic-force-microscopy and the transmission-electron-microscopy results show regularly-spaced alternating lines with a periodicity of 2 $\mu$m. The magnetic-force-microscopy results reveal the periodic patterns of magnetic domains. The Kerr hysteresis loops of sample were measured by using a magneto-optical microscope. The enhanced magneto-optical properties were observed in the first-order diffracted beam. It was also found that the films with a spatially periodic magnetic structure can be relatively easily fabricated by selectively crystallization of a paramagnetic $Co_2MnSi$ amorphous film, which crystallizes into a ferromagnetic phase upon illumination with sufficiently intense laser light.

**J1 120 Non-lithographic Fabrication of Magnetic Nanodot Arrays*** BI-CHING SHIH, *University at Buffalo, the State University of New York* MIN NI, *University at Albany, State University of New York* HAO ZENG, *Department of Physics, University at Buffalo, the State University of New York, Buffalo, NY14260* Highly-ordered magnetic nanodot arrays with tunable size and interdot spacing have been fabricated by electron-beam evaporation through ultra thin porous anodic alumina (PAA) templates. The PAA templates were fabricated by a 2-step anodization process in a 0.3 M oxalic acid electrolyte at room temperature, with an anodization voltage ranging from 20 to 60 V. The aspect ratio were controlled by the second anodization time. In order to get porous arrays with through holes, the aluminum layer and the barrier layer were removed by wet chemical etching. The template was then placed on a solid substrate as a shadow mask for subsequent deposition of magnetic nanodots. The magnetic properties of Ni nanodot arrays with 50 nm diameter and 80 nm spacing were studied in detail. The dots are superparamagnetic at room temperature. They become ferromagnetic at approximately 170 K. The coercivity at low temperatures is found to be much higher than that of continuous Ni films, due to a transition of magnetization reversal mechanisms from domain wall motion to spin rotation. A significant reduction in the Curie temperature is observed, which is attributed to the finite size effect.

**J1 121 Magnetic Thermal Hysteresis in (Co, Fe)/Tb Multilayers** MARIA HOSSU, *Department of Physics, University of Texas at Arlington, Arlington, TX, 76019* ALI KOYMEN, *Department of Physics, University of Texas at Arlington, Arlington, TX, 76019* In plane and out of plane magnetic thermal hysteresis have been measured to investigate the ferrimagnetic behavior of (Co, Fe)/Tb multilayers. Due to antiferromagnetic coupling between the (Co, Fe) and Tb, the multilayers behave like artificial ferrimagnets. For $[Co\ (30Å)/Tb\ (45\ Å)]_8$ the measurement of magnetic moment (M) as a function of temperature shows that magnetic phase transition occurs at different temperatures during the heating (superheating) and cooling (supercooling) cycles resulting in a characteristic **bow-tie** shaped thermal hysteresis curve for **M (T)**.The width of the thermal hysteresis was measured to be to be around 90 K in an external magnetic field of 2000 Oe. Increasing the field to 4000 Oe reduces the thermal hysteresis width to about 40 K and above 6000 Oe the thermal hysteresis disappears. Co/Tb multilayers with thicker layers show the same trend, however, the width of the thermal hysteresis is generally smaller at a given magnetic field.

**J1 122 Magnetic properties of double-layer vanadium oxides and vanadium oxide nanotubes.** NATASHA A. CHERNOVA, SAMUEL T. LUTTA, CHRIS JACOBS, M. STANLEY WHITTINGHAM, *Institute for Materials Research, SUNY at Binghamton, Binghamton NY 13902-6000* PETER Y. ZAVALIJ, *Department of Chemistry and Biochemistry, University of Maryland, College Park, MD 20742-4454* Double-layer $V_8O_{20}$ compounds[1] intercalated with various cations and the vanadium oxide nanotubes (VONTs) $VO_{2.4}\ [C_{12}H_{28}N]_{0.31} \cdot 0.56H_2O$ were prepared using hydrothermal method and characterized by x-ray diffraction, TGA, TEM, FTIR. Magnetic properties were studied using SQUID magnetometer. Depending on the intercalated cation type, the magnetic susceptibility of $V_8O_{20}$ compounds reveal presence of small clusters or infinite linear chains with antiferromagnetic (AF) exchange. VONTs show a spin gap, which is well described by the simple model of magnetic dimers with AF exchange. Various ion exchange and red-ox reactions are performed on VONTs. Structure and magnetic properties of the resulting compounds are discussed. No ferromagnetic response from the VONTs reacted with BuLi is found[2]. The work is supported by the National Science Foundation through grant DMR 0313963.

**J1 123 Thermal and Quantum Peierls Transitions in Organic Charge-Transfer Salts** SHARON BEWICK, ZOLTAN SOOS, *Princeton University* The choice of donors (D) and acceptors (A) governs the charge-transfer $\rho$ in organic CT salts with mixed one-dimensional DADA stacks. Strong D and A yield $\rho \sim 0.9$ stacks of radical ions with thermally accessible spin and charge degrees of freedom whose Peierls transition can be described by a Hubbard model with site energies. The same microscopic model describes CT salts with smaller and variable $\rho \sim 0.5$ in which neutral-ionic and/or Peierls transitions occur in the ground electronic state. Quantum transitions are driven by volume changes, with negligible thermal population of excite states. CT salts with thermal or quantum Peierls transitions are identified. Conflicting magnetic, vibrational and structural data in several CT salts are resolved in terms of mobile spin solitons, a dimerized ground state and a Peierls transition beyond the crystal's thermal stability.

**J1 124 Avalanches in Mn12-Acetate: ''Magnetic Burning''** SEAN McHUGH, Y. SUZUKI, D. GRAYBILL, M.P. SARACHIK, *Department of Physics, City College of New York/CUNY, New York, New York* N. AVRAHAM, Y. MYASOEDOV, H. SHTRIKMAN, E. ZELDOV, *Department of Condensed Matter, Weizmann Institute of Science, Rehovot, Israel* R. BAGAI, N.E. CHAKOV, G. CHRISTOU, *Department of Chemistry, University of Florida, Gainesville, FL* From local time-resolved measurements of fast reversal of the magnetization in single crystals of the molecular magnet $Mn_{12}$-acetate, we have shown [1] that the magnetization avalanche spreads as a narrow interface that propagates through the crystal at a constant velocity roughly two orders of magnitude smaller than the speed of sound. This phenomenon is

closely analogous to the propagation of a flame front (deflagration) through a flammable chemical substance. The propagation speed of the avalanche depends on the energy stored in each molecule, which can be controlled and tuned using an external magnetic field. We report studies of propagation speed with different external fields in $Mn_{12}$-acetate. [1] Yoko Suzuki, M.P. Sarachik, E.M. Chudnovsky, S. McHugh, R. Gonzalez-Rubio, N. Avraham, Y. Myasoedov, H. Shtrikman, E. Zeldov, N.E. Chakov and G. Christou, Phys. Rev. Lett. 95, 147201 (2005).

**J1 125 Time Evolution of the Magnetization of Mn-12 Acetate above 1.8 K.** REEM JAAFAR, Y. SUZUKI, D. GRAYBILL, M.P. SARACHIK, *City College of New York* R. BAGAI, G. CHRISTOU, *University of Florida, Gainesville* It is well known that the decay of the magnetization of the molecular magnet Mn12-acetate is not a simple exponential. From measurements using a commercial Quantum Design MPMS magnetometer between 3 K and 1.8 K, we present the results of a detailed study of the time evolution of the magnetization as it increases from zero (following zero-field cooling) in response to longitudinal magnetic fields up to 400 Oe. Fits to the data will be shown for distributions of characteristic times (Gaussian, Lorentzian and others) of different widths in response to magnetic fields near and away from a tunneling resonance. The effect of temperature and transverse field will be discussed.

**J1 126 Edge excitations in quantum spin chains*** CHANGFENG CHEN, *University of Nevada, Las Vegas* We explore the nature of the topological edge excitations in quantum spin chains using both analytical valence-bond-solid analysis and numerical simulations. The results reveal new excitation modes that are associated with a topological order in the spin chains. Experimental implications will be discussed.

*This work was supported in part by the Department of Energy.

**J1 127 Record Two-Halide Exchange in Cu(2,5-dmpz)$Br_2$: Theory and Experiment** R. BUTCHER, C.P. LANDEE, M.M. TURNBULL, *Clark University, Worcester, MA 01610* J. NOVOA, J. RIBAS, *Departament de Quimica Fisica, Universitat de Barcelona, Barcelona, Spain.* Cu(2,5-dmpz)$Br_2$ (2,5-dmpz = 2,5-dimethylpyrazine) is an antiferromagnetic rectangular lattice, with the S=1/2 copper ions bridged along one axis through the pyrazine molecules and through Cu-Br.. Br-Cu contacts in a transverse direction. Large orbital overlap is obtained by the very short Br-Br distances plus the linear arrangement of the copper and bromine atoms. The magnetic susceptibility corresponds to an exchange strength of $J/k_B \approx$ 160 K, a record for exchange for two bromide contacts. Numerical techniques have been developed for calculating two-halide contact magnetic exchange interactions from first principles [1,2]. They predict the same exchange strength for Cu(2,5-dmpz)$Br_2$ based only on the structural parameters of the compound. We present the magneto-structural correlations in Cu(2,5-dimethylpyrazine)$Br_2$ and compare this to two other known pyrazine complexes; Cu(pyrazine)$CuBr_2$ and Cu(2,3-dimethylpyrazine)$Br_2$. 1. M. Deumal et al, Polyhedron **22** 2235-2239 (2003). 2. M. Deumal et al, Euro. J. Inorg. Chem. **2005**, 4697-4706.

**J1 128 Magnetic properties of Co-Rh and Ni-Rh nanostructures** JAVIER GUEVARA, *Escuela de Ciencia y Tecnología, Universidad de San Martín, Argentina and Dept Física, CAC-CNEA, Argentina* TRISTANA SONDON, *Dept Fisica, CAC-CNEA, Argentina and Instituto Sabato, UNSAM, Argentina* ANDRES SAUL, *CRMCN-CNRS, Campus de Luminy Case 913, 13288 Marseille Cedex 9 France* We study the evolution of the magnetic properties of Co-Rh and Ni-Rh nanostructures (free-standing monolayers and wires) on Rh content ($x$). It is known that dimensionality affects the magnetic properties of the materials. Rh is non magnetic in bulk, but shows magnetic order as free-standing monolayer or nano- wire, being $1.03\mu_B$ and $0.26\mu_B$ the corresponding magnetic moments, calculated by using the *abinitio* Wien-2k code. In the case of $Co_{1-x}Rh_x$ and $Ni_{1-x}Rh_x$ wires, the evolution of the Rh magnetic moment is similar for both cases, being enhanced with respect to pure Rh wire value and reaching the largest values at x=.5 ($1.36\mu_B$ and $1.31\mu_B$ respectively). For $x > 0.5$ all the magnetic moments fall. For $x < .5$ the Co and Ni magnetic moments reach values larger than the corresponding pure wire and than their saturation magnetic moments. In the case of mixed monolayers the Rh and Ni magnetic moments are not enhanced as Co or Ni content increases, however Co $\mu$ is enhanced without crossing its saturation value. By alloying with Co or Ni, Rh wires enhanced their magnetic moments, while mixed monolayers' Rh magnetic moments are not enhanced.

**J1 129 $^{51}$V-NMR investigation of the spin-frustrated magnet $Ni_3V_2O_8$.*** W.G. CLARK, P. RANIN, GUOQING WU, G. GAIDOS, *UCLA Physics and Astronomy* G. LAWES, *Wayne State U. Physics* A.P. RAMIREZ, *Lucent Bell Labs* R.J. CAVA, *Princeton U. Chem.* M. HORVATIC, C. BERTHIER, *Grenoble High Magnetic Field Lab.* The $Ni^{2+}$ ions in the Kagomé-staircase lattice compound $Ni_3V_2O_8$ form an electron spin $S = 1$ system with a geometrically frustrated magnetization and a rich variety of phases below 10 K. Here, we report a study of the local magnetic field and its fluctuations using $^{51}$V NMR measurements of the spectrum, the spin-phase memory time ($T_2$), and the spin-lattice relaxation rate ($1/T_1$) over a broad range of magnetic field and temperature. Above 10 K, the local field from the $Ni^{2+}$ ions follows a Curie-Weiss law. In the ordered phases below 10 K, the NMR spectrum has a very broad structure that changes according to the particular phase. Also, below 10 K, $1/T_1 \propto T^2$. These features suggest that $1/T_1$ is dominated by $Ni^{2+}$ electron moment fluctuations whose dynamics are driven by two-dimensional antiferromagnetic coupling.

*The work done at UCLA was supported by NSF Grant DMR-0334869.

**J1 130 Variation of critical temperature with dilution in a 3D-XY insulating ferromagnet*** G.C. DEFOTIS, R.A. HUDDLESTON, B.C. ROTHERMEL, J.H. BOYLE, E.S. VOS, Y. MATSUYAMA, A.T. HOPKINSON, *College of William and Mary* A very rare 3D-XY insulating ferromagnet is the molecular material Fe(III) bis(diselenocarbamate) chloride, ordering near 3.4 K. The XY anisotropy arises because of a large zero-field splitting of the quartet crystal field ground term, with a positive axial splitting parameter making the (+1/2,-1/2) Kramers doublet low-lying. Intermolecular exchange interactions operate via Fe-Se...Se-Fe contacts. We have succeeded in diluting this material to significant degrees with a diamagnetic near structural isomorph, Zn(II) bis (dithiocarbamate). Analysis of dc susceptibility and magnetization data leads to estimates of the ferrromagnetic ordering temperature in undiluted, 0.137, and 0.202 Zn-mole fraction diluted material. Compositions are determined by atomic absorption spectropho-

tometry. The ordering temperature decreases moderately with increasing dilution, at a rate typical of three-dimensional systems and much slower than in two-dimensional materials. It is more difficult to distinguish among spin interaction models based on the data.

*Supported by NSF-SSC Grant No. DMR-0085662 and by an ACS-PRF grant.

**J1 131 A Yttrium Iron Garnet-Lead Zirconate Titanate Phase Shifter** G. SRINIVASAN, A.S. TATARENKO, *Oakland University* M.I. BICHURIN, *Novgorod State University, Russia* Tunable microwave phase shifters are of interest for miniature oscillators and phased array antenna systems. Traditional ferrite phase shifters use magnetic tuning systems that are slow, demand high power, and are not miniature in size. Here we discuss the design, fabrication and characterization of a novel electric field tunable phase shifter based on a yttrium iron garnet (YIG) – lead zirconate titanate (PZT) bilayer. The electrical control of the phase shift is realized through magnetoelectric (ME) interaction. The phase shifter consisted of a microstrip transmission line with stubs of $\lambda/8$ and $3\lambda/8$ lengths for generating circularly polarized microwave magnetic field in the YIG-PZT resonator. The ME resonator was made from 124 micron thick (100) YIG film on GGG and 0.5 mm thickness PZT with electrodes. The operating frequency of the phase shifter was set by applying appropriate bias magnetic field. The phase shift vs. electric field E characteristics was linear or quadratic in E, depending on the operating frequency. The maximum phase shift was 180 deg. and showed an insertion loss of 1.5-2.0 dB at 5 GHz and 3-4 dB at the frequency 10 GHz. The ME phase shifter is capable of rapid tuning, miniature in size and dissipates practically zero power. – The work was supported by grants from ONR, ARO and NSF.

**J1 132 A Magnetic Field Tunable Lens of Left-Handed Material** A.S. PETROV, R.V. PETROV, M.I. BICHURIN, *Novgorod State University, Russia* G. SRINIVASAN, *Oakland University* D. VIEHLAND, *Virginia Tech.* The design, fabrication and characterization of lenses of left handed materials (LHM) based on ferrite spheres are presented. A unit-cell constructed from cross-wire resonators with 2-mm diameter polycrystalline yttrium iron garnet spheres at the center was used. The ferrite sphere facilitated LHM elements with magnetic-field dependent permeability. The focal length of the LHM lens, therefore, could be tuned with a magnetic field. The studies show that the YIG-cross-wire resonators are ideal tunable LHM lenses. The lens characteristics were measured in the frequency range from 1 to 18 GHz. For example, the focal point of the lens could be tuned over a length of 2 cm by varying the magnetic field from 4100 to 4125Oe at 11.5 GHz. - supported by a grant from the NSF.

**J1 133 A Negative-Index Metamaterial Unit Cell** R.V. PETROV, M.I. BICHURIN, *Novgorod State University, Russia* D. VIEHLAND, *Virginia Tech.* G. SRINIVASAN, *Oakland University* Metamaterials with a negative index of refraction can be realized in an array of straight wires and split-ring resonators (SRRs). Such structures will have a negative permittivity and permeability at a specific frequency. Here we provide the details on the design and characterization of a modified negative-index material (NIM) that uses cross-wire resonators (CWR). The resonators were made of copper wires having a diameter of 0.2 mm. Comparison of properties at 11.5 GHz for NIMs constructed with SRR and CWR is presented. For the NIM lens with CWR, precise control of the focal point is possible; the edges in the profile for intensity vs. distance are well defined, and the maximum achievable focal length is higher than for the split-ring NIMs. - supported by a grant from the NSF.

**J1 134 Study of Complete Elliptic Integrals with a goal of Improving Computation of Axisymmetric Fields** JOSEPH W. RUDMIN, *Physics Dept. James Madison Univ* In recent years I have been investigating the Complete Elliptic Integral of the First Kind, K, with a goal of finding a rapidly convergent power series R such that K can be written in terms R with the non-analyticities subtracted off or divided out. The singularities in K are logarithmic in nature, so that power series expressions of K converge slowly. Progress in this study will be presented.

**J1 135 Magnetization dynamics of two interacting spins in an external magnetic field** WILLIAM COFFEY, *Dept. Electronic & Electrical Engineering, Trinity College, Dublin 2, Ireland* HAMID KACHKACHI, *Lab. Magnétisme et d'Optique, Université de Versailles St. Quentin* YURI KALMYKOV, *Université de Perpignan, 52 Avenue Paul Alduy, 66860 Perpignan Cedex, France* SERGEY TITOV, *Institute of Radio Engineering and Electronics of the Russian Academy of Sciences, Fryazino, 141190, Russia* The longitudinal relaxation time of the magnetization of a system of two exchange coupled spins subjected to a strong magnetic field is calculated exactly by averaging the stochastic Gilbert-Landau-Lifshitz equation for the magnetization, i.e., the Langevin equation of the process, over its realizations so reducing the problem to a system of linear differential-recurrence relations for the statistical moments (averaged spherical harmonics). The system is solved in the frequency domain by matrix continued fractions yielding the complete solution of the two spin problem in external fields for all values of the damping and barrier height parameters. The magnetization relaxation time extracted from the exact solution is compared with the inverse relaxation rate from Langer's theory of the decay of metastable states [J. S. Langer, Ann. Phys. (N.Y.) **54**, 258 (1969)], which yields in the high barrier and intermediate-to-high damping limits the asymptotic behavior of the greatest relaxation time.

**J1 136 A Comparison of Various Update Schemes Used in Monte Carlo Simulations of Stoner-Wohlfarth Particles*** CHRISTOPHER RUSSELL, KARL UNRUH, *University of Delaware* The hysteresis loops for non-interacting Stoner-Wohlfarth particles have been simulated by the Monte Carlo (MC) method as a function of the temperature, the magnitude of the angular aperture used to update the magnetization direction, and the total number of MC steps. Comparing the coercivity obtained from these hysteresis loops with those obtained from Néel's relaxation model has allowed two different sets of consistent MC parameters to be determined (in the sense that the simulated hysteresis loops will reproduce the temperature dependence of the Néel coercivity). The first set allows the use of a physical temperature but requires the magnitude of the update aperture to be temperature dependent (at a fixed number of MC steps). The second set allows the use of a constant update aperture but requires the introduction of an effective temperature (again at a fixed number of MC steps).

*This work has been supported by ARO DEPSCOR grant no. W911NF-04-1-0264

**J1 137 Toy model of an electron interacting with two classical spins** WILLIAM SCHWALM, JUANA MORENO, *Physics Univ. N. Dakota* We consider a single electron governed by a tight-binding Hamiltonian, $H = H^{(o)} + V$, where $H^{(o)}$ stands for the band structure of the crystal and $V$ is a double-exchange type interaction between the electron and two localized classical spins, $\vec{S}_1 \cdot \vec{J} + \vec{S}_2 \cdot \vec{J}$, where $\vec{S}_1$ and $\vec{S}_2$ are classical spins and $\vec{J}$ is electron angular momentum. We study the dynamics of the system as a function of the distance and the angles between the two spins. By summing over electron states we learn about the effective interaction between the two spins. We discuss the connection of this model with ferromagnetism in dilute magnetic semiconductors.

**J1 138 Relaxation of the magnetization in biaxial superparamagnetic particles in the presence of a strong uniform magnetic field** Y. KALMYKOV, *MEPS, Université de Perpignan, 52 Avenue Paul Alduy, 66860 Perpignan, France* W. COFFEY, *Dept. Electronic & Electrical Engr., Trinity College, Dublin, Ireland* B. OUARI, *MEPS, Université de Perpignan, 52 Av. Paul Alduy, 66860 Perpignan, France* S. TITOV, *Inst. of Radio Eng. & Electronics, Russian Acad. Sci., Fryazino, 141190, Russia* The longitudinal relaxation time of the magnetization and the spectrum of the complex magnetic susceptibility are evaluated for biaxial single domain ferromagnetic particles in the presence of a strong uniform magnetic field. The relaxation time is estimated for all dissipation regimes, i.e., very low damping, intermediate-to-high damping, and turnover, using the method of Coffey et al. [Adv. Chem. Phys. **117**, 483 (2001)]. It is shown that the simple asymptotic formulae for the greatest relaxation time so obtained are in complete agreement with the relaxation time calculated from the infinite hierarchy of linear differential-recurrence equations for the statistical moments. This hierarchy, which governs the relaxation of the magnetization of an individual particle, is derived by averaging the governing stochastic Gilbert equation over its realizations. The exact solution of the system of moment equations is obtained by matrix continued fractions. Simple analytic equations, which allow one to accurately predict the spectrum of the longitudinal complex susceptibility for wide ranges of the barrier height and dissipation parameters, are also proposed.

**J1 139 A Novel Class of Helical Nanostructures: Paradigms for their Design and Synthesis Using Imprint Lithography and Carbon Nanotubes** DAVID SMALLING, *Undergraduate* This research focuses on the use of solenoid-like configurations which are both microscopic and macroscopic, to make energy conversions between electrical energy and other forms. Numerous conceptual models are to be evaluated for the construction of an environment in which a charged particle could be allowed travel along a helical path of extremely small pitch and comparatively large large radius. The two main types of solenoid designs discussed, are lithographically synthesized solenoids and coiled carbon nano tube solenoids. For future identification the family of structures described will be referred to as Zeta ($\zeta$) Structures. In the case of a $\zeta$ solenoid, the objective would be to create a solenoid whose general structure is macroscopic but comprises a conductive trace which is on the nano-scale, In the case of such a solenoid the current flowing $I$ and the magnetic flux $B$ would be related approximately by $B \approx 1.256 \times 10^3 I$. Such a situation gives rise to a very fascinating relationship between B and I. This means that if a current of say 1 ampere was made to flow through the solenoid, a magnetic flux of 1250 Tesla would be generated. The defining characteristic of $\zeta$ structures is their overall macroscopic dimensions which comprise high level nano-scale repetition. This research discusses theoretical propositions for the development of a class sub micron structures defined by a unique helical foundation, to be used for the generation of magnetic fields.

**J1 140 Comparative Study of the Magnetic Properties of Ba-Ferrite Thin Films Deposited on Different Substrates*** W. J. YEH, JOEL KREHBIEL, A. R. ABUZIR, *Department of Physics, University of Idaho* The Barium ferrite ($BaFe_{12}O_{19}$) film is an attractive candidate for the self-biased microwave circulator application. The requirement for this application is that the Barium ferrite films have excellent c-axis orientation with moderate $H_c$ value and good squareness, so that Barium ferrite films can be self-biased to eliminate the requirement of the external DC magnetic field. We have used the magnetron sputtering to deposit Ba-ferrite films onto silicon, MgO and sapphire substrates. All of the films were deposited in the same $Ar + O_2$ atmosphere at elevated substrate temperatures to optimize the magnetic properties in terms of c-axis orientation. The films were studied by VSM, XRD, SEM and MOKE. It was found that Barium ferrite thin films on silicon substrates had coercivity value of 3000 Oe with squareness of 0.6 with moderate c-axis orientation. Films deposited on MgO showed better c-axis orientation. However, the values of $H_c$ and squareness were low. Films deposited on sapphire showed the best c-axis orientation. The coercivity value of 3000 Oe and the squareness of 0.93 in perpendicular direction were achieved. Based on our results sapphire is the promising substrate choice for growing Barium ferrite films for the self- biased circulator application.

**J1 141 Control of magnetic and ferroelectric phase in multiferroic (Tb, Bi)$MnO_3$ system** TAE-HWAN JANG, MURALIDHARAN RAJARAM, CHAN-HO YANG, TAE YEONG KOO, YOON HEE JEONG, *Dept. of Physics and Electron Spin Science Center and Pohang Accelerator Laboratory, Pohang University of Science and Technology* Various magnetic ferroelectrics have been discovered and extensively studied because of the possibility of coupling between electric and magnetic degrees of freedom and their potential technological applications. However, the two transitions from electric and magnetic origins have a big difference in their temperature range of occurrence and there is a rare possibility to get two critical points in the same temperature region. We report highly polarizable cation modification effects of multiferroic $TbMnO_3$ polycrystalline system on magnetic and ferroelectric phase transition. Random replacement of $Tb^{3+}$ with $Bi^{3+}$ induces low frequency relaxation in magnetic susceptibility reminiscent of relaxor behavior. The special role of $Bi^{3+}$ ions is emphasized because the anomalous behavior has not been observed in other non-magnetic cation substituted $TbMnO_3$ systems. Various accompanying phenomena such as magnetic and ferroelectric relaxational behavior, structural anisotropy, and tuning of electromagnetic coupling are also discussed. Controllability of both magnetic and ferroelectric phase by the combination of Bi-substitution and driving frequency suggests a new possibility for getting two transitions having different origin at the same temperature point.

**J1 142 Role of oxygen vacancy in ferromagnetic Mn-doped ZnO films** S.Y. PARK, Y.J. YOO, P.J. KIM, Y.P. LEE, *Hanyang University* T.H. KIM, *Ewha Woman University* J.-H. KANG, *Kookmin University* We report that $Zn_{1-X}Mn_XO$ (x = 0.4) films grown by reactive magnetron co-sputtering have ferromagnetism at temperatures above 300 K. The ferromagnetic behavior is sensitive to not only the carrier concentration but also the film growth parameters, such as the substrate, substrate temperature, deposition rate and oxygen partial pressure ($P_{O2}$) during deposition. In this study, we focused on the role of oxygen vacancy for the ferromagnetism in $Zn_{1-x}Mn_xO$ films with $x \leqslant 0.05$. In order to fabricate high-quality samples, the preparation was performed in an ultrahigh vacuum, and the accurate $P_{O2}$ was monitored using a residual gas analyzer during deposition. The magnetic and the structural properties of films were characterized by SQUID and XRD, respectively. The normal-mode and oxygen-resonance-mode RBS were carried out to confirm the mount of Mn, Zn and O contents. The film, prepared at an oxygen partial pressure of $2.2x10^{-7}$ Torr, exhibits a strong ferromagnetism with *T*c above 300 K, while the films at an partial pressure of higher than $1.2x10^{-6}$ Torr show the nonmagnetic behaviors. Our results can be elucidated with a theoretical model by Coey [1] that the oxygen vacancy could results in the magnetic ordering of Mn-doped ZnO film by the enhancement of overlap between *s*-band and imputity *d*-band. [1] J. M. D. Coey et al., Nat. Mater. **4**, 173 (2005).

**J1 143 Magnetoelectric effect in $HoMnO_3$** N. HUR, A. SAXENA, M.F. HUNDLEY, *Los Alamos National Laboratory, Los Alamos, NM 87545* S.B. KIM, S.-W. CHEONG, *Dept. of Physics & Astronomy, Rutgers University, Piscataway, NJ 08854* Multiferroic rare earth manganites have attracted a renewed interest because of recent observations of the giant coupling between ferroelectricity and magnetism in these materials. In particular, hexagonal $HoMnO_3$ has been one of the most actively studied systems among them. For incidence, novel dielectric phase transitions and electric field induced ferromagnetism have been observed recently. However, any direct observation of magnetoelectric effect has not been made. In this presentation, I will discuss the effect of magnetic structure change on the electric polarization in $HoMnO_3$ studied by measuring the polarization change as a function of the temperature and magnetic fields.

**J1 144 Negligible Magnetism in transition metal (Cr, Mn, Fe, Co) doped Nb:SrTiO3*** SHIXIONG ZHANG, SATISH OGALE, WEGDAN RAMADAN, SANKAR DHAR, DARSHAN KUNDALIYA, THIRUMALAI VENKATESAN, *Center for Superconductivity Research, Department of Physics, University of Maryland, College Park, MD 20742-4111* LIANFENG FU, NIGEL BROWNING, *Lawrence Berkeley National Laboratory, NCEM, 1 Cyclotron Road, MS 72-150, Berkeley, CA 94720* In order to realize the possibility of carrier induced ferromagnetism in transition metal (TM) doped $SrTiO_3$, we have performed magnetic, electronic transport, and micro-structural measurements on 2% TM doped $SrTi_{0.98-x}Nb_xO_{3-\delta}$ (x=0.000, 0.005,0.010) thin films. Unfortunately, no unambiguous signature of ferromagnetism is observed in this system, even though its conductivity is seen to be greatly improved by the enhancement of carrier density due to Niobium doping. High-resolution Z-contrast Scanning Transmission Electron Microscopy shows no evidence of clustering, while Electron Energy Loss Spectroscopy indicates that the TM is enriched on the surface of the film whereas Niobium is mostly distributed in the bulk. It is believed that the absence of strong ferromagnetism in this system may be attributed to a spatial separation of the spins contributed by the TM and the carriers from Nb in the $SrTiO_3$ matrix.

**J1 145 Dependence of Ferromagnetic Properties on Carrier Transfer in $(Ga_{1-x}Mn_x)N$** H. C. JEON, S. J. LEE, T. W. KANG, T. W. KIM, JOONGOO KANG, K. J. CHANG, QSRC, DONGGUK UNIVERSITY SEOUL TEAM, ELECTRICAL AND COMPUTER ENGINEERING, HANYANG UNIVERSITY SEOUL COLLABORATION, DEPARTMENT OF PHYSICS, KAIST DAEJEON COLLABORATION, Among many types of DMS materials, $(Ga_{1-x}Mn_x)As$ DMS have been mostly studied. However, since the highest $T_c$ obtained from the $(Ga_{1-x}Mn_x)As$ has been 172 K, which is too low for practical applications. As alternative DMS materials with the high $T_c$, $(Ga_{1-x}Mn_x)N$ DMSs are of current interest because their $T_c$ values can be as high as room temperature. Theory predicts that the ferromagnetic properties observed in GaMnN material system depends on the occupancy of the Mn energy band in GaMnN and the position of the Fermi level relative to this band. Carriers (holes) in the Mn energy band are needed to mediate ferromagnetic interaction: the depletion and enhancement of carrier concentration in the band will change the ferromagnetic properties of GaMnN. Even though many studies concerning the growth and characterization of $(Ga_{1-x}Mn_x)N$ have been carried out, systematic studies are required to understand the carrier-mediated ferromagnetism which is assumed to play an important role in enhancing the Tc by increasing hole carrier concentrations. This work will demonstrate this concept by studying the carriers to mediate ferromagnetism in various GaMnN structures, hence affecting the ferromagnetic properties of the GaMnN.

**J1 146 Magnetism of Discrete, $L1_0$ Ordered FePt Nanoparticles** HAO ZENG, *Department of Physics, the State University of New York, Buffalo, NY 14260* MICHAEL DEMARCO, *Department of Physcs, Buffalo State College* DAREN LI, PING LIU, *Department of Physics, University of Texas at Arlington* Discrete, $L1_0$ ordered FePt nanoparticles have been made by annealing the as-synthesized nanoparticles in the presence of NaCl powder.[1] These particles exhibit high degree of chemical ordering and very large coercivity at room temperature. The temperature dependent magnetic properties of these non-aggregated nanoparticles have been studied systematically as a function of particle size. The magnetization reversal behavior of 4 nm particles can be well explained by Stoner-Wohlfarth coherent rotation model, while that of 8 nm and 15 nm particles is more complicated. Mossbauer spectroscopy measurements indicate the existence of a paramagnetic phase in these highly ordered nanoparticles. The amount of the second phase decreases with temperature but persists even in liquid He temperature. This is attributed to canted spins at the particle surfaces. [1]K. Elkins, D. Li, N. Poudyal, V. Nandwana, Z. Jin, K. Chen and J.P. Liu, J. Phys. D: Appl. Phys. 38, 2306 (2005).

**J1 147 Silicon and III-V compound nanotubes: Structural and electronic properties** ENGIN DURGUN, SEFAATTIN TONGAY, SALIM CIRACI, *Bilkent University* Unusual physical properties of single-wall carbon nanotubes have started a search for similar tubular structures of other elements. We present a theoret-

ical analysis of single-wall nanotubes of silicon and group-III-V compounds. Starting from precursor graphenelike structures we investigated the stability, energetics, and electronic structure of zigzag and armchair tubes using the first-principles pseudopotential plane wave method and finite temperature ab initio molecular dynamics calculations. We showed that (n,0) zigzag and (n,n) armchair nanotubes of silicon having $n \geq 6$ are stable but those with $n < 6$ can be stabilized by internal or external adsorption of transition metal elements. Some of these tubes have a magnetic ground state leading to spintronic properties. We also examined the stability of nanotubes under radial and axial deformation. Owing to the weakness of radial restoring force, stable Si nanotubes are radially soft. Undeformed zigzag nanotubes are found to be metallic for $6 \leq n \leq 11$ due to the curvature effect; but a gap starts to open for $n \geq 12$. Furthermore, we identified stable tubular structures formed by the stacking of Si polygons. We found AlP, GaAs, and GaN (8,0) single-wall nanotubes stable and semiconducting. Our results are compared with those of single-wall carbon nanotubes. [1] E. Durgun, S. Tongay, and S. Ciraci Phys. Rev. B 72, 075420 (2005).

## J1 148 COMPLEX STRUCTURED MATERIALS POSTER SESSION

**J1 149 Self-Assembly of Nanoporous Silica: Synthesis, Morphogenesis, Functionalization, and Applications** YAROSLAV KIEVSKY, IGOR SOKOLOV, *Clarkson University* We study the process of self-assembly and growth of nano(meso)porous silica particles and film via surfactant templating. Process of formation of the mesoporous silica includes growth of the liquid crystalline template and solidification of this template via polymerization of silica precursor. Material obtained as a result of such synthesis (e.g., MCM-41) features highly uniform porosity, a large variety of shapes and their sizes. To control the assembly of the desired shapes, we study their morphogenesis. New conditions of self-assembly are found to form monoshaped nanoporous fibers. Recently suggested Origami-type mechanism for synthesizing a rich family of nanoporous silica shapes (cones, hollow tubes, and helixes) is examined. Shape details and their evolution are analyzed by means of XRD, SEM, TEM, AFM, and optical microscopy techniques. The shapes can possibly serve as templates for various electronic and optical applications. Nanoporous shapes are the prospective hosts for lasing dyes (sealing laser dye molecules inside the silica pores saves them from oxidation and prevents their dimerization). Color coded silica beads are interesting for tagging in security applications and labeling in biology. Diffusion from the nanoporous shapes can be used for a control drug release. Another application of mesoporous silica is the coating of optical fibers by uniform low refractive index film with a good adhesion – a possible host for laser dyes or quantum dots.

**J1 150 Synthesis of Hollow Carbon Nanofibers and Filled Carbon Nanotubes using Chemical Vapor Deposition Technique.** KEVIN SHAY, EVGENIYA MOISEEVA, GAMINI SUMANASEKERA,* *Department of Physics, Universityof Louisville* Hollow carbon nanofibers (CNFs) and filled carbon nanotubes were created using chemical vapor deposition (CVD). Hollow carbon nanofibers were synthesized in porous anodic aluminum oxide templates (AAO) by CVD of methane ($CH_4$) with ferrocene ($C_{10}H_{10}Fe$), indium tin oxide (ITO) and iron nitride ($Fe(NO_3)_3$) as catalyst at 910°C. Carbon nanotubes were filled with iron using CVD of methane. The source of iron in this process was ferrocene. Both the nanostructures were viewed under SEM and TEM. The CNFs grown within the pores of the aluminum oxide membranes are uniform with lengths of about 50 mm and outer diameters of about 200 nm. A diameter of 20-30 nm was measured for the iron filled sample. The magnetic transport properties of the samples will be presented.

**J1 151 Raman studies of crystallization and photo-darkening in HARP a-Se targets*** R.E. TALLMAN, B.A. WEINSTEIN, *Physics Department, SUNY at Buffalo, NY* A. REZNIK, J.A. ROWLANDS, *Sunnybrook Women's College Health Science Center, Toronto* M. KUBOTA, K. MIYAKAWA, Y. OHKAWA, K. TANIOKA, *NHK Science and Technical Labs., Tokyo* T. KAWAI, *Hamamatsu Photonics, Tokyo* The build-up of light-induced defects in the a-Se targets of High-gain Avalanche Rushing Photoconductor (HARP) cameras is important for the robustness of these detectors. Recent experiments show that the photo-induced dark spots in HARP targets exhibit irreversible and reversible components, i.e., spot transparency is only partly restored by heating to 35C, $\sim$ 1C below the a-Se glass transition. [1] We report Raman studies of laser(2mW HeNe)-induced crystallization in a-Se camera targets. The rate of increase in the trigonal c-Se Raman intensity (233 $cm^{-1}$ peak) is measured itvs. exposure time for local temperatures in the range 25 – 65 C, as found from Stokes-to-anti-Stokes ratios. Lateral- and depth- profiling by optical microscopy easily correlate the Raman-detected crystallization regions with visual damage. Further studies itvs. temperature and HARP-target usage are in progress to unravel the damage mechanisms. [1] A. Reznik et. al., submitted to J. Non-Cryst. Solids.

**J1 152 Equilibrium Atomic Configurations Studies and Electron Paramagnetic Resonance of Binuclear Niobium Molecules in Li-Nb Phosphate Glass Dielectrics.** SABRINA ARRINGTON-PEET, RAKHIM RAKHIMOV, VLADIMIR GAVRILENKO, *Center of Materials Research, Norfolk State University, Norfolk VA 23504* Equilibrium atomic configurations of binuclear niobium complexes Nb-O-Nb both free-standing and that embedded in lithium niobium phosphate glass (LNPG) are studied by total energy minimization method using itab initio pseudopotentials within density functional theory. Measurements of electron paramagnetic resonance revealed nonequivalent distribution of the charge and electron spin density between two Nb atoms. Measurements and theoretical analysis indicate that niobium atoms could exist in either of the two forms, $Nb^{4+}$-$Nb^{4+}$ or $Nb^{3+}$-$Nb^{5+}$. The Nb atoms in freestanding molecule are equivalent with oxygen atom having only one local equilibrium position in the center of the molecule, indicating centro-symmetric structure. When the Nb complex is embedded into the glass the effect of external potential in LNPG resulted in an appearance of two non-equivalent configurations for the central oxygen atom in the molecule. Predicted nonequivalent geometries of the Nb-O-Nb complex embedded into LNPG is confirmed experimentally. Mechanism of the distortion is discussed.

**J1 153 X-ray absorption spectroscopic studies of the coordination environment of rare earth ions in novel rare earth phosphate glasses** HASITHA GANEGODA, KANISHKA MARASINGHE, *University of North Dakota* NATHANIEL WYCKOFF, RICHARD BROW, CARLO SEGRE, *Illinois Institute of Technology* MALI BALASUBRAMANIAN, *Argonne National Laboratory* Rare earth (RE) phosphate glasses ($RE_2O_3$-$P_2O_5$) have exciting magnetic and optical properties with numerous potential applications. These properties depend heavily on the atomic structure, especially the rare earth coordination environment. A series of rare earth (namely neodymium, praseodymium, gadolinium, and erbium) phosphate glasses having low rare earth ion concentrations have been studied with rare earth $L_{III}$ edge X-ray absorption spectroscopy (XAS). Rare earth coordination environment appears to undergo an abrupt change when the $RE_2O_3$ concentration exceeds approximately 15 mol%. Implications of this structural change will be discussed and results from XAS technique will be compared with those obtained with X-ray and neutron diffraction techniques.

**J1 154 Electron density, geometric structure and vibration spectra of endohedral $M_{1-3}@C_{60}$ (M = Mn, Co, Fe, Gd) metallofullerenes** G. P. LI, R. SABIRIANOV, W. N. MEI, *Department of Physics, University of Nebraska at Omaha, Omaha, Nebraska 68182* P. A. DOWBEN, *Department of Physics, University of Nebraska, Lincoln, Lincoln NE 68588-0416* X. C. ZENG, *Department of Chemistry, University of Nebraska, Lincoln, Lincoln NE 68588-0416* Endohedrally doped buckminster fullerene C60 with metallic clusters of $M_{1-3}$, (M = Mn, Co, Fe and Gd) are studied by using density functional theory (DFT), projector augmented wave (PAW) and pseudo-potential (PP) methods. Optimized molecular geometries are obtained from varying the positions of these two/three metal atoms together with the $C_{60}$ cage and finding the energy minimum while considering different multiplicities and magnetic configurations. Subsequently the vibrational frequencies of the cluster, electric and magnetic dipole moments are calculated and compared with experiments. Upon the molecular properties are thoroughly studied, we construct different crystal models utilizing these metallofullerenes and employ the local density approximation (LDA)+U techniques to account for many-body effects.

**J1 155 Energy Radiation from Plasmons on Nanotubes** ANTONIOS BALASSIS, GODFREY GUMBS, *Hunter College of CUNY* A formalism has been developed for calculating the rate of transfer of energy from a current of charged particles to multiwalled and a linear array of nanotubes. Numerical calculations are presented for tubules of various radii and impact parameters of the moving charged particles. The dispersion relation of the coupled tubules interacting through the Coulomb interaction has several branches corresponding to excitation of electrons within a subband as well as between energy subbands. The electric field of the current excites these modes but one of them is unstable and radiates energy. This is demonstrated in the spectrum of energy transfer with a ''dip'' unlike the other plasmon modes which have a ''peak'' for arbitrary impact parameter. The single-particle excitation spectrum does not have an instability for any charged particle velocity or impact parameter.

**J1 156 Hysteresis in single-walled carbon nanotube field–effect transistors: Experiments, a model, and implications** S. KAR, *Department of Materials Science and Engineering, Rensselaer Polytechnic Institute, Troy New York* S. TALAPATRA, *Rensselaer Nanotechnology Center, Rensselaer Polytechnic Institute, Troy New York* A. VIJAYARAGHAVAN, *Department of Materials Science and Engineering, Rensselaer Polytechnic Institute, Troy New York* C. SOLDANO, *Department of Physics, Applied Physics and Astronomy, Rensselaer Polytechnic Institute, Troy New York* R. VAJTAI, *Rensselaer Nanotechnology Center, Rensselaer Polytechnic Institute, Troy New York* S.K. NAYAK, *Department of Physics, Applied Physics and Astronomy, Rensselaer Polytechnic Institute, Troy New York* O. NALAMASU, P.M. AJAYAN, *Department of Materials Science and Engineering, Rensselaer Polytechnic Institute, Troy New York* Hysteresis in carbon nanotube FETs is understood to be due to charge injection from the nanotube to its surrounding dielectric. We present a simple yet effective model to understand and analyze this phenomenon, wherein the charge injection and its subsequent redistribution has been modeled as a series RC circuit. A set of experiments validates this model, and also fits previously published data by other groups. Our work provides an in-depth picture of the parameters, which play a crucial role in modifying the transfer characteristics in nanotube FETs under different experimental conditions.

**J1 157 Networking Carbon Nanotubes for Integrated Electronics.** J.M. ROMO-HERRERA, M. TERRONES, H. TERRONES, *Advanced Materials Dept IPICyT, Camino Presa Sn Jose 2055 Lomas 4a Sec, SLP 78216 Mexico* V. MEUNIER, *Computer Science & Mathematics Div and CNMS, ORNL POBox 2008, TN 37831-6367 USA* The unique electronic and mechanical properties of individual Carbon Nanotubes (CNTs) have attracted much interest as candidates for molecular electronic devices and reinforced materials. However, their integration in organized architectures remains a major challenge. Recent breakthroughs reported on the Self-Assembly of 1D Nanostructures [1], and on the coalescence mechanism for interconnecting CNTs [2], point to the possibility of designing and obtaining Ordered Networks based on CNTs (ON- CNTs). We propose a set with different complex architectures of ON- CNTs based on –but not limited to– armchair and zigzag nanotubes. In addition to the study of the energetics of the structures, we have systematically investigated their electronic transport properties in the framework of the Landauer-Buttiker formalism and equilibrium Green functions. To take curvature into account, we employed a semi-empirical Hamiltonian based on 4 orbitals (s,px,py,pz) per carbon atom. Further insight is obtained analyzing the electron pathways from a scattering point of view, which allows a real-space analysis of the wave function from the transmitted electrons across the structure. **J1 158 Band structure and absorption spectrum of double-walled zigzag carbon nanotubes in an electric field*** YEN-HUNG HO, G. W. HO, M. F. LIN, *Department of Physics, National Cheng Kung University* C. P. CHANG, *Center for General Education, Tainan Woman's College of Arts and Technology* The electronic structure of the (9,0)-(18,0) double-walled zigzag carbon nanotubes in the presence of a uniform transverse electric field is studied by the tight-binding model. The electric field could induce the semiconductor-metal transition, change the direct gap into the indirect gap, alter the subband curvatures, destroy the double degeneracy, produce the new band- edge states, make more

subbands group around the Fermi level, and widen the $\pi$-band width. Such effects are directly reflected in density of states and optical excitation spectra. The absorption spectra exhibit a lot of prominent peaks, mainly owing to the rich one-dimensional energy subbands. The intensity, the number, and the frequency of absorption peaks are strongly modulated by the electric field. The modulation of electronic and optical properties is amplified by the parallel magnetic field. The predicted electronic and optical properties can be, respectively, verified by the conductance measurements and the optical spectroscopy.

**J1 159 Electronic and optical properties of finite carbon nanotubes in an electric field** R.B. CHEN, *Center of General Studies, National Kaohsiung Marine Univ.* C.H. LEE, M.F. LIN, *Dept. of Physics, Natl. Cheng Kung Univ.* C. P. CHANG, *Center for General Education, Tainan Woman's College of Arts Tech.* The effects, caused by the geometric structure and a transverse electric field (**E**), on the electronic and optical properties of quasi-zero-dimensional finite carbon nanotubes are explored by employing the tight-binding model coupled with a curvature effects. It is found that the electronic properties (discrete state energies, symmetry of electronic states, energy spacing, and state degeneracy) are significantly affected by **E** and the geometric structure (radius, length, and chirality). The electric field, by lowering the symmetry of finite carbon nanotubes, modifies the electronic properties. Thus, the optical excitation spectra, excited by electric polarization parallel to the nanotube axis, exhibit rich delta- function-like peaks, which reveal the characteristics of the electronic properties. Therefore it follows that geometric structure and **E** influence the low-energy absorption spectra, i.e., the change of frequency of the first peak, the alternation of the peak height, and the production of the new peaks. Moreover, the very complicated optical absorption spectra are characteristic for individual the chiral carbon nanotube due to its specific geometric structure. Above all, the predicted absorption spectra and the associated electronic properties could be verified by optical measurements. Supported by NSC 94-2112-M-022-001; NSC 94-2112-M-165-001; NSC 94-2112-M-006-002.

**J1 160 Electronic excitations and deexcitations in narrow-gap carbon nanotubes*** C. W. CHIU, Y. H. HO, M. F. LIN, *Department of Physics, National Cheng Kung University* F. L. SHYU, *Department of Physics, Chinese Military Academy* Temperature could induce some free carriers in narrow-gap carbon nanotubes. Such carriers exhibit rich intraband single- particle excitations and collective excitations. Only the low- frequency e-h excitations are the effective deexcitation channels in the carrier decay. The Coulomb decay rates are dominated by the screened loss function and the carrier distribution function. They are very sensitive to the changes in nanotube radius and temperature, but not wave vector. Narrow- gap carbon nanotubes quite differ from moderate-gap and metallic carbon nanotubes in electronic excitations and carrier relaxation.

**J1 161 Efficacy of the Thermalized Quantum Potential Approach for Modeling Nanoscale Semiconductor Devices.** SHAIKH AHMED, *Dept. of Electrical and Computer Engr., Purdue University* DRAGICA VASILESKA, *Dept. of Electrical Engr., Arizona State University* GERHARD KLIMECK, *Dept. of Electrical and Computer Engr., Purdue University* CHRISTIAN RINGHOFER, *Dept. of Mathematics, Arizona State University* We propose a novel parameter-free effective potential scheme for use in conjunction with particle-based simulations of alternative semiconductor device technologies. The method is based on perturbation theory around thermodynamic equilibrium and leads to a quantum potential which depends on the energy and wavevector of each individual electron. The computation of the quantum potential involves only the evaluation of pseudo-differential operators and can be effectively facilitated using Fast Fourier Transform (FFT) algorithms. Our investigations suggest that for low doping densities, as it is usually the case in alternative device structures, such as dual-gate, FinFET and nanowire devices, the Hartree correction term (computationally expensive) can be neglected and the quantum correction for the Barrier potential/field term (one-dimensional and time-independent adding no additional computational cost) needs be included in the model only. Excellent agreement has been obtained with our Effective Potential Monte Carlo device simulations data and the results that utilize the NEGF formalism.

**J1 162 Optical Trapping and Torquing of C60 Nanorods*** DOUGLAS BONESSI, KEITH BONIN, *Wake Forest University* THAD WALKER, *University of Wisconsin* We have optically trapped and studied C60 polymer nanorods with diameters of 300-500 nm and lengths of 1-3 microns. The primary goal is to measure opto-electronic properties of the C60 polymer rods. This is accomplished by observing the rotational motion of the rods in a water sample when a light torque is applied. We also hope to report on opto-electronic properties of even smaller rod-shaped objects (of diameters less than 100 nm).

**J1 163 Heavy Ion Interactions with Nanotubes and Nanowires** B.W. JACOBS, V.M. AYRES, R.M. RONNINGEN, A.F. ZELLER, E.H. CAREY, M.A. CRIMP, *Michigan State University, East Lansing, MI 48824* M.P. PETKOV, *NASA JetPropoulsionLaboratory, Pasdena, CA 91109* S.L. RUTLEDGE, J.B. BENAVIDES, H.C. SHAW, *NASA Goddard Space Flight Center, Greenbelt, MD 20771* D. LIU, *Muniz Engineering, Inc., Greenbelt, MD 20771* J.B. HALPERN, M.Q. HE, G.L. HARRIS, *Howard University, Washington, DC 20059* We will present investigations of the response of single and multi wall carbon nanotubes, electrospun carbon nanofibers and gallium nitride nanowires to high-Z heavy ion radiation that simulates space radiation environments. The heavy ion radiation experiments were performed at the National Superconducting Cyclotron Laboratory at Michigan State University, whose available beams and beam energies well match the energy spectra of abundant charged particles in galactic cosmic rays. In these experiments, the nanotubes and nanowires were irradiated in two separate series of experiments using Krypton primary beams with mass numbers 86 and 78 respectively. Explorations of the fundamental mechanisms of radiation interactions and damage propagation in reduced dimensionality systems, and in nanoscale systems with high surface to bulk ratios and small overall volumes, will be presented.

**J1 164 A Novel Vibrational Mode in Carbon Systems** MORINOBU ENDO, *Shinshu University, Japan* MAURICIO TERRONES, *IPICYT, Mexico* Y.A. KIM, TAKUYA HAYASHI, HIROYUKI MURAMATSU, *Shinshu University, Japan* RIICHIRO SAITO, *Tohoku University, Japan* FEDERICO VILLALPANDO-PAEZ, SHIN GRACE CHOU, MILDRED S. DRESSELHAUS, *MIT, USA* We report on the identification of a novel resonant Raman mode located at itca. 1850 $cm^{-1}$, which is related to vibrations of linear carbon chains. This mode, termed ?the coalescence inducing mode? (CIM), was observed during the merging of highly purified double-walled carbon nanotubes (DWNTs) induced by thermal annealing and boron doping. In our case, the CIM mode arises from the generation of short 1D carbon chains established covalently between adjacent tubes. These chains trigger nanotube coalescence via a zipper model, and as the tubes merge the CIM vibration disappears. Theoretical calculations demonstrate that this vibrational frequency corresponds to linear chains with a few carbon atoms. The CIM mode could now be used to identify sp hybridized carbon in various systems such as irradiated graphite, polymerized $C_{60}$ molecules, functionalized fullerenes and nanotubes, carbynes, polymers, nanographites, etc.

**J1 165 Growth and characterization of aligned ZnO nanorods** T. WILLIAMS, K. ZHANG, D. HUNTER, K. LORD, A.K. PRADHAN, *Center for Materials Research, Norfolk State University* We report the growth of aligned ZnO nanostructures on pulsed-laser deposited ZnO epitaxial film-substrates synthesized by vapor transport of the evaporation of pure Zn metal powders followed by subsequent condensation. Remarkable arrangements of uniform ZnO nanorods were found on ZnO film by varying the synthesis conditions. The nanorods grow preferentially from a hexagonal ZnO base. High-density aligned nanorods of 60-100 nm diameter and 10-20 $\mu$m in length grew at the center of the substrate over a large area. Structural and spectroscopic properties clearly indicate that the nanorods are of superior and defect-free in quality. The ZnO nanorods have also been grown on Si and sapphire substrates. Details of the results will be presented.

**J1 166 Intensity dependent Raman spectra of pristine and functionalized carbon nanotubes.*** CHARLES BLACKLEDGE, *Oklahoma State University* DEOKJIN YU, *Oklahoma State University* MAXIM TCHOUL, *Oklahoma State University* XIAOMING JIANG, *Oklahoma State University* WARREN FORD, *Oklahoma State University* JAMES WICKSTED, *Oklahoma State University* Raman spectra of polymer functionalized and pristine single wall carbon nanotubes (SWNTs) are presented. The intensity ratio of the disorder (D band) to the tangential (G band) increases after polymer functionalization. Generally Raman spectra of ensembles of SWNTs indicate sample inhomogeneity such as the presence of many different nanotube symmetries and diameters. Laser induced changes in SWNT Raman spectra were also investigated. We observe temporally the laser induced loss of the intensities of the RBMs from small SWNTs and the metallic G band. This is attributed to selective oxidation of smaller carbon nanotubes that primarily consist of metallic SWNTs in our samples. Under identical conditions, the spectral changes of pristine samples are greater than those of polymer functionalized SWNTs. These results confirm that pristine small diameter SWNTs are more reactive than large ones.

**J1 167 Percolation Model of Magnetoelectric Effects in Ferrite/Piezoelectric Bulk Composite** V.M. PETROV, M.I. BICHURIN, D.S. TUSKOV, *Novgorod State University, Russia* G. SRINIVASAN, *Oakland University* A bulk composite consisting of ferrite-ferroelectric phases shows magnetoelectric (ME) effects that are product properties of the magnetostrictive deformation and piezoelectric charge generation.Bulk composites with strong ME effects are desirable over layered samples due to superior mechanical strength. Here we discuss a percolation approach for modeling the ME effect in bulk composite [1]. We calculated percolation threshold corresponding to structural phase transition of bulk composites from the state with ME interactions to a state with no ME interactions.Expressions for longitudinal and transverse low-frequency ME voltage coefficients have been obtained. Volume fractions corresponding to peak ME voltage coefficients are given. We obtained a piezoelectric volume fraction of 0.45 for maximum ME effect in bulk samples of lead zirconate titanate and nickel-cobalt ferrite. These estimates are in excellent agreement with data. supported by a grant from the NSF. [1] V. M. Petrov, M. I. Bichurin, V. M. Laletin, N. Paddubnaya, and G. Srinivasan, itMagnetoelectric Interaction Phenomena in Crystals-NATO Science Series II. Vol. 164, Eds. M. Fiebig, V. V. Eremenko, and I. E. Chupis (Kluwer Academic Publishers, London, 2004), p.65-70.

**J1 168 Analysis of the Behaviour of Nanocomposites by Multiscale Simulation*** WOONG LEE,† *Yonsei University* WOO-SUNG JUNG, *Korea Advanced Institute of Science and Technology* JAE-MIN MYOUNG, *Yonsei University* Hierarchical multiscale simulation scheme was introduced for the analysis of the mechanical behaviour of nanocomposites. Aluminium matrix composites reinforced with uniformly dispersed carbon nanotube (CNT) was chosen as a model system. Ab initio simulation was first carried out to estimate inter-atomic potential between a CNT and an Al atom and to determine type of bonding between CNT and Al. This fundamental information was then passed onto the molecular dynamic (MD) simulation in which the interface properties between the matrix and the reinforcement was characterised in terms of load-displacement behaviour by simulating a CNT pullout test. Continuum analysis wad carried out with this interface properties to finally extract representative properties of CNT-reinforce Al matrix nanocomposites using representative volume element approach. Fracture behaviour was also estimated by analysing possible crack paths within the nanocomposites.

**J1 169 Microscopic Mechanism of Reinforcement and Conductivity in Polystyrene/Carbon Nanotube Composites** T.-E. CHANG, S. RHODES, A. KISLIUK, W. J. BRITTAIN, A. P. SOKOLOV, *University of Akron* Carbon nanotube (CNT) is one of the most studied materials for the polymer reinforcement due to their extraordinary mechanical properties, superior thermal and electronic properties, and high aspect ratio. However, to unlock the potential of CNTs for applications, CNTs must be well dispersed in polymer matrix and the microscopic mechanism of polymer reinforcement by CNTs must be understood. The main goal of the presented research is to analyze structure and conductivity and enhance mechanical properties of polystyrene/carbon nanotube composites. Polystyrene matrix composites reinforced with single-wall carbon nanotubes (SWNTs) were prepared with different

nanotubes concentrations. Microscopic structure and conductivity of composites is analyzed using Raman scattering and dielectric measurement. Studies on the tangential mode in the Raman spectra indicated well-dispersed SWNTs in polymer matrix. We show that conductivity appears in composites already at very low concentrations, hinting at the formation of a 'percolative' network even below 0.5% of the SWNT.

**J1 170 Adsorption of Supercritical Carbon Dioxide in Aerogels as Studied by SANS and Neutron Transmission Techniques*** GEORGE WIGNALL, YURI MELNICHENKO, DAVID COLE, *Oak Ridge National Laboratory* HENRICH FRIELINGHAUS, *Forschungszentrum, Julich* Small-angle neutron scattering (SANS) has been used to study the adsorption behavior of supercritical carbon dioxide (CO2) in porous Vycor glass and silica aerogels. Measurements were performed at T = 35C and 80C as a function of pressure up to P = 25 MPa. The neutron transmission data were used to monitor the ''excess'' adsorption of CO2 at different pressures. The adsorption of CO2 is significantly higher in aerogels than in activated carbons and silica gels. SANS data have revealed the existence of highly compressed adsorbed phase with the density close to the density corresponding to van der Waals volume of carbon dioxide. The results demonstrate the utility of SANS combined with transmission measurements to study the adsorption of supercritical fluids in porous materials.

**J1 171 First-principles phonon calculation for Al-(Re,Mn)-Si 1/1-1/1-1/1 approximants** N. NAGASAKO, *Toyota Central R&D Labs., Inc.* R. ASAHI, *Toyota Central R&D Labs., Inc.* T. TAKEUCHI, *Nagoya University* A very low thermal conductivity ( $\sim$ 1 W/Km) and a relatively large Seebeck coefficient in Al-based Mackay-type icosahedral quasicrystal have attracted much interest aiming for thermoelectric applications. We performed first-principles phonon calculations for the Al-(Re,Mn)-Si 1/1-1/1-1/1 approximants [1] to elucidate mechanism of their low thermal conductivity. The total energy and atomic force were calculated for a modeled $Al_{17}(Re,Mn)_4Si_2$ unit cell containing 138 atoms using the projector augmented wave method implemented in VASP code [2], and were then utilized for obtaining a phonon dispersion by the direct method [3]. The calculated lattice specific heat showed very good agreement with experiment, confirming validity of the present calculations. We found localized optical modes with a relatively low frequency ( $\sim$ 2 THz) in the phonon dispersion. We discuss the low thermal conductivity in comparison between the Al-Re-Si and Al-Mn-Si systems via averaged group velocity and umklapp phonon scattering related to these optical modes. Parlinski, Phonon 3.11 (2002).

**J1 172 Interaction of Surface Modified Carbon Nanotubes with Supercritical Carbon Dioxide*** NIHAT BAYSAL, BANU UNSAL, *Department of Chemical Engineering, Yeditepe University, Istanbul 34755, Turkey* RAHMI OZISIK, *Materials Science and Engineering, Rensselaer Polytechnic Institute, Troy, NY 12180, USA* The properties of carbon nanotube (CNT)-polymer nanocomposites are far below than those calculated, mainly due to poor dispersion or interface quality. This is particularly difficult for single walled carbon nanotubes (SWNTs) as they tend to form bundles or ropes that are difficult to exfoliate. Supercritical fluid (SCF) assisted processing is one of the methods that can be used to exfoliate/disperse CNTs along with modifiying the interface of the CNTs. Molecular dynamics simulations were performed to understand how the surface modifiers behave near SWNT surface with and without the presence of SCF molecules. It is also important to understand the diffusivity of SCF molecules between SWNT bundles and the effect of surface modifiers on diffusion. Octane and itn-perflourooctane molecules were used as surface modifiers with varying tethering density and carbon dioxide ($CO_2$) was chosen as the SCF. Results showed that the system with highest number of itn-perfluorooctanes presented the highest degree of success in separating the SWNTs in the presence of $CO_2$.

**J1 173 The influence of electric field on optical properties of the few-layer graphene with AB-stacking*** CHILANG LU, Y.C. HUANG, M.F. LIN, *Department of Physics, National Cheng Kung University* C.P. CHANG, *Center for General Education, Tainan Woman's College of Arts & Technology* R.B. CHEN, *Center for General Education, National Kaohsiung Marine University* The effect of perpendicular electric field **E** on optical properties of the AB-stacked few-layer graphene, made up of two, three, or four graphite sheets, is explored through the gradient approximation. In contrast to the featureless optical spectra of graphene, the low-energy absorption spectra of few-layer graphene with AB-stacking exhibit many jumping structures, which result from the band edge states caused by the stacking effect, in the absence of electric field. Remarkably, **E** causes the subband (anti)crossing, changes the subband spacing, produces the scillating bands, and increases the edge states. It, therefore, follows that the field-modulating-spectra with sharp peaks are generated. Moreover, the frequency of peak, which is strongly dependent on the layer number and the field strength, is predicated. Above all, the predicted absorption spectra and the associated electronic properties could be verified by the optical measurements.

**J1 174 Cluster Formation and Corralling Effect in Two Dimensional Binary Mixtures*** DONGSHENG ZHANG, MARCELO CARIGNANO, IGAL SZLEIFER, *Department of Chemistry, 560 Oval Dr., Purdue University, West Lafayette, IN 47907-1393* We study the formation of ordered clusters of nanoparticles in binary mixtures in two dimensions using Monte Carlo simulations. The necessary conditions for the formation of highly ordered clusters are: the size mismatch between the two components and a long-range soft repulsions between the large particles. The degree of order of the clusters depends on the concentration of large particles. We show the conditions upon which compression of the layer induces squeezing out of the large particles from the interface. Our findings explain recent experimental observations on

poloxamer-lipid mixtures and provide guidelines for how to form ordered clusters of nanoparticles in two dimensions.

**J1 175 A molecular-dynamics study of defects and failure mechanisms in strained heteroepitaxial interfaces*** JARROD E. SCHIFFBAUER, *West Virginia University, Physics Department* MARTINA E. BACHLECHNER, *West Virginia University, Physics Department* The formation and growth of pits and pit-like structures through a delamination-driven mechanism have been observed in the analysis of comprehensive molecular dynamics simulations of a laterally strained $Si(111)/Si_3N_4(0001)$ interfacial system. These phenomena contribute to the ultimate mechanical failure of the simulated samples. Several factors play a key role the nucleation and growth of the pits including temperature and strain rate. Here we present an overview of the dependence of pit nucleation and morphology on both global and local conditions for a representative range of temperatures and applied strain rates.

*Supported in parts by NASA.

**J1 176 The hierarchy of 1D-, 2D- and 3D-dimensional LPS in Cu-Pd and Ag-Pd: A first-principles study*** S. BÄRTHLEIN, E. WINNING, S. MÜLLER, *Universität Erlangen-Nürnberg, Germany* G.L.W. HART, *Northern Arizona University, Flagstaff, Arizona 86011-6010* A. ZUNGER, *National Renewable Energy Lab, Golden, Colorado 80401* Throughout many decades the marvelous variety of so-called long-periodic superlattices (LPS) - being constructed from stacks of $L1_2$ with a certain period $M$ after which an anti-phase boundary is introduced - has been a matter of interest for binary compounds consisting of Pd and noble metals such like Cu, Ag and Au. Whereas $Au_{0.75}Pd_{0.75}$ puts forth the $D0_{23}$ (i.e. $M = 2$) structure as ground state [1], $Cu_{0.75}Pd_{0.75}$ and $Ag_{0.75}Pd_{0.75}$ exhibit LPS3 (i.e. $M = 3$) as $T = 0$K ground state. Moreover, the formation enthalpies for a whole class of superlattices are almost degenerated. In order to control the energetical hierarchies of *all* LPS in question the usual 1D-LPS configuration space must be overcome. We therefore demonstrate how for each system a set of suitable interactions can be constructed by first principles means. Questions concerning a complete description and exhaustive predictive power will be asked and answered by a mixed-space cluster expansion that allows us to handle 1D-LPS with average $M$, 2D- and 3D-LPS with arbitrary integer $M$ and to predict their energies in order to investigate their abilities to serve as ground state candidates. [1] S. Barabash et al., submitted to Phys. Rev. B.

**J1 177 Statistical studies of the propagation of a signal through a disordered system** JOSHUA DACHMAN-SOLED, *Department of Physics, Yeshiva University* GABRIEL CWILICH, *Department of Physics, Yeshiva University* We have considered the propagation of a signal through a certain layered nanostructure by modeling it as a collection of random one- dimensional interfaces, through which a coherent wave can be transmitted or reflected while being scattered at each interface. We have previously used a simple model where a persistent random walk ( the ''t-r'' model in 1- D) is used as a representation of the propagation of the signal in such a medium [(1)] We will present here some extensions of those results to analyze the total transmission through a chain when a random distribution of the transmittance of the scatterers is included. Some of the statistical properties of the system will be discussed, and some results of possible extensions to more than one dimension in the context of this model will be presented. (1) Nanotechnology, v13, 274, (2002).

**J1 178 Density Functional Study of a Typical Thiol on Perfect Au(111) Surfaces** GUAN WANG, *National Research Council Research Associate* WILLIAM SANDBERG, *Laboratory for Computational Physics and Fluid Dynamics, Naval Research Laboratory, Washington, DC* STEVEN KENNY, *Univ. of Loughborough, U. K.* We investigated systematically the static, dynamical and mechanical properties of a typical thiol-Au surface system at the density functional level. The computational approach uses optimized atomic-like orbits for efficiency and parallel computation. Ab initio results show the equilibrium configuration of the thiol on gold surfaces is in agreement with other computational methods. We found, from ab initio molecular dynamics simulations, that this tethering system keeps stable at 300, 350, and 370 degrees K. We studied the energy profiles that reflect the behaviors of the tethered thiol under normal and parallel stretches. The obtained rupture force is comparable with AFM measurements. We found the rupture force of thiols on gold surfaces is directional. We also show the process by which multiple successive ruptures of the tether occur with the surface. These results should be useful in understanding failure dynamics of tailored biosurfaces in microfluidic devices where fluidic sheer and normal forces are of concern.

**J1 179 Magnetic, magneto-optical and dielectric properties of ferromagnetic semiconductors $CdCr_2S(Se)_4$ from first-principles calculations** GUANG-YU GUO,*HAI-QING LIN, *Department of Physics, Chinese University of Hong Kong, Shatin, Hong Kong* Recently, $CdCr_2S_4$ has been found to exhibit fascinating relaxor ferroelectricity and colossal magnetocapacitive effect.To understand this and other interesting properties, we have calculated the electronic structure, exchange coupling, optical dielectric constant and magneto-optical Kerr rotation of $CdCr_2S_4$ and $CdCr_2Se_4$. The calculations are based on density functional theory with generalized gradient approximation plus on-site Coulomb correlation (GGA+U). The all-electron full potential linearized augmented plane wave (FLAPW), frozen core full potential projector augmented wave (PAW), and also all-electron tight-binding linear muffin-tin orbital methods (TB-LMTO) are used. In this contribution, we will present the obtained exchange coupling parameters, magneto-optical Kerr rotation spectra and dielectric constants. In particular, we will discuss the possible origins of the obtained ferroelectricity in these materials.

*On sabbatical leave from Department of Physics, National Taiwan University, Taipei, Taiwan

**J1 180 Ferromagnetic properties of epitaxial manganite films on $SrTiO_3$/Si heterostructures** D. HUNTER, B. LASLEY, K. LORD, T.M. WILLIAMS, R.R. RAKHIMOV, A.K. PRADHAN, *Center for Materials Research, Norfolk State University* We report on the growth and magnetic properties of epitaxial LSMO films on Si (100) and Si (111) substrates using $SrTiO_3$ template layer, which demonstrate magnetic and electrical properties at and above room temperature. The growth conditions were optimized by varying substrate temperature and oxygen partial pressure. The grain of 20 nm in size coalesced with increasing substrate temperature,

revealing very smooth film surface. The magnetization data show magnetic transition and magnetic hysteresis at and above room room-temperature. The ferromagnetic resonance studies show anisotropic effects related to ferromagnetic properties of films. The details of the structural and magnetic properties will be presented.

**J1 181 Polarizability of carbon nanotube peapods from first-principles*** KISEOK CHANG, YOUNG-GUI YOON, *Chung-Ang University* We calculate polarizability of carbon nanotube peapod from first-principles. The calculated result gives information about electronic screening effects of carbon nanotubes. Recently, the structure has been suggested as bucky shuttle memory devices and three-terminal switching devices. The polarizability and the screening effects may play an important role for the control of that type of devices. We discuss our results in the context of nanoelectronics application.

*The authors would like to acknowledge the computational support from KISTI under 'the 7th Strategic Supercomputing Applications Support Program' with Dr. S. M. Lee as the technical supporter.

**J1 182 Structural and electronic properties of a bucky-ferrocene molecule from first-principles*** JINWOO JEONG, YOUNG-GUI YOON, *Chung-Ang University* Bucky-ferrocene molecules have been synthesized from fullerene and ferrocene molecules. The molecules have features of both components. We performed first-principles electronic structure calculations of a bucky-ferrocene based on $C_{60}$ fullerene and ferrocene molecules in a supercell geometry. We got local minimum structures with geometry optimization from different initial configurations. Orientation of methyl groups and pentacene leads to states in small energy range. Possible device applications of the molecule are discussed.

**J1 183 Supramolecular Lysophospholipid-Carbon Nanotube Complexes Enable Cellular Studies** APPARAO RAO, YONNIE WU, JESSICA MOORE, PU-CHUN KE, *Clemson University* LABORATORY OF SINGLE-MOLECULE BIOPHSYICS AND POLYMER PHYSICS TEAM, NANOMATERIALS LABORATORY TEAM, PROTEOMICS LABORATORY TEAM, Single walled carbon nanotubes (SWNTs) have found tremendous applications in electronics, nanophotonics, chemical and biosensing, and very recently, in nanomedicine. The bottleneck for many of these applications is the inherent insolubility of SWNTs due to their mutual interactions. Here we report that lysophospholipids, or single-chained phospholipids offer unprecedented solubility for SWNTs. The biocompatibility of lysophospholipids is unsurpassed since they occur naturally in the cell membrane. Using transmission electron microscopy we show lysophospholipids wrap SWNTs as striations whose size and regularity are affected by the polarity of the lysophospholipids. These findings shed light on the debate over the binding mechanism of amphiphilic polymers and cylindrical nanostructures and has implications on the design of novel supramolecular complexes and nanodevices. Since the head groups of lysophospholipids can be functionalized with tags such as quantum dots, antioxidants, and monoclonal antibodies, our method opens the door for utilizing nanomaterials for itin vivo imaging, gene and drug therapy, and novel nanomedicine.

**J1 184 Time-resolved photoluminescence of single wall carbon nanotubes** CHRISTOPHE VOISIN, SÉBASTIEN BERGER, GUILLAUME CASSABOIS, CLAUDE DELALANDE, PHILIPPE ROUSSIGNOL, *LPA-ENS, 24 rue Lhomond, 75005 Paris, France* XAVIER MARIE, *LNMO-INSA, Toulouse, France* Time-resolved photoluminescence measurements are performed on ensembles of isolated (6,5) single wall carbon nanotubes after a selective picosecond excitation of the second transition of the semiconducting nanotubes. These measurements give insight into the carrier dynamics in the bright nanotubes. The carrier dynamics in bright nanotubes is non exponential reflecting the inhomogeneous distribution of life times. However two contributions to the relaxation are distinguishable within the experimental resolution: a fast component of the order of 10 ps and a smaller long living component of about 100 ps. When cooling the sample down to 10 K, the relative weight of the slow component increases with a characteristic temperature of 150 K. Only a small increase of about 30% of the quantum yield is observed at low temperature. No clear relation between emission energy and life time is observed. In light of recent publications these results suggest that the monoexponential relaxation process in one single nanotube might be either fast or slow and that the proportion of both kind of processes is modified by the temperature with a typical energy of 15 meV.

**J1 185 Effects of the Modification of Single- and Double-Wall Carbon Nanotubes: A Theoretical Study of Field Emission Properties** BRAHIM AKDIM, *Air Force Research Lab* TAPAS KAR, *Utah State University* XIAOFENG DUAN, *ASC/MSRC* RUTH PACHTER, *Air Force Research Lab* In this work, we report first principles calculations of modified single-wall carbon nanotubes (SWCNTs) by $O_3$ and –COOH functionalization, as well as of double-wall carbon nanotubes (DWCNTs) by Cs surface adsorption. Properties related to field emission, including the effects of an applied electric field to mimic the emission environment, as well as structural parameters, are discussed. The results, which suggest a suppression of the emission upon ozone adsorption and carboxy-functionalization in SWCNTs, but an enhancement with Cs surface adsorption, are explained in detail. Finally, the effects of treating DWCNTs with Cs adsorption, as compared to our previous results for SWCNTs, are summarized.

**J1 186 Dissociation of Water on Ti-Decorated C nanostructures*** YANG LEI, *Queen Mary, University of London* WENGUANG ZHU, *Harvard University* SHENG MENG, *University of Texas & ORNL* ZHENYU ZHANG, *University of Tennessee & ORNL* ZHENGXIAO GUO, *Queen Mary, University of London* Direct thermal splitting of water produces pure hydrogen but requires exceptionally high temperatures, making practical implementation challenging. Here we use first-principles simulations to show that water can dissociate on Ti decorated carbon nanostructures, such as graphenes and nanotubes. The behavior of water molecules approaching a Ti adatom is investigated. A single water molecule dissociates freely on a Ti-decorated graphene layer. A small energy barrier has to be overcome to dissociate a second water molecule, with the released H atoms readily combining to form $H_2$. As the number of water molecules further increases, the Ti adatom will dissociate from the graphene layer. We find similar results for when a Ti atom is adsorbed on a carbon nanotube. When more Ti atoms are adsorbed on the outside of the carbon nanotube, the energy barrier against dissociating water

molecules is greatly decreased. We also explore the effects of replacing Ti by other potential catalytic elements.

*Supported by UCDOE, USNSF, & EPSRC/UK-SHEC.

**J1 187 Field Emission of Electrons From Transparent Carbon Nanotube Sheets.** ALEXANDER KUZNETSOV, *NanoTech Inst., The Univ. of Texas at Dallas* ALEXANDER ZAKHIDOV, *Dept. of Phys., Moscow State Univ., Moscow, Russia* MEI ZHANG, SERGEY LEE, RAY BAUGHMAN, ANVAR ZAKHIDOV, *NanoTech Inst., The Univ. of Texas at Dallas* The well-ordered aligned arrays of multiwalled carbon nanotubes were used to make strong and transparent carbon nanotube sheets, prepared by dry spinning from oriented MWCNT forests [1]. Study of electron field emission (FE) shows phenomenally low threshold fields $<$ 0.5 V/mm with very high current densities and steep I-V curves. Also some unusual features observed in IV curves including step-like current increase and hysteresis behavior. Some possible explanations are proposed. Such CNT transparent sheets can be used as high current, high stability field emission sources which are at the same time transparent and can be used as an optical polarizer. The prototype of high luminosity fluorescent lamp with CNT sheets as a cathode was created. [1] M. Zhang, S. Fang, A. Zakhidov, S.B. Lee, A. Aliev et.al., Science, 309,(2005) 1215.

**J1 188 Microwave plasma enhanced chemical vapor deposition growth of small-diameter CNTs using the polymer based catalysts** PENG WANG, *U. of North Carolina at Chapel Hill* JENNIFER LU, *Agilent Inc.* OTTO ZHOU, *Dept. of Physics and Astronomy U. of North Carolina at Chapel Hill* DEPT. OF PHYSICS AND ASTRONOMY COLLABORATION, AGILENT INC. COLLABORATION, Microwave plasma enhanced chemical vapor deposition (MPECVD) has emerged to be a promising candidate method to realize the growth of carbon nanotubes (CNTs) at a temperature of several hundred degrees Celsius. Among various catalysts, metal-containing polymers have the advantage of easy particle size and density controlling. Here we report to produce carbon nanotubes by using metal-containing polymers at 604 $^{o}$C. There are two to six wall layers. The diameter is consistently in the range of 4 to 7 nm. The control of the density and the length of the as grown nanotubes are discussed. The field emission property is characterized.

**J1 189 Hückel theory of large-scale planar organic structures** WILLIAM SCHWALM, *University of North Dakota* MIZUHO SCHWALM, *University of Minnesota-Crookston* Hückel theory applies, if at all, to the $\pi$ orbitals of planar organic molecules, treating only one $p_z$-like basis function for each atomic site. The only advantage of this is that one has closed formulas for properties of rather large, complex structures. We develop $\pi$-orbital Green function calculations for $\vec{k}_{\|}$ resolved density of states of ordered layers of organic adsorbates, such as might pertain to angle-resolved photoemission. Simple-minded though it may be, the theory leads to closed formulas for a wide variety of molecular architectures.

**J1 190 Quantum transport through a carbon nanotube under a time-dependent electric field.** MONICA PACHECO, *Universidad Santa Maria, Valparaiso, Chile* PEDRO ORELLANA, *Universidad Catolica del Norte, Antofagasta, Chile* We investigate quantum transport through single-wall carbon nanotubes (CNT) connected to leads in the presence of an externally imposed time-dependent transverse electric field. A time-oscillating potential uniform in space induces the apparition of side-bands in the spectrum and therefore the tunneling current is drastically modified. To obtain the conductance and the density of states of the CNT, we adopt the equation of motion approach and we calculate the retarded and advanced Green's function defined in terms of the creation and annihilation operator of the electron in the CNT. We analyze the conductance spectra as a function of the frequency and amplitude of the external time-varying potential. We found that above a critical value of the electric field intensity, an enhancement of the conductance, or suppressed resistance, as a function of the electric field strength occurs. This effect can be explained in terms of photon-assisted transport. The conductance increases displaying oscillations which amplitude shows a strong dependence on the frequency of the electric field. For low frequencies, in the microwave range, the oscillations evolve to a structure of well defined steps. The steps in the normalized resistance as a function of the field strength appear for energies corresponding to the Van Hove singularities of the LDOS of the CNT.

**J1 191 Carbon Nanotubes as Counter Electrodes for Gratzel Solar Cells** HASAN SHODIVE, ALI ALIEV, MEI ZHANG, SERGEY LEE, RAY BAUGHMAN, ANVAR ZAKHIDOV, *The University of Texas at Dallas, NanoTech Institute, BE 26, P.O. Box 830688, Richardson, TX 75083* The role of interfaces is very critical for solar cell devices which use nanostructured materials. Dye Sensitized Solar Cells (DSSC) are devices which parts are interfacial in character and physico –chemical processes occur at the interface of two distinct media. DSSC are of great interest due to combination of their high efficiency and relatively low cost. An effective counterelectrode with high electrochemical activity is an important component of DSSC to enhance its practical utility. Presently used Pt coated ITO counterelectrode can not be applied in flexible DSSC architectures, while there is a growing need for flexible anodes which are transparent and have desired interface characteristics. In this work in order to search for such materials for counter electrode in dye sensitized solar cells, newly developed strong and transparent and modified carbon nanotube sheets [1] are used in interfacial counter electrode. To increase the electrochemical activity of the anode the CNT sheets are coated with highly conductive SWCNT and compared with pure multiwall CNT sheets. We show that the transparent sheets of SWCNT/MWCNT perform as a flexible anode and as electrochemical catalyst and also can be used in tandems of dye sensitized solar cells as transparent charge recombination or interconnect layers. [1] M. Zhang, S. Fang, A. Zakhidov, S.B. Lee, A. Aliev et.al., Science, 309, (2005) 1215.

**J1 192 Is a DNA-Wrapped Metallic Nanotube Still Metallic?** S.E. SNYDER, S.V. ROTKIN, *Department of Physics, Lehigh University, Bethlehem, PA, email: ses7@lehigh.edu* Modeling suggests that essential changes in electronic band structure can result from the helical wrapping of single-stranded DNA around a single-walled carbon nanotube (SWNT). The metal-to-semiconductor transition of a metallic nanotube is one of many possible changes. As SWNT/DNA hybrids become more popular, it is of great practical importance to determine how the charged backbone of single-stranded DNA may affect SWNT properties. As a first approximation, the change in band structure is modeled by considering the Coulomb interaction with a charged helical wrap. A range of models is developed to address a variety of wrappings of both metallic and semiconducting tubes. Parameters

of the model include width, charge profile, and axial and angular displacement of the helix, periodicity along the helix, and, indirectly, chiral angle of the wrap. Band gap changes are shown to be fairly robust for axial and angular shifts of the helix. Trends of the band gap and strength of the potential perturbation with tube diameter and wrapping angle are explored. DNA is just one of several polymers which are presumed to helically wrap SWNTs and thereby disperse SWNTs in solution. Therefore, our study is relevant for electronics applications which require individual nanotubes dispersed via polymer wrapping.

**J1 193 Parameter identification procedure for the Density-Gradient model*** PETRU ANDREI, *Florida State University* The existing methods for the computation of parameters of the Density-Gradient model [M. G. Ancona et al, Phys. Rev. B **39**, 9536 (1989)] are based on the comparison of the model with one-dimensional Poisson-Schrödinger computations. While this approach gives good results for devices in which the carriers are confined in only one direction, it is not appropriate for devices in which the carriers are confined in more than one direction. Such devices include short-channel MOSFET and SOI devices, FinFETs, etc. In this presentation we propose a new identification technique based on the effective-mass Schrödinger equation. Our identification technique can be easily applied to 2- and 3-dimensional semiconductor systems. The model parameters are found by using the electron and hole concentrations computed in the framework of the effective-mass Schrödinger equation. Special attention is paid to the computation of the electron effective mass entering in the Density-Gradient equations since these equations are widely used in n-channel nanoscale transistor simulations.

*This work is supported by the Army High Performance Computing Research Center under agreement number DAAD19-01-2-0014.

**J1 194 The Lowest Energy Structures of Si-24 Cluster*** J. RUFINUS, *Widener University* We present the results of computational calculations of the lowest energy structures of Silicon 24 cluster. The calculations were done in the framework of DFT with PBE exchange functional. The initial structures were calculated using a Genetic Algorithm. Approximately 1000 structures were recalculated using Gaussian 03 (with the basis set 6-31G) to determine the lowest energy structures.

*The computations were performed in part on the NSF Terascale Computing System at the Pittsburgh Supercomputing Center.

**J1 195 Density Functional Study of Strain Effects on the Energy Gap in Silicon Nanoclusters** XIHONG PENG, AZAR ALIZADEH, NITIN BHATE, SURYA GANTI, *GE Global Research, Niskayuna, NY 12309* PRADEEP SHARMA, *Department of Mechanical Engineering, University of Houston, Houston, TX 77204* SAROJ NAYAK, SANAT KUMAR, *Departments of Physics and Chemical Engineering, Rensselaer Polytechnic Institute, Troy, NY 12180* It is well known that nanoscale Si clusters are photo luminescent. In parallel, industry routinely exploits the dramatic strain dependence of the band gap of bulk Si for electronics applications. We have discovered, using density functional calculations that the combined role of finite size and strain leads to previously unanticipated effects on the energy gap in Si clusters. Both hydrostatic and non-hydrostatic strains were applied to the clusters with sizes up to 2nm. For the hydrostatic strain, which maintains the tetrahedral bonding network in Si, the effects of strain on the energy gap exhibits size dependence. The behavior can be classified in three distinct regimes that will be discussed in detail. For non-hydrostatic strains, which result in distortion of the tetrahedral bonds, the coupling between the energy gap and strain is largely independent of the cluster size. The mechanisms responsible for the coupling between the gap and strain are proposed. The relative shifts of the energy gap for hydrostatic and non-hydrostatic strains are compared.

## J1 196 FLUIDS AND SOFT MATTER POSTER SESSION

**J1 197 Anomaly in the heat capacity of triethylamine and water** RUTH SHEWMON, RYAN HARTSCHUH, D.T. JACOBS, *Physics Department, The College of Wooster, Wooster OH 44691* The heat capacity $C_p$ of the liquid-liquid mixture triethylamine-water has been precisely measured using our own computer-based data acquisition and control, adiabatic calorimeter. A step process of adding heat and then waiting several minutes for a stable temperature assures equilibrium values for the heat capacity from the known heat added and the resulting change in temperature. For a sample with a much larger concentration of triethylamine than the critical concentration, we observe strikingly different behavior in the heat capacity than that observed near-critical. The unusual behavior is reproducible and may be due to a structure forming in the sample. We acknowledge support from NSF-REU grant DMR 0243811.

**J1 198 Extrinsic homogeneity of non-cubic periodic minimal surface families** GERD E. SCHROEDER, *Applied Maths, RSPhysSE, Australian National University, 0200 ACT, Australia* ANDREW FOGDEN, *Institute for Surface Chemistry, P.O. Box 5607, SE-11486 Stockholm, Sweden* STEPHEN T. HYDE, *Applied Maths, RSPhysSE, Australian National University, 0200 ACT, Australia* Infinite periodic minimal surfaces (IPMS) form the structural basis of cubic phases in copolymer, lipid or surfactant self-assemblies. Although few non-cubic equilibrium phases have been reported to date, there are compelling reasons to study non-cubic IPMS: first, they offer possible transition structures between bicontinuous cubic phases. Second, the reason why soft systems (that favour homogeneity but not explicitly symmetry) exhibit phases of cubic symmetry is still uncertain. We use the concept of *medial surfaces* to quantify *packing homogeneity*, i.e. variations of the channel radius within the structure. This analysis is carried out on IPMS families that are degradations of the cubic P, D and G surfaces (the rPD, rG, tG, tD tP, and H). We show that the cubic G and D are locally maximally homogeneous, whereas the cubic P has at least one relative that is more homogeneous. We discuss the implications for molecular self-assembly (chain stretching), and compare this result to analyses of curvature fluctuations. G.E. Schöder, S.J. Ramsden, A. Fogden, S.T. Hyde, Physica A **339**, 137–144 (2004) and G.E. Schröder, S.J. Ramsden, A.G. Christy, S.T. Hyde, Eur. Phys. J. B **35**, 551–564 (2003)

**J1 199 Synchrotron studies of nanocrystal thin film self-assembly*** DIEGO PONTONI, KYLE ALVINE, *DEAS, Harvard University, Cambridge,MA, 02138* ANTONIO CHECCO, OLEG GANG, BEN OCKO, *BNL, Upton, NY, 11973* PETER PERSHAN, *DEAS, Harvard University, Cambridge, MA, 02138* FRANCESCO STELLACCI, *MIT, Cambridge, MA, 02129* This work is aimed at exploring the mechanisms of formation and dissolution of nanocrystal 2D and 3D assemblies in the presence of nano-thin wetting films. In particular monolayers of bimodal/polydisperse thiol-stabilized gold nanocrystals are studied. In-situ synchrotron X-ray grazing incidence diffraction reveals that upon adsorption of a good solvent for the nanocrystals, the monolayer first expands and then undergoes a transition to a bilayered/disordered state. A detailed physical model for the corresponding X-ray reflectivity data suggests that the transition starts when the substrate is completely covered by the monolayer as a result of its expansion into 2D voids. Further liquid adsorption forces the expulsion of nanocrystals from the monolayer by vertical displacement. The first nanocrystals to be expelled are the large ones. The whole process is reversible upon slow decrease of the adsorbed liquid.

*Work supported by the NSF (NSF03-03916). Synchrotron measurements performed at X22B, National Synchrotron Light Source, Brookhaven National Lab and supported by DOE grants DE-FG02-88ER45379 and DE-AC02-98CH10886.

**J1 200 Self-Assembly of Porphyrin J-Aggregates** VALENTINAS SNITKA, *Research Center for Microsystems and Nanotechnology, Kaunas University of Technology, Lithuania* MINDAUGAS RACKAITIS, *Bridgestone CRT, Akron OH, USA* GINTARE NAVICKAITE, *Research Center for Microsystems and Nanotechnology, Kaunas University of Technology, Lithuania* The porphyrin nanotubes were built by ionic self-assembly of two oppositely charged porphyrins in aqueous solution. The porphyrins in the acid aqueous solution self-assemble into J-aggregates, wheels or other structures. The electrostatic forces between these porphyrin blocks contribute to the formation of porphyrin aggregates in the form of nanotubes, enhance the structural stability of these nanostructures. The nanotubes were composed mixing aqueous solutions of the two porphyrins - anionic Meso-tetra(4- sulfonatophrnyl)porhine dihydrochloride ($TPPS_4$) and cationic Meso-tetra(4-pyridyl)porphine ($T_4MPyP$). The porphyrin nanotubes obtained are hollow structures with the length of 300 nm and diameter 50 nm. Photocatalytic porphyrins are used to reduce metal complexes from aqueous solution and to control the deposition of Au from $AuHCl_4$ and Au nanoparticles colloid solutions onto porphyrin nanotubes. Porphyrin nanotubes are shown to reduce metal complexes and deposit the metal selectively onto the inner or outer surface of the tubes, leading to nanotube-metal composite structures.

**J1 201 Longitudinal complex dielectric polarizability and relaxation times of polar molecules in a biaxial liquid crystal phase** YURI KALMYKOV, *MEPS, Université de Perpignan, 52 Avenue Paul Alduy, 66860 Perpignan Cedex, France* WILLIAM COFFEY, *Department of Electronic and Electrical Engineering, Trinity College, Dublin 2, Ireland* BACHIR OUARI, *MEPS, Université de Perpignan, 52 Avenue Paul Alduy, 66860 Perpignan Cedex, France* SERGEY TITOV, *Institute of Radio Engineering and Electronics of the Russian Academy of Sciences, Fryazino, Moscow Region, 141190, Russia* The longitudinal relaxation time and the complex dielectric polarizability of rod-like molecules with dipole moment parallel to the long axis in a biaxial nematic liquid crystal are calculated using as model the rotational Brownian motion in a mean field potential so reducing the problem to a set of linear differential-recurrence relations for the appropriate equilibrium orientational correlation functions. The solution of this set is obtained by matrix continued fractions. Simple analytic equations (based on the exponential separation of the time scales of the intrawell and overbarrier (interwell) relaxation processes), allowing one to understand the qualitative behavior of the system and accurately predicting the longitudinal complex polarizability for a wide range of the barrier height and anisotropy parameters, are proposed.

**J1 202 Critical behavior at the isotropic to nematic phase transition in a bent-core liquid crystal** DAVID WIANT, STRAHINJA STOJADINOVIC, KRISHNA NEUPANE, SUNIL SHARMA, *Physics Dept. Kent State U.* KATALIN FODOR-CSORBA, *Hungarian Research Institute for Solid State Physics and Optics* ANTAL JAKLI, *Liquid Crystal Institute Kent State U.* JAMES GLEESON, SAMUEL SPRUNT, *Physics Dept. Kent State U.* Magnetic birefringence and dynamic light scattering measurements of orientational order parameter fluctuations at the isotropic- nematic phase transition of a bent-core liquid crystal reveal a pretransitional temperature dependence consistent with the standard Landau-deGennes mean field theory. However, the transition in the bent-core compound is more weakly first-order ($T_{NI} - T^* \approx 0.4°C$), the leading Landau coefficient is $\sim$ 10 times lower, and the viscosity associated with nematic order fluctuations is $\sim$ 50 times higher, than typically observed in calamitic (rod- shaped) liquid crystals. These anomalies can be explained by an unconventional optically isotropic phase composed of complexes of bent-core molecules. Also, we will present preliminary magnetic birefringence and density measurements at temperatures above the nematic-isotropic transistion which support the existence of an optically isotropic state.

**J1 203 Dielectric Properties of Binary Mixtures of MBBA and 7CB** JOHN GAMBLE, SHILA GARG, *Physics Department, The College of Wooster, Wooster OH 44691* The dielectric properties of mixtures of 4-methoxyybenzylidene-4-butylaniline (MBBA) and 4-n-heptyl-4'-cyanobiphenyl (7CB) were investigated at different molar concentrations. The isotropic-nematic phase boundary was determined for various mixtures in order to calculate the nematic range. For some concentrations, there was a second transition to a higher order smectic phase, most likely a Smectic G. Our previous work on MBBA and 5CB indicated that there was strong interaction between the two mesogens at certain concentrations. We find similar strong interactions for mixtures around the 1:1 molar concentration. Planar and homeotropic cells were constructed in order to measure the two different dielectric permittivities, $\varepsilon_{||}$ and $\varepsilon_{\perp}$. The cells were maintained at a fixed reduced temperature $\tau$ during the measurements, since the nematic range and transition temperatures were different for each mixture. From the $\varepsilon_{||}$ and $\varepsilon_{\perp}$ data, we calculated the dielectric anisotropy $\Delta\varepsilon = \varepsilon_{\parallel} - \varepsilon_{\perp}$ as a function of molar concentrations of the mixtures.

**J1 204 Thermal Conductivity of Silica Aerogels from Computer Simulations** BRIAN GOOD, *NASA Glenn Research Center* Aerogels are of current interest to the aerospace community; their light weight and low thermal conductivity make them suitable for use in lightweight thermal insulation. The gels typically exhibit a

complex structure; the smallest observed feature is a 2-5nm ''primary'' particle of amorphous silica. The primary particles aggregate to form ''secondary'' particles an order of magnitude larger, and these, in turn, form pearl-necklace structures whose details depend on the density. The gels appear to exhibit fractal dimensionality, at least over a small range of length scales. In this work, we investigate the relationship between the structure of the gels, their dimensionality and density, and their thermal conductivity. We model the secondary-particle aggregate structure using a modified diffusion limited cluster aggregation (DLCA) scheme, which produces qualitatively different structures at low and high densities that are consistent with experimental observation. At lower densities, we find evidence for a transition from fractal behavior at small length scales to compact mass scaling at larger lengths. We model the thermal conductivity by assigning a size-dependent thermal conductance to each secondary particle, and an effective thermal conductivity to the gas assumed to be present in the pores between the particles. The conductivity of the gel-gas network is obtained using standard numerical techniques. The scaling of the thermal conductivity with density, fractal dimension, and the ratio of silica to gas conductivities is discussed.

**J1 205 Dynamics of multiple glass states** NORA GRANETO, ANDRZEJ LATKA, PIOTR HABDAS, *Dept. of Physics, Saint Joseph's University* We study concentrated colloidal suspensions, a model system which exhibits a glass transition. Using microscopy techniques we directly observe the microscopic behavior of the colloidal particles as the glass transition is approached. Moreover, by adding polymer to the colloidal suspension we induce ''sticking'' between the colloidal particles. When such attractive force is introduced to a hard-sphere colloidal glass, the system enters a liquid phase. Increasing the polymer concentration even further causes the system to enter another glass state – an attractive glass. We investigate the particle dynamics as system enters multiple glass states. Particularly, we focus on single particle jumps and effect of caging on the particles' dynamics.

**J1 206 Statistical Mechanics of Hydrodynamically Coupled Colloidal Spheres in Optical Vortices** YAEL ROICHMAN, *New York University* DOV LEVINE, *Technion, Israel Institute of Technology* DAVID G. GRIER, *New York University* Optical vortices are ring-like optical traps created by strongly focusing a helical mode of laser light. Colloidal particles trapped in an optical vortex are driven around its circumference by the vortex's orbital angular momentum flux. A set of such circulating spheres may be viewed as a system of perpetually sedimenting particles. Like sedimenting spheres, colloid in a vortex experience a uniform body force. They also interact with each other hydrodynamically. Unlike sedimenting spheres, those in an optical vortex remain in the field of view indefinitely and can be studied in great detail. In addition, the circulating colloid can be subjected to a nonuniform static potential energy landscape created by varying the intensity of light around an optical vortex's circumference. This elegant model system allows us to study the effect of hydrodynamic coupling on the mutual sedimentation of several particle with varying sizes. We find that sedimentation of a bidispered mixture of colloids forms stable couples of particles as opposed to the less stable structure of monodipersed particles sedimenting. We also demonstrate that fluctuations in the particles' trajectories can be used to gauge their system's departure from equilibrium.

**J1 207 Measuring the transverse magnetization of rotating ferrofluids** MANFRED LÜCKE, J. EMBS, S. MAY, C. WAGNER, A. KITYK, A. LESCHHORN, *University Saarbrücken* We report on measurements of the transverse magnetization of a ferrofluid rotating as a rigid body in a constant magnetic field, $\mathbf{H}_0$, applied perpendicular to the axis of rotation. The rotation of the fluid leads to a non-equilibrium situation, where the ferrofluid magnetization, $\mathbf{M}$, and the magnetic field within the sample, $\mathbf{H}$, are no longer parallel to each other. The off-axis magnetization perpendicular to $\mathbf{H}_0$ is measured as a function of both the applied magnetic field, $H_0$, and the angular frequency $\Omega$. The latter ranges from a few Hz to frequencies well above a characteristic inverse Brownian relaxation time. Our experimental results strongly indicate that the transverse magnetization is caused only by a small fraction of the collodial ferromagnetic particles. The effect of the polydispersity of the ferrofluid is discussed. Experimental results are compared to predictions based on several theoretical models. A single-time relaxation approach for the so-called effective field and a field dependent Debye relaxation of $\mathbf{M}$ yield reasonably good shapes of the curves of transverse magnetization versus $\Omega$. However, like the other models they overestimate their magnitudes.

**J1 208 Effect of Associative Polymers on the Foaming Properties of Surfactant Solutions*** ALFREDO CERVANTES, EMMANUEL ROBLES, *Departamento de Investigación en Polímeros y Materiales, Universidad de Sonora* HERIBERTO ACUÑA, ROGELIO GAMEZ, AMIR MALDONADO, *Departamento de Física, Universidad de Sonora* Aqueous foams are materials which have many industrial applications. Their stability is affected by three mechanisms: bubble coalescence (film rupture), coarsening (gas diffusion) and drainage (gravity-driven liquid flow). The aim of this work is to obtain some insight into the effect of associative polymers on the foamability, foam stability and drainage of surfactant solutions. The foams were produced by air bubbling and by the turbulent mixing method. The surfactant is SDS and the associative polymers studied are HEUR and POE-Stearate. We studied the effect of polymer concentration for each macromolecule. The results show that two opposite effects are present when the polymer concentration is increased: for low polymer concentrations, foamability and foam stability is higher than for high concentrations. Results are discussed in terms of the properties of the solution: surface tension, electrical conductivity, bulk viscosity, etc.

*We acknowledge financial support from Universidad de Sonora.

**J1 209 Elasticity of the FCC Hard Sphere Crystal from two point microrheology** MATTHEW SULLIVAN, *Princeton University / Schlumberger-Doll Research* KUN ZHAO, ANDREW HOLLINGSWORTH, P.M. CHAIKIN, *Princeton University / New York University* WILLIAM B. RUSSEL, *Princeton University* We present a measurement of the full elastic tensor of a hard sphere colloidal crystal. Our system consists of concentrated suspensions of monodisperse PMMA-PHSA particles suspended in a density-matching solvent mixture of decalin and tetrachloroethylene. Single crystals are heterogeneously nucleated from a surface template to produce large face centered cubic (FCC) single crystals. The two-point displacement correlations are measured using confocal microscopy and video analysis. These show a $1/r$ decay with distance and an angular dependence that can be used to determine the three elastic constants of the FCC crystal.

**J1 210 Computer simulations of SDS/dodecanol (hexadecanol) monolayers at water/air interface*** HECTOR DOMINGUEZ, *Instituto de Investigaciones en Materiales, Universidad Nacional Autonoma de Mexico (UNAM). Mexico 04510* MARGARITA RIVERA, *Instituto de Fisica, Universidad Nacional Autonoma de Mexico. Mexico 01000* Simulations of monolayer mixtures of amphiphlic molecules were investigated to study the effects of the polar head groups in the structure of the monolayer at the water/air interface. The binary mixture was composed of sodium dodecyl sulfate (SDS) and dodecanol (hexadecanol) molecules For the low dodecanol concentration molecules two monolayer mixtures were prepared. In the first monolayer all the dodecanol molecules were placed together in the center of the simulation box whereas in the second monolayer those molecules were uniformly distributed in the surface area in such a way that they were a part from each other. Simulations of both systems indicate that the dodecanol tails in the first monolayer are more straight and more ordered than those in the second monolayer. When simulations of SDS/hexadecanol are performed it is observed that the tilt angle and the order of the tails are different respect to the SDS/dodecanol mixtures.

*We acknowledge CONACYT- Mexico grant 42842-F

**J1 211 Role of membrane composition in the formation and stability of buds** KURT A. SMITH, ANNA C. BALAZS, *University of Pittsburgh* Using dissipative particle dynamics we study the behavior of buds in amphiphilic bilayer membranes. These buds occur during phase separation when line tension between the two phases comes to dominate the bending rigidity of the membrane. We show that the inclusion of twin-tail amphiphiles, which segragate to the interface between the two phases, is a means to controlling the onset of budding. In addition they stabilize the neck when budding does occur, by acting essentially as stitches, thereby increasing the energy needed to detach the bud from the membrane.

**J1 212 Competing interactions in two dimensional Coulomb systems: Surface charge heterogeneities in co-assembled cationic-anionic incompatible mixtures** SHARON LOVERDE, YURI VELICHKO, MONICA OLVERA DE LA CRUZ, *Department of Materials Science and Engineering, Northwestern University* A binary mixture of oppositely charged components confined to a plane such as cationic and anionic lipid bilayers may exhibit local segregation. The relative strength of the net short range interactions, which favors macroscopic segregation, and the long range electrostatic interactions, which favors mixing, determines the length scale of the finite size or microphase segregation. The free energy of the system can be examined analytically in two separate regimes, when considering small density fluctuations at high temperatures, and when considering the periodic ordering of the system at low temperatures (F. J. Solis, S. I. Stupp and M. Olvera de la Cruz J. Chem. Phys. 122 (5), 054905 (2005)). A simple Molecular Dynamics simulation of oppositely charged monomers, interacting with a short range Lennard Jones potential and confined to a two dimensional plane, is examined at different strengths of short and long range interactions. The system exhibits well-defined domains that can be characterized by their periodic length-scale as well as the orientational ordering of their interfaces. By adding salt, the ordering of the domains disappears and the mixture macroscopically phase segregates in agreement with analytical predictions.

**J1 213 Circular Couette cell for two-dimensional turbulence experiments in sheared flow: initial results.*** JOHN V. ULMEN, PAUL W. FONTANA, MARTIN KEARNEY-FISCHER, *Seattle University* An experiment to study turbulence in quasi-two-dimensional flows with a controlled mean flow shear has been built. Experiments are underway to investigate the suppression of turbulent transport by sheared flow as seen in geostrophic flows and laboratory fusion plasmas. The apparatus, a circular Couette cell, uses a liquid film of dilute soap solution suspended freely in an annular channel with a rotating outer boundary. The channel is $7cm$ wide with an average radius of $46.5cm$, and can be rotated at angular speeds exceeding $10rad/s$. Mean flow profiles will be presented showing the effect of air resistance on the flow; damping lengths on the order of $1mm$ are observed. Turbulence is driven independently via electromagnetic forcing. The rate of turbulence injection can be varied continuously, and its spatial scale corresponds to the spatial frequency of an array of NdFeB magnets. Diagnostics include particle imaging velocimetry, two-point laser Doppler velocimetry, and thickness measurements via reflection interferometry. Initial results and plans for upcoming measurements will be presented.

*Supported by the M. J. Murdock Charitable Trust, Research Corporation, and the NSF-MRI program.

**J1 214 Droplet pinch off of diluted polymer solutions** CHRISTIAN WAGNER, RAINER SATTLER, *Universitaet des Saarlandes* JENS EGGERS, *University of Bristol* Tiny amounts of polymers can alter the flow behaviour of simple liquids dramatically. An aesthetic and instructive example is the detachment process of a droplet of a polymer solution, e.g. a diluted DNA solution. It is characterized by the suppression of the pinch off finite time singularity and the formation of a cylindrical filament between the droplet and the nozzle. On later stages of the experiments beads on a string a formed. Their generation can be well explained with scaling arguments of the intrinsic time scales of the experiment. The dramatic increase of resistance against the flow is macroscopically described by the elongational viscosity. It is a crucial parameter in many different industrial processes where contraction flows are generic. A pure elongational flow stretches the macromolecules at maximum and we use different experimental techniques simultaneously to relate macroscopic flow profiles with microscopic polymer configurations.

**J1 215 Motility in multicomponent fluids*** ROBERT MAGERLE, STEPHAN WEISS, NICOLAUS REHSE, *Technische Universitaet Chemnitz* During annealing in air thin films of polystyrene-block-polypropylene and similar block copolymers decompose and form a phase separating multi-component polymeric fluid where domains coarsen similar as in a binary mixture. At a certain threshold of domain size, two domains form a droplet which starts to move spontaneously across the surface. We show that a chemical reaction with oxygen is required for this motion for which we have determined the effective activation energy. We discus a model for droplet motion and speculate about the relevance of the underlying physics for the motility of biological cells and their ultra-cellular compartments.

*Supported by Deutsche Forschungsgemeinschaft (SFB 481)

**J1 216 Characterization of diffusion in supersaturated solutions using T-sensors*** KRISTEN BLOSCHOCK, *Georgetown University Department of Physics* RUSSEL ROSS, *Georgetown University Department of Physics* EDWARD VAN KEUREN, *Georgetown University Department of Physics* Measurement of the molecular diffusivity has provided much of the evidence for cluster formation in supersaturated solutions. The recent development of the T-sensor, a microfluidics laminar flow device, enables rapid determination of molecular diffusion coefficients. In this device, fluids in two channels meet and undergo laminar flow, with diffusion occurring perpendicular to the direction of flow in the channel. We have used fluorescence imaging of molecules in a T-sensor to study diffusion in supersaturated solutions of several dyes. When they self-assemble, these molecules exhibit characteristic changes in fluorescence emission. Therefore, using imaging we can determine both the state of aggregation and the diffusion coefficient. We will present results of experiments with one channel containing a molecular solution and the second a miscible non-solvent; the diffusional mixing induces nucleation and growth of nanocrystals.

*This work was supported by the National Science Foundation, Grant DMR 0348955.

**J1 217 Self-organizing flow in a multi-component driven system - interacting lattice gas simulation** RAS PANDEY, *Naval Research Laboratory and University of Southern Mississippi* JOE GETTRUST, *Naval Research Laboratory* We consider a mixture of mobile particles $(A,B)$ described by their molecular weight, interaction, and miscibility gap on a discrete lattice of size $L_x \times L_y \times L_z$. The source of particles is at the bottom $(z = 1)$ of the lattice with open top $(z = L_z)$. The Metropolis algorithm is used for stochastic moves of particles with a hydrostatic pressure bias (H). Periodic boundary conditions are used along the transverse directions with open longitudinal ends. Particles continue to enter the lattice from the source and are driven by bias, concentration gradient, and thermal energy against gravity. Net flow of particles occurs and a steady-state is reached with a self-organized morphology. Self-organizing structures and flow flux rates are examined as a function of bias for a range of molecular weight ratios for non-equilibrium steady-state system with non-conservative mass/volume. Response of the flux density shows linear and nonlinear behavior depending on the range of the bias with an eruptive response at extreme values of the bias.

**J1 218 Distributions and seeps of driven mixture around a slit in porous media - interacting lattice gas simulation** JOE GETTRUST, *Naval Research Laboratory* RAS PANDEY, *Naval Research Laboratory and University of Southern Mississippi* We consider a porous medium with a slit on a discrete lattice of size $L_x \times L_y \times L_z$. The porous matrix is generated by a random distribution of immobile barriers on a fraction of the lattice sites. A longitudinal slit of width $L_s$ spans from bottom to top through the center of the lattice. The source of particles specified by their molecular weight, interaction, and miscibility gap is connected to the bottom $(z = 1)$ of the lattice with an open top $(z = L_z)$. The Metropolis algorithm is used for stochastic moves of particles with a hydrostatic pressure bias $(H)$. Periodic boundary conditions are used along the transverse directions with open longitudinal ends. Particles continue to enter the lattice from the source. Particles flow from bottom to top reaching a steady-state where we examine their seeps and distributions. We find that the steady-state distributions of constituents and their local mobility in the slit and the surrounding regions depend on bias and porosity with strong correlations at high bias.

**J1 219 Self-Organized Criticality in a Bead Pile** MEGAN MILLER, TUAN NGUYEN, ELIZABETH BAKER, D.T. JACOBS, *Physics Department, The College of Wooster, Wooster OH 44691* This experiment examined a conical bead pile and the distribution of avalanche sizes when using uniform 3mm stainless steel spheres (''beads''). A bead pile is built by pouring beads onto a circular base where the bottom layer of beads has been glued randomly. Beads are then individually dropped from a fixed height after which the pile is massed. This process is repeated for thousands of bead drops. By measuring the number of avalanches of a given size that occurred during the experiment, the resulting distribution could be compared to a power law description as predicted by self-organized criticality. We had found in an earlier experiment that glass beads dropped from a small height were consistent with a simple power-law, but if dropped from larger heights then a power-law times an exponential was needed. The stainless steel beads always had a distribution that deviated from a simple power-law with larger deviations as the beads were dropped from larger heights. In addition, we observed a different power-law exponent than that found for glass beads yet a similar dependence on drop height. We acknowledge support from NSF-REU grant DMR 0243811.

**J1 220 Effect of Relative Material Stiffness of Binary Mixture Components to Compression*** CRAIG BENTHAM, *Pfizer Ltd., Sandwich, Kent, UK* MEENAKSHI DUTT, *University of Cambridge* BRUNO HANCOCK, *Pfizer Inc., Groton, Connecticut, USA* JAMES ELLIOTT, *University of Cambridge* Typical powder blends will have constituent particles which will differ in material properties, such as stiffness, resulting in variation of coordination number and contact slipping state, at a local particle scale. At a macroscopic scale, the relative properties of the various components will influence the force and stress response of the blend to an external load or strain. Of particular curiosity is the distribution of load as a function of contact stiffness. We present numerical results from our studies on binary mixtures with components whose relative stiffness (Young's modulus) has been varied systematically. These mixtures settle under gravity followed by compression at a constant strain rate. In addition, we discuss the correlations between the contact slipping state, stiffness, and the load sustained.

*Special Acknowledgements to Pfizer for funding

**J1 221 Granular templating: effects of boundary structure on particle packings under simultaneous shear and compression*** BRUNO HANCOCK, *Pfizer Inc., Groton, Connecticut, USA* MEENAKSHI DUTT, *University of Cambridge* CRAIG BENTHAM, *Pfizer Ltd., Sandwich, Kent, UK* JAMES ELLIOTT, *University of Cambridge* We present our findings on the effect of various confining substrates, both crystalline and amorphous, on spherical granular particles, packed under gravity followed by the simultaneous application of shear and compressive strains. We show that a substrate templated with the BCC (100) plane, whose void and particle packing structures are identical, is most suitable for inducing crystallization mimicking the substrate structure. Our results for both templated substrates show the compressive strain dominating the shear strain.

*Special Ackowledgements to Pfizer for funding

**J1 222 A Particle-Substrate Model and Its Applications to Cooling and Driven Granular Systems*** ROBERT BEHRINGER, *Duke University* MEENAKSHI DUTT, *University of Cambridge* A complete understanding of the microscopic dynamics of a monolayer of identical spheres moving on a substrate must encompass the effects of collisions and the substrate on the particles. We begin from first principles by considering collections of spherical frictional particles that roll and slip on a flat static substrate. We present a numerical model which accounts for collisional and surface frictional dissipation and their influence on particle dynamics for a quasi 2-dimensional cooling granular material. We apply this model to a simulation of the granular collider experiment (Painter et al., Physica D (2003)), in which collections of particles collided as they moved radially inward on a substrate. We find an agreement between the experimental and numerical results. We extend this model further to study a horizontally vibrated particle-substrate system. We show that the ratio of the substrate acceleration to the particle-substrate static frictional force per unit mass (Kondic, Phys Rev. E (1999)) dominates the individual particle dynamics and the collision dynamics. We will present results from our numerical experiments which further higlight the critical role of static friction, relative to the driving acceleration.

*Special acknowledgements to NSF support: NSF-DMR-0137119

**J1 223 Flux from a vibrated granular medium** KE CHEN, MATTHEW STONE,*RACHEL BARRY, MATTHEW LOHR, WILLIAM McCONVILLE, *Dept. of Physics and Materials Research Inst., Penn State University* KIT KLEIN, *Dept. of Computer Engr., Penn State University* BEN-LI SHEU, *Dept. of Physics and Materials Research Inst., Penn State University* ANDREW MORSS,† *Dept. of Physics and Materials Research Institute, Penn State University* THOMAS SCHEIDEMANTEL, PETER SCHIFFER, *Dept. of Physics and Materials Research Inst., Penn State University* We have studied vertically vibrated granular media by measuring the flux through a hole in the container's bottom surface. We find that when fully fluidized, the flux is controlled by the peak velocity of the vibration, $v_{max}$, i.e., the flux is nearly independent of the frequency and acceleration amplitude for a given value of $v_{max}$. The flux decreases with increasing peak velocity and then becomes constant for the largest values of $v_{max}$. We demonstrate that the data at low peak velocity can be quantitatively described by a hydrodynamic model. By contrast, the nearly constant flux at larger peak velocity signals a crossover to a state in which the granular density near the bottom is insensitive to the energy input to the system. This research was supported by the NASA through grant NAG3-2384 and the NSF REU program through grant DMR 0305238.

**J1 224 Quicksand** DANIEL BONN, *ENS/LPS and WZI, UvA* Quicksand is the generic name for unstable soils reputed to trap anyone who treads on it. Popular wisdom has it that one should not move when trapped in quicksand, as motion makes one sink in even deeper and that once trapped, it is difficult to escape. We provide an explanation for these observations by studying the most commonly encountered form of natural quicksand. We show that a spectacular liquefaction of the material occurs when a stress is applied to the material: the liquefaction is the reason why one sinks away, and it is more pronounced for larger stresses. By constructing laboratory quicksand, we demonstrate that the liquefaction is due to the structure: quicksand is a loose granular packing of sand particles stabilized by a clay matrix that forms a particulate gel. The stress liquefies the clay matrix, and the granular assembly collapses, expulsing water. This results in a densely packed system that practically impossible to dilate: it is for this reason that once trapped it is difficult to get out of quicksand. A sinking test demonstrates that, due to buoyancy, it impossible to drown in the quicksand.

**J1 225 Properties of uniformly heated and sheared granular gases. A DSMC simulation.** FRANCISCO VEGA REYES, *Departamento de Fisica, Universidad de Extremadura, E-06071 Badajoz, Spain* We study a monodisperse hard sphere granular gas by means of the Direct Monte Carlo Simulation (DSMC) of the associated Enskog-Boltzmann equation. Due to the kinetic energy loss in the interparticle collisions, the granular temperature decays to the zero unless there is some kind of energy input. We consider two types of energy input. One, heating, process through which kinetic energy is added directly to the particles; and two, shearing of the granular gas. We focus particularly in the uniform steady states. Contrary to elastic hard sphere gases, in granular gases the steady uniform shear state is possible (i.e., a constant linear velocity profile with steady uniform density and temperature). This state is a reference point in the study of granular gases. We analyse the relevant magnitudes (like stress tensor) in the different energy input cases, as a function of the inelasticity.

**J1 226 Networks of Liquid Bridges and Clusters in Wet Granular Systems** MARIO SCHEEL, STEPHAN HERMINGHAUS, RALF SEEMANN, *MPI for Dynamics and Self-Organization, Bunsenstr. 10, D-37073 Göttingen, Germany* The macroscopic mechanical properties of a dry granulate change dramatically when small amounts of liquid are added. This is due to capillary bridges forming between mutually adjacent grains in the pile, which exert an attractive force by virtue of the surface tension of the liquid. If much more liquid is added, the liquid clusters, and the stability of the pile is reduced. Although the tensile strength of wet granulates can be roughly estimated from the capillary forces, a quantitative theory of the mechanical properties of granulate requires a detailed understanding of the topology of the complex network of capillary bridges and clusters. We have determined the macroscopic properties in model granulates with a vertical fluidization experiment, as well as the microscopic geometry of the distribution of liquid within the pile via x-ray microtomography. The transition from capillary bridges to clusters or the percolation can be clearly observed in both the fluidization experiments and the tomographic imaging.

**J1 227 Flow of Polymer Solutions in Nansocale Slit Pores** JAIME A. MILLAN, MOHAMED LARADJI, *Physics Dept., University of Memphis* YONGMEI WANG, *Chemistry Dept., University of Memphis* We present results from extensive and systematic molecular dynamics simulations of semi-dilute and cocentrated polymer solutions in nanoscale slit pores. We will particulary report on the effects of the polymer concentration, molecular weight and flow rate on the profiles of the velocity field, polymer concentration, and radii of gyration of the polymer chains across the slit.

**J1 228 Kinematics of a sphere moving through a non-Newtonian liquid** HANS WHEELERSBURG, NORA GRANETO, PIOTR HABDAS, *Dept. of Physics, Saint Joseph's University* When a sphere moves through a non-Newtonian liquid, it creates an envelope of sheared liquid around the sphere. By using different tube sizes and pulling the sphere at different velocities we examine the dimensions of the envelope and study the effect of the walls of the tube on the sphere in motion. Also we study how the drag force acting on the sphere varies with the tube size, sphere velocity, sphere size, and the properties of the non-Newtonian liquids (i.e. yield stress). In a Newtonian liquid, the drag force acting on the sphere is proportional to the velocity of the sphere and follows the Stokes Law. The drag force acting on a sphere moving through a non-Newtonian liquid does not follow this dependence and we are currently investigating the relationship of the drag force on velocity in non-Newtonian liquids.

**J1 229 Spreading of Advected Tracers in a Creeping Flow in a Rectangular Channel** MIRON KAUFMAN, We have developed an analytical solution [M. Kaufman, 2003 AIChE Annual Meeting Conference Proceedings] of the Navier-Stokes equation for the two-dimensional incompressible flow in a rectangular cavity in the limit of zero Reynolds number. An analytical solution for the fluid velocity along the axis of a parallelepiped, again in the Stokes limit, is also known. In this work we combine the two solutions to get analytically the three-dimensional creeping flow inside a channel in the shape of a parallelepiped. We integrate numerically the velocity vector to get trajectories of tracers advected by the fluid. We analyze the spreading in space of the tracers by calculating the time evolution of the entropy.

**J1 230 Spinning Rods: Experiment & Theory*** JONATHAN TOLEDO, *University of North Carolina at Chapel Hill* RICHARD M. McLAUGHLIN, ROBERTO CAMASSA, TERRY JO LEITERMAN, RICHARD SUPERFINE, JING HAO, LEANDRA VICCI, ADAM BROOKS, *University of North Carolina, UNC RTG FLUIDS GROUP* UNC RTG FLUIDS GROUP TEAM, Mixing and transport properties of the fluid motion induced by a slender rod attached to a plane sweeping out a cone are examined in a table- top experiment. This experiment is used to validate an exact solution for the motion of a spheroid sweeping out a double cone in free space and an asymptotic solution for a slender body attached to a plane. Validation of the theory is used to examine mixing and transport of the same experiment on the microscale.

*RTG NSF DMS-0502266

**J1 231 Influence of Pressure on Fast Dynamics in Polymers** B. BEGEN, A. KISLIUK, A.P. SOKOLOV, *University of Akron* V.N. NOVIKOV, *IA&E, Russian Academy of Sciences* K. NISS, A. CHAUTY-CAILLIAUX, C. ALBA-SIMIONESCO, *Université de Paris-Sud* B. FRICK, *Institut Laue-Langevin* Recent experiments reveal a strong correlation between the fast dynamics and the fragility of glass forming liquids. It is known that both density and thermal energy influence significantly the structural relaxation and the glass transition in most of the glass forming systems. However, not much is known about the influence of volume and temperature on the fast dynamics. In this contribution, we present light and neutron scattering study of the influence of pressure on fast dynamics and elastic properties in polymers. Our results show that the boson peak frequency increases with pressure stronger than the sound velocity. We observed that the boson peak intensity decreases under pressure stronger in Raman scattering than in neutron scattering suggesting a decrease in the light-to-vibrations coupling coefficient $C(v)$. We argue that variations in $C(v)$ might be related to amplitude of structural fluctuations. We speculate that change in disorder and/or overall density under pressure is the main cause for the observed variations.

**J1 232 Fragility, spatially heterogeneous dynamics, and enhanced translational self-diffusion in low molecular weight glassformers*** MARIE K. MAPES, STEPHEN F. SWALLEN, M.D. EDIGER, *University of Wisconsin, Madison* Recent measurements of self-diffusion coefficients in prototypical small molecule glassformers reveal behaviors believed to be universal for low molecular weight fragile glasses. These behaviors include enhanced translational motion and a self-diffusion controlled crystallization regime. Similar enhancements in self-diffusion relative to the Stokes-Einstein relation have been found for two glassformers of similar fragility: *o*-terphenyl with around 100 times faster self-diffusion than expected at $T_g$ +3 K, and ittris-naphthylbenzene, with around 400 times faster diffusion at $T_g$. The temperature range of enhanced motion also overlaps a range of self-diffusion controlled crystal growth. The origin of enhanced diffusion is often attributed to spatially heterogeneous dynamics thought to exist in fragile glassformers. Relaxation time distributions in the literature for *o*-terphenyl and ittris-naphthylbenzene, and their relationships with enhancement of self-diffusion, fragility, and heterogeneous dynamics are discussed.

**J1 233 Dynamics of magnetic colloids** ARTUR ERBE, MICHAEL KOEPPL, LARYSA BARABAN, FLORIAN MERKT, PAUL LEIDERER, *FB Physik, Universitaet Konstanz, Germany* Colloidal suspensions are fascinating examples of soft matter, but also model systems for studying the behavior of atoms and molecules. Here we present the dynamic behavior of superparamagnetic particles and the fabrication and characterization of magnetically anisotropic particles. Transport of the superparamagnetic particles (diameter of 4.7 $\mu$m) is characterized through narrow constrictions on the scale of 60 $-$ 100 $\mu$m in an externally applied magnetic field. In this system we observe the formation of lanes depending on the interparticle interactions and the particle densities. In order to create a larger range of interparticle interactions we also produce anisotropic particles by evaporation of metallic caps on top of the colloidal particles (for these experiments we use nonmagnetic silica colloids). These particles can have a well-defined magnetic moment, given by the material of the cap. We determine this moment using the magnetooptic technique.

**J1 234 Informational Self Organization in Isotopically Random Soft Structures** ALEXANDER A. BEREZIN, *McMaster University* Stable isotopicity can potentially account for self organization and informational proliferation in soft matrices, gels and even fluids. This can be a key to explain seeming ''impossibility'' of such claims as memory effects in water. Within isotopicity paradigm (A.A. Berezin, Isotopic diversity in natural and engineering design, In: Design and Nature, WIT Press, 2004, 411-419) pattern enhancement upon successive dilutions can be attributed to ''avalanche'' cascade formation of informationally rich and numerically redundant ''Arnold tongues'' akin to strange attractors. Furthermore, even biological and medical ''phenomenol-

ogy'' which we currently put under umbrella term ''immune systems'' can be operationally interpreted through quantum computer informational processing in isotopic neural networks using diversity of nuclear spins of different isotopes. Under action of informational attractor (analogy with Aristotelian causa finalis) ''decay'' process of patterns can be slower than build up of informational redundancy (morphic resonance). The latter can be envisioned as a kind of informational ''Huygens principle'' in which formation of global (wave) front (here: informational front) results from superposition of virtual sources at previous stage of cascade process. Nonlocal aspects of isotopic quantum computing can potentially provide connector to infinititude (perhaps even Cantor uncountable) library of patterns and serve as yet another bridge between physics and biology.

**J1 235 Quantifying spatiotemporal chaos in Rayleigh-Benard convection** MAGNUS EINARSSON, *Virginia Tech* M.R. PAUL, *Virginia Tech* P.F. FISCHER, *Argonne National Laboratory* One of the biggest challenges of modern science is to gain further understanding of large spatially extended systems driven far-from-equilibrium. Such systems often exhibit spatiotemporal chaos yielding aperiodic behavior in both space and time that is difficult to characterize. Diagnostics based upon the Lyapunov exponents and eigenvectors are explored as a way to quantify spatiotemporal chaos in Rayleigh-Benard convection in an experimentally realistic cylindrical domain. This is done through large-scale parallel numerical simulations and the results are used to gain new physical insight into the behavior of spatiotemporal chaotic systems.

**J1 236 Modeling microcapsules moving through microchannels of differing geometries** ALEXANDER ALEXEEV, ROLF VERBERG, ANNA BALAZS, *Chemical Engineering Department, University of Pittsburgh, Pittsburgh, PA* We study the dynamic behavior of deformable microcapsules in microchannels, which are roughly comparable in size to the diameter of the capsules. The capsules model synthetic polymeric microcapsules or biological cells, such as leukocytes. The microcapsules are driven to move through the channels by an imposed pressure gradient or flow field. Each microcapsule consists of an elastic shell that is filled with a viscous fluid. To model this multi-component system, we combine the lattice Boltzmann model for fluid dynamics and the lattice spring model for the micromechanics of elastic solids. We determine the effects of the mechanical properties of the elastic capsule and the characteristics of the imposed flow on the dynamics of the capsules as they move inside microchannels with sinusoidal and undulating geometries. We also isolate conditions that lead to a trapping of the capsule inside the channel. The findings provide insight into the behavior of cells within biological vessels and provide guidelines for regulating the motion of polymeric microcapsules with microfluidic devices.

**J1 237 Deviation of a Jet at a T junction at low Reynolds number** PASCAL PANIZZA, WILFRIED ENGL, *LOF/CNRS* KOUSKE OHATA, *LOF* ANNIE COLIN, *LOF/CNRS* We study the hydrodynamic behaviour of a laminar jet flowing through a channel when it reaches a junction. We observe the existence of two possible flow regimes, namely the splitting and deviation of a jet in the most simple microfluidic configuration, namely a T junction. The transition between the two regimes is not monitored by the shape of the T junction nor by capillary effects, but can be easily anticipated in terms of the hydrodynamic properties of the flow. We present a simple hydrodynamic model which is in very good agreement with observed experimental jet behaviour. The transition between both regime acts as a flow or viscosity comparator. We show how this effect can be used for the design of digital and integrated microfluidic devices

**J1 238 Fluids Moving Past Smooth Hydrophilic Surfaces – Slip?** JANET WONG, SUNG-CHUL BAE, LIANG HONG, STEVE GRANICK, *Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign* Recent experiments challenge the traditional view that fluids satisfy the ''no-slip'' boundary condition. While the amount of slip observed differs between research groups, it is now generally accepted that the no-slip boundary condition need not hold strictly – if the surface is smooth and hydropobic. What happens if the surface is wetted by the moving fluid? This work describes hydrodynamic studies of fluid between two crossed cylinders in a surface forces apparatus, using a new method of mica cleaving that appears to produce different findings from those obtained from classical methods. Aqueous salt solutions with various ion concentrations were used with mica as the confining surface. The role of salt concentration was explored. Independently, the fluorescence lifetime of fluorescent dyes was used to measure the near-surface ionic conditions independent of a force measurement.

**J1 239 Enhanced Fluid Mixing in Nanochannels: A Molecular Dynamics Study** ERIC C.J. OLIVER, GARY W. SLATER, *University of Ottawa* The efficient mixing of fluids is of paramount importance in several applications such as lab-on-a-chip and microfluidic devices. The main limitation to efficiency is that on small scales where the Reynolds number of the flow is low, mixing is dominated by diffusion. Purely diffusive motion is very slow and is an inefficient mixing mechanism unless the channel width is extremely small. Starting with the basic result for diffusive mixing of a binary fluid in a Poiseuille flow we explore methods to enhance the level of mixing between the two fluid species. We simulate the system using Molecular Dynamics and model the fluids as assemblies of Lennard-Jones beads. In order to increase the rate of mixing we have forced lateral motion in the fluid using configurations of mid-stream posts. Specifically, posts set in a prism-like structure have proven to be extremely well suited to reducing the channel length required to achieve complete mixing. In order to measure efficiency we have proposed a mathematical function that quantifies the level mixing associated with a fluid element. Furthermore, we have developed a basic theory for the position of the mixing front in a flow with spatially dependent velocity and diffusion coefficient.

**J1 240 Effects of Membrane Material Properties on the Deformation of Elastic Capsules in a Shear Flow*** KIT YAN CHAN, CHARLES EGGLETON, *UMBC* The deformation process of elastic capsules in a simple shear flow is studied numerically using the immersed boundary method to probe the influence of membrane material properties. Membrane models that are representative of linear elastic membrane (Hookean law), strain hardening membrane (Skalak), and strain softening membrane (Mooney-Rivlin, neo-Hookean) and the Evans-Skalak model developed from thermodynamic principles to represent the behavior of a lipid bilayer and a cytoskeletal network, are used to study the effects of membrane material properties on the response of the capsule at various shear rates. Simulation results indicate that both

the time to reach steady state and the final steady shape of the capsule are sensitive to the choice of the membrane model and parameter values used. These experimentally measurable quantities may be compared with computations for determining suitable model of a particular capsule of interest, and the associated material properties. Local strain and energy distributions computed also provide additional information that is not easily accessible experimentally.

**J1 241 Molecular dynamics modeling of nanoparticle dielectrophoresis** EMPPU SALONEN, EMMA TERAMA, *Lab of Physics and HIP, Helsinki Univ of Tech, Finland* ILPO VATTULAINEN, *Lab of Physics and HIP, Helsinki Univ of Tech, Finland; Memphys-Center of Biomembrane Physics, SDU; Inst of Physics, Tampere Univ of Tech, Finland* MIKKO KARTTUNEN, *Lab of Computat Engineering, Helsinki Univ of Tech, Finland; Dept of Applied Math, Univ of Western Ontario, Canada* We have used molecular dynamics simulations to study nanoparticle dielectrophoresis (DEP), i.e., motion induced by a coupling of the particle polarization to a non-uniform electric field. In the first simulations we have considered the case of a single spherical colloid in a non-conductive solvent [1]. This approach has given qualitative information on the limitations of DEP transport due to the thermal motion of the manipulated particles at different DEP coupling strengths. In addition, we have studied changes in the DEP transport efficiency due to particle aggregation. The results of the modeling are compared to analytical studies [2,3] as well as experiments. [1] E. Salonen et al., Eur. Phys. J. E. 18 (2005) 133. [2] J. P. Huang et al., Phys. Rev. E 67 (2003) 021403. [3] J. P. Huang et al., Phys. Rev. E 69 (2004) 051402.

**J1 242 An internal splash: Levitation and Long Transients of Falling Spheres in Stratified Fluids*** RICHARD PARKER, BYRON HUFF, RICHARD McLAUGHLIN, ROBERTO CAMASSA, *University of North Carolina* UNC RTG FLUID GROUP TEAM, We present measurements regarding new phenomena arising with falling bodies in sharply stratified (two layer) fluids.[1] Specifically, the newly observed phenomena in which a heavy falling sphere stops and reverses its motion before ultimate descent to the bottom is further explored through careful adjustment of the bottom layer fluid density. An experimental study is presented which documents the bounce amplitude and long layer residence times as function of the bottom layer density for several spheres of different densities. Finally, we present the behavior associated with beads of adjustable density and varying size.

**J1 243 Flow through a laboratory sediment sample: hydraulic conductivity by computer simulation modeling** EDWARD BRAITHWAITE, *Naval Research Laboratory* ALLEN REED, *Naval Research Laboratory* RAY SEYFARTH, *University of Southern Mississippi* RAS PANDEY, *Naval Research Laboratory and University of Southern Mississippi* JOE GETTRUST, *Naval Research Laboratory* Digitized catscan image of a three dimensional laboratory sediment sample provides a host matrix of size $100^3$. The porosity of the sample is 0.282, i.e., below the site percolation threshold of a cubic lattice. Despite a high fraction of sediment barriers, visualizations reveal that the ramified channels of connected pores span across the sample. A coarse grained description is used to model fluid by interacting particles in spirit of classical lattice gas. As in experiments, the source of the fluid is connected at one end of the sample in our computer simulations. The fluid constituents execute their stochastic motion via Metropolis algorithm and flow through the sample with periodic boundary condition across transverse boundaries. From the net flow of fluid, we estimate the flux density and the hydraulic conductivity in steady-state. We also consider pressure bias (H) to investigate the response. Results of transport, flux rate, and distribution of fluid will be presented.

**J1 244 Acoustic modulation of pharmaceutical sprays** SORIN MITRAN, *UNC* HUGH SMYTH, *UNM* ANTHONY HICKEY, *UNC* We consider the effect of acoustical radiation upon the particle size distribution in pharmaceutical sprays. A mixed particle hydrodynamic-Eulerian technique is used to model the propagation of acoustic waves through the spray and the effect of the acoustic radiation upon spray droplets. A model for droplet breakdown based upon normal mode oscillations is employed to capture acoustically induced modifications of the particle size distribution. Measurements are presented for metered dose inhalers and compared to theoretical predictions.

**J1 245 Arranging Droplets for Microfluidics** CRAIG PRIEST, ENKHTUUL SURENJAV, MAGDALENA ULMEANU, STEPHAN HERMINGHAUS, RALF SEEMANN, *Max-Planck-Institute for Dynamics and Self-Organization* The online generation, organization and manipulation of monodisperse droplets in confinement present new possibilities for microfluidics. Droplets make excellent compartments for handling minute quantities of chemical, biological and particulate materials. When confined, a high dispersed phase volume fraction emulsion, i.e. gel emulsion, will self-organize into well-defined arrangements. The possible arrangements are dependent on the droplet size and the length-scale of the confining geometry. In this work, we have studied the organization of monodisperse gel emulsions in microchannels for application in microfluidic processing. The high degree of spatial order exhibited by gel emulsions facilitates the precise manipulation of a droplet, or group of droplets, using geometry alone.

**J1 247 Critical Behavior Of Uniformly Uniaxial Magnets** DEMETRIS NICOLAIDES, *Bloomfield College* Real magnetic systems never obey rotational invariance because the lattice itself is not completely rotation-invariant. The simple case of phase transitions in a magnetic system with broken rotational symmetry, described by a single, m-component vector order parameter, with uniform uniaxial perturbation in only the first component, is a prototype example. Renormalization group theory found that this kind of magnets experience phase transition of the second order, into either the easy axis of magnetization, or that they have critical behavior analogous to an (m-1)-component spin system. The present work extends this study to cover the more complex case of two coupled, continuous, anisotropic, m-component vector order parameters, having frozen-in, uniform, uniaxial anisotropies. These anisotropies are due to nonmagnetic impurities, and affect

the trial (mean-field) critical temperature of only the first component of each order parameter. The study is done with the help of a phenomenological model which considers fluctuations partially. It is shown that when both coupled vector order parameters are anisotropic, the order-disorder phase transition is always of the second order, into either the uniaxial or the (m-1)- isotropic phase. This is despite the fact that for the isotropic case of two coupled order parameters, the phase transition is a fluctuation-induced first order.

**J1 248 Dynamical mean-field theory of the Hubbard-Holstein model at half-filling: electron-phonon interaction effects on the finite temperature Mott transition** JAE HYUN YUN, HANYONG CHOI, GUN-SANG JEON, HYUN C. LEE, TAE-HO PARK, We study the Hubbard-Holstein (HH) model which indludes both the electron-electron and electron-phonon interactins characterized by $U$ and $g$, respectively, by empolying the dynamical mean-field theory in combination with Wilson's numerical renormalization group technique. We fix $g = 0.1W$ ($W$=bandwidth of the conduction electrons) and calculate the finite temperature phase diagram of metal-insulator transition in the $U - T$ plane. We will discuss in particular how the critical $U$ values, $U_{c1}$ and $U_{c2}$, and the critical temperature $T_c$ of the Mott transition are changed by the electron-phonon interaction.

**J1 249 Magnetic and transport properties of V-doped $La_{0.7}Ca_{0.3}MnO_3$** J.S. PARK, K.K. YU, Y.P. LEE, *q-Psi and Dept. of Physics, Hanyang Univ., Seoul, Korea* Y.S. LEE, *Division of Information Communication and Computer Engineering, Hanbat National University, Daejeon, Korea* J.-H. KANG, *Department of Nano and Electronic Physics, Kookmin University, Seoul, Korea* The effects of substitution of V for Mn on the electronic and the magnetic properties of $La_{0.7}Ca_{0.3}MnO_3$ have been investigated. The samples show a reentrant magnetic behavior as the V doping is increased. The V doping into the Mn sites leads to a mixed-phase ground state consisting of the ferromagnetic insulating and the ferromagnetic metallic phases at low temperatures. The magnetic relaxation was observed in both the ferromagnetic and the reentrant spin-glass phases, which means the existence of frustration and magnetic disorder in the samples. It was found that the V-doped manganites with aging effect bear the characteristics of a reentrant ferromagnet.

**J1 250 Heat bath approach to Landau damping and Pomeranchuk quantum critical points** JOHAN NILSSON, ANTONIO CASTRO NETO, *Boston University* We study the problem of the damping of collective modes close to a Pomeranchuk quantum critical point in a Fermi liquid. In analogy with problems in dissipative open quantum systems, we derive the Landau damping of a Fermi liquid by integrating out a macroscopic number of degrees of freedom from a generating functional. Being a reformulation of the linearized Boltzmann equation this approach reproduces well-known results from the theory of Fermi liquids. We also study the Bethe-Salpeter equations within the Landau theory and discuss the implications of these results on quantum phase transitions of the Pomeranchuk type and its dynamical exponent, z. We apply our results to the electronic nematic instability and find z=3 in the collisionless limit.

**J1 251 Magnetic Phases of λ-$(BETS)_2FeCl_4$ investigated by proton NMR spectroscopy.** GUOQING WU, W.G. CLARK, P. RANIN, S.E. BROWN, *UCLA Physics and Astronomy* L. BALICAS, *NHMFL Tallahassee* L.K. MONTGOMERY, *Indiana U. Chem.* The organic conductor λ-$(BETS)_2FeCl_4$, is of interest because of its unusual phases, which include a paramagnetic metal (PM), an antiferromagnetic insulator (AFI), and a field-induced superconducting phase. Important drivers for these phases are the 3d $Fe^{3+}$ moments (spin $S_d = 5/2$) from the $FeCl_4^-$ anions and the $\pi$ conduction electrons (spin $S_\pi = 1/2$) in the BETS donor molecules, which generate a correlated $\pi$-d electron system. Here, we report a proton NMR spectroscopy study of these phases in a small ($\sim 3\ \mu$g) single crystal of λ-$(BETS)_2FeCl_4$ using an applied field of 9 T over the temperature ($T$) range 2-180 K. The results show a complex spectrum that broadens and is shifted as $T$ is lowered in the PM phase, and additional changes associated with the PM-AFI transition. The main spectral features at all $T$ are attributed to the large dipolar field from the 3d $Fe^{3+}$ ions at the proton sites. A phenomenological model provides a reasonable fit to them. On lowering $T$ through the PM-AFI transition at 3.5 K, the spectrum smears and its second and first moments change discontinuously. These features indicate that the transition is first order and that the $\pi$-d interaction is important for its properties. The work at UCLA is supported by NSF Grants DMR-0334869 (WGC) and 0203806 (SEB).

**J1 252 Improved thermoelectric characteristics of misfit-layered cobaltites $Ca_3Co_{4-x}Fe_xO_{9+\delta}$.*** CHIA-JYI LIU, LI-CHEN HUANG, WEN-CHING HUNG, *Department of Physics, National Changhua University of Education* JENG-LUNG CHEN, CHING-LIN CHANG, *Department of Physics, Tamkang University* We have measured the electrical resistivity, Seebeck coefficients and thermal conductivity as a function temperature for a new series of oxides $Ca_3Co_{4-x}Fe_xO_9$ (x=0, 0.05, 0.1, 0.15, 0.2) prepared by the conventional solid state reaction. Structural parameters were refined with a superspace group of X2/m(0b0)s0 using powder X-ray diffraction data. With the substitution of $Fe^{+2}$ for $Co^{+3}$, the resistivity ($\rho$) decreases, while the thermoelectric power (S) also increases simultaneously. In the low temperature regime from 15 K to 60 K, the electrical conductivity follows the Mott's law of the form $\exp[T_0/T^{-1/4}]$, suggesting the variable-range-hopping transport. The thermoelectric power also shows the same transport mechanism in the same temperature regime. The x = 0.05 sample exhibits a higher power factor value (3.3 $\mu W/K^2$-cm) than that of undoped $Ca_3Co_4O_9$ (1.2 $\mu W/K^2$-cm) at 300K, indicating the improvement of the thermoelectric characteristics upon Fe substitution for Co.

*This work was supported by National Science Council of R. O. C. under the Grant No. NSC 94-2112-M018-001.

**J1 253 Computational Toolkit for First-Principles Multicomponent Alloy Thermodynamics*** TECK TAN, NIKOLAI ZARKEVICH, D.D. JOHNSON, *Materials Science and Engineering, University of Ilinois Urbana-Champaign* A ''toolkit'' for the simulation of alloy thermodynamics has been developed by integrating first-principles, electronic-structure calculations and the cluster expansion (CE) with Monte Carlo (MC) methods. This Thermal Toolkit (TTK) is aimed at producing reliable thermodynamics of alloys with limited input from the user. Given an alloy, TTK first generates a comprehensive set of structures, automatically submits an electronic-structure calculation to determine the

structural energies, stores the structure and its energy in a database,[1] then constructs the CE via the structural inversion method that conforms to a set of mathematical conditions to produce an optimal truncated cluster expansion.[2] Using this optimal CE, a MC code (included in TTK) can be used to calculate thermodynamic properties, such as structural phase diagram (T vs c). We present here example application and functionality of TTK on binary and ternary alloy.

*We acknowledge funding from NSF ITR grant DMR-03-25939 and DOE grant DE-FG02-03ER46026.

**J1 254 Resonant X-ray Scattering Study of Quadrupolar Ordering in $DyB_4$** SUNGDAE JI, C. SONG, J. KOO, K.-B. LEE, *eSSC and Dept. of Physics, Pohang University of Science and Technology, Pohang, 790-784, South Korea* Y.J. PARK, *Pohang Accelerator Laboratory, Pohang University of Science and Technology, Pohang, 790-784, South Korea* J.S. RHYEE, B.K. CHO, *Center for Frontier Materials and Dept. of Materials Science and Engineering, GIST, Gwangju, 500-712, South Korea* Resonant x-ray scattering was performed on $DyB_4$ to observe a quadrupolar ordering. It is demonstrated that anisotropic tensor susceptibility (ATS) resonances due to ordering in Dy 4*f* states can be seperated from those due to atomic displacements, such as Jahn-Teller distortion, by tuning the incident x-ray energies. An ATS resonance at 7.792 keV, corresponding to antiferro-type quadrupolar (AFQ) ordering, was observed to have different azimuthal angular dependence and polarizations from those of magnetic resonance. The AFQ order parameter is developed concomitantly with monoclinic phase transition below 12.3 K, and its magnitude is proportional to quadratic of the monoclinic angle.

**J1 255 Smoothing and Bootstrapping in Numerical Studies of Lattice Statistical Models** VOLTAIRE TEODORESCU, *Northern Illinois University* We investigate the applicability and estimate efficiency for Monte Carlo type simulations in lattice models of magnetic materials. In particular, an improved algorithm based on smoothed bootstrapping of Markov chains is applied to the two-dimensional Ising model. We report the results based on several smoothing functions.

**J1 256 Magnetic and transport properties of $La_{0.7}Ca_{0.3}MnO_3/BaTiO_3$ and $La_{0.7}Sr_{0.3}MnO_3/BaTiO_3$ bilayered films** V.G. PROKHOROV, *Institute of Metal Physics, Academy of Science of Ukraine, Kiev, 03142 Ukraine* Y.P. LEE, K.K. YU, S.Y. PARK, *q-Psi and Department of Physics, Hanyang University, Seoul, 133-791* V.L. SVETCHNIKOV, *National Center for HREM, TU Delft, 2628AL, The Netherlands* The magnetic and the transport properties of $La_{0.7}Ca_{0.3}MnO_3/BaTiO_3$ (LCMO/BTO) and $La_{0.7}Sr_{0.3}MnO_3/BaTiO_3$ (LSMO/BTO) bilayered films, prepared by the rf-magnetron sputtering, have been investigated. For comparison, the same data for the LCMO and the LSMO films, deposited on the bare $LaAlO_3$ (LAO) substrates, are obtained as well. The microstructural analysis reveals that LCMO/BTO and LSMO/BTO have the biaxial tensile in-plane and compressive out-of-plane strains, while LCMO/LAO and LSMO/LAO are reversely in the compressive in-plane and tensile out-of-plane strains. The films with biaxial tensile in-plane lattice strains undergo the magnetic transition at a higher temperature than those with biaxial compressive ones. This suggests that the Mn-O-Mn bond angle, controlled by the lattice strain, plays more important role in the formation of spin ordering in the manganite film than the modification of Mn-O bond length. The observed enhancement of magnetoresistance at room temperature in LSMO/BTO provides an advance for the development of new hybrid ferromagnetic/ferroelectric devices.

**J1 257 Kondo Transport at Low Temperature and Electron-electron Interaction in Dilute Mn-doping $Na_{0.7}CoO_2$ Systems** JINCANG ZHANG, ZAIQING ZHANG, YAN XU, CHAO JING, SHIXUN CAO, *Shanghai University* DEPARTMENT OF PHYSICS, SHANGHAI UNIVERSITY TEAM, The layer transition-metal oxide $Na_\gamma CoO_2$ engendered much interest to physicists due to its promising thermoelectric properties. Its anomalous large thermoelectric power and low electrical resistivity in combination with low thermal conductivity is difficult to be understood in the framework of conventional band picture. In this paper, we present the results of low-temperature transport behaviour and its dependence on applied magnetic field for dilute Mn doping $Na_{0.7}Co_{1-x}Mn_xO_2$ systems with x=0, 0.03, 0.07, 0.1. The results show that the transport properties are very sensitive to Mn doping and a novel resistivity minimum was found with a characteristic of metallic-semiconductor transition at low temperature for all the doping samples. And the best fitting was made in the framework of Kondo scattering and the electron-electron (e-e) interaction in a wide temperature range of 2-100 K. The weak dependent on the external field prove that the present $Na_{0.7}Co_{1-x}Mn_x$ is a strong disorder system and there exists an enhancing e-e interaction, which reflects a typical characteristic of strong correlation systems. The results prove that the layer $Na_\gamma CoO_2$ is a kind of typical Kondo-like oxide as like the dilute convention alloys.

**J1 258 Study of the one-band model for colossal magnetoresistive manganites using the Truncated Polynomial Expansion Monte Carlo Method** CENGIZ SEN, *National High Magnetic Field Laboratory and Department of Physics, Florida State University, Tallahassee, FL* ELBIO DAGOTTO, *Oak Ridge National Laboratory, Oak Ridge, TN and Department of Physics, University of Tennessee, Knoville, TN* The recently proposed Truncated Polynomial Expansion Method (TPEM) for spin-fermion systems is tested using the one-band double exchange model with finite Hund coupling $J_H$ in the clean limit. Two dimensional lattices as large as $48\times 48$ are studied, far larger than those that can be handled with standard exact diagonalization (DIAG) techniques for the fermionic sector. Phase diagrams are obtained, showing first-order transitions separating ferromagnetic metallic from insulating states. A huge magnetoresistance is found at low temperatures by including small magnetic fields, in excellent agreement with experiments. By comparing results between the two methods, TPEM and DIAG, on small lattices, and by analyzing the systematic behavior with increasing cluster sizes, it is concluded that the TPEM is accurate to handle realistic manganite models on large systems. Our results pave the way to a frontal computational attack of the colossal magnetoresistance phenomenon using double-exchange like models, on large clusters, and including quenched disorder.

**J1 259 The effect of substrate induced strain on the electronic soft matter in thin films of the manganite**

**$(La_{1-y}Pr_y)_{0.67}Ca_{0.33}MnO_3$ ($y$ = 0.5, 0.6)** JACOB TOSADO, TARA DHAKAL, SUNGHEE YUN, AMLAN BISWAS, *Department of Physics, University of Florida, Gainesville, FL* For most hole-doped manganites, the low temperature phase is either a ferromagnetic metal (FMM) or charge-ordered insulator (COI). At certain compositions the competition between the FMM and COI phases leads to a mixed phase state in which both these phases coexist. In this mixed phase state, changing the temperature, magnetic field or strain modifies the spatial arrangement and relative proportions of these two phases. This property of manganites is reminiscent of electronic soft matter. We have studied the effect of substrate-induced strain on this electronic soft matter by measuring the magneto-transport properties of $(La_{1-y}Pr_y)_{0.67}Ca_{0.33}MnO_3$ (LPCMO,$y$ = 0.5, 0.6) thin films of different thicknesses. The temperature –magnetic field ($T - H$) phase diagram of LPCMO shows four distinct phases itviz., the COI phase, the FMM phase, a static phase separated (SPS) state and a fluid phase separated (FPS) state. Our experimental results show that as the thickness of the thin film increases (i.e. the substrate induced strain decreases), the SPS state expands and covers more area in the phase diagram at the expense of the FPS state.

## J1 260 SURFACES, INTERFACES, AND THIN FILMS POSTER

**J1 261 Structure of Photonic Multilayer Films Created by Plasma Enhanced Chemical Vapor Deposition (PECVD)** SOMESHWARA PERI, BRIAN HABERSBERGER, BULENT AKGUN, MARK FOSTER, *Institute of Polymer Science* HAO JIANG, TIMOTHY BUNNING, *Air Force Research laboratory* CHARLES MAJKRZAK, *NIST Center for Neutron Research* The structures of copolymer films created by PECVD were studied for the first time using neutron reflectivity (NR) and x-ray reflectivity (XR). Both homopolymer films of benzene (PP-B) and octafluorocyclobutane (PP-OFCB) and copolymer films of HMDS and OFCB made using different feed ratios were considered. In HMDS-OFCB copolymer films, we observed a transient structure next to the substrate as seen previously for homopolymer OFCB films. PP-B films swelled approximately 200 % in deuterated-THF vapor and PP-OFCB swelled approximately for 30 % in deuterated-toluene vapor, indicating that for these processing conditions PP-B films are much less highly crosslinked than are PP-OFCB films. We have measured for the first time the variation in crosslink density with depth for homopolymer films created by PECVD.

**J1 262 TOF MS studies of the BN and carbon laser ablated plasma (YAG-laser, $\lambda_{exc}$ = 1064 nm).** VLADIMIR MAKAROV, DACHUN HUANG, *University of Puerto Rico, Dept of Chem* ARTUTO HIDALGO, GERARDO MORELL, *University of Puerto Rico, Dept of Phys* BRAD WEINER, *University of Puerto Rico, Dept of Chem* In the present study, TOF MS spectra of the ablated ions from the BN-ceramic, amorfus carbon, graphite and fullerene-60 surfaces were recorded for different distances between the target surface and work (analytical) area of the TOF MS and for different radiation density of the laser radiation. The averaged energy and temperature of the ablated ions were estimated. The mechanism of the plasma formation in all cases studied was analyzed and discussed.

**J1 263 Pair distribution functions of silicon/silicon nitride interfaces*** DENG CAO, MARTINA E. BACHLECHNER, *West Virginia University, Physics Department* Using molecular dynamics simulations, we investigate different mechanical and structural properties of the silicon/silicon nitride interface. One way to characterize the structure as tensile strain is applied parallel to the interface is to calculate pair distribution functions for specific atom types. The pair distribution function gives the probability of finding a pair of atoms a distance $r$ apart, relative to the probability expected for a completely random distribution at the same density. The pair distribution functions for bulk silicon nitride reflect the fracture of the silicon nitride film at about 8 % and the fact that the centerpiece of the silicon nitride film returns to its original structure after fracture. The pair distribution functions for interface silicon atoms reveal the formation of bonds for originally unbound atom pairs, which is indicative of the interstitial-vacancy defect that causes failure in silicon.

*Supported in parts by NASA.

**J1 264 Interaction of H atom with Si(111)4x1-In surface** SANG-YONG YU, *Korea Research Inst. of Standards and Science* GEUNSEOP LEE, *Inha Univ., Inchon, Korea* HANCHUL KIM, *Korea Research Inst. of Standards and Science* D. LEE, *Chungnam Univ., Daejeon, Korea* JA-YONG KOO, *Korea Research Inst. of Standards and Science* Using scanning tunneling microscopy (STM) measurements and itab initio calculations, the interaction of an H atom with the Si(111)4x1-In surface at room temperature is investigated. It is found that the H atom preferentially adsorbs at the bridge site between the In chain and the Si Seiwatz chain and break an In-Si bond to form a Si-H bond. Experimentally, the adsorption of H is influenced by the registry of the Si substrate and preferentially occupies one of the two zigzag In chains to the other, while the little difference is found in the calculated adsorption energy. The adsorbed H atom induces not only a localized lattice distortion but also a distant electronic perturbation near the Fermi level, which appears as out-of-phase period-doubled (x2) charge ordering in the filled- and the empty-state STM images. These perturbations induced by the two nearby H atoms in the same row interfere to make the inbetween x2 modulation enhanced or suppressed depending on the H-H distance. The x2 perturbed region remains metallic, distinguishing it from the insulating low-temperature 4x2 (8x2) phase. The observed x2 perturbation away from the H-adsorbate is found to be the theoretical ground state of the In/Si(111) surface predicted by density-functional theory, which is stabilized by the presence of the surface defect.

**J1 265 Tetracene thin film morphology on hydrogen-passivated Si(100)*** JUN SHI, ANDREW TERSIGNI, XIAORONG QIN, *Department of Physics, University of Guelph* Initial stage of vacuum evaporated tetracene films on hydrogen-passivated Si(100) substrates has been investigated by scanning probe microscopy. Three-dimensional crystalline islands and dendrites have been obtained at low deposition rates, exhibiting contributions of lateral and vertical edge-diffusions in growth and

local surface effects. The absence of the 3D structures has been achieved at a proper range of deposition rates and a layer-by-layer thin film growth mode has been obtained. Results suggest that the obtained thin film phase defines a kinetic path for the formation of uniform films.

*Supported by Natural Sciences and Engineering Research Council (NSERC) of Canada

**J1 266 Oxidation of Hafnium studied by X-ray photoelectron spectroscopy.*** A CHOURASIA, W. JOHNSTON, *Texas A&M University-Commerce* The oxidation of hafnium has been studied by X-ray photoelectron spectroscopy. Two types of experiments were conducted. In both types, thick films of hafnium were deposited on a metal substrate using the electron beam deposition technique. In one set of experiments, the substrate temperature was in the range between 100C and 500C. The deposition chamber was filled with oxygen at a very low pressure while the film was getting deposited. In the second set of experiments, substrate was kept at room temperature during the hafnium film deposition. The film was then subjected to post-deposition annealing in an oxygen atmosphere. The hafnium XX core level and oxygen 1s core level were recorded in the high resolution mode. The thickness of the oxide films have been determined from the XPS spectra using the Quantitative Analysis by SES software. The study provides a comparison of the oxide formation as a function of substrate temperature in the two cases.

*Research Corporation Award; Faculty Research Enhancement TAMU-Commerce

**J1 267 Self Alignment of Wafer Stacks via Pattern Modification of Self Assembled Monolayer Surface Energies*** ERNEST WALKER, *North Carolina State University* HANS HALLEN, *North Carolina State University* Self assembled monolayers (SAMs) are deposited on oxide layer, and characterized by ellipsometry and contact angle. Vinyl-terminated SAMs are oxidized to carboxyl-termination, which changes the wetting characteristics. Measurements of sliding friction between combinations of these layers is measured and discussed. The relative surface energies can also be obtained. From these data, the relative importance of friction and forces resulting from surface energy gradients can be determined, and wafer self-alignment masks evaluated.

*Air Force grant

**J1 268 Reciprocal Space Mapping of Thin $La_x$ Mn $O_3$ Films of Varying Thickness** M.A. DELEON, T. TYSON, *New Jersey Institute of Technology, Applied Physics* C. DUBOURDIEU, *Laboratoire des Máteriaux et du Génie Physique UMR CNRS 5628, INPG, 38402 St.Martin d'Héres, France* J. BAI, *ORNL* In order to understand the growth of ultrathin manganite films on substrates, we made reciprocal space maps in the 004, 404, and 044 pseudocubic directions of $La_xMnO_3$ films deposited on $LaAlO_3$ (LAO) via metal-organic chemical vapor deposition. The x-ray maps exhibit the strain effects of the lattice-substrate mismatch and the effects of a twinned interface on the growth of films. Reciprocal space mapping provides more accurate lattice parameters and strain effects from lattice-substrate interface mismatch. A characteristic feature of the LAO substrates is twinning, which results in multiple structural components of the films, similar lattice parameters but differing orientation. These characteristics reveal crucial aspects of deposition processes to be inspected in assuring high-quality films. This research is supported by NSF DMR-0209243 and DMR-0512196.

**J1 269 H Adsorption on RH (110) Surface** SHAO-PING CHEN, *Los Alamos National Laboratory* We have used the density functional theory to study the H adsorption phenomena on Rh (110) surface with H coverage from 0.33 to 2.00 mono-layers. We found H atom favors the three- fold coordinated site as observed experimentally. We confirmed the existence of 1x3-H, 1x2-H, 1x3-2H, 1x1-2H ordered structures. We also found that the proposed 1x2-2H structure for coverage of 1.0 is not the lowest energy configuration. We have proposed a new 1x2-2H structure which needs to be tested by future experiments.

**J1 270 Influence of diffusion on submonolayer island growth during hyperthermal deposition onto Cu(100) and Cu(111)** MIKA JAHMA, MARKO RUSANEN, *Laboratory of Physics, Helsinki University of Technology* ISMO KOPONEN, *Department of Physical Sciences, University of Helsinki* TAPIO ALA-NISSILA, *Laboratory of Physics, Helsinki University of Technology* We consider the influence of realistic island diffusion rates to homoepitaxial growth on metallic surfaces using a recently developed rate equation model [1] which describes growth in the submonolayer regime with hyperthermal deposition. To this end, we incorporate realistic size and temperature-dependent island diffusion coefficients for the case of homoepitaxial growth on Cu(100) and Cu(111) surfaces [2]. We demonstrate that the generic features of growth remain unaffected by the details of island diffusion, thus validating the generic scenario of high density of small islands found experimentally and theoretically for large detachment rates. However, the details of the morphological transition and scaling of the mean island size are strongly influenced by the size dependence of island diffusion. This is reflected in the scaling exponent of the mean island size, which depends on both temperature and the surface geometry. [1] I.T. Koponen et. al, Phys. Rev. Lett. **92**, 086103 (2004) [2] M.O. Jahma et. al, Surface Science, in press.

**J1 271 Self-assembly of nanoparticle/copolymer mixtures** JINBO HE, RAVISUBHASH TANGIRALA, KEVIN SILL, TODD EMRICK, THOMAS RUSSELL, *Department of Polymer Science & Engineering, University of Massachusetts, Amherst, MA 01003* XUEFA LI, JIN WANG, YAO LIN, *Argonne National Laboratory, Argonne, IL 60439* ALEXANDER BOKER, *Lehrstuhl fur Physikalische Chemie II, Universitat Bayreuth, 95440 Bayreuth, Germany* ANNA BALAZS, *Department of Chemical and Petroleum Engineering, University of Pittsburgh, Pittsburgh, Pennsylvania 15261* Mixtures of polystyrene-itblock-poly (2-vinylpyridine) with tri-*n*-octylphosphine oxide-(TOPO)-covered CdSe nanoparticles were chosen to test the theoretical prediction of synergistic effects between two self-organization systems. Preliminary results confirmed that hierarchical structures were provided, with poly (2-vinylpyridine) cylindrical microdomains oriented normal to the surface and CdSe-TOPO nanoparticles self-assembly at the surface, that balanced the surface tensions of the P2VP with that of PS. Detailed structure evolution was revealed by in-situ grazing incidence small angle x-ray scattering (GISAXS) during thermal annealing. Results from these studies indicated that the orientation of the mcrodomains began at the free surface and propagated in the film towards the substrate. This

one-step self-orienting, self-assembly process, without the use of external fields, opens a simple route for fabrication of nanostructured materials having hierarchical order, with applications including chemical sensing, separation, catalysis, high-density data storage and photonic materials.

**J1 272 Equilibrium shape and dislocation nucleation in strained epitaxial nanoislands** J. JALKANEN, *Helsinki University of Technology, Finland* O. TRUSHIN, *Institute of Microelectronics and Informatics, Russia* K. ELDER, *Oakland University* E. GRANATO, *Instituto Nacional de Pesquisas Espaciais, SP Brasil* T. ALA-NISSILÄ, *Helsinki University of Technology, Finland* S.-C. YING, *Brown University* We study numerically the equilibrium shapes, shape transitions and dislocation nucleation of small strained epitaxial islands with a two-dimensional atomistic model, using simple pair potentials [1]. We first map out the phase diagram for equilibrium island shapes as a function of island size and lattice misfit with the substrate. When the interactomic potential minimum depth $\epsilon$ is the same for substrate and adsorbate, the latter either wets the surface or has one of three generic equilibrium island shapes. As $\epsilon$ favours substrate-adsorbate interface, Stranski-Krastanow growth mode emerges between complete wetting and island formation zones while in the opposite case the islanding zone is extended. A simulation based extrapolation scheme predicts an optimal island shape for attractive $\epsilon$. The energy barriers and transition paths between different island shapes and dislocation nucleation in initially coherent islands are investigated with Nudged Elastic Band method. We also discuss the elastic behaviour of these systems in terms of the Phase Field Crystal model [2]. [1] J. Jalkanen, O. Trushin, E. Granato, S. C. Ying, and T. Ala-Nissila, Phys. Rev. B 72, 081403 (2005) [2] K. Elder and M. Grant, Phys. Rev. E **70**, 051605 (2004).

**J1 273 The Structure of Adsorbed Methane on the MgO(100) Surface from Inelastic Neutron Scattering and First-Principles Calculations** M.L. DRUMMOND, B.G. SUMPTER, W.A. SHELTON, JR., *Oak Ridge National Laboratory* J.Z. LARESE, *University of Tennessee* The adsorption of molecules onto a solid surface is a phenomenon with important ramifications in areas such as catalysis, corrosion, and electronics. We have used plane-wave, psuedopotential-based density functional calculations, in conjunction with inelastic neutron scattering (INS), to evaluate the structure of methane on the MgO(100) surface. The combination of high-resolution INS and high-quality calculations has proven extremely versatile in determining the structural arrangement, despite the existence of multiple energetically favorable arrangements. The structures for adsorbed methane mono-, bi-, and higher order adlayers are discussed.

**J1 274 c(4x2) Reconstruction of Manganese Tetramers on Mn3N2 (001) Studied by Scanning Tunneling Microscopy** RONG YANG, *Ohio University* HAIQIANG YANG, *Ohio University* ARTHUR SMITH, *Ohio University* We have investigated the growth of antiferromagnetic Mn3N2 on MgO(001) by molecular beam epitaxy. Two orientations [(010) and (001)] of this structure are grown controllably on MgO(001), depending on the growth conditions. The bulk structure is face- centered tetragonal with 2 layers of MnN followed by 1 layer of Mn. Here we present results for the (001) surface. STM images show smooth terraces and atomic steps. On some of the terraces a unique and new reconstruction is seen, resolved as square Mn tetramers in a c(4$\times$ 2) structural arrangement. Two domains of the tetramer reconstruction, rotated by 90 $^\circ$ to each other, occur. A model is presented for this square Mn tetramer reconstruction, in which the Mn atoms of the tetramer layer belong to the Mn layer at the surface in the MnN- MnN-Mn stacking sequence. The work is supported by NSF9983816 and 0304314.

**J1 275 Intrinsic Surface Reconstructions of Zinc-Blende GaN(001) Studied by Scanning Tunneling Microscopy*** ARTHUR R. SMITH, MUHAMMAD HAIDER, RONG YANG, COSTEL CONSTANTIN, HAMAD AL-BRITHEN,[†] ERDONG LU, NANCY SANDLER, *Nanoscale & Quantum Phenomena Institute, Ohio University* PABLO ORDEJON, *Instituto do Ciencia de Materiales de Barcelona, Bellaterra, Barcelona, Spain* The intrinsic structures of semiconductor surfaces are important for epitaxial growth and future applications. Here we present a scanning tunneling microscopy study of the clean zinc-blende GaN(001) surface, free from the presence of arsenic. We find a sequence of reconstructions for the clean surface, beginning with 4x3 and including c(4x12), 4x7, c(4x16), 4x9, and c(4x20). Generally, all of these reconstructions are row-like. The 4x3 is a semiconducting surface structure with a bandgap, measured using tunneling spectroscopy, of 1.14 eV; the 4x3 is obtained under Ga-poor surface conditions and is compared with a model calculated using ab-initio techniques. The other reconstructions are metallic, obtained under Ga-rich surface conditions. They can be modeled using simple adatom schemes on top of a bulk-like Ga atom termination.

**J1 276 First-principles study of adsorption and migration on the (001) surfaces of cubic BN*** HIROAKI KOGA, TSUYOSHI MIYAZAKI, *National Institute for Materials Science* SATOSHI WATANABE, *The University of Tokyo* TAKAHISA OHNO, *National Institute for Materials Science* This first-principles study examines the behavior of boron and nitrogen adatoms on the dimer-reconstructed (001) surfaces of cubic boron nitride (cBN), to find low-barrier migration pathways that control the vapor-growth of cBN. Adatom dynamics on the surfaces of wide band gap semiconductors such as cBN (with $\sim$ 6 eV gap) and diamond is an uncharted field of surface science: Because these materials have very strong, directional bonds, the adatoms may choose unlikely adsorption sites and migration pathways, to minimize the induced strains. For example, we have found that a N adatom on a N dimer row of cBN(001) migrates using a site-exchange reaction, rather than migrating on the dimer row. The calculated energy barrier for the site-exchange pathway is mere 0.9 eV, in contrast with the large barrier (over 4 eV) of the dimer row pathway. At the meeting, we report such low-barrier pathways on cBN(001), and also discuss a new approach to cBN epitaxy that exploits them.

**J1 277 Anchoring to the Nanoworld: Spectroscopic Investigation of Atomic Metal Strings Adsorbed on GaN** CHE-CHEN CHANG, CHIEN-HUA LUNG, *National Taiwan University* It is now possible to produce structures that are only a few tens to a few nanometers in size using techniques which involve the self assembly or the chemical functionality-guided arrangement of atoms, molecules and nanospecies. Their devices, however, are useless unless they are able to communicate with the outside world and with one another. This study explored the possibility of fabricating metal contacts from the bottom up on semiconductors using a linear metal atom string complex, which was chelated by dipyridylamino ligands and terminated at both ends by one Cl atom each, for CVD. More than 75% of the string complex exposed at 105 K to the GaN(0001) surface was chemisorbed dissociatively, with one of its terminal Cr-Cl bonds disrupted and the other pointing freely outwards. The chelate structure of the adsorbed complex was stable until reaching $\sim$ 340 K, at which temperature detachment of some of its ligands occurred. The ligand desorption followed the first-order kinetics, with a desorption energy of 21.5 kcal/mol. The detachment of the ligand from the complex caused the metal chain axis to lie down on the surface. Consequently, the Cr-Cl bond on the free end of the chain interacted with the surface, causing other ligands to desorb from the surface at the higher substrate temperature of $\sim$ 540 K.

**J1 278 Negative differential resistance of TEMPO on Si(111)** ANN-SOFIE HALLBACK, HAROLD J W ZANDVLIET, BENE POELSEMA, *University of Twente* Negative differential resistance (NDR) has been observed for individual 2,2,6,6-tetramethyl-1-piperidinyloxy (TEMPO) molecules, adsorbed on Si(111) at room temperature. Measurements were performed in ultra high vacuum (UHV) using scanning tunneling microscopy (STM) and -spectroscopy (STS). NDR effects were observed exclusively at negative bias voltage on the used n-type Si(111) sample. TEMPO was observed to adsorb preferentially at corner adatom sites of the Si(111)-7x7 structure. Although the Si(111)-7x7 reconstruction was conserved, local defects were observed in the vicinity of the TEMPO adsorbates.

**J1 279 Reflectance anisotropy spectra of CdTe(001) surfaces*** RAUL VAZQUEZ, BERNARDO MENDOZA, NORBERTO NARZATE, *Centro de Investigaciones en Optica A. C.* We calculate reflectance anisotropy (RA) spectra of a clean Cd-terminated CdTe(001) surface which exhibits $c(2 \times 2)$ reconstruction, and clean Te-terminated CdTe surfaces with $(2 \times 1)$, $(1 \times 2)$ and $c(2 \times 2)$ surface reconstructions. Theoretical spectra are obtained from two aproaches: an *ab initio* pseudopotential calculation in the framework of the density functional theory and within the local density approximation (DFT-LDA), and a microscopic formulation based on a semi- empirical tight binding approach which includes spin-orbit (SO) interactions[1]. We show how RA spectrum changes when SO coupling is taken into account and compare our theoretical results with experimental results[2]. We find a good agreement between experimental and theoretical spectra. [1] R. A. Vázquez-Nava, B. S. Mendoza and N. Arzate, Phys. Stat. Sol. b **242** 3022 (2005); R. A. Vázquez-Nava, B. S. Mendoza and C. Castillo Phys. Rev. B **70**, 165306 (2004) [2] R. E. Balderas-Navarro, K. Hingerl, W. Hilber, D. Stifter, A. Bonanni and H. Sitter, J. Vac. Sci. Technol. B **18** 2224 (2000).

**J1 280 Local Valence Structure of Fe in Fe3Si/GaAs(001)** KUAN-LI YU, HSUEH-HSING HUNG, LING-YUN JANG, *National Synchrotron Radiation Research Center* MING-WEI HONG, *Department of Materials Science and Engineering, National Tsing Hua University* RAY NIEN KWO, *Department of Physics, National Tsing Hua University* A high quality, eptiaxial magnetic films of $Fe_3Si$ on GaAs(001) substrates were studied in our experiment. $Fe_3Si$ is ferromagnet and can be regarded as a Heusler-like alloy with a composition of $Fe_2FeSi$. There is possibility that $Fe_3Si$ is a half metal which is an ideal candidate for spin injection, although the calculated density of states for bulk $Fe_3Si$ does not predict half-metallic behavior. By using diffraction anomalous fine structure measurement, there is chance to look at the anomalous effect on the different atom sites. Two diffraction of $Fe_3Si$ were measured as (002) and (004) to understand the local electron density structure in different Fe sites and the spectra show significant different features. By carefully handling these DAFS results, there is chance to understand the structure of the local density of state of the Fe atoms in different crystal sites.

**J1 281 Angle-resolved Ultra-violet Photoelectron Spectroscopy Study of Epitaxial $CrO_2$ films grown on $TiO_2$ Substrates** DANIEL BORST, *University of New Orleans* CARL VENTRICE, *Unversity of New Orleans* G. MIAO, *University of Alabama* ARUN GUPTA, *University of Alabama* Chromium dioxide is predicted to be a half-metallic oxide. Although there is experimental evidence that $CrO_2$ is half-metallic at low temperature, attempts to make devices based on $CrO_2$ have yielded very low efficiencies. To study the electronic properties of the surface region of $CrO_2$, we have performed ARUPS measurements on epitaxial $CrO_2$ films. The $CrO_2$ thin films have been deposited on (100) and (110)-oriented TiO2 substrates by chemical vapor deposition, using $CrO_3$ as a precursor. The effects of sputtering of the $CrO_2$ films to remove the outer layer of $Cr_2O_3$ and of annealing the films in oxygen to heal surface defects has been studied. Sputtering results in shifts in the onset of valence emission away from the Fermi edge by as much as 0.5 eV, which is opposite of what would be expected for a half-metallic system. Annealing of the films above 450 $^o$C results in spectra similar to $Cr_2O_3$.

**J1 282 Ga-doping effect on superconductivity for Ba8Si46 clathrates*** RUIHONG ZHANG, YANG LIU, XINGQIAO MA, NING CHEN, GUOHUI CAO, YANG LI, *Department of Physics, University of Science and Technology Beijing* We present a joint experimental and theoretical study of the superconductivity and electronic structures in type-I Ga-doped silicon clathrates. The superconducting critical temperature in Ba8Si46-xGax is shown to decrease strongly with gallium content increasing. These results are corroborated by first-principles simulations calculated from the density-functional theory with plane waves and pseudopotentials. The simulations show that Ga doping results in a large decrease of electronic density of states in Fermi level, which can explain the superconducting critical temperature decrease with Ga-doping in the BCS theoretical frame.

*National Natural Science Foundation of China (Grant No.50372005)

**J1 283 The Ferromagnetic Hafnium Dioxide Thin Films Prepared by Pulsed Laser Deposition** YUNG M. HUH, R. VASELAAR, *Physics Department, South Dakota State University, Brookings, SD 57007* J. ZHANG, D.J. SELLMYER, *Department of Physics and Astronomy, University of Nebraska, Lincoln, NE*

*68588* The ferromagnetic hafnium dioxide (HfO2) thin films were prepared using pulsed laser deposition (PLD) system. Ferromagnetic moment was completely suppressed and revived as HfO2 film was annealed in vacuum and air. The variation of ferromagnetic moment was investigated to study the origin of the ferromagnetism in HfO2 system. X-ray diffraction showed that the c-plane is perpendicular to the growth direction. Strong anisotropic moment was observed for applied magnetic fields along the parallel and perpendicular to the c-plane.

**J1 284 Inelastic electron tunneling spectroscopy of decanethiol on Au(111) at elevated temperatures** ANN-SOFIE HALLBACK, HAROLD J W ZANDVLIET, BENE POELSEMA, *University of Twente* We have studied decanethiol self-assembled monolayers (SAMs) on Au(111) in UHV by inelastic electron tunneling spectroscopy (IETS) performed with a scanning tunneling microscope (STM). This study reveals inelastic peaks, which can successfully be assigned to molecular vibration modes (Au-S or S-C stretch modes, and C-C stretch mode or $CH_2$ modes). It is remarkable that these modes can be detected already at 77 K, i.e. at a much higher temperature than commonly used in IETS measurements.

**J1 285 Quantum size effect on the diffusion barriers and growth morphology of Pb/Si(111)** TZU-LIANG CHAN, CAI-ZHUANG WANG, MYRON HUPALO, MICHAEL TRINGIDES, KAI-MING HO, *Ames Laboratory-U.S. DOE. and Department of Physics and Astronomy, Iowa State University* Using first-principles total energy calculations, we have studied the diffusion barriers of Pb adatoms on a free-standing Pb(111) film as a function of film thickness. We found that diffusion of an adatom on the Pb film has very low barriers (less than 60 meV). A bi-layer oscillation in the diffusion barriers due to quantum size effect (QSE) is observed, with lower barrier on the odd-layered,relatively unstable Pb films. The diffusion barrier difference between the odd-and even-layered film is found to be as large as 40 meV. This big difference in the diffusion barriers due to QSE is the origin of the intriguing growth morphology of Pb islands on Si(111) surface observed in the STM experiments: the growth of a Pb layer on Pb islands with unstable heights starts from the periphery and moves towards the center, while the nucleation of the next layer on stable Pb islands starts away from the periphery.

**J1 286 Substrate Dependence on the Allotropic Transformation and the Morphology of Ultrathin Bi Films on Si(111)*** S. YAGINUMA, T. NAGAO, K. NAGAOKA, *NIMS, Tsukuba, Japan* M. MAEKAWA, *Kanazawa Univ.* J.T. SADOWSKI, *IMR. Tohoku Univ.* M. SAITO, *Kanazawa Univ.* Y. FUJIKAWA, T. SAKURAI, *IMR. Tohoku Univ.* T. KAKAYAMA, *NIMS. Tsukuba, Japan* Bismuth film grows via an intriguing thickness-driven allotropic transformation from a {012}-oriented phase to a bulk-like (001) phase. We compare the growth of Bi films on the Si(111)-7x7 surface with that on the Si(111)-$\beta - \sqrt{3}$x$\sqrt{3}$-Bi surface by use of electron diffraction and scanning tunneling microscopy. Small amount of Bi(001) nanocrystals can nucleate on the 7x7 substrate from the very beginning of the growth $\sim$ 1 monolayer (ML). They stabilize with 3 bilayer height in a perfect commensurate manner on the 7x7 substrate because of lattice contraction as predicted from our itab initio calculations, and thus lead to the growth of the highly-crystalline (001) films. On the $\beta - \sqrt{3}$x$\sqrt{3}$-Bi surface, on the contrary, the (001) nuclei is not observed in the initial stage of the growth and the Bi{012} films survive, and thus the nucleation of the (001) phase is inhibited up to $\sim$ 15 ML.

*This work has been supported by ICORP JST and Grants-in-Aid from JSPS

**J1 287 Comparative studies of Pb films on different substrates by first-principles calculations*** YU JIA, *Zhengzhou University, China & ORNL* BIAO BU, *Inst. of Phys. CAS, China* H.H. WEITERING, *The University of Tennessee & ORNL* ZHENYU ZHANG, *ORNL & The University of Tennessee* Quantum growth of ultrathin Pb on Ge(111) and Cu(111) substrates up to more than 25 monolayers are studied using total energy calculations within density functional theory. Our studies show that the surface energy, work function, and lattice relaxation of these films all oscillate strongly with the film thickness. The oscillation pattern is always even-odd with interruptions by crossovers, in good agreement with experimental observations. However, the positions of the crossovers and the separation between the crossovers depend on which substrate is used. These results are rationalized based on the interplay between Friedel oscillations, quantum size effects, and charge transfer effects.

**J1 290 Study of Nanopore Sculpting with Noble Gas Ion Beams at Various Energies** BRADLEY LEDDEN, ERIC KRUEGER, JIALI LI, *University of Arkansas* We report on experiments using noble gas beams: Helium, Neon, Argon, Krypton, and Xenon, at energies of 1keV, 3keV, and 5keV to controllably fabricate nanopores in freestanding silicon nitride membranes. Utilizing computer simulations (SRIM and TRIM), and a surface adatom diffusion model to describe the phenomenon of nanopore formation, we evaluate the conditions, specifically the ion energy, responsible for highly controllable fabrication of solid state nanopores. Additionally, we present methods to determine the thickness of the grown film as well as the thickness profile of the nanopore.

**J1 291 Surface-enhanced Raman spectroscopy of the nitrided $SiO_2$/SiC interface*** S.H. CHOI, *Vanderbilt University* M. PARK, D. WANG, J.R. WILLIAMS, *Auburn University* W. LU, *Fisk University* S. DHAR, L.C. FELDMAN, *Vanderbilt University* AUBURN UNIVERSITY COLLABORATION, FISK UNIVERSITY COLLABORATION, Performance of silicon carbide (SiC) field effect devices is limited by poor channel mobility due to the high density of oxide/dielectric interface states, ($D_{it}$). In general $D_{it}$ is crystal-face dependent. Carbon clusters generated by the high temperature oxidation process, are assumed to be the major contributor to this high defect density. Nitric oxide (NO) annealing reduces the interface states and results in an enhanced mobility, although the physical/chemical mechanisms are not yet established. We report a surface enhanced Raman spectroscopy (SERS) analysis of the 4H-SiC/$SiO_2$ interface, clearly showing carbon cluster bands, on the C (carbon-terminated) face. The concentration of the carbon clusters on the C-terminated interface is much higher than that of the Si-face, consistent with the higher $D_{it}$ on the C-face. Furthermore, NO annealing results in a reduction of the cluster concentration. This result provides direct experimental evidence that carbon clusters exist at the as-grown interface and the effect of NO anneal at atmospheric pressure suggest removal of these interfacial carbon defects.

**14:30**
**K1 1 Trapped Ion Optical Clocks.**
PATRICK GILL

For the last fifty years, the international standard of time has been the caesium atomic clock, which is based on the 9.2 GHz microwave absorption in caesium-133 atoms. The recent Nobel Physics award to T W Haensch and J L Hall for their development of widespan femtosecond comb metrology has recognised the major role that femtosecond combs have made to the progress of optical frequency standards, and their use, going forward, as optical clocks. Such single trapped ion and cold atom optical clocks are now capable of challenging the best caesium fountain microwave clocks available. High accuracy frequency measurement of the single trapped ion optical frequency standards such as $^{199}Hg^+$ [1], $^{88}Sr^+$ [2], and $^{171}Yb^+$ [3] by means of femtosecond combs referenced to the primary caesium fountain standard has now resulted in uncertainties at the $10^{-15}$ level. These measurements are close to being limited by the caesium standard itself. Looking forward, it now becomes attractive to reverse the ''directionality'' of accuracy provision by referencing the comb to the optical frequency standard itself, and this concept has already been demonstrated [4]. The optical clock so formed can then deliver full accuracy of the optical standard to about a million comb modes across the visible and near infra-red, and,

through the comb repetition rate frequency, to the microwave and rf regions. This presentation will review recent results and expected future capabilities of these optical clocks, particularly in respect of the single cold $^{88}Sr^{+}$ ion quadrupole and $^{171}Yb^{+}$ ion octupole clock transitions. **K1 2 Precision Spectroscopy of Hydrogen and Femtosecond Laser Frequency Combs.**
THOMAS UDEM, *MPI fuer Quantenoptik*

A femtosecond frequency comb is a simple and compact tool that allows the phase coherent connection of the radio frequency domain (below 100 GHz) with the optical domain (above 200 THz). It greatly simplified high precision optical frequency measurements and provides the long awaited clockwork mechanism for an all-optical atomic clock. We have used such a frequency comb to measure the absolute frequency of the 1S-2S two-photon transition in atomic hydrogen, i.e. comparing it with the Cs ground state hyperfine splitting. By comparing data taken in 2003 with earlier measurements in 1999 we can set an upper limit on the variation of the 1S-2S transition frequency of ( $-$ 29 $\pm$ 57) Hz within 44 months. To derive limits on the drift rates of fundamental constant such as the fine structure constant, we combine these measurements with other optical frequency measurements in $Hg^{+}$ and in $Yb^{+}$ performed at NIST, Boulder/USA and at PTB, Braunschweig/Germany respectively. This combined method gives precise and separate restrictions for the fractional time variation of the fine structure constant and the Cs nuclear magnetic moment measured in Bohr magnetons. The latter is a measure of the drift rate of the strong interaction. We also report on efforts to convert the frequency comb technology to much shorter wavelength. Based on intra cavity high harmonic generation an XUV (up to 60 nm) frequency comb is generated with a repetition rate of more than 100 MHz useful for high resolution laser spectroscopy in this region.

**K1 3 Precision measurement meets ultrafast science.***
JUN YE, *JILA, NIST and Univ. of Colorado*

Phase control of a single-frequency continuous-wave laser and the electric field of a mode-locked femtosecond laser has now reached the same level of precision, resulting in sub-optical-cycle phase coherence being preserved over macroscopic observation times exceeding seconds. The subsequent merge of CW laser-based precision optical-frequency metrology and ultra-wide-bandwidth optical frequency combs has produced remarkable and unexpected progress in precision measurement and ultrafast science. A phase-stabilized optical frequency comb spanning an entire optical octave ( $>$ 300 THz) establishes millions of marks on an optical frequency ''ruler'' that are stable and accurate at the Hz level. Accurate phase connections among different parts of electromagnetic spectrum, including optical to radio frequency, are implemented. These capabilities have profoundly changed the optical frequency metrology, resulting in recent demonstrations of absolute optical frequency measurement, optical atomic clocks, and optical frequency synthesis. Combined with the use of ultracold atoms, optical spectroscopy and frequency metrology at the highest level of precision and resolution are being accomplished at this time. The parallel developments in the time domain applications have been equally revolutionary, with precise control of the pulse repetition rate and the carrier-envelope phase offset both reaching the sub-femtosecond regime. These developments have led to recent demonstrations of coherent synthesis of optical pulses from independent lasers, coherent control in nonlinear spectroscopy, coherent pulse addition without any optical gain, and coherent generation of frequency combs in the VUV and XUV spectral regions. Indeed, we now have the ability to perform completely arbitrary, optical, waveform synthesis, complement and rival the similar technologies developed in the radio frequency domain. With this unified approach on time and frequency domain controls, it is now possible to pursue simultaneously coherent control of quantum dynamics in the time domain and high precision measurements of global atomic and molecular structure in the frequency domain. These coherent light-based precision measurement capabilities may be extended to the XUV spectral region, where new possibilities and challenges lie for precise tests of fundamental physical principles.

**K1 4 The Hg/Al single-atom, optical clocks: on the path to inaccuracies below $10^{-17}$.***
JAMES BERGQUIST, *NIST*

For the past fifty years, atomic standards based on the frequency of the cesium ground-state hyperfine transition have been the most accurate timepieces in the world. Recently, we reported a comparison between the cesium fountain standard NIST-F1, which has been evaluated with an inaccuracy of about $4 \times 10^{-16}$, and an optical frequency standard based on an ultraviolet transition in a single, laser-cooled mercury ion for which the fractional systematic frequency uncertainty was below $7.2 \times 10^{-17}$ [1]. We have also compared the frequency of the mercury ion optical clock to that of an optical standard based on the $^{1}S_0 \leftrightarrow {}^{3}P_0$ transition of $^{27}Al^{+}$ at 267 nm, which offers several attractive features as a single-ion optical clock. Its sharp natural linewidth, small electric quadrupole moment, and low quadratic Zeeman coefficient (0.7 $Hz/B^2$) allow for high stability and accuracy, but until recently, precision spectroscopy of $Al^{+}$ had not been possible, because it lacked an accessible, laser-cooling transition. However, with the development of quantum logic based spec-

troscopy [2, 3] a single aluminum ion can be efficiently probed. In our realization of this scheme, a single $^{9}Be^{+}$ ion is trapped together with the single Al ion in a linear Paul trap and is used to sympathetically cool the Al ion and to detect its internal state after the clock radiation is applied. We will report the latest results of the frequency comparison of the two optical standards and the implication these comparisons might have toward improved tests of the stability of Fundamental Constants. **K1 5 Exploring the states of light: from photon counting to quantum information.**
SERGE HAROCHE, *Collège de France and ENS Paris*

Forty years ago, the seminal papers of Roy Glauber have given a complete analysis of photon counting and light coherence, combining in a single theoretical framework a description of the granular and wave-like features of radiation. Glauber's theory has since then explained countless landmark experiments in quantum optics and has become an essential tool to understand the role played by photons in the physics of quantum information. We will describe a few experiments which illustrate the importance of Glauber's work in modern quantum optics. In addition, we will stress that complementary wave and particle behaviors are not restricted to light. They are also exhibited by atomic matter in Bose Einstein condensates. As we will see, Glauber's formalism of coherent states and particle counting has also found a remarkable testing ground in this new domain of research at the boundary between atomic and condensed matter physics.

**K2 1 Metal-insulator transition in $CuIr_2S_4$: XAS results, structure revisited, electronic structure proposed.**
MARK CROFT, *Rutgers University*

Interestingly, the magnetism in the spinel compound $Fe_3O_4$ (loadstone), constitutes the correlated electron material/problem of the greatest antiquity known to man. The Verwy transition problem in $Fe_3O_4$ is, by comparison, young at only 67 years of age. Recently experimental and theoretical insights into such exotic magnetic, charge, and orbital orderings in transition metal (T) spinel compounds have been rapidly emerging. The leitmotifs in these works involve: frustrated tripartite crossing 1D chains of edge-sharing T-ligand octahedra; T-d($t_{2g}$) orbital ordering onto subsets of these chains which involve d-d overlap; dimmer formation on these chains; and/or charge ordering on the chains dependent on band filling. Understanding the low temperature structural and metal (M) to insulator (I) transition in the spinel compound $CuIr_2S_4$ provides a key link in the generalization to other such systems. S *K*-edge X-ray absorption spectroscopy (XAS) measurements across this M-I transition reflect a dramatic Ir *d*-electronic state redistribution[1]. These results stimulated a detailed re-evaluation of the of *I*-phase crystal structure in terms of: decoupled chains of $IrS_6$ octahedra along the (110)-type directions; and an $Ir^{3+}$ ($Ir^{4+}$-$Ir^{4+}$) $Ir^{3+}$ repeat pattern ordering, where the ($Ir^{4+}$-$Ir^{4+}$) pair forms a dimmer. Further, the electronic state changes, evidenced by the XAS, motivated a model in which the I-phase involves: an orbital ordering of the highest lying $t_{2g}$ electron into 1D chains; the 3/4 filling of this 1D band dictating the periodicity of the orbital/charge ordering; and the direct $t_{2g}$-$t_{2g}$ dimmer bonding production of an antibonding state prominent in the S-K edge spectrum. The generalization of these concepts to other transition metal spinels will be addressed. [1]M. Croft, W. Caliebe, H. Woo, T. A. Tyson, D. Sills, Y. S. Hor, S-W. Cheong, V. Kiryukhin, and S-J. Oh, Phys. Rev. B 67 (Rapid Comm.), 201102 (2003).

**K2 2 Charge carriers in spinel $AlV_2O_4$ order below 700K.**
YOICHI HORIBE, *Department of Physics, Osaka Prefecture University*

$AlV_2O_4$ with the spinel structure shows some magnetic and electric anomalies around 700K, which originate from the formation of the charge ordered (CO) structure. [1,2] In this talk, we will report a structural model of the CO structure in $AlV_2O_4$, which was obtained by electron diffraction, synchrotron x-ray diffraction and magnetic measurements. The CO structure is characterized by the formation of V clusters ''heptamers,'' each of which is consisting of 7 vanadium

atoms and is in a spin- singlet state as a total. Note that the number of electrons per site is still fractional in this CO structure. In addition, theoretical consideration suggests that this unique molecular-like V heptamer is stabilized by a strong bonding of vanadium $t_{2g}$ orbitals. This work has been done in collaboration with Drs. S. Mori, T. Katsufuji, Y. Motome, N. Furukawa, H. Ishibashi, N. Ikeda and K. Kato. [1] K. Matsuno, et al., J. Phys. Soc. Jpn. **70**, 1456 (2001). **K2 3 Orbital Superstructures in Spinels.**
DANIEL KHOMSKII, *II.Physikalisches Institut, Universitaet zu Koeln*

Orbital degrees of freedom often lead to specific types of orbital and spin ordering. Complicated and interesting superstructures are observed in B-sublattice of spinels. This is connected with the geometric frustration of this lattice and with the interconnection of edge-sharing $MO_6$ octahedra, which is especially important for transition metals with partially-filled $t_{2g}$ levels. In some such systems ($MgTi_2O4$, $CuIr_2S_4$, $AlV_2O_4$) there appears strange superstructures with the formation of spin gap states. In other cases ($ZnV_2O_4$) structural transitions, apparently connected with orbital ordering, are followed by long-range magnetic ordering. Last but not least, the famous Verwey transition in magnetite $Fe_3O_4$ leads to a very complicated structural pattern, accompanied by the appearance of ferroelectricity. In this talk I will discuss all these examples, paying main attention to an interplay of charge, spin and orbital degrees of freedom. In particular, for $MgTi_2O4$, and $CuIr_2S_4$ we proposed the picture of orbitally-driven Peierls state [1]. Similar phenomenon can also explain situation in $ZnV_2O_4$ [2], although the corresponding superstructure has not yet been observed experimentally. Finally, I propose the model of charge and orbital ordering in magnetite [3], which uses the idea of an interplay of site- and bond-centered ordering [4] and which seems to explain both the structural data and the presence of ferroelectricity in Fe $_3O_4$ below Verwey transition. **K2 4 Probing spin correlations with phonons in the strongly frustrated magnet: ZnCr2O4.***
ANDREI SUSHKOV, *Materials Research Science and Engineering Center, University of Maryland*

Geometrically frustrated magnets can resist magnetic ordering and remain in a strongly correlated paramagnetic state well below the Curie-Weiss temperature. The spin-lattice coupling can play an important role in relieving the frustration in these systems. In ZnCr2O4, an excellent realization of the Heisenberg antiferromagnet on the pyrochlore network, a lattice distortion relieves the geometrical frustration through a spin- Peierls-like phase transition at Tc=12.5 K with a lowering of the symmetry from cubic to tetragonal. Conversely, spin correlations strongly influence the elastic properties of a frustrated magnet. By using infrared spectroscopy and published data on magnetic specific heat, we demonstrate that the frequency of the Cr optical phonon triplet in ZnCr2O4 tracks the nearest-neighbor spin correlations above Tc.* Below Tc, the triplet splits into a singlet and a doublet, separated by 11 cm- 1. This splitting gives a direct measurement of the spin- Peierls order parameter. From analysis of the ion displacements in the phonon modes we can conclude that direct Cr-Cr exchange dominates in ZnCr2O4. These experiments result in a clear understanding of spin-phonon coupling in ZnCr2O4 in contrast to other oxide magnets. Recent ab initio calculations** confirm the magnetic origin of both the phonon splitting in ZnCr2O4 and the frequency shifts in the ferromagnetic insulating spinel CdCr2S4. *A.B. **K2 5 Orbital ordering in transition-metal spinels.**
PAOLO G. RADAELLI, *ISIS facility, Rutherford Appleton Laboratory, Chilton, Didcot, OXON OX11 0QX, UK*

Transition-metal spinels (general formula $AB_2X_4$) have been for many years the subject of intense experimental and theoretical activity. Structurally, the most interesting feature of these systems is the fact that the *B* cation occupies the nodes of a pyrochlore lattice, which is known to be geometrically frustrated. Therefore, one can explore how their natural tendency to order in the charge, magnetic and orbital sectors is affected by geometrical frustration. Orbital Ordering (OO) occurs when the orbital degeneracy of an extended concentrated system is lifted, typically through a distortion of the lattice. This may result in either single orbital occupation or alternation/modulation of the orbital occupancy, with or without an associated charge ordering. The degree of charge localization is another important issue: in highly localized systems, one can speak of a cooperative Jahn-Teller (JT) effect, but this paradigm is no longer sufficient in the present of significant electronic hopping. Both $e_g$ and $t_{2g}$ orbitals are relevant for transition-metal spinels; $e_g$ systems, such as $ZnMn_2O_4$, tend to display the strongest JT effects, with direct coupling to the lattice. More recently, significant attention has been devoted to the possibility of orbital ordering in ions with partial $t_{2g}$ occupation, such as $Ti^{3+}$ and $V^{4+}$ ($3d^1$) and $V^{3+}$ ($3d^2$) and their electron/hole-symmetric counterparts. With respect to $e_g$ systems, $t_{2g}$ systems have a greater

degeneracy and weaker coupling to the lattice, and can give rise to significant hopping, due to the direct overlap of the $t_{2g}$ orbitals along the $<110>$ crystallographic directions of the spinel structure. Recent results on Ti, V, Fe and Ir spinels will be discussed, with particular reference to the relation between the complex crystallographic superstructures and the changes in transport (metal-insulator transitions) and magnetic (paramagnetic-diamagnetic transitions) properties at the ordering temperatures.

**K3 1 Evidence for Quantum Criticality in Electron-doped Cuprates.***
YORAM DAGAN, *School of Physics and Astronomy Tel Aviv University*

The electron-doped cuprates have attracted a lot of scientific interest recently. The antiferromagnetic (AFM) phase in these cuprates may persist well into the superconducting dome and vanish in a quantum critical point. We describe experimental evidence for a quantum phase transition near optimum doping in the electron-doped material $Pr_{2-x}Ce_xCuO_{4-\delta}$: The normal state Hall coefficient, at 350mK, exhibits a remarkable change at this doping. This singular behavior is accompanied by significant changes in the temperature dependence of the resistivity below 20K [1]. In addition, at low temperatures, a spin scattering magnetoresistance appears in the underdoped region, increases in magnitude at optimum doping and suddenly vanishes at the critical doping where also the upturn in resistivity ($d\rho/dT < 0$) disappears. [2] Supporting evidence for the quantum critical scenario from neutron scattering and infrared measurements and the nature of the ordered phase will be discussed. Our tunneling experiments show that the normal state tunneling gap is not directly related to the AFM order. T*, the temperature at which the normal state tunneling gap disappears, is greater than $T_c$ for the underdoped region and it follows $T_c$ on the overdoped side. [3] This behavior suggests finite pairing amplitude above $T_c$ on the underdoped side. [1] Y. Dagan et al., PRL., **92**, 167001 (2004). [2] Y. Dagan et al., PRL., **94**, 057005 (2005). [3] Y. Dagan et al., PRL., **94**, 187003 (2005).

**K3 2 Evolution of superconductivity in electron-doped cuprates.***
GIRSH BLUMBERG, *Bell Labs, Lucent Technologies*

The superconducting (SC) phase diagram of the electron-doped cuprates has been explored by Raman spectroscopy as a function of polarization, temperature and magnetic field. The SC gap magnitudes in optimally- and over-doped samples are in agreement with the single particle spectroscopy measurements. An in-gap collective mode has been observed in the $B_{2g}$ channel for the under-doped samples. The SC coupling strength decreases with increasing Ce concentrations from the strong- coupling regime for the under-doped sample to a weak-coupling at optimal doping and beyond. The persistence of SC coherence peaks in the $B_{2g}$ channel for all dopings implies that superconductivity is mainly governed by interactions in the vicinity of $(\pm \pi/2a, \pm \pi/2a)$ regions of the Brillouin zone (BZ). Well- defined SC coherence peaks in the $B_{1g}$ channel occur for optimally-doped samples and this implies that the electron-like carriers near the $(\pm \pi/a, \pm \pi/4a)$ and $(\pm \pi/4a, \pm \pi/a)$ regions of the BZ are also gapped at this doping. Low energy scattering below the SC coherence peak energies for all dopings and Raman symmetries is due to nodal QPs. However, the order parameter is more complicated than a simple monotonic $d_{x^2-y^2}$. We have studied the field and temperature dependence of the SC gap magnitude and the integrated intensity of the $2\Delta$ coherence peaks and extract an effective upper critical field line $H^*_{c2}(T,x)$ at which the superfluid stiffness vanishes. The field dependence of the measured SC gap reveals an estimate of $H^{2\Delta}_{c2}(T,x)$, an upper critical field at which the SC amplitude is suppressed by field. For optimally-doped samples, the field effectively suppresses the superfluid stiffness while the SC amplitude survives higher fields suggesting a phase fluctuation regime for these samples.

**K3 3 Recent Photoemission Results for the Electron-Doped Superconductors.**
TAKASHI TAKAHASHI, *Tohoku University*

Recent improvement in the energy and angular resolution of angle-resolved photoemission spectroscopy (ARPES) enabled us to investigate the detailed electronic structure in electron-doped high-temperature superconductors (HTSC), which have a relatively smaller energy-scale of superconductivity compared to hole-doped systems. In this talk, we report our recent ARPES results[1,2] focusing on the many-body interaction and the superconducting-gap symmetry in electron-doped HTSC. We have performed high-resolution ARPES measurements on $Nd_{2-x}Ce_xCuO_4$ and observed that the quasiparticle (QP) effective mass around o$\pi$sg_p is strongly enhanced due to opening of an antiferromagnetic (AF) pseudogap. Both the QP effective mass and the AF pseudogap are strongly anisotropic with the largest magnitude near the hot spot, which is defined as an intersection point of the Fermi surface and the AF zone boundary. Temperature-dependent measurements have revealed that the AF pseudogap survives at temperatures much higher than $T_N$ (Néel temperature), possibly due to the short-range AF correlation remaining even above $T_N$. The AF pseudogap gradually decreases with doping and is abruptly filled up near the boundary between the AF and superconducting phases. To study the anisotropy of superconducting gap in electron-doped HTSC, we have performed high-resolution ARPES on $Pr_{0.89}LaCe_{0.11}CuO_4$. We observed that the momentum dependence of superconducting gap is basically consistent with the $d_x2_{-y}2$–wave symmetry, but it obviously deviates from the simple $d_x2_{-y}2$ gap function. The maximum superconducting gap is not observed at the zone boundary as expected from the simple $d_x2_{-y}2$ gap symmetry, but it is located around the hot spot where electrons are thought to be strongly coupled to the AF spin fluctuation. All these ARPES results suggest that the electronic stricture and the superconducting behavior are strongly dominated by the AF interaction in electron-doped HTSC. 1) H. Matsui, K. Terashima, T. **K3 4 Recent Magnetic Neutron Scattering Experiments on the Electron-Doped Superconductor $Nd_{2-x}Cu_xCuO_4$.**
EUGENE MOTOYAMA, *Stanford University*

The study of the fascinating properties of the high-$T_c$ superconductors has arguably been one of the most important themes in physics during the past two decades. One of the fundamental issues in this quest is the investigation of the different roles of hole vs. electron doping of the Mott insulator parent compounds in order to attain superconductivity. While the vast majority of experimental studies has focused on the properties of the hole-doped materials, there has been renewed interest in the electron-doped side of the of the high-$T_c$ phase diagram. We present recent magnetic neutron scattering experiments on the prototypical compound $Nd_{2-x}Ce_xCuO_4$. Our work takes advantage of the fact that the upper critical field is relatively small for the electron-doped materials, and it provides new insight into the connection between antiferromagnetism and superconductivity. Among our new findings are a linear magnetic field effect on the superconducting magnetic gap and the evolution of the instantaneous spin correlations from the antiferromagnetic to the superconducting phase.

**K3 5 New Class of T'-structure Cuprate Superconductors.***
MICHIO NAITO, *Tokyo University of Agriculture and Technology (TUAT)*

High-temperature superconductivity has been discovered in $La_{2-x}Ba_xCuO_4$ that derives from the undoped mother compound $La_2CuO_4$ crystallizing in the $K_2NiF_4$ (so-called $T$) structure with oxygen octahedra surrounding the copper ions. It has been common sense that high-temperature superconductivity develops upon doping such an antiferromagnetic Mott-insulator with charge carriers. $La_2CuO_4$ is also the basis of the electron-doped cuprate superconductors of the form $La_{2-x}Ce_xCuO_{4+y}$, which however crystallize in the $Nd_2CuO_4$ ($T'$) structure without apical oxygen above or below the copper ions of the $CuO_2$-plane. Due to the vicinity to the structural phase transition into the $T$-structure the study of the undoped or low doped mother compound with $T'$-structure is difficult. However, using the itisovalent substituents Y, Sm, Eu, Gd, Tb, or Lu for La, nominally undoped $La_2CuO_4$ can be synthesized by molecular beam epitaxy in the $T'$-structure. The surprising result is that all these nominally itundoped $T'$-compounds are itsuperconductors with fairly high critical temperatures over 20 K. This suggests a phase diagram for this new class of electron doped cuprates, in which the Mott-insulating, antiferromagnetic ground state is not obtained.

**K4 1 Nanocrystals, Nanowires and the Role of Quantum Confinement.***
JAMES CHELIKOWSKY, *University of Texas at Austin*

One of the most challenging issues in materials physics is to predict the properties of matter at the nanoscale. In this size regime, new structural and electronic properties exist that resemble neither the atomic, nor solid state. By changing the size of the system, inherently intensive properties become extensive properties, which can be strongly altered from the macroscopic limit. Such properties can have profound technological implications, e.g., at small length scales a poor optical material like silicon can be converted to an optically active one. Unfortunately, the development of theoretical methods to predict the properties of these systems is formidable challenge. Nanoscale systems may contain thousands of electrons and atoms, and often possess little symmetry. I will illustrate some recent advances in this area based on methods that are designed to exploit high performance computational platforms. I will present real space pseudopotential techniques for solving the electronic structure problem within density functional theory (see http://www.ices.utexas.edu/parsec). I will apply these techniques to systems ranging from clusters of a few dozen atoms to systems containing over a thousand atoms. I will present predictions for the structural and electronic properties of semiconductor nanowires and nanocrystals, intrinsic and doped, and will resolve some outstanding issues in the literature.

**K4 2 Near-field intensity correlations in metal-dielectric nano-composites.**
HUI CAO, *Northwestern University*

Spatial correlations of field and intensity are indicative of the nature of wave transport in random media and have been widely investigated in the context of electromagnetic wave propagation in disordered dielectric systems However, less is known of near-field intensity correlations in metallic random systems, which can exhibit rich phenomena due the involvement of intrinsic resonance effects-surface plasmons. Neither is clear the difference between correlation functions in metallic and dielectric systems. This paper presents the first experimental study of near-field intensity correlations in metal-dielectric systems in regimes where localization and delocalization are expected. Significant differences are observed between the spatial intensity correlations functions in metal-dielectric systems and those of purely dielectric random media. In disordered metallic nanostructures, surface plasmon modes are governed by the structural properties of the system and may be strongly localized. Recent theoretical studies of metallic nanoparticle aggregates suggest that the eigenmodes of such systems may have properties of both localized and delocalized states. However, it is not clear how such eigenmodes impact the propagation or localization of surface plasmon polaritons excited by impinging light, an issue addressed in this study. In the current experiment, the concentration of metal particles on a dielectric surface $p$ was varied over a wide range to control the amount of scattering. Spatial intensity correlations obtained from near-field optical microscopy (NSOM) images show a transition from propagation to localization and back to propagation of optical excitations in planar random metal-dielectric systems with increase in metal filling fraction.

**K4 3 Carbon Nanotubes: Recent Results and Directions.**
HONGJIE DAI, *Stanford University*

This talk will present our latest research on single walled carbon nanotubes. We have been using carbon nanotube as a model system to study interesting nanoscale problems concerning materials synthesis, solid-state physics and devices, surface science and nanobiotechnology. This presentation will cover our latest results in, (1) Controlled synthesis of nanotube structures on surfaces. (2) Coherent quantum electron transport and diffusive electron-phonon scattering phenomena in suspended nanotubes. (3) Pushing the performance limit of nanotube transistors, and (4) interfacing carbon nanotubes with biological systems including living cells.

**16:18**
**K4 4 Exploiting the unique electronic and mechanical properties of carbon and boron nitride nanotubes.**
ALEX ZETTL, *University of California at Berkeley*

Carbon and boron nitride nanotubes have unusual geometrical features that affect their electronic, thermal, and mechanical properties. I will discuss relevant experimental studies of the underlying physics, as well as possible applications including sensors, nanoscale electric motors, high frequency tunable resonators, and phonon waveguides.

**K5 1 Multi-Wavelength and Nonlinear Quantum Cascade Lasers.**
CLAIRE GMACHL, *Princeton University*

Quantum Cascade (QC) lasers are a rapidly evolving mid-infrared technology well suited for chemical sensing applications. For sensing of trace gas mixtures, large molecules, or liquids, probing at a single wavelength is often not sufficient, but the analyte must be sampled at various wavelengths. Here, we will discuss various means of providing multi-wavelength emission from QC lasers. Four different routes are currently being investigated. First, the active waveguide core of a QC laser can be subdivided into substacks of different active regions, hence allowing for multi-wavelength emission. We will discuss the design optimization procedures employed to develop a multi-wavelength laser module with several wavelengths covering the 7 – 13 $\mu$m wavelength range. Second, QC lasers can be designed to emit different wavelength light when operated at different (positive or negative) bias settings. We have recently developed such a QC laser capable of emitting at $\sim$ 8 and $\sim$ 11 $\mu$m. Third, nonlinear QC lasers that in addition to QC laser active regions also include nonlinear mixing regions emit light not only at the fundamental frequency, but also at nonlinear frequencies. Second harmonic generation with up to 2 mW of nonlinear light has recently been demonstrated. Finally, QC lasers with very broad gain spectra can in principle be used to tune over significant wavelength ranges using an external cavity. A key component for such tunability is a low reflectance laser facet to suppress laser action based on feedback from the laser facets. We will show approaches to facet reflection reduction through sub-wavelength facet patterning. This work is supported through collaboration with Pacific Northwest National Labs / Battelle by DARPA L-PAS, the DOE, and the NSF ECS-0400615. This work is being conducted in collaboration with A. Dirisu, S.S. Howard, Z. Liu, O. Malis, G. Shu, D.L. Sivco, and F. Toor.

**K5 2 Ultrasensitive Quantum-Limited Far-Infrared Detectors.***
DANIEL PROBER, *Yale University*

Superconducting tunnel junction (STJ) direct detectors have been developed for submillimeter astronomy. Photons with energy greater than the superconducting gap of the aluminum absorber break Cooper pairs and generate excess quasiparticles, inducing an extra tunneling current through the STJ. To monitor the response of the STJ with large readout bandwidth and maximal sensitivity, we use a novel readout which uses radio frequency (RF) reflectometry, like the readout invented for the RF-SET. (1) For calibration of the detector, we have developed a in-situ, on-chip, hot-cold submillimeter photon source, a gold microbridge. When it is voltage biased, emitted noise from the microbridge couples via a microstripline to the detector. This provides a calibrated photon source with near unity coupling, very fast ( $<$ ns) chopping, and calculable power output. Cooling is by outdiffusion of hot electrons (2). We present recent detection results in the range 100 140 GHz. These demonstrate the expected good responsivity, high sensitivity, and fast response times. The readout approach is easily used with a frequency multiplexed readout, allowing economy of cold electronics. Ultimate sensitivity may require the use of an RF-SET as the readout, for NEP below NEP below $10^{-20}$ W/(Hz)$^{1/2}$. -Research with J.D. Teufel, M. Shen, L. Frunzio, C. M. Wilson, T.J. **K5 3 Electronically Tunable Terahertz Detection Using Plasmons.**
ERIC SHANER, *Sandia National Labs*

Spectroscopy in the millimeter-wave to THz frequencies has received a great deal of recent interest for security applications and chemical identification. This talk will address detectors that utilize plasmons in high-mobility GaAs/AlGaAs quantum well structures to provide a frequency tunable detector response. While there are various competing detection schemes based on plasmons, here we will cover the grating-gate detector along with a variant having enhanced performance called the split-grating gate detector. The basic device consists of source and drain electrical contacts along with a single grating-gate that spatially modulates both the incident radiation and the carrier density in a quantum well channel. The plasmon frequency underneath the gate lines is tuned by changing the carrier density with an applied gate bias. When this plasmon frequency is in resonance with the incident radiation field, a resonant peak is found in the photoresponse. The split-gate devices work in a similar fashion, except with additional gates in the device used to build larger nonlinearities into the system. By doing so, we have observed a several order of magnitude increase in responsivity. Currently, the grating-gate style of detector covers a frequency range from 150GHz to 800GHz at temperatures ranging

from 4K to 80K, however, the ultimate frequency and temperature limits of these detectors are not currently known. The ability to tune the detector response by simply changing a gate voltage leads to an attractive spectrometer-on-a-chip where no moving parts would be needed for THz spectral analysis. **K5 4 Designing the emission of THz Quantum Cascade Lasers with surface plasmon photonic structures.**
ALESSANDRO TREDICUCCI, *NEST CNR-INFM and Scuola Normale Superiore*

The development of quantum cascade lasers operating at terahertz frequencies is proceeding at a very rapid pace. For their successful practical implementation, specific requirements have now to be addressed, particularly concerning the properties of the emitted radiation. Single-mode THz lasers with distributed feedback resonators have been achieved and a new technique involving surface plasmon gratings has been demonstrated to improve performances. The latter also offers the possibility of constructing distributed Bragg gratings as a replacement for high-reflection coatings or to implement vertical emitting devices. Solutions allowing broad tuneability are examined, either relying on external cavity set-ups or more unconventional external electrical control.

**K5 5 Mid-Infrared Through Terahertz Cameras Based on Superconducting Technology.***
DAN SCHMIDT, *NIST, Boulder*

A new generation of cameras is set to make a tremendous impact on the field of mid-infrared to Terahertz astronomy. Take for example, the SCUBA-II instrument to be deployed on the James Clerk Maxwell Telescope at Mauna Kea, Hawaii. The existing SCUBA instrument has two arrays of 37 and 91 pixels, observing at 850 $\mu$m and 450 $\mu$m. The SCUBA-II arrays have 5120 pixels each and the noise contribution from the detectors is less than the sky load noise. As a result, large regions of the sky can be mapped about 1000 times faster. Superconducting thin film devices play multiple critical roles in these large format arrays. We will discuss the superconducting detector, multiplexing, and amplifier technology developed at NIST Boulder by the Quantum Sensors Project and the integration all of these technologies into a science grade imaging array. We will also survey the role that superconducting detectors, multiplexers, and thin film refrigerators will play in future instruments at both longer and shorter wavelengths.

**K6 1 Controlling Carbon Nanotube Quantum Devices.**
NADYA MASON, *University of Illinois at Urbana-Champaign*

The unique properties of nanotubes make them attractive candidates for a variety of quantum devices. We present transport data on nanotube-based quantum devices that demonstrate both one-dimensional physics and quantum-dot behavior. We show how voltages applied to narrow metallic gates can be used to produce localized depletion regions in the underlying tubes. A single depletion region in a nanotube with ohmic contact electrodes creates a quantum point contact, while a pair of depletion regions defines the quantum dot. Local gate voltages tune the conduction through point contacts, the transparencies of tunnel barriers, and electrostatic energies within single and multiple dots. We will show how this full gate control allows us to measure and control quantum phenomena such as quantized conductance steps and ''Honeycomb'' charge stability patterns in nanotube devices.

**K6 2 Dielectrophoretic gating and phase separation of particles for micro- and nano-fluidic biodetection applications.***

CONRAD JAMES, *Sandia National Laboratories*

Performance metrics for biological detection systems are significantly impacted by their ability to separate target analytes from background materials, a process that aids in the elimination of false positives. We report here several implementations of an electro-hydrodynamic technique for separating analytes in nanoliter sample volumes. This technique, AC dielectrophoresis (DEP) accompanied by field-induced phase transitions, includes electric field- and shear-induced phenomena to modify local concentrations of suspended particles. This non-optical separation technique relies upon intrinsic electric polarizability, and thus requires no time-consuming and costly labeling steps. We have demonstrated biological and non-biological particle separation, and both batch-mode and continuous flow configurations have been developed. The dielectrophoretic gating technique has been optimized to produce large electric field gradients ($\nabla E^2 \sim 10^{20} V^2/m^3$) and we are currently applying this technique for particle chaperone preconcentration and nucleic acid purification. For the first application, we have achieved 100x preconcentration factors and high efficiency particle valving with no degradation in flowrate. This technique will prove useful for bead-based assay systems utilizing packed beds or high throughput flow cytometry. In the second application, we have preconcentrated dsDNA target molecules, and shown that preconcentration of false-positive inducing ssDNA reporter oligonucleotides is negligible. This method can be integrated on-chip, providing a significant advantage over conventional off-chip purification technologies such as centrifugation and precipitation. We will also present our results in traveling wave DEP, a technique which utilizes phase-quadrature signals to preconcentrate and transport particles without the use of hydrodynamic forces.

**K6 3 Enhanced Physical Properties of Quantum-Confined Europium Sulfide Nanocrystals** MARCELA REDIGOLO, DMITRY S. KOKTYSH, SANDRA J. ROSENTHAL, JAMES H. DICKERSON, *Vanderbilt University* Synthesis and characterization of sub-2.0 nm europium sulfide nanocrystals is presented. Of particular interest is the behavior of the optical, magnetic, and magneto-optical properties as the nanocrystal diameter decreases, approaching the quantum confinement regime. The physical properties of these materials are dominated by 4f ionic transitions, which are affected directly by the nanocrystal size, due to nearest and next-nearest neighbor couplings. We believe that nanocrystal size, surface strain, and surface passivation will enhance the observable physical characteristics of the nanomaterials. To our knowledge, this would be the first evidence of quantum confinement effects in europium chalcogenide nanocrystals. Calculations of the Bohr radii of the 4f transition establish the upper limit on the nanocrystal size that exhibits blue shifts in the fluorescence and, perhaps, enhancements on the magnetic moment ($\mu_{eff}$). Structural properties are characterized by transmission electron microscopy, selected area electron diffraction, and x-ray diffraction. Absorption and photoluminescence spectroscopy measurements also are presented to describe the optical properties of the nanocrystals.

**15:54**

**K6 4 Network Structures in ABC Block Copolymers** THOMAS EPPS, MICHAEL FASOLKA, *NIST, Polymers Division* FRANK BATES, *University of Minnesota* At mesoscopic length scales interfacial curvature and packing geometry often reflect the self-assembly of molecules with prescribed architectures and directed interactions. It is well known that block copolymers microphase separate into periodic structures controlled by interaction parameters, volume fractions, and degree of polymerization. Some of the most promising morphologies in block copolymers are the periodic network phases, which generally have superior mechanical properties when compared to their one- and two-dimensional counterparts. We investigated the phase behavior of linear poly(isoprene-*b*-styrene-*b*-ethylene oxide) (ISO) triblock melts and discovered three triply-periodic networks. Two cubic network phases were found, along with an orthorhombic network in our bulk studies. It is also important to expand knowledge of free and substrate surface energy effects on triblock films, as the greater surface to volume ratio, relative to bulk materials, increases the influence of these parameters on thin film morphologies. To this end, we studied the effects of surface energy on the structure of the same ISO triblocks mentioned above. These films were examined on gradient substrates using AFM and XPS. Surface energy and PI content were found to influence the polymer nanostructures. The results we obtained demonstrate the importance of exploring both the thin film and bulk behavior of polymeric materials.

**K6 5 Local Structure and Photoluminescence Decay Dynamics in Undoped and $Mn^{2+}$ Doped ZnSe Nanoparticles** THADDEUS NORMAN, *Lawrence Livermore National Lab* CHRISTIAN GRANT, *Rutgers University* EDWARD OLANO, *University of California, Santa Cruz* EDWARD CASTNER, *Rutgers University* FRANK BRIDGES, JIN ZHANG, *University of California, Santa Cruz* Undoped and $Mn^{2+}$-doped ZnSe nanoparticles were synthesized from molecular cluster precursors. The nanoparticles were characterized using UV-VIS, PL, ESR, and XAFS. These studies confirmed the presence if $Mn^{2+}$ dopant in the host ZnSe lattice, and suggested the existence of two distinct $Mn^{2+}$ sites in the ZnSe lattice. Energy transfer dynamics in $Mn^{2+}$-doped ZnSe nanoparticles were also studied using time-integrated and time-resolved spectroscopic techniques. Time-resolved picosecond PL and femtosecond transient absorption studies show that the $Mn^{2+}$ doping substantially shortens the lifetimes of both the band-edge excitonic states and the shallow trap states. Energy transfer from ZnSe to $Mn^{2+}$ likely follows two mechanisms: one that involves mediation through trap states and another without.

**K6 6 New Approach Towards Aqueous Functional Nanostructures via Amphiphilic Coordination Networks.**
JUAN NOVERON, *University of Texas at El Paso*

The unprecedented use of designed amphiphiles with coordination- capable head groups that allow for the traditional coordination- directed networks to further self-assemble into nanostructures with novel complexity and function will be presented. With this approach the versatile chemistry of transition metals and the properties that amphiphiles exhibit in aqueous media are combined to generate extraordinary materials with interesting functions such as gene-encapsulation and delivery, drug- delivery vehicles, and hydrogen storage materials.

**16:54**
**K6 7 Effects of interfacial bonds and strain on the formation of InAs/GaSb Self Organized Nanostructures.***
DONNA STOKES, *University of Houston*

Interfacial effects play an important role on the formation of self-organized nanostructures based on the morphological instability of strained semiconductor multilayers. For many III-V systems with a misfit of less than 1%, instability occurs at some critical layer thickness, which is typically large ( $>$ 150 Å). However, for the non-common anion strained system, InAs/GaSb, the instability is observed at a thickness of a few monolayers. In this presentation, the results of a structural analysis by x-ray diffraction of an InAs/GaSb planar and nanowire superlattice grown by molecular beam epitaxy (MBE) with different interfacial bonds will be presented. Cross sectional scanning tunneling microscopy (XSTM) and atomic force microscopy (AFM) were also used to probe the physical structure of the superlattices. The effects of the strain and interfacial bond on the formation of the nanostructures will be discussed as well as how they may be manipulated to control the formation of these nanostructures in this system and other III-V systems. Also presented will be the results from a preliminary analysis of the effects of the nanostructure on the optical properties of the system.

**K7 1 Adaptive Biasing Force Method for Vector Free Energy Calculations.**
ERIC DARVE, *Stanford*

The adaptive biasing force method is an efficient technique to compute the potential of mean force along a reaction coordinate and for alchemical transformations. We present recent developments of the method for vector free energy calculations (i.e. for several reaction coordinates or for multiple alchemical transformations). General formulas are derived and their relative merit is discussed. In particular, many techniques require the ability to calculate second order derivatives and are therefore cumbersome to implement for complex reaction coordinates. We present new formulations requiring first derivatives only. Our approach will be compared with other popular techniques such as metadynamics. Application examples will be provided for simple examples, such as alanine dipeptide, and a more advanced one: the insertion of an amphipathic helix inside a cell membrane. For the latter, we will examine the stability of the inserted peptide relative to the interfacial configuration and its role in the association of individual peptides into larger multimeric structures, such as cellular channels. Our candidate for studies is the synthetic peptide $(LSLLLSL)_3$. It was shown experimentally that, in the presence of an electric field, the orientation changes from parallel to the membrane to perpendicular and the location of the center-of-mass (COM) changes from the membrane surface to the center of the lipid bilayer. Experimental results, however, provide no information about stability of individual helices in the transmembrane orientation. We will present results on the free energy surface of insertion of $(LSLLLSL)_3$ as a function of two coordinates: the distance of the COM of the peptide to the center of the membrane and the orientation of the helix relative to the membrane surface. Our results show that there is a global minimum corresponding to the parallel orientation at the water-membrane interface. The transmembrane arrangement of a single peptide is only metastable, i.e. it corresponds to a local minimum.

**15:06**
**K7 2 New Distributed Multipole Methods for Accurate Electrostatics for Large-Scale Biomolecular Simultations.**
CELESTE SAGUI, *North Carolina State University*

An accurate and numerically efficient treatment of electrostatics is essential for biomolecular simulations, as this stabilizes much of the delicate 3-d structure associated with biomolecules. Currently, force fields such as AMBER and CHARMM assign ''partial charges'' to every atom in a simulation in order to model the interatomic electrostatic forces, so that the calculation of the electrostatics rapidly becomes the computational bottleneck in large-scale simulations. There are two main issues associated with the current treatment of classical electrostatics: (i) how does one eliminate the artifacts associated with the point-charges (e.g., the underdetermined nature of the current RESP fitting procedure for large, flexible molecules) used in the force fields in a physically meaningful way? (ii) how does one efficiently simulate the very costly long-range electrostatic interactions? Recently, we have dealt with both of these challenges as follows. In order to improve the description of the molecular electrostatic potentials (MEPs), a new distributed multipole analysis based on localized functions – Wannier, Boys, and Edminston-Ruedenberg – was introduced, which allows for a first principles calculation of the partial charges and multipoles. Through a suitable generalization of the particle mesh Ewald (PME) and multigrid method, one can treat electrostatic multipoles all the way to hexadecapoles all without prohibitive extra costs. The importance of these methods for large-scale simulations will be discussed, and examplified by simulations from polarizable DNA models.

**15:42**
**K7 3 Flexibility in Biomolecules: Beyond Molecular Dynamics.***
MICHAEL THORPE, *Center for Biological Physics, Arizona State University*

Molecular dynamics is unable to explore the conformations large protein complexes, viral capsids etc. Using Lagrange constraints for covalent bonds, hydrogen bonds, hydrophobic tethers, and van der Waals excluded volumes, Monte Carlo dynamics uses ghost templates to efficiently guide rigid clusters via the flexible joints between them. The generation a new protein conformation typically requires about 100 milliseconds CPU time. Specifically, input from a single X-ray crystallographic structure can generate an ensemble of structures remarkably similar to those observed in NMR. Further applications are pathways for ligand docking, misfolding proteins and viral-capsid swelling. The software used for this work is available either interactively or for downloading via flexweb.asu.edu.

**16:18**
**K7 4 Enhanced conformational sampling via novel variable transformations and very large time-step molecular dynamics.***
MARK TUCKERMAN, *New York University*

One of the computational grand challenge problems is to develop methodology capable of sampling conformational equilibria in systems with rough energy landscapes. If met, many important problems, most notably protein folding, could be significantly impacted. In this talk, two new approaches for addressing this problem will be presented. First, it will be shown how molecular dynamics can be combined with a novel variable transformation designed to warp configuration space in such a way that barriers are reduced and attractive basins stretched. This method rigorously preserves equilibrium properties while leading to very large enhancements in sampling efficiency. Extensions of this approach to the calculation/exploration of free energy surfaces will be discussed. Next, a new very large time-step molecular dynamics method will be introduced that overcomes the resonances which plague many molecular dynamics algorithms. The performance of the methods is demonstrated on a variety of systems including liquid water, long polymer chains simple protein models, and oligopeptides.

**K7 5 Reaction Path Reaction path potential for complex biomolecular systems derived from mixed QM/MM methods.***
WEITAO YANG, *Department of Chemistry Duke University*

The reaction path potential (RPP) follows the ideas from the reaction path Hamiltonian of Miller, Handy and Adams for gas phase reactions but is designed specifically for large systems described with QM/MM methods. RPP is an analytical energy expression of the combined QM/MM potential energy along the minimum energy path (J. Chem. Phys. 121, 89, 2004). An expansion around the minimum energy path is made in both the nuclear and the electronic degrees of freedom for the QM subsystem, while the interaction between the QM and MM subsystems is described as the interaction of the

MM charges with polarizable QM charges. The input data for constructing the reaction path potential are energies, frequencies and electron density response properties of the QM subsystem. RPP provides a potential energy surface for rigorous statistical mechanics and mixed quantum/classical reaction dynamics calculations of complex systems, as will be shown for several enzymes. Recent further development in determining QM/MM free energy reaction paths will also be presented.

**K8 1 Mechanisms of Reversible Shear Thickening in Concentrated Colloidal Dispersions** NORMAN WAGNER, *Center for Mol. & Eng. Thermodynamics, Dept. of Chemical Engineering, Univ. Delaware, Newark, DE 19711* Experimental studies on model systems of colloidal and nanoparticles dispersions of spherical, elliptical and plate-like particles, where both rheology and mictrostructure are measured, are summarized and compared to illustrate the salient features of reversible shear thickening in well-defined model systems. Reversible shear thickening is shown to be stress-controlled and a connection between the transition from ''continuous'' to ''discontinuous'' shear thickening and underlying thermodynamic phase transitions (liquid-crystal, and liquid- nematic) is demonstrated. Theoretical models based on particle micromechanics which include lubrication hydrodynamics are shown to successfully predict the onset of reversible shear thickening. Small angle neutron scattering and light scattering measurements indicate the formation of ''hydroclusters'' as the source of the increased viscous dissipation and validate the micromechanical modeling. A comparison is made between reversible shear thickening and jamming in concentrated colloidal and nanoparticles dispersions under shear and extensional flows.

**14:42**
**K8 2 Nature of Strain-Induced Nonlinearity in Filled Rubbers** XIAORONG WANG, *Bridgestone Americas, Center for Research & Technology, Akron, OH 44317* CHRISTOPHER G. ROBERTSON, We present evidence suggesting the existence of an analogy between dynamic strain-induced nonlinearity in modulus of filled rubbers and physics of the glass transition of glass-forming materials and the jamming transition of vibrated granular materials. This analogy stems from the fact that shear strain in dynamic measurements introduce fluctuations in fillers that can be described by an ''effective temperature.'' The nonlinearity in modulus of filled rubbers simply reflects a de-jamming transition of fillers in rubber matrices. Filled rubbers with respect to strain therefore display many unusual phenomena, including the asymmetric kinetics, crossover effects, and the glass-like transitions. In addition, the jamming transition in filled rubbers also behaves as an isoenergetic thermodynamic transition. This evidence suggests that although jamming is kinetic, it may also be thermodynamic in nature. The coexistence of kinetic and thermodynamic descriptors of the jamming transition is analogous to observations of thermoreversible gels. Based on those results, we propose a unified phase diagram for jamming transitions. The significance of the new jamming phase diagram is that it has incorporated variables that are all derivable from Hamiltonians and may facilitate crucial comparisons between theories and experiments. **K8 3 Transition rates in the Lennard-Jones binary mixture*** YASHENG YANG, BULBUL CHAKRABORTY, JANÉ KONDEV, *Martin Fisher School of Physics, Brandeis University* The slow relaxation in glass forming liquids approaching the glass transition is often described by the Vogel-Fulcher-Tammann (VFT) equation which predicts a diverging viscosity at a non-zero temperature. The origin of this anomalously slow relaxation is an outstanding problem. Recent work (PRE 70, 060501(R) (2004)) shows that a system will obey the VFT equation near a critical point if the transition rates between different macrostates have an asymmetric form: energy lowering rates depend only on the entropy change and energy raising rates depend only on the energy change. Here we investigate this mechanism for glassy dynamics in the the Lennard-Jones binary mixture (LJBM); a well-known glass former. The transition rates between different inherent structures (local minima of the potential energy) are calculated using the interval-bisection method. We find that the energy lowering transition rates are not temperature-sensitive, while the energy raising ones depend on the temperature. The dynamics in the IS energy space is however, non Markovian. We discuss these findings in light of the proposed mechanism for glassy relaxation characterized by a VFT form.

**K8 4 Pushing on colloids: How a gel can stress a glass.**
DANIEL BLAIR, *Harvard University*

We employ a novel technique to for the application of external mechanical and osmotic stress on dense suspensions of colloidal particles. Thermally expandable NIPA hydrogels are used to confine a sediment of colloidal particles. By allowing the gel to expand up to ten times it's initial volume, we dramatically compress the sediment. Using laser

scanning confocal microscopy, we directly measure the effects of increased stress on the properties of a colloidal hard sphere suspensions. We observe the appearance of heterogeneities as the particles are pushed together. We will present results on the analysis of the local volume and dynamical properties of these heterogeneities and postulate their equivalence to characteristic features of analogous systems near their jamming transition.

**K8 5 Microscopic dynamics of recovery in sheared concentrated depletion gels** R. L. LEHENY, B. CHUNG, R. BANDYOPADHYAY, D. LIANG, *Johns Hopkins U.* S. RAMAKRISHNAN, C. F. ZUKOSKI, *UIUC* J. L. HARDEN, *U. of Ottawa* We describe x-ray photon correlation spectroscopy and diffusing wave spectroscopy investigations of concentrated depletion gels formed from nanoscale silica colloids in solutions of nonabsorbing polymer. The experiments track the changing microscopic dynamics as these jammed, nonergodic systems recover following the cessation of large shear. The two techniques provide a quantitatively coherent picture of the dynamics as ballistic or convective motion of colloidal clusters whose internal motion is arrested. While the evolution of the dynamics possesses features characteristic of nonergodic soft solids, including a characteristic relaxation time that grows linearly with the time since cessation of shear, comparison with the behavior of quenched supercooled liquids indicates the dynamics are not directly related to traditional aging and rejuvenation phenomena in glasses.

**K8 6 Local Disturbances of Binary Colloidal Glass Systems** BENJAMIN BLUTH, *Emory University* PIOTR HABDAS, *St. Joseph's University* ERIC R. WEEKS, *Emory University* We look at local disturbances in colloidal systems as they approach the glass transition. A colloidal system is a fluid filled with microscopic particles which can serve as a model for the atoms of a glass. When the concentration of these particles becomes sufficiently large the particles can no longer move. This is the point which we refer to as the glass transition. We study systems at concentrations just below the glass transition by ''pulling'' a magnetic bead through the sample using an external magnetic field. In our samples there are particles of two distinct sizes that have been dyed such that they fluoresce at different wavelengths. This allows the microscope to differentiate between the two sizes and gives us the ability to isolate and analyze their respective motions independently. From this we examine the motion of the surrounding colloids as the magnetic bead is pulled through the sample, and characterize the behavior as the glass transition is approached.

**K8 7 Polymer Statics and Dynamics in Confined Geometries** JOSHUA KALB, BULBUL CHAKRABORTY, *Brandeis University* Current work on biological systems and glass forming polymers (JCP 106, 6176 (1997)) has led to an interest in the study of single polymer systems. The main questions concern relaxation phenomena and the shape adopted by single polymers under hard and soft boundaries. Little is known about the possibility of inducing a glass transition through pure dimensional confinement. We are concerned with whether or not there is a critical value of the confining length scale. Both structure and relaxation can be described using scaling arguments and tested with Monte Carlo simulations using the bond-fluctuation algorithm (Macromolecules 21,2819 (1988)), which uses a lattice representation of the polymer chain with excluded volume effects. We look at the effects of confinement on a itsingle polymer chain by measuring quantities such as the magnitude end-to-end vector, the radius of gyration, and single monomer motion (JACS 124, 20 (2004)). A primary question is whether the self-avoidance constraint manifests itself in a manner similar to kinetically constrained models of the glass transition. Understanding how these quantities change with various confining geometries will lead to a deeper understanding of biological structures and glass formation. Work supported by NSF-DMR 0403997.

**K8 8 Nonlinear behavior of a driven probe in a colloidal suspension near the Glass Transition.** JASON HAY, *Emory University* PIOTR HABDAS, *St. Joseph's University* ERIC R. WEEKS, *Emory University* By applying a force to isolated microscopic magnetic particles embedded in a PMMA colloidal suspension a nonlinear relationship between the applied force and the measured velocity was measured with the assistance of a confocal microscope. Over short time scales it is possible to observe a threshold force, below which no apparent motion is detected. The value of this threshold force is highly dependent upon the concentration of the sample. At stronger forces, the velocity of a driven magnetic particle displays a power law dependence upon the applied force. In particular, the behavior becomes increasingly nonlinear as the concentration is raised toward the colloidal glass transition point. This behavior was consistent across numerous samples with different concentrations and a varying size ratio of PMMA to magnetic particle.

**K8 9 Yielding in concentrated emulsions** ANNIE COLIN, *LOF Université Bordeaux 1* SÉBASTIEN MANNEVILLE, *CRPP* LYDIANE BECU, *CRPP* We studied the non linear rheological response of two kinds of soft glassy materials: direct concentrated emulsions with and without a short range interparticle attraction induced by adding surfactant. Using high frequency ultrasonic velocimetry, the velocity profiles in a Couette cell are recorded simultaneously to the global rheological data during start up experiments. Under applied shear rate in the vicinity of the yielding transition, the gel ie the adhesive emulsion separates into a liquid state sheared rapidly at a rate higher than a substantial critical shear rate and a static solid region. The static region disappears at high shear rate. On the contrary, the glass ie the non adhesive emulsions flows homogeneously. Below the yield stress the emulsions remains solid like whereas above it becomes liquid like. Under applied shear rate no coexisting states between a liquid like phase and a solid like phase are evidenced. Our data point out that ''glass'' and ''gel'' flow differently in the vicinity of the yielding transition suggesting that the involved mechanisms are not universal.

**K8 10 Numerical studies of two-dimensional *k*-core percolation** ANDREA LIU, *University of Pennsylvania* LINCOLN CHAYES, *UCLA* JEN SCHWARZ, *Syracuse University* The disconnected-connected phase transition in *uncorrelated* percolation has long been known to exhibit a continuous phase transition.

Is this property retained when *correlations* between occupied sites are incorporated into percolation? An example of such a model is *k*-core percolation. In *k*-core percolation a constraint is introduced where a site can remain occupied only if it has at least *k* occupied neighbors; otherwise it is removed from the lattice. The mean field *k*-core transition is random first-order (or hybrid). What then is the nature of the *k*-core transition in finite-dimensions? We show numerical evidence for a hybrid transition in two-dimensions for a variant of *k*-core where there is an additional constraint of pseudo-force-balance. Using finite-size scaling analysis we demonstrate that there is a jump in the usual order parameter at the transition along with, not one, but two, diverging correlation length exponents, neither of which scale as 1/2 (or 1). This model may have some implications for the jamming transition.

**16:54**
**K8 11 Generic rugged landscapes under strain and the possibility of rejuvenation in glasses** DANIEL LACKS, BRITTANY ISNER, *Case Western Reserve Universty* A strain-dependent random landscape model shows that many aspects of the mechanical response of disordered materials are universal, and arise from the rugged nature of the energy landscape. Simulations with this model demonstrate that states produced by mechanical deformation will generally be distinct from the states traversed during thermal aging. This behavior is a generic consequence of a rugged energy landscape, and is independent of any specific microstructure of the material. Thus, mechanical deformation does not literally ''rejuvenate'' a material, although the states produced by mechanical deformation may in some ways resemble less aged systems.

**17:06**
**K8 12 The frequency distribution of mechanically stable packings** GUO-JIE GAO, JERZY BLAWZDZIEWICZ, COREY O'HERN, *Yale University* We generate mechanically stable packings of soft particles in 2D using an algorithm in which we successively grow or shrink purely repulsive grains and minimize the total energy at each step until particles are just at contact and at rest. We focus on small systems of up to 20 particles, and thus we are able to enumerate nearly all of the possible mechanically stable packings. Complete enumeration allows us to factorize the probability distribution, $P(\phi)$, for obtaining a mechanically stable state at packing fraction $\phi$ into algorithm-dependent and independent contributions, $\beta(\phi)$ and $\rho(\phi)$. $\rho(\phi)$ is the probability density to obtain a distinct mechanically stable packing at $\phi$, while $\beta(\phi)$ is the frequency with which each distinct state occurs. We found several remarkable features of the frequency distribution. For example, the frequency averaged over bins of width $d\phi$ grows exponentially with increasing packing fraction. In addition, distinct mechanically stable packings within $d\phi$ can occur with frequencies that differ by orders of magnitude. We also add thermal fluctuations to these stable configurations to understand the relationship between the frequency and shape of the potential landscape near the stable configurations.

**K10 1 First-principles statistical mechanics for heterogeneous catalysis.**
KARSTEN REUTER, *Fritz-Haber-Institut, Faradayweg 4-6, D-14195 Berlin*

We present a first-principles approach to heterogeneous catalysis that quantitatively describes the activity over a wide range of realistic environmental situations of varying temperatures and pressures. Within a first-principles statistical mechanics setup [1], density-functional theory is first used together with transition state theory to accurately obtain the energetics of all relevant processes. Subsequently the statistical mechanics problem is solved by kinetic Monte Carlo simulations. This two-step approach enables us to gain microscopic insight into the system, following its full dynamics from picoseconds up to seconds and explicitly considering the detailed statistical interplay of all elementary processes, i.e., by fully accounting for the correlations, fluctuations and spatial distributions of the chemicals at the catalyst surface. In the application to CO oxidation at a $RuO_2(110)$ model catalyst, we compute the composition and structure of the catalyst surface in reactive environments ranging from ultra- high vacuum to technologically relevant conditions with pressures of the order of atmospheres and elevated temperatures [2]. For all these conditions the obtained conversion rates are in unprecedented quantitative agreement with existing experimental data. The catalytic activity is narrowly peaked in environments, where the surface kinetics builds a disordered and dynamic adsorbate composition at the surface. In the full concert of the large number of processes occurring in this active state, the chemical reaction with the most favorable energy barrier contributes only little to the overall $CO_2$ production. **K10 2 Kinetics and equilibrium properties of supercooled salt solutions in contact with ice and water vapor** MARCELO CARIGNANO, PAUL SHEPSON, IGAL SZLEIFER, *Purdue University* The kinetics of ice growth from salt solutions and the final equilibium systems are studied by Molecular Dynamics simulations. Two systems are investigated. In one a liquid layer of supercooled salt solution is sourronded by ice walls. In the other, the liquid layer is in contact with an ice block on one side and water vapor on the other side. We found that the kinetics of ice growth in both cases is slower than the corresponding system with no ions. A faster ice growth is obserbed on the prismatic plane than on the basal plane of the ice. In the cases where complete freezing is achieved, the final systems have all the ions participating in cluster formations. In the system with water/vapor interface, complete freezing is not reached, leaving the ions solvated in a quasi liquid layer. The density profiles of the ions show their preference to be closer to the water/ice interface than to the water/vapor interface. The simulations enable the understanding of the mechanisms for ice formation under different solution conditions, and the final equilibrium properties of the studied systems.

**K10 3 Thermodynamic and Kinetic differences between solid superheating and liquid supercooling** XIAN-MING BAI, MO LI, *School of Materials Science and Engineering, Georgia Institute of Technology* When surface melting is properly suppressed, a solid can be heated above its melting temperature, which is called superheating. Although many explanations were proposed for solid superheating in the past century, its nature and extent still remain veiled. It is commonly assumed that solid superheating is a reverse process of liquid supercooling. The classical nucleation theory was directly applied to estimate the liquid nucleation rate and the upper limit of superheating despite the lack of decisive test of this analogy. Here we present our investigation of the thermodynamic and kinetic differences between superheating and supercooling via molecular-dynamics simulations. It is shown that the large elastic energy associated with internal melting and solid-liquid interface disorder play important roles in superheating. The growth rate is anisotropic for supercooling, but isotropic for superheating. Supercooling can be well described by the classical nucleation theory, whereas superheating shows many exceptions. The underlying mechanisms for these differences are discussed.

**K10 4 Why does 5-mthyl-2-pyrimidinone fluoresce? An ab initio study of the photophysics of a fluorescent DNA pyrimidine analog.** KURT KISTLER, SPIRIDOULA MATSIKA, *member* The photophysical properties of gas phase 5-methyl-2-pyrimidinone, a fluorescent DNA/RNA pyrimidine analog, have been calculated using multi-reference configuration-interaction with three levels of dynamical electron correlation included. The bright state at vertical excitation is $S_2$ ($\pi\pi^*$) at 4.42 eV. An $S_1$-$S_2$ seam originates close to vertical, and a gradient pathway from this seam leads to a global minimum on the $S_1$ surface. A conical intersection between $S_1$ and $S_0$ (itci01) was found, but all levels of theory show that this conical intersection is significantly higher than the minimum, supporting fluorescence from $S_1$. The details for this energetic inaccessibility, and the emission energy calculated (2.36 - 2.75 eV), depend on the level of theory used. Pathways along the $S_1$ surface when no dynamical or intermediate dynamical correlation is included show a small barrier along with a second minimum in the $S_1$ path from vertical to ci01. When higher level of correlation is included ( $\sim$ 130,000,000 configurations) the barrier vanishes, the secondary minimum becomes global, the energy of ci01 increases, and the fluorescence energy becomes closer to experimental. Thus the importance of dynamical correlation when studying the photophysics of the DNA/RNA bases theoretically is underscored.

**K10 5 Interactions between nanoparticles in supercritical fluids** SERGEI EGOROV, *University of Virginia* This talk presents a theoretical study of interactions between sterically stabilized spherical nanoparticles in a supercritical solvent. The theory is used to analyze the effect of particle size, solvent density, and solvent-ligand interaction strength on the potential of mean force between the particles. Experimentally observed size- selective precipitation of nanoparticles is rationalized in terms of the behavior of the density profiles of stabilizing ligands as a function of particle size and solvent thermodynamic conditions. The theory yields the same general trends as observed in experiments, namely, an increased stability of nanoparticle dispersions at higher solvent densities and for smaller particle sizes.

**15:54**

**K10 6 Effects of co-adsorbed C and K on energetics of CO oxidation on Pd(111)*** FAISAL MEHMOOD, SERGEY STOLBOV, TALAT S. RAHMAN, *Department of Physics, Kansas State University, Manhattan, KS 66506* In the course of catalytic oxidation of CO, carbon may atomically adsorb on catalyst surface and change (presumably poison) its reactivity. On the other hand, the reactivity of many catalysts is enhanced upon alkali co-adsorption. To gain insight into the nature of these effects, we carried out ab initio electronic structure calculations based on density functional theory with the generalized gradient approximation. The energetics and reaction pathways for CO oxidation on the clean Pd(111) and on Pd(111) co-adsorbed with C or K are calculated. We find that even at coverages as small as 1/12 ML, co-adsorbed C increases the activation energy barrier for the reaction by 20%, while K reduces it by 10%. This clearly shows the role of K as a promoter and C as a poison for this catalytic reaction. To understand the microscopic mechanism of these phenomena, we analyze the effects of the co-adsorbate coverage and the CO — co-adsorbate distance on the activation energy barriers and the local densities of electronic states and valence charge densities calculated for the initial and transition states of the reaction.

**K10 7 Parallel Temperature-Accelerated Dynamics Simulations of Epitaxial Growth*** Y. SHIM, J. G. AMAR, *University of Toledo* B. P. UBERUAGA, A. F. VOTER, *Los Alamos National Laboratory* The temperature-accelerated dynamics (TAD) method is a powerful tool for carrying out non-equilibrium simulations of systems with infrequent events over extended timescales. However, since the computational time for a typical TAD simulation

increases rapidly with the number of atoms $N$, TAD simulations have so far been limited to relatively small system sizes. By applying a recently proposed synchronous sublattice algorithm to parallel TAD simulations, we have been able to simulate the evolution of systems over much larger length- as well as time-scales. As a first test of our method, we have carried out simulations of the surface diffusion of Cu atoms on the Cu(100) surface. In contrast to serial TAD simulations for which the computational time scales as $N^{2.5} - N^3$, in our parallel TAD simulations the computational time scales as $log(N)$ and may even be independent of $N$ for larger system sizes. In particular we find that for intermediate size systems our parallel TAD simulations are several orders of magnitude faster than the corresponding serial TAD simulations. Preliminary results for low-temperature multilayer Cu/Cu(100) growth obtained using parallel TAD simulations are also presented.

**K10 8 Hydration and Dewetting near Fluorinated Superhydrophobic Plates** RUHONG ZHOU, XIN LI, JINGYUAN LI, MARIA ELEFTHERIOU, The water dynamics near a nanoscale fluorinated ($CF_3(CF_2)_7(CH_2)_2SiH_3$) surface as well as the possible dewetting (water drying) transition within two such superhydrophobic surfaces (plates) have been studied with molecular dynamics simulations. A partial water dewetting with an expansion of approximately 7-8Å and a water density $\sim$ 20% lower than the bulk is found near the single superhydrophobic surface. More remarkably, a strong dewetting transition is found in the inter-plate region for the double plates with a critical distance $D_c$ up to 10Å (3-4 water diameters). This transition, although occurring on a microscopic length scale, is reminiscent of a first order phase transition from liquid to vapor. Furthermore, simulation results show that the fluorinated carbons are more hydrophobic than their hydrogenated counterparts (with $D_c = 8.0$Å) in terms of the dewetting transition critical distance, despite their much larger partial charges and dipoles. The unusual superhydrophobicity of fluorocarbons is found to be related to their larger surface areas, while the intrinsic hydrophobicity is roughly the same for both fluorocarbons and hydrocarbons based on a detailed water-plate interaction energy profiling. Somewhat surprisingly, we find that even though the electrostatic energies do contribute slightly more in the fluorocarbon plates than the hydrocarbon plates, the van der Waals energies dominate the water-plate interactions (with more than 90% contributions for close shells) and they contribute almost the same in both plates.

**K10 9 Metastable States and Population Dynamics in the Linkage Isomer Compound Sodium-nitro-prusside** BERNARD DELLEY, JÜRG SCHEFER, *Paul Scherrer Institut Switzerland* DOMINIK SCHANIEL, THEO WOIKE, *U. Cologne* Two long-lived metastable states S1 and S2 can be produced in $Na_2$ $[Fe(CN)_5NO]2H_2O$ by illumination with light in the spectral range 380-580 nm. Local minima in the ground state energy hypersurface as given by density functional theory are in agreement with the linkage isomerism model. We identify S2 with a side on bonded NO configuration and S1 with an inverted one. We have shown that that thermal properties, vibrational spectrum, optical properties and the Mossbauer spectrum are predicted in agreement with experiment. We find that the crystal model gives a significantly improved account of spectral differences between the ground and S1 state as compared to the free anion model. On the basis of the energy surfaces we estimate thermal depopulation rates and explore the dynamics of direct population of S1 induced by blue light.

**16:42**

**K10 10 Effect of the substrate-adsorbate coupling on the dispersion of phonons of CO on Cu(001).*** TALAT S. RAHMAN, *Kansas State University* KLAUS PETER BOHNEN, *Forschungzentrum Karlsruhe* MARISOL ALCANTARA ORTIGOZA, *Kansas State University* In order to understand the effect of the substrate on the dynamics of the adsorbate we have carried out first principle calculations of the dispersion of phonons of the c(2x2) CO overlayer on Cu(001) based on the Density Functional Theory, using ultrasoft pseudopotentials and the PBE-GGA approximation for the exchange-correlation energy. Comparing with frozen-substrate calculation, at the gamma point, we found that the frequencies of the C-O stretch mode, $\nu 1$, and the adsorbate-substrate stretch mode, $\nu 2$, are almost independent of the substrate. However, while $\nu 2$ is dispersionless, $\nu 1$ presents a 10 meV dispersion at the M-point. The frustrated translation and frustrated rotation modes present a dispersion of less than 5 meV, nevertheless having the frustrated translation mode such a low energy a $\sim$ 1 meV dispersion is rather considerable. Moreover, Helium atom scattering studies of this mode found that it splits into two branches everywhere other than the $\Gamma$ point; they attributed one branch to the frustrated translation mode of a perfect c(2x2) CO overlayer, and the other one to defects in the same. Here we show that the splitting is an intrinsic feature of the perfect c(2x2) CO overlayer.

**K11 1 Sum-Frequency Spectroscopy as a Novel Probe for Molecular Chirality.***
Y. RON SHEN, *University of California at Berkeley*

Conventional techniques to probe molecular chirality, such as circular dichroism (CD), suffer from poor sensitivity because they are electric-dipole forbidden. Sum-frequency generation (SFG) is electric-dipole allowed even in chiral liquids, and therefore could be a more sensitive spectroscopic technique for probing molecular chirality in both electronic and vibrational transitions. We describe here a series of experiments that explore such a possibility. Despite the finding that chiral SFG is intrinsically weak for various reasons, we have succeeded in observing chiral SFG at both electronic and vibrational transitions with monolayer sensitivity. This work was supported by the U.S. Department of Energy.

**K11 2 Chiral Phenomena in Nonlinear Optic.**
GARTH SIMPSON, *Purdue University*

Frequency doubling (second harmonic generation, SHG) and frequency mixing (sum frequency generation, SFG) are remarkably sensitive probes of interfacial structure. The application of these techniques in studies of biological systems and interfaces is particularly exciting, given their high sensitivity to chirality. Whereas absorbance measurements yield circular dichroic (CD) ratios of a few fractions of a percent, these same molecular systems can easily produce CD ratios approaching 100% in thin films. In order for these emerging techniques to successfully undergo the transformation from academic curiosities to practical instrumental tools for biological characterization, experimental and theoretical advances are required. Novel ellipsometric approaches for polarization analysis have been developed to yield greater information content with simpler instrumentation. As a complement to these experimental studies, new and relatively simple theories

have been proposed for interpreting the relationships between the detected signals and the molecular/macromolecular structures at the interfaces. Applications of these combined experimental and theoretical techniques include the demonstration of label-free methods for real-time biosensing, chiral-specific detection and analysis with ultra-high sensitivity, and the quantification of changes in protein secondary structure from polarization analysis.

**K11 3 Multiple-Sequence Two-Dimensional Infrared Spectroscopy of *N*-Acetyl-L-Prolinamide*** SOOHWAN SUL, DENIS KARAISKAJ, YING JIANG, NIEN-HUI GE, *Department of Chemistry, University of California at Irvine* Femtosecond nonlinear 2D IR spectroscopy has been applied to study the conformational distribution of a model dipeptide, *N*-acetyl-L-prolinamide, in chloroform. Using rephasing, non-rephasing, and reverse photon echo pulse sequences at several polarization conditions, we resolved new spectral features associated with multiple conformers that were difficult to discern by linear IR spectroscopy. Ab initio calculations in vacuo suggested the existence of a major ittrans-$C_7$ and a minor itcis structure. Calculated 2D spectra based on these structures agree reasonably well with experimental spectral features obtained at parallel polarizations, but better agreement between the calculated and experimental cross-peak patterns can be reached if the major conformer takes a structure deviated from the $C_7$ form. We will discuss our results in relationship with earlier findings from NMR studies and MD simulations.

**K11 4 Investigation of Surface Mounted Molecular Rotors Through Optical Second Harmonic Generation** JAMES D. WALKER, CHARLES T. ROGERS, *Dept. of Physics, Univ. of Colorado, Boulder, CO 80309* GREGG S. KOTTAS, JOSEF MICHL, *Dept. of Chemistry, Univ. of Colorado, Boulder, CO 80309* Exploiting the lack of inversion symmetry near a surface, optical surface second harmonic generation (SHG) can be a powerful tool for probing molecular monolayers (or multilayers) adhered to such a surface. In particular, spectroscopy by resonant SHG (Ti:Sapph laser pulses plus Optical Parametric Oscillators and frequency doubling) can provide insight into the orientation of the different sections of the molecular rotor (rotator and axle). The molecular population's orientation can then be studied in the presence of externally applied electric fields, given that the rotator has an intrinsic electric dipole moment, as well in variable temperature UHV environments (down to approx. 30 Kelvin). Concentrating on an anthracene based rotor molecule, synthesized in-house and utilizing silane attachment chemistry on fused silica substrates, we will describe progress made in probing the population's orientation through SHG as well as sample preparation and characterization (linear UV-VIS spectroscopy, FTIR, and XPS).

**K11 5 VSFS studies of soluble monolayers formed by linear and branched alcohols at the air/water interface** SÜLEYMAN CAN, DEESHA MAGO, ROBERT WALKER, *Department of Chemistry and Biochemistry, University of Maryland* Vibrational Sum Frequency Spectroscopy (VSFS) was used to examine the molecular structure and organization of linear and branched octanol and nonanol monolayers adsorbed to the air/water interface. Vibrational bands in the CH stretching region – specifically the symmetric and antisymmetric normal modes of the methyl and methylene groups as well as bands resulting from Fermi Resonance interactions – were used to characterize molecular orientation. Complementing these studies were a full series of surface tension measurements designed to measure surface excess concentrations at full monolayer coverage. VSFS data show that branched alcohols attached to an odd carbon (such as 3-nonanol) create monolayers having very similar surface structures and surface coverages, regardless of where the alcohol functional group is attached. Functional substitution at an even-carbon (2-octanol), however, leads to a monolayer having expanded surface coverage (44 sq. Angstroms/molecule) but a surprisingly high degree of conformational order. These results are examined in terms of a competition between hydrogen bonding of the alcohol with the water sub-phase and the tendency of alkyl chains to pack together in close registry.

**K11 6 Recent Progress in Molecular Dynamics Simulation of Vibrational Sum Frequency Generation Spectroscopy.**

AKIHIRO MORITA, *Institute for Molecular Science*

While the visible-IR Sum Frequency Generation (SFG) spectroscopy is a powerful probe of interfaces using a second-order optical process, understanding of the experiments involves many factors to be addressed, including surface density and thickness, molecular orientation, local environment, and higher-order bulk terms. Assignment of the spectra is also complicated by overlap or interference of vibrational components. Therefore, practical methods of analysis with the help of reliable theoretical calculations will greatly benefit the SFG experiments. We have developed computational methods of vibrational SFG spectroscopy in combination of ab initio molecular modeling and molecular dynamics simulation. These methods allow direct calculation of SFG spectra from a molecular model without resorting to empirical spectral fitting. An essential ingredient of the theoretical methods is calculation of frequency-dependent nonlinear susceptibility that may be dominated by vibrational effects. We have proposed two ways of modeling of the nonlinear susceptibility, based on the energy representation and the time-dependent representation. This talk summarizes the progress of these theoretical methods and application to aqueous interfaces.

**K11 7 Vibrational Spectroscopy and Symmetry Specific Vibrational Energy Relaxation of Ethanol Molecule: A Study with Sum Frequency Generation and Photoacoustic Stimulated Raman Spectroscopy** HONG-FEI WANG,* *Institute of Chemistry, Chinese Academy of Sciences* SHI-LIN LIU,† *Department of Chemical Physics, University of Science and Technology of China* Orientational analysis of Sum Frequency Generation Vibrational Spectroscopy (SFG-VS) of un-deuterated ethanol indicated that the assignment of its C-H stretching vibrations in the literature was troublesome. The assignments were clarified using deuterated ethanols with their SFG-VS spectra at the vapor/liquid interface, and photoacoustic stimulated Raman spectra in the vapor phase. Comparison of SFG-VS spectra at vapor/liquid interface, infrared and Raman spectra in liquid phase, and photoacoustic stimulated Raman spectra in vapor phase of both un-deuterated and deuterated ethanol at room temperature indicated that the vibrational energy relaxation dynamics of ethanol molecule is significantly different for its symmetric and asymmetric C-H vibrational modes. These results showed that surface nonlinear spectroscopic methods can be used as effective tools for interrogating spectroscopy of molecules in bulk and vapor phases.

**K11 8 New forms of chiral spectroscopy: optical activity revisited** PEER FISCHER, AMBARISH GHOSH, *Rowland Institute at Harvard, Harvard University* Fresnel showed that an isotropic medium gives rise to optical rotation if its refractive indices for left- and right-circularly polarized light are unequal. Such is the case in optically active liquids, i.e. non-racemic solutions of chiral molecules. Nonlinear optical techniques have recently been developed that do not require the use of circularly polarized light to detect chirality. Here we present a new form of chiral spectroscopy which arises in linear optics and which yields information identical to that of conventional optical rotatory dispersion, yet without the need for a polarization analysis. The technique is independent of the optical path-length through the sample and permits optical activity to be imaged.

**K11 9 Structural properties and organization of hexadecanol isomers at the air/water interface** ROBERT WALKER, *Department of Chemistry and Biochemistry, University of Maryland* SÜLEYMAN CAN, *Department of Chemistry and Biochemistry, University of Maryland* DEESHA MAGO, *Department of Chemistry and Biochemistry, University of Maryland* A wealth of experimental data and theoretical modeling has led to well-honed intuition about the surface properties and structure of symmetric amphiphiles adsorbed to liquid surfaces. Less clear is how asymmetric amphiphiles organize in two dimensions at different surface coverages. We have studied the structure and two dimensional phase behavior of hexadecanol isomers adsorbed to the air/water interface. These isomers include the linear, n-hexadecanol as well structures with the alcohol functional group in the 2-, 3-, and 4-positions. Surface pressure methods are employed to study thermodynamic behavior of these insoluble monolayers, and vibrational sum frequency generation – a vibrational spectroscopy with surface specificity – is used to probe the molecular conformation and orientation of molecules within films. At their equilibrium spreading pressures, both 1- and 2- hexadecanol form very compact films having a high degree of conformational order and molecular areas of 19 and 28 sq. Angstroms/molecule in the tightly packed limit. In contrast, monolayers formed by 3-hexadecanol and 4-hexadecanol are much more disordered - but very similar to each other - and occupy much larger areas/molecule (75 sq. Angstroms/molec) in the tightly packed limit.

**K12 1 Subsurfactant Epitaxy for Ferromagnetic Semiconductors.**
HANNO H. WEITERING, *The University of Tennessee and Oak Ridge National Laboratory*

In this talk, I will discuss a discovery that is expected to have due impacts in two forefront areas of materials research. First, I will introduce ''subsurfactant epitaxy'' as a novel kinetic pathway toward the synthesis of non-equilibrium structures and materials [1,2]. The discovery of subsurfactant growth is of broad fundamental- and paramount practical interest, particularly within the context of doping functional materials. Secondly, we have successfully applied this conceptual advance to alleviate a major bottleneck problem in spintronics, namely how to fabricate dilute magnetic semiconductors with ferromagnetic ordering temperatures that exceed room temperature by a comfortable margin while minimizing the structural disorder and inhomogeneities that are intrinsic to high doping levels. Here, we demonstrate that controlled Mn doping of Ge via subsurfactant epitaxy produces ferromagnetic ordering temperatures well above room temperature at doping levels that are at least 20 times lower than those typically invoked in other fabrication techniques. Detailed comparison between samples grown by conventional MBE [3-5], and samples grown via the subsurfactant procedure [2] indicates the vastly superior structure-property relationship of the latter. Subsurfactant epitaxy thus stands as a new and powerful avenue toward superior dopant control in dilute magnetic semiconductors and potentially other semiconductor applications that require doping levels far above the thermodynamic solubility limit. **K12 2 Manganese silicide thin films on Si(001).** MICHAEL KRAUSE, ANDREW STOLLENWERK, VINCENT LABELLA, *College of Nanoscale Science and Engineering, University at Albany-SUNY, Albany, New York 12203* Theoretical considerations suggest that epitaxial MnSi thin films should order ferromagnetically on Si(001). This substantiates the hope that the Mn-Si system might be utilized as spin injectors through a Schottky barrier in future spintronics applications. Both thin and ultrathin films of manganese silicide on Si(001) have been investigated with different STM based techniques. In the ultrathin film regime three-dimensional manganese silicide islands form upon annealing. No closed and flat films have been found. With increasing annealing time the density of islands per surface area decreases while the average size of the remaining islands increases. The time dependence of the coarsening shows the typical characteristics of surface diffusion limited Ostwald Ripening. The activation energy for the clustering of Mn on Si(001) has been found to be 2.6 eV. Thicker (6 nm) continuous MnSi films were investigated using ballistic electron emission microscopy (BEEM) at 80 K to study the electrical properties. The BEEM spectra indicate a complex band structure at the MnSi/Si(001) interface. The MnSi overlayers show a high elastic scattering rate compared to Au/Si(001).

**K12 3 Kinetic stabilization of Fe ultra-thin film on GaAs(100) grown at low temperature** JAE-MIN LEE, SE-JUNG OH, *School of Physics & CSCMR, Seoul National University, Seoul 151-747, Korea* J.-Y. KIM, K.-J. KIM, *Pohang Accelerator Laboratory, Pohang University of Science and Technology, pohang 790-784, Korea* S.-U. YANG, J.-S. KIM, *Department of Physics, Sookmyung womens University, Seoul, Korea* We grew ultra-thin Fe films on GaAs(100) at low temperature (around 130K) to suppress chemical reactions between Fe and substrate atoms (interface alloying and As- surface segregation). For various Fe film thickness ranging from 1 to 30Å, we preformed photoemission experiment using synchrotron radiation to characterize the growth kinetics, and compared them with Fe films of similar thickness grown at room temperature. We confirmed that the interface alloying is obviously decreased at low temperature, and the surface segregation of As is blocked when Fe film is grown around 130K. As a result, more abrupt interface can be obtained in the low temperature growth. Furthermore, these Fe films grown at low temperature are found to be stable against As segregation even when the sample is annealed up to room temperature.

**K12 4 In-Situ Atomic-Scale Scanning Tunneling Microscopy Investigations of Cr on GaN Surfaces*** ARTHUR R. SMITH, MUHAMMAD HAIDER, ERDONG LU, WENZHI LIN, RONG YANG, COSTEL CONSTANTIN, HAMAD AL-BRITHEN,† *Ohio University* SMITH GROUP TEAM, Currently there is much interest in the magnetic properties of magnetically-doped nitride semiconductors. For purposes of doping GaN with Mn or Cr, it is important to investigate the action of these dopants on the clean surface under epitaxial growth conditions. In this study, we investigate the surface of GaN which has been doped with Cr during molecular beam epitaxial growth using in-situ scanning tunneling microscopy. In addition, we also investigate the surface of GaN which has been exposed to a fraction of monolayer of Cr deposited directly on the clean surface. For low concentrations, we find that the Cr can incorporate into the Ga lattice positions, participating in the known 3x3 and 6x6 reconstructions of GaN(000-1). For higher percentages of Cr, a novel Cr nanowire structure forms at the surface. Efforts are underway to study the magnetic properties of these surfaces.

**K12 5 Epitaxial Growth of Binary Ferromagnetic $Mn_{3-\delta}Ga$ Thin Films on Wurtzite GaN(0001) and Investigation by Atomic Scale Scanning Tunneling Microscopy** E.D. LU, R. YANG, M.B. HAIDER, C. CONSTANTIN, A.R. SMITH, *Condensed Matter and Surface Science Program, Department of Physics and Astronomy, Ohio University, Athens, OH 45701* J.W. KNEPPER, F.Y. YANG, *Physics Department, Ohio State University, 191 Woodruff Avenue, Columbus, OH 43210* Due to increasing interest in developing new magneto-optical and magneto-electronic devices, and spin injection sources in spintronics applications, ferromagnetic (FM)\MnxGay is an attractive candidate system to explore. Here we report that binary FM $Mn_{3-\delta}Ga(1.14< \delta < 2.0)$ single crystalline thin films has been epitaxially grown on (*w*)-GaN(0001)surfaces using molecular beam epitaxy. The face-centered tetragonal structure of $Mn_{3-\delta}Ga$ thin films with CuAu-$L1_0$ type ordering has been determined *insitu* by both reflection high energy electron diffraction and atomic-scale scanning tunneling microscopy. The epitaxial relationship of the $Mn_{3-\delta}Ga$ with GaN(0001) is $(111)[1\bar{1}0]_{MnGa} \parallel (0001)[1\bar{1}00]_{GaN}$ and $(111)[11\bar{2}]_{MnGa} \parallel (0001)[11\bar{2}0]_{GaN}$. The hysteresis loops of the thin films show magnetic anisotropy along itin-plane and itout-of-plane directions. It is found that Curie temperature and magnetic moments of the $Mn_{3-\delta}Ga$ thin films are closely related to the Mn content, and the reconstruction changes from $1\times$ 1 to $2\times$ 2 by increasing the ratio of Mn to Ga during the growth. Thus, we have achieved reconstruction-control of magnetic properties.

**K12 6 Indium nitride growth on Si(100) by femtosecond pulsed laser deposition** MOHAMED HAFEZ, HANI ELSAYED-ALI, *Old Dominion University* Deposition of indium nitride (InN) on Si(100) is performed under ultrahigh vacuum with an amplified Ti:sapphire laser (130 fs) operating at a wavelength of 800 nm. The objective is to grow single crystal InN films on Si(100). An intermediate layer of indium on Si(100)-($2\times$ 1) is prepared to avoid surface nitridation and decrease the lattice mismatch between the InN and Si(100). Reflection high-energy electron diffraction (RHEED) is used in situ during the deposition to study the growth dynamics and the surface structure of the grown

films. Growth of indium on Si(100)-(2× 1) by femtosecond pulsed laser deposition showed high-quality 2D films. The initial 2D indium layers on Si(100)-(2× 1) formed in the In-(2× 1) structure at room temperature and the In-(4× 3) structure at a substrate temperature of 653-693 K. Growth of InN on the In-(2× 1) and In-(4 × 3) buffer layer is discussed. The morphology of the InN films is examined by ex situ atomic force microscopy (AFM) and scanning electron microscopy (SEM).

**16:06**

**K12 7 Influence of temperature on mobility and carrier density of InN films** JAGDISH THAKUR, *Wayne State University* V.M. NAIK, *University of Michigan-Dearborn* R. NAIK, D. HADDAD, G.W. AUNER, *Wayne State University* H. LU, W.J. SCHAFF, *Cornell University* We have investigated temperature dependence of Hall mobility and carrier density for thin InN films with low and high carrier density grown by Molecular Beam Epitaxy (MBE) and Plasma Source Molecular Beam Epitaxy (PSMBE), respectively. At very low temperatures, a large concentration of carriers which are temperature independent is observed in both the low and high density films. However, the behavior of mobility for the low density film is different from that of the high density film particular for temperatures less than 300K. For the low density film, mobility increases with temperature and passes through a maximum around 250 K in contrast to temperature independent mobility observed for the high density film for T $<$ 300K. Theoretically, we investigated the temperature dependence behavior of the mobility using Born-scattering and found the presence of charged dislocation in the low density film. At higher temperatures the mobility is determined by the electrons scattering from the longitudinal-optical (LO) phonons.

**16:18**

**K12 8 Electrolyte-based capacitance voltage analysis of InN** J.W. AGER III, K.M. YU, *Lawrence Berkeley National Laboratory, Berkeley, CA* R.E. JONES, D.M. YAMAGUCHI, S.X. LI, *Lawrence Berkeley National Laboratory and UC Berkeley, Berkeley, CA* W. WALUKIEWICZ, *Lawrence Berkeley National Laboratory, Berkeley, CA* E.E. HALLER, *Lawrence Berkeley National Laboratory and UC Berkeley, Berkeley, CA* H. LU, W.J. SCHAFF, *Cornell University, Ithaca, NY* The electron affinity of InN, 5.8 eV, is larger than for any other known semiconductor. As a result, InN has a surface accumulation layer of electrons reflecting pinning of the Fermi level ca. 0.9 eV above the conduction band edge. In addition, all metals form an ohmic contract to InN, so that it is not possible to measure the space charge distribution using standard capacitance voltage (CV) measurements. We show that electrolyte solutions can be used to make blocking contacts to InN and that under reverse bias conditions, the surface accumulation layer and up to ca. 10 nm of the underlying InN can be depleted. Analysis of CV data obtained under these conditions using the Poisson equation allows net charge as a function of depth to be modeled. In n-type InN, good agreement with bulk Hall effect data is obtained when the depletion region is extended to $>$ 5 nm below the surface. In Mg-doped InN, modeling of the CV data produces evidence for ionized acceptors below a surface inversion layer.

**16:30**

**K12 9 Observation of Quantized Electron Accumulation States in InN(0001−)** LEYLA COLAKEROL, HAE-KYUNG JEONG, LUKASZ PLUCINSKI, SHANCAI WANG, ALEX DEMASI, KEVIN SMITH, *Department of Physics, Boston University* PAPO CHEN, THEODORE MOUSTAKAS, *Department of Electrical and Computer Engineering, Boston University* We report a study of the surface and bulk electronic structure of InN(0001–) thin films using high resolution synchrotron radiation excited angle-resolved photoemission. The InN thin films were grown by plasma-assisted molecular beam epitaxy on *c*-plane sapphire. Samples were cleaned both by annealing in ultra-high vacuum (UHV) and by cycles of nitrogen ion bombardment followed by UHV annealing. We have observed a series of quantized states above the Fermi level ($E_F$), for a narrow range of excitation energies and band momenta. These states have a parabolic dispersion around the surface Brillouin zone center and are due to an electron accumulation layer in the conduction band. The number of states observed is a function of annealing temperature. We observe an increase in the number of states following sputtering, which is likely due to segregation of In metal to the surface. Up to four individual free electron states are observed. Supported in part by the NSF, the U.S. ARO, and by the U.S. AFOSR. Experiments were performed at the NSLS.

**16:42**

**K12 10 Electron Mobility of InN*** REBECCA JONES, SONNY LI, EUGENE HALLER, *Materials Sciences Div., Lawrence Berkeley National Laboratory, and Dept. of Materials Science and Engineering, University of California, Berkeley, CA* KIN MAN YU, WLADEK WALUKIEWICZ, HENRICUS VAN GENUCHTEN, JOEL AGER, *Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA* LEON HSU, *General College, University of Minnesota, Minneapolis, MN* HAI LU, WILLIAM SCHAFF, *Dept. of Electrical and Computer Engineering, Cornell University, Ithaca, NY* We use irradiation with 2 MeV $H^+$ and $He^+$ ions to create donor-like point defects in InN films and thereby predictably control the free electron concentration and mobility over a large conductivity range. Calculations of theoretical electron mobilities coupled with experimental annealing studies (at temperatures up to 500$^o$C) suggest at least two types of donor-like defects are formed by the irradiation: singly-charged nitrogen vacancies and triply-charged, relaxed indium vacancies. Under annealing at these temperatures, the nitrogen vacancies appear stable, while the indium vacancies are removed. The annealing creates InN films with electron mobilities well above those of as-grown films at similar concentrations. We use these results to analyze the factors limiting the mobility in as-grown InN films.

**16:54**

**K12 11 Role and Effect of Native Defect Complexes in InN** XIANGMEI DUAN, CATHY STAMPFL, *School of Physics, The University of Sdyney* CONDENSED MATTER THEORY TEAM, We have carried out the first-principles density-functional theory calculations to investigate the structural and electronic properties and the formation energies of native point defect complexes in InN. We report an extensive and systematic study of possible configurations and different concentrations, focusing on the nitrogen- and indium-vacancies. Nitrogen vacancies prefer to be situated close to one another resulting in local metallic indium-rich regions or ''clustering''; while indium vacancies prefer to be separated, or to cluster together, where neighbouring under-

coordinated N atoms spontaneously form N2 molecules. These defect structures induce marked changes in the states in the egion of the band gap, which may explain the wide variation in experimentally determined band-gaps (see e.g. [1]). [1] T. V. Shubina, et al. Phys. Stat. Sol. (a) 202, 377 (2005).

**K12 12 Photoinduced magnetic and electronic phenomena in organic magnetic semiconductor $V(TCNE)_{x\sim2}$** JUNG-WOO YOO, R. SHIMA EDELSTEIN, A. J. EPSTEIN, *The Ohio State University, Columbus, OH 43210* K. I. POKHODNYA, JOEL S. MILLER, *Univeristy of Utah, Salt Lake City, UT 84112* $V(TCNE)_{x\sim2}$ is a fully spin-polarized half- semiconductor, whose magnetic order exceeds room temperature ($T_c > 350$ K), and electronic transport follows hopping mechanism in the Coulomb energy split in $\pi^*$ band. Substantial decrease of magnetization by illuminating with light ($\lambda = 457.9$nm) has been found at low temperature ($T < 100$K). The photo-excited metastable state has a lifetime $> 10^6$s at low temperatures and completely relaxes to the state before illumination after annealing upto 250K. Photoinduced ESR analysis indicates strong increase of magnetic anisotropy by light irradiation. We also report substantial increase of conductivity induced by illumination with light ($\lambda = 457.9$nm). The temperature dependence of resistivity clearly indicates substantial decrease in activation energy for electronic hopping. The photoinduced effect is proposed to originate from structural changes triggered by $\pi \rightarrow \pi^*$ excitation in (TCNE) molecules, which leads modification of the orbital wavefunction resulting in changes of magnetic exchange energy $J$ and the activation energy $\Delta E$. *Supported in part by AFOSR Grant No. F49620-03-1-0175 and DOE Grant No. DE-FG02-01ER45931 and DE-FG02-86ER45271.

**K13 1 Thermal Chemistry of $N_2$, $CO_2$, and $CH_4$ on Cesiated Pt(111)** KRISTY DEWITT, LETICIA VALADEZ, IAN HARRISON, *Department of Chemistry, University of Virginia, Charlottesville, VA 22904* MERRICK DEWITT, *SPARTA, Inc., 1911 N. Fort Myer Drive, Suite 1100, Arlington, VA, USA 22209* Promoting transition metal surfaces with alkali metals is known to drastically reduce the surface work function. We have investigated the effect of Cs promotion on the thermal chemistry of $CH_4$, $N_2$ and $CO_2$ using temperature programmed desorption (TPD). At low Cs coverage the $CH_4$TPD peak broadens and shifts to higher temperature. As the Cs coverage increases further three $CH_4$ peaks develop: one at higher temperature than on a bare Pt surface, and two at lower temperatures. With Cs coverage of one saturation monolayer (it$\theta_{sat} = 0.41$ ML) or more only the lowest temperature peak remains. $CH_4$ sticking also varies as a function of Cs coverage. $N_2$ displays similar behavior to $CH_4$ in response to coadsorption of Cs, but does not stick to Cs multilayers. $CO_2$ exhibits very unusual behavior as a function of Cs coverage. At low Cs coverage the physisorbed $CO_2$ peak broadens, then splits into a doublet, with one peak at higher temperature than the ''normal'' $CO_2$ peak, and the other at lower temperature. With increasing Cs coverage $CO_2$ begins to dissociate, evidenced by high temperature recombinative desorption and the presence of chemisorbed CO. As the Cs coverage approaches $\theta_{sat}$ the physisorbed peak disappears entirely, and only dissociative chemisorption is seen.

**14:42**

**K13 2 Observation and Manipulation of Subsurface Hydride in Pd(111)** CHARLES SYKES, *Tufts University* LUIS FERNANDEZ-TORRES, *University of Puerto Rico at Cayey* SANJINI NANAYAKKARA, *Penn State University* BRENT MANTOOTH, *Geo-Centers* RYAN NEVIN, *University of Wisconsin-Madison* PAUL WEISS, *Penn State University* We have observed and manipulated hydrogen atoms beneath the surface of a Pd(111) crystal using low-temperature scanning tunneling microscopy (STM). The subsurface region of Pd can be populated with hydrogen atoms from the bulk by applying voltage pulses from a STM tip. Topographic and local electronic data characterizing subsurface hydrogen in these stable sites is presented. We discuss our ability to selectively populate subsurface sites with hydrogen and present a full STM characterization of this state. This phenomenon is explained with an inelastic excitation mechanism, whereby hydrogen atoms in the bulk are excited by tunneling electrons and are promoted to more stable sites in the subsurface region.

**14:54**

**K13 3 Oxygen-Induced Faceting of Ir(210)** TIMO JACOB, PAYAM KAGHAZCHI, MATTHIAS SCHEFFLER, *Fritz-Haber Institute, Faradayweg 4-6, D-14195 Berlin, Germany* Although rough clean metal surfaces usually have higher surface free energies than their closed-packed analogs, adsorbates are able to modify this behavior and cause changes in surface morphology through reconstructions or facet formations. Using different surface sensitive techniques (e. g. STM or LEED) Madey *et al.* [1] found that Ir(210) shows interesting surface faceting at high oxygen coverages ($\theta > 0.5$ ML). The facets were identified as three-sided nanoscale pyramids with two (311) and one (110) planes. In oder to understand this effect we used density functional theory in combination with the *ab initio* atomistic thermodynamics and studied the influence of an oxygen atmosphere on the structure of Ir(210). Assuming an oxygen partial pressure of 1 atm, it turned out that below $T < 1000$ K the oxygen-covered facets are thermodynamically more stable than non-faceted O/Ir(210). Further heating reverts the substrate structure to planar O/Ir(210). While most nanoscale pyramids consist of smooth and unreconstructed planes, some (110) facets show a complex reconstructed superstructure. Thus, present studies aim on the stability and an atomistic understanding of those structures. [1] I. Ermanoski *et al.*, *Surf. Sci.* **549**, 1 (2004).

**K13 4 The Nature of Metal-Oxygen Bonding at Corundum (0001) Surfaces in the Presence of Oxygen** EMILY JARVIS,* ORKID COSKUNER, ANNE CHAKA, *National Institute of Standards and Technology, Physical and Chemical Properties Division, Computational Chemistry Group* Metal oxides are of critical importance in a variety of applications ranging from gas sensing to catalysis to environmental containment of heavy metals. In all of these cases, it is the surface chemistry that is essential to the necessary function. The detailed surface structure is heavily de-

pendent on the physical and chemical features of the surroundings, and its reactivity is largely dictated by the nature of the local bonding character. We use all electron density functional calculations combined with itab initio thermodynamic predictions to explore surfaces of several corundum-structured metal oxides as a function of oxygen partial pressure, which is a crucial first step in understanding corrosion, passivation, and catalysis. Additionally, we apply quantum mechanical wavefunction-based methods with the goal of elucidating the local bonding character of these surfaces. Our calculations provide detailed insight into the nature of the chemical bonding at chromia and hematite (0001) surfaces with M=O termination, i.e., the chromyl- and ferryl-terminated surfaces, and explain the dissimilar thermodynamic predictions for the alumina (0001) surface relative to these transition metal oxide surfaces.

**K13 5 Theoretical treatment of excited electronic states of adsorbates on metals: electron attachment to $CO_2$ adsorbed on Pt(111)*** JERRY WHITTEN, LAURA SREMANIAK, *North Carolina State University* Photochemistry involving adsorbates on metals often proceeds by photoexcitation of the metal followed by transient attachment of photoemitted electrons to the adsorbate. First principles theoretical methods suitable for describing electronic states embedded in a near continuum of metal to metal excitations are described and an application to electron attachment to $CO_2$ adsorbed on Pt(111) is reported. Wavefunctions are constructed by itab initio configuration interaction methods which allow a rigorous resolution of states and differentiation between competing pathways of molecular desorption and dissociation. An embedding theory is used to achieve high accuracy in the adsorbate-surface region. The overall process can be understood as formation of an electron attached state at an energy lower than the work function of the metal, localization of the metal hole and attraction of the charged adsorbate to the metal. Optimum geometries are calculated and pathways between these geometries determine whether molecules will desorb, dissociate by bond rupture directly in the excited electronic state, or dissociate after return to the ground state potential energy surface via vibrational processes. The influence of a coadsorbed potassium electron donor atom on the energy required to form the electron attachment state is also reported.

**K13 6 Quantum Nature of Hydrogen on Metals: Ground-State Geometry of Vacancies** SUNGHO KIM, SEONG-GON KIM, *Mississippi State University* STEVEN C. ERWIN, *Naval Research Laboratory* When hydrogen is adsorbed on a Pd(111) surface, very simple vacancy defects – which form quite commonly – exhibit fundamentally quantum wavelike behavior. Conventional wisdom has it that the quantum nature of hydrogen and other light atoms is only rarely manifested, typically in specially designed experimental protocols. A great many studies have proceeded under the assumption that, for most purposes, as long as the electronic motion is handled quantum mechanically, the nuclear motion of hydrogen can be treated classically. We show that this approximation fails badly in a very simple system. Moreover, by treating the problem fully quantum mechanically, several recent experimental finding [Mitsui et al, Nature 422, 705 (2003)] can be plausibly interpreted as having a fundamentally quantum origin. In particular, we present new ground-state geometry of hydrogen vacancies on Pd(111) surface that are obtained from a full quantum treatment of the hydrogen nuclear motion. This new structures enable us to predict that all vacancy defects to have an unexpected triangular appearance in scanning tunneling microscopy; recent experiments have found precisely this behavior.

**K13 7 Positron annihilation induced Auger electron spectroscopic study of the changes in the top layers of electrodeposited $Cu_2O$ surfaces resulting from vacuum annealing** M. NADESALINGAM, *University of Texas at Arlington* J. ZHU, N. FAZLEEV, S. MUKHERJEE, N. R. DE TACCONI, S. SOMASUNDARAM, C.R. CHENTHAMARAKSHAN, K. RAJESHWAR, A. H. WEISS, Positron Annihilation induced Auger electron Spectroscopy (PAES) and electron stimulated Auger Spectroscopy (EAES) were used to measure changes in the surface of electrodeposited $Cu_2O$ resulting from vacuum annealing. The PAES measurements show a very large increase in the intensity of the Cu MVV Auger peak after annealing at 535 K. Similar but significantly smaller changes were observed in the EAES spectra consistent with the fact that PAES is primarily sensitive to the top-most atomic layer due to the fact that the positrons are trapped just outside the surface prior to annihilation while EAES samples several atomic layers. The PAES and EAES data indicate that vacuum annealing of $Cu_2O$ results in a surface with a high concentration of Cu in the top-most atomic layer. Research supported by the Welch Foundation Y-1100 and NSF DMR 98-12628.

**K13 8 Atomic-scale study of the Rh/$\gamma$-alumina catalytic system** SHUPING ZHUO, *School of Chem. Eng., Shandong Univ. of Tech.* YIPING PENG, *Condensed Matter Sci. Div., ORNL* STEPHEN PENNYCOOK, *Condensed Matter Sci. Div., ORNL* KARL SOHLBERG, *Chem. Dept., Drexel Univ.* Prerequisite to the non-empirical design and refinement of improved heterogeneous catalysts is the identification of the atomic-scale structure and properties of the catalytically active sites. We report an investigation of the Rh/$\gamma$-alumina system, which is representative of many common heterogeneous catalysts that consist of transition metals dispersed on a high surface area support. Previous atomic-resolution Z-contrast STEM observations have shown Rh-containing ''rafts'' on the (100) exposure. This finding is surprising given that the preferred exposure of $\gamma$-alumina is (110). First-principles density functional studies and image simulations suggest that these Rh-containing structures consist of the high-pressure rhodium sesquioxide (II) phase growing on the surface. The high pressure phase of rhodium sesquioxide and $\gamma$-alumina (100) exposure yield improved interface match over the regular rhodium sesquioxide phase and $\gamma$-alumina (110) exposure.

**K13 9 Nature of Versatile Chemisorption on TiC(111) and TiN(111)*** BENGT I LUNDQVIST, CARLO RUBERTO, ALEKSANDRA VOJVODIC, *Department of Applied Physics, Chalmers University of Technology, SE-412 96, Göteborg, Sweden* Extensive density-functional calculations on the polar TiX(111) (X = C, N) surfaces show (i) for the clean surfaces strong Ti3d-derived surface resonances (SR's) at the Fermi level, unlike on the stable TiX(001) surfaces, and X2$p$-derived SR's in the upper valence band, and (ii) for chemisorption of atoms in the first three periods pyramid-shaped trends in atomic adsorption energies Eads, with an extremely strong O-atom bond. The adsorption is

successfully described by a by us proposed concerted-coupling model (CCM), where adsorbate states couple to both kinds of SR's in a concerted way, and which is consistent with trends in the adsorbate-induced DOS and explains the characteristic variations in Eads and in bond lengths, as well as radical differences between TiX(111) and TiX(001), and similarities and small differences between TiC and TiN. The versatility of chemisorption on TiX(111) and the general nature of CCM indicate both ramifications and predictive abilities in, e.g., growth and catalysis.

*Support from the Swedish Research Council and the Swedish Foundation for Strategic Research via the ATOMICS consortium is gratefully acknowledged, as well as allocation of computer time at UNICC (Chalmers) and SNIC (Swed. Nat. Infrastr. for Computing).

**K13 10 Depth Profiling and Interface Analysis by Time-of-Flight Secondary Ion Mass Spectrometry (TOF-SIMS): Potential, Performance and Limitations.** COREY FOSTER, *ION-TOF USA* SVEN KAYSER, THOMAS GREHL, RUDOLF MOELLERS, EWALD NIEHUIS, *ION-TOF GmbH* TOF-SIMS has always been a very sensitive tool for surface spectroscopy and imaging. In recent years TOF-SIMS has improved significantly for traditional dynamic SIMS applications. Operated in the so-called dual-beam mode, where the sample is sputtered with a low energy sputter beam, while the analysis is performed in the center of the sputter crater using a high energy beam, TOF-SIMS provides high-sensitivity depth profiling capabilities comparable to quadrupole or magnetic sector mass spectrometers. Providing parallel mass detection, high mass resolution, advanced charge compensation and 3D imaging capabilities, TOF-SIMS has developed considerable advantages for the characterization of technologically advanced materials. In this study we investigated the depth resolution, detection limits, quantification and reproducibility now available with TOF-SIMS. During this talk we will show examples and applications of TOF-SIMS depth profiling in the field of inorganic materials and compare the depth profiling capabilities of TOF-SIMS instruments with other dynamic SIMS machines.

**16:30**

**K13 11 Insight into the mechanisms of metal ion binding in hexagonal tungsten bronze** SHANE KENNEDY, SUZANNE SMITH, MAXIM AVDEEV, ALEX FUCHS, *Bragg Institute and Institute of Materials Engineering Science, Australian Nuclear Science and Technology Organisation, Lucas Heights, NSW, Australia* Tungsten trioxides and their alkali-metal-intercalated products $M_zWO_{3+}$ show potential for application in electrodes, as ion exchangers, catalysts and the treatment of radioactive waste. Hexagonal tungsten bronze (HTB) was selected for the present work because its structure features hexagonal channels, of diameter $\sim$ 0.54 nm, that may be useful for selective and reversible binding of metal ions. X-ray and neutron powder diffraction were used to provide an insight into the mechanisms of metal ion binding of the Mo doped HTB's. Combined Rietveld refinement of the X-ray and neutron diffraction shows that doping with Mo degrades the crystallinity of HTB, in particular by creating a high degree of disorder in the a-b planes. Structural information combined with solution chemistry indicates several potential mechanisms of binding and metal ion exchange sites. This type of investigation provides invaluable information for new strategies in the design of inorganic sorbents and their optimization for metal ion separation.

**16:42**

**K13 12 Adsorption of NO on Rh(111) studied by STM.** J.H.A. HAGELAAR, *Eindhoven University of Technology* C.F.J. FLIPSE, The ability of Rhodium to efficiently dissociate NO makes it the most suitable metal for the removal of nitrogen oxides from automotive exhaust gasses in catalytic converters. Using a STM, the adsorption of NO on Rh(111) was studied in ultra high vacuum. First, the NO is adsorbed at T=200 K, giving rise to two structures with coverages of 0.5 ML and 0.75 ML. These structures differ from the 0.5 ML (4x2)-2NO and 0.75 ML (2x2)-3NO structures found in literature. Once a structure was obtained, the sample was cooled down to 4.8K to perform inelastic electron tunneling spectroscopy (IETS) on the individual molecules within the structure. The molecules in the 0.5 ML structure showed a significant shift in the NO-stretch frequency compared to the expected frequency of 1600 $cm^{-1}$. These results will be presented and discussed in detail.

**16:54**

**K13 13 Picosecond real time observation of low energy electron scattering from large molecules on surfaces** CLAUDIO CIRELLI, *Physik Institut, Universitaet Zuerich, CH-8057, Switzerland and Physikalisch-Chemisches Institut, JL-Universitaet, D-35392 Giessen, Germany* MATTHIAS HENGSBERGER, ANDREI DOLOCAN, JUERG OSTERWALDER, THOMAS GREBER, *Physik Institut, Universitaet of Zuerich, CH-8057, Switzerland* HERBERT OVER, *Physikalisch-Chemisches Institut, J.L. Universitaet, D-35392 Giessen, Germany* In order to observe in real time structural changes of molecules, it is necessary to develop a technique providing both nanometer and picosecond resolution. This task is tackled with a time resolved Low Energy Electron Diffraction (LEED) experiment in a pump-probe scheme. The pump pulses are 800 nm 100 fs laser light pulses and the probe 60eV energy electron pulses. Using a novel electron gun with a measured energy resolution of 0.7eV at 100eV, we observe transient changes in the differential scattering cross section and an energy shift of the diffracted LEED spot up to about 250meV. As this energy shift is pump fluence dependent, we can assign it to the onset of a space charge effect created by the pump beam on the sample surface. Conclusions about surface space charge and molecular dynamics can be drawn by tracking this effect on the picosecond timescale. Results on the response of the bare Cu(111) surface and of $C_{60}$/Cu(111) will be presented. [1] A. Dolocan et al., Jap. J. Appl. Phys. 45 (2006)

## SESSION K16: FOCUS SESSION: MOLECULAR-SCALE ELECTRONICS II

**K16 1 Inelastic scattering effects on single molecule spectroscopy: Consequences for Negative Differential Resistance** JASON PITTERS, *National Institute for Nanotechnology - NRC* ROBERT WOLKOW, *University of Alberta* The adsorption of styrene and cyclopentene on Si(100) has been studied with scanning tunneling microscopy and spectroscopy. Blinking of mol-

ecules in images and irregularities in current-voltage spectra and in current-time traces are analyzed. It is also shown that NDR-like features in IV spectra of both styrene and cyclopentene molecules are not consistently present. Such erratic behavior cannot be accounted for by voltage controlled resonant alignment of adsorbate and substrate energy levels but is consistent with random configuration change driven by inelastically scattered electrons. These random processes, which include molecular rearrangement, desorption and/or decomposition occur with increasing frequency at larger voltage and current settings. It is concluded that the molecules studied do not exhibit negative differential resistance due to a resonant tunneling mechanism. Conditions where resonant NDR may be observed are discussed.

**14:42**
**K16 2 Calculations of the structural, electronic and transport properties of self-assembled monolayers of porphyrins on the Si(001) surface** FILIPE J. RIBEIRO, W. LU, J. BERNHOLC, *North Carolina State University* Self-assembled monolayers (SAMs) of organic molecules on surfaces have very promising technological applications. The oxidation states of porphyrins are currently being explored to store charge in a controllable way, aiming at the development of multi-state molecular memories. We present the results of theoretical calculations on the structural, electronic and transport properties of chemisorbed porphyrins on a hydrogen-passivated Si(001) surface. Density-functional calculations were performed to optimize the structural parameters of the adsorbed porphyrins using a real-space multi-grid approach. Electron transport properties for a porphyrin molecule attached to two Si(001) leads were calculated using a non-equilibrium Green's function method in a basis of optimally localized orbitals. Our results show that the current, negligible at low voltages, exhibits a very strong non-linear behavior for bias voltages above 1.5 V, including multiple regions of negative differential resistance (NDR). The multiple NDRs may lead to multi-state molecular devices.

**14:54**
**K16 3 Theory of molecular hysteresis switch** MORTKO KOZHUSHNER, *Institute of Chemical Physics, RAS* IVAN OLEYNIK, *University of South Florida* Molecular hysteresis switching has been recently observed in a series of experiments that measured the I-V spectrum of bipyridyl-dinitro oligophenylene-ethylene dithiol (BPDN) based molecular devices [1]. The experimental observations clearly show the presence of Coulomb blockade in single organic molecules that is responsible for the voltage-induced switching. We present the theory of the hysteresis switch which explains the non-linear hysteresis I-V characteristics based on the mechanisms of Coulomb blockade and the existence of two different molecular conformations of neutral and charged states of the molecule. **K16 4 Theory of Molecular Electron Transport.**
SHASHI KARNA, *US Army Research Laboratory*

Thanks to the curiosity and devoted research of physicists and chemists over the past century and a half, electron transport in extended system has been a well understood phenomenon and has lead to today's all pervasive, monolithic, microelectronics technology. However, despite intense interest and ensuing research since the 1950s, an understanding of electron transport in confined systems, such as molecules and nano-scale atomic particles, remains limited. In this talk, I shall present an overview of our current understanding of the physics and chemistry of electron transport in molecules and at the molecule-solid interface. The effect of electronic structure, chemical bonding, physical dimension, stereochemistry, and external perturbation on molecular electron transport will be discussed.

**K16 5 Electrical and structural switching in [2] rotaxane molecular electronic devices** YONG-HOON KIM, *Korea Institute for Advanced Study* WILLIAM A. GODDARD III, *California Institute of Technology* In the effort to identify good candidates of molecular electronics, two-families of redox-controllable mechanically interlocked supramolecular complexes – bistable catenanes and bistable rotaxanes – have attracted much attention. Carrying out large-scale first-principles matrix Green function calculations combined with classical force-field molecular dynamics simulations, we study the charge transport properties of a monolayer of full (including stoppers) bistable rotaxane molecules in their realistic folded conformations. We will discuss (i) the universal nature of the identified switching mechanism in comparison with the [2] catenane device, (ii) the robustness of the switching signal with respect to thermal fluctuations, and (iii) the nature of molecule-electrode barriers that play an important role in inducing a structural switching between the bistable conformations of the molecule, a precondition of observing the electrical switching.

**15:54**
**K16 6 Low temperature transport study of the nitro molecules** NABANITA MAJUMDAR, Z. MARTIN, N. SWAMI, L. HARRIOTT, *University of Virginia* Y. YAO, J. TOUR, *Rice University* D. LONG, R. SHASHIDHAR, *Geo Center R&D Center* Various research groups, including ours, have observed switching with memory behavior at room temperature from a monolayer of oligo(phenylene ethynylene) (OPE) molecules with a nitro sidegroup.[1,2] This switching behavior has the potential to be used in molecular electronic devices. However, the transport mechanisms of this ''nitro'' molecule are not well understood. Understanding the transport mechanisms of the nitro molecules may help identify the underlying cause of the switching behavior. We performed a systematic study of the transport characteristics of OPE molecules

with and without a nitro side group in our nanowell test device[3] at various temperatures between 60K and 300K. We observed non-switching exponential current-voltage characteristics from OPEs without the nitro side group. The mechanism of transport was determined to be hopping with a transport barrier of 0.03± .01 V between 100K to 300K. Switching with memory behavior as well as non-switching exponential I-V characteristics were observed from the nitro molecules at various temperatures. The transport mechanism in switching devices was determined to be hopping with an activation barrier of 0.26± .08 V between 200K and 300K. However, a significantly lower activation barrier similar to that of OPEs without a nitro group was estimated for the nitro molecule devices that did not show any switching behavior.

**16:06**

**K16 7 Theoretical Study of Spin-Polarized Electron Tunneling via $C_{60}$ Molecules** HAIYING HE, RAVINDRA PANDEY, *Department of Physics, Michigan Technological University, Houghton, MI 49931* SHASHI KARNA, *US Army Research Laboratory, Weapons and Materials Directorate, Aberdeen Proving Ground, MD 21005-5069* The controlled injection and transport of spin-polarized electrons through organic molecules has drawn increasing attention in recent years due to its potential applications in molecular and molecular-nano hybrid electronics and sensors. In this talk, we will present the results of a theoretical study of spin-polarized electron tunneling via $C_{60}$ molecules in contact with ferromagnetic nickel electrodes. In this system, the resistance varies as the magnetic moments in the two electrodes are tuned from parallel to anti-parallel alignment. Particular attention is given to the chemical bonding features in the molecule-electrode interface, which leads to the observed difference in magnetoresistance.

**16:18**

**K16 8 Is Electron Transport In Boron Nanotube Ballistic?** KAH CHUN LAU, RANJIT PATI, RAVINDRA PANDEY, *Department of Physics, Michigan Technological University, Houghton, MI* SHASHI P. KARNA, *US Army Research Laboratory, Weapons and Materials Research Directorate, ATTN: AMSRD-ARL-WM, Aberdeen Proving Ground, MD 21005-5069* The electron transport in single-walled boron nanotube is studied using the Landauer-Buttiker multi-channel approach in conjunction with the tight-binding method. The calculated results predict a ballistic transport in boron nanotubes, with a relatively lower resistances as compared to that of a single-walled carbon nanotube. The electron-deficient character in bonding of elemental boron may be attributed to its higher conductivity.

**16:30**

**K16 9 Active Transport Orbitals in Electron Propagator Calculations on Molecular Wires.** YURI DAHNOVSKY, *Department of Physcs & Astronomy, University of Wyoming* V.G. ZAKRZEWSKI, *Department of Chemistry, Kansas State University* ALEXEY KLETSOV, *Department of Electrical Engineering, University of Wyoming* J.V. ORTIZ, *Department of Chemistry, Kansas State University* YURI DAHNOVSKY AND ALEXEY KLETSOV COLLABORATION, V. J. ORTIZ AND V. G. ZAKRZEWSKI COLLABORATION, Ab initio electron propagator methodology may be applied to the calculation of electrical current through a molecular wire. A new theoretical approach is developed for the calculation of the retarded and advanced Green functions in terms of the electron propagator matrix for the bridge molecule. The calculation of the current requires integration in a complex half-plane for a trace that involves terminal and Green function matrices. Because the Green function matrices have complex poles represented by matrices, a special scheme is developed to express these ''matrix poles'' in terms of ordinary poles. An expression for the current is derived for a terminal matrix of arbitrary rank. For multi-terminal terminals, the analytical expression for the current is given in terms of pole strengths, poles and terminal matrix elements of the electron propagator. It is shown that Dyson orbitals with high pole strengths and overlaps with terminal orbitals are most responsible for conduction of electrical current.

**16:42**

**K16 10 Electron Propagator Calculations on Molecular Wires.** J.V. ORTIZ, V.G. ZAKRZEWSKI, *Department of Chemistry, Kansas State University, 111 Willard Hall, Manhattan, KS 66506-3701* ALEXEY KLETSOV, *Department of Electrical Engineering, University of Wyoming, 1000 E. University Avenue, Laramie, WY 82071* YURI DAHNOVSKY, *Department of Physics & Astronomy/3905, University of Wyoming, 1000 E. University Avenue, Laramie, WY 82071* J. V. ORTIZ AND V. G. ZAKRZEWSKI COLLABORATION, YURI DAHNOVSKY AND ALEXEY KLETSOV COLLABORATION, Several molecular wires are studied by an itelectron propagator method using a non-self-consistent formalism for the calculation of Keldysh functions. This approach is based on diagrammatic approximations for describing electron correlation in a bridge molecule that have been successful in the itab initio determination of electron binding energies. In this work, we compute nonequilibrium Keldysh functions in order to find the dependence of current on applied voltage for particular molecular wires. Quantum chemical calculations are performed for several molecular bridges and require additional computational method development of established electron propagator techniques. The extended molecule approach is adopted. Results are compared with experimental data and other quantum chemical approaches, especially those based on density functional theory.

**16:54**

**K16 11 Molecular conductance at finite voltage: bias driven evolution of Kohn-Sham-orbitals** MAX KOENTOPP, *Rutgers University, Department of Chemistry* FERDINAND EVERS, *Institute of Nanotechnology, Research Center Karlsruhe, Germany* KIERON BURKE, *Rutgers University, Department of Chemistry* Ground state density functional theory calculations yield the exact electron density if the exact exchange-correlation functional is employed. The evolution of the equilibrium density with parametric changes in the Hamiltonian, e.g. realized by a change in the electrostatic potential, can provide crucial information about transport properties, like the Coulomb blockade. To test our ideas, we perform model calculations using the quantum chemistry package TURBOMOLE for a diode molecule, which exhibits the structure of a double quantum dot and has been investigated experimentally [1]. In particular, we explain the origin of the characteristic peak structure in the differential conductance. Our results are consistent with the interpretation that the stepwise increase of the conductance occurs when the number of occupied levels of one of the dots, that have an energy above the lowest unoccupied level of the other dot, increases by one. [1] M. Elbing, R. Ochs, M. Koentopp, M. Fischer, C. von Hänisch, F. Weigend, F. Evers, H. Weber, M. Mayor, Proc. Nat. Acad. Sci. USA **102**, 8815 (2005).

**14:30**
**K17 1 Dynamic studies of the growth of Si and Ge nanostructures.**
FRANCES ROSS, *IBM TJ Watson Research Center*

By making observations in real time during the growth of nanostructures, it is possible to obtain kinetic data which help us to determine the physical phenomena controlling growth. In this presentation we will describe the growth of Si and Ge nanowires by the vapour-liquid-solid process. Observations were made in a transmission electron microscope during ultra high vacuum chemical vapour deposition of Si and Ge onto substrates covered by Au catalyst. We will show that wire length and diameter are controlled by the diffusion of the catalyst along the wire surfaces, and that this diffusion is driven by a coarsening process. We will compare nanowire growth with the formation of Ge quantum dots by self-assembly during strained layer epitaxy, in which surface diffusion of Ge driven by coarsening also plays an essential role in controlling the structures formed. We will describe spontaneous roughening of Si and Ge nanowire surfaces, a phenomenon which may have analogues in the formation of surface roughness in SiGe alloy thin films. We will finally discuss the control of wire structure for the fabrication of novel devices.

**15:06**
**K17 2 Silicon nanostructures grown by solid phase epitaxy** PETER HADLEY, *Kavli Institute, TU Delft* YANN CIVALE, *DIMES, TU Delft* LIS NANVER, *DIMES, TU Delft* Silicon nanocrystals can be grown by depositing amorphous silicon (a-Si) on a thin metal layer and then annealing this bilayer. The silicon diffuses through the metal and forms crystals at the metal substrate interface in a process called solid phase epitaxy (SPE). This process has been investigated for many metals (Au, Al, Pd, Ni, Cr, Fe, Co, Ti, V, Rh) and it is observed that the temperature where the significant diffusion takes place is roughly half the eutectic temperature for metals that form a eutectic composition with silicon and it is roughly half the melting temperature for the metals that form a silicide. Using this process, it is possible to deposit crystalline silicon at low temperature. In the past, uniform metal/a-Si bilayers were used. Here we describe experiments where contact windows were opened through silicon oxide before the bilayer was deposited and the metal was patterned before the annealing step. This results in the selective deposition of the silicon crystals. Devices made by this process will be described.

**15:18**
**K17 3 Patterning of Ge nanoparticles by focused electron beam*** NAN JIANG, *Department of Physics, Arizona State University* We demonstrate that Ge nano-particles can be precipitated in $GeO_2$ and $GeO_2$-$SiO_2$ efficiently by the high-energy focused electron beam. The dynamic process of nanoparticle precipitations in these oxides were observed from the TEM images in real time, and analyzed using time-resolved electron energy loss spectroscopy (TREELS). The composition and structure of the precipitated nanoparticles were determined using both high-spatial resolution EELS and diffraction techniques. It was found that the particles are pure Ge and the average size increases slightly with the irradiation time. The dependences of size of nanoparticles on dose and dose rate of electron beam were also statistically analyzed, which is important to optimize experimental conditions to control the size of patterned nanoparticles. The mechanism involving the nucleation and growth process on surfaces is responsible for the precipitation of Ge in $GeO_2$. This was obtained through the thickness dependence of precipitation process. The patterned nanoparticles were then fabricated using the scanning (STEM) mode in a single step process. We noted that the production of Ge nanoparticles using this method is impressively efficient; less than a second is needed to create a large assembly of nanoparticles simultaneously under parallel illumination mode in TEM. Using the focused electron probe, a single particles can be formed within several tens milliseconds.

**K17 4 Near-infrared photoluminescence of germanium nanocrystal synthesized in inverse micelle** ZHIFENG REN, *Boston College* WENZHONG WANG, *Boston College* KEDA WANG, *Boston College* DAXING WANG, *Boston College* In this work we study photoluminescence (PL) properties of Ge nanocrystals prepared via a low-temperature inverse micelle solvothermal route. The as-prepared nanocrystals have an average diameter of $\sim$ 24 nm. Visible- and near-IR PL is observed from the pure nc-Ge samples at room temperature. We present the PL results in the near-IR range. The PL was excited using either 488-nm or 632-nm laser lines. The luminescence signal was dispersed by a grating monochromator and then collected by a liquid-nitrogen cooled Ge detector. The lock-in technique was used with a light chopper at a frequency of 17 Hz. We found two peaks located at $\sim$ 1.37 eV (905 nm) and $\sim$ 1.45 eV (855 nm). Those are within the wavelength range for optical communications. Upon oxidation the relative intensity of the 1.45 eV peak was enhanced. And then the intensity decreased after hydrogen annealing. Meanwhile, the changes of 1.37 eV peak is negligible upon either oxidation or

hydrogen annealing. The origination of the near-IR luminescence peaks is discussed. The 1.45 eV peak is more likely related with the surface states of the nc-Ge particles; while, the 1.37 eV peak is more likely originated from the bulk of the nc-Ge.

**15:42**
**K17 5 Strain driven organization of SiGe islands on ultra-thin Si cantilevers*** CLARK S. RITZ, *University of Wisconsin, Madison* FRANK S. FLACK, MICHELLE M. ROBERTS, DONALD E. SAVAGE, MAX G. LAGALLY, Silicon/germanium 3-D islands have long been studied, both to improve understanding of growth mechanisms in strained epitaxial films and for potential applications as quantum dots (QDs). Self assembly of these QDs into ordered arrays is technologically important, and has been partially achieved through various forms of substrate strain patterning. We experimentally study the effects of substrate local compliancy on the organization of epitaxially grown Ge and Si(1-x)Ge(x) QDs. We form the QDs through the Stranski-Krastanov growth mode on single-crystal ultra-thin Si cantilevers with thicknesses on the order of 20nm. Films are deposited using molecular beam epitaxy and ultra-high vacuum chemical-vapor deposition (CVD) to grow islands on one or both sides of the cantilevers, respectively. Both types of samples show QD ordering along cantilever edges; however, CVD-grown films exhibit additional ordering. Angled SEM imaging shows a strong anti-correlation between the positions of islands grown on the top and bottom faces of the cantilevers. The crystallographic orientation of the cantilevers also plays a role, as islands order better when edges are aligned along [100] (the soft elastic direction). Results will be interpreted in the context of continuum elasticity theory.

**K17 6 Controlled Movement of SiGe/Si Microtubes in Suspension** MINRUI YU, ROBERT BLICK, *Department of Electrical and Computer Engineering, University of Wisconsin-Madison* Microtubes are potential vehicles for chemical or drug delivery. By applying electric potentials on specially arranged electrodes, SiGe/Si microtubes suspended in liquids are moved in a controllable fashion to designated positions. Such manipulation mechanism is also applicable to smaller entities such as nanotubes.

**16:06**
**K17 7 Field Emission from a Nanomechanical Pillar*** HYUN KIM, HUA QIN, ROBERT BLICK, *Laboratory for Molecular Scale Engineering, Electrical and Computer Engineering, University of Wisconsin-Madison* MICHAEL WESTPHALL, LLOYD SMITH, *Department of Chemistry, University of Wisconsin-Madison* We have measured the field emission in a nano-electromechanical structure in which a nanometre silicon pillar oscillates in between the source and drain electrodes. The device consists out of a mechanically flexible pillar with a length of some 200 nm and a diameter of some 50 nm and allows for mechanical resonant excitations at radio frequencies (10 $\sim$ 1000 MHz) and mechanical clocking of the field emitted electrons. Operation of the device at room temperature in the frequency range of 300 $\sim$ 400 MHz is presented. For AC and DC drive, the current shows a rich frequency dependent response. A modified Fowler-Nordheim field emission curve is observed and attributed to the effect of oscillating pillar excited by an alternating electric field.

**K17 8 Silicon Nanowire Devices.**
THEODORE KAMINS, *Quantum Science Research, Hewlett-Packard Laboratories, Palo Alto CA 94304*

Metal-catalyzed, self-assembled, one-dimensional semiconductor nanowires are being considered as possible device elements to augment and supplant conventional electronics and to extend the use of CMOS beyond the physical and economic limits of conventional technology. Such nanowires can create nanostructures without the complexity and cost of extremely fine scale lithography. The well-known and controllable properties of silicon make silicon nanowires especially attractive. Easy integration with conventional electronics will aid their acceptance and incorporation. For example, connections can be formed to both ends of a nanowire by growing it laterally from a vertical surface formed by etching the top silicon layer of a silicon-on-insulator structure into isolated electrodes. Field-effect structures are one class of devices that can be readily built in silicon nanowires. Because the ratio of surface to volume in a thin nanowire is high, conduction through the nanowire is very sensitive to surface conditions, making it effective as the channel of a field-effect transistor or as the transducing element of a gas or chemical sensor. As the nanowire diameter decreases, a greater fraction of the mobile charge can be modulated by a given external charge, increasing the sensitivity. Having the gate of a nanowire transistor completely surround the nanowire also enhances the sensitivity. For a field-effect sensor to be effective, the charge must be physically close to the nanowire so that the majority of the compensating charge is induced in the nanowire and so that ions in solution do not screen the charge. Because only induced charge is being sensed, a coating that selectively binds the target species should be added to the nanowire surface to distinguish between different species in the analyte. The nanowire work at Hewlett-Packard Laboratories was supported in part by the Defense Advanced Research Projects Agency.

**K17 9 Carrier transport in Ge nanowires / Si substrate heterojunction** E.-K. LEE, B. KAMENEV, L. TSYBESKOV, *New Jersey Institute of Technology* S. SHARMA, T.I. KAMINS, *Hewlett-Packard Laboratories* Semiconductor nanowires (NWs) attached to lattice-mismatched single-crystal substrates form quasi-one-dimensional (QOD) heterojunctions (HJs) where efficient structural relaxation might occur due to high surface-to-volume ratio. Current-voltage characteristics in Ge NW/(p+)Si samples with nearly micron-long Ge NWs exhibit metal-type conductivity with ohmic behavior and little conductivity temperature dependence. In contrast, Ge NW/(n+)Si samples display significant change in conductivity as a function of temperature with an activation energy up to 200 meV. In a narrow temperature interval near 150 K we observed current instabilities and oscillations for Ge NW/(n+)Si. At higher temperatures we find negative differential photoconductivity at low forward biases. Our experimental results are explained using a model of nearly ideal Si substrate/Ge NW hetero-interfaces.

**K17 10 A theoretical study of Si and Ge nanowires.** A. FAZZIO, J. T. ARANTES, CEDRIC ROCHA LEÃO, ANTÔNIO J. R. DA SILVA, *Instituto de Física, Universidade de São Paulo* We have performed a systematical itab initio study of the electronic and structural properties of pure Ge and Si nanowires (NWs), as well as Ge nanowires doped with Mn atoms. All our results are obtained via total energy Density Functional Theory (DFT) calculations within the generalized gradient approximation and pseudopotentials. The growth directions for all wires were considered to be along the (110) direction, and they present a hexagonal cross section formed by the intersection of <111> and <001> planes, with all the dangling bonds saturated with H atoms. We have considered three different diameters of SiNW's of similar shapes: 2.01 nm, 2.67 nm e 3.61 nm. In particular, we analyze how their properties, such as dispersion relations, band gaps and structural properties, like nearest neighbor distances, vary with the diameter. Similar calculations were also performed for the Ge NWs. In this latter case we have also investigated Mn doping. We focused on tetrahedral interstitial and substitutional sites, and conclude that the most stable position for Mn is substitutional at the surface of the nanowire.

**K17 11 Single-hole tunneling and Coulomb blockade in the strain-relaxation-induced quantum ring** GUOHUA WANG, D. TAMBE, A. ZASLAVSKY, V. SHENOY, *Department of Physics and Division of Engineering, Brown University* D. SYPHERS, *Physics Department, Bowdoin College* We fabricated an ultrasmall Si/SiGe strained vertical quantum dot in the Coulomb blockade regime, where strain relaxation in the SiGe quantum well creates a ring-like confinement potential. [1] The resonant tunneling characteristics contains features near the threshold due to single-hole tunneling and Coulomb blockade. The features are steps in one bias polarity and peaks in the other, which we attribute to the differences in the dynamic occupation of the dot due to double Si barrier asymmetry. The spacing of the features gives the charging energy of the quantum ring. When magnetic fields are applied parallel to the tunneling direction, the evolution of the single-hole tunneling features with magnetic fields reveals cusps arising from the angular-momentum transition of the single-particle ground state of the quantum ring in the magnetic field, and the periodicity of the cusps in magnetic field is consistent with the calculated one from h/e, the magnetic flux quantum. Unlike single-carrier tunneling into quantum dots, our data on the tunneling into a quantum ring show no evidence of a singlet-triplet transition. [1] J. Liu et al, Phys. Rev. Lett. 89, 096804 (2002).

**K18 1 Stimuli Responses of Topology-Controlled Polymer Networks and Liquid Crystalline Gels.**
KENJI URAYAMA, *Kyoto University*

In this talk I will present and discuss the stimulus-response relationships of topology-controlled polymer networks and liquid crystalline gels. I will assess several modern entanglement theories of rubber elasticity on the basis of the multi-axial stress-strain data of end-linked polydimethylsiloxane (PDMS) networks with well-characterized structures. The dynamics of guest linear PDMS in host PDMS networks will also been discussed as a function of mesh size and molecular mass of guest chains. I will also demonstrate the highly extensible or damping elastomers of PDMS by simply controlling the topological characteristics such as the conformation of network chains, the amount of trapped entanglement and pendant chain. Furthermore, I will present the volume transition accompanying the shape variation induced by nematic-isotropic transition in liquid crystalline gels. I will also reveal the electrically-driven deformation coupled to director rotation in nematic gels.

**K18 2 Self-Assembly of Magnetic Particles into Polymer Chains and Networks** JACK DOUGLAS, *Polymers Division, NIST* WOLFGANG LOSERT, JUSTIN STAMBAUGH, *Department of Physics, University of Maryland* KEVIN VAN WORKUM, *Polymers Division, NIST* The increasing demand to manufacture structures at the nanoscale has made it necessary to pursue new fabrication strategies based on self-assembly. Although it is generally appreciated that this type of ordering process relies on the interplay of directional and isotropic interactions to guide the organization process, the theoretical principles governing this process remain uncertain. There is clearly a need for the development of itreal model systems exhibiting self-assembly and for their intensive investigation by experimental and simulation studies, in conjunction with analytic modeling. Since particle size is not an intrinsic limitation in this type of study, we investigate the self-assembly of vertically vibrated magnetic 'beads' (spheres with embedded magnets) into dynamic polymer chains where the effective temperature of the fluid is determined by the shaking velocity. Self-assembly is assumed to be described by equilibrium polymerization and we perform Monte Carlo simulations for this model fluid at thermodynamic equilibrium. The experiments, simulations and analytic calculations lead to a self-consistent description of the self-assembly process in this fluid. We regulate polymer branching by adding beads having relatively short embedded magnets that are characterized by appreciable itmultipoleinteractions in addition to the dipole interaction.

**K18 3 Electrical Properties of Poly(ethylene oxide)-based Ionomers as Single Ion Conductors** RALPH H. COLBY, SHICHEN DOU, SHIHAI ZHANG, ROBERT J. KLEIN, JAMES P. RUNT, KARL T. MUELLER, *Materials Research Institute, Pennsylvania State University* Polyethers, such as poly(ethylene oxide) (PEO) are of interest for development of advanced lithium batteries because $Li^+$ ions have facile transport in this media. We make ionomers based on PEO by reacting poly(ethylene glycol) (PEG) oligomers with the sodium salt of dimethyl 5-sulfoisophthalate. Since the sulfonate group is covalently bonded to the chain, it is essentially immobile and hence these materials are single-ion conductors. The charge spacing on the chain can be directly controlled by the molar mass of the PEG oligomers (we use M = 400, 600 and 900) used in the synthesis. Conductivity depends strongly on temperature, with nearly identical conductivities in all of our samples at the same $T - T_g$, suggesting that $Li^+$ ion transport is controlled by segmental motion of the PEO. Using the onset of electrode polarization (usually considered a nuisance in dielectric spectroscopy) we quantitatively estimate the free ion concentration and mobility, based on work of MacDonald (1952 & 1974) and Coelho (1983 & 1991). The temperature dependence of the free ion concentration is described by a simple pairing energy, which decreases in going from $Li^+$ to $Na^+$ to $Cs^+$, consistent with larger ions being less strongly bound to the sulfonate groups. The ion mobility shows a Vogel-Fulcher temperature dependence, as anticipated by the polymer's segmental motion controlling ion mobility.

**K18 4 Rheological Properties of Nanotube – Polymer Nanocomposites** RAMANAN KRISHNAMOORTI, TIRTHA CHATTERJEE, *University of Houston* Single walled carbon nanotubes represent the next generation of nanoparticles for the development of polymer nanocomposite materials with potential in multifunctional applications. We have successfully dispersed such SWNTs in various polymer nanocomposites and have recently examined the linear and non-linear viscoelastic measurements. The nanocomposites in the melt state of the polymer demonstrate solid – like behavior beyond a percolation threshold, which in many of these nanocomposites is below 0.1 wt % SWNT. The plateau modulus (corresponding to the stress supported by the percolated nanoparticle network structure) scales as the volume fraction of the SWNTs to the third power and inconsistent with current fractal models. The onset of the non-linear behavior occurs at progressively lower strain values with increasing SWNT concentration and is similar to other filled polymers. Interestingly the recovery of the polymer network following large strain is extremely slow and is similar to materials that are classified as soft- glassy materials.

**K18 5 Non-Newtonian Behavior of Diblock and Triblock Copolymer Solutions** HIROSHI WATANABE, *ICR, Kyoto University* Non-Newtonian flow behavior was examined for butadiene-styrene (BS) diblock and BSB triblock copolymers dissolved in a S-selective solvent, dibutyl phthalate (DBP). Spherical domains of the non-solvated B blocks were arranged on a bcc lattice in both solutions at equilibrium, as revealed from SANS. The solutions exhibited significant thinning under steady flow, which was well correlated with the disruption of the bcc lattice detected with SANS. The lattice disruption was most prominent at a shear rate comparable to the frequency of B/S concentration fluctuation. For the BS/DBP solution, the recovery of the lattice structure after cessation of flow was the slowest for the most heavily disrupted lattice, as naturally expected. In contrast, for the BSB/DBP solution, the recovery rate was insensitive to the magnitude of lattice disruption. This peculiar behavior of the BSB solution suggests that the rate-determining step of the recovery in this solution is the transient B/S mixing required for reformation of the S bridges connecting the B domains.

**K18 6 Arm Retraction of Star and Dangling Polymers in the Absence of Dynamic Dilution** DANIEL A. VEGA, *Department of Physics. Universidad Nacional del Sur. CONICET. Argentina* The dynamic response of model polymer networks containing low contents of star shaped and linear dangling polymers was studied through stress relaxation experiments. As compared with their melts, the behavior of star and dangling polymers leads to a dynamic response with unprecedented large relaxation times. By comparing data of star melts with those corresponding to stars and dangling chains residing in polymer networks, the effects of dynamic dilution were clearly identified. Since in polymer networks the dynamic dilution effect is suppressed, we were able to experimentally test the validity of the potential for arm retraction proposed by Pearson and Helfand.

**K18 7 Consequences of Switchable Solvent Quality on the Self-Assembly of Block Copolymers in a Nematic Liquid Crystal**

**Solvent** JULIA KORNFIELD, The microstructure of a diblock copolymer having a coil and liquid crystalline blocks dissolved in liquid crystal (LC) solvent is exceptionally sensitive to changes in the LC order; the quality of the solvent changes discontinuously across the LC phase transitions. This ''switchable solvent quality'' manifests itself in the nanostructure and rheology of solutions of AB diblocks with a polystyrene (PS) block (''coil'' type) and a side-group liquid crystalline polymer block (SGLCP) dissolved in the LC solvent 5CB. The nematic order of the solvent presents a large entropic penalty to solvation of the PS block, but in the isotropic phase it is a good solvent for PS. The SGLCP is soluble in both the nematic and isotropic phases. In these block copolymers, the LC solvent switches from being strongly selective toward the SGLCP block to being a good solvent for both blocks at the isotropization point. Pairwise thermodynamic interactions between the LC solvent, PS, and the SGLCP are inferred from the ternary phase diagram of homopolymer solutions in 5CB. In the nematic phase, unfavorable 5CB-PS interactions dominate at all concentrations. In the isotropic phase, segregation occurs even though 5CB is a good solvent for both blocks driven by either the slight preference of isotropic 5CB for SGLCP at $c < c^*$ or SGLCP-PS interactions at $c > c^*$.

**K18 8 Swelling and Elasticity of Entangled Polymer Networks** MICHAEL RUBINSTEIN, *University of North Carolina* JONATHAN CAMPBELL, *Massachusetts Institute of Technology* SERGEY PANYUKOV, *Russian Academy of Sciences* We develop and solve a molecular model for nonlinear elasticity of entangled polymer networks, called non-affine slip-tube model. Each chain passes through a sequence of slip-links. The topological constraints imposed by neighboring network chains on a given one are represented by the confining potential acting on the slip-links. This topological potential restricts fluctuations of the network chains to the non-affinely deformed confining tube and changes upon network deformation. The non-affine tube model puts softer restriction on swelling gels, leading to larger equilibrium swelling ratio. It also predicts that weakly-entangled networks initially swell following the dependencies of entangled gels, but as soon as affine length reaches the size of network strand, further swelling is described by unentangled gel relations. The non-affine tube model predicts stronger concentration dependence of elastic modulus, $G$, than affine model, as well as weaker dependence of $G$ on preparation concentration. The non-affine tube model also predicts a cross-over at the preparation condition to a much stronger concentration dependence of elastic modulus, $G$, upon de-swelling and weaker dependence of $G$ on preparation concentration.

**K18 9 Electric Field Response of Electroclinic Liquid Crystal Elastomers** BANAHALLI RATNA, *Naval Research Laboratory* CHRISTOPHER SPILLMANN, JAWAD NACIRI, Supramolecular ordered assemblies such as liquid crystal elastomers provide an excellent framework for incorporating anisotropy as well as functionalities in materials that respond to external stimuli. Electroclinic Liquid Crystal Elastomers (ELCEs) are of particular interest due to their ability to exhibit linear actuation under an applied voltage. The crosslinked elastomer network consists of chiral liquid crystal mesogens attached to a polymer backbone and exhibiting a chiral smectic A phase with large field induced tilt angle. The response of these materials to electric field and their mechanical properties will be discussed.

**K18 10 Brownian dynamic simulations of electrophoresis and electro-stretching of DNA molecules in polymer gels.** RONALD LARSON, *University of Michigan* RICHARD GRAHAM, *University of Leeds* We derive a model for the motion of long DNA chains entangled in a concentrated gel matrix in the presence of a strong electric field. The model is adapted from a tube-based slip-link approach, which was originally intended to model the rheology of entangled polymer fluids, and is suitable for solution by Brownian dynamic simulation. We account for the constraining effect of the surrounding matrix, motion due to the electric field and finite extensibility of the DNA chain. We are able investigate the effect of molecular weight and field strength on the DNA drift velocity in a constant electric field, along with molecular stretching in an oscillating field. Both examples have applications in DNA separation and sequencing. Our approach includes a detailed treatment of the chain end motion through the matrix, which our simulations demonstrate has a significant role in the DNA dynamics, particularly in oscillating fields. The model provides a convenient formalism for further refinements. For example, large fields may tend to cause hernia-like chain loops to protrude from the main tube. Furthermore, to model matrices comprised of linear polymers we can include the effect of constraint release, in which the confinement experienced by the DNA is diminished by the motion of the matrix chains.

**16:54**

**K18 11 Diffusion and Equilibration in Surfactant-Bearing Interfaces** NITASH BALSARA, BENEDICT REYNOLDS, MEGAN RUEGG, CLAYTON RADKE, *University of California, Berkeley* The efficacy of surfactants for stabilizing interfaces between immiscible fluids depends on both thermodynamic and dynamic effects. Dynamic effects are especially important when the fluids are immiscible high molecular weight polymers. Block copolymers are used to stabilize interfaces between immiscible polymers. The chain-like character of polymers leads to molecular entanglement, which leads to extremely slow dynamics. We have prepared two surfactant-bearing polymeric interfaces that are initially out of equilibrium. The distance between the interfaces was varied from 50-600 nm, and the transport of the surfactant molecules was measured by dynamic secondary-ion mass spectroscopy. This transport depends on diffusion coefficients and the depth of the thermodynamic potential wells that trap the surfactant molecules at the interfaces. The diffusion coefficients were measured in independent experiments. The depth of the thermodynamic potential well was calculated using self-consistent field theory (SCFT), which required Flory-Huggins interaction parameters and statistical segment lengths measured by small angle neutron scattering. This enables a comparison of our experimental interfacial transport measurement and theoretical predictions with no adjustable parameters.

**17:06**

**K18 12 Thermodynamically Self-Consistent Theory of Crystalline Polymer Blends*** THEIN KYU, *University of Akron* Thermodynamically self-consistent theory has been developed to determine phase diagrams of binary crystalline polymer blends. The original Flory diluent theory, although captures the liquidus line, is unable to account for the solidus line due to the inherent assumption of complete immiscibility of solvent in the solid crystal. This over-simplification has led to the $\chi$ parameter obtained from the melting point depression curve to be at variance with the $\chi$ parameter by small-angle neutron scattering. The present theory

takes into account all possible interactions such as amorphous-amorphous, crystal-amorphous, amorphous-crystal, and crystal-crystal interactions to predict various phase diagrams involving liquid-liquid, liquid-solid, and solid-solid coexistence regions bound by liquidus and solidus lines. It was found that the crystal-amorphous interaction is the major contributor to the melting point depression rather than the conventional Flory-Huggins $\chi$ parameter. However, in the limit of the complete insolubility of the solvent in the crystal phase, the original Flory diluent theory is recovered. In collaboration with Rushikesh Matkar, University of Akron.

**K18 13 Polymer nano-adhesion promoted by surface mobility**
KEIJI TANAKA, TOSHIHIKO NAGAMURA, *Kyushu University* KYUSHU UNIVERSITY TEAM, We here propose a novel nano-adhesion technique on the basis of enhanced surface mobility in polymer films. As materials, monodisperse polystyrene and deuterated polystyrene (PS and dPS) with number average molecular weight of 29k were used. The surface and bulk glass transition temperatures were 294 and 373 K, respectively. PS bilayers were prepared, and were annealed at a temperature between the surface and bulk Tgs for a given time. Then, interfacial adhesion strength (G) was measured. In addition, adhesion measurement by a scanning force microscope using a probe tip covered with the PS layer was made. In this case, the adhesion area was also on nanometer level. Hence, this experiment is denoted as nano-adhesion hereafter. For both experiments, G value first increased with increasing time and then reached a constant. This implies that segments moved across the interface even at a temperature below the bulk Tg and thus adhesion took place at the interface. To confirm this, the interfacial evolution for the (PS/dPS) bilayers was examined by dynamic secondary ion mass spectroscopy. Since G value was linearly proportional to interfacial thickness, it was claimed that the adhesion at the bilayer interface was mainly governed by the interfacial thickening. Interestingly, G value by nano-adhesion measurement was much larger than that for a bilayer at a given time. The difference can be explained in terms of the completeness of the interfacial formation.

**K19 1 Exchange interactions of DMS alloys in the GW approximation.***
MARK VAN SCHILFGAARDE, *Arizona State University*

Dilute Magnetic semiconductors are a new but little understood class of materials, and in particular the origin of ferromagnetism in these materials. As we will show, the LSDA combined with the rigid-spin approximation fails to predict the observed magnetism in many of these materials, and a key question is whether the failing is due to the approximations made, or is something else going on? The best understood of DMS is zincblende $Mn_xGa_{1-x}As$, with $x \lesssim 0.1$. Optimally grown thin films have been recently shown to exhibit conventional temperature-dependent magnetization behavior with $T_c \sim 170$K. Using a standard LDA linear-response technique the LSDA total energy is mapped analytically onto a Heisenberg hamiltonian, which is analyzed for random and partially ordered structures. Temperature-dependent properties were investigated using a form of the Cluster Variation method for the Heisenberg model. The calculated $T_c$ is predicted to increase with $x$ to $x=15\%$, reaching $T_c \sim 250$K. For still larger $x$, $T_c$ is predicted to fall and turn antiferromagnetic when $x > 50\%$. Clustering and spin-orbit coupling are both found to reduce $T_c$. Thus in this case the theory falls in good agreement with observed values for low concentration. An analysis shows the Mn $e_g$ levels are responsible for the antiferromagnetic contribution. We show that suitable short-period superlattices can minimize this contribution, thus signficantly enhancing $T_c$. Many other less well studied DMS alloys–particularly nitride and oxide compounds–have now been reported with $T_c$ exceeding 300K. Several of these cases were investigated, and the LSDA linear-response predicts low $T_c$, typically $T_c < 100$K. Moreover, the LDA results for $Mn_xGa_{1-x}As$ at large $x$ are at variance, with observed ferromagnetism in a quantum dot of MnAs in the zincblende phase[1]. To address validity of the LSDA+rigid approximation, a we present results from a recent implementation of self-consistent *GW* calculation of the spin susceptibility. As will be described *GW* alters the exchange parameters in even in elemental transition metals, and the changes in transition metal compounds can be dramatic. [1]K. Ono et al, J. Appl. Phys. **91**, 8088 (2002).

**K19 2 Combinatorial design of high-temperature ferromagnetic semiconductors from first principles** ALBERTO FRANCESCHETTI, SERGEY DUDIY, SERGEY BARABASH, ALEX ZUNGER, *National Renewable Energy Laboratory, Golden, CO 80401* J. XU, M. VAN SCHILFGAARDE, *Arizona State University, Tempe, AZ 85287* The Curie temperature $T_C$ of Mn-doped GaAs depends strongly on the arrangement of the substitutional Mn dopants. For example, the highest $T_C$ reported so far was attained in thin GaMnAs layers embedded in GaAs. However, an exhaustive search of all possible configurations to find those that maximize $T_C$ is difficult, due to the astronomically large number of possibilities. Here we address this problem by parametrizing the Curie temperature of a set of $\sim$ 50 input configurations, calculated from first principles using linear-response theory and Monte Carlo simulations, in terms of configuration variables (cluster expansion). Once established, this expansion allows us to search almost effortlessly the Curie temperature of arbitrary configurations of Mn dopants in GaAs. We find that the highest $T_C$ ($>$ 350K) is achieved for $(GaAs)_m/(MnAs)_n$ superlattices in the (201) crystallographic orientation, with (m,n)=(4,1). Our general approach of cluster expanding *electronic or magnetic properties* of complex systems opens the way to first-principles combinatorial design of materials with prescribed transition temperatures. This work was supported by DARPA, under NREL contract No. DEAC36-98-GO10337.

**K19 3 First-principles study of the effects on ferromagnetic coupling in Mn/GaAs digital ferromagnetic heterostructure by free holes Injection and Be co-dopant** MEICHUN QIAN, WARREN PICKETT, C.Y. FONG, *Department of Physics, Univ. of California Davis* We use density functional theory to study the effect of free holes injection and Be co-dopant on the ferromagnetic coupling in Mn/GaAs digital ferromagnetic heterostructure (DFH). The injection of free holes is simulated by assigning a range of concentrations of missing electrons in unit cell. The $\delta$-layer doping of Mn atoms in GaAs introduces three spin-polarized hole bands which are the consequence of hybridization between the *d*-states of the Mn atoms and the *p*-states of the nearest neighboring As atoms. The distribution of hole charge density shows that these spin-polarized holes are confined to the vicinity of the Mn $\delta$-layer. After the injection of free holes, the Fermi energy $E_F$ is lowered, then the number of spin-polarized holes in the layer of MnAs is increased monotonously. We characterize the ferromagnetic coupling by the total energy difference between the ferromagnetic and the antiferromagnetic phases, $E_{FA}$, per one pair of Mn atoms. The results of $E_{FA}$, $E_F$, and the projected spin-polarized holes at Mn and the nearest neighboring As atoms are shown as a function of concentration of the injected free holes. We demonstrate the enhancement of the ferromagnetic coupling, which is in agreement with the experimental results of Nazmul et al.[1]. In contract, after the Be co-dopant in Mn/GaAs-DFH, the ferromagnetic coupling is deteriorated. We will give the explanation. [1] A. M. Nazmul et at. Phys. Rev. B67, 241308(R) (2003).

**15:30**

**K19 4 Mn doped InP nanowires: An ab initio study** TOME SCHMIDT, *Universidade Federal de Uberlandia* PEDRO VENEZUELA, *Universidade Federal Fluminense* JEVERSON ARANTES, ADALBERTO FAZZIO, *Universidade de Sao Paulo* We investigated the electronic and magnetic properties of Mn doped InP nanowires. Our study was based on total energy density functional calculations. The Mn dopants were placed substitutionally in In atom sites. We have found that the most energetically favorable position for the Mn atom is near the surface. However, a small amount of Mn atoms will be located at ''bulk-like'' positions in the wire. When the Mn atoms are in ''bulk-like'' positions, the Mn-3d majority-spin-orbitals appear in two different regions of the valence band (VB): about 2.0 eV below the top of the VB and resonant with the top of the VB. In these cases there is also an empty orbital in the gap whit p-character. The total valence spin-densities ($\rho_\uparrow - \rho_\downarrow$), for a single Mn atom in any of the configurations studied here, show a strong localized magnetic moment around the Mn atom site. In order to study the magnetic coupling we also did calculations with two Mn atoms in each cell. For several configurations studied, we concluded that if both Mn atoms are in ''bulk-like'' positions the system presents ferromagnetic ordering. On the other hand, if at least one of the Mn atoms is located near the surface, there is no magnetic ordering or the system is antiferromagnetic.

**15:42**

**K19 5 Ab-initio Prediction of Conduction Band Spin Splitting in Zincblende Semiconductors** ATHANASIOS CHANTIS, MARK VAN SCHILFGAARDE, TAKAO KOTANI, *Arizona State University* We use a recently developed self-consistent *GW* approximation to present systematic *ab initio* calculations of the conduction band spin splitting in III-V and II-V zincblende semiconductors. The spin orbit interaction is taken into account as a perturbation to the scalar relativistic Kohn-Sham hamiltonian. These are the first calculations of conduction band spin splittings based on a quasiparticle approach. We show that the self-consistent *GW* scheme accurately reproduces the relevant band parameters, and is therefore expected to be a reliable predictor of spin splittings. The results are compared to the few available experimental data and a previous calculation based on a model one-particle potential. We show that the commonly used $\mathbf{k} \cdot \mathbf{p}$ hamiltonian is missing contributions, and cannot reliably reproduce the splittings.

**K19 6 Microscopic Hamiltonian for dilute magnetic semiconductors** YUCEL YILDIRIM, *ORNL, UT, FSU* ADRIANA MOREO, *ORNL, UT* GONZALO ALVAREZ, *ORNL* ELBIO DAGOTTO, *ORNL, UT* We formulated a real space Hamiltonian to study the effect of dilute magnetic doping of III-V semiconductors. A p-type valence band is considered and nearest neighbor hopping of holes in a diamond lattice is allowed. The relevant hopping parameters between orbitals are obtained using the Slater technique. Considering the effects of the spin-orbit interactions the number of degrees of freedom per site is reduced from 6 (3 orbitals and two spin orientations for the p bands) to 4 (the four projections corresponding to j=3/2 which is the quantum number of the heavy and light hole bands). The ferromagnetic interaction between the doped magnetic impurities and the spin of the mobile holes is written in the appropriated base. The numerical values of the hopping parameters and Hund interaction are obtained from the literature for the different compounds and, thus, there are no free

parameters. The properties of the materials are calculated using numerical techniques. The newly developed TPEM method allows us to consider lattices as big as 6x6x6 cubes containing 8 ions each. Finite size effects are very small when systems larger than 3x3x3 cubes are considered. For Mn doped GaAs we reproduce the experimentally observed Curie temperatures for all the studied values of effective hole dopings. For Mn doped GaN our results predict above room temperature Tc's.

**16:06**

**K19 7 Electron-mediated ferromagnetism and negative $s-d$ exchange splitting in semiconductors*** SU-HUAI WEI, GUSTAVO M. DALPIAN, *National Renewable Energy Laboratory* Magnetic semiconductors have many unique physical properties that can be used for magneto-optical and spintronic applications. Currently, most of the studies on magnetic semiconductors are focused on hole-mediated FM systems. In this work we discuss several approaches that can enhance the spin-splitting at the conduction band edge and consequently induce electron-mediated stabilization of ferromagnetic semiconductors. We show that kinetic $s-d$ coupling can be introduced through chemical ordering and/or strain. We find that quantum confinement has a large effect on the spin- splitting at the conduction band edge. It can effectively reverse the sign of the conduction band splitting, thus, sheding light on the recent puzzling experimental observation that $s-d$ exchange splitting is negative in semiconductor superlattices. Finally, we show that, using rare-earth elements as magnetic dopants, the symmetry-allowed $s-f$ coupling can lead to a large splitting at the conduction band edge.

**K19 8 Theory of magnetic circular dichroism in GaMnAs*** JIAN-MING TANG, MICHAEL E. FLATTÉ, *University of Iowa* We present a newly developed theoretical approach to calculate the magnetic circular dichroism in diluted magnetic semiconductors. Our approach uses the tight-binding method to incorporate the spin-orbit coupling and to obtain the electronic structure over a sufficiently wide energy range. The optical transitions from the valence band to the impurity band that can not be treated in the effective mass theories are included in our calculations. We consider GaMnAs, in which the Mn dopants interact with the GaAs host through the p-d exchange interaction. Our calculations show spin-polarized acceptor states, and resonances within the valence bands. The local density of states near the valence band edge is significantly enhanced by these resonances and qualitatively different from what is obtained from models based on rigid-band shift. We find that the optical transition from deep in the valence band to the impurity band can be stronger than the transition from the valence band edge to the conduction band edge, and can account for the broad positive peak in the magnetic circular dichroism data.

**K19 9 Electrical conductivity in disordered spin-dependent media: application to diluted magnetic semiconductors*** FEDIR KYRYCHENKO, CARSTEN ULLRICH, *Department of Physics and Astronomy, University of Missouri-Columbia* Most theoretical calculations of the electrical conductivity and optical response in diluted magnetic semiconductors (DMSs) treat disorder in relaxation time approximation, using phenomenological relaxation times. However, the role of disorder in III-V DMS materials, particularly the non-trivial effects of spin-dependent scattering from magnetic impurities, requires more careful consideration. In this work we go beyond the relaxation time approximation and derive the electrical conductivity in spin-dependent disordered systems based on the equation of motion for the paramagnetic current-current response function. The general expression relates the full current response function to the set of full system spin-density response functions and is valid for any strength of disorder. We present numerical results for conductivities and dielectric functions in the weak disorder limit, treating carriers with a simple parabolic band model and electron interactions within RPA. For various system parameters we study the relative importance of Coulomb and spin-dependent scattering processes. Special attention is paid to the effects of spatially correlated versus random scattering centers.

**K19 10 Ferromagnetism of $Ga_{1-x}Mn_xAs$ and Weiss theory of Curie temperature in the coherent potential approximation*** SZE-SHIANG FENG, MOGUS MOCHENA, *Florida A&M University* Using spin-$\frac{1}{2}$ description of valence holes and Kondo coupling between local spins and carriers, the zinc-blende GaAs-based III-V diluted magnetic semiconductors (DMS) are studied in the coherent potential approximation (CPA). We use the exact Hilbert transformation of the face-centered cubic (fcc) density of states (DOS). Our calculated relation of ground-state energy and impurity magnetization shows that ferromagnetism is always favorable at low temperatures. For very weak Kondo coupling, the density of states (DOS) of the host semiconductor is modified slightly. Impurity band can be generated at the host band bottom only when Kondo coupling is strong enough. Using Weiss molecular theory, we predict a nonlinear relation of Curie temperature with respect to Kondo coupling. Our calculated $T_C$ agrees with measured values very well.

**K19 11 The ($T = 0$) Phase Diagram of the RKKY model*** DONALD PRIOUR, JR., SANKAR DAS SARMA, *University of Maryland* We consider magnetic moments (e.g. Mn ions in $Ga_{1-x}Mn_xAs$) coupled via the indirect exchange RKKY interaction. We obtain via Monte Carlo the $T = 0$ phase diagram as a function of Mn density $n_i$ and the relative carrier (hole) concentration $n_c/n_i$. As evidenced by a diverging correlation length and the magnetic susceptibility, the boundary between the ferromagnetic (FM) and paramagnetic (PM) phases constitutes a line of zero temperature critical points with behavior very similar to that of a percolation transition. In particular, ferromagnetic clusters increase in size and ultimately coalesce to span the system as the phase boundary is approached from the PM side. In the dilute limit, we find that bulk ferromagnetism vanishes for $n_c/n_i > 0.1$. We also incorporate the local antiferromagnetic superexchange coupling between nearest neighbor magnetic impurities, eliminating ferromagnetism above a Mn density threshold $n_i^{\mathrm{crit}}$. We discuss the impact of a finite carrier mean free path $l$, which we include as a damping factor in the RKKY range function.

Among our findings for an $l$ on the order of the lattice constant $a$ is an expansion of the ferromagnetic region in the phase diagram, though with a suppression of the Curie Temperature $T_c$. We determine the values of $n_i, n_c$, and $l$ which maximize $T_c$.

**K19 12 Photo-induced ferromagnetism in dilute magnetic semiconductors through Bogoliubov-Valatin transformation**
SUBODHA MISHRA, SASHI SATPATHY, *Department of Physics and Astronomy, University of Missouri-Columbia, Columbia, MO 65211* GOURI S. TRIPATHI, *Department of Physics, Berhampur University, Orissa, India* The dilute magnetic semiconductor is an emerging area of interest because of their possible applications in spintronics. One can control ferromagnetism in these materials by shining light on the sample. The incident light creates extra carriers (electrons and holes) across the band gap, thereby enhancing the carrier-mediated ferromagnetism between the localized Mn moments. The effect is studied by a model Hamiltonian that includes the kinetic energy and Columb interaction terms and the coupling of carriers to light. The Hamiltonian is solved by B-V transformation and then minimizing the ground-state energy by a variational method. We study how the critical temperature varies with light frequency and coupling of light to the carrieres.

**K19 13 Intrinsic Resistance of Magnetic Topological Defects**
ANH KIET NGUYEN, ROMAN SHCHELUSKIN, ARNE BRATAAS, *Norwegian University of Science and Technology* We show that magnetic topological defects in zincblende magnetic semiconductors have an intrinsic resistance against ballistic transport of holes with spin-orbit coupling. The intrinsic resistance is independent of the real space size and detailed shape of the defects, provided that their spatial variations are sufficiently smooth. Rather, it depends on the shape of the defects in the magnetic orderparameter space. For typical parameters, the intrinsic resistance of a domain wall defect is as large as the geometrical resistance and should therefore be experimentally measurable.

**K20 1 Spin-lattice coupling from first principles.**
CRAIG FENNIE, *Rutgers University*

The hexagonal manganites are a class of multiferroic materials that are simultaneously ferroelectric and antiferromagnetic, in which many physically interesting and potentially technologically relevant manifestations of spin-lattice coupling have been observed. Chromium spinels such as $ZnCr_2O_4$ and $CdCr_2S_4$ are antiferromagnetic and ferromagnetic insulators respectively, each displaying a differrent manifestation of a spin-lattice effect. In $ZnCr_2O_4$ a large magnetically induced phonon anisotropy has been observed while mode-dependant phonon anomalies have been measured in $CdCr_2S_4$. With the continuing advances in theoretical algorithms such as the LSDA+U method and in computational power it is now possible to study structurally and magnetically complex solids such as these using density-functional first-principles methods. Here, I describe a first-principles approach to study the influence of magnetic order on the phonons and dielectric properties of $YMnO_3$, $ZnCr_2O_4$, and $CdCr_2S_4$, our ongoing investigation of the coupling between the magnetic order and polarization in hexagonal manganites, and the search for ferroelectric behaviour in the simple ferromagnet $CdCr_2S_4$.

**K20 2 Magnetic Phase Diagrams of Hexagonal $ErMnO_3$, $TmMnO_3$ and $HoMnO_3$***
F. YEN, C. R. DELA CRUZ, B. LORENZ, Y. Y. SUN, *Department of Physics and TcSUH, University of Houston* C. W. CHU, *also in LBNL, Berkeley and HKUST, Hong Kong* M. M. GOSPODINOV, *Institute of Solid State Physics, Bulgarian Academy of Sciences, Bulgaria* Multiferroic rare earth manganites have attracted special attention because of the coexistence of ferroelectric and magnetic orders resulting in higher-order magnetoelectric effects and complex phase diagrams at low temperature. We investigate the magnetic phase diagrams of $RMnO_3$ (R = Er, Tm, Ho) and show that all phase boundaries are well determined by sharp changes in their dielectric properties proving the existence of strong spin-lattice coupling. The stability range of the AFM order below the Neel temperature of $RMnO_3$ (R=Er, Tm) extends to far higher magnetic fields than previously assumed. For the case when R = Ho, the magnetic phase diagram was found to be extremely complex including new phases with yet unknown magnetic structures. Hence, we extend the phase diagram to higher external magnetic fields up to 14 Tesla for all of the three aforementioned compounds. The detection of these phase boundary lines is through anomalies of the dielectric constant, DC and AC magnetization.

**K20 3 Molecular beam epitaxy of $YMnO_3$ on GaN (0001)***
YEWHEE CHYE, TAO LIU, DEBIN LI, KYOUNGNAE LEE, THOMAS MYERS, DAVID LEDERMAN, *Multifunctional Materials Laboratory, Dept of Physics, West Virginia University*

Ferroelectric oxide thin films on semiconductors have attracted considerable attention from the physics and engineering communities for their potential applications in nonvolatile memory, piezoelectric, microwave devices, etc. In this work, we describe the molecular beam epitaxial (MBE) growth of the ferroelectric oxide $YMnO_3$ on GaN. $YMnO_3$ is an obvious candidate of oxide films on GaN because they both have hexagonal lattice structure and the lattice constant of $YMnO_3$ is approximately 2 times that of GaN. $YMnO_3$ films are grown on GaN (0001)-on-sapphire templates using MBE. Y and Mn are evaporated using effusion cells. Reactive oxygen was generated by a RF plasma source. The structure of the films as characterized by in-situ RHEED, x-ray diffraction, and atomic force microscopy will be discussed.

*Supported by the ONR (grant N00014-02-1-0974), the AFOSR (MURI Grant F49620-03-1-0330), and the NSF (grant CIAM 0502825).

**K20 4 Dependence of the Properties of MBE-grown Multiferroic $YMnO_3$/GaN Heterostructures on the Growth Temperature and Post-growth Annealing Processes*** TAO LIU, YEWHEE CHYE, CAMERON KEENAN, THOMAS MYERS, DAVID LEDERMAN, *Multifunctional Materials Laboratory, Dept of Physics, West Virginia University* We report on the molecular beam epitaxy (MBE) of multiferroic $YMnO_3$ on c-plane GaN. Study and understanding of these $YMnO_3$/GaN heterostructures are important for potential applications in multifunctional materials and structures. Atomic force microscopy revealed that the $YMnO_3$ films grown at different temperatures have significantly different morphologies. X-ray diffraction showed that there is a $30^o$ rotation between the unit cells of $YMnO_3$ and GaN. Samples grown at the optimal growth temperature are ferroelectric at room temperature, with a large remnant polarization, and magnetic at low temperatures. The difference between magnetic field-cooled and zero-field-cooled behavior at low temperatures indicates the presence of antiferromagnetic frustration or ferromagnetic behavior. The effects of different growth temperatures and post-growth annealing will be discussed.

*Supported by the ONR (grant N00014-02-1-0974), the AFOSR (MURI Grant F49620-03-1-0330), and the NSF (grant CIAM 0502825).

**15:42**

**K20 5 Structural, ferroelectric, and magnetic properties of epitaxial $YMnO_3$ thin films grown on wurtzite-structure materials** AGHAM POSADAS, JENG-BANG YAU, JUNG HAN, CHARLES AHN, *Yale University* KAREN JOHNSTON, KARIN RABE, *Rutgers University* JEFFREY NEATON, *Lawrence Berkeley National Laboratory* STEFANO GARIGLIO, *University of Geneva* Thin films of the multiferroic oxide $YMnO_3$ have been grown on single crystal substrates with the wurtzite crystal structure, including GaN and ZnO with different polarities. Films have also been grown on the wurtzite derivative 6H-SiC. X-ray diffraction reveals epitaxial, c-axis oriented growth on all of these crystals. The measured ferroelectric polarization is similar to that of single crystal $YMnO_3$, and magnetization measurements reveal frustrated antiferromagnetic ordering in the plane of the film. X-ray diffraction also reveals an epitaxial relationship that is associated with a very large ( $\sim$ 10%) in-plane strain for growth on GaN. This unusual observation is explained by first principles calculations of the strain and bonding energies.

**15:54**

**K20 6 Doping effect on ferroelectric microstructure in $YMnO_3$.** S. MORI, J. TOKUNAGA, Y. HORIBE, *Department of Physics, Osaka Prefecture University* T. ASADA, Y. KOYAMA, *Department of Materials Sceince, Waseda University* T. KATSUFUJI, *Department of Physics, Waseda University* $YMnO_3$ is one of the typical multiferroic materials showing the coexistence of the antiferromagnetic and ferroelcrric orders at low temperature. In this work, we have investigated doping effect on ferroelectric microstructure in $YMnO_3$ by both electron diffraction and real-space imaging techniques. We found that the large ferroelectric domains with several micron meters change into the ferroelectric microdomains with the size of 20-30nm by substituting $Y^{3+}$ ions for $Ca^{2+}$ and $Zr^{4+}$ ions. In addition, diffuse scatterings elongated along both the [110] and [001] directions were found, which were similar to those found in $YMn_{0.825}Ti_{0.175}O_3$ exhibiting the enhanced magnetocapacitance effect. [1] The lattice instability in the Mn triangle lattice induced by the partial substitution at $Y^{3+}$ site should have some influence on the coupling between magnetic and ferroelectric orders. [1] S.Mori et al., Phys.Rev.B (in press).

**16:06**

**K20 7 Multiferroicity of $RMn_{1-x}Ga_xO_3$ (R = Ho, Y) and $Ho_{1-x}Y_xMnO_3$** H.D. ZHOU, J.C. DENYSZYN, JOHN. B. GOODENOUGH, *The University of Texas at Austin* $RMn_{1-x}Ga_xO_3$ (R = Ho or Y) and $Ho_{1-x}Y_xMnO_3$ single-crystals have been prepared. The experimental results revealed that the $c$ axis decreases with increasing temperature with a larger $|dc/dT|$ above $T_C$ than below it. This shows that the cooperative $MnO_5$ site rotations responsible for the ferrielectricity expend energy to induce the ferroic $R^{3+}$-ion displacements along the $c$ axis. Ga doping raises the ferrielectric Curie temperature $T_C$ and the Mn-spin reorientation temperature $T_{SR}$ while lowering $T_N$ of the Mn spins and the Ho magnetic ordering temperature $T_2$. The data show (i) an important coupling between the $Mn^{3+}$-ion and $Ho^{3+}$-ion spins; (ii) a $T_{SR}$ that is driven by the cooperative $MnO_5$ site rotation and $R^{3+}$-ion displacements that control the $c$ lattice parameter. Y doping favors the formation of $P6_3'$cm' magnetic phase below $T_N$, and enhances the temperature region of $P6_3'$cm' phase. Therefore, $T_{SR}$ for the transition from $P6_3'$c'm to P6'$_3$cm' phase increases with increasing $x$, but $T_{SR}$ disappears for $x > 0.8$ samples because the $P6_3'$cm' phase already occupies the whole temperature region below $T_N$. The thermal conductivity data also support an enhanced spin-lattice interaction above $T_N$ in the geometrically frustrated (GF) Mn-spin system.

**K20 8 Multiferroicity in the Mixture of Orthorhombic and Hexagonal $RMnO_3$ (R=rare earths)** CHENGLIN ZHANG, GUHA SABYASACHI, SANG-WONK CHEONG, *Rutgers University* Orthorhombic perovskite $RMnO_3$ (R = Tb, Dr) shows an incommensurate magnetic/lattice modulation below $\sim$ 40 K and a lock-in transition below $\sim$ 25 k. The system becomes ferroelectric at the lock-in transition. On the other hand, hexagonal $RMnO_3$ (R = Ho-Lu, Y) exhibits ferroelectricity with a much higher transition temperature ( $\approx$ 1000 K) and a magnetic ordering transition at $\sim$ 100 k. We will report the results of our comprehensive study of

what happens when these two types of ferroelectric 113 compounds are mixed.

**16:30**
**K20 9 Magneto-thermal conductivity in multiferroic $HoMnO_3$** YOUNG JAI CHOI, PETER A. SHARMA, SANG-WOOK CHEONG, It is well known that multiferroic $HoMnO_3$ exhibits a rich phase H-T diagram. We have discovered that thermal conductivity of hexagonal $HoMnO_3$ shows an unconventional diversity of anomalies at low temperatures under external magnetic fields. In order to understand the origin of these anomalies, we have performed comprehensive characterization experiments on the multiferroic compound, including measurements of dielectric constant, DC and AC magnetic susceptibility, and polarization as functions of temperature and applied magnetic field.

**16:42**
**K20 10 Magnetoelectric and magnetoelastic effects in a triangular lattice antiferromagnet $CuFeO_2$** T. KIMURA, A.P. RAMIREZ, *Bell Laboratories, Lucent Technologies* J.C. LASHLEY, *Los Alamos National Laboratory* Magnetoelectric and magnetoelastic effects related to a phase transition into noncollinear magnetic phase have been investigated for single crystals of $CuFeO_2$ with a frustrated triangular lattice. $CuFeO_2$ exhibits several long-wavelength magnetic structures related to the spin frustration, and it is found that finite electric polarization, namely inversion symmetry breaking, occurs with noncollinear but not at collinear magnetic phases. This result demonstrates that the noncollinear spin structure is a key role to induce electric polarization, and suggests that frustrated magnets which often favor noncollinear configurations can be plausible candidates for magnetoelectrics with strong magnetoelectric interaction.

**16:54**
**K20 11 Landau Theory of the Magnetic Phases of Hexagonal Rare Earth Manganites*** IRAM MUNAWAR, STEPHANIE CURNOE, *Department of Physics and Physical Oceanography/ Memorial University of Newfoundland* A group theoretical analysis is presented on the magnetic structure of rare earth atoms in the multiferroic hexagonal manganites $RMnO_3$ (R=Ho, Er, Tm, Yb, Sc, Y) which exhibit the coexistence of ferroelectricity ($T_c \sim 900$ K) and antiferromagnetism ($T_N \sim 100$ K). Using Landau theory, a phenomenological model of the free energy based on four one-dimensional magnetic order parameters has been developed. Coupling of the various order parameters leads to complex magnetic field – temperature phase diagrams in qualitative agreement with experimental data. References: [1] S. H. Curnoe and I. Munawar, Magnetic Phases of Rare Earth Hexagonal Manganites, Proceedings of The International Conference on Strongly Correlated Electron Systems SCES '05, July $26^{th}$ - $30^{th}$, 2005, Vienna, Austria, (accepted on July 29, 2005 to be published in Physica B) [2] Manfred Fiebig. **K21 1 Giant Enhancement of Colloidal diffusion in a Corrugated Optical Vortex** SANG-HYUK LEE, DAVID G. GRIER, *Department of Physics and Center for Soft Matter Research New York University* We experimentally study thermally driven velocity fluctuations of a Brownian particle in a tilted washboard potential. Our system consists of a single fluid-borne colloidal sphere driven by a holographically projected superposition of optical vortices. A single optical vortex is a ring-like optical trap created by focusing a helical mode of laser light. Torque exerted by an optical vortex's orbital angular momentum flux drives a trapped colloidal particle around its circumference. Superposing two optical vortices with opposite helicities and different amplitudes creates a corrugated optical vortex with sinusoidal intensity variations around its circumference. The resulting tilted washboard potential admits both static trapped states and dynamic running states. Digital video microscopy measurements of the resulting particle trajectories reveal a hundred-fold enhancement of the effective self-diffusion coefficient near the static-to-running transition.

**K21 3 A Constant Force Dielectrophoretic Cell** MARIA KILFOIL, VINCENT PELLETIER, ANDREW SCOTT, ALLAN HALDANE, *McGill University* We fabricated an especially designed cell to study colloidal suspension under an isomotive dielectrophoresis force. Under such conditions, the effects of a uniaxial force on gel structure and crystallization can be studied with an absolute control on its magnitude. Since the force is horizontal by design, we can take advantage of the higher resolution on the horizontal axis to obtain more precise particle locations. Preliminary results are shown.

**15:06**
**K21 4 Electric Double Layer Structures near Rough Surfaces: Molecular Dynamics Simulation** DAEJOONG KIM, ERIC DARVE, *Stanford University* S. S. Dukhin in Surface and Colloid Science (1974) mentioned both the possibility of increase in zeta potential due to surface roughness and the possibility of decrease, depending on Debye length relative to surface roughness. In this work we report our results of molecular dynamic (MD) simula-

tions on electric double layer structures near solid surfaces having roughness with the order of magnitude of Debye length. For computational simplicity only counter-ions are present. We computed static and dynamics properties including density profiles of water and ions, electrostatic potential distributions due to ions, polarization density profiles and self-diffusivities of water and ions. We also performed nonequilibrium MD to simulate electroosmotic flows. From electrostatic potential distributions and slip plane locations, we computed zeta potential and found that it decreases with surface roughness. It also showed a dependency on the spatial frequency of surface roughness. For comparison we used the Helmholtz-Smoluchowski relation and found the same trend. Currently we are studying pressure-driven flows, a computational counterpart to streaming current experiments. One of the purposes is to find more exact locations of slip planes by fitting to Poiseuille flow solutions. We are also simulating model systems with co-ions to investigate the possibility of charge inversion and other effects.

**15:18**

**K21 5 Heterogeneities in Two-Dimensional Pinned Liquids** JING-XIAN LIN, *T-12 and T-CNLS, Los Alamos National Laboratory; University of California, Riverside* CHARLES REICHHARDT, *T-13 and T-CNLS, Los Alamos National Laboratory* ZOHAR NUSSINOV, *T-11, Los Alamos National Laboratory* LEONID P. PRYADKO, *University of California, Riverside* CYNTHIA J. OLSON REICHHARDT, *T-12 and T-CNLS, Los Alamos National Laboratory* We introduce a model system in which the amount of heterogeneous motion in a liquid phase just above melting can be controlled directly. Using numerical simulations, we place a two-dimensional assembly of repulsively interacting colloids on a commensurate triangular substrate of pinning sites, and then randomly deactivate a fraction $n_p$ of the pinning sites. Heterogeneous motion is induced when the unpinned colloids melt at lower temperatures than the pinned colloids, and this heterogeneity can be controlled by changing the fraction of active pinning sites. The melting transition occurs in a single step for $n_p = 0$ or 1, and is considerably broadened for partially pinned samples. We measure the noise fluctuations of the dislocation density as a function of time and find a maximum noise power when $n_p = 0.5$. Signatures of a two step melting process appear for up to 3/4 of the pinning sites removed. We also correlate the regions of high mobility with regions of high dislocation density, and analyze the heterogeneity using the Van Hove correlation function.

**15:30**

**K21 6 Computation of Super-Hydrophobic States and Stability*** YONGKANG CHEN, *Portland State University* DANNY BOLLEDDULA, RYAN JENSON, MARK WEISLOGEL, Super-hydrophobic fluid phenomena have been the focus of an increasing number of research investigations over the past decade. Perhaps the greatest achievements recently have come by way of the highly controlled surfaces that can be produced using any one of a number of rapidly expanding surface microfabrication techniques. In this work we present a numerical approach to systematically probe both the states and stability of certain (super- or ultra-) hydrophobic surfaces as they depend on surface porosity, specific surface feature size and geometry, and fluid properties such as 'equilibrium' contact angle and surface tension. Drop stability in terms of critical roll-off angles, advancing and receding contact angles (hysteresis), Bond number, and effective contact angle is computed and used as a measure of 'superhydrophobicity.' Both Wenzel and Cassie hydrophobic states are analyzed by the numerical method.

**15:42**

**K21 7 Design of Porous Wick Structures: Steady Flows*** MARK WEISLOGEL, RYAN JENSON, YONGKANG CHEN, LAWRENCE MELVIN III, Methods of analysis developed for capillary flows in large complex containers for spacecraft are applied to microscale networks of interconnected repeat units to develop design methodologies to compute optimal geometries for high performance microporous materials and structures on Earth. The fundamental transport mechanism in the media is the interior corner geometry. The specific objectives of the research focus on the optimization of high performance wick structures employed in advanced two-phase passive cooling systems for microelectronic thermal control. The analysis employs the governing transport equations in a cell-by-cell approach to compute optimal pore structures in the low saturation limit where the media may be effectively modeled as a nodal network of interconnected interior corners and solved by matrix methods. The 'all analytic' method under development does not employ empirically determined constants or highly varying numerical coefficients as other pore-scale investigations. Example pore geometries solved to date for steady flows clearly identify the origins of the manifold improvements possible in select porous structures. Applications for such methods are also helpful to improving transport processes in porous media such as fabrics and membranes.

**15:54**

**K21 8 Capillary waves at the water liquid-vapor interface** AHMED E. ISMAIL, GARY S. GREST, MARK J. STEVENS, *Sandia National Laboratories* Evidence for capillary waves at the liquid-vapor interface of water is presented from molecular dynamics simulations. The total interfacial width includes a correction term which depends logarithmically on the length $L_\parallel$ of the simulation cell parallel to the interface, and which is inversely proportional to the surface tension $\gamma_{cw}$. Comparison of $\gamma_{cw}$ for system sizes up to $10^5$ molecules to $\gamma_p$, obtained from the difference between the pressure parallel and the pressure perpendicular to the interface, yields adequate agreement only if one fits the interfacial profile to an error function and not to a hyperbolic tangent, as often assumed. Results for $\gamma$ for a number of atomistic three-site (SPC/E, TIP3P, TIP3P-CHARMM, and TIP3P-Ew) and four-site (TIP4P and TIP4P-Ew) non-polarizable water models are compared to experiment for temperatures from 300 K to 500 K, and for a variety of interaction cutoffs and reciprocal-space mesh refinements. Our results show that the SPC/E model is more accurate than the other available three-site models, while the original TIP3P model is closer to experimental data than its more recent parameterizations.

**16:06**

**K21 9 Self-assembly of Colloid-Polymer Mixtures Confined by Soft Walls** YU-QIANG MA, *National Laboratory of Solid State Microstructures, Nanjing University, Nanjing 210093, China* We discuss how to control self-assembled ordering structures in colloid-polymer systems confined by soft walls, and find that with varying the colloidal concentration, the colloidal self- assembly undergoes a series of symmetry-changing transitions, due to the competition between the elastic entropy effect of soft walls and steric packing effect of colloids.

**16:18**

**K21 10 Rheological response of emulsions of drops immersed in electric fields.** ARTURO FERNANDEZ, *The Catholic University of America* Direct numerical simulation is used to examine the temporal response of an emulsion of drops immersed in an electric field. When a drop is immersed in a suspending fluid of different electrical properties, and an electric field is applied, surface electric charges accumulate on the boundary between drop and suspending fluid. These charges, coupled with an electric field, lead to the appearance of electric stresses at the interface between the fluids. When an emulsion is immersed between two plates moving at different velocities, the microstructure and rheological properties depend on the competition between electric and hydrodynamical forces. We present a study of these phenomena for DC and AC electric fields. The effect on microstructure is quantified by the PDF, and on rheological properties by effective viscosity and normal stress difference. The numerical simulations show that fluid shear, electrical properties of both fluids, frequency for an AC electric field, and intensity are the main parameters governing the response of the system.

**16:30**

**K21 11 Applications of Quartz Tuning Forks to Liquid Property Measurements** JAMES BENNETT, LEONID MATSIEV, OLEG KOLOSOV, *Symyx Technologies* Sensor technology for fluid samples often measures a single physical parameter per sensor and for many applications this is sufficient. In some cases however, characterization of the state or condition of a fluid can be improved through the simultaneous measurement of multiple physical parameters. We will discuss our work in the application of flexural mechanical resonators such as quartz tuning forks to the characterization of fluids. We have previously shown that if a tuning fork resonator is immersed in a fluid, the changes in resonator response can be used to determine physical properties of the fluid. We will describe the development of a measurement system based on a tuning fork resonator, the associated electronics and analysis software. This system can provide simultaneous measurement of liquid properties such as viscosity, density, dielectric constant and ac conductivity. We have applied the tuning fork sensor to the characterization of fluids over a range of temperatures and conditions. Simultaneous measurement of viscosity, density and dielectric constant can provide information about the state or condition of the fluid. For example, for motor oils, clear differences in the measured parameters are observed between fresh and used oils and may be correlated to the oil condition.

**16:42**

**K21 12 Phase Segregation and Patterning in Two Dimensional Systems: Competition Between Van der Waals and Electrostatic interactions** SHARON LOVERDE, *Department of Materials Science and Engineering, Northwestern University* FRANCISCO SOLIS, *Department of Biophysics, Arizona State University* MONICA OLVERA DE LA CRUZ, *Department of Materials Science and Engineering, Northwestern University* The formation of heterogeneities on surfaces, such as microdomains found in synthetic and natural lipid membranes, has not yet been yet fully explored from a theoretical point of view. It has been proposed, for example, that lipid rafts arise in membranes due to lipid-lipid and/or lipid-protein interactions. We consider a coarse-grained model of a mixture of charged lipids interacting within a monolayer. We analyze this model both analytically and with molecular dynamics simulations, and find a rich phase diagram. The complex phase behavior is generated by the competition between the short range van der Waals interactions and long range electrostatic interactions. In particular, we observe phase coexistence between an ''ionic gas'' phase with a dense patterned solid phase. We have examined the phase diagram of the system as a function of net charge density and charge asymmetry.

**16:54**

**K21 13 Binary Lennard-Jones Fluids: A Look Through Time Series Analysis*** THEODOROS KARAKASIDIS, ATHANASIOS FRAGKOU, ANTONIOS LIAKOPOULOS, *Hydromechanics Laboratory, School of Engineering, University of Thessaly, 38334 Volos, Greece* In this paper we discuss the dynamical behavior of a binary Lennard-Jones fluid simulated at the atomic scale using Molecular Dynamics. The system was simulated at several fluid states as a function of system density and temperature and its instantaneous temperature was recorded. We report preliminary results on time-series analyses of the instantaneous system temperature as well as of the temperature of its two constituents. In this course we employ both linear (autocorrelation function and power spectrum) and non-linear tools (average mutual information and correlation dimension). It turns out that the time series present a complex $1/f^{\alpha}$ behavior. The dependence of the regimes on the physical state of the system is discussed.

**K21 14 2D Lennard-Jones as complex liquid** ALEXANDER PATASHINSKI, *Northwestern University* RAFAL ORLIK, ANTONI MITUS, *Polytechnic University, Wroclaw, Poland* MARK RATNER, *Northwestern University* The high viscosity, large relaxation times, and other signature features of complex liquids are associated with substantial local order and long-living significant liquid structures in these liquids. In 3D Lennard-Jones liquids, representing simple liquids, no detectible structural local order in 13-atom clusters was found at the melting line. In contrast to that, the 2D Lennard-Jones liquid appears locally ordered: about half of the atoms are, at any time, in recognizable hexagonal cages. We present results of a study of the statistics and dynamics of local order in 7-atom clusters in 2D Lennard-Jones-based system. The study includes states along a supercritical isotherm in the range of densities where the system changes from disordered liquid to ordered solid state.

**K22 1 Time-domain diffracted magnetooptic Kerr probing of magnetization dynamics of patterned magnet arrays*** XIAOBIN ZHU, *University of Alberta* FABIAN GIESEN, ZHIGANG LIU, MARK FREEMAN, *University of Alberta* HIROYUKI AKINAGA, *AIST, Japan* We probe the ultrafast magnetooptic Kerr effect in the diffracted spots of a patterned array of magnets, which serve as diffraction grating. This technique, diffracted MOKE, provides valuable information, as the off-specular spots contain the finite spatial frequencies of the magnetic moment configuration [1-3]. In this talk, we will present the D-MOKE study in the time domain of a 2 $\mu$m sized Permalloy square array and a 1 $\mu$m sized Permalloy disk array. The time-domain measurements are performed using a time resolved scanning Kerr microscopy in its spectroscopic mode [4]. Due to spatial averaging, we find that time-domain curve shows faster damping compared with individual magnets. We also find that the sensitivity of the Kerr signal is enhanced at the first order. Through Fourier transformation of the time-domain data, and through comparison with micromagnetic simulation, information about magnetic normal modes in individual magnets is extracted. [1] M. **K22 2 Ultrafast Laser Spin Wave Measurement of Temperature Dependent Magnetic Anisotropy of Half-Metallic Chromium Dioxide** ANNE REILLY, *College of William and Mary* HAILONG HUANG, *College of William and Mary* KEOKI SEU, *College of William and Mary* Recent work has shown that the all-optical ultrafast laser production and detection of spin waves can provide useful measurements of anisotropy in magnetic thin films [1,2]. A pump laser pulse momentarily affects the magnetic anisotropy, perturbing the magnetization, which relaxes towards a new equilibrium by means of coherent oscillation. The coherent oscillation is detected by the magnetoopitcal Kerr effect. We present a study of the temperature dependence of the magnetocrystalline anisotropy of half-metallic CrO2 thin films from temperatures 10 K to 363 K. At higher temperatures, the oscillations are approximately single frequency. The anisotropy constants obtained by analyzing the oscillation frequencies as a function of applied fields using the Landau Lifshitz Gilbert equation agrees with measurements made by other techniques, particularly ferromagnetic resonance. Interesting features of the temperature dependence, as compared to ferromagnetic metals such as Co, Ni and Fe, will be highlighted. 1. M. Van Kampen et al., Phys. Rev. Lett. 88, 227201 (2002) 2. D. **K22 3 Interface magnetization switching and precession in Fe/AlGaAs (001)** GUNTER LUEPKE, HAIBIN ZHAO, DIYAR TALBAYEV, *College of William and Mary* AUBREY HANBICKI, CONNIE LI, BEREND JONKER, *Naval Research Laboratory* Understanding of interface magnetic properties is a key for efficient spin-polarized injection in semiconductor spintronic devices. Here, we have measured the reversal process of the Fe interface layer magnetization in Fe/AlGaAs (001) using magnetization-induced second harmonic generation (MSHG), and compared it with the bulk magnetization obtained from magneto-optic Kerr effect (MOKE). The switching characteristics are distinctly different – single step switching occurs at the interface layer, while two-jump switching occurs in the bulk Fe for the magnetic field orientations employed. The different switching processes lead to a deviation angle of 40-85$^o$ between interface and bulk magnetization, which may result from reduced exchange interaction and different magnetic anisotropies at the interface. We also use time-resolved MSHG to investigate the coherent magnetization precession at the interface, and compare with the bulk spin precession obtained from time-resolved MOKE. The different switching behaviors are further revealed in the precession dynamics. The field dependence of precession frequency provides a quantitative analysis of magnetic anisotropies of the interface layer.

**K22 4 Excitation of single-frequency spin waves in exchange-biased IrMn/Co by ultrafast laser repinning** KEOKI SEU, HAILONG HUANG, ANNE REILLY, *Department of Phyiscs, College of William and Mary* We have excited and detected coherent spin waves in exchange-biased IrMn/Co using the all-optical ultrafast laser pump probe technique. The laser pump produces changes in the exchange biasing which launches spin waves which are detected by the magnetooptical Kerr effect. The oscillations are single frequency and can be described according to ferromagnetic resonance equations. Unlike previous work in these systems [1-3], oscillations have been detected when the applied magnetic field is along any direction relative to the pinning axis, including directly along the easy axis, and in fields larger than the magnetic saturation. This is contrary to energetic arguments and predictions from the Landau Lifshitz Gilbert equation [1]. Our suggested mechanism for these oscillations is a destruction and re-pinning of the exchange-bias interaction, introducing a 'kick' required for the magnetization to precess. Evidence of this ultrafast laser repinning will be presented. 1 Ganping Ju, et al., Phys. Rev. B. 62 1171 (2000). 2 M. C. Weber, et al., Eur. Phys. J. B. 45 243 (2005). 3 Ganping Ju, et al., Phys. Rev. Lett. 82 3705 (1999).

**K22 5 Optically induced magnetization dynamics in manganite films studied by time-resolved magneto-optical Kerr effect 1.** DIYAR TALBAYEV, HAIBIN ZHAO, GUNTER LUEPKE, *The College of William and Mary* ADYAM VENIMADHAV, JUN CHEN, QI LI, *Pennsylvania State University* Magnetization precession is the fastest way to switch magnetic memory elements. We studied optically-induced magnetization dynamics in epitaxial $La_{2/3}Sr_{1/3}MnO_3$ (LSMO) and $La_{2/3}Ca_{1/3}MnO_3$ (LCMO) films on different substrates. Both uniform precession of magnetization and spinwaves were observed. The precession frequency is governed by magnetic anisotropy that depends on the strain state of the films. In LSMO, compressive and tensile strain induces uniaxial normal-to-plane anisotropy. Similar behavior was observed in

tensile-strained LCMO. However, a large in-plane anisotropy was discovered in LCMO on $NdGaO_3$. The field-dependent relaxation times of the decaying precession are in 100 – 1400 ps range. The corresponding Gilbert damping parameter is field-dependent and decreases sharply with increasing field in LSMO films. The research was supported in part by the National Science Foundation and the Department of Energy.

**K22 6 Laser induced ultrafast magnetization dynamics in CoPt multilayer** A. BARMAN, S. WANG, H. SCHMIDT, *School of Engineering, University of California Santa Cruz, 1156 High Street, Santa Cruz, CA 95064* A. BERGER, *Hitachi Global Storage Technologies, San Jose Research Center, 650 Harry Rd., San Jose, CA 95120* We study femtosecond laser induced magnetization dynamics in CoPt multilayer structures in the presence of an externally applied magnetic field. The dynamics revealed three different time regimes. The first few hundred femtoseconds show an instantaneous demagnetization, followed by a quick recovery within next few picoseconds. Subsequently, an oscillatory motion comes into play whose frequency is field dependent and attributed to the precessional motion of magnetization. The sudden heating with laser pulses causes a rapid change in the anisotropy of the sample that results in a change in the equilibrium orientation of magnetization and triggers a precession. The precessional dynamics completely decays within 100ps leaving it to a slower recovery of magnetization. Analysis of the time-resolved magnetization shows a single precessional mode at higher fields, while several modes become apparent at lower fields. The dependence of different frequency modes and their damping on the applied field are studied to understand the dynamics in more detail. The effects of the anisotropy field distribution and different multilayer compositions on the dynamic response will also be discussed.

**K22 7 Ultrafast coherent control of Spin- and magnetization dynamics.**
THEO RASING,* *Insitute for Molecules and Materials*

The manipulating of the electron spin is not only relevant for magnetic storage but may also lead to the development of novel electronic devices with new characteristics (so-called spintronics). Therefore, the investigations of the physical mechanisms underlying the manipulation of electron spin in ferromagnets, semiconductors and hybrid ferromagnet/semiconductor structures constitute at present an exciting area of research. Due to the fact that in antiferromagnets no angular momentum is associated with the order parameter, spin dynamics in these materials is intrinsically much faster than in ferromagnets, expanding the area of spin-dynamics even more [1]. Femto-second laser excitation opens the way to excite magnetic systems on a time scale much shorter than fundamental time scales such as spin-lattice relaxation or precession times. This has already lead to surprising and exciting results like changes in magnetization on a sub-picoscond time scale [2]. Fs laser pulses can also be used to generate short magnetic field pulses, that allow coherent control of the magnetization dynamics [3]. Recent progress in this area will be discussed, demonstrating in particular the use of time resolved magneto-optical methods to investigate the static and dynamic properties of magnetically ordered structures and the possibility of direct spin manipulation with optical fields[4,5]. **K22 8 Ferromagnetic Resonance of a Single Nanoscale Magnet Driven by an RF Spin-Transfer Torque.** JACK SANKEY, *Cornell University* P.M. BRAGANCA, I.N. KRIVOROTOV, A.G.F GARCIA, D.C. RALPH, R.A. BUHRMAN, By applying a spin-polarized RF current through Py/Cu/$Py_{0.65}Cu_{0.35}$ spin-valve nanopillar devices approximately 100 nm in cross section, we have excited ferromagnetic resonance modes in the Cu-doped Py ''free'' layer. We detect the resonance via a DC voltage generated through mixing of the RF current and the oscillating magnetoresistance from the precessing magnetization. We find two different regimes of behavior. For small applied DC currents, we observe simple ferromagnetic resonance. The frequency-widths of the resonant peaks are related to the intrinsic magnetic damping, with the damping decreasing approximately linearly with DC current. In this regime we can also characterize the nonlinearities of the resonances from peak-shape analysis at larger RF currents. For DC currents large enough to excite spontaneous magnetic precession, we find a second regime in which the applied RF current produces phase locking, with a distinctive line shape. In both regimes, we observe dynamical modes not seen previously in DC-driven dynamical measurements.

**16:30**

**K22 9 FMR spectroscopy of individual nanopillars** GREGOIRE DE LOUBENS, VLADIMIR V. NALETOV,*OLIVIER KLEIN, *CEA Saclay, Service de Physique de l'Etat Condense* We have performed FMR spectroscopy on perpendicularly magnetized hybrid nanopillars (lateral sizes range between 500 nm and 2 $\mu$m) using a Magnetic Resonance Force Microscope. The sensitivity of this technique allows us to measure an individual sample. Firstly, 100 nm thick Permalloy (Py) disks sandwiched by Cu have been

studied. It is found that the lowest energy mode is an edge mode localized at surfaces instead of being the uniform precession. The study of the dynamics in the non linear regime shows that the damping of this edge mode decreases with increasing power, which favors its excitation at high power level compare to the other modes. Secondly, Py100/Cu10/Py10 (nm) devices showing GMR effect have been measured and we have studied the spectral changes induced by high DC current densities J flowing through them. FMR spectra at J=0 are compared to those of single magnetic layer disks and qualitatively interpreted. The influence of the Oersted field and of the temperature increase when J$\neq$ 0 is quantified and a small effect of spin transfer is extracted.

**K22 10 Ferromagnet dynamics in a driven spin valve** JOERN N. KUPFERSCHMIDT, SHAFFIQUE ADAM, PIET W. BROUWER, *Laboratory of Atomic and Solid State Physics, Cornell University, Ithaca, NY, 14853* The magnetoresistance of a ferromagnet/normal-metal/ferromagnet trilayer depends on the relative orientation of the two magnetic moments. We analyze out-of-plane precession of the magnetization for a soft ferromagnetic layer in such a geometry, where the system is driven by an alternating charge current. We consider the effect of both spin-torque and spin-pumping on the magnetization dynamics and find that these have signatures in the magnetoresistance.

**16:54**

**K22 11 Strong interactions between a nanomagnet and a microcavity mode*** ÖNEY O. SOYKAL, M.E. FLATTÉ, *Department of Physics and Astronomy, University of Iowa, Iowa City, IA* We consider the interaction of a nanomagnet with a single mode of a microcavity in a fully quantum treatment. We derive the interaction Hamiltonian from Maxwell's equations by introducing the fully quantized forms of the spherical electromagnetic solutions. For a nanomagnet acting as a macrospin, within a cavity roughly 1 $mm^3$ in volume, the magnet-microwave mode coupling is $\sim 10^{-7}$eV. Strong coupling can therefore be seen if the quality factor of the cavity exceeds 1000.

**K22 12 Magnetic permeability and dielectric permittivity of ferrite materials in millimeter waves.** KONSTANTIN KOROLEV, *Institute of Radioengineering and Electronics of RAS, Moscow, Russia; Tufts University, Medford, MA 02155, USA* LAKSHMI SUBRAMANIAN, MOHAMMED AFSAR, *Tufts University, Medford, MA 02155, USA* Magneto-optical approach for the measurements of complex magnetic permeability and dielectric permittivity of solid and powdered strontium ferrite materials have been performed in the frequency range of 34-120 GHz. Free-space quasi-optical millimeter wave spectrometer equipped with a backward wave oscillator as a tunable source of coherent radiation provides the transmittance spectra in transverse magnetic field up to 7.5 kOe. Frequency dependences of dielectric and magnetic parameters of strontium ferrites have been calculated by matching theoretical curves to the experimental transmittance spectra. Shift of the ferromagnetic resonance to higher frequencies and the broadening of the zone of strong absorption in transverse magnetic field have been observed for solid ferrite materials. A relation between the specific gravity and the saturation of magnetization for these materials has been found. The shift of ferromagnetic resonance frequency vs. specific gravity has been observed. The correlations between complex dielectric permittivity and magnetic permeability and density of the samples have been observed.

**17:18**

**K22 13 Multiphoton antiresonance in large-spin systems** CHRISTIAN HICKE, MARK DYKMAN, *Michigan State University* We show that multiphoton resonance in a $S > 1$ spin system is accompanied by anticrossing of the responses in resonating states. This anticrossing accompanies the standard anticrossing of quasienergy levels. It leads to antiresonance: the ratio of the vibration amplitude to the modulation amplitude in one of the states becomes much less and in the other state much larger than in the weak-modulation limit. The response anticrossing can be observed by adiabatically sweeping the modulation frequency through multiphoton resonance. The shape and overall width of the dip/peak of the response as function of frequency strongly depend on the modulation amplitude. The effect has no analog in two-level systems and is sensitive to the parameters of the spin. It is most pronounced when the spin Hamiltonian in the absence of driving is $H_0 = \omega_0 S_z + \gamma S_z^2$. In this case several states experience multiphoton resonance at a time. The higher-order terms in $S_z^2$ lead to smearing of the antiresonance. We also study the response of the spin when the modulation is sharply turned on. The antiresonance leads to oscillations of the response with the multiphoton Rabi frequency. Their amplitude strongly depends on the modulation amplitude. The effect is compared with multiphoton antiresonance in a nonlinear oscillator [1]. [1] M. I. Dykman and M. V. Fistul, Phys. Rev. B **71**, 140508(R) (2005).

## SESSION K23: QUANTUM MAGNETS: BEC AND 2D

**K23 1 Thermodynamic and Magnetostriction Measuremetns of the Bose-Einstein Condensate $NiCl_2$-4SC$(NH_2)_2$** V.S. ZAPF, *National High Magnetic Field Lab at Los Alamos National Lab* V. CORREA, *NHMFL, Tallahassee, FL* D. ZOCCO, M. JAIME, N. HARRISON, A. LACERDA, *NHMFL, LANL* C.D. BATISTA, *T-11, LANL* T. MURPHY, E. PALM, S. TOZER, *NHMFL, Tallahassee, FL* A. PADUAN-FILHO, *Universidade de Sao Paulo, Brazil* We investigate Bose-Einstein condensation (BEC) of magnons in the organic magnet $NiCl_2$-4SC$(NH_2)_2$ (DTN). For magnetic fields applied along the tetragonal c-axis, the antiferromagnetically (AFM) ordered Ni spins can be recharacterized as a system of effective bosons with a hard-core repulsive interaction where the AFM transition corresponds to BEC. New, detailed data of the field-temperature phase diagram of DTN have been taken by means of thermodynamic measurements to dilution fridge temperatures. The magnetic field-temperature quantum phase transition line $H_c$-$H_{c1} \sim T^{\alpha}$ approaches a power law at low temperatures, with an exponent $\alpha$ at the quantum critical point that is consistent with the BEC theory prediction of $\alpha = 3/2$. In addition, new magnetostriction data at dilution refrigerator temperatures

will be presented. In the AFM ordering regime, field-induced $2^{nd}$ order changes in the lattice parameters create field-dependent AFM and spin-orbit coupling parameters, which can in turn distort the phase diagram at high fields.

**14:42**

**K23 2 High Magnetic Field Susceptibility Measurements for $BaCuSi_2O_6$** K. M. PURCELL, C. MARTIN, T. P. MURPHY, E. C. PALM, S. W. TOZER, *NHMFL-FSU* S. E. SEBASTIAN, I. R. FISHER, *Stanford University* We have measured the change in magnetic susceptibility of the spin gap system $BaCuSi_2O_6$ at high magnetic fields (33T) utilizing the change in the resonant frequency of a tunnel diode oscillator (TDO). At temperatures below T$\sim$ 3K, measurements reveal the presence of a critical field $H_{c1}$, characterized by a jump in magnetic susceptibility. The evolution of $H_{c1}$ with temperature is in good agreement with the previous magnetization and specific heat measurements and with the theoretical predictions for the realization of Bose-Einstein condensate by the spin system of $Cu^{2+}$ dimers. This technique provides the opportunity for future investigation of this material at high pressures.

**14:54**

**K23 3 Dimensional reduction at the BEC quantum critical point in $BaCuSi_2O_6$.** SUCHITRA SEBASTIAN, IAN FISHER, *Stanford University* NEIL HARRISON, MARCELO JAIME, PETER SHARMA, *NHMFL, Los Alamos National Laboratory* CRISTIAN BATISTA, *Theoretical Division, Los Alamos National Laboratory* LUIS BALICAS, *NHMFL, Tallahassee* NAOKI KAWASHIMA, *Institute for Solid State Physics, University of Tokyo* We present results on the magnetic spin dimer system $BaCuSi_2O_6$, which can be tuned across a Bose-Einstein condensation (BEC) quantum critical point (QCP) to an ordered BEC of spins by applying an external magnetic field. Experimental results reveal a continuous crossover in critical scaling behaviour near the QCP from 3d to 2d BEC universality, indicating that dimensionality itself is an emergent property at the QCP of this particle density-tuneable BEC. Geometrical frustration leading to inter-layer decoupling is identified as the mechanism responsible for this unique manifestation of a lower dimensional QCP in the 3d $BaCuSi_2O_6$ spin system. While the theoretical concept of dimensional reduction has been extensively discussed in many different contexts as a route to low dimensionality in bulk materials, this is the first experimental realisation of dimensionally reduced criticality.

**15:06**

**K23 4 Field-Induced Quantum Criticality in a Two-Dimensional Antiferromagnet*** TAO HONG, MICHEL KENZELMANN, MATTHEW BOULOUBASIS, DANIEL REICH, COLLIN BROHOLM, *Johns Hopkins University* MATTHEW STONE, *Oak Ridge National Laboratory* EMILY DUNKEL, SUBIR SACHDEV, *Harvard University* We describe neutron scattering measurements on the two-dimensional spin gap antiferromagnet piperanzium hexachlorodicuprate (PHCC) in the vicinity of quantum critical point at which the spin gap is closed by an applied magnetic field. We measure the energy and damping of the propagating $S_z = 1$ mode above the spin gap; both quantities become strongly temperature dependent at the critical field. The temperature dependence of the mode energy is successfully described by a self-consistent Hartree-Fock theory of interacting spin excitations.

*Work at the Johns Hopkins University was supported by the NSF under Grants No. DMR-0306940. Work at Harvard University was supported by NSF under Grants No. DMR-0537077. Work at NCNR was supported by NSF under Grants No. DMR-0086210

**15:18**

**K23 5 Magnon decay in gapped quantum spin systems** ALEXEI KOLEZHUK,*SUBIR SACHDEV, *Harvard University, Department of Physics* In the O(3) $\sigma$-model description of gapped spin systems, $S = 1$ magnons can only decay into *three* lower energy magnons. We argue that the symmetry of the quantum spin Hamiltonian often allows decay into *two* magnons, and compute this decay rate in model systems. For a realistic model describing two-dimensional spin dimer material $(C_4H_{12}N_2)Cu_2Cl_6$ (known as PHCC), we compare our results for the momentum-dependent magnon linewidth with recent measurements by Stone *et al.* (e-print cond-mat/0511266) and extract new information on the exchange coupling pattern in this material. For $S = 1$ Haldane chains, we show that two-magnon decay is allowed in the full lattice description, even though it cannot be induced by any allowed term written in powers and gradients of the $\sigma$-model field. We present estimates for the behavior of the magnon linewidth in Haldane gap chains and discuss relation to the recent experimental work.

*Supported by the Heisenberg Fellowship of DFG; on leave from Institute of Magnetism, National Academy of Sciences of Ukraine.

**15:30**

**K23 6 Impurity induced Knight shifts in 2D antiferromagnets** SEBASTIAN EGGERT, *University Kaiserslautern, Germany* FABRIZIO ANFUSO, *Chalmers University, Gothenburg, Sweden* The local response to a uniform field around vacancies in the two-dimensional (2D) spin-1/2 Heisenberg antiferromagnet is determined by numerical quantum Monte Carlo simulations as a function of temperature. It is possible to separate the Knight shifts into uniform and staggered contributions on the lattice which are analyzed and understood in detail. The contributions show interesting long and short range behavior that may be of relevance in NMR and susceptibility measurements. For more than one impurity remarkable non-linear enhancement and cancellation effects take place. We predict that the Curie impurity susceptibility will be observable for a random impurity concentration even in the thermodynamic limit.

**15:42**

**K23 7 Variational ground states of 2D antiferromagnets in the valence-bond basis*** JIE LOU, ANDERS SANDVIK, *Boston University* We use a variational method to study two-dimensional $S = \frac{1}{2}$ Heisenberg antiferromagnets in the valence bond basis. The wave function is of the form $|\psi\rangle = \Pi h(x_{ij}, y_{ij})(i,j)$, where $(i,j)$ represents a singlet formed by the spins at sites $i$ and $j$; $(i,j) = 1/\sqrt{2}\,(\uparrow_i\downarrow_j - \downarrow_i\uparrow_j)$, and $h(x_{ij}, y_{ij})$ is the amplitude corresponding to a bond coneenting two spins with seperation $(x_{ij}, y_{ij})$. The form $h \sim 1/r^p$, where $r$ is the distance, was studied prevously. The best variational energy was obtained for $p = 4$. Now we optimize all $h(x,y)$by combining a standard Newton method and a conjugate gradient method. For systems with up to 16 $\times$ 16 spins, the energy of the optimized wave function deviates by

less than 0.1% from the exact ground state energy. The spin-spin correlations are also very well reproduced. The exponent $p = 3$ in agreement with recent Monte Carlo simulations. We also investigates this class of wave functions for a quantum-critical bilayer model.

*Supported by NSF grant No. DMR-0513930

**15:54**

**K23 8 Dynamics of $S = 1/2$ Antiferromagnetic clusters*** LING WANG, ANDERS SANDVIK, *Boston University* A site diluted 2-d Quantum Heisenberg Antiferromagnet undergoes a Neel to disordered phase transition at the classical percolation density $p^*$, since the sublattice magnetization $m$ has a nonvalishing value on the percolating cluster. Although this implies that some of the exponents of the transition are equal to those of classical percolation, exponents involving dynamics are non-classical. We investigate the quantum dynamics of diluted systems at the percolation point by Lanczos diagonalization, generating histograms of the singlet to triplet excitation gap $\Delta$ for clusters of different size $N$. We investigate the finite-size scaling of the average and typical $\Delta$, to determine the dynamic exponent $z$. In a clean d-dimensional system with Neel order, $\Delta$ scales as $1/L^z$ with $z = d$, which arises from the quantum rotor states when the rotational symmetry has not been broken. As a direct generalization, it has been proposed that $z = D_f$ holds for the percolating clusters, where $D_f$ is the fractal dimensionality; $D_f = 91/48$. This has not been confirmed numerically, however, and there remains the possibility that there could be other excitations of the clusters leading to $z > D_f$. In addition to the Lanczos calculations, we also investigate the the distribution of the stagged susceptibility $\chi(\pi,\pi)$ and the stagged structure factor $S(\pi,\pi)$, which give information on the quantum dynamics through sum rules.

*Supported by NSF grant No. DMR-0513930

**16:06**

**K23 9 Variational Study of the Two-dimensional Hubbard Model at half-filling** YUNG-CHUNG CHEN, *Department of Physics, Tunghai University, Taiwan* H.C. CHIEN, *Physics, National Tsing Hua University, Taiwan* CHIH-TIN SHIH, *Physics, Tunghai University, Taiwan* The ground-state properties of the half-filled two-dimensional Hubbard model is systematically investigated by the variational wave function with d-wave supercondcting and anti-ferromagnetic correlations. The enhanced pairing correlation observed in the previous Gutzwiller approximation is found to be strongly suppressed by the doublon-holon and antiferromagnetic correlations. In order to check this result, power-Lanczos method is employed to improve the variational wave function. It is found that that pairing is not stable against antiferromagnetic long-range order. Possible models for the theory Gossamer superconductivity will be discussed in this paper.

**16:18**

**K23 10 Investigations of the 2D Isinglike magnet, $ZnMn_2O_4$** WILLIAM RATCLIFF, YING CHEN, YIMING QIU, QING HUANG, JEFFREY LYNN, *National Institute of Standards and Technology, NCNR* SUNMOG YEO, SANG CHEONG, *Rutgers University, Department of Physics* PAULA PICCOLI, ARTHUR SCHULTZ, *Argonne National Lab, IPNS* $ZnMn_2O_4$ crystallizes at high temperatures in the spinel structure. At lower temperatures, it undergoes a Jahn Teller distortion which lowers its symmetry to tetragonal. At lower temperatures ($T_N \sim 60$K), the system orders magnetically. Fits to the order parameter, line shape of powder diffraction peaks, and the direct observation of rods of scattering in single crystal diffraction experiments show the system to be two dimensional. This is likely due to an interplay of orbital ordering and frustration. In this talk, I present the results of recent neutron diffraction experiments performed on this compound and discuss the nature of the magnetism.

**16:30**

**K23 11 Novel magnetic structure of one monolayer Fe on Ir(111)** STEFAN HEINZE, KIRSTEN VON BERGMANN, ELENA VEDMEDENKO, MATTHIAS BODE, ROLAND WIESENDANGER, *Institute of Applied Physics, University of Hamburg, Jungiusstrasse 11, 20355 Hamburg, Germany* GUSTAV BIHLMAYER, STEFAN BLÜGEL, *Institut für Festkörperforschung, Forschungszentrum Jülich, 52425 Jülich, Germany* Due to the interplay between symmetry, nearest-neighbor spacing, and hybridization with the substrate surprising magnetic ground-states can occur for monolayer films such as the two-dimensional antiferromagnetism of Fe on W(001) [1]. Much more complex magnetic structures have been predicted for monolayer thick films of an antiferromagnet on a triangular lattice given e.g. by an (111) fcc surface. To our knowledge, however, there is no experimental proof. Here, we report a novel, nanometer scale magnetic structure for one monolayer Fe on Ir(111). Based on the observed contrast in spin-polarized scanning tunneling microscopy (SP-STM) measurements a giant magnetic unit cell consisting of 15 Fe atoms is suggested. Our first-principles calculations show that the proposed magnetic state is indeed more favorable than all possible magnetic solutions describable by the classical Heisenberg model including interactions between neighbors of arbitrary distance. We find that the $3d - 5d$ hybridization between the Fe ML and the Ir substrate plays a key role for the unusual magnetic behavior. [1] A. Kubetzka *et al.*, Phys. Rev. Lett. **94**, 087204 (2005).

**16:42**

**K23 12 Magnetic order and lattice anomalies in the $J_1$-$J_2$ model system $VOMoO_4$** ALESSANDRO BOMBARDI, *Diamond Light Source* LAURENT CHAPON, *ISIS-Rutherford Laboratory* IRENE MARGIOLAKI, *ESRF* CLAUDIO MAZZOLI, *ESRF* SABINE GHONTIER, *CNRS* FABIENNE DUC, *CNRS-Toulouse* PAOLO RADAELLI, *ISIS-Rutherford Laboratory* High resolution x-ray and neutron powder diffraction measurements were performed on polycrystalline $VOMoO_4$. Below $\simeq 40$ K the system orders in a simple Néel antiferromagnetic state (propagation vector $\vec{k} = 0$), indicating a dominant role of the nearest-neighbor interactions. The order is three dimensional but the reduced saturated magnetic moment $m$ of 0.41 (1) $\mu_B/V^{4+}$ at 2 K indicates strongly 2D character and enhanced quantum fluctuations. On cooling, there is no evidence of a reduction of the crystal symmetry. However, neutron diffraction indicates an anomalous evolution of the lattice parameters, which can be related to the onset of magnetic correlations.

**K23 13 Field-induced thermal transport in low-dimensional antiferromagnets*** ALEXANDER CHERNYSHEV, *UC Irvine* Recent thermal transport experiments in a number of low-dimensional antiferromagnets such as $K_2V_3O_8$, $Nd_2CuO_4$, $Pr_2CuO_4$, $TlCuCl_3$ and others have shown that the low-temperature thermal conductivity can be strongly increased by a modest magnetic field. It was suggested that this effect could be due to the field-induced heat transport by spin excitations. We show that in most of the reported cases the observed enhancement

of the thermal conductivity is not of spin, but of phononic nature. That is, the increase in the thermal conductivity occurs because of the decrease of the scattering of phonons on spin excitations. This decrease is due to the field-induced gaps in the spin-excitation spectra. Our calculations reproduce quantitatively all characteristic field-dependencies observed in experiments such as increase of the thermal conductivity and its saturation in higher fields. A number of suggestions for future experiments is made.

**K23 14 Magnetic Properties of a Novel Fe(II) itmeso-tetra(4-pyridyl)porphyrin Network** DUSAN DANILOVIC, CHYAN LONG LIN, TAN YUEN, *Department of Physics, Temple University* LONG PAN, JING LI, *Department of Chemistry & Chemical Biology, Rutgers University, Piscataway, NJ 08854* Magnetic properties of Fe(II) itmeso-tetra(4-pyridyl)porphyrin [Fe(TpyP)], a newly discovered metalloporphyrin network, were investigated using magnetic susceptibility $M(T)/H$, isothermal magnetization $M(H)$, and heat capacity $C(T)$ measurements. The crystal structure of Fe(TpyP) at room temperature is orthorhombic with a space group Cmca (No. 64). And this network gives rise to an unprecedented two-dimensional paddle-wheel-like pattern (a $4^4$ topology). The results of $M(T)/H$ on powder samples of Fe(TpyP) show that the effective moment $\mu_{eff}$ of $Fe^{2+}$ is 5.52 $\mu_B$ at 340 K, close to the expected value for a high spin $Fe^{2+}$ ($S = 2$) ion. $\mu_{eff}$ increases to 5.90 $\mu_B$ as $T$ decreases to the range of 170 K $< T <$ 220 K, and then decreases monotonically as $T$ decreases further. The behavior of $\mu_{eff}$ in the high temperature region may be attributed to a positive $Fe^{2+}$-$Fe^{2+}$ coupling. The low field ($H \leq$ 4 kG) $M(T)/H$ data reveal an anomalous behavior of this compound in the low temperature region which seems spin-glass-like. A small hysteresis was observed in $M(H)$ measured at 2 K. No anomaly was seen in the $C(T)$ data from 1.6 to 25 K.

**K23 15 Signatures of one-dimensional localization of magnetically quantized carriers in graphite: power-law hopping mechanism.** ARTHUR HEBARD, *University of Florida* XU DU, *Rutgers University* DMITRI MASLOV, RONOJOY SAHA, *University of Florida* We present results of a transport study on highly oriented pyrolytic graphite (HOPG) in ultra-quantum limit magnetic fields (B$>$ 8T) applied along the c-axis (z direction). For temperatures in the range 2K$<$ $T <$ 20K, the measured in-plane resistivity $\rho_{xx}$ follows a metallic-like $T^{1/3}$ dependence while the c-axis **resistivity** $\rho_{zz}$ exhibits an insulating-like linear temperature dependence. We show that the c-axis transport behavior can be explained within the context of a power-law hopping mechanism, in which phonons cause localized electrons to hop over distances on the order of the localization length with a frequency of $1/\tau_\phi \propto T$. The corresponding resistivity behaves as $\rho_{zz.} \propto \tau_\phi \propto T^{-1}$. The temperature range for this picture to hold is justified by the semimetal-like properties of HOPG. Both the in-plane and c-axis behavior agree well with the model of electrons almost localized by strong magnetic fields in the presence of long-range disorder, which predicts that $\rho_{xx} \propto \rho_{zz}^{1/3} \propto T^{1/3}$ [1] [1] S. S. Murzin, JETP Lett. **45**, 283 (1987).

**K24 2 Cracks and Topological Defects in Nematic Nanotube Gels** A.G. YODH, M.F. ISLAM,*A.M. ALSAYED, Z. DOGIC, M. NOBILI, J. ZHANG, FANGFU YE, T.C. LUBENSKY, *Department of Physics & Astronomy, University of Pennsylvania* We have created [1] and studied [2] lyotropic nematic gels composed of aligned single wall carbon nanotubes (SWNTs) in a crosslinked N-isopropyl acrylamide (NIPA) polymer matrix. These composites are created by dispersing surfactant stabilized SWNTs at low concentration in a solution of NIPA monomer that is then polymerized and crosslinked to form a gel, and then inducing a temperature-dependent volume-compression transition of the NIPA gel. Quantitative measurements of SWNT order parameter reveal a concentration-dependent crossover from isotropic to nematic phases. Due to the coupling of nematic order and elasticity of the polymer matrix, we also observe: (i) undulations and then cusping of the gel sidewalls, (ii) a nematic director that evolves as the gel sidewalls deform, (iii) networks of surface cracks that are orthogonal to the nematic director, and (iv) fissures at the sidewall cusps and associated topological defects that would not form in liquid nematics. This work is supported by grants from NSF (MRSEC DMR 05-20020 and DMR-0505048) and NASA NAG8-2172. References: 1. Islam, Alsayed, Dogic, Zhang, Lubensky, Yodh, PRL **92**, 088303 (2004). 2. **K24 3 Composite Polymer Nanofibers with Carbon Nanotubes and Titanium Dioxide Particles with Photocatalytic Activity** SHAHAR KEDEM, YARON PAZ, YACHIN COHEN, *Technion, Israel* Composite nanofibers containing Multi Walled Carbon Nanotubes (MWCNT) and nanometric $TiO_2$ particles dispersed in poly(acrylonitrile) (PAN) were prepared by the electrospinning (ES) technique. The fabricated nanofibers, the diameters of which were in the 20-200 nm range, contained well-oriented nanotubes and spherical $TiO_2$ nanoparticles in close proximity. The carbon nanotubes stabilize the polymer nanofibers against photodegradation by UV radiation, as compared with nanofibers composed only of PAN and $TiO_2$. Preliminary results on the photocatalytic activity of these nanofibers in decomposition of organic molecules will be reported.

**15:30**

**K24 4 The Impact of Sample Preparation on Polymer Carbon Nanotube Nanocomposites.** CHANG-UK LEE, *University of Tennessee, Knoxville* MARK DADMUN, *University of Tennessee, Knoxville* The dispersion of multi-walled carbon nanotubes (MWNTs) in a polymer matrix is a critical parameter that impacts the ability of that MWNT to improve the properties of the polymer matrix. In this study, the impact of the sample preparation process on the dispersion and properties of the resultant nanocomposite is discussed. Additionally, the impact of intermolecular interactions

between the MWNT and polymer matrix on the mechanical properties of the polymer nanocomposites was investigated. Polymer nanocomposites composed of 1 wt% MWNT and poly(styrene-co-4-vinyl phenol) (PS-co-VPh) random copolymers were prepared by three different methods, including melt-mixing and solution casting. The MWNT are either oxidized to incorporate oxygenated defects or utilized as received. DMA results suggest that solution casting allows the formation of more intermolecular hydrogen bonding between MWNT and polymers than melt mixing. DMA data also suggests that more intermolecular hydrogen bonding results in improved mechanical properties of the resultant polymer nanocomposites.

**K24 5 NMR Characterization of the Interface in Polyurethane/Carbon Nanotube Composites** PETER MIRAU, *Air Foirce Research Laboratory* DANIEL POWERS, *Air Foirce Research Laboratory* JENNIFER GARBER, *Wright State University* HILMAR KOERNER, *Air Force Research Laboratory* RICHARD VAIA, *Air Force Research Laboratory* Solid-state proton NMR has been used to investigate the structure and dynamics of shape recovery polymers and composites with carbon nanotubes (CNTs). The thermoplastic polyurethane (Morthane) has both soft and hard segments. The soft segments are mobile at ambient temperature and give rise to a 2 kHz-wide proton signal. The protons signals shift and broaden with the introduction of CNTs. The proton spin- lattice and spin-spin relaxation times are relatively insensitive to the presence of CNT, demonstrating that the broadening is a consequence of proximity of the CNTs rather than a change in the molecular dynamics. The structures of the films in the stretched and relaxed states are probed using proton spin diffusion experiments. The results show the hard segments form 12 nm-sized domains and that the spin diffusion curves are very sensitive to the onset of soft-segment crystallinity as the samples are stretched. The effect of CNTs on the domain sizes and spacings are also measured in stretched and relaxed films.

**15:54**

**K24 6 Single-wall carbon nanotube aerogels** M. B. BRYNING, *University of Pennsylvania* M. F. ISLAM, *Carnegie Mellon University* L. A. HOUGH, *Rhodia* A. G. YODH, *University of Pennsylvania* Aerogels of single-wall carbon nanotubes (SWNTs) were created by freeze drying and critical point drying of aqueous SWNT gels. The resulting aerogels maintain the strongly-connected three-dimensional SWNT network of the original gel and have density less than 0.1 g/cm3. While these pure SWNT aerogels are self-supporting, reinforcement with small amounts of added polyvinylalcohol (PVA) produces much stronger structures that are easy to handle. Electrical conductivity of order 1 S/cm is observed in the self-supporting aerogels, and similar conductivity can be achieved in PVA-reinforced aerogels through additional processing. The aerogels can be backfilled with polymers such as epoxy to create composite materials that retain the high conductivity of the network. Other potential applications for these structures, such as sensors, actuators, and thermoelectric devices, are currently being explored. This work is supported by grants from NSF (MRSEC DMR05-20020 and DMR-0505048) and NASA NAG8-2172.

**16:06**

**K24 7 Polymer crystallization-driven, periodical patterning on carbon nanotubes** LINGYU LI, CHRISTOPHER LI, *Drexel University* We report herein a unique means to periodically pattern polymers on carbon nanotubes (CNTs) using controlled polymer crystallization method. CNTs were periodically decorated with polymer lamellar crystals, resulting in nano hybrid shish-kebab (NHSK) structures. The periodicity of adjacent kebabs varies from 20 - 150 nm. The kebabs are approximately 5 nm thick (along CNT direction) with a lateral size of $\sim$ 20 nm to micrometers, which can be readily controlled by varying crystallization conditions. Both polyethylene and Nylon 66 were successfully decorated on single-walled carbon nanotubes (SWNT), multi-walled carbon nanotubes (MWNT), as well as vapor grown carbon nanofibers (CNF). The formation mechanism was attributed to ''size dependent soft epitaxy.'' NHSK structure was discussed with an emphasis on the periodicity of adjacent kebabs. The influence of experimental parameters on the periodicity was investigated in details Since NHSK formation conditions depend upon CNT structures, it further provides a unique opportunity for CNT separation. The reported method opens a gateway to periodically patterning polymers and different functional groups on individual CNTs in an ordered and controlled manner, an attractive research field that is yet to be explored.

**16:18**

**K24 8 Alignment and Alignment Modulation of Single Wall Carbon Nanotubes Using Lyotropic Chromonic Liquid Crystals** M. F. ISLAM, *Department of Chemical Engineering and Department of Materials Science & Engineering, Carnegie Mellon University, Pittsburgh, PA 15213* I. I. SMALYUKH, O. D. LAVRENTOVICH, *Chemical Physics Interdisciplinary Program and Liquid Crystal Institute, Kent State University, Kent, Ohio 44242* A. G. YODH, *Department of Physics & Astronomy, University of Pennsylvania, Philadelphia, PA 19104-6396* We report alignment and local alignment modulation of single wall carbon nanotubes (SWNTs) dispersed in a nematic solvent of lyotropic chromonic liquid crystals (LCLCs). Polarized optical absorption suggests that when SWNTs are coated with surfactant molecules, e.g., sodium dodecyl benzene sulfonate (NaDDBS), the SWNTs align along the nematic director of the LCLCs, possibly due to elastic interaction between the anisotropic SWNTs and the nematic field of the LCLCs. In contrast, if the SWNTs are not coated with surfactant, then SWNTs align normal to the LCLC nematic director, possibly due to $\pi - \pi$ interactions between the aromatic groups of the LCLCs and the graphitic surface of SWNTs. We describe these observations and show that SWNTs can easily be realigned via realignment of nematic LCLCs using a magnetic field of only a few KGauss. This work is supported by grants from NSF (MRSEC DMR 05-20020 and DMR-0505048) and NASA NAG8-2172.

**16:30**

**K24 9 Theoretical investigation of the atomic and electronic structure of amino acids on Si(100) surfaces** XUAN LUO, GEFEI QIAN, CELESTE SAGUI, CHRISTOPHER ROLAND, *Department of Physics, NCSU* There are currently considerable efforts underway to combine silicon-based device technology with myriad of organic molecules, thereby fabricating new structures that take advantage of the tunable electronic and optical properties of organic molecules. A key aspect of this integration process is binding of the organics to the silicon surfaces. As part of this effort, we have been investigating the binding of several amino

acids – the building blocks for proteins – on the Si (100) surface with state-of-the art density functional theory methods. Specifically, the binding between the buckled Si(100) and the NH2, CH2, COOH, C=0 and NC entities at various surface sites have been investigated. We report and discuss on the resulting structures and their electronic properties.

**16:42**
**K24 10 Dynamics of poly(ethylene oxide)/$Li^+$ complexes confined in 1nm slits** GEORGIOS POLIZOS, *Penn State University* VIKRAM KUPPA, *Massachusetts Institute of Technology* ANDREAS SCHÖNHALS, *Federal Institute of Materials Research and Testing, Berlin, Germany* EVANGELOS MANIAS, *Materials Science and Engineering, Penn State University, University Park, PA* Poly(ethylene oxide) (PEO)/$Li^+$ complexes were nanoscopically confined in 1nm slit pores between inorganic solids of controlled $Li^+$ charge surface density (*cf.* varied cation exchange capacity $Li^+$ montmorillonites). The experimental systems were prepared by direct melt intercalation and investigated by dielectric relaxation spectroscopy over broad frequency and temperature ranges. Ionic conductivity/diffusion effects and the interfacial polarization relaxation process (due to the motion of the $Li^+$ ions in the slits) are systematically explored and analyzed. We present their dependences on frequency, temperature, $Li^+$ surface density, and PEO/$Li^+$ interactions. The above results are discussed in the context of previous Molecular Dynamics computer simulations, and mechanisms associated with the existence of water in the slit are thus identified.

**16:54**
**K24 11 Development of New Elastomers and Elastic Nanocomposites from Plant Oils** LIN ZHU, *Dept Chemical Engineering* RICHARD WOOL, *University of Delaware* Economic and environmental concerns lead to the development of new polymers from renewable resources. In this research, new elastomers were synthesized from plant oil based resins. Acrylated oleic methyl ester (AOME), synthesized from high oleic triglycerides, can readily undergo free radical polymerization and form a linear polymer. To achieve the elastic properties, different strategies have been developed to generate an elastic network and control the crosslink density. The elastomers are reinforced by nanoclays. The intercalated state has a network structure similar to thermoplastic elastomers in which the hard segments aggregate to give ordered crystalline domains. The selected organically modified clay and AOME matrix have similar solubility parameters, therefore intercalation of the monomer/polymer into the clay layers occurs and the nano-scale multilayered structure is stable. itIn situ intercalation and solution intercalation were used to prepare the elastic nanocomposites. Dramatic improvement in mechanical properties was observed. Changes of tensile strength, strain, Young's modulus and fracture energy were related to the clay concentration. The fracture surface was studied to further understand clay effects on the mechanical properties. Self-Healing of the intercalated nanobeams, thermal stability, biocompatibility and biodegradability of this new elastomer were also explored.

**17:06**
**K24 12 Simulations of Polymer Nanocomposites** THOMAS CLANCY, *National Institute of Aerospace* Simulations of polymer nanocomposites were undertaken in order to determine the effect of molecular structure on macroscopic properties. Due to the large amount of interfacial area present in nanostructured materials, the effect of structural details at this interface is influential in the resulting material properties. These simulations focus on variation in molecular structural details at this interface and the effect on the resulting macroscopic properties of the nanocomposite.

**17:18**
**K24 13 Characterizing the structural properties of organic-inorganic hybrid semiconductors by first-principles calculations** CHANG-YOUN MOON, GUSTAVO DALPIAN, YONG ZHANG, SU-HUAI WEI, *National Renewable Energy Laboratory* XIAOYING HUANG, JING LI, *Department of Chemistry and Chemical Biology, Rutgers University* Recently, a new type of hybrid materials $A_{II}B_{VI}(en)_{0.5}$, consisting inorganic II-VI semiconductor slabs connected by organic molecule spacers have been synthesized. [1] These materials have the advantage of possessing both inorganic and organic constituents: good electric and optical properties of the inorganic part, and the easiness of assembly of the organic part. [1,2] In this work, using first principles method, we study the stability and structural properties of $A_{II}B_{VI}(en)_{0.5}$ (A=Zn or Cd, B=S, Se, or Te, and en=ethylenediamine) in the known $\alpha$ and $\beta$ phases. We found that the relative stability of the $\alpha$ and $\beta$ phases of the hybrids is closely related to the intrinsic stability of the two phases of the inorganic semiconductor constituent: wurtzite (WZ) and zincblende (ZB). An inorganic compound with WZ ground state will prefer to exist in the $\alpha$ phase, whereas a ZB compound will prefer to exist in the $\beta$ phase.The relative stability is also affected by the size of the inorganic constituents and the spacing and bond angle of the en molecules. The results are analyzed by considering the contribution from the organic and inorganic part separately. [1] X. Huang et al., J. Am. Chem. Soc. 122, 8789 (2000); 125, 7049 (2003). [2] B. Fluegel et al., Phys. Rev. B 70, 205308 (2004)

**K25 2 Conformational transition of polybenzimidazole in N,N-Dimethylacetamide/lithium chloride.** CHRISTOPHER SHOGBON, *Rensselaer Polytechnic Institute* HAIFENG ZHANG, BRIAN BENICEWICZ, YVONNE AKPALU, *Rensselaer Polytechnic Institute, Troy,NY.* JEAN-LUC BROUSSEAU, *Brookhaven Instruments Corporation, Holtsville, NY.* Static light scattering and circular dichroism techniques have been used for the first time to study the chain conformation of a previously synthesized *m*-PBI sample in DMAc/LiCl. The chain conformation was studied as a function of a) polymer concentration (0.1 to 20 mg/mL) at a fixed salt concentration of 4 % LiCl and b) salt concentration (0.05 to 7 %) at a fixed polymer concentration of 0.3 mg/mL. As polymer or salt concentration was increased, the chains collapsed initially, and then underwent fluctuations in size without a significant decrease in their average size. The collapse

was associated with a conformational transition from random coil to an ''extended wormlike'' chain. At polymer concentrations greater than 9 mg/mL, the average size of the polymer chain is relatively constant at 31.2 ± 1.7 nm. Circular dichroism measurements confirmed the conformational transitions that had been observed by indicating optical activity at polymer concentrations above 2 mg/mL. These results contribute to our overall understanding of chain stiffness and conformational transitions in PBI polymers, which may play an important role in the preparation of polymer electrolyte membranes via sol-gel processing.

**15:18**

**K25 3 Nanostructured Polymer Electrolytes** OMOLOLA ODUSANYA, *University of California, Berkeley* MOHIT SINGH, *Lawrence Berkeley National Laboratory* NITASH BALSARA, *University of California, Berkeley* We present results on work on polystyrene-b-polyethyleneoxide copolymer electrolyte membranes. The volume fraction of the ethylene oxide block is 0.38 and molecular weight of each block is 36 kg/mol and 25 kg/mol respectively for the polystyrene and ethyleneoxide blocks. These electrolytes were made by doping with lithium bis(trifluoromethylsulfonyl)imide salt with the ratio of Li ion / ethylene oxide units ranging from 0.02 to 0.1. The salt/polymer samples were pressed into 1.0mm thick and 4.0 mm ID pellets in an air-free environment and measurements were made from 80$^o$C to 120$^o$C. Transmission Electron Microscopy and Small Angle X-ray Scattering experiment results indicate that our samples have a perforated hexagonal morphology. Conductivity results using AC impedance spectroscopy show that we are able to achieve values of $\sim$ 0.0001 S/cm, well within the theoretical upper limit expected for these samples while maintaining a high mechanical integrity of about 0.1GPa as determined from rheology. Achieving the combination of high conductivity with mechanical strength, which we observe in our results, has been a major problem in the battery research community.

**15:30**

**K25 4 Proton Conducting Membranes from Fluorinated Poly(Isoprene)-itblock-Sulphonated Poly(Styrene): A Structure Vs Property Study.*** AKINBODE ISAACS-SODEYE, SAMUEL GIDO, *University of Massachussetts Amherst* TIANZI HUANG, JIMMY MAYS, *University of Tennessee Knoxville* Proton Conducting Membranes used in Fuel Cells typically comprise of ionomers, having hydrophobic backbones and hydrophilic acid bearing side chains. Cell Efficiencies are limited by membrane morphology amongst other things. This study is a step towards tuning the morphology and ultimately properties of our relatively cheaper fluorinated Poly(Isoprene)-block-sulphonated Poly(Styrene) block copolymer ionomer membranes, made from post polymerization modified PS-PI. Work on random and graft copolymer ionomers especially Nafion $^{TM}$ have shown that morphologies of membranes from such materials vary with temperature, water content, counterion and No. of acid groups per chain etc. Analysis of our membranes using USAXS and SANS aims to explore the above mentioned variables; furthermore methanol permeability and proton conductivity will be studied using a diffusion Cell and impedance spectroscopy respectively.

**K25 5 Proton transport through polymeric membranes** XINYU WANG, *Dept. of Physics, Univ. of Mass.* RICH WOUDENBERG, *Dept. of Polymer Science and Engr., Univ. of Mass.* OZGUR YAVUZCETIN, *Dept. of Physics, Univ. of Mass.* SERGIO GRANADOS, *Dept. of Polymer Science and Engineering, Univ. of Mass.* BRYAN COUGHLIN, *Dept. of Polymer Science and Engr., Univ. of Mass* MARK TUOMINEN, *Dept. of Physics, Univ. of Mass.* M.T. TUOMINEN TEAM, E.B. COUGHLIN COLLABORATION, Hydrogen fuel cells have drawn increasing attention from researchers because of the steadily declining supply of fossil fuels. A key component of a fuel cell is a membrane that is an efficient conductor of protons, but not electrons or molecules. Nafion currently is the dominant material chosen for this purpose, with proton conductivity facilitated by an imbibed network of water. Unfortunately, this material loses its conductivity as it becomes dehydrated at elevated temperatures. In this work we make a detailed examination of the physics of proton conductivity in anhydrous polymeric membranes though temperature-dependent DC current-voltage characterization, AC impedance spectroscopy and Hall effect measurements. We assess the relevance of fundamental proton conductivity models involving thermo-mechanical and electro-mechanical transport mechanisms. This work is supported by DOE grant 10759-001-05, NSF grant DMR-0306951 and MRSEC.

**15:54**

**K25 6 Performance of Nanostructured Polymer Electrolytes in Li Batteries** MOHIT SINGH, *LBNL* LOLA ODUSANYA, *UC berkeley* NITASH BALSARA, *UCB/LBNL* Batteries that employ Li anodes for high energy density applications suffer from failures due to side reactions and dendrite growth on the Li electrodes. A recent theory by Newman and Monroe (2005) shows that dendrite formation can be prevented if the shear modulus of the electrolyte can be increased by several orders of magnitude without a concomitant decrease in conductivity. The nanostructured polymer electrolyte (PE) in our study has a modulus of a glassy polymer. AC impedance measurements on Li/PE/Li systems show that the PE has high ionic conductivity. We present experimental data on the performance of a novel nanostructured dry PE in a Li/PE/Li battery. We report the DC cycling measurements, interfacial resistance measurements, and dendrite growth characteristics in Li/PE/Li cells. The performance of the nanostructured PE is compared with that of PE based on the homopolymer poly(ethylene oxide), which is a benchmark for dry polymer electrolytes.

**16:06**

**K25 7 PEO mobility in nanoparticle-filled polymer electrolytes as measured by neutron scattering** SUSAN FULLERTON, JANNA MARANAS, *Penn State* VICTORIA GARCIA SAKAI, *NIST Center for Neutron Research* The mobility of poly(ethylene oxide) [PEO] is measured for solid polymer electrolyte systems of PEO/LiClO4 and PEO/LiClO4/Al2O3, where LiClO4 is the lithium salt and Al2O3 is the nanoparticle filler. While the addition of nanoparticles has been shown to improve conductivity in solid polymer electrolytes, the molecular mechanism is unclear. Some suggest the addition of nanoparticles increases PEO mobility, while others suggest nanoparticles act like crosslinkers, pinning PEO at the ether oxygen atoms - decreasing PEO mobility. The glass transition temperatures of polymer electrolytes filled and unfilled with nanoparticles differs by only a few degrees, making it difficult to interpret the influence of nanoparticle fillers on PEO mobility. However, mobility can be directly measured by quasi-

elastic neutron scattering, and has previously been used to measure a system of PEO/LiClO4. We measure PEO mobility using the High-Flux Backscattering Spectrometer [HFBS] and the Disk Chopper Time-of-Flight Spectrometer [DCS] at the NIST Center for Neutron Research in Gaithersburg, Maryland. The two techniques measure motion on a timescales ranging from 240 ps to 2 ns, and 0.1 ps to 40 ps respectively. PEO mobility is measured for filled and unfilled solid polymer electrolytes at 323K. The addition of LiClO4 imparts a second, slower process, and the addition of nanoparticle fillers increases PEO mobility.

**16:18**

**K25 8 Effects of Temperature and Dissolved $LiClO_4$ on the Viscoelastic and Dynamic Properties of Poly(ethylene oxide), (PEO) Melts** R.B. BOGOSLOVOV, J.C. SELSER, S. PENG, *Department of Physics, University of Nevada, Las Vegas* Poly(ethylene oxide)/lithium perchlorate ($PEO/LiClO_4$) complexes are widely studied as a prototype solid polymer electrolyte in rechargeable lithium-polymer batteries. Characterizing the structure and dynamics of the system in its molten state is important for understanding the role of the polymer environment in lithium ion transport and conductivity. A fiber-optic coupled Fabry-Perot interferometer is employed in the investigation of the electrolyte viscoelastic and dynamic properties, which are both related to the intrachain local mobility and therefore to ion diffusion. The properties of the system are studied as a function of composition, temperature, and frequency. Structural relaxation processes are observed both in the neat polymer melt and in the salt containing electrolytes. A unique *q*-dependent measurement is performed, allowing the investigation of the Brillouin frequency and linewidth as a function of frequency. It revealed a double-step relaxation in the gigahertz frequency range. The two relaxations are identified as secondary relaxations with Maxwell-Debye character.

**16:30**

**K25 9 Local Ion Motion and Interactions in Single-Ion Polymer Electrolytes via Dielectric Spectroscopy** ROBERT KLEIN, SHIHAI ZHANG, SHICHEN DOU, RALPH COLBY, JAMES RUNT, *Materials Science and Engineering, Pennsylvania State University* A novel method is presented whereby the parameters quantifying the conductivity of polymer electrolytes can be extracted from the phenomenon of electrode polarization in dielectric spectroscopy. The validity of the model was confirmed by examining the effects of sample thickness and temperature, as well as by comparison of predicted and measured conductivities. Ion mobilities and mobile ion concentrations of neat and 'gel' forms are compared for poly(ethylene oxide)-based sulfonated ionomers. The mobile ion concentration of the neat ionomers was found to be a surprisingly low fraction of the total ion concentration, but increases substantially in the gel ionomers. Furthermore, the temperature dependence of mobility changes from VFT-like for the neat ionomers, to more Arrhenius-like for the gel ionomers. In addition, adding plasticizers to the ionomer significantly influences the local beta process, and the effects are quantified as a function of the dielectric constant and donor number of the plasticizer, and related to the conductivity.

**16:42**

**K25 10 Confined Water in Ionic Membranes: Studied by NMR** LILIN HE, *Department of Chemistry, Clemson University, South Carolina, 29634-0973* CY FUJIMOTO, *Chem.and Bio. Technologies, Sandia National Laboratories, Albuquerque, New Mexico 87185-0888* CHRISTOPHER CORNELIUS, *Chem.and Bio. Technologies, Sandia National Laboratories, Albuquerque, New Mexico 87185-0888* DVORA PERAHIA, *Department of Chemistry, Clemson University, South Carolina, 29634-0973* Proton NMR studies have been carried out to identify the location and dynamics of water confined within highly rigid sulfonated ionomer membranes. Understanding the dynamics and location of water molecules within polymeric ionic membrane, is critical to their many potential uses from fuel cell application to water purifying membranes. The magnetic relaxation times are sensitive to the degree of confinement of the molecules and the chemical environment affects the resonance frequency (chemical shift) of the water. Three different environments have been identified, highly mobile, almost free water molecules, partially confined in hydrophilic environment and water molecule that penetrated into the hydrophobic regime. Where surprisingly no fast exchange between these sites was detected even at room temperature. The distribution between these sites strongly depend on the degree of ionization of the polymers.

**16:54**

**K25 11 E-Field Dependent Conduction Mechanisms in Low Density Polyethylene*** JERILYN BRUNSON, J.R. DENNISON, *Utah State University* Successful conduction mechanisms have been developed for amorphous solids and semi-conductors for electric field dependent charge carrier mobility. Where electrons are the primary charge carriers, their mobility is dependent on their probability of hopping between potential well trapping sites. Extending these conduction mechanisms to polymers, resistivity can be directly related to carrier mobility within the bulk. A series of low electric field resistivity measurements at constant temperature have been made to test the Poole-Frenkel theory of field-enhanced hopping conduction in low density polyethylene.

SCHMIDT, MATTHIAS WAGNER, *Institut für Anorganische und Analytische Chemie, Johann Wolfgang Goethe-Universität, Marie Curie-Str. 11, 60439 Frankfurt/Main, Germany* We use first principles methods to study the electronic properties of a Cu(II) coordination polymer. We have introduced two substitutions on the polymer in order to investigate the influence of the change of constituents in the hydroquinone molecule on the interactions between the metal centers. Furthermore, we have introduced two different ligand molecules in order to simulate the effect of satellite molecules in a real sample in the laboratory. In the preparation and analysis of the structures, we optimize computational efficiency and precision by employing four different methods: We initially prepare structures with classical force field methods, then we relax the rough structure by ab initio molecular dynamics. The analysis is done with a

full-potential linearized augmented plane-wave (LAPW) method and by downfolding with the N-th order muffin tin orbitals (NMTO) method. We find subtle changes of the interaction between the metal centers and of the band structure with each substituent or ligand molecule.

**K25 13 Computer simulation of supramolecular assembly by metal-ligand complexation*** SHIHU WANG, CHUN-CHUNG CHEN, ELENA E. DORMIDONTOVA, *Macromolecular Science and Engineering, Case Western Reserve University, Cleveland, OHIO 44106* Monte Carlo simulations were employed to study the supramolecular assembly of oligomers end-functionalized by ligands capable of complexation with metal ions. The properties of these metallo-supramolecular polymers strongly depend on the oligomer concentration, strength of complexation, and metal-to-ligand ratio. At high oligomer concentration the average molecular weight exhibits a maximum near the stoichiometric composition and decreases for higher or lower metal content. On the other hand, at low oligomer concentration the molecular weight shows a local minimum around the stoichiometric composition. This unusual behavior is attributed to the larger population of small rings around the stoichiometric composition, which make up a significant fraction of the overall molecular weight at low oligomer concentration. This effect is especially pronounced at low temperature, where the fraction of rings is higher. The fraction of chains and rings for different concentrations, temperatures and oligomer lengths were calculated and compared with experimental data.

**K26 1 Conformational Dynamics of Adenylate Kinase: The Effects of Temperature and Mutation on Friction, Memory, and Reactivity** LUCAS WATKINS, KARL DUDERSTADT, SUCHARITA BHATTACHARYYA, HAW YANG, *Department of Chemistry, University of California Berkeley* Enzymes reside on a convoluted free energy surface. This free energy surface generates the conformational dynamics that control activity. We use single molecule Förster Resonance Energy Transfer measurements to study these conformational dynamics and the physics that underly them in a model enzyme, Adenylate Kinase (AK), which catalyzes the disproportionation of ADP into AMP and ATP. Our microscope records time-dependent single-molecule trajectories as a list of single photon arrival times. We treat the distance trajectory that generates this data as a manifestation of a many-dimensional Langevin equation, projected onto the coordinate defined by our two labeling sites. Using a likelihood-based approach, we can then directly extract the potential of mean force and the friction coefficient from the raw photon-by-photon trajectories. Temperature-dependent studies allow calculation of entropy and enthalpy profiles from the measured potentials of mean force, while mutants in functionally-important regions allow us to understand the role of individual residues in dynamics and catalysis. Ultimately, this newly-developed method allows us to begin to draw direct connections between structure, dynamics, and reactivity.
