**W21 7 Observation of polarization current accompanying smectic A electroclinic reorientation** RENFAN SHAO, LIXING WANG, CHRISTOPHER D. JONES, DAVID A. COLEMAN, DUONG NGUYEN, MICHI NAKATA, JOSEPH E. MACLENNAN, *LCMRC and Univ of Colorado* PER RUDQUIST, *Chalmers Univ of Tech* DAVID M. WALBA, NOEL A. CLARK, *LCMRC and Univ of Colorado* We have been studying the liquid crystalline material W530, and report observations of polarization current of the field-induced molecular reorientation in the SmA phase. W530 exhibits the following phase diagram on cooling: isotropic – SmA – uncharacterized Sm'X' – metastable SmC – crystal. The temperature range of the SmA and SmX phases is $\sim$ 50[r]C, and x-ray diffraction (XRD) shows very little layer spacing change throughout the width of these two phases, while the SmC fractional layer compression is $\sim$ 5%. The SmX is nearly identical in appearance to the SmA phase under depolarized light microscopy (DPLM). However, when measuring polarization current while cooling from SmA to SmX, two polarization peaks appear throughout the range of the SmX phase. By adapting the Langevin model for deVries SmA, we are able to explain the two polarization peaks. Through a combination of DPLM cone angle and birefringence measurements, dielectric spectroscopy measurements, aligned sample and powder XRD experiments, and freely suspended film observations, we are able to show that the previously uncharacterized phase is a deVries SmA. Work supported by NSF MRSEC Grant DMR-0213918.

**W21 8 Defects in liquid crystal nematic shells** A. FERNANDEZ-NIEVES, A.S. UTADA, V. VITELLI, D.R. LINK, D.R. NELSON, D.A. WEITZ, *Harvard University* We generate water/liquid crystal (LC)/water double emulsions via recent micro-capillary fluidic devices [A. S. Utada, et.al. Science 308, 537 (2005)]. The resultant objects are stabilized against coalescence by using surfactants or adequate polymers; these also fix the boundary conditions for the director field n. We use 4-pentyl-4-cyanobiphenyl (5CB) and impose tangential boundary conditions at both water/LC interfaces by having polyvinyl alcohol (PVA) dispersed in the inner and outer water phases. We confirm recent predictions [D. R. Nelson, NanoLetters 2, 1125 (2002)] and find that four strength $s=+1/2$ defects are present; this is in contrast to the two $s=+1$ defect bipolar configuration observed for bulk spheres [A. Fernandez-Nieves, et.al. Phys. Rev. Lett. 92, 105503 (2004)]. However, these defects do not lie in the vertices of a tetrahedron but are pushed towards each other until certain equilibration distance is reached. In addition to the four defect shells, we observe shells with two $s=+1$ defects and even with three defects, a $s=+1$ and two $s=+1/2$. We argue these configurations arise from nematic bulk distortions that become important as the shell thickness increases. Finally, by adding a different surfactant, so-

dium dodecyl sulphate (SDS), to the outer phase, we can change the director boundary conditions at the outermost interface from parallel to homeotropic, to induce coalescing of the two pair of defects in the four defect shell configuration to yield two defect bipolar shells.

**W21 9 Water as a Wetting Agent for Liquid Crystal Films** ERGYS SUBASHI, RAFAEL GARCIA, *Worcester Polytechnic Institute* The dewetting of nCB liquid crystals from silicon wafer surfaces was first observed in 1999 [1] and has since grown into a subject of great fascination. The dewetting behavior occurs within a narrow coexistence region just below the nematic-to-isotropic phase transition temperature. When a wetted film is brought within this coexistence region, the film splits into two film thicknesses that are in apparent equilibrium with each other. A tentative but highly controversial explanation for this phase diagram has been proposed van Effenterre [2] in terms of mean field forces acting within the film. In our laboratory, we have undertaken a high-resolution measurement of the shape of this dewetting region for 5CB on silicon in search of evidence for the existence of fluctuation-induced forces that affect the thickness of these films. We have found, to our surprise, that ambient humidity affects the wetting behavior. Based on preliminary evidence taken thus far, water appears to act as a wetting agent that promotes the wetting of 5CB on silicon. We will present measurements showing how water affects the two-film thickness coexistence region. [1] F Vandenbrouck et al., Phys. Rev. Lett. 82, 2693 (1999). [2] D. Van Effenterre et al., Phys. Rev. Lett. 87, 125701 (2001).

**W21 10 Surface morphology of SiO deposited substrates and alignment of nematic LC*** LEELA JOSHI, SATYENDRA KUMAR, *Department of Physics, Kent State University, Kent, OH 44242* RICCARDO BARBERI, *Physics Department, University of Calabria, 87036 Rende (CS), Italy* Glass substrates with thin film of SiO are known to align nematic liquid crystals homogeneously for oblique deposition. X-ray reflectivity was employed to probe the surface morphology of approximately 150Å thick SiO films deposited at different landing angles. The interfacial roughness and morphological anisotropy was determined along the two orthogonal in-plane directions and the average electron density profile of the film calculated. The results show that the homogeneous and planar aligning films consists of SiO film with different roughness anisotropy and film thickness. The results will be discussed in light of previous reflectivity and AFM results on SiO [1] and other [2] surfaces. [1]. R. Barberi, Giocondo, G.V. Sayko, AK. Zvezdin, Phys. Lett. **A213**, 293 (1996). [2]. S. Kumar, J.-H. Kim, and Y. Shi, Phys. Rev. Lett. **94**, 077803 (2005).

**W21 11 Crystal Nucleation behavior near gas-liquid spinodal line** LIMEI XU, *Boston University* GIANCARLO FRANZESE, *Universitat de Barcelona* SERGEY V. BULDYREV, *Yeshiva University* H. E. STANLEY, *Boston University* The complex problem of crystal nucleation is currently at stage. Using molecular dynamics simulations, we study the crystal nucleation behavior of colloids modeled by hard-core particles with narrow square well attractive potential. For this system the liquid gas critical point lies below the gas-crystal equilibrium line. We investigate how the nucleation rate depends on the pressure and density, in particular in the vicinity of the liquid-gas spinodal. We find that there is a correlation between nucleation rate and spinodal line. We interprete our results using classical nucleation theory.

**W21 12 Entropy driven formation of a chiral liquid crystalline phase of helical rods** ZVONIMIR DOGIC, *Rowland Institute at Harvard University* EDWARD BARRY, ZACH HENSEL, MICHAEL SHRIBAK, *Marine Biological Laboratory, Woods Hole* RUDOLF OLDENBOURG, *Marine Biological Laboratory, Woods Hole* We study the liquid crystalline phase behavior of a concentrated suspension of helical flagella isolated from Salmonella typhimurium. With increasing concentration, a suspension of helical flagella undergo an entropy driven first order phase transition to a liquid crystalline state having a novel chiral symmetry. Flagella are prepared with different polymorphic states, some of which have a pronounced helical character while others assume a rod-like shape. We show that the static phase behavior and dynamics of chiral helices are very different when compared to simpler achiral hard rods.

**16:54**

**W21 13 Dynamics of Director Fluctuations in Confined and Filled Liquid Crystals.** EDWIN ARROYO, SARMISTHA BASU, FOUAD ALIEV, *University of Puerto Rico* Dynamic light scattering was applied to study the influence of randomness as well of boundary conditions (planar-axial and homeotropic-radial) and layer thickness (at nanoscale) of 5CB and 8CB confined to random porous matrices, to cylindrical pores and filled with Aerosil particles (hydrophilic and hydrophobic) on phase transitions and relaxation of director orientational fluctuations. For confined 8CB in the nematic phase two well-defined relaxation processes were for confined liquid crystals. The first process is associated with bulk-like nematic director fluctuations. The second relaxation process (with relaxation time slower than the first one) is most likely due to the fluctuations in layers nearest the wall surface. We found that for homeotropic boundary conditions of confined liquid crystal, the pore wall-liquid crystal interactions influence on the properties of the surface layer is stronger than in the case of axial orientation, particularly, and the influence of boundary conditions on N-Sm-A phase transition in confined 8CB is stronger than on isotropic- nematic phase transition. The separation between the first and the second (slow) process is clearer for thinner layers and the amplitude of slow process is greater for thinner layers. This suggests that the slow process is surface related relaxation. This relaxation was observed in filled liquid crystals as well.

**W21 14 Micro-focus synhrotron X-ray diffraction study of novel mesomorphic porphyrin derivatives*** SHIN-WOONG KANG, LANFANG LI, QUAN LI, *Kent State University, Kent, OH 44242* MICHI NAKATA, *University of Colorado, Boulder, CO 80309* BRANDON CHAPMAN, RONALD PINDAK, *Brookhaven National Laboratory, Upton, NY 11973* SATYENDRA KUMAR, *National Science Foundation, 4201 Wilson Blvd., Arlington, VA 22230* The mesophase structures of three novel mesomorphic porphyrin derivatives were examined using polarized optical microscopy and microfocus synchrotron X-ray diffraction at various temperatures using a beam with a 14 $\mu$m$\times$ 14 $\mu$m cross-section at the bending magnet beamline of Sector 20 at the Advanced Photon Source. The x rays were diffracted from microscopic monodomains in thin glass cells while simultaneously

observing the optical textures. The results confirmed a hexagonal arrangement of discotic columns in the liquid crystalline phase. At a lower temperature, highly ordered plastic crystal phase was obtained. The results of the microdiffraction experiment and promising properties of these compounds as a carrier transporting material will be presented.

**W21 15 Stochastic Rotation Dynamics: generalizations and applications for non-ideal fluids, binary mixtures and colloids** THOMAS IHLE, *Department of Physics, North Dakota State University* ERKAN TUZEL, *School of Physics and Astronomy, University of Minnesota* DANIEL KROLL, *Department of Physics, North Dakota State University* A particle-based algorithm for the coarse-grained modeling of a fluctuating Solvent, namely Stochastic Rotation Dynamics (SRD), was recently introduced by Malevanets and Kapral[1]. This algorithm describes a fluid with an ideal gas equation of state and has been successfully applied to study polymers, colloids, and vesicles in flow. Here, we present generalizations of SRD for modeling fluids with non-trivial equations of state[2]. In particular, we show how to model a simple liquid with a non-ideal equation of state by incorporating excluded volume effects. We show the thermodynamic consistency of the model by independently measuring the pressure, density fluctuations and the speed of sound and compare with analytical results. This idea is extended to model binary mixtures with a miscibility gap; and the phase diagram of such a mixture will be presented. Furthermore, colloids are included in the SRD solvent and results for colloidal suspensions driven by external forces will be shown. [1] A. Malevanets, R. Kapral, J. Chem. Phys. 110, 8605 (1999). **W22 1 The Structure and Magnetic Properties of Nanoparticles and Their Arrays.**
JOSEPH DVORAK, *Montana State University*

The physics of magnetic nanoparticles and arrays is a very important topic of current research. Many questions remain. How does the structure of a single nanoparticle influence its magnetic properties? For instance, core/shell interactions can increase the coercivity and lead to exchange biasing, causing ferromagnetic rather than superparamagnetic behavior. At what thickness does the oxide shell begin to behave like an antiferromagnet? How do uncompensated surface spins affect the magnetic behavior? In addition, novel nanoparticle structures can lead to interesting physical behavior. In a bio-inspired approach, we are synthesizing ithighly monodisperse oxide nanoparticles inside of protein cages. For these systems, magnetocrystalline anisotropy plays an important role; the surface anisotropy term becomes large, reducing the total particle moment. However, we find that the encapsulating protein shell reduces the surface anisotropy and increases the particle moment. Furthermore, we have synthesized mixed phase gamma-$Fe_2O_3$/CoO nanoparticles with large exchange biasing. Further questions arise for nanoparticle arrays. Dipole interactions modify the collective magnetic behavior. What are the strength and orientation of these interactions, and how do they depend on particle size, spacing, itand array ordering. Recent experiments have shown the importance of array order in determining the collective magnetic properties. The physics of magnetic nanoparticles is rich and complex, and depends upon both the structure of the individual particles and their assemblies. By using synchrotron based magnetic circular dichroism, small angle X-ray scattering and neutron scattering, we have been able to quantify many aspects of both nanoparticle and array structures. A quantitative understanding of these structural relationships has led to a better understanding of their magnetic behavior.

**W22 2 Particle Size Control of Polyethylene Glycol Coated Fe Nanoparticles*** B. SRINIVASAN, M.J. BONDER, Y. ZHANG, D. GALLO, G.C. HADJIPANAYIS, *Department of Physics and Astronomy, University of Delaware, Newark, DE 19716* Recent interest in Fe nanoparticles with high magnetization is driven by their potential use in biomedical applications such as targeted drug delivery, MRI contrast enhancement and hyperthermia treatment of cancer. This study looks at the use of a polyethylene glycol (PEG) solution to mediate the particle size and therefore control the coercivity of the resulting nanoparticles. Iron nanoparticles were synthesized using an aqueous sodium borohydride reduction of ferrous chloride by a simultaneous introduction of reagents in a Y- junction. The resulting product was collected in a vessel containing a 15 mg/ml carboxyl terminated polyethylene glycol (cPEG) in ethyl alcohol solution located under the Y junction. By varying the length of tubing below the Y junction, the particle size was varied from 5-25 nm. X-ray diffraction data indicates the presence of either amorphous Fe-B or crystalline alpha Fe, depending on the molar ratio of reagents. Magnetic measurements indicate the particles are ferromagnetic with values of coercivity ranging from 200-500 Oe and a saturation magnetization in range of 70-110 emu/g. The XRD shows that the particles are not affected by the polymer coating.

**W22 3 Using Single Nanoparticle Devices to Investigate Nanojunction GMR and TMR** J.J. KAVICH, R.H. KODAMA, *University of Illinois at Chicago, Chicago, IL 60607* J.W. FREELAND, *Advanced Photon Source, Argonne National Laboratory, Argonne, IL 60439* High-pressure sputtering / cluster-beam deposited single nanoparticle devices were fabricated to study giant magneto- resistance (GMR) and tunneling magneto-resistance (TMR) of nano- junctions. The junction used to investigate GMR was formed by the point contact of a nearly spherical $\sim$ 20 nm diameter ferromagnetic (FM) particle on a FM thin film deposited on a silicon substrate. The particles were covered with a thick $Al_2O_3$ dielectric layer. The tunneling device is identical, except for an additional $Al_2O_3$ tunnel barrier sandwiched between the FM particle and film. Using a focused ion beam (FIB), small apertures were milled in the dielectric layer to expose individual particles and metallic contacts were subsequently deposited. Other contacts were made directly to the underlying FM film creating a simple two- contact measurement geometry. Temperature dependent TMR and GMR are presented for isolated particles that are independent of proximity and ensemble effects. This work is supported by the ACS Petroleum Research Fund.

**W22 4 High Frequency Properties of Magnetodielectric Composites Consisting of Oriented Fe-based Flakes Embedded in a Polymeric Matrix*** MICHAEL GOLT, *University of Delaware* XIAOKAI ZHANG, *University of Delaware* THOMAS EKIERT, *University of Delaware* SHRIDHAR YARLAGADDA, *Center for Composite Materials* KARL UNRUH, *University of Delaware* JOHN XIAO, *University of Delaware* Magnetodielectric composites containing small ferromagnetic inclusions in a continuous dielectric matrix could be useful high frequency materials if relatively large and similar values of the permeability ($\mu$) and permittivity ($\varepsilon$) could be obtained. This potential, however, can not be fully achieved for spherical inclusions because their demagnetizing fields severely limit the effective permeability of the composite. Therefore, we have prepared and studied a series of magnetodielectric composites containing oriented Fe-based flakes. The flakes were produced by a mechanical deformation technique and were typically several 100 $\mu$m wide and several $\mu$m thick. These flakes were mixed with a styrene based liquid resin and aligned in an applied magnetic field prior to polymerizing the resin. X-ray diffraction and hysteresis loop measurements confirm a significant degree of alignment. Permeability and permittivity measurements indicate that values of $\mu$ and $\varepsilon$ in excess of 20 can be achieved in these samples with small losses when the loading fraction of the Fe flakes approaches 50%.

**W22 5 Fabrication of Ordered Mesoporous Silica with Encapsulated Iron Oxide Particles using Ferritin-Doped Block Copolymer Templates** D. HESS, J. WATKINS, *Univ. of Mass.* R. NAIK, *W-P AFB* Recently, two-dimensional arrays of iron oxide clusters were fabricated by dip-coating a silica substrate into an aqueous solution. Here we report the encapsulation of ferritin in 3D mesoporous silica structures by the replication of block copolymer templates in supercritical $CO_2$. In our approach, preparation of the highly ordered, doped template via spincasting and microphase separation and silica network formation occur in discreet steps. A solution of an amphiphilic PEO-PPO-PEO triblock copolymer (Pluronic) template, horse spleen ferritin and a low concentration of PTSA acid was prepared and spin-coated onto a Si wafer. Upon drying the block copolymer microphase separates resulting in partitioning of the acid catalyst and ferritin to the hydrophilic domain. The polymer template was then exposed to a solution of supercritical carbon dioxide and tetraethyl orthosilicate (TEOS) at 125 bar and 40$^o$C. Equilibrium limited $CO_2$ sorption in the block copolymer template resulted in modest dialation of the microphase segregated structure. Under these conditions, the precursor was readily infused into the copolymer and reacted within the hydrophilic domain containing the acid catalyst. The resultant film was calcined in air at 400$^o$C for 6 hours producing a well-ordered iron oxide-doped mesoporous silica film. TEM and XRD revealed crystalline iron oxide structures within the mesoporous silica supports. Magnetic properties were analyzed using a superconducting quantum intereference device (SQUID).

**W22 6 Synthesis of Barium hexaferrite nanoparticles for functional multilayers** S.L. MORROW, N.A. FREY, S. SRINATH, H. SRIKANTH, *Functional Materials Laboratory, Physics Department, University of South Florida,* Magnetic barium ferrite ($BaFe_{12}O_{19}$or BaM) nanoparticles were synthesized by a two system microemulsion process. X-ray diffraction of these nanoparticles confirmed the presence of a dominant hexagonal BaM phase. The magnetic characterization of the nanoparticles was performed using a Physical Properties Measurement System (PPMS). The M-H hysteresis of the BaM, at 5K and 300K, displays a saturation magnetization of $\sim$ 68 emu/g, 48 emu/g and large coercivities of $\sim$ 2300 Oe, 3100 Oe respectively, consistent with bulk BaM. The zero field cooled (ZFC) and field cooled (FC) curves illustrate that superparamagnetism was not present in the BaM below 300K. These particles will be used to prepare multilayers of ferroelectric and ferromagnetic films by depositing on a ferroelectric polymer (polyvinylidene fluoride) matrix using the Langmuir-Blodgett technique. The functional properties of these multilayers will be discussed. Work supported by NSF grant #CTS-0408933 and NSF Integrated Interdisciplinary Nanoscience REU DMR 0243997.

**W22 7 Theory of Brillouin Light Scattering from Ferromagnetic Nanospheres*** PING CHU, DOUGLAS MILLS, *University of California, Irvine* We develop the theory of Brillouin light scattering (BLS) from spin waves in ferromagnetic nanospheres, within a framework that incorporates the spatial variation of the optical fields within the sphere. Through use of our recent theory [1] of exchange dipole spin wave modes of the sphere, we develop a method which properly normalizes the eigenvectors. We then describe the BLS spectrum associated with the first few dipole/exchange spin wave modes with emphasis on their relative intensity. We also discuss the stokes/anti stokes ratio. [1] Rodrigo Arias, Ping Chu and D. L. Mills, Phys. Rev.B71, 224410 (2005).

**W22 8 Self Assembled $CoFe_2O_4$ Nanoparticles within Block Copolymer Films: Structural and Magnetic Properties** G.C. PAPAEFTHYMIOU, A.J. VIESCAS, *Villanova University, Villanova, PA* S.R. AHMED, P. KOFINAS, *University of Maryland, College Park, MD* Nanosize $CoFe_2O_4$ particles have been synthesized by self-assembly within diblock co-polymers, through a room-temperature templating strategy, amenable to large scale

fabrication. XRD, TEM, SQUID and Mossbauer studies are combined in order to explore the morphological, structural, micromagnetic and interfacial characteristics of this nanocomposite system. TEM micrographs indicate low polydispersity, with particle size of 9.6 nm diam. Low temperature Mossbauer studies predict average sub lattice saturation hyperfine magnetic fields H (A) =501 kOe and H [B] = 527 kOe, respectively, for the tetrahedral and octahedral iron coordination sites of the ferrite spinel structure. Superparamagnetic relaxation processes, analyzed within a cubic magnetic anisotropy model, give a magnetic anisotropy density K = $3.23x10^5 J/m^3$, while SQUID magnetometry predicts a saturation coercivity of 6.1 kOe. Deviations from bulk $CoFe_2O_4$ and unsupported $CoFe_2O_4$ nanoparticles are discussed in terms of finite-size effects and interfacial interactions.

**16:30**

**W22 9 Magnetization of iron clusters from first-principles calculations*** JAMES R. CHELIKOWSKY, *University of Texas* MURILO L. TIAGO, *University of Minnesota* SHEN LI, *Rutgers University* MANUEL M.G. ALEMANY, *Universidade de Santiago de Compostela, Spain* YUNKAI ZHOU, YOUSEF SAAD, *University of Minnesota* The magnetic moment of Fe clusters as function of number of atoms has been observed to show a slow decrease from the isolated atom value (4 Bohr magnetons) to its bulk value of 2.2 Bohr magnetons per atom. In addition, a series of peaks has been observed, for which the causes are not yet fully understood (see Billas, Chatelain, and de Heer, Science, 1994). We analyze the dependence of total magnetic moment, local magnetic moment, cohesive energy and other physical quantities in iron clusters $Fe_n$ ($1 < n < 250$), and compare these results with available experimental data. We use a real-space method, pseudopotentials and first-principles DFT to obtain the properties of the cluster in its ground state. Calculations are done using the PARSEC code ( www.ices.utexas.edu/parsec). We also discuss some of the recently developed capabilities of PARSEC.

**W22 10 Chern-number spin Hamiltonians for magnetic nanoclusters by ab-initio methods** TOR OLOF STRANDBERG, *Kalmar/Lund University* HONGKI MIN, *University of Texas, Austin* CARLO M. CANALI, *Kalmar/Lund University* ALLAN H. MACDONALD, *University of Texas, Austin* Combining field-theory methods and ab-initio calculations, we construct an effective Hamiltonian with a single giant-spin degree of freedom, capable of describing the low-energy spin dynamics of ferromagnetic metal nanoclusters consisting of up to a few tens of atoms. In our procedure, the magnetic moment direction of the Kohn-sham SDFT wave-function is constrained by means of a penalty functional, allowing us to explore the entire parameter space of directions, and to extract the magnetic anisotropy energy and the Berry curvature functionals. The average of the Berry curvature over all magnetization directions is a Chern number, a topological invariant that can only take on values equal to multiples of half-integers, which represents the dimension of the Hilbert space of the effective spin system. The spin Hamiltonian is obtained by quantizing the classical anisotropy-energy functional, after a change of variables which yields a constant Berry curvature. We illustrate this procedure by explicitly constructing the Hamiltonian for dimers and trimers of Co and Cr, whose spin dynamics has been recently investigated experimentally by STM methods.

**W22 11 The coupling of magnetic and dielectric properties in magnetic nanoparticles** R. TACKETT, *Wayne State University* O. MASALA, *UCSB* B. ADHIKARY, R. NAIK, *Wayne State University* A.P. RAMIREZ, *Bell Labs* R. SESHADRI, *UCSB* G. LAWES, *Wayne State University* The low frequency dielectric properties of it$\gamma$-$Fe_2O_3$ and $MnFe_2O_4$ magnetic nanoparticles have been investigated. These samples showed frequency dependent dielectric anomalies near their respective magnetic blocking temperatures suggesting a coupling between the magnetic and dielectric properties of the systems. In addition, the samples exhibited considerable magnetocapacitance above the magnetic blocking temperature. The magnetic field induced change in the dielectric constant was shown to be proportional to the square of the magnetization, suggesting that the dielectric properties of these systems are strongly connected to the distribution of magnetic moments in the samples. The results will be discussed in the framework of a theory explaining how magnetodielectric effects can arise from magnetoresistance in a Maxwell-Wagner capacitance model.

**17:06**

**W22 12 A new magnetization-reversal strategy for Stoner particles** XIANGRONG WANG, ZHOUZHOU SUN, *The Hong Kong University of Science and Technology* A new strategy is proposed aimed at substantially reducing the minimal magnetization switching field for a Stoner particle. Unlike the normal method of applying a static magnetic field which must be larger than the magnetic anisotropy, a much weaker field, proportional to the damping constant in the weak damping regime, can be used to switch the magnetization from one state to another if the field is along the motion of the magnetization. The concept is to constantly supply energy to the particle from the time-dependent magnetic field to allow the particle to climb over the potential barrier between the initial and the target states.

**17:18**

**W22 13 Structural, Magnetic and Dynamical Properties of Dipolar Nanoparticles** PETER ENTEL, STEPHAN BUSCHMANN, ALFRED HUCHT, *Theoretische Physik, Universitt Duisburg-Essen, D-47048 Duisburg* We investigated the structural, magnetic and collective properties of dipolar nanoparticles. The dynamic of the systems is determined by differential equations for the translational and rotational degrees of freedom, which are studied using molecular dynamics. The interaction potential of the particles consists of both an anisotropic dipolar interaction and an isotropic hard-sphere potential. Dependent on the temperature and external magnetic field, the system is found to be in different states. These states can be characterized by their respective structural ordering, that is closely related to the magnetic and energetic properties of the assembly of particles. In the ground state the

particles arrange themselves in closed rings due to the anisotropic nature of the interaction. Besides this structure also the formation of metastable chains and network-like structures can be observed. Thermal excitations lead to a destabilization while the influence of an external magnetic field depends on its relative orientation with respect to the structures. In this work the phase diagrams in two and three dimensions of the various structures are determined as a function of temperature and external field.

**W23 1 Ab initio Study of Mirages and Magnetic Interactions in Quantum Corrals.**
VALERIY STEPANYUK, *Max-Planck Institute, Halle Germany*

We present the state of the art ab initio studies of mirages and magnetic interactions in quantum corrals. Our results demonstrate that quantum corrals could permit to manipulate the exchange interaction between magnetic adatoms on metal surfaces at large distances. We show that the spin-polarization of surface-state electrons can be projected to a remote location by quantum states of corrals. Our study gives a clear evidence that the 'spin-polarization transfer' takes place in a mirage experiment of Manoharan et al.,[2]. We find that the spin-polarization of surface-state electrons on transition metal surfaces[3] can be manipulated by quantum corrals. Our results reveal that an atomic motion in quantum corrals could be strongly affected by the quantum confinement of surface-state electrons. 1. V. S. Stepanyuk, L. Niebergall, W. Hergert, P. **W23 2 Noncollinear magnetism in antiferromagnetic manganese chalcogenides** KOHJI NAKAMURA, TORU AKIYAMA, TOMONORI ITO, *Mie University* A.J. FREEMAN*, *Northwestern University* Metastable zincblende compounds of transition-metal pnictides and chalcogenides have recently become the subject of much attention due to their unique properties exhibiting combinations of magnetism and semiconductivity. Here we investigate magnetism in the antiferromagnetic (AFM) transition-metal chalcogenides, namely MnSe and MnTe, by using the FLAPW method.[1] Assuming a collinear magnetic structure, we demonstrate that the AFM structure consisting of alternating Mn (001) spin-up and spin-down planes is favored over the ferromagnetic state, since the majority-spin *d*-bands are completely filled and so achieve the half-filling state that leads to the superexchange interaction. However, with FLAPW calculations that now treat full noncollinear magnetism,[2] we find that the lowest energy state is a noncollinear AFM structure — the so-called AFM type III structure — which relaxes frustration in the AFM Mn moment alignment on the fcc sublattice, a result that agrees with neutron experiments.[3] *Supported by NSF MRSEC through the NU MRC.

**W23 3 Embedded Clustering and Metastable Magnetism in Transition-Metal doped III-Nitrides*** CUI XIANGYUAN, *The University of Sydney* JULIA MEDVEDEVA, *University of Missouri-Rolla* ARTHUR J. FREEMAN, *Northwestern University* BERNARD DELLEY, *Paul-Scherrer-Institut* CATHERINE STAMPFL, *The University of Sydney* From extensive density-functional theory calculations [1] we find that Cr atoms in GaN prefer to form embedded clusters, occupying Ga sites [2]. Significantly, for larger than 2-Cr- atom clusters, states containing antiferromagnetic coupling with net spin in the range 0.06-1.47 $\mu_B$/Cr are favored. Similar behavior is found for Mn:GaN, and Cr:AlN and Mn:AlN. We show that various configurations may coexist leading to a strong dependence of the magnetic properties on the growth conditions. This elucidates many puzzling observations such as the 5 (20-30) times lower value of the measured magnetic moment on Cr (Mn) as compared to the theoretically predicted one for the isolated dopants. In addition to the expected ground high spin (HS) states for isolated Mn and Fe in GaN (4 $\mu_B$/Mn and 5 $\mu_B$/Fe), metastable low spin (LS) states (0 $\mu_B$/Mn and 1 $\mu_B$/Fe) are found. The transition between the HS and LS states corresponds to an intra-ionic electron transfer between the $t_2$ and $e$ orbitals, accompanied by a spin-flip process. [1] B. Delley, J. Jchem. **W23 4 Optimized Effective Potential Method for Non-Collinear Magnetism** CLAUDIA AMBROSCH-DRAXL, SANGEETA SHARMA, JOHN K. DEWHURST, *University Graz* NICOLE HELBIG, STEFAN KURTH, EBERHARD K. U. GROSS, *Free University Berlin* SAM SHALLCROSS, *Linköping University* LARS NORDSTRÖM, *Uppsala University* A description of non-collinear magnetism in the framework of spin-density functional theory is presented for an exact exchange energy functional which depends explicitly on two-component spinor orbitals. The equations or the effective Kohn-Sham scalar potential and magnetic field are derived within the optimized effective potential framework. We have implemented this formalism within the full-potential linearized augmented planewave method, with an unconstrained magnetization density. Our calculations for Co and Fe

show that the overestimation of moments seen in previous work was an artifact of the decoupled equations used. We further demonstrate, with the example of a magnetically frustrated Cr monolayer, how intra-atomic non-collinearity may be underestimated by local functionals.

**15:42**

**W23 5 Spin susceptibility calculation based on the QP self-consistent GW method** TAKAO KOTANI, *ASU* MARK VAN SCHILFGAARDE, *ASU* Recently we have developed the quasiparticle self-consistent *GW* method (QPsc*GW*) based on the full-potential LMTO method. The method is designed to determine the best independent-particle picture. The most significant impact is that QPsc*GW* covers rather wide-range of materials, including semiconductor and transition metal oxides with acceptable accuracy [1,2]. In contrast to LDA+ $U$, QPsc*GW* can provide reasonable description of the $d$ band position relative to the $sp$ band without any free parameters. The $d$ band position critically affects the exchange coupling between magnetic ions. We are now developing the method to calculate the dynamic spin susceptibility based on the QPsc*GW* method. We will show results for elemental transition metals and zincblende(ZB)-type of materials including magnetic ions. We have found that the ferromagnetic phase of ZB-MnAs is stable, contrary to the LDA result. In addition, we will show analysis of the exchange-coupling between magnetic ions. **W23 6 A band theory for magnetic cuprates based on self-interaction free local density approximation** VINCENZO FIORENTINI, ALESSIO FILIPPETTI, *SLACS and Physics Dept., University of Cagliari* The pseudo-SIC approach is based on an approximate form of self-interaction corrected (SIC) Kohn-Sham Equations. We overview the functionalities of this method applied to cuprates, which are prototypes of difficult materials for standard local-spin density functional theories such as LSDA (or even GGA). Indeed, theories based on local exchange-correlation potentials fail to predict the correct spin-polarized ground-state solution expected for the low-magnetization state (S=1/2) of the Cu(I) ions, thus describing these systems as metallic and nonmagnetic. Here we present our results for a series of relevant cases, including CuO, $Cu_2O$, $CuGeO_3$, and $YBa_2Cu_3O_{6+x}$, showing that the pseudo-SIC is capable to correct the gross failures of LSDA, restoring the expected S=1/2 electronic ground state and an overall satisfying description of the chemistry and the electronic and magnetic properties of these systems. Furthermore, since the pseudo-SIC is designed to work for metals as well as for insulators we can approach the challenging task of studying by first-principles the insulating-metal transition in doped Mott insulators. We will consider the example of Mn-doped CuO, where Mn-doping induces a simultaneous insulating-to-metal and antiferromagnetic-to-ferromagnetic phase transition.

**16:06**

**W23 7 Interplay of Vacancy Defects and Magnetism in Carbon Structures** YIMING ZHANG, SAIKAT TALAPATRA, SWASTIK KAR, ROBERT VAJTAI, SAROJ NAYAK, PULICKEL AJAYAN, *Rensselaer Polytechnic Institute* Magnetic properties of diamond and graphite with vacancy defects have been studied using spin-polarized plane-wave basis density functional theory. Various scenarios of vacancy defects are investigated in these two allotropic configurations. The calculation shows that the vacancy defect concentration and nearby bonding structure is critical to determine the induced magnetism. The total magnetism start to decrease after vacancy accumulation reach the interacting configuration, in both diamond and graphite. We also shows that foreign species like nitrogen close to the vacancy is able to further enhance the magnetic moment in graphite.

**16:18**

**W23 8 The effect of disorder and short-range correlations on ferromagnetism in dilute magnetic semiconductors** B. MORITZ, *University North Dakota, University of Cincinnati* K. MIKELSONS, *University of Cincinnati, Oak Ridge National Lab* J. MORENO, *University of North Dakota* M. JARRELL, *University of Cincinnati* R. S. FISHMAN, *Oak Ridge National Lab* We use the Dynamical Cluster Approximation (DCA) and double exchange model, coupling spin one-half holes to magnetic impurities, to study the ferromagnetic transition in semiconductors doped with transition metal magnetic ions. Our approach includes the effect of local dynamics as well as short-range correlations between the magnetic impurities. We systematically incorporate the effect of disorder in the impurity positional configurations with a new algorithm, based on the DCA, specific to dilute systems. This new algorithm serves as a replacement for the Traveling Cluster Approximation and Coherent Potential Approximation. We focus on the appearance of the impurity band and the development of the magnetization for a range of coupling strengths and hole and impurity concentrations. In addition, we discuss the effect of impurity clustering on the hole mobility and the ferromagnetic transition temperature. We conclude that the successful design of spintronic nanostructures based on ferromagnetic semiconductors must include an understanding and careful analysis of disorder and spatial correlations.

**16:30**

**W23 9 Spatial correlations, spin-orbit coupling, and ferromagnetism in Ga(Mn)As** K. MIKELSONS, *University of Cincinnati, Oak Ridge National Lab* B. MORITZ, *University of North Dakota, University of Cincinnati* S. KANCHARLA, *Oak Ridge National Lab* J. MORENO, *University of North Dakota* R.S. FISHMAN, *Oak Ridge National Lab* M. JARRELL, *University of Cincinnati* The self-consistent Dynamical Cluster Approximation (DCA) is used to study the effect of strong spin-orbit coupling in models of GaMnAs. Both heavy and light carrier bands, degenerate at the $\Gamma$-point, are included using the spherical approximation. Local dynamics as well as short-range spatial correlations are studied using the DCA, adapted for impurity systems in the dilute limit. The critical temperature for ferromagnetism is obtained for different arrangements of magnetic impurities and a range of coupling strengths and carrier concentrations. These calculations clearly demonstrate the suppression of the ferromagnetic transition temperature when one accounts for spatial correlations between impurities and the reduction in saturation magnetization due to the strong spin-orbit coupling.

**W23 10 Structural, electronic and magnetic properties of Mn-doped GaAs(110) surface** ALESSANDRO STROPPA, MARIA PERESSI, *Dep. of Theoretical Physics, University of Trieste and DEMOCRITOS National Simulation Center, Trieste (Italy)* First principles total-energy pseudopotential calculations have been performed to investigate structural, electronic—including scanning tunneling microscopy (STM) images—and magnetic properties of

the (110) cross-sectional surface of Mn-doped GaAs. We have considered configurations with Mn in interstitial positions in the uppermost surface layers with Mn surrounded by As ($Int_{As}$) or Ga ($Int_{Ga}$) atoms. The presence of Mn on the GaAs(110) surface originates strong local distortion in the underlying crystal lattice, with variations of interatomic distances up to 8%. In both cases, $Int_{As}$ and $Int_{Ga}$, the surface electronic structure is half-metallic (or *nearly* half metallic) with details strongly dependent on the local Mn environment. The atoms surrounding the Mn impurity show an induced polarization resulting in a ferromagnetic Mn–As and antiferromagnetic Mn–Ga configuration respectively in the two cases. The simulation of the STM images show very different patterns of the impurity region in the two cases, suggesting that they could be easily discerned by STM analysis. We have also simulated STM images of Mn interstitials pairs on surface. The comparison of the simulated images with recent experimental cross-sectional STM images of Mn $\delta$-doped GaAs is discussed.

**16:54**
**W23 11 Structures and magnetic properties of Cr-doped GaN nanotubes** QIAN WANG, QIANG SUN, PURU JENA, *VCU* YOSHIYUKI KAWAZOE, *IMS, Japan* VCU TEAM, IMS JAPAN COLLABORATION, The electronic and magnetic properties of Cr-doped GaN nanotubes are investigated theoretically from first principles using the generalized gradient approximation (GGA) as well as LSDA+U method. We have shown that GaN single wall nanotube, which was generated from GaN wurtzite crystal undergoes large structural relaxation and resemble the structure of carbon (9,0) single wall nanotubes. In addition, it is stable at room temperature. Cr-doped GaN single wall and multiwall nanotubes are ferromagnetic with each Cr atom carrying a magnetic moment of about 2.67 it$\mu_B$. This ferromagnetic coupling is mediated by the neighboring N atoms which are weakly polarized and carry a magnetic moment of -0.18 it$\mu_B$. These results are not sensitive to the tube diameter, Cr concentration, and the level of correlation. Thus, Cr doped GaN nanotubes may be a robust system for applications in spintronics.

**17:06**
**W23 12 Ferromagnetism in Mn doped GaN Nanowires** QIANG SUN, QIAN WANG, PURU JENA, *VCU* Using density functional theory and generalized gradient approximation for exchange and correlation potential we show that the magnetic coupling of Mn atoms in the nanowires, unlike that in the thin film, is ferromagnetic in spite of the thickness of the wire and the contraction of the Mn-Mn and Mn-N bond distances. This ferromagnetic coupling, brought about due to the confinement of electrons in the radial direction and the curvature of the Mn-doped GaN nanowires' surface, is mediated by N as is evidenced from the overlap between Mn 3*d* and N 2*p* states. The Mn atoms prefer to occupy the nearest neighbor positions on the outer surface of the wire and carry a magnetic moment ranging from 0.56 to 3.5 it $\mu_B$/atom depending on the thickness of the wire. Calculations of the anisotropic energy show that the magnetic moment orients preferably along the $[10\bar{1}0]$ direction while the wire axis points along the [0001] direction. The flexibility of both controlling the magnetic coupling and the magnetic moment by choosing the dimensionality and the size of the wire may be useful in practical applications. The results are in agreement with the recent experimental data which show that Mn-doped GaN nanowire can be ferromagnetic without the presence of other defects.

**17:18**
**W23 13 First-principles calculation of Mn Atoms on the CuN/Cu(100) Surface*** CHIUNG-YUAN LIN, *IBM Almaden Research Center, San Jose, CA 95120-6099 and Stanford University Department of Applied Physics, Stanford, CA 94305-4090* BARBARA JONES, ANDREAS HEINRICH, *IBM Almaden Research Center, San Jose, CA 95120-6099* The electronic structure is calculated using GGA+U for one and two Mn atoms on a single CuN layer coated on the Cu(100) surface. This unique insulator-metal junction surface prevents the Mn spins from being screened by the conduction electrons and at the same time allows experimentalists to pass tunneling electrons through the Mn atoms to flip their spins. Our spin-density analysis shows that Mn atoms in such a surface preserve their atomic spins S=5/2. This result agrees with a recent STM measurement on such systems. Electron-density change and surface relaxation due to the Mn atoms are also analyzed.

**W24 1 Nanoimprint Lithography: Process Induced Stresses and Pattern Stability.** CHRISTOPHER SOLES, *NIST*

Nanoimprint lithography is emerging as an economical technique for fabricating polymeric nanostructures. Features as small as 10 nm in a hard master or mold can be faithfully replicated by imprinting this master into a polymer film. At elevated temperatures and pressures, the molten polymer fills the nanoscale cavities of the mold. When the film is cooled to the vitreous state and the mold removed, freestanding polymeric nanostructures remain. In this presentation we illustrate that the NIL process induces large degrees of residual stress into these structures. Upon heating imprinted nanostructures to just above the glass transition temperature of the polymer, a physical relaxation of the nanostructure

shape occurs. The features shrink in height and broaden in width with increased annealing time. However, this decay or slumping of the imprinted pattern is not driven by a simple viscous flow. High molecular mass polymer patterns slump faster than their low molecular mass analogs, contrary to the viscosity changes. Rather, the high viscosity resins generate greater shear stresses along the mold interfaces that lead to extensional flow of the polymer in the fill directions of the patterns. This traps residual stresses in the nanostructures when they are cooled into the glassy state. We quantify this slumping process using X-ray scattering and reflectivity techniques for a range of polymers and pattern sizes and explore potential relations with the glass transition of the polymer within the nanostructure.

**W24 2 Nanometer-scale control of the crystallization of oligomers and polymers.**
ALAIN M. JONAS, *Universite catholique de Louvain*

The ability to control the position and local orientation of organic crystals at the nanometer scale paves the way to the fabrication of hybrid nano-devices displaying better properties. Here, we present two ways to control the assembly of organic chain compounds into nanometric crystals of defined location or orientation. We first show how the location of crystals of model oligomers can be directed by chemical nano-templates [1]. The templates are obtained by combining electron-beam lithography with the deposition of self-assembled monolayers [2]. These surfaces can then be used to control a variety of assembly processes [3], such as the crystallization of model alkane-1-ol oligomers in solution. By using directing maps with the appropriate chemical inks, nano-squares, nano-corrals and nano-lines of organic crystals are rapidly and massively grown at pre-defined locations, at least down to 60 nm. At this scale, confinement effects mediated by van der Waals forces become prominent, providing a unique handle to design crystal growth. Then, we show how the nucleation and orientation of polymer crystals can be controlled by nano-imprint lithography [4]. The combination of confinement, and of preferential nucleation at the vertical walls of the nano-molds probably arising from partial chain orientation due to the polymer flow during embossing, results in local control over the 3D orientation of the crystals. We demonstrate that crystals may be guided through complex geometries, and investigate the case of systems where conflicting instructions are delivered to the crystallizing chains. References: [1] J. **W24 3 UV Polarizer Fabricated by Diblock Copolymer Lithography** KOJI ASAKAWA, VINCENT PELLETIER, MINGSHAW WU, DOUGLAS H. ADAMSON, RICHARD A. REGISTER, PAUL M. CHAIKIN, *Princeton University* Transmission UV polarizers are desired for next-generation semiconductor device fabrication using ArF or $F_2$ excimer laser lithography. Controlling polarization is essential especially for high numerical aperture (NA) immersion lithography processes. The polarizer requirements are thickness less than 1 mm and low absorption of the light used for the exposure. A wire grid polarizer is ideal for this purpose but it requires wires with a pitch less than quarter of wavelength of the light. A cylinder-forming polystyrene-polyhexylmethacrylate diblock copolymer (PS-PHMA, 21-64 kg/mol) was used as a mask for fabrication because its cylinders macroscopically align by simple application of shear stress, and the PHMA domains etch faster than PS by reactive-ion etching (RIE), providing sufficient contrast for pattern transfer. The diblock was spin-coated on a UV transparent fused silica substrate and shear-aligned. The stripe pattern was transferred by RIE onto the substrate by a multilayer technique to enhance the pattern height, then a metal was deposited by evaporation. Finally, the remaining polymer was lifted off to complete the wire grid, having a 33nm pitch (16.5nm line and space). The UV light polarization characteristics of these grids will be presented.

**15:54**
**W24 4 Simple Analytic Model for Nanowire Array Polarizers** VINCENT PELLETIER, KOJI ASAKAWA, MINGSHAW WU, RICHARD REGISTER, PAUL CHAIKIN, *Princeton University* Cylinder-forming diblock copolymers can be used to pattern nanowire arrays on a transparent substrate to be used as a polarizer, as described by Koji Asakawa in a complementary talk at this meeting. With a 33nm period, these wire arrays can polarize UV radiation, which is of great interest in lithography, astronomy and other areas. One can gain an analytical understanding of such an array made of non-perfectly conducting material of finite thickness using a model with an appropriately averaged complex dielectric function in an infinite wavelength approximation. This analysis predicts that the grid can go from an E-polarizer to an H-polarizer as the wavelength decreases below a cross-over wavelength, and experimental data confirm this cross-over. The overall response of the polarizing grid depends primarily on the plasma frequency of the metal used and the volume fraction of the nanowires, as well as the grid thickness. A numerical approach is also used to confirm the analytical model and assess departure from infinite wavelength effects. For our array dimensions, the polarization is only slightly different from this approximation for wavelengths down to 150nm.

**16:06**
**W24 5 Robust Nanopatterns from Self-Assembly of a Diblock Copolymer and an Inorganic Precursor** HO-CHEOL KIM, LINNEA SUNDSTROM, LESLIE KRUPP, EUGENE DELENIA, CHARLES RETTNER, MARTHA SANCHEZ, MARK HART, YING ZHANG, *IBM Watson Research Center* Nanoscopic patterns from self-assembled block copolymer thin films have been recognized as a promising route to sub-lithographic patterns on substrates. Line patterns from lamellar phase of block copolymers are particularly attractive as they can be used as an etch mask for transferring patterns into substrates. A few organic block copolymers have been studied for generating line patterns by controlling the orientation of lamellar microdomains. The organic nature of the block copolymers, however, often gives poor thermal stability and etching contrast, which limits potential applications. Indeed robust nanostructures of sub-lithographic length scales are highly desirable to comply with common nanofabrica-

tion processes. Here we report a simple method to create robust nanoscopic line patterns on surfaces from self-assembly of mixtures of a diblock copolymer and an inorganic precursor. The organic diblock copolymer directs the structure of the inorganic precursor and can be removed by thermal treatment. By tuning the interfacial energy at two interfaces, normally oriented lamellar patterns of approximately 20nm half-pitch and 40nm thick were obtained. Results on transferring patterns to substrate will be reported as well.

**16:18**

**W24 6 Fabrication of inorganic photonic crystals from interference lithography** JUN HYUK MOON, SHU YANG, *Department of Materials Science and Engineering, University of Pennsylvania, Philadelphia, Pennsylvania 19104* We have fabricated 3D FCC-like microstructure using multi-beam interference pattern. This polymeric structure was used as a sacrificial template. Silica was deposited into the pores by alternating exposure to water and silicon tetrachloride vapors under atmospheric pressure and at room temperature. This inorganic structure can provide a platform for the deposition of high refractive index materials such as silicon, germanium, and titania. We investigate the photonic bandgap property of this structure as a function of refractive index as well as filling ratio. Using a two-parameter level-set approach, we find that the FCC-like structure has multiple complete photonic bandgaps at 2-3 and 7-8 bands, respectively, while the bandgap width is sensitive to the morphology of coated-structure. Our calculation results suggest that the complete-filled structure possessed a wider photonic bandgap between 2 and 3 bands than the incompletely-coated core-shell structure.

**16:30**

**W24 7 Effects on Low Voltage Electron Beam Lithography** MEHDI BOLORIZADEH, *EM Facility, University of Tennessee* DAVID C. JOY, *Oak Ridge National Laboratory* To examine the practical limits and problems of low voltage operation we have studied e-beam lithography in the low (few keV) to ultra-low ( $<$ 500eV) energy range, employing commonly used resists such as PMMA and compared the results to those from conventional high voltage processing. We have directly imaged, exposed and developed resist profiles as well as deposited metal after liftoff, using scanning electron microscopy, and compared to our advanced Monte Carlo simulations which incorporate elastic, inelastic, fast secondary electrons, and plasmon contributions. The results show that the exposed profiles and resolutions experimentally achieved at low energy can only be matched by simulations which include a significant FSE and plasmon contributions to the energy PSF. With an optimized resist thickness proximity effects are greatly reduced and process latitude is improved.

**16:42**

**W24 8 Hierarchical Organization of Nanoparticle Composites through Nano-Imprinting** AZAR ALIZADEH, CHRIS KEIMEL, KENNETH CONWAY, ANDREA PETERS, *GE Global Research, Niskayuna, NY 12309* Formation of highly ordered and morphologically controlled nanoparticle/polymeric assemblies is highly desirable in a variety of applications including optoelectronics, sensing, photonics and catalysis. Structure-guiding polymer matrices, such as block copolymers, have demonstrated to be an effective means for controlling the composite morphology as well as localizing particles in nanoscale domains. Yet, fabrication of polymer/nanoparticle composites with precise control over final morphology and particle location is still a major challenge. In this paper, we will show the use of nano-imprint lithography to pattern polystyrene/gold composites at different length scales (20 nm to 1micron). Imprint lithography (the technique of physically pressing and deforming a polymer layer for patterning purposes) is a low cost and high throughput alternative to conventional patterning. PS coated gold nanoparticles were synthesized following Brust's method and subsequently dispersed in PS matrices of varying molecular weights. Nano- imprinting was conducted under different temperature and pressure conditions. TEM, SEM, AFM and UV-Vis techniques were used to characterize these composites.

**W24 9 Mesoscale Simulation of the Lithography Process*** GRANT WILLSON, *The University of Texas* GERARD SCHMID, *Molecular Imprints, Inc Austin, Texas* JASON MEIRING, *The University of Texas* Process simulation is an important tool for the semiconductor industry. Optimization of the microlithography process is extremely expensive since exposure tools that cost in excess of 20 million dollars, which could be dedicated to manufacturing, must be used in the optimization experiments. There exist several commercial simulation packages that work efficiently and accurately all of which are based on parameterized continuum models. Continuing improvements in materials and equipment for microlithography have now provided the ability to print circuit elements with minimum dimensions approaching the size of the molecules that comprise the photoresist. As a result, stochastic and molecular scale effects such as line edge roughness have become an increasing concern and may limit continued progress in this industry. These effects can not be captured by continuum models. Hence, we have worked to develop a mesoscale simulation of the process. The simulator is based upon with discretization of the photoresist film into cells on a three dimensional lattice and a Monte Carlo approach. The entire process has now been simulated in this way. New models for reactive transport, polymer dissolution, etc. have been incorporated in this simulator. Progress will be reported.

**W24 10 New Directions in 3-D Multiphoton Lithography.** JOHN FOURKAS, CHRISTOPHER LAFRATTA, *University of Maryland* RICHARD FARRER, *Pine Manor College* LINJIE LI, *University of Maryland* MICHAEL NAUGHTON, *Boston College* Multiphoton absorption polymerization (MAP) is a promising technique for the lithographic fabrication of 3-D microdevices. However, this technique also has two major shortcomings that have so far precluded its use in the mass production of devices. First, MAP is an inherently serial technique, and structures must be created on a voxel-by-voxel basis. Second, the fabrication of many desirable 3-D devices requires incorporation of materials other than polymers. We will discuss our recent progress in attacking both of these problems. We have developed soft-lithographic techniques that allow for the creation of complex 3-D structures that can include closed loops based on master structures created using MAP. We have also developed a technique that allows for the selective deposition of materials that include metals, metal oxides, and biomolecules on desired regions of 3-D structures fabricated with MAP. We demonstrate the use of the latter technique in the creation of functional microinductors.

**17:18**
**W24 11 High efficient LEDs having columnar structure surface fabricated by block copolymer lithography** AKIRA FUJIMOTO, KOJI ASAKAWA, *Corporate Research and Development Center, Toshiba Corporation* Recently, the internal quantum efficiency of LEDs has improved, but the external efficiency remains low due to the high refractive index of semiconductors. To extract more light, a columnar structure with sub-micron period was fabricated on the LED surface by block copolymer lithography. Since the desired pattern is relatively larger than the block copolymer microdomains, a super-high molecular weight block copolymer was used. The polystyrene (PS) - polymethyl methacrylate (PMMA) diblock copolymer was used in this study since the PMMA has a much faster etch rate than the PS by reactive-ion etching (RIE). The PMMA was removed by RIE, and the gallium phosphide (GaP) substrate was etched by chlorine-based inductively coupled plasma RIE using the remaining PS dots as a mask. The optical extraction efficiency of the patterned substrates improved 2.6 times compared to unprocessed flat GaP substrates; the pillars' height was 450 nm, diameter was 100 nm, and pitch was 150 nm. We also prototyped a real LED and increased light emission volume 1.8 times compared with conventional LED at the same energy consumption.

**W25 1 Tunable and Reversible Swelling of a p(tBA)-*b*-p(HEMA-itco-DMAEMA) Block Copolymer** KYLE GUICE, YUEH-LIN LOO, *University of Texas at Austin* Hydroxyethyl methacrylate (HEMA) and dimethylaminoethyl methacrylate (DMAEMA) have been investigated as precursor materials for pH-responsive hydrogels. DMAEMA in these hydrogel systems allows for pH-tunability, as it is reversibly protonated below its pKa (7.5). In this work, we present the design of a nano-structured hydrogel diblock copolymer whose major block consists of a statistical copolymer of p(HEMA-itco-DMAEMA) (30.5 kg/mol) polymerized at the azeotropic composition (71 mol% HEMA), with a poly(tert-butyl acrylate), p(tBA), (12.1 kg/mol) minor block. The resulting diblock copolymer is narrow in molecular weight distribution (PDI = 1.24) and spontaneously self-assembles to form hexagonally-packed p(tBA) cylinders (R = 9.5 nm) within a p(HEMA-itco-DMAEMA) matrix in the solid state. When swollen in an aqueous medium, hydrophobic p(tBA) cylinders serve as physical cross-links. We monitor the extents of swelling by quantifying changes in the characteristic (10) spacing of the hexagonal lattice by SAXS. Swelling is tunable and reversible with changes in pH; we observe 35% and 21% swelling relative to the dry state at pH 5 and 8.5, respectively.

**14:42**
**W25 2 Highly Responsive Self-Assembled Gels from Triblock Copolymers in Liquid Crystal Solvent** NEAL SCRUGGS, *California Institute of Technology* RAFAEL VERDUZCO, *California Institute of Technology* JULIA KORNFIELD, *California Institute of Technology* Triblock copolymers having random coil endblocks and a side-group liquid crystalline polymer (SGLCP) midblock self-assemble in small-molecule liquid crystal (LC) solvent to form highly responsive gels. In these block copolymers, the LC solvent switches from being strongly selective toward the SGLCP block below its isotropic-nematic transition ($T < T_{NI}$) to being a good solvent for both blocks in the isotropic phase. In the nematic phase, the LC solvent is a poor solvent for the polystyrene (PS) endblocks, driving them to physically associate to form the network crosslinks. In the isotropic phase, at dilute polymer concentrations, the PS endblocks are solubilized to yield a solution of free polymer chains. Synergistic coupling between polymer and solvent results in a gel with novel properties; the orientational order of the nematic LC solvent imparts electo-optic and mechano-optic properties that are forbidden by symmetry in isotropic gels, and the polymer network provides memory via long-time relaxation processes that do not exist in the bulk LC. Gels can be aligned into a single-crystal monodomain by applied shear, electric fields, magnetic fields, or surface effects, and the alignment state is preserved by the network's elastic restoring force. Insights into the structure and dynamics of the gels are gained by rheometry, small-angle neutron scattering, and electro-optical switching experiments.

**14:54**
**W25 3 Nanoparticle-reinforced associative PLA-PEO-PLA hydrogels** SARVESH AGRAWAL, NAOMI SANABRIA-DELONG, SURITA BHATIA, GREGORY TEW, *University of Massachusetts Amherst* Hydrogels of poly(lactide)-poly (ethylene glycol)-poly (lactide) have potential applications in drug delivery and tissue engineering. Control over the structure and rheology of the gels is of fundamental importance for the use of this polymer in medical applications. We have performed a complete rheological and structural characterization of these hydrogels using dynamic mechanical rheology, SANS, and USAXS. These polymers form very stiff hydrogels and the structure and properties of these materials can be substantially modified by varying the crystallinity or degree of polymerization (DP) of the hydrophobic PLA block. We have also created reinforced hydrogels with enhanced mechanical properties by addition of laponite nanoparticles. Our recent studies show that the elasticity of the PLA-PEO-PLA hydrogels can be enhanced by orders of magnitude by addition of small amounts of laponite particles to the hydrogels. It is expected that the triblock copolymer micelles adsorb on the surface of the laponite particles to form additional junctions in the hydrogels leading to enhancement in their elasticity. We verify this hypothesis using DLS and SANS techniques.

**15:06**
**W25 4 Controlling the Self-Assembly of ABCBA Pentablock Copolymer Gels in Water Solution by the Hydrophobic Effect*** JOSHUA ANDERSON, ALEX TRAVESSET, *Iowa State University* We characterize the phases of a system of non-ionic pentablock copolymers with an ABCBA structure in water solution, where the A and C blocks are hydrophobic and the B blocks are hydrophilic. Coarse-grained simulations are performed using molecular dynamics with the solvent modeled implicitly, and the interaction potential includes a parameter that controls the quality

of the solvent. In a good solvent, spherical micelles form and assemble into a swollen gel. We examine the aggregation number, gyration radii, micelle superstructures and percolation at various concentrations for this phase. As the B blocks become less hydrophilic, which occurs for increasing temperature, the micelles move close to one another and expel water. There is a gradual phase transition from spherical micelles to cylindrical worm-like micelles. We model the further expelling of water by increasing the concentration of polymers in the simulation and find that a lamellar phase forms. We compare our simulations with experimental results on recently synthesized modified Pluronic systems.

**W25 5 PEO Hydrogels Prepared by End-linking with PAMAM Dendrimers** BURCU UNAL, RONALD C. HEDDEN, End-linking is a preferred synthetic technique for preparing polymer networks and gels for fundamental structure/property studies. End-functionalized telechelic linear polymers are joined to a multifunctional crosslinker to form a network in which the molar mass of the polymer chains between chemical crosslink points is known. Although end-linked elastomers prepared in bulk have been well-studied over the preceding decade, much remains to be learned about how the presence of a good solvent affects the equilibrium swelling and modulus of end-linked gels. We prepared well-defined hydrogels in a good solvent (water) by linking epoxide end-functionalized, linear poly(ethylene oxide) (PEO) to the amine endgroups of poly(amidoamine) (PAMAM) dendrimers of generations 0, 2, and 4. Dendrimers can serve as well-defined macromolecular crosslink junctions because they can have nearly monodisperse numbers of reactive endgroups. We have characterized how reaction conditions such as junction functionality, polymer concentration at preparation, ratio of crosslinker endgroups to precursor endgroups, and precursor molar mass affect gelation and equilibrium swelling. We will discuss the somewhat surprising observation of ''superabsorbent'' behavior in selected PAMAM-PEO gels.

**15:30**

**W25 6 Probe diffusion in polymer solutions and hydrogels using fluorescence correlation spectroscopy** ARIEL MICHELMAN-RIBEIRO, *NIH / Boston University* HACENE BOUKARI, *NIH* FERENC HORKAY, *NIH* RALPH NOSSAL, *NIH* We apply fluorescence correlation spectroscopy (FCS) to measure the diffusion of small fluorescent probes (TAMRA, Mw = 430 Da; dextran, Mw = 10 kDa) in poly(vinyl alcohol) (PVA) solutions and hydrogels. PVA is a linear, neutral, biocompatible polymer, whose hydrogels have many biotechnology applications, such as drug-delivery devices and tissue scaffolds. The FCS measurements indicate that the probe diffusion decreases when the polymer solution is cross-linked. Further, the more the polymer chains are cross-linked, the slower the particles diffuse. These results suggest that the cross-link density, which is often ignored in the analysis of probe diffusion data in gels, must be taken into account. Remarkably, we find that the apparent diffusion time and the elastic modulus of the gels show a linear correlation.

**W25 7 Large-strain deformation and fracture of tough hydrogels** REBECCA WEBBER, GUILLAUME MIQUELARD, COSTANTINO CRETON, *ESPCI* JIAN PING GONG, *Hokkaido University* Highly-swollen, chemically-crosslinked hydrogels generally behave in a very brittle manner, fracturing suddenly after a small amount of reversible deformation. Because of their importance as biomaterials, it is useful to control and augment the resistance to fracture of these materials. Tougher, stronger hydrogels are emerging, and it is important to understand the structural origins of strength in these relatively robust, highly-swollen, polymer systems. We have investigated the rheological, mechanical and fracture properties of tough hydrogels, using novel testing techniques and focusing on the high-strain compression and tension behavior. Results from large-strain and fracture experiments were correlated to the chemical structure of the hydrogels. Because we believe that the mechanical properties of these tough hydrogels are due to the presence of dissipative mechanisms at the molecular level, we have explored several methods of synthesis to create these materials.

**W25 8 Rheological behavior of Slide Ring Gels.** VIVEK SHARMA, JONG SEUNG PARK, JUNG O. PARK, *School of Polymer, Textile and Fiber Engineering* MOHAN SRINIVASARAO, *School of Polymer, Textile and Fiber Engineering and School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA* Slide ring gels were synthesized by chemically crosslinking, sparsely populated $\alpha$-cyclodextrin ($\alpha$-CD) present on the polyrotaxanes consisting of $\alpha$-CD and polyethylene glycol (PEG). [1] Unlike physically or chemically crosslinked gels, slide ring gels are topological gels where crosslinks can slide along the chain. [2] We investigate the rheological behavior of these gels swollen in water and compare their viscoelastic properties to those of physical and chemical gels. We also study the equilibrium swelling behavior of these gels. [1] Okumura and Ito, Adv. Mater. 2001, 13, 485 [2] C. Zhao et al, J. Phys. Cond. Mat. 2005, 17, S2841

**16:06**

**W25 9 Mechanical and swelling properties of PDMS interpenetrating polymer networks** CLAUDE COHEN, SEONG HYUN YOO, *Cornell University* Poly(dimethylsiloxane) (PDMS) interpenetrating networks (IPNs) of a large and a small molar mass PDMS were prepared. Six series of IPNs were obtained by first tetra-functionally end-linking long vinyl-terminated PDMS neat or in a 50 per cent solution with unreactive PDMS chains. These networks were then dried and swollen with short reactive telechelic PDMS that were subsequently end-linked. We found that the correlation between modulus (E) and equilibrium swelling (Q) in toluene of the PDMS IPNs obeys a scaling relation identical to that of normal uni-modal PDMS networks. The results of the toughness of the networks represented by the energy required to rupture them were analyzed in terms of a recent model by Okumura (Europhysics Letters 67(3), 470, 2004). A modified version of this model that assumes each component of the double network to be subjected to an equal stress gives a good representation of the data.

**16:18**

**W25 10 Generation of Oriented Buckling Patterns by Modulation of Local Elastic Moduli** EDWIN CHAN, ALFRED CROSBY, *University of Massachusetts* Wrinkling patterns based on elastic instabilities are interesting due to the spontaneous formation of relief structures that consists of a dominant periodicity. While a wide variety of soft materials has been utilized to generate surface buckling patterns, alignment of these structures has only been demonstrated previously through pre-defined topographic patterns. In this contribution, we introduce a new methodology to producing aligned, or patterned, surface wrinkles through the manipulation of the local stress distributions. We define the specific regions of local differences in the elastic moduli of a poly(dimethyl siloxane) (PDMS) elastomer by selective oxidation of the PDMS surface into a silicate thin film. Subsequent swelling with a photopolymerizable monomer provides the buckling stress necessary for the formation of aligned surface wrinkles. We show that geometric confinement of the oxidized regions coupled with an osmotic stress controls the formation and orientation of the wrinkling structures.

**16:30**

**W25 11 Melting Point Depression of Small Molecules in Crosslinked and Uncross-linked Polyisoprene: Deviations from Flory-Huggins Theory*** QIAN QIN, GREGORY MCKENNA, *Texas Tech University* Thermoporosimetry (TPY) is becoming increasingly used to study nano-scale heterogeneity in polymers. The starting point for TPY is the Gibbs-Thomson (GT) relation between melting point and inverse crystal size. In the case of polymers, the Flory-Huggins (FH) model predicts that there is a depression of melting point due to the mixing of the polymer and the solvent molecules, and this needs to be taken into account. The first step in analysis of heterogeneity size using TPY and the GT equation requires that there be quantitative agreement between FH and the melting points in the uncross-linked rubber. We find that both benzene and hexadecane exhibit excessive melting point depressions in uncross-linked polyisoprene. This may imply that the uncross-linked polymer is divided into 'nanoheterogeneities.' We further find that the heat of fusion decreases as polymer concentration increases for the benzene, but not for the hexadecane. To our knowledge this is the first systematic investigation of the validity of melting of small organics in un-cross-linked polymers using the FH expressions.

**W25 12 Elastic Fluctuations and Rubber Elasticity** XIANGJUN XING, *Syracuse University* PAUL GOLDBART, *University of Illinois* LEO RRADZIHOVSKY, *University of Colorado* A coarse-grained phenomenological model is constructed to describe both phonon fluctuations and elastic heterogeneities in rubbery materials. It is a nonlocal, spatially heterogeneous generalization of the classical model of rubber elasticity, and with a tunable repulsion interaction. This model can also be derived from the Vulcanization theory. The residual stress and the non-affine deformation field, as well as their correlations, are calculated perturbatively, to the leading order of quenched randomness. It is explicitly shown that the interplay between the repulsive interaction and quenched randomness induces non- affine deformation. The spatial correlations of the non- affine deformation field and residual stress exhibit power-law scaling, with no characteristic length scale. We also calculate the contributions to the elastic free energy from both thermal and quenched fluctuations for arbitrary deformation. We find that they naturally explain the universal features in the Mooney-Rivlin plot of the stress-strain curve for rubbery materials. The (disorder averaged) thermal fluctuation of monomers is shown to depend on deformation, and becomes anisotropic upon shear deformation, as long as the repulsive interaction is finite.

**W25 13 Developing a lattice spring model to simulate the behavior of polymer gels** VICTOR YASHIN, ANNA BALAZS, *Department of Chemical Engineering, University of Pittsburgh, Pittsburgh, PA* A basic feature of responsive polymer gels is an inherent coupling of multiple physicochemical processes with a finite deformation of the material. We have developed a new, computationally efficient approach - the gel lattice spring model (gLSM) - which allows us to model responsive gels that undergo relatively large deformations in 2D. We start by writing an equation for the energy of the deformed gel in terms of the invariants of the strain tensor. We introduce the representative, rectangular-shaped unit element of the system, obtain an approximation of the total gel energy as a function of the coordinates (nodes) of this element, and derive the equations for the forces acting on the nodes. In accordance with the two-fluid model of gel dynamics, we assume a purely relaxational dynamics by taking the velocity of a node to be proportional to the force acting on that site. Using this gLSM, we simulate the structural evolution of a swelling gel in 2D, and the propagation of the swelling-deswelling waves through a rectangular chemo-responsive gel undergoing the Belousov-Zhabotinsky reaction.

**W25 14 MD simulations of chemically reacting networks: analysis of permanent set** DANA ROTTACH, *University of New Mexico* JOHN CURRO, JOANNE BUDZIEN, GARY GREST, AIDAN THOMPSON, *Sandia National Laboratories* The Independent Network Model (INM) has proven to be a useful tool for understanding the development of permanent set in strained elastomers. Our previous work showed the applicability of the INM to our simulations of polymer systems crosslinking in strained states. This study looks at the INM applied to theoretical models incorporating entanglement effects, including Flory's constrained junction model and more recent tube models. The effect of entanglements has been treated as a separate network formed at gelation, with additional curing treated as traditional phantom contributions. Theoretical predictions are compared with large-scale molecular dynamics simulations.

**17:18**

**W25 15 A Gaussian Slip-Link Model for Polymer Single and Double Networks** JAY D. SCHIEBER, *Professor* MAHNAZ ESKANDARI, *Ph.D. student* HAMID ARASTOOPOUR, *Professor* In this study, we developed Schieber's slip-link model for lightly cross-linked polymers assuming the equilibration of deformed Gaussian chains. Our simulation consists of two steps: preparation and deformation. In the preparation step, cross-links and slip-links are assumed to be distributed randomly along the chain, but with independent statistical parameters: the average number of Kuhn steps between entanglements, $N_e$, and the average number of Kuhn steps between cross-links, $N_c$. In the second step, the cross-links and slip-links are deformed affinely, but since the chain can slide through the slip-links, its deformation is non-affine. The

stress tensor can be determined as a function of deformation using Brownian dynamics as a sort of Monte Carlo algorithm. The Mooney plot of our simulation result has good agreement with most experimental data for uniaxial elongation deformation for cross-linked NR, PDMS, and PBd. The model is used to predict values for the Mooney plot parameters ($C_1$ and $C_2$) as a function of $N_e$ and the $N_c/N_e$ ratio. The $C_2/C_1$ ratio is found to be strongly dependent on $N_c/N_e$, but weakly dependent on $N_e$. This observation provides a new way of predicting the cross-link density and separating it from the entanglement density and for systems of known $N_e$ and $N_c$, the model requires no adjustable parameters. We are also developing our model for double network polymers in order to demonstrate different applications for the model.

**W26 1 Direct Observation of Thymine Dimer Repair in DNA by Photolyase.**
DONGPING ZHONG, *Ohio State University*

Departments of Physics, Chemistry, and Biochemistry, Programs of Biophysics, Chemical Physics, and Biochemistry, The Ohio State University, Columbus, 191 West Woodruff Avenue, OH 43210. Photolyase uses light energy to split ultraviolet-induced cyclobutane pyrimidine dimers in damaged DNA, but its molecular mechanism has never been directly revealed. We report here the direct mapping of catalytic processes through femtosecond synchronization of the enzymatic dynamics with the repair function. We observed direct electron transfer from the excited flavin cofactor to the dimer in 170 ps and back electron transfer from the repaired thymines in 560 ps. Both reactions are strongly modulated by active-site solvation to achieve maximum repair efficiency. These results show that the photocycle of DNA repair by photolyase is through a radical mechanism and completed on subnanosecond time scale at the dynamic active site with no net electron change in redox states of the flavin cofactor.

**W26 2 Near-infrared femtosecond laser assisted cell membrane permeabilization** CHENG PENG, ROBERT PALAZZO, INGRID WILKE, *Rensselaer Polytechnic Institute* The controlled delivery of membrane impermeable molecules into single living cells (micro-injection) is important for a variety of applications such genomics, proteomics or drug screening and testing. Recently, it has been demonstrated that opto-injection with tightly focused ( $\sim$ 300nm) femtosecond (fs) laser pulses at near-infrared (nir) wavelengths (700-1100nm) has the potential to create highly localized transient pores in single living cells with high cell survival rates and transfection efficiency. We have investigated the creation of transient pores in single living BAEC cells by focused fs nir laser pulses dependent on the incident laser intensity by dye uptake studies. Our experimental data agree very well with the experimentally and theoretically determined thresholds for laser-induced plasma formation and LIB. We observe that pore creation is observed for laser intensities of $4.0 \times 10^{12}$W/cm$^2$ and higher. For laser intensities above $3.3 \times 10^{13}$W/cm$^2$ BAEC cells are irreversibly destroyed. Within these two limits the pore size increases logarithmically with increasing laser intensity. This functional dependence is explained by considering the Gaussian intensity distribution across the laser focal spot. The physical understanding of the relationship between pore size and laser intensity allows the control of the number of molecules delivered into a cell per unit time through the control of the pore size.

**W26 4 DFT calculation of photo-induced charge transfer in organic molecule** MARK PEDERSON, *Naval Research Laboratory* TUNNA BARUAH, *University of Texas at El Paso* We propose a method for obtaining the charge transfer time for a chromophore-donor-acceptor system from density functional theory. Our calculations are done on a porphyrin-carotene-$C_{60}$ molecular triad. The geometry of the large molecular triad was optimized at the all-electron level using GGA. We are considering single electron excitations, the energies of which are obtained using a newly developed approach. The electronic dipolar transition probabilities are calculated from Einstein's A and B coefficients. However, in real systems the polarization effects play an important role in the transfer process since the charge separated

states can possess huge dipole moments. The stabilization of the large dipole state can be calculated from the classical dipole-dipole interaction and the polarizability of the surrounding medium. The stabilization of the dipole states is an important aspect which dominates the charge transfer process and therefore the rise time. The efficiency of the molecule as a solar energy converter will also be discussed.

**W26 5 Structural colours in blue-banded bee** JONES WAN,* LIXIIN DAI, JENSEN LI, KWOK-KWONG FUNG, CHE-TING CHAN, *Department of Physics, Hong Kong University of Science and Technology* Periodic, micro-textured biological materials are ubiquitous in nature. Electromagnetic waves at different frequencies are selectively reflected by such materials. This phenomenon is the origin of structural colours observed in variety of insects. In this work, we analyze the mechanisms that lead to the bluish-green colour of the blue-banded bee feathers. The reflection spectrum of the blue-banded bee feather was calculated by the transfer matrix method (TMM). The reflection peaks found are compatible within the experimental data. In addition to Bragg scattering, guided resonance has been observed in our theoretical calculation, which leads to a novel understanding of the structural colours in blue-banded bees.

**W26 6 Wavelength-Dependent Conformational Changes of Collagen in Mid-IR Ablation** M. SHANE HUTSON, YAOWU XIAO, *Dept of Physics and Astronomy, Vanderbilt University and VIIBRE - Vanderbilt Institute for Integrative Biosystem Research and Education* MINGSHENG GUO, *Dept of Physics, Fisk University* Single pulses of the Mark-III free electron laser have been used to ablate porcine corneas at a fluence of 240 J/cm$^2$ and wavelengths of 2.77 and 6.45 $\mu$m. As previously characterized, the non-volatile ablation debris shows evidence of wavelength-dependent collagen fragmentation. We have measured micro-Raman spectra of the debris and the ablation crater to determine if any wavelength-dependent conformational changes have taken place. Comparison of the spectra from two different wavelengths shows that a 938 cm$^{-1}$ Raman band – assignable to the peptide C$_{C=O}$-C$_\alpha$ stretch of collagen – loses substantial intensity during 6.45-$\mu$m ablation, but not in 2.77-$\mu$m ablation. This intensity decrease may be associated with a reduction of collagen triple-helix structure. Other spectral techniques yield mixed results; signatures for the loss of triple-helix structure are evident in UV-CD and some aspects of $^{13}$C-NMR spectra, but not in FTIR spectra. Raman measurements on thermally-treated corneal slices display similar changes at high temperatures, suggesting that higher protein temperatures are reached during ablation at 6.45 $\mu$m when compared to 2.77 $\mu$m. These observations suggest that any pre-vaporization loss of protein structural integrity includes not only collagen fragmentation, but also a loss of collagen triple-helix structure.

**W26 7 Novel protection mechanisms against singlet oxygen formation by the Chl *a* molecule in the cytochrome $b_6f$ complex of oxygenic photosynthesis** SERGEI SAVIKHIN, *Department of Physics, Purdue University* HANYOUP KIM, NARANBAATAR DASHDORJ, *Department of Physics, Purdue University* HUAMIN ZHANG, JIUSHENG YAN, WILLIAM CRAMER, *Department of Biological Sciences, Purdue University* A Chl molecule is known to produce highly toxic singlet oxygen under light illumination as a result of energy transfer from its triplet excited state to oxygen. To prevent that, a carotenoid is typically positioned close to a Chl molecule ( $\sim$ 4 Å) in Chl containing proteins to ensure rapid triplet-triplet energy transfer from Chl to carotenoid. Surprisingly, the X-ray structures of the cytochrome $b_6f$ complex show that the $\beta$ -carotene is much too far from the only Chl *a* found in this complex to provide effective protection by the usual triplet-triplet energy transfer mechanism. Our optical femtosecond time resolved experiments on diluted samples as well as on the single crystals of the $b_6f$ complex suggest that the Chl *a* is protected by two novel mechanisms: (i) the yield of the Chl *a* triplet state formation is reduced through electron-transfer exchange with the nearby amino acid residues, and (ii) a long distance triplet energy transfer to carotenoid mediated by a third mobile molecule (NSF MCB- 0516939, NIH GM-38323).

**16:42**

**W26 8 Electrostatic Steering of Functional Dynamics in GFP** J. TIMOTHY SAGE, *Northeastern Univ.* GEORGI Y. GEORGIEV, *Assumption College* JASPER J. VAN THOR, *University of Oxford* Distinctive photodynamic properties of the green fluorescent protein (GFP) from the jellyfish *A. victoria* result from charge transfer processes involving the autocatalytically generated chromophore. We investigate structural changes in response to chromophore photoionization at cryogenic temperatures, using both X-ray crystallography and polarized infrared measurements on oriented single crystals. These measurements identify conformational changes of Gln 69, Cys 70, and an associated H-bonded cluster of internal water molecules in the chromophore environment. These structural changes take place at 100 K, far below the ''dynamical transition'' traditionally regarded as enabling functional protein motions. This contrasts with the prevailing view that the rigid interior of the GFP $\beta$-barrel sterically inhibits nonradiative processes. Instead, we propose that rapid rearrangements of the chromophore environment enhance the fluorescence quantum yield by stabilizing the abruptly altered charge distribution in the radiative state. We suggest that the conformational response to charge transfer influences two fundamental and useful spectroscopic properties of GFP—the large frequency separation between excitation and emission and the efficient fluorescence.

**16:54**

**W26 9 Terahertz Dielectric Response of Photoactive Yellow Protein (PYP): Influence of Conformational-Vibrational State during Photocycle and Hydration Effects** JOSEPH KNAB, JING-YIN CHEN, *Physics Department, University at Buffalo, Buffalo, NY 14260* WOUTER HOFF, *Department of Microbiology and Molecular Genetics, Oklahoma State University, Stillwater, OK 74078* ANDREA MARKELZ, *Physics Department, University at Buffalo, Buffalo, NY 14260* Protein conformational change alters flexibility and conformational-vibrational modes that occur on a picosecond or sub-picosecond time scale. Terahertz dielectric measurements are sensitive to protein flexibility as they directly probe the density of states of these vibrational modes. Using terahertz time-domain spectroscopy, we measured the dielectric response of PYP thin films as a function of resting and photointer-

mediate state. The absorbance increases smoothly as a function of frequency while the index of refraction exhibits no frequency dependence. A sharp transition in the dielectric response of the ground state is observed at 86% relative humidity (r.h.), corresponding to the point where the protein film has lost $\sim$ 50 water molecules relative to a 100% r.h. environment. Similar transitions observed for hen egg white lysozyme and cytochrome c correspond to the filling point of the first hydration shell.

**17:06**

**W26 10 Novel Photo-Protecticon Mechanisms in Chlorosomes from Green Sulfur Bacterium itChlorobium Tepidum** HANYOUP KIM, SERGEI SAVIKHIN, *Department of Physics, Purdue University, West Lafayette, IN 47907* HUI LI, JULIA MARESCA, DONALD BRYANT, *Department of Biochemistry and Molecular Biology, The Pennsylvania State University, University Park, PA 16802* Chlorosome is the largest known photosynthetic light-harvesting antenna complex that incorporates thousands of bacteriochlorophtylls (BChl) and carotenoids (Car) in a closely packed quasi-regular structure. BChl is known to produce highly toxic singlet oxygen as the result of energy transfer from their excited triplet states to oxygen molecules. It has been proposed that that the carotenoids in chlorosome serve both light harvesting and photo-protection functions, transferring light excitations to nearby BChl and simultaneously quenching excited triplet state of BChl. However, experiments indicate that photoprotective role of carotenoids in chlorosomes is not as extensive as expected—photo-degradation of carotenoid-free mutants occurs only twice faster than photo-degradation of native complexes. An additional non-conventional photoprotection mechanism must exist in chlorosomes. The possible nature of this mechanism is discussed based on optical kinetic measurements of BChl and Car excited states.

**W26 11 Hydration Dependence of Energy Relaxation Time for Cytochrome C** SHUJI YE, JING-YIN CHEN, JOSEPH R. KNAB, ANDREA MARKELZ, *Physics, University at Buffalo, SUNY* Hydration plays a critical role in protein dynamics. Here we consider the effects of hydration on energy relaxation for an electronically excited heme protein cytochrome c. We measure the hydration dependence of energy relaxation time of cytochrome C films after photoexcitation in the Soret regionusing two-color pump/probe time resolved transmission measurements. Thin films were prepared from cytochrome C/ Trizma buffer solutions and mounted in a hydration controlled cell. We used 400nm ( $\sim$ 3 mW) to pump the B band and 800 nm ( $\sim$ 1 mW) to probe the III band. The III band corresponds to the charge-transfer transition between heme $\pi$ and iron d orbital, and is assigned to the ground electronic state of the heme. Therefore this band can be used to probe the ground state population. Three separate dynamic components were observed: a very fast transient $\tau_1 \sim$ 200 fs; a several hundred femtosecond component ($\tau_2$); and a recovery of the ground state absorption($\tau_3$). We find $\tau_3$ apparently decreases with decreasing hydration while $\tau_1$ and $\tau_2$ are independent of hydration.

**W28 1 The phase diagram of the organic charge transfer salts $(TMTTF)_2X$*** F. ZHANG, *UCLA* W. YU, B. ALAVI, A. BAUR, C. A. MERLIC, S. E. BROWN, We report on NMR spectroscopy and relaxation measurements probing the temperature/pressure phase diagram of the quasi-one-dimensional organic conductor $(TMTTF)_2SbF_6$. This material undergoes a charge ordering (CO) phase transition at $T = 156K$, and the ground state is antiferromagnetic (AF) at ambient pressure. Our experiments show that the AF ground state is supressed sharply by applying hydrostatic pressure and a new phase appears at higher pressure. At intermediate pressures, magnetic ordering is suppressed to temperatures below the minimum measured so far, $T = 2K$. The nature of the high pressure phase is not yet established; there are features consistent with both spin-Peierls (SP), and antiferromagnetic ordering. We discuss the possible role of counterion disorder in producing an inhomogenous system consistent with our observations, and the implications for a general phase diagram for the TMTTF/TMTSF family of organic conductors.

**W28 2 Intermolecular bonding in conjugated polymers: The effect on aggregate morphology.** JEREMY SCHMIT, *Brandeis University* ALEX LEVINE, *UCLA* Intermolecular interactions play an important role in the mechanical and optical properties of conjugated polymer films and solutions. However, the nature of such inter-polymer interactions is poorly understood. We present a calculation showing that in the tight-binding approximation, conjugated polymers that approach each other on the angstrom length scale will form weak, covalent-like bonds. These bonds then drive the formation of aggregate structures. The morphology of the aggregates formed by the polymers depends on the net binding strength of the interaction. At low bond strength, the polymers form loose aggregates, while strong bonds lead to the formation of tight bundles with an effective persistence length one order of magnitude greater than the free polymer.

**14:54**

**W28 3 Effects of polymer side chains on the self-assembling of conjugated polymer in thin film** YUNFEI JIANG, *Chemistry Department, Clemson University, Clemson, SC, 29634-0973* YI-QING WANG, *School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA 30332* UVW H. F. BUNZ, *School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA 30332* DVORA PERAHIA, *Chemistry Department, Clemson University, Clemson, SC, 29634* Conjugated polymers are inherently semi-conducting and optically active materials, with immense potential applications in organic electro-optical devices. The chemical structure of the polymer including the rigidity of the backbone and the nature of substituents affect their association as well as their electro-optical response. The following work reports the effects of different side chains on the structure and fluorescence of highly conjugated polymer, poly-(para phenyleneethynylene) (PPE). When substituted by long

polylactide side chains they self-assemble into wires with fingerprint-like arrangement, casting from chloroform solutions on oxidized silicon wafer. With increasing content of poor solvent, the dimension of the structures increased and then crystallized area appeared, as showed in AFM studies. The introducing of the long flexible polymer side chains has significantly reduced the stacking between rigid backbones. This in tern results in a frequency shift in their fluoresces response, indication changes in the electronic levels. Direct measurements of the electronic levels using ATM are currently in progress.

**15:06**

**W28 4 Chain morphologies in semi-crystalline polyfluorene: evidence from Raman scattering*** S. GUHA, C. VOLZ, M. ARIF, *Department of Physics, University of Missouri-Columbia MO* Organic semiconductors, such as short-chain oligomers and long- chain polymers, are now a core constituent in numerous organic and organic-inorganic hybrid technologies. Polyfluorenes (PF) have emerged as attractive alternatives to other polymers due to their strong blue emission and high charge carrier mobilities. Almost all PF derivatives utilize side-chain substitution that improves solution processing and confers new functionality. There are many ambiguities regarding structure- property relationships in various side-chain substituted PFs. Di-octyl substituted PF (PF8) is known for its mesomorphic behavior, multitude of crystalline phases, and several conformational isomers that depend on the torsional angle between monomer units. In particular, the $\beta$ phase that represents a more planar backbone conformation dominates the optical emission although it appears as a minority constituent. We present Raman scattering studies of PF8 as a function of thermal cycling, which establishes a connection between the conformational isomers and the side and main chain morphology. Density-functional calculations of the vibrational spectra of single chain oligomers in conjunction with the experimental results demonstrate the incompatibility of the $\beta$ phase with the overall $\alpha$ crystalline phase in PF8.

**W28 5 Structural Changes in Phthalocyanine Thin Films from Analyte Vapor Exposure*** THOMAS GREDIG, GE LIU, CORNELIU N. COLESNIUC, *Department of Physics, UC San Diego* FOREST I. BOHRER, ANDREW C. KUMMEL, *Department of Chemistry and Biochemistry, UC San Diego* IVAN K. SCHULLER, *Department of Physics, UC San Diego* Organic phthalocyanine thin films were fabricated with varied thicknesses and varied grain size structure. These films act as gas sensors as detected via conduction measurements due to analyte vapors. We have observed structural changes with high-resolution x-ray diffraction due to exposure to different analyte vapors. In thin films with small grains ( $\sim$ 30nm diameter), low-angle irreversible changes and high-angle reversible variations were observed. We associate the irreversible behavior with current drift observed in transport measurements. In contrast, reversible variations of the first Bragg peak of the phthalocyanine are compared to the sensing changes in conductivity from exposure to analyte vapors.

**W28 6 Electronic Structure of Potassium-doped Magnesium Phthalocyanine measured using Soft X-ray Spectroscopies.** YUFENG ZHANG, SHANCAI WANG, LEYLA COLERK-EROL, TIMOTHY LEARMONTH, LUKASZ PLUKINSKI, KEVIN SMITH, *Boston University* JAMES DOWNES, *SCPS, Victoria Univeristy of Wellington* ANNE MATSUURA, *Air Force Office of Scientific Research* We report a synchrotron radiation-excited resonant soft x-ray emission spectroscopy (XES) study of the electronic structure of magnesium phthalocyanine (MgPc) doped with potassium. XES measures directly the element specific partial density of states (PDOS) in solids. The electronic structure near the Fermi level in organic systems can be accurately measured by using this non-ionizing spectroscopy. The MgPc films were grown itin-situ by using a custom designed ultra-high vacuum organic molecular beam deposition system, and transferred under vacuum to the spectrometer system. As with our earlier study of Cu-Pc and vanadium oxide phthalocyanine (VO-Pc), the K-doped MgPc films were discovered to be highly susceptible to synchrotron radiation beam damage. We successfully circumvented this effect by continuous translation of the films during measurement. We find that the measured C $2p$ PDOS for K-doped MgPc differs from that of pure MgPc, and will discuss the possible origins of these results. Supported in part by ACS Petroleum Research Fund, and by the NSF. Experiments were performed at the NSLS.

**W28 7 Polaron transport in triphenylene-based discotic liquid crystals** VOLODIMYR DUZHKO, *Department of Physics, Case Western Reserve University, OH 44106* ALEXANDER N. SEMYONOV, ROBERT J. TWIEG, *Department of Chemistry, Kent State University, OH 44242* KENNETH D. SINGER, *Department of Physics, Case Western Reserve University, OH 44106* We report on the investigation of charge carrier transport in the columnar phase of the triphenylene-based discotic liquid crystal, hexapentyloxytriphenylene, by the time-of-flight technique. The hole mobility was found to be temperature and electric field dependent with a maximum value of $2\times\ 10^{-3}$ cm$^2$/Vs. Its temperature dependence is described by a $T^{-n}$ power law, with an electric field dependent n varying from 2.5 to 4.5 corresponding to electric field values from $5\times\ 10^4$ V/cm to $5\times\ 10^3$ V/cm, respectively. The drift velocity of charge carriers is a linear function of the electric field for small fields below $5\times\ 10^4$V/cm and tends to saturation at strong fields. These results are interpreted in the framework of correlated polaron motion as described by the non-adiabatic low-temperature limit of Holstein's small polaron theory. The applicability of the Holstein polaron model to triphenylene-based materials showing thermally activated or temperature-independent carrier mobilities will be discussed.

**W28 8 Atomic Force Microscope-Based Surface Potential and Surface Photovoltage Studies of Porphyrin Nanorod Thin Films** TODD HOLDEN, *Brooklyn College of CUNY* WALTER SMITH, *Haverford College* A.D. SCHWAB, *Appalachian State University* J.C. DE PAULA, *Lewis and Clark College* We have performed atomic force microscope-based surface potential and surface photovoltage measurements on porphyrin grown as nanorods about 5 nm in diameter and 1 micron long. These nanorods have been shown to have peculiar photoconducting properties in that the photoconductivity grows under light illumination for up to 1 hour. In addition, when a current is flowed through the nanorods,

they become ''trained.'' That is after the light is turned off and the ends of the nanorod are short circuited together, a small current will flow opposite to the direction of the original photocurrent. The material exhibits nanoscale potential fluctuations as well as selective surface potential sensitivity to light. These offer some insight to the material's novel properties.

**16:06**

**W28 9 Holographic liquid crystal photonic materials stabilized with monoacrylate LC monomer.** AUGUSTINE URBAS, ERIC BECKEL, VINCENT TONDIGLIA, LALGUDI NATARAJAN, TIMOTHY BUNNING, *AFRL* Active structured optical materials such as dynamically tunable photonic crystals have potential technological applications in imaging and communications. Structured liquid crystal materials are especially promising for their observed high performance and wide range of dynamic response. In addition, they provide multiple routes of response, including electro-optic and photo-optic. Reverse mode holographic polymer dispersed liquid crystals (HPDLCs) are typically fabricated by multiple laser beam exposure of an LC photo-sensitive syrup containing diacrylate liquid crystal (LC) monomer. The function of the diacrylate monomer is to form the basis of a highly crosslinked network which stabilizes regions with high polymer content. The use of monoacrylate functional liquid crystals in this application has the potential of tuning the stabilizing effect of the polymer network by changing the crosslink density. This affects the switching time and the contrast between stabilized and unstabilized regions of the patterned structure. These parameters are particularly important to photo-switchable patterned photonic structures containing azobenzene derivatives. The effects on electro-optic and photo-optic properties of reverse mode HPDLCs containg of different monoacrlyate functional liquid crystal fractions in the stabilizing patterned polymer network will be presented.

**16:18**

**W28 10 Electrooptic Properties of Holographic Polymer-Stabilized Cholesteric Liquid Crystals** ERIC BECKEL, MELISSA INGRAM, *Air Force Research Laboratory* LALGUDI NATARAJAN, VINCENT TONDIGLIA, RICHARD SUTHERLAND, *Science Applications International Corporation* TIMOTHY BUNNING, *Air Force Research Laboratory* Cholesteric liquid crystals (CLCs) have attracted significant attention for uses in photonic and electrooptic devices, such as photonic crystals, light switches, and display applications. These materials selectively reflect circularly polarized light due to the existence of a macroscopic helical structure. Application of an electric field reorients the LC from a planar geometry to a homeotropic alignment, eliminating the reflection notch. This LC reorientation to the clear state is rapid with the application of an electric field. After the electric field is removed, the return to the cholesteric orientation is compounded by the long lifetime of a highly scattering focal conic state. To avoid this undesired prolonged focal conic lifetime, a small concentration of monomer can be polymerized, which acts as a memory for the rapid return into the cholesteric state. In this research, we examine the effect of holographically patterning the polymer stabilization. Reflection grating patterning is studied and varying bilayer spacings are examined. This research shows the possibility of minimal notch broadening, with no apparent chirp in the reflection notch. Additionally, we examine the possibility of incorporating a narrow notch Bragg reflection at a differing wavelength than the CLC broad reflection notch, within the same device.

**W28 11 High Refractive Index Poly(thiophene) for Organic 3-D Photonic Crystals with a Complete Photonic Band Gap*** MATTHEW J. GRAHAM, *The University of Akron* SHI JIN, *CUNY, Staten Island* FRANK W. HARRIS, *University of Akron* STEPHEN Z.D. CHENG, *The University of Akron* Photonic crystals (PC) with a complete 3-D photonic band gap (PBG) require materials with sufficient refractive index ($n$) contrast to be in specific 3-D periodic structures on the length scale of light. Currently, only inorganics have an adequate $n$ to open a complete 3-D PBG. Poly(thiophene) (PT), a sulfur containing conjugated polymer, is predicted to have a sufficient $n$, but this has not been realized. By optimizing the electropolymerization of PT including reaction rates, temperatures, additives, and reactant concentrations, high quality PT films with an adequately high $n$ can be synthesized. Using a density differential colloidal crystallization technique, which allows the crystallization process to approach thermodynamic equilibrium, high quality templates were produced. A nano-mechanical annealing technique was developed to enable the further perfection of the entropy driven structures. The next step is to combine these to fabricate an organic 3-D PC with a complete PBG.

**16:42**

**W28 12 Thermopower of Pentacene Thin-film Transistors** DANIEL LENSKI, ALEXANDRA CURTIN, M.S. FUHRER, *University of Maryland* FUHRER NANOTECHNOLOGY GROUP TEAM, The mechanism of conduction in organic thin-film transistors remains poorly understood, though it is generally thought that conduction occurs via hopping in a disordered band tail. Thermopower in principle can give additional information about the density of states D(E), and the dependence of the mobility on D(E); such information can be used to discriminate between various conduction mechanisms. We report for the first time measurements of the thermopower of pentacene thin films on $SiO_2$/Si in a field-effect transistor configuration as a function of charge carrier density and temperature. This work was supported by the Laboratory for Physical Sciences.

**W28 13 In-Situ Measurements of Organic Electronic Devices Fabricated via Transfer Printing on Flexible Substrates** ANDREW TUNNELL, DANIEL R. HINES, VINCE W. BALLAROTTO, MIHAELA BREBAN, ELLEN D. WILLIAMS, *Laboratory for Physical Sciences and Department of Physics, University of Maryland, College Park, MD.* Transfer printing was used to fabricate high quality organic thin-film transistors (TFT) on flexible substrates. The model system of a pentacene (Pn) TFT with 600 nm thick poly(methyl methacrylate) dielectric layer and gold electrodes on a polyethylene terephthalate substrate has shown a mobility (adjusted for contact resistance) of 0.237 $cm^2$/Vs, on/off ratio of $10^5$ and threshold voltage of -7 V. To optimize the transfer printing parameters of the Pn semiconductor layer, mobility and contact resistance were studied as a function of printing temperature and pressure. The best TFT devices resulted from printing at 120 $^oC$ and 600 psi. A detailed study of the effect of transfer printing on the device properties was performed via in-situ measurements of drain current (ID) as a function of both

drain (VD) and gate (VG) voltages. Details of the in-situ measurements while transfer printing the Pn layer will be presented and discussed. *Work supported by the Laboratory for Physical Sciences, College Park, MD and ARDA.

**W29 1 Self-Organization of Networks Via Synchrony-Dependent Plasticity** JACK WADDELL, MICHAL ZOCHOWSKI, *University of Michigan - Physics* We employ an adaptive parameter control technique based on a previously developed measure that detects phase/lag synchrony in the system to dynamically modify the structure of a network of non-identical, weakly coupled Rössler oscillators. Two processes are simulated: adaptation, under which the initially different properties (such as frequency) of the units converge, and aggregation, in which coupling between units is altered and clusters of interconnected elements are formed based on the temporal correlations. We show that adaptation speed depends on connectivity and topology, with more global connections resulting in greater temporal order and faster convergence of adaptation. We find that aggregation leads to unidirectional clusters, and that asymmetric aggregation (with differing rates for increasing or decreasing coupling strength) has an optimum ratio of rates to make denser clusters that maintain their selectivity. Combining adaptation and aggregation results in clusters of identical oscillators with bi-directional coupling. An optimum ratio of process rates results in stable coupling between the units. Change from this ratio may result in annihilation of the network for slow aggregation, or more numerous, denser, and more transient clusters for faster aggregation.

**W29 2 Phase reduction analysis of coupled neural oscillators: application to epileptic seizure dynamics** DAISUKE TAKESHITA, *University of Missouri at St. Louis* YASUOMI SATO, *J.W. Goethe-University* SONYA BAHAR, *University of Missouri at St. Louis* Epileptic seizures are generally held to be result from excess and synchronized neural activity. To investigate how seizures initiate, we develop a model of a neocortical network based on a model suggested by Wilson [1]. We simulate the effect of the potassium channel blocker 4-aminopyridine, which is often used in experiments to induce epileptic seizures, by decreasing the conductance of the potassium channels ($g_K$) in neurons in our model. We applied phase reduction to the Wilson model to study how $g_K$ in the model affects the stability of the phase difference. At a normal value of $g_K$, the stable phase difference is small, but the neurons are not exactly in phase. At low $g_K$, in-phase and out-of-phase firing patterns become simultaneously stable. We constructed a network of 20 by 20 neurons. By decreasing $g_K$to zero, a dramatic increase in the amplitude of mean field was observed. This is due to the fact that in-phase firing becomes stable at low $g_K$. The pattern was similar to local field potential in 4-aminopyridine induced seizures. Therefore, it was concluded that the neural activity in drug-induced seizure may be caused by a bifurcation in stable phase differences between neurons. [1] Wilson H.R., J. Theor. Biol. (1999) 200, 375-388 [2] Ermentrout, G.B. and Kopell, N., SIAM J. Math. Anal. (1984), 215-237

**14:54**
**W29 3 Effect of Delays and Network Topology in Spatiotemporal Pattern Formation** RHONDA DZAKPASU, MICHAL ZOCHOWSKI, *Department of Physics, Biophysics Research Division, University of Michigan* Synchronization between connected neurons is believed to play a role in the processing of information within the brain. This implies a temporal ordering in the discharge of their electrical signals but since the axons have a finite length over which a signal must traverse, information relating to a particular process and emanating from different neurons reaches a target neuron after a time delay. We investigate the effects of delays on the formation of temporally ordered states in a model network with SWN topology. We show that incorporation of two different types of delay, length independent and length dependent, lead to dramatically different properties of the network. In the first case, the formation of global random connections leads to an increase in temporal ordering, while in the second case locally ordered clusters are annihilated and form a disordered state.

**15:06**
**W29 4 Inhibitory Synaptic Coupling and Spatiotemporal Synchrony in a Neural Model** ROXANA CONTRERAS, *University of Missouri-Saint Louis* SONYA BAHAR, *University of Missouri-Saint Louis* We study the behavior of an array of neurons, connected by excitatory and inhibitory synapses, when the relative proportion of such connections is varied. The cells, described by the Huber-Braun model [1], exhibit different bursting states as parameters such as temperature and coupling strength are tuned. In a recent paper [2], stochastic phase synchronization was studied in this model, using gap-junction type connections. Here, we extend this work to more realistic synaptic connectivities, to investigate the connection between bursting and synchronization, which has been implicated in the triggering of pathological processes such as epilepsy, since synchronous firing in neuronal populations is viewed as a hallmark of seizures. We also present evidence suggesting that noise could be responsible for transitions between various types of field potential oscillations, reminiscent of the transitions between spike-and-wave firing and low voltage fast activity observed in the epileptic cortex. [1] H. A. Braun, M. T. Huber, M. Dewald, K. Schäfer, and K. Voigt. Computer simulations of neuronal signal transduction: the role of nonlinear dynamics and noise. Intl. J. Bifurcation and Chaos 8(5): 881-889, 1998. [2] S. Bahar. Burst-enhanced synchronization in an array of noisy coupled neurons. Fluctuation and Noise Letters 4(1):L87-L96, 2004.

**W29 5 Attentional modulation of stimulus competition in a large scale model of the visual pathway** CALIN BUIA, *University of North Carolina at Chapel Hill* PAUL TIESINGA, *University of North Carolina at Chapel Hill* Neurons in cortical area V4 are sensitive to shape and have large receptive fields. In a typical visual scene there are multiple objects in the V4 cell's receptive field, only a few of which may be behaviorally relevant. The visual system is capable of selecting relevant objects by increasing the neural response to them and reducing the response to non-relevant objects. Neuronal synchrony may play an important role in this

process. Using a large-scale network model of the visual pathway, we study the emergence of shape selectivity in V4, the competition between different objects for control of the firing rate of individual V4 neurons, the attentional modulation of this stimulus competition and the role of synchrony.

**W29 6 Specificity, promiscuity, and the structure of complex information processing networks** CHRISTOPHER MYERS, *Cornell University* Both the top-down designs of engineered systems and the bottom-up serendipities of biological evolution must negotiate tradeoffs between specificity and control: overly specific interactions between components can make systems brittle and unevolvable, while more generic interactions can require elaborate control in order to aggregate specificity from distributed pieces. Complex information processing systems reveal network organizations that navigate this landscape of constraints: regulatory and signaling networks in cells involve the coordination of molecular interactions that are surprisingly promiscuous, and object-oriented design in software systems emphasizes the polymorphic composition of objects of minimal necessary specificity [C.R. Myers, Phys Rev E 68, 046116 (2003)]. Models of information processing arising both in systems biology and engineered computation are explored to better understand how particular network organizations can coordinate the activity of promiscuous components to achieve robust and evolvable function.

**W29 7 Modeling of signal transduction in bacterial quorum-sensing** ANDREW FENLEY, *Virginia Tech* SUMAN BANIK, *Virginia Tech* RAHUL KULKARNI, *Virginia Tech* Several species of bacteria are able to coordinate gene regulation in response to population density, a process known as ''quorum-sensing.'' Quorum-sensing bacteria produce, secrete, and detect signal molecules called autoinducers. For several species of bacteria in the *Vibrio* genus, recent results have shown that the external autoinducer concentrations control the expression of regulatory small RNA(s) which are critical to the process of quorum-sensing. We present a theoretical analysis of the network which relates the rate of small RNA expression to the external autoinducer concentrations. We relate the results from our modeling to previous experimental observations and suggest new experiments based on testable predictions of the model.

**15:54**

**W29 8 Sloppiness is universal in systems biology: making predictions nonetheless** RYAN GUTENKUNST, *Physics, Cornell* FERGAL CASEY, *Applied Math, Cornell* JOSHUA WATERFALL, *Physics, Cornell* KEVIN BROWN, *Molecular and Cellular Biology, Harvard* CHRISTOPHER MYERS, *Theory Center, Cornell* JAMES SETHNA, *Physics, Cornell* Quantitative models of complex biological systems often possess dozens of unknown parameters. We argue that such systems are universally ''sloppy''; their behaviors are orders of magnitude more sensitive to moves in some directions in parameter space than others. To establish this, we survey models from the literature and show that their ''complete and perfect data'' Fisher Information Matrices possess eigenvalues typically spanning a range of more than $10^6$. Sloppiness implies that collectively fitting model parameters to even the best experimental data will tightly constrain only a few parameter combinations, perhaps suggesting the necessity of a difficult experimental program to measure each individual parameter. An example demonstrates, however, that a collective fit to a modest amount of real data may tightly constrain model behavior even though it only poorly constrains many parameter combinations. Low uncertainty predictions can thus be made without knowledge of precise values for individual parameters.

**16:06**

**W29 9 Inference and analysis of gene-regulatory networks in the bacterium B.subtilis** CLAIRE CHRISTENSEN, *Dept. of Physics, Penn State University* ANSHUMAN GUPTA, *Dept. Chem. E., Penn State University* REKA ALBERT, *Dept. of Physics, Penn State University* COSTAS MARANAS, *Dept. Chem. E., Penn State University* We present the methods and results of a two-stage modeling process that generates candidate gene-regulatory networks of the bacterium B.subtilis from experimentally obtained, yet mathematically underdetermined microchip array data. By employing a computational, linear correlative procedure to generate these networks, and by analyzing the networks from a graph theoretical perspective, we are able to verify the biological viability of our simulated networks, and we demonstrate that our networks' graph theoretical properties are remarkably similar to those of other, more well-studied biological systems. We test the robustness of the inference process first by introducing noise into the experimental data, and then by comparing the graph theoretical properties of the resulting perturbed networks to those of the original networks.

**16:18**

**W29 10 Sensitivity-based approach to optimal experimental design in a receptor trafficking and down regulation model** FERGAL CASEY, JOSHUA WATERFALL, RYAN GUTENKUNST, *Cornell University* KEVIN BROWN, *Harvard University* CHRISTOPHER MYERS, JAMES SETHNA, *Cornell University* We apply the ideas of optimal experimental design to systems biology models: minimizing a design criterion based on the average variance of predictions, we suggest new experiments that need to be performed to optimally test a given biological hypothesis. The estimated variance in predictions is derived from the sensitivities of protein and chemical species in the model to changes in reaction rates. The sensitivities also allow us to determine which interactions in the biological network dominate the system behavior. To test the design principles, we have developed a differential equation model incorporating the processes of endocytosis, recycling and degradation of activated epidermal growth factor (EGF) receptor in a mammalian cell line. Recent experimental work has discovered mutant proteins that cause receptor accumulation and a prolonged growth signal. Our model is optimized to fit this mutant experimental data and wild type data for a variety of experimental conditions. Of biological interest is the effect on surface and internalized receptor levels after the overexpression or inactivation of regulator proteins in the network: the optimal design method allows us to fine tune the conditions to best predict the behavior of these unknown components of the system.

**16:30**

**W29 11 Stochasticity in the Expression of LamB and its Affect on λ phage Infection** EMILY CHAPMAN, XIAO-LUN WU, *University of Pittsburgh* λ phage binds to itE. Coli's lamB protein and injects its DNA into the cell. The phage quickly replicates and after a latent period the bacteria bursts, emitting mature phages. We developed a mathematical model based on the known physical events that occur when a λ phage infects an itE.Coli cell. The results of these models predict that the bacteria and phage popu-

lations become extinct unless the parameters of the model are very finely tuned, which is untrue in the nature. The lamB protein is part of the maltose regulon and can be repressed to minimal levels when grown in the absence of inducer. Therefore, a cell that is not expressing any lamB protein at that moment is resistant against phage infection. We studied the dynamic relationship between λ phage and itE. Coli when the concentration of phage greatly outnumbers the concentration of bacteria. We study how the stochasticity of the expression of lamB affects the percentage of cells that the λ phage infects. We show that even in the case when the maltose regulon is fully induced a percentage of cells continue to persist against phage infection.

**16:42**

**W29 12 Control of lineage stability and its role in resolving cell fates** ARYEH WARMFLASH, *University of Chicago* AARON DINNER, *University of Chicago* We synthesize experimental data from recent studies to construct a computational model for the gene regulatory network that governs the development of immune cells and use it to explain several surprising results. At the heart of the model is a cross-antagonism between the macrophage-promoting factor Egr and the neutrophil-promoting factor Gfi. This module is capable of giving rise to both graded and bistable responses. Increasing the concentrations of these factors forces the system into the bistable regime in which cells can decide stochastically between fates. This bistable switch can be used to explain cell reprogramming experiments in which a gene associated with one cell fate is induced in progenitors of another. In one such experiment, C/EBP$\alpha$, a neutrophil promoting factor, was induced in B cell progenitors which then differentiated to macrophages. Our model shows that if C/EBP$\alpha$ is induced early, it can induce differentiation to a neutrophil. In B cell progenitors, however, the bistable switch is already in a macrophage promoting state. Thus, expression of C/EBP$\alpha$ cannot activate the neutrophil pathway, but it can repress the B cell pathway and promote macrophage differentiation.

**16:54**

**W29 13 Role of finite-size fragments in analysis of DNA replication** JOHN BECHHOEFER, HAIYANG ZHANG, *Dept. of Physics, Simon Fraser University* In higher organisms, DNA replicates simultaneously from many origins. Recent in- vitro experiments have yielded large amounts of data on the state of replication of DNA fragments. From measurements of the time dependence of the average size of replicated and non-replicated domains, one can estimate the rate of initiation of DNA replication origins, as well as the average rate at which DNA bases are copied. One problem in making such estimates is that, in the experiments, the DNA is broken up into small fragments, whose finite size can bias downwards the measured averages. Here, we present a systematic way of accounting for this bias by deriving theoretical relationships between the original domain-length distributions and fragment-domain length distributions. We also derive unbiased average-domain-length estimators that yield accurate results even in cases where the replicated (or non-replicated) domains are larger than the average DNA fragment. Then we apply these estimators to previously obtained experimental data to extract improved estimates of replication kinetics parameters.

**17:06**

**W29 14 Stochastic dynamics of macromolecular-assembly networks.** LEONOR SAIZ, *Memorial Sloan-Kettering Cancer Center* JOSE VILAR, *Memorial Sloan-Kettering Cancer Center* The formation and regulation of macromolecular complexes provides the backbone of most cellular processes, including gene regulation and signal transduction. The inherent complexity of assembling macromolecular structures makes current computational methods strongly limited for understanding how the physical interactions between cellular components give rise to systemic properties of cells. Here we present a stochastic approach to study the dynamics of networks formed by macromolecular complexes in terms of the molecular interactions of their components [1]. Exploiting key thermodynamic concepts, this approach makes it possible to both estimate reaction rates and incorporate the resulting assembly dynamics into the stochastic kinetics of cellular networks. As prototype systems, we consider the itlac operon and phage λ induction switches, which rely on the formation of DNA loops by proteins [2] and on the integration of these protein-DNA complexes into intracellular networks. This cross-scale approach offers an effective starting point to move forward from network diagrams, such as those of protein-protein and DNA-protein interaction networks, to the actual dynamics of cellular processes. [1] L. Saiz and J.M.G. Vilar, submitted (2005). [2] J.M.G. Vilar and L. Saiz, Current Opinion in Genetics & Development, 15, 136-144 (2005).

**17:18**

**W29 15 Selective advantage for sexual reproduction*** EMMANUEL TANNENBAUM, *Ben-Gurion University of the Negev* We develop a simplified model for sexual replication within the quasispecies formalism. We assume that the genomes of the replicating organisms are two-chromosomed and diploid, and that the fitness is determined by the number of chromosomes that are identical to a given master sequence. We also assume that there is a cost to sexual replication, given by a characteristic time $\tau_{seek}$ during which haploid cells seek out a mate with which to recombine. If the mating strategy is such that only viable haploids can mate, then when $\tau_{seek} = 0$, it is possible to show that sexual replication will always outcompete asexual replication. However, as $\tau_{seek}$ increases, sexual replication only becomes advantageous at progressively higher mutation rates. Once the time cost for sex reaches a critical threshold, the selective advantage for sexual replication disappears entirely. The results of this talk suggest that sexual replication is not advantageous in small populations per se, but rather in populations with low replication rates. In this regime, the cost for sex is sufficiently low that the selective advantage obtained through recombination leads to the dominance of the strategy. In fact, at a given replication rate and for a fixed environment volume, sexual replication is selected for in high populations because of the reduced time spent finding a reproductive partner.

CHRISTOPHER OBER, *Cornell University*

The control of the physicochemical properties of surfaces in contact with biological systems represents a fundamental issue in many applications ranging from coatings to biotechnology and microelectronics. In particular, advances in biotechnology depend on the ability to fashion materials with precise control of feature size and functionality. This presentation focuses on issues of specific and non-specific binding and strategies being developed to control both. Examples of specific binding that enable investigation of cell function will be presented. The broader issue of non-specific binding and how it relates to fouling release will also be discussed in terms of surface structure. Both polar and non-polar surfaces have been investigated and each type shows promise for release specific biological systems. The identification of a ''universal'' surface for release of all biological systems remains elusive.

**W30 2 Universality Classes and Unusual Thermodynamics of Unbinding Transitions of Semi-flexible Polymers Confined to a Surface** LEONARDO GOLUBOVIC, *Physics Department, West Virginia University* LIANGHUI GAO, *Max Planck Institute for Colloids and Surfaces, Potsdam, Germany* We theoretically address unbinding of semi-flexible polymers from long line-like attractive potential wells of various forms. These transition phenomena are seen in recent experiments with DNA adsorbed on microstructured supported cationic lipid membranes, and they provide a new way to stretch single DNA molecules [Hochrein, Leierseder, Golubovic, and Raedler, 2005]. For simple attractive potential wells (''rectangular wells'') the transition is of the second order. Heat capacity divergence however has a non-standard from, $C\sim 1/[|Tc - T| \log(|Tc - T|)]$, marked by a logarithmic correction related to the fact that the probability to find the polymer within the well region vanishes as $\sim 1/\log(|Tc-T|)$ at the transition point. On the other hand, for attractive potential wells having a hard wall potential added on one side, the transition becomes a non-standard hybrid between the first and second order phase transitions: the probability to find the polymer within the well approaches a non-zero value as the transition is approached and then it discontinuously drops to zero (producing a latent heat consumption). However, interestingly, in addition to the latent heat consumption, an unusual heat capacity divergence (of the form $C\sim 1/|Tc - T|^{1/2}$) also occurs as the polymer unbinding point is approached.

**15:18**
**W30 3 Polymer confinement and bacterial gliding motility** JUNHWAN JEON, ANDREY DOBRYNIN, *Polymer Program, Institute of Materials Science, Department of Physics, University of Connecticut* Cyanobacteria and myxobacteria use slime secretion for gliding motility over surfaces. In cyanobacteria the slime is extruded from the nozzle-like pores of 14-16 nm outer diameter and approximately 7nm inner diameter located near the septa that separate the cells of a filament. The pores are inclined at an angle of 30-40 degrees relative to the cell axes, and are oppositely directed on both sides of the septum. Such pore orientation provides directionality for the slime secretion as well as cell motion. To understand the mechanism of gliding motion and its relation to slime polymerization, we have performed molecular dynamics simulations of a molecular nozzle with growing inside polymer chains. These simulations show that the compression of polymer chains inside the nozzle is a driving force for its propulsion. There is a linear relationship between the average nozzle velocity and the chain polymerization rate with a proportionality coefficient dependent on the geometric characteristics of the nozzle such as its length and friction coefficient. This minimal model of the molecular engine was used to explain the gliding motion of cyanobacteria and myxobacteria over surfaces.

**W30 4 Direct Observation of Biaxial Confinement of a Semi-flexible Filament in a Channel** M.C. CHOI, *Univ. of Calif. Santa Barbara* J.H.KIM, M.W.KIM, S.Y.KWON TEAM,*O.PELLETIER, Y.LI, P.A.PINCUS, C.R.SAFINYA TEAM,†C.D.SANTANGELO TEAM,‡Z.WEN TEAM,§ We have studied the biaxial confinement of a semi-flexible filament in a channel by in situ video fluorescence microscopy*. As the channel width decreases, F-actin undergoes a transition from a 2D random regime to a 1D biaxially confined regime, leading to an increased effective persistence length. A theoretical calculation shows that the tangent-tangent correlation function in the confined regime shows a minimum, then reaches to a constant at long distances, indicating that confinement induces long-range order in a semi-flexible filament. The location of the minimum of the experimental correlation function is consistent with our theoretical calculation. **W30 5 Conformation of Lysozymes Confined to nano Particles** YUYING WEI, R. KENNETH MARCUS, DVORA PERAHIA, *Chemistry Department Clemson University* Confinement of biomolecules while retaining their activity is a key to many applications. The main challenge lies in the fact that when protein molecules interact with other particles they often lose their tertiary structure, resulting in irreversible reduction of their biological activity. The interfacial interactions of including direct chemical interactions, morphological factors, as well as adsorption under shear and hydrodynamic characteristics of flow next to the interfaces are among the factors that control the configuration. Using lysozyme as a model protein, the effects of physical absorption as a function of the topography of the confining surface from flat to curve with controlled roughness will be discussed. Atomic Force Microscopy together with small angle neutron studies correlated with measurements of retaining the degree of helicity in the system, provide a new insight into the factors that affect the conformational changes in protein upon confinement. While the chemical nature of the surface is an important parameter the topography of the surface determine many characteristics from the amount of absorption to distribution as well as the desoption of the protein.

**15:54**

**W30 6 Interaction forces and surface morphology of microtubule-associated protein tau** KENNETH ROSENBERG, *University of California, Santa Barbara* JENNIFER ROSS, *University of Pennsylvania* ERIC FEINSTEIN, STUART FEINSTEIN, JACOB ISRAELACHVILI, *University of California, Santa Barbara* The microtubule-associated protein tau exists in six isoforms due to alternative mRNA splicing and is localized in the axons of neuronal cells. These isoforms differ by the inclusion of 3 or 4 microtubule-binding imperfect repeat regions (31 aa each) at the C-terminal end of the protein or by 0, 1, or 2 N-terminal end inserts (29 aa each). Using a surface forces apparatus (SFA), we have measured the interaction forces as a function of distance between two symmetric layers of tau protein (all six isoforms) adsorbed onto mica. By comparing the interaction forces between the different isoforms, it is clear that the tau protein forms a brush-like layer on the mica surface which swells upon increasing ionic strength. Additionally, we have looked at an asymmetric system with one surface of tau opposite bare mica. In the asymmetric system of tau and an opposing mica surface, there is a $> 10^2$ increase in the magnitude of this adhesive force suggesting that the tau-mica interaction is much more adhesive than the tau-tau interaction. These data clearly show that tau adsorbed onto mica acts as a spacer and due to the cross-bridging between the mica surfaces, provides a strong adhesion, as has been observed in vitro with microtubules.

**16:06**

**W30 7 Surface Plasmon Resonance Studies of Polysaccharide Self-Assembly on Cellulose** ABDULAZIZ KAYA, ALAN R. ESKER, *Virginia Tech Department of Chemistry (0212) Blacksburg, VA 24061* WOLFGANG G. GLASSER, *Virginia Tech Department of Wood Science and Forest Products (0323) Blacksburg, VA 24061* Wood is a multiphase material consisting of cellulose crystals embedded within a non-crystalline heteroepolysaccharide (hemicellulose) and lignin rich phase. The hierarchial arrangement of these three chief components in wood produces excellent properties like resistance to fracture and toughness. Through the study of polysaccharide self-assembly onto a model cellulose surface, further insight into the interactions between hemicelluloses and cellulose can be gained. In our study, we synthesized pullulan cinnamates with different degrees of substitution of cinnamoyl groups as a model for a hemicellulose with lignin-like moieties. Surface plasmon resonance measurements probe the self-assembly behavior of pullulan and pullulan cinnamate onto a cellulose coated gold surface. Our results suggest that pullulan does not adsorb onto the model cellulose surface, whereas pullulan cinnamate does. These preliminary results signify the important role that lignin-like substituents play on hemicellulose self-assembly onto cellulose surfaces.

**16:18**

**W30 8 Assembly artificial proteins and conjugated porphyrins for biomolecular materials*** TING XU, *University of Pennsylvania* JOE STRZALKA, SHIXIN YE, SOPHIA WU, JIAYU WANG, *University of Massachusetts, Amherst* THOMAS P. RUSSELL, MICHAEL THERIEN, *University of Pennsylvania* J. KENT BLASIE, *University of Pennsylvania* It is non-trivia to incorporate both the electron donor and acceptor in a controlled manner into amphiphilic 4-helix bundle peptides. Extended pi-electronsystems have been designed and tailored, with appropriate donors, acceptors and constituents, exhibit selected light-induced electron transport and/or proton translocation over large distances. We studied the binding between a series of conjugated porphyrins and the designed amphiphilic 4-helix bundles peptides at selected locations. Incorporation of the conjugated porphyrins into the 4-helix bundle did not interfere the protein secondary structure or the 4-helix bundle formation. The amphiphilic protein/cofactor complexes have good thermal stability.The artificial protein Langmuir monolayers, both the apo- and holo-form, can be oriented vectorially at the air/water interface upon compression. GID show a glass-like inter-bundle positional ordering in the monolayer plane. We will discuss the efforts on re-designing the artificial proteins to incorporate them into these nanoporous templates made from diblock copolymers.

*DOE, NSF-MRSEC, NIH

**16:30**

**W30 9 Structural Transitions of F-actin Polyelectrolyte Bundles in the Presence of Strongly Size-mismatched Cations** ROBERT CORIDAN, *Dept. of Physics, University of Illinois, Urbana-Champaign* LORI K. SANDERS, *Dept. of Materials Science and Engineering, University of Illinois, Urbana-Champaign* WUJING XIAN, *Dept. of Materials Science and Engineering, Dept of Bioengineering, University of Illinois, Urbana-Champaign* GERARD C. L. WONG, *Dept of Materials Science and Engineering, Dept. of Physics, Dept. of Bioengineering, University of Illinois, Urbana-Champaign* In the presence of multivalent cations, the polyelectrolyte F-actin exhibits the phenomenon of 'like-charge attraction'. Simple divalent ions cause F-actin to form close-packed bundles with an interstitial 1-D density wave of ions along the length of the bundle. Lysozyme, a nonavalent (+9) cationic globular protein (45Åx25Åx25Å) causes F-actin to form similar bundles, with a larger inter-actin distance and an incommensurate 1-D column of close-packed lysozyme along the three-fold tunnel within the bundle. Using genetically engineered lysozyme with different charges, we examine the competition of these cationic agents and their effect on F-actin bundle structure.

**16:42**

**W30 10 Defect Induced Morphologies of Biopolymer Bundles** AJAY GOPINATHAN, *Department of Phyics, University of California, Santa Barbara* MARK HENLE, *Department of Chemistry and Biochemistry, University of California, Los Angeles* URI RAVIV, *Materials Research Laboratory, University of California, Santa Barbara* DANIEL NEEDLEMAN, *Department of Systems Biology, Harvard University* Bundles of stiff biopolymers, such as actin and microtubules, form important structural elements in the cell, including filopodia, microvili, cilia and contractile rings. These structures perform specific functions that rely crucially on their mechanical properties, which in turn depend on the internal organization of the bundles. Recent experiments on microtubule bundle formation in the presence of multivalent counterions [D. J. Needleman, et. al, Proc. Natl. Acad. Sci., **101** 16099 (2004)] have observed that the bundles adopt static curved configurations whose wavelengths are several orders of magnitude less than their persistence length. In this talk, we show that these severe distortions can be explained by the presence of edge dislocation and twist defects, indicating that these defects could play a significant role itin vivo.

**16:54**

**W30 11 Polyamine Induced Bundling of F-actin** GLENNA Z. SOWA, *University of California, Los Angeles* DAVID S. CANNELL, *University of California, Santa Barbara* EMIL REISLER, *University of California, Los Angeles* ANDREA J. LIU, *University of Pennsylvania* To better understand the mechanism of F-actin bundle formation, we have measured the phase boundary between isotropic F-actin and F-actin bundles as a function of polyamine concentration. F-actin was incubated with spermine or spermidine overnight, and the samples were spun at low speeds to separate bundles from unbundled F-actin. The relative amounts of actin in the pellet and supernatant were determined via gel electrophoresis. With this approach, we have mapped the phase boundary between bundled F-actin and isotropic unbundled F-actin for two F-actin/polyamine linker systems. Surprisingly, the dependence of bundle formation on actin concentration is small to non-existent. At the actin concentrations we studied, actin tends to form bundles at or above a single linker concentration. In order to understand the interactions holding F-actin together in bundles, we used NMR to determine where the polyamines were with respect to the bundled and unbundled phases of actin. Surprisingly, the spermine and spermidine did not segregate with the bundled actin indicating that they do not bind to the actin strongly even though their addition to F-actin solutions induces bundle formation.

**17:06**

**W30 12 The fluctuating-rod limit of semiflexible biopolymers** ASHOK PRASAD, YUKOH HORI, JANÉ KONDEV, *Brandeis University Physics Department* We study the mechanical properties of semiflexible polymers, such as DNA and actin, in the ''fluctuating rod'' limit. This limit is attained when the contour length of the polymer is comparable to its persistence length, or when thermal fluctuations have been smoothed out by a large applied force. In this limit, we compute the exact average end-to-end distance and shape of the polymer for boundary conditions that correspond to different single molecule stretching experiments. We consider both the case of a force applied at one end of the polymer, when the tension is uniform along the chain, and the case of an applied field, when the tension increases linearly. For the latter case, we derive the force-extension relation valid for a wide range of electric field strengths, which may be used to extract the effective charge density of actin in solution. We also show that the experimental condition of axis-clamping by a laser tweezer gives rise to a measurable effect on its force-extension properties. This calculation underscores the importance of taking the entropic effects of the boundary conditions into account in single molecule experiments. This work is supported by NSF DMR-0403997. JK is a Cottrell Scholar of Research Corporation.

**17:18**

**W30 13 Statistical and Mechanical Properties of Semiflexible Polymers in an External Field** YA LIU, BULBUL CHAKRABORTY, *Martin Fisher School of Physics, Brandeis University* Semiflexible polymers such as the double-stranded DNA, are well described by the worm-like chain model originally proposed by Kratky and Porod (Rec. Trav. Chim. 68, 1106, (1949)). Recent work has focused on understanding statistical properties such as their end-to-end distribution function (J.Chem.Phys 121, 6064 (2004), PRE 71, 031803 (2005)) and their mechanical properties in response to a stretching force or the electric field (PRE 72, 041918 (2005)). The problem becomes very complicated unless the long-chain or rod-like-chain approximations for the persistence length are made. Self-avoidance effects are always neglected even for long chain in two dimensions and for confined polymers where these effects could become important. We make use of the Bond Fluctuation Algorithm (Macromolecules 21, 2819(1988)) to study the behavior of semiflexible polymers for all persistence lengths and investigate the relationship of their shape to the persistence length, the chain length and the external field. We will compare our results for the extension of a polymer under a constant stretching with analytical results in weak and strong force limit (PRE 72, 041918 (2005)). This work has been supported by NSF-DMR 0403997.

**SESSION W31: NANOTUBES: DEVICES**
**Thursday Afternoon, 16 March 2006**

**W31 1 High On-Currents in Doped Schottky-Barrier Nanotube Transistors** YUNG-FU CHEN, MICHAEL FUHRER, *Department of Physics and Center for Superconductivity Research, University of Maryland, College Park, MD 20742-4111, USA* For many contact metals, the short channel single-walled carbon nanotube field-effect transistor (SWNT-FET) has been understood as a ballistic Schottky barrier-FET (SB-FET), in which high on- currents may be realized with thin gate dielectrics through narrowing of the SB by the gate field [1]. Recently Ohmic contacts to nanotubes have been achieved through the use of high work function metals; such devices show high on-currents and near-ideal subthreshold swings [2]. Here we demonstrate that SWNTs in ambient on $SiO_2$ are p-doped. Doped SB-SWNT- FETs exhibit high on-currents due to thinning of the SB by doping, but retain the poor subthreshold behavior of SB-FETs. Dopants in SWNT-FETs can be removed by applying up to 50 V drain bias in vacuum, corresponding to dissipated power of $>$ 1 mW. Undoped devices

exhibit much lower on-currents, and intrinsic, ambipolar behavior with symmetric SB. This work is supported by National Science Foundation under Grant No. 0102950. [1] S. Heinze, et al., Phys. Rev. Lett. 89, 106801 (2002). [2] A. Javey, et al., Nature 424, 654 (2003).

**14:42**

**W31 2 Temperature and Carrier-Density Dependence of 1/f Noise in Single-walled Carbon Nanotube Transistors** DAVID TOBIAS, MASA ISHIGAMI, C.J. LOBB, MICHAEL S. FUHRER, *Center for Superconductivity Research, Department of Physics, University of Maryland College Park, College Park, MD 20742* Field-effect transistors (FETs) have been fabricated from individual semiconducting single-walled carbon nanotubes (SWNTs) grown by chemical vapor deposition on $SiO_2$/Si substrates and contacted by metal (Cr/Au) electrodes. We have measured the low-frequency anomalous noise (1/f noise) in such SWNT-FETs as a function of temperature and charge carrier density. This material is based upon work supported by the National Science Foundation under Grant No. 0102950 and the Center for Superconductivity Research.

**14:54**

**W31 3 Optical switching of functionalized carbon nanotube transistors** JULIEN BORGHETTI, VINCENT DERYCKE, PASCALE CHENEVIER, ARIANNA FILORAMO, MARCELLO GOFFMAN, JEAN-PHILIPPE BOURGOIN, *LEM, CEA-Saclay SPEC, 91191 Gif-sur-Yvette, France* STEPHANE LENFANT, DOMINIQUE VUILLAUME, *IEMN, Avenue Poincaré, 59652 Villeneuve d'Ascq, France* Carbon Nanotube (CNT) transistors can emit or detect photons at wavelengths defined by the CNT chirality. To extend their capabilities in optoelectronics, it is important to be able to tune this wavelength independently of the CNT structure. A way to achieve such a goal is to chemically functionalize the CNT. In the present study, we demonstrate that drastic photo-induced modifications of the electrical characteristics of self-assembled CNT transistors functionalized by photoactive polymers can be achieved. We show that the polymer film acts as a wavelength dependent 'optical gate', which is much more efficient than a conventional electrostatic gate and can induce changes in conductance exceeding four orders of magnitude. The switching mechanism involves the creation and separation of photo-excited charges in the polymer, the spatial distribution and relaxation rates of which are studied taking advantage of the very high charge sensitivity of the CNT transistor.

**15:06**

**W31 4 Large Area Aligned Arrays of SWNTs for High Performance Thin Film Transistors.** COSKUN KOCABAS, *University of Illinois Urbana Champaign Department of Physics* SEONG JUN KANG, JOHN ROGERS, *University of Illinois Urbana Champaign Materials Science and Engineering* This talk will emphasize a convenient method for generating large scale, horizontally aligned arrays of pristine, single walled carbon nanotubes (SWNTs). The approach uses guided growth, by chemical vapor deposition (CVD), of SWNTs on Y-cut single crystal quartz substrates. Studies of the growth reveal important relationships between the density and alignment of these tubes, the CVD conditions and the morphology of the quartz. Electrodes and dielectrics patterned on top of these arrays yield thin film transistors (TFTs) that use the SWNTs as effective thin film semiconductors. Channel length scaling of device mobility, on current and off current provide insights into the transport characteristics. Combining the aligned arrays with random networks, which are grown simultaneously through the use of patterned catalysts, yields 'all-tube' based devices. The ability to build high performance devices of this type suggests significant promise for large scale aligned arrays of SWNT in electronics, sensors and other applications.

**15:18**

**W31 5 Field-Effect Transistors Assembled From Functionalized Carbon Nanotubes** CHRISTIAN KLINKE, JAMES HANNON, ALI AFZALI, PHAEDON AVOURIS, *IBM Research Division* We have fabricated field effect transistors from carbon nanotubes using a novel selective placement scheme. We use carbon nanotubes that are covalently bound to molecules containing hydroxamic acid functionality. The functionalized nanotubes bind strongly to basic metal oxide surfaces, but not to silicon dioxide. Upon annealing, the functionalization is removed, restoring the electronic properties of the nanotubes. The devices we have fabricated show high ON current (about 1 uA) and an ON/OFF ratio of more than 1e6.

**15:30**

**W31 6 Template-directed Self-assembly of Carbon Nanotube Field-Effect Transistors** STEPHEN MCGILL, SALEEM RAO, PRADEEP MANANDHAR, *Physics & MARTECH, Florida State University, Tallahassee, FL* SEUNGHUN HONG, *Physics & Nano-Systems Institute, Seoul National University, Seoul, South Korea* PENG XIONG, *Physics & MARTECH, Florida State University, Tallahassee, FL* We pattern self-assembled monolayers (SAMs) of organic molecules to control the interactions between carbon nanotubes and inorganic surfaces. Deposition of the SAMs forms a template that directs the placement and alignment of nanotubes on lithographically defined electrodes to create field-effect transistors (FETs). Our assembly process is highly scalable and we demonstrate parallel fabrication of five FETs on a single substrate. These FETs exhibit large ''on'' currents of $\sim 1\mu$A with ''on/off'' ratios as high as $10^6$. Furthermore, our devices exhibit novel functionality by operating hysteresis-free without passivation of the nanotube or electrode surfaces. These features may lead to enhanced performance for delicate sensing applications utilizing these devices. We discuss the electrical characteristics of these FETs and contrast them with other state-of-the-art devices and assembly strategies. This work has been supported by NSF NIRT grant ECS-0210332.

**15:42**

**W31 7 Gas Sensitivity of Carbon Nanotube Devices*** J. H. CHEN, MASA ISHIGAMI, M. S. FUHRER, E. D. WILLIAMS, *Department of Physics, University of Maryland, College Park, Maryland 20742* We have measured the gas sensitivity of field effect transistors made from individual single-walled carbon nanotubes in an ultra high vacuum environment. We exposed nanotube devices to varying partial pressures of oxygen and argon. We will compare the results to existing theoretical calculations for oxygen sensitivity of carbon nanotubes and discuss the ultimate gas sensitivity for these devices.

*Materials Research Science and Engineering Center at University of Maryland, College Park and Director of Central Intelligence Postdoctoral Fellowship Program

**15:54**

**W31 8 Single Walled Carbon Nanotube-based Aqueous Sensors** SARAH LASTELLA, ARAVIND VIJAYARAGHAVAN, SWASTIK KAR, PULICKEL M. AJAYAN, CHANG Y. RYU, *Rensselaer Polytechnic Institute* Single walled carbon nanotube (SWNT) field effect transistors (FETs) have been utilized as chemical specific sensors by incorporating a sensitizing agent into the nanotube sidewalls. Here we report the non-covalent sidewall functionalization of SWNT FETs through the adsorption of macro-organic molecules. The modified SWNT FETs recognize changes in pH and oxidation states through a change in current flow across the devices. These uniformly dispersed nanotubes, grown directly on the FET substrate prior to electrode deposition, enhance the available tube surface area for molecular adsorption, and thus enhance the signal sensitivity.

**16:06**

**W31 9 Atomic Nanotube Welders.** MORINOBU ENDO, HIROYUKI MURAMATSU, TAKUYA HAYASHI, YOONG-AHM KIM, *Shinshu University, Japan* GREGORY VAN LIER, JEAN-CHRISTOPHE CHARLIER, *Université Catholique de Louvain, Belgium* HUMBERTO TERRONES, *IPICYT, Mexico* MILDRED S. DRESSELHAUS, *MIT, USA* MAURICIO TERRONES, *IPICYT, Mexico* We demonstrate that the incorporation of boron between double walled carbon nanotubes (DWNTs) during thermal annealing results in covalent nanotube ''Y'' junctions, DWNT coalescence and the formation of flattened multi-walled carbon nanotubes (MWNTs). The processes occur via the merging of adjacent tubes which is triggered by B interstitial atoms. In order to demonstrate the unique welder properties of B in the process, we have carried out itAM1 molecular dynamics simulations at high temperatures and itab-initio calculations. We observe that B atom interstitials between DWNTs are responsible for the rapid establishment of covalent connections between neighboring tubes (polymerization). Once B is in the lattice, tube faceting (polygonization) starts to occur, and the electronic properties are expected to change dramatically.

**16:18**

**W31 10 Quantized conductance observed in reversible atomic contacts fabricated by template electroplating using an on-membrane anode*** ZUXIN YE, WENHAO WU, *Texas A&M University* We report a new template electroplating method for fabricating reversible atomic contacts between a long nanowire and a macroscopic contact pad. In comparison to a typical template method using a standing-alone anode, we directly evaporate the anode on one of the porous membrane surfaces. Single nanowires, upon emerging from the pores, make reversible atomic contacts with the on-membrane anode via a self-terminating mechanism. Quantized conductance steps have been observed in a controlled fashion during deposition and dissolution. This method can potentially be applied for the controlled fabrication and integration of nanowires, point contacts, and nanosized interconnects in template-based nanofabrication.

*Supported by NSF Grant No. DMR-0551813.

**16:30**

**W31 11 Structural and Transport Properties of Dielectrophoretically Assembled Interconnects*** BIROL OZTURK, *Department of Physics, Oklahoma State University, Stillwater, OK 74078* ISHAN TALUKDAR, *Department of Physics, Oklahoma State University, Stillwater, OK 74078* PREM THAPA, *Department of Physics, Oklahoma State University, Stillwater, OK 74078* CHARLES BLACKLEDGE, *Department of Physics, Oklahoma State University, Stillwater, OK 74078* DANIEL GRISCHKOWSKY, *School of Electrical and Computer Engineering, Oklahoma State University, Stillwater, OK 74078* BRET FLANDERS, *Department of Physics, Oklahoma State University, Stillwater, OK 74078* Dielectrophoresis was used to form $\sim$ 140nm diameter interconnects composed of gold nanorods between targeted points in a circuit. Cleanroom-based lithographic procedures were used to produce identical arrays of electrodes, improving the sample-to-sample reproducibility of the interconnect-conductances to $\sim$ 10%. Transmission electron microscopy and low temperature conductivity analyses indicate that the Coulomb Blockade associated with the individual nanorods is the primary conductance-limiting feature. To further improve the reproducibility of the structural and transport properties of dielectrophoretic interconnects, we investigate submicron wire formation in aqueous solutions of indium acetate. Our preliminary data show that single crystal wires with submicron diameters may be fabricated from such solutions.

*Supported by the National Science Foundation.

**16:42**

**W31 12 DNA-Functionalized Carbon Nanotubes for Chemical Sensing*** M. CHEN, C. STAII, S. KHAMIS, A.T. JOHNSON, J.E. FISCHER, *U. of Pennsylvania* A GELPERIN, *Monell Senses Center* We demonstrate nanoscale sensors based on single-stranded DNA (ss-DNA) as the chemical recognition site and single-walled carbon nanotube field effect transistors (swCN-FETs) as the electronic readout component. SwCN-FETs functionalized with ss-DNA respond to gaseous analytes that do not cause a detectable current change in bare swCN-FETs. The response differs in sign and magnitude depending on the type of analyte and the DNA base sequence. The sensors maintain a constant response through at least 50 air-analyte cycles, and have response and recovery times on the scale of seconds. Furthermore, ss-DNA is found to chemically gate swCN-FET. The analytes used are found to interact with both the nanotube and the substrate. This sensor is promising for electronic olfaction systems consist of coupled sensor arrays and an odor recognition algorithm. Applications range from homeland security to disease diagnosis.

**W31 13 Electrical transport behavior of all - carbon nanotube - based three terminal junctions*** YUN-HI LEE, JE-MIN YOO, JONG-HEE LEE, *Department of Physics, Korea University, Seoul, Korea* NDPL TEAM, In this study, we propose a process for suspended itin situ lateral growth of all - carbon nanotube(CNT) based junction and report on the high current capacity of the CNT junction, especially, its current (I) response characteristics with and after UV. Furthermore, the analogy between current suppression and reversible switching of capacitor was studied by capacitance(C) spectroscopy. The designed diluted magnetic impurity doped oxide film was adopted as catalyst for the fabrication of all - CNT-based junction. 40 suspended junctions was tested and normally, one junction produced current of a few uA/1um at room temperature. The suspended CNT with the same electrode materials is expected to operate with ambipolarity. The nearly same low barrier height for the hole and electron conduc-

tion was estimated via I-T(K) measurements. Also, the surface of CNT was easily cleaned by low intensity UV treatment, resulting in a highly conductive channel that showed high current carrying behavior. Our result can be applied to develop a practical, accessible system for forming reproducible nanoelectronic junctions as well as to accelerate the realization of all low dimensional molecular devices.

**W31 14 Energy Conversion Efficiency in Nanotube Optoelectronics** FRANÇOIS LÉONARD, *Sandia National Laboratories* DEREK STEWART, *Cornell Nanoscale Facility* We present theoretical performance estimates of nanotube optoelectronic devices under bias. Current-voltage characteristics of illuminated nanotube *p-n* junctions are calculated using a self-consistent non-equilibrium Green's function approach. Energy conversion rates in the tens of percent range are predicted for incident photon energies near the band gap energy. In addition, the energy conversion rate increases as the diameter of the nanotube is reduced, even though the quantum efficiency shows little dependence on nanotube radius. These results indicate that the quantum efficiency is not a limiting factor for use of nanotubes in optoelectronics.

**17:18**

**W31 15 A Novel Nanotube-on-Insulator (NOI) Approach toward Single-Walled Carbon Nanotube Devices** CHONGWU ZHOU, XIAOLEI LIU, DAIHUA ZHANG, *University of Southern California* We present a novel nanotube-on-insulator (NOI) approach to produce high-yield nanotube devices based on aligned single-walled carbon nanotubes. First, we managed to grow aligned nanotube arrays with controlled density on crystalline, insulating sapphire substrates, which bear analogy to industry-adopted silicon-on-insulator substrates. Based on the nanotube arrays, we demonstrated registration-free fabrication of both top-gated and polymer-electrolyte-gated field-effect transistors with minimized parasitic capacitance. In addition, we have successfully developed a way to transfer these aligned nanotube arrays to flexible substrates. Our approach has great potential for high-density, large-scale integrated systems based on carbon nanotubes for both micro- and flexible electronics.

## SESSION W32: GLASSY AND AMORPHOUS SYSTEMS

**Thursday Afternoon, 16 March 2006**
**329, Baltimore Convention Center at 14:30**
**Michael Mehl, Naval Research Laboratory, presiding**

**14:30**

**W32 1 First-principles investigation of pressure-induced amorphization in zeolites** INMACULADA PERAL, JORGE INIGUEZ,* *ICMAB–CSIC* Crystalline zeolites can be transformed into amorphous structures by application of pressure, without ever forming a liquid. Upon release of the applied pressure, some zeolites transform back to their crystalline structure while others do not. Thus, zeolites are very interesting from the point of view of the theories trying to explain *reversible* amorphization by pressure [Cohen et al., JNCS 307-310, 602 (2002)]. On the other hand, recent studies of the amorphization process in zeolites have led to the identification of co-existing phases of the same composition but markedly different densities and degrees of disorder [Greaves et al., Nat. Mats. 2, 622 (2003)]. Further, it has been argued that upon application of pressure (or, equivalently, temperature) zeolites render a low-entropy, low-density, amorphous phase that could constitute a new type of glass, with physical properties that might differ considerably from those of *typical* glasses obtained by slow cooling from the melt. In this talk we will report a first-principles investigation of the structural changes induced by pressure in zeolites. More precisely, we will show results for three zeolites with the so-called LTA structure (Na-ZK4, Na-A, and an idealized $SiO_2$ system with the ZK4 structure). We will discuss the implications regarding the various amorphous phases experimentally found and the reversibility of the amorphization.

**W32 2 Glass transition and viscosity of simple glasses and liquids*** TAKESHI EGAMI, *University of Tennessee* S. JOSEPH POON, *University of Virginia* VALENTIN LEVASHOV, *University of Tennessee* RACHEL AGA, JAMES MORRIS, *Oak Ridge National Laboratory* The theoretical understanding of liquids and glasses at an atomistic level lags well behind that of crystalline materials, even though they are important in many fields including biology and the medical sciences. We present a simple microscopic model for the glass transition based on topological fluctuations in the bonding network. The model makes predictions for important parameters of the glassy state, such as the glass transition temperature, $T_g$, and the liquid fragility coefficient, $m$, based on microscopic variables. Excellent agreement with a number of experimental observations from metallic glasses is demonstrated. A key to this success is to focus on the dependence on Poisson's ratio, following the work of Novikov and Sokolov,[1] that characterizes the interaction between local density and shear fluctuations. To our knowledge, this is the first model to predict $T_g$ and $m$ quantitatively from microscopic variables. It presents a simple conceptual framework that should provide the basis for a more general microscopic understanding of liquids and glasses, including molecular systems. 1. V. N. Novikov and A. P. Sokolov, Nature, **431**, 961-963 (2004).

**14:54**

**W32 3 Temperature induced density anomaly in Te rich liquid Germanium Tellurides: p versus sp3 bonding?*** CHRISTOPHE BICHARA, *CNRS -CRMCN University Aix-Marseille, France* MARK JOHNSON, *Institut Laue Langevin, Grenoble, France* JEAN-YVES RATY, *University of Liege, Belgium* The density anomaly of liquid $Ge_{0.15}Te_{0.85}$ measured between 633K and 733K is investigated with ab initio Molecular Dynamics calculations at four temperatures and at the corresponding experimental densities. For box sizes ranging from 56 to 112 atoms, an 8 k-points sampling of the Brillouin zone is necessary to obtain reliable results. Contrary to other Ge chalcogenides, no sp3 hybridization of the Ge bonding is observed. As a consequence the negative thermal expansion of the liquid is not related to a tetra-

hedral bonding as in the case of water or silica. We show that it results from the symmetry recovery of the local environment of Ge atoms that is distorted at low temperature by a Peierls-like mechanism acting in the liquid state in the same way as in the parent solid phases.

**W32 4 Giant photocontraction effects in obliquely-deposited chalcogenide glass thin-films*** M. JIN, P. BOOLCHAND, *University of Cincinnati* T. RAJAGOPALAN, K.L. CHOPRA, *Indian Institute of Technology, New Delhi* $Ge_xSe_{1-x}$ thin-films at several obliqueness angles $\alpha$ (= 0, 20, 45, 60, 80) and compositions x ( = 0.15, 0.20, 0.23, 0.25 and 0.33) were vapor-deposited, and examined in Raman scattering and SEM measurements both in the pristine and illuminated state. The films, placed in an inert ambient, were exposed to Hg lamp radiation, and photo-contraction of the films established using a profilometer. Raman scattering of the pristine and exposed films were studied as a function of depth using a confocal microscope attachment. Our results show (i) Raman scattering of the normally deposited ($\alpha$ = 0) films in the pristine state are similar to those of corresponding bulk glasses, (ii) obliquely deposited films at x = 1/3 reveal Raman lineshapes that change qualitatively with $\alpha$, suggestive of nanoscale phase separation of the films, while those at x = 0.23 show Raman lineshapes that are largely independent of $\alpha$, (iii) the photocontraction effect maximizes in the $0.20 < x < 0.25$ range, confirming the earlier finding (ref1) (iv) light illumination partially undoes effects associated with nanoscale phase separation. Possible interpretation of these results in relation to origin of photocontraction effects will be presented. *Supported by NSF grant DMR 04-56472. 1.Bhanwar Singh, S. Rajagopalan, P. K. Bhat, D. K. **W32 5 Non-perturbative Renormalization Group Study of A Kinetically Constrained Model for Glasses** HAI QIAN, *The James Franck Institute and Department of Physics, The University of Chicago* We study a dynamic field theory, which is based on the dynamic heterogeneity, with the non-perturbative renormalization group (NRG) method. Dynamic heterogeneity has been observed both experimentally, and in numerical simulations. It may play an important role in the physics of glass transition. Dynamic heterogeneity means that the slow dynamics of glass formers is dominated by the spatial fluctuations. And the length scales of dynamically correlated regions increase when the system approaches the glass transition, together with the increase of time scale. This is similar to the conventional dynamic critical phenomena. People have derived a dynamical field theory for a kinetically constrained model based on the Fredrickson-Anderson (FA) model, which puts the dynamic heterogeneity at its core. Here we study this field theory with the NRG method. The NRG method is not restricted to small parameters, and thus can be applied to more general cases. The critical exponents are calculated, and the phase structure is given. Especially the 1D spatial dimension case, which is difficult for the usual perturbative calculation, is also studied. Other possible models are also mentioned.

**W32 6 Self-organization of glass networks in a model with equilibration*** MARC-ANDRÉ BRIÉRE, M.V. CHUBYNSKY, NORMAND MOUSSEAU, *Département de physique and RQMP, Université de Montréal* Recent experimental results suggest the existence of an intermediate phase in covalent glasses attributed to a self-organization of the glass network minimizing its internal stress. While a number of models have been proposed recently to explain this phenomenon, a full understanding of the network self-organization and the intermediate phase is lacking. We modify a previously studied model,[*] in which a network is grown in a way that keeps it stressless, by allowing continuous equilibration as the mean coordination is increased while still avoiding stress. In our model, an unusual intermediate phase appears, in which both rigid and floppy networks have a chance to occur, a result similar to that obtained by Barré *et al.* for less realistic Bethe lattices. We discuss various structural properties of the resulting self-organized networks, as well as some results for the entropy cost of self-organization. [*] M.F. Thorpe, D.J. Jacobs, M.V. **W32 7 The Impact of Liquid Structure and Long Range Diffusion on Glass Formation and Nanoscale Devitrification*** K. F. KELTON, *Department of Physics, Washington University, St. Louis, MO 63130* Recently, synchrotron X-ray diffraction measurements of electrostatically levitated samples revealed a growing icosahedral order in many undercooled metallic liquids and alloys. In a TiZrNi liquid, this icosahedral order catalyzed the nucleation of a metastable icosahedral phase, instead of the stable C14 tetrahedral Laves phase, confirming a half-century-old hypothesis made by Frank that connects the crystal nucleation barrier with the local structure of the liquid. This is one example of a growing number of cases of multiple order parameter coupling in nucleation, which are not readily described within the framework of the commonly used classical theory of nucleation. The implications for glass formation, nanoscale devitrification and the role of microalloying of such coupled nucleation processes and of a new coupled flux kinetic model for nucleation are discussed.

**W32 8 Thermally Activated Processes in Polymer Glasses** VIVEK PARIHAR, DAVID DROSDOFF, ALLAN WIDOM, *Northeastern University* YOGENDRA SRIVASTAVA, *Northeastern University & University of Perugia, INFN* A derivation is given for the Vogel-Fulcher-Tammann thermal activation law for the glassy state of a bulk polymer. Our microscopic considerations involve the entropy of closed polymer molecular chains (i.e. polymer closed strings). For thin film polymer glasses, one obtains open polymer strings in that the boundary surfaces serve as possible string endpoint locations. The Vogel-Fulcher-Tammann thermal activation law thereby holds true for bulk polymer glass but does not hold true in the ultra thin film limit of polymer glass.

**W32 9 Transient nucleation in a Zr-Ti-Cu-Ni-Al metallic glass*** Y. T. SHEN, K. F. KELTON, *Dept. of physics, Washington University, St. Louis* Upon annealing Zr-Ti-Cu-Ni-Al bulk metallic glasses (BMG) crystallize to a nano-quasicrystal/amorphous composite. To probe the nucleation processes that underlie this microstructure formation we have determined the nucleation rate as a function of temperature, employing the two-step annealing method commonly used in silicate glasses. Samples were first annealed at temperatures where the nucleation rates were high, but the growth rates were low to produce a population of nuclei. These were subsequently grown to an observable size for transmission electron microscopy study by annealing at a higher temperature where the nucleation rate is small. We present the first quantitative time-dependent nucleation data obtained for a metallic glass by this method. The data are analyzed in terms of the classical theory of nucleation and an extended kinetic model that includes the coupling between the interfacial attachment and long-range diffusion fluxes.

**W32 10 The role of Ti in the formation of Zr-Ti-Cu-Ni-Al glasses*** T.H. KIM, A.K. GANGOPADHYAY, L.Q. XING, G.W. LEE, Y.T. SHEN, K. F. KELTON, *Dept. of Physics, Washington U., St. Louis, MO* A.I. GOLDMAN, *Ames Laboratory USDOE and Iowa State U., Ames, IA* R.W. HYERS, *U. Mass, Amherst, MA* J.R. ROGERS, *NASA MSFC, Huntsville, AL* It has been widely reported that glass formation improves in $Zr_{62}Cu_{20}Ni_8Al_{10}$alloys when small amounts of Ti are substituted for Zr. Glasses containing greater than 3 at.% Ti crystallize to a metastable icosahedral phase, suggesting that Ti enhances icosahedral short range order (ISRO) in the liquid/glass, making crystallization more difficult during cooling. Based on itin-situ high-energy synchrotron diffraction studies of electrostatically levitated (ESL) supercooled liquids and rapidly quenched amorphous alloys, we demonstrate ISRO in all cases irrespective of the Ti concentration. Further, our ESL solidification studies show that Ti inhibits surface crystallization, but does not improve glass formation.

**W32 11 High-Energy X-ray Diffraction Study of Liquid Structure of Zr-based Binary Alloys** AKITOSHI MIZUNO, SEIICHI MATSUMURA, MASAHITO WATANABE, *Gakushuin University* SHINJI KOHARA, MASAKI TAKATA, *Japan Synchrotron Radiation Research Institute* High-energy (E = 113 keV) synchrotron x-ray diffraction experiments were performed for metallic glass-forming Zr-Cu alloys in the liquid state at high temperatures. Accurate structure information of highly reactive melts has been obtained by applying conical nozzle levitation technique as a containerless method. The total structure factor extracted for the liquid $Zr_{50}Cu_{50}$ alloy near its melting temperature shows a particular shoulder at the high-$Q$ side on the second peak as well as the liquid $Zr_{70}Cu_{30}$ alloy. This feature of structure factor is similar to those of structure factors observed in deeply undercooled metallic liquids or metallic glasses, in which local icosahedral short range ordering was found to exist. With the use of reverse Monte Carlo simulation analysis, it was demonstrated that short-range ordered clusters exist even in the equilibrium liquid state of $Zr_{70}Cu_{30}$ alloy.

**W32 12 Elasticity and conductivity thresholds in solid electrolyte glasses*** D. NOVITA, P. BOOLCHAND, *University of Cincinnati* M. MALKI, F. FAYON, *CNRS-Orleans* M. MICOULAUT, *University of Paris VI* The solid electrolyte glass, AgI, possesses a low mean coordination number [1], and when alloyed in the base oxide glass, $AgPO_3$, steadily lowers the connectivity of the alloyed glass, (AgI)x(AgPO3)1-x, as reflected in reduction of glass transition temperatures $T_g(x)$. Non-reversing enthalpy associated with $T_g$s vanish in the $0.10 < x < 0.35$ range, the reversibility window, which we identify with the Intermediate elastic phase [2]. Glasses at $x < 0.10$ belong to the Stressed-Rigid while those at $x > 0.35$ to the Floppy elastic phase. Electrical conductivity, $\sigma(x)$, reveal a mild increase near $x = 0.10$ as glasses become unstressed, and a pronounced increase near $x = 0.35$, when glasses become floppy. The correlation between $\sigma(x)$ and the elastic phases opens a new paradigm in understanding electrical transport in glasses. Chains of $PO_4$ tetrahedra ( $Q^2$) present in the pristine oxide are steadily cut and eventually transformed into rings as networks become less connected with increasing x, as revealed by Raman and $P^{31}$ NMR measurements. **W32 13 Chemical alloying induced collapse of reversibility windows in ternary As-S-I glasses*** FEI WANG, *Department of EE, California Polytechnic State University* P. BOOLCHAND, *Department of ECECS, University of Cincinnati* Thermally reversing windows represent glass compositions across which glass transitions are thermally reversing in character. These windows have been observed in several chalcogenide glasses, and are identified[1] with self-organized phases of glassy networks. Upon alloying halogen (iodine) in base chalcogenide glasses (Ge-Se, Ge-S), the reversibility windows collapse[2] about the mean-field rigidity transition. We attempt to understand this behavior better. We have now synthesized ternary glass compositions of the type, $(AsI_3)_x(As_{0.30}S_{0.70})_{1-x}$ and $(AsI_3)_y\ (As_2S_3)_{1-y}$ over wide composition ranges of x and y, and have examined them systematically in Raman scattering and MDSC experiments. Along with earlier results[3] on binary $As_zS_{1-z}$ glasses, the present results permit mapping the reversibility window over the glass forming range of the present As-S-I ternary. The results show the window region to be of nearly triangular shape, with a base extending in the $0.20 < z < 0.27$ range and a vertex located near $y = 0.28$. A possible interpretation of the results will be presented. * Supported by NSF grant DMR-04 -56472 1. P.Boolchand et al.Phil. Mag 85,3823

**W32 14 Glass structure and electrical conductivity in $(As_2S_{3\ 1-x}\ (Ag_2S)_x$*** C. HOLBROOK, P. CHEN, D. NOVITA, P. BOOLCHAND, *University of Cincinnati* We have synthesized titled glasses in the $0 < x < 0.16$ range, and have examined them in modulated DSC experiments. The starting materials, $As_2S_3$ and $Ag_2S$ lumps, were reacted in evacuated fused quartz tubings, and glasses synthesized by water-quench of homogenized melts. Thermal measurements used a TA instruments model 2920 operated at 3[r]C/min scan rate and 1[r]C/100s modulation rate. Preliminary results reveal a single glass transition in the $0 < x < 0.05$ range, which steadily decrease from a value of 210[r]C at $x = 0$ to 182[r]C near $x = 0.05$. In contrast, bimodal glass transitions are observed at $x > 0.09$, with one $T_g(1)$ near 167[r]C and the second, $T_g(2)$ near 186[r]C, and with the endotherm associated with $T_g(1)$ steadily increasing with x. Non-reversing enthalpies associated with $T_g$s are found to steadily decrease in the $0 < x < 0.09$ range, to nearly vanish in the $0.10 < x < 0.12$ range and to increase thereafter ( $x > 0.12$).These findings suggest that glasses at low x ( $< 0.09$) are Stressed- rigid, those at $x > 0.12$ Floppy while those in between in the Intermediate phase[1]. The present results correlate well with earlier[2] electrical conductivity results in suggesting the possibility of an elastic origin to the conductivity thresholds in solid electrolyte glasses. 1. **W32 15 New glasses in the alumina-calcia-monazite ($LaPO_4$) system: structural evidence from NMR, Raman scattering and thermal properties*** ROBERT MARZKE, *Physics and Astronomy, Arizona State University, Tempe, AZ 85287-1504* SUSAN BOUCHER, *Chemistry and Biochemistry, Arizona State University, Tempe, AZ 85287-1604* JEREMY PIWOWARCZYK, *Physics and Astronomy, Arizona State University, Tempe, AZ 85287-1504* GEORGE WOLF, *Chemistry and Biochemistry, Arizona State University, Tempe, AZ 85287-1604* A new group of glasses has been synthesized from the well-known compounds $CaAl_2O_4$ and $(CaO)_{12}(Al_2O_3)_7$, melted together with monazite ($LaPO_4$) in compositions containing 2 to > 75% of the latter. Raman and $^{31}P$ NMR spectra in the solid state show that $PO_4$ groups do not share bridging oxygens, i.e. that the materials are orthophosphates. Thermal properties and $^{27}Al$ NMR in both liquid and solid states indicate the presence of a strong aluminate network, based upon $AlO_4$ tetrahedra sharing corners. P/Al TRAPDOR NMR measurements show that P and Al are in close proximity in the glasses, most likely sharing P-O-Al linkages. However, clear and unambiguous signatures of the aluminate network are still sought. Models for the structures of these glasses, drawn from experiment, will be presented.

**W33 1 Designing elastic sheets to self-assemble in a viscous environment** SILAS ALBEN, MICHAEL BRENNER, *Harvard University* A recent work by Boncheva et al. (Proc. Nat. Acad. Sci. 2005 102: 3924-3929) has raised some basic issues about designable self-assembly within the context of planar elastic sheets which fold into 3D structures under magnetic forces. While being agitated in water, millimeter-scale structures were shown to fold with varying success depending on the locations of magnets on the sheets. Our work considers how to design such structures, an understanding of which will be necessary when moving this process to the micron scale. Among the important parameters are the geometry of the flat sheet, the configurations of the magnets, and the ratios of magnetic to elastic forces. We consider this problem using a numerical model of an elastic sheet, and restrict to the simpler case of electrostatic forces in a quasi-static limit. We identify a simple algorithm for choosing configurations of electrostatic charges, and select ratios of charge strength to elastic energy using physical arguments. We then demonstrate our algorithm on dynamical foldings of a sphere and more general geometries, in the overdamped viscous regime. We also give an asymptotic formula for the elastic energy in the thin-plate limit.

**W33 2 Dynamic self-assembly of magnetic particles on the fluid interface: surface wave assisted effective magnetic exchange** ALEXEY SNEZHKO, IGOR ARANSON, WAI-KWONG KWOK, *Materials Science Division, Argonne National Laboratory, 9700 South Cass Avenue, Argonne, IL 60439* Novel dynamic self-assembled multi-segment magnetic structures (''snakes'') induced by a vertical alternating magnetic field in an ensemble of magnetic particles suspended on a liquid/air interface are reported. We demonstrate that these structures are directly related to surface waves in the liquid generated by the collective response of magnetic microparticles to the alternating magnetic field. The segments of magnetic ''snake'' exhibit long-range antiferromagnetic ordering mediated by the surface waves, while each segment is composed of ferromagnetically aligned chains of microparticles. To describe observed magnetic behavior of the generated structures we propose a simple phenomenological model where the effect of surface waves is replaced by an effective exchange interaction. In the framework of the proposed model the effective exchange constants corresponding to different regimes of magnetic driving were extracted from the experimental data.

**W33 3 Demonstration of shape selectivity in depletion-induced colloidal aggregation** STEPHANE BADAIRE, JOSEPH W. WOODY, CECILE COTTIN-BIZONNE, ABRAHAM D. STROOCK, *Dept of Chemical and Biomolecular Engineering - Cornell University* We have developed a set of monodisperse, non-spherical colloids using photolithography in order to elucidate fundamental questions related to the role of shape in defining colloidal phase behaviour and, eventually, to build new micro-

structured materials. Our goal is to use depletion and DLVO forces to induce specific and directional interactions during the aggregation process of these non-spherical colloids. We will first describe the development and basic characterization of these particles, including index of refraction, zeta potential, polydispersity, and surface roughness. We will then present an initial state diagram of depletion-induced structure, and provide mechanistic insight into the role of specific characteristics of the particles in defining this behaviour. We will finally discuss theoretical calculations of the expected interactions and the possibility of generalizing the results to other colloidal systems.

**W33 4 Pattern formation and liquid crystallinity in evaporating drops of gold nanorods.** KYOUNGWEON PARK, VIVEK SHARMA, *School of Polymer, Textile and Fiber Engineering* MOHAN SRINIVASARAO, *School of Polymer, Textile and Fiber Engineering and School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA* The drying drops of colloidal rods on glass provide a coffee ring type stain accompanied by formation of highly birefringent deposit, suggesting lyotropic liquid crystalline phase forms prior to deposit formation. Further, Liesegang ring like patterns which have concentric deposits, appear on drying, only under specific conditions, and in optical microscope show similar birefringent bands. Similar experiments done on carbon coated copper TEM grids and observed under TEM, show smectic and nematic-like phases as well as create vortex-like assembly of nanorods reminiscent of defect structures in liquid crystals, and are likewise explained in terms of lowest energy configuration of twist configuration. In the present, work we compliment the rich experimental observations, by proposing mechanisms that explain formation of concentric rings, as well as other complex patterns using both the existing framework based on coffee ring stain models and on basis the observed liquid crystalline phase behavior.

**15:18**

**W33 5 Molecular Detection with Self-Assembled Gold Nanoparticle Wires** J.B. HUTCHISON, *George Washington University* J.A. HOFFMANN, *George Washington University* J.W. SUN, *George Washington University* M.E. REEVES, *George Washington University* Recently, we have reported the creation of gold nanowires by evaporation-driven vertical colloidal deposition (VCD) of gold nanoparticles. Subsequently, we have noted systematic changes in conductivity associated with post-deposition annealing. Here we describe the change in room temperature conductivity of gold nanoparticle wires after exposure to thiol-derivatized molecules. A self-assembled gold nanoparticle wire is immersed into a solution of octadecanethiol (ODT) dissolved in ethanol. An ODT molecule comprises a sulfur atom and a short hydrocarbon chain. The sulfur atoms form metallic bonds with the conduction electrons on the surface of the gold nanoparticles, and the high surface to volume ratio of the wire allows us to see a marked jump in resistance. We have seen roughly a 10 percent increase in the resistance of previously annealed wires when immersed in 2 millimolar ODT solution. Further experiments include measurement of resistance as a function of thiol-concentration and as a function of wire preparation prior to immersion.

**15:30**

**W33 6 Orientational Order of Molecular Assemblies on Inorganic Crystals*** JAEHUN CHUN, *Department of Chemical Engineering, Princeton University* DUDLEY SAVILLE, *Department of Chemical Engineering, Princeton University* JE-LUEN LI, *Department of Chemistry, Princeton University* HANNES SCHNIEPP, *Department of Chemical Engineering, Princeton University* ROBERTO CAR, *Department of Chemistry, Princeton University* ILHAN AKSAY, *Department of Chemical Engineering, Princeton University* Surfactant micelles form oriented arrays on crystalline substrates such as HOPG (Highly Ordered Pyrolytic Graphite) although registration is unexpected since the template unit cell is small compared to the size of a rod-like micelle. In addition, with atomic force microscopy, we show that orientational ordering is a dynamic, multi-molecule process. Interaction energy calculations based on molecular simulations reveal that orientational energy differences on a molecular scale are too small to explain matters. However, treating the cooperative processes as a balance between van der Waals torque on a large, rod-like micellar assembly and Brownian motion shows that orientation is favored. Our study provides a physical insight on regulation of self-assembly structures at small length scale.

**W33 7 Vesicle-Templated Supramolecular Assembly of Alginate Nanogels** JENNIFER HONG, *National Institutes of Standards and Technology NIST/University of Maryland College Park* WYATT VREELAND, *NIST, Analytical Chemistry Division CSTL* SRINIVASA RAGHAVAN, *University of Maryland College Park. Department of Chemical & Biomolecular Engineering* LAURIE LOCASCIO, *NIST, Analytical Chemistry Division CSTL* MICHAEL GAITAN, *NIST, Semiconductor Electronics Division EEEL* In this work, large uni- and multilamellar dipalmitoyl phosphatidylcholine (DPPC) liposomes (800-900 nm in diameter) were used as templates for the formation of alginate gels. DPPC liposomes encapsulating sodium alginate were prepared in a 15 mM NaCl buffer solution by the solvent injection method, followed by several freeze/thaw cycles to achieve higher encapsulation efficiency and larger vesicle size. Purified liposomes were placed in a 10 mM CaCl2 buffer solution and permeabilized by heating and cooling over the phase transition temperature (Tm) of DPPC. The increased membrane permeability at the Tm allowed calcium ions from the surrounding buffer solution to traverse the membrane to the interior region and subsequently crosslink the encapsulated alginate. Removal of the lipid by detergent resulted in nanogels that were similar in size (800-900 nm in diameter) to the template liposome, as characterized by multi-angle and dynamic light scattering techniques. In the future these nanogels may be useful for single-molecule encapsulation or controlled release applications.

**15:54**

**W33 8 Self-Assembly of Two Dimensional Hard Rod Fluids in the Presence of Surface Barriers** DEREK A. TRIPLETT, KRISTEN A. FICHTHORN, *The Pennsylvania State University* Hard rods are interesting building blocks for assembly as they organize themselves into different phases depending on their aspect ratio and concentration. Much work has been done to develop an understanding of the various phases exhibited by bulk, hard-rod flu-

ids in two and three dimensions. For applications in nanoelectronics, it is desirable to be able to assemble nanowires into various structures conducive to nanocircuitry. In this work, we use Monte Carlo simulations to examine the phase behavior of two different systems involving two-dimensional, colloidal nanowires. In the first study, we probe the influence of regularly spaced surface barriers on the ordering of two-dimensional hard rods. By varying the spacing between the barriers and their size relative to the rods, we demonstrate that a number of interesting phases can be achieved, indicating that surface barriers can effectively tune the alignment of the rods. In a second study, we probe the hard-sphere templated assembly of colloidal nanowires. We demonstrate that a number of interesting and potentially beneficial phases occur as the rod length relative to the sphere diameter, rod aspect ratio, and concentration is varied.

**16:06**

**W33 9 Multipolar interaction model for microtubule self-assembly*** KYLE GUSTAFSON, *Univ. of MD, Dept. of Physics, IREAP* JUSTIN STAMBAUGH, *MIT Lincoln Lab.* WOLFGANG LOSERT, *Univ. of MD, Dept. of Physics, IPST and IREAP* Tubulin protein monomers (m = 50 kDa, d = 4-5 nm) are known to self-assemble into biologically significant structures called microtubules. Calculations for microtubule models using the full crystallographic structure of tubulin are prohibitive. As a substitute, we investigate a simpler multipolar interaction model of tubulin which can capture important features of microtubules. We present energy-minimization calculations showing that a four point-charge rectangular model reproduces the 0.93 nm staggering of observed microtubules. We then attempt to validate these static Coulomb calculations with molecular dynamics (MD) using NAMD (from the Theoretical and Computational Biophysics group at the University of Illinois). These simulations include electrostatic interactions, stiff bonded interactions, a Lennard-Jones potential and Langevin damping. The results of the MD simulations are strongly dependent on each of these influences. We find stable filaments of tubulin using the multipole model in MD simulations. When these filaments are combined into a realistic microtubule in MD, an energy minimum is found which supports a stable tube. The study encompasses fraying of tube ends, staggering angle, and ring stability for tubulin and microtubules based on our simple, four charge multipolar model.

**W33 10 Thermoreversible Vesicle-to-Micelle Transitions in Surfactant-Salt Mixtures** AIMEE KETNER, TANNER DAVIES, SRINIVASA RAGHAVAN, *Department of Chemical and Biomolecular Engineering, University of Maryland, College Park, MD 20742* Mixtures of the cationic surfactant, CTAB and the organic compound, 5-methyl salicylic acid (5mS) spontaneously self-assemble into unilamellar vesicles at room temperature. Upon heating, these vesicles undergo a thermoreversible transition to wormlike micelles. This phase transition results in a 1000-fold increase in the solution viscosity with increasing temperature. Small-angle neutron scattering (SANS) measurements show that the phase transition from vesicles to micelles is a continuous one, with the vesicles and micelles co-existing over a range of temperatures. A mechanism for the above phase transition is proposed, based on the desorption of bound aromatic counterions from the vesicle as a function of temperature.

**16:30**

**W33 11 Self-assembly models for lipid mixtures** DIVYA SINGH, *Johns Hopkins University* LIONEL PORCAR, *NIST Center for Neutron Research* PAUL BUTLER, *NIST Center for Neutron Research* URSULA PEREZ-SALAS, *UC, Irvine* Solutions of mixed long and short (detergent-like) phospholipids referred to as ''bicelle'' mixtures in the literature, are known to form a variety of different morphologies based on their total lipid composition and temperature in a complex phase diagram. Some of these morphologies have been found to orient in a magnetic field, and consequently bicelle mixtures are widely used to study the structure of soluble as well as membrane embedded proteins using NMR. In this work, we report on the low temperature phase of the DMPC and DHPC bicelle mixture, where there is agreement on the discoid structures but where molecular packing models are still being contested. The most widely accepted packing arrangement, first proposed by Vold and Prosser had the lipids completely segregated in the disk: DHPC in the rim and DMPC in the disk. Using data from small angle neutron scattering (SANS) experiments, we show how radius of the planar domain of the disks is governed by the effective molar ratio $q_{eff}$ of lipids in aggregate and not the molar ratio $q(q = [\mathrm{DMPC}]/[\mathrm{DHPC}])$ as has been understood previously. We propose a new quantitative (packing) model and show that in this self assembly scheme, $q_{eff}$is the real determinant of disk sizes. Based on $q_{eff}$, a master equation can then scale the radii of disks from mixtures with varying $q$ and total lipid concentration.

**W33 12 End-to-End Adhesion of Short Duplex DNA Oligomers** TOMMASO BELLINI, *University of Milano, Italy* NOEL CLARK, *University of Colorado* The classic model for the formation of liquid crystal phases of rod shaped objects was presented by Onsager, who showed that hard rods of length L and diameter D form a nematic phase when volume fraction is $f > fc = 4D/L$. This criterion is obeyed reasonably well for rod-shaped nucleosomal [150 base pair (bp)] B-DNA duplexes (L = 50nm, D = 2nm). Recently we found, however, that very short duplex B-DNA oligomers, 6bp – 20bp (2 to 6nm) in length, form similar nematic and columnar LC phases, even though their L/D ratio is almost 1 and $f << fc$. We attribute these phases to intermolecular interaction which provides an end-to-end adhesion force between these short oligomers to form extended anisotropic ''living polymers.'' The theory of the formation of such anisotropic aggregates will be reviewed and applied to the DNA observations. Work supported by NSF MRSEC Grant DMR 0213918 and NSF Grant 0072989.

**W33 13 Modeling of fractal intermediates in the self-assembly of silicatein filaments*** MEREDITH MURR, *UCSB* GUNJAN THAKUR, *UCSB* IGOR MEZIC, *UCSB* DANIEL MORSE, *UCSB* Silicateins are proteins with catalytic, structure-directing activity that are responsible for silica biosynthesis in certain sponges, Self-assembly of the silicatein monomers and oligomers was previously shown experimentally (Murr and Morse 2005) to form fibrous structures through the formation of diffusion limited, fractally patterned aggregates on the path to filament formation. We present a diffusion-limited aggregation (DLA) based model that is capable of capturing the basic properties of this self-assembly process. The Silicatein oligomer is modeled with three sites of attachment. Rules of attachment are specified that allow for specific interaction between these sites when oligomers are in proximity. The process differs from a DLA process in the follow-

ing: 1) The process of aggregation is continued dynamically, i.e. the growing structures are spatially distributed and keep diffusing as they are growing 2) The molecules are oriented. Thus rotational diffusion is important. 3) The attachment can happen at more than 1 site and the strength of the active sites can be varied. We show that the self-assembled structures have a good level of similarity with the in-vitro experimental results. We quantify this by comparing the fractal dimension of the experimental data and the model output.

**W33 14 Structure of Porous Columns Self-assembled from Dendritic Dipeptides*** PAUL HEINEY, MIHAI PETERCA, VENKAT BALAGURUSAMY, *Physics Dept., Univ. of Pennsylvania* STEVEN HUDSON, *National Inst. of Standards and Technology* ANDRES DULCEY, VIRGIL PERCEC, *Dept. of Chemistry, Univ. of Pennsylvania* Synthetic pores are an important step in the development of biomimetic materials incorporating features such as trans-membrane channels, gene delivery, protein folding, and selective encapsulation. We have used small-angle xray scattering to study helical pores self-assembled from dendritic dipeptides. The main features of the supramolecular assembly are computed by least-squares fitting the parameters of a simplified structural model to the x-ray diffraction data. This work reports the supramolecular assembly temperature stability and conformational changes of the 3-dimensional packing as a function of dipeptide structure and stereochemistry. The results provide a methodology to design the synthetic pores in order to control the pore size and separation at the Å level, according to the desired function.

**W33 15 X-ray Study of the Electrical Double Layer at the Oil - Water Interface*** ALEKSEY TIKHONOV, *CARS-The University of Chicago* Our understanding of the structure of the insulator/electrolyte solution interface is of fundamental importance in describing electrochemical processes in systems involving membranes, absorbers, catalysts, surfactants, or surfaces of other dielectrics. Due to the specific interaction of the solvent with the insulator, a heterogeneous highly polarized region or an electrical double layer forms at the boundary between bulk phases. We studied the spatial structure of the transition region between n-hexane (insulator) and silica sol (electrolyte) solution by x-ray scattering. The structure factor of the interface and the angular dependence of the grazing incidence small-angle scattering can be explained by the interfacial model, which agrees with the theory of the electrical double layer, shows the separation of positive and negative charge, and consists of three layers, i.e., a thin layer of $Na^+$, a monolayer of nanocolloidal particles as the part of the diffuse layer, and a low-density layer sandwiched between them.

**14:30**

**W34 1 Scaling fields and the nature of liquid-gas asymmetry in fluids** JINGTAO WANG, *University of Maryland* CLAUDIO CERDEIRIÑA, *Universidad de Vigo, Spain* MIKHAIL ANISIMOV, JAN SENGERS, *University of Maryland* Fisher and coworkers [Phys. Rev. Lett. **85**, 696 (2000); Phys. Rev. E **67**, 061506 (2003).] recently suggested that in fluids the two theoretical scaling fields, commonly known as ''ordering'' and ''thermal,'' are mixtures of three physical fields, namely, chemical potential, temperature, and pressure. We have examined experimental consequences of this formulation (''complete scaling'') with regard to the asymmetry of vapor-liquid coexistence in real fluids. By analyzing the coexisting curves of various fluids, we have shown that the vapor-liquid asymmetry originates from two different sources: one from mixing of chemical potential and pressure into the thermal field and another one from mixing of pressure into the ordering field. The first source is attributed to a correlation between entropy and density, whereas the second source is associated with the excluded volume. Real fluids can be mapped into the symmetric lattice-gas (Ising-like) model by a redefinition of the order parameter that can be now expressed through a combination of density, entropy, and molar volume. We have also demonstrated which molecular parameters of fluids control these two sources of vapor-liquid asymmetry.

**W34 2 NMR characterization of complex fluids by diffusion – relaxation distribution functions** MARTIN HURLIMANN, *Schlumberger - Doll Research* ALBINA MUTINA, *Kazan State University, Russia* Many natural fluids are complex mixtures of different types of molecules. As an example, the molecular composition of crude oils typically consists of molecules with a number of carbon atoms that range between one to over 100. In addition to the diverse size, the constituent molecules can be classified into different chemical classes, such as saturates, aromatics, resins and asphaltenes. It is well known that measurements of diffusion and NMR relaxation times can give information on molecular size. We demonstrate that two-dimensional diffusion – relaxation time distribution functions, f(D,T2), can provide a more unique fingerprint of complex fluids with information on both chain length distribution and chemical composition. The new approach is illustrated with results for different crude oils. The experiments were conducted at a Larmor frequency of 5 MHz and temperatures between 10 C and 58 C. The measurements show a strong correlation between the distributions of diffusion coefficients and relaxation times that are sample specific. The diffusion - relaxation correlation function provides information on the correlation between the rotational and the translational diffusion coefficients of each component of the fluid.

**W34 3 Structural Change of the Mixtures of Ionic Liquid and Water Studied by Infrared Absorption Spectroscopy** DOSEOK KIM, YOONNAM JEON, JAEHO SUNG, *Department of Physics and Interdisciplinary Program of Integrated Biotechnology,*

*Sogang University, Seoul 121-742 Korea* YUKIO OUCHI, *Department of Chemistry, Nagoya University, Chikusa-ku, Nagoya 464-8602 Japan* Infrared absorption spectra of the mixtures of ionic liquid and water (1-butyl-3-methylimidazolium tetrafluoroborate, $[BMIM]BF_4$) with varying concentrations were obtained by Attenuated Total Reflection (ATR) method. Investigation of the spectra in the OH-stretch vibration range indicated the structural change of the water with the change in the concentration. At very low concentration of water, two peaks around $3600cm^{-1}$ were assigned to the monomeric form of water molecules weakly hydrogen bonded to the $BF_4^-$ anions. With the increase in the water concentration, the broad feature at $\sim 3460cm^{-1}$ corresponding to the bulk water took over the above monomeric peaks, which gradually redshifted with the increased water concentration. In the range from 2800 to $3200cm^{-1}$ for the various CH-stretch vibration modes in the cation, the peaks in this ranged blueshifted with the increase in the water concentration. This blueshift was as much as $\sim 7cm^{-1}$ for the $CH_3$ vibration modes of butyl chain while it hardly changed for the modes for the CH attached to the imidazolium core, suggesting varying degree of interactions between the carbon-bonded hydrogen and the water molecules.

**W34 4 Weighted density functional theory for water** SAHAK PETROSYAN, DAVID ROUNDY, JEAN-FRANCOIS BRIERE, TOMÁS ARIAS, *Cornell University* We report a weighted density functional theory for water that correctly describes bulk properties of water as well as perturbations at large and small length scales. Calculation of the free energy of solvation for hard sphere solutes of different sizes verifies that this functional gives a simple description of the hydrophobic effects in water. Use of this functional within a joint-density functional theory framework allows a rigorous replacement of molecular water with a continuum in Kohn-Sham calculations of systems in equilibrium with a solution.

**15:18**

**W34 5 Small-angle neutron scattering study of pH dependence of the liquid structure factor of concentrated solutions of eye lens gamma-B crystallin** KENNETH DESMOND, GEORGE THURSTON, *Department of Physics, Rochester Institute of Technology* ANNA STRADNER, PETER SCHURTENBERGER, *Department of Physics, U. Fribourg* We are evaluating the pH dependence of the liquid structure of aqueous solutions of the eye lens protein, gammaB crystallin, near its critical point for liquid-liquid phase separation, to help evaluate the influence of protein charge on the phase separation. We have obtained small-angle neutron scattering data from gammaB crystallin solutions at pH 6.4, 7.1 and 7.4 in a 0.1 M sodium phosphate buffer, and at pH 4.5 in a 0.020M sodium acetate buffer, all in D2O. Protein concentrations ranged from 6 to 260 mg protein/ml solution and the scattering vector magnitude (q) ranged from 0.004 to 0.45 inverse Angstroms. At pH 6.4 to 7.4 liquid structure factors vs. concentration and temperature near the cloud point for liquid-liquid phase separation are well represented, in general, by the Baxter sticky sphere model. In contrast, at pH 4.5, concentrated gammaB shows a very different liquid structure indicating highly repulsive interprotein interactions, consistent with both high net protein charge and reduced screening.

**15:30**

**W34 6 Phase behavior and mixing-demixing transitions in binary liquid mixtures with spherical and non-spherical interactions*** ENRIQUE DIAZ-HERRERA, *Depto. de Fisica, UAM-I (MEXICO)* GUILLERMO RAMIREZ-SANTIAGO, *Instituto de Fisica, UNAM (MEXICO)* J. ANTONIO MORENO-RAZO, *Depto. de Fisica, UAM-I (MEXICO)* We have carried out extensive equilibrium molecular dynamics simulations to study the temperature versus density phase diagrams and the mixing-demixing transition line in fluid equimolar binary mixtures modeled by: (i) Lennard-Jones, (ii) Stock-Mayer, and (iii) Gay- Berne molecular interactions. These studies are performed as function of miscibility parameter, $\alpha = \epsilon_{AB}/\epsilon_{AA}$, where $\epsilon_{AA} = \epsilon_{BB}$ and $\epsilon_{AB}$ stand for the parameters related to the attractive part of the intermolecular interactions for similar and dissimilar particles, respectively. When the miscibility of the Lennard-Jones mixture varies in the range $0 < \alpha < 1$, a continuous critical line of consolute points $T_{cons}(\rho)$, appears. This line intersects the liquid-vapor coexistence curve at different positions depending on the values of $\alpha$, yielding mainly three different topologies for the phase diagrams. These results are in qualitative agreement to those found previously for square well and hard-core Yukawa binary mixtures. We also carry out a detailed study of the liquid-liquid interfacial and liquid-vapor surface tensions, as function of temperature and miscibility as well as its relationship to the topologies of the phase diagrams. Similar studies and analysis are also performed for Stock-Mayer and Gay-Berne binary mixtures.

**W34 7 Confined Fluids: the Time Variable in the Force-Distance Profile** JANET WONG, SUNG-CHUL BAE, STEVE GRANICK, *Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign* Hitherto-overlooked time dependence is known to play a prominent role in determining the friction of confined fluids. In this study, for the first time we introduce the time variable into measuring force-distance profiles of several simple alkane fluids. The existence of near-surface layered structures in confined fluids is generally manifested as oscillatory forces in force-distance profiles obtained using surface forces apparatus (SFA) and atomic force miscroscopy (AFM) experiments. While it is generally agreed that the rate of the experiment should be slow enough to achieve a quasi-static state, it is less clear what the appropriate rate should be. In this study, while maintaining the experimental time scale uniformly slow enough to avoid trivial hydrodyanamically-induced surface deformations, we demonstrate time dependence in the measured force-distance profile. The role of time scale on the actual structure of the confined fluid will be discussed.

**15:54**

**W34 8 Spectroscopic Observation of Fluid Molecular Alignment in a Molecularly-Thin Confined Geometry** MINSU KIM, SHAN JIANG, SUNG CHUL BAE, STEVE GRANICK, *Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign* For the first time, we present data of molecular alignment of a linear chain (1,3-dicyanopropane) under confinement. Confinement was produced between two mica surfaces within a surface forces apparatus (SFA) and measurements employed confocal Raman spectroscopy. We focused on the $CH_2$ symmetric stretch vibrations and CN triple bond stretch vibrations. A polar plot of Raman band intensity as a function of incident light polarization allows us to determine the orientation and order

parameter of alignment. It is confirmed that alignment can be achieved in molecularly-thin films. The decrease of alignment as the film thickness increases will be mentioned. Also, the effect of shear on molecular alignment will be discussed.

**16:06**
**W34 9 Active Microrheology of Dense Colloidal Suspensions** ALEXANDER MEYER, ERIC M. FURST, *Department of Chemical Engineering, University of Delaware* We investigate the active microrheology of a colloidal suspension using laser tweezers. The experimental system described here is composed of a hard sphere suspension of fluorescent, index-matched poly(methyl methacrylate) particles seeded with a low concentration of index-mismatched melamine probes. The probe particles are held in an optical trap and subjected to a uniform flow, enabling measurements of the suspension microrheology. Additionally, confocal microscopy is used to obtain non-equilibrium microstructural information. An anisotropic pair distribution function, with a dense region at the leading surface of the probe and a wake trailing it, is observed as the Péclet number increases to much greater than unity. This structural transition gives rise to a shear thinning regime in the measured microviscosity. The results are in qualitative agreement with recent simulation [I. C. Carpen and J. F. Brady, J. Rheol. 49, 1483-1502 (2005)], and demonstrate the non-linear microrheology of colloidal suspensions.

**16:18**
**W34 10 Nonlinear microrheology of wormlike micelle solutions using magnetic nanowire probes** NATHAN CAPPALLO, CLAYTON LAPOINTE, ROBERT L. LEHENY, DANIEL H. REICH, *Johns Hopkins University* Using ferromagnetic Ni nanowires we investigate the local mechanical properties of wormlike micelle solutions composed of equimolar concentrations of the surfactant cetylpyridinium chloride (CPCl) and sodium salicylate (NaSal). Rotating the nanowires with external magnetic fields, we access both linear and nonlinear regimes of the fluid's rheology. The linear viscosity at low rotation rates is strongly temperature dependent as expected from mechanical rheometry experiments. At high rotation rates the viscosity exhibits pronounced shear thinning that is independent of temperature. The onset of the nonlinear response is characterized by a hysteretic shear thickening that is strongly dependent on temperature, but has no counterpart in the macroscopic rheometry. Further, the nonlinear regime coincides with a transient, anisotropic shear-induced state in the fluid that generates a torque on the wire, causing it to tip out of the plane of rotation when the field is removed.

**W34 11 Myelin figures: an Elastic Instability?** LING-NAN ZOU, SIDNEY R. NAGEL, *The James Franck Institute, the University of Chicago* Myelin figures form when certain lamellar phase surfactants swell upon exposure to water. The formation of these myelins, which are tubular structures composed of multiple bilayers of surfactant, is puzzling because it represents the formation of a higher bending-energy configuration from a lower bending-energy initial state. We show that single myelins can be produced in isolation and require a driving force to form and grow; they retract into their parent structure when the driving is removed. We present a model, consistent with our experimental observations, where the formation of myelins is due to an elastic instability of the lamellar phase under internal stress. We propose an experiment to test of this model in comparison to other models, such as that of Huang et al.[1] [1]J.-R. Huang, L.-N. Zou, and T. A. Witten, Eur. Phys. J. E (2005). DOI: 10.1140/epje/e2005-00035-8.

**W34 12 Charge fluctuations and correlations in finite electrolytes** YOUNG C. KIM, *Laboratory of Chemical Physics, NIDDK, NIH, Bethesda, 20892* MICHAEL E. FISHER, *Institute for Physical Science and Technology, University of Maryland, College Park, 20742* Charge fluctuations, $\langle Q_\Lambda^2 \rangle$, for the 1:1 equisize hard-sphere electrolyte with the diameter $a$ are computed via grand canonical Monte Carlo simulations, where $Q_\Lambda$ is the total charge inside a subvolume $\Lambda$ contained in a simulation box of dimensions $L \times L \times L$ with periodic boundary conditions. The charge fluctuations increase like the surface area $|\partial\Lambda|$ as $\Lambda$ increases, even for small system sizes $L \leqslant 12a$. For slabs of dimensions $L \times L \times \lambda L$ with $0 < \lambda < 1$, the scaled charge fluctuations, $\langle Q_\Lambda^2 \rangle / |\partial\Lambda|$, approach the thermodynamic limits exponentially fast. The extrapolations to $L \to \infty$ then yield the Lebowitz length, $\xi_L(T,\rho)$, where densities $\rho \lesssim 3\rho_c$ and temperatures $T \gtrsim T_c$ have been studied. An exact asymptotic expression is obtained for $\langle Q_\Lambda^2 \rangle$. This enables one to compute the charge correlation length $\xi_Z(T,\rho)$ precisely. The results for $\xi_Z(T,\rho)$ agree with Debye-Hückel-type theories at low densities, but show deviations as the density increases. Charge oscillations at higher densities are also observed, as anticipated theoretically. [1] Y. C. Kim, E. Luijten, and M. E. Fisher, Phys. Rev. Lett. **95**, 145701 (2005).

**W34 13 Solid or Liquid ? – Kinetically induced solidification in a simple nanoconfined liquid*** PETER HOFFMANN, *Wayne State University* GEORGE MATEI, *Wayne State University* SHIVPRASAD PATIL, *Wayne State University* AHMET ORAL, *Bilkent University* For many years there has been a controversy regarding the supposed solidification of simple liquids when they are confined to a few nanometer film thickness. By using a novel, ultra-small amplitude Atomic Force Microscopy (AFM) technique, we have found that solidification in these systems seems to be due to a kinetic effect and does not occur in thermodynamic equilibrium. In particular, we studied OMCTS confined between a flat silicon surface and a silicon tip and found that at very low approach speeds ( < = 0.3 Å/sec) the confined fluid remains liquid-like with no change in mechanical relaxation time from the bulk, although ordering is observed in the stiffness and damping of the film. However, when approaching the tip slightly faster at or above 6 Å/sec, the liquid suddenly changes properties dramatically. In the ordered regime, damping is greatly reduced and the mechanical relaxation times show large peaks, indicating an elastic, solid-like response. This result suggests that the observed solidification is a non-equilibrium effect induced at very long time scales.

**W34 14 Investigation of Liquid Transport/Diffusion through a Nanopore Driven by a Constant Pressure/Chemical Potential**

**Difference.** CUNKUI HUANG, *University of Alberta* KUMAR NANDAKUMAR, *University of Alberta* PHILLIP CHOI, *University of Alberta* LARRY KOSTIUK, *University of Alberta* Fluid transport/diffusion through a nanopore in a membrane was investigated by using a novel molecular dynamics approach proposed in this study. The advantages of this method, relative to dual-control-volume grand-canonical molecular dynamics (DCV-GCMD), are that it eliminates disruptions to the system dynamics that normally created by inserting or deleting particles from control volumes, and that it functions well for dense systems as the number of particles in the studied system remain fixed. Using this method, we examined liquid argon transport/diffusion through a nanopore by performing non-equilibrium molecular dynamics (NEMD) simulations under different back-pressures/chemical potentials. The MD code was validated firstly by comparison with published experimental data, and NEMD results of the present method show that constant pressure/chemical potential difference across the membrane was readily achieved. The soundness of classical Navier-Stokes (NS) solutions for these nanochannel flows was also checked by direct comparison between the NS predictions and results from the proposed NEMD method. The density distributions along the nanopore for both methods were found to be significantly different, but the velocity profile had a similar pattern, although some difference between them exists.

**W34 16 Vectorial Loading of Processive Motor Proteins: Microtubule buckling experiment revisited** MICHAEL E. FISHER, *Institute for Physical Science and Technology, University of Maryland, College Park, MD 20742,* YOUNG C. KIM, *Laboratory of Chemical Physics, NIDDK, NIH, Bethesda, MD 20892* Experiments on the motor protein kinesin by Howard and coworkers (1996) observed the buckling of partially clamped microtubules caused by bound motors responding to the induced parallel, $F_x$, and perpendicular, $F_z$, load components. To analyze such results, we have applied simple mechanochemical models for vectorial loads $F = (F_x,F_y,F_z)$ by implementing a three-dimensional free-energy landscape formulation. An expression for the velocity, $V(F_x,F_z;[ATP])$, is obtained by fitting to the velocity and randomness data of Block and coworkers (2003) who imposed both resisting ($F_x < 0$) and assisting ($F_x > 0$) loads. While our results agree qualitatively with the buckling experiments, the analysis predicts that the velocity *decreases* under perpendicular loading ($F_z > 0$) contrary to the conclusion of Howard and coworkers. This suggests the possibility that the geometry of stressed microtubules might influence the mobility of kinesin motors.

**W36 1 Excitonic Effects and the Optical Properties of Silicon Nanowires.***
M.Y. CHOU, *Georgia Institute of Technology*

Semiconductor nanowires have potential applications in many fields such as optoelectronics, photovoltaic cells, and especially device miniaturization. The excited-state properties are of critical importance in the design of these functional devices. The low dimensionality and reduced size tend to strengthen the effective Coulomb interaction in these nanostructures. In this study, we focus on the correlated electron-hole states in semiconductor nanowires and the influence of this excitonic effect on the optical absorption spectra. First-principles calculations are performed for a hydrogen-passivated silicon nanowire of a diameter of 1.2 nm. Using plane waves and pseudopotentials, the quasiparticle states are calculated within the many-body perturbation theory with the so-called GW approximation. It is found that the fundamental gap depends on both the orientation and size of the wire, and that the gap increases as the diameter decreases in an inverse quadratic fashion [1]. The electron-hole interaction is then evaluated by the Bethe-Salpeter equation (BSE). The enhanced Coulomb interaction in this confined geometry not only gives rise to an unusually large exciton binding energy of more than 1 eV (compared to a value of 14.7 meV in silicon bulk), but also significantly modifies the relative strength of the absorption peaks. The characteristics of these exciton states will be discussed. [1] ''Quantum Confinement and Electronic Properties of Silicon Nanowires,'' X. Zhao, C. M. Wei, L. Yang, and M. Y. Chou, Phys. Rev. Lett. 92, 236805 (2004).

**W36 2 Electronic structures and optical properties of silicon nanowires** JUN LI, *Northwestern University* ARTHUR FREEMAN, Recent optical spectroscopic[1] and theoretical/computational studies[2] challenge the previous consensus on the nature of the optical properties of Si nanowires (SiNW). Here, we present results of precise theoretical FLAPW[3] determinations of the electronic structures and optical properties of (001) and (111) one nm SiNW. The electronic states at the gaps demonstrate a strong orientation dependent parabolic character in the Brillouin zone and a clear entanglement in real space between 1D and 2D dimensions of the wire. The local symmetry imposed by quantum confinement quenches the transitions around the gap, yielding an optically inactive direct gap. The observed (001) photoluminescence is attributed to a transition rooted in an $Si_8$ ring. The optical structure in the experimental range is well reproduced by our first-principles calculations that include the screened exchange-LDA correction to the well-known failure of the LDA. Our predictions about the anisotropy and orientation dependent optical absorption are easily verified experimentally. Work supported by DARPA B529527//W-7405-Eng-48.

**W36 3 Comparison of the optical properties of bare and capped GaAs nanowires** L.M. SMITH, THANG B. HOANG, L.V. TITOVA, H.E. JACKSON, *Dept. of Phys., Univ. of Cincinnati, Cincinnati, OH 45221* J.M. YARRISON-RICE, *Dept. of Phys., Miami Univ., Oxford, OH 45056* YONG KIM, H.H. TAN, C. JAGADISH, *Australian National University, Australia* We study the optical properties of single bare GaAs nanowires and GaAs/AlGaAs core/shell nanowires fabricated by the VLS technique. SEM and AFM images show that the wires are uniform in length (3-4$\mu$m long) and needle-shaped. Low temperature photoluminescence measurements of individual nanowires indicate that the quantum efficiency of the core/shell nanowires is significantly larger compared to the uncapped nanowires. We believe that the reason for the low emission efficiency of the uncapped nanowires is the significant influence of the surface-related non-radiative trap states. We anticipate that time-resolved measurements will show a significant increase of the recombination lifetime in the core/shell nanowires compared to the uncapped nanowires due to the passivation of the surface-related states by the AlGaAs shell. We acknowledge the support of the NSF through grants 0071797, 0216374, and the Australian Research Council.

**W36 4 Linear optical absorption in silicon and GaAs nanocrystals*** MURILO L. TIAGO,† *University of Minnesota, Twin Cities* JAMES R. CHELIKOWSKY, *University of Texas at Austin* The linear optical spectrum of Si and GaAs nanocrystals containing up to 100 atoms is calculated and discussed. We use two first-principles theories: time-dependent density-functional theory in the local adiabatic approximation (TDLDA), and the many-body solution of the Bethe-Salpeter equation (BSE). Both theories predict a strong blue shift in the energy-resolved polarizability and in the absorption cross section, which is characteristic of confined systems in the nanoscale. When many-body effects are included, in the framework of the BSE, the low-energy range of the spectrum is modified in two ways: the energy of excitation lines increases by almost 1 eV, as a result of self-energy and screening corrections; and the oscillator strength of those lines is enhanced. In bulk semiconductors, many-body effects are known to produce exciton lines and enhanced absorption in the low-energy range of the spectrum. Although the size of the nanocrystals studied is much smaller than the radius of Wannier excitons, the enhancement in oscillator strength is suggested to have the same source as excitonic effects in bulk samples.

**W36 5 Light from Silicon-Based Nanostructures.**
LUCA DAL NEGRO, *MIT & Boston University*

Si-nanocrystals (Si-nc) embedded in $SiO_2$ glass matrices shows undoubtedly efficient room temperature light emission under optical pumping and sizable optical gain and light amplification have been demonstrated [1]. However, the presence of an insulating $SiO_2$ matrix prevents the fabrication of reliable and efficient electrically-driven devices and the efficiency of light emission is severely curtailed by the slow radiative lifetime of Si-nc. An alternative possibility is offered by the nucleation of Si-nc in dielectric hosts with smaller band-gaps. In this talk we will show our results on light-emitting Si-rich silicon nitride films (SRN) and photonic structures obtained by Plasma Enhanced Chemical Vapor Deposition (PE-CVD) followed by low temperature (500-900°C) thermal annealing [2]. The optical properties of SRN films are studied by micro-Raman and photo luminescence spectroscopy and demonstrate the presence of small Si-clusters with nanosecond recombination time and negligible emission thermal quenching. The electrical transport properties of SRN films are also investigated and efficient charge injection at low bias voltages is demonstrated. Additionally, we show that SRN matrices are suitable for efficient energy sensitization of Er ions emitting at 1.54 $\mu$m. The light emission mechanism in SRN nanostructures is studied by DFT−LDA first principles calculations showing that, largely Stokes−shifted, nanosecond−fast and efficient light emission in PE−CVD deposited SRN samples originates from strongly localized excitons transitions at the surface of small Si−nc ($\sim$ 1−2 nm) embedded in Silicon nitride [3].

Additionally, we show that the presence of bridging nitrogen groups at the surface of small Si nanocrystals can explain the origin of the experimentally measured Stokes−shift and the nanosecond relaxation times [3].

**W36 6 Optical characterizations of one-dimensional wetting layers in InGaAs/GaAs quantum dot chains** XIAOYONG WANG, CHIH-KANG SHIH, *Department of Physics, the University of Texas at Austin* ZHIMING WANG, GREGORY SALAMO, *Department of Physics, University of Arkansas* We report spectroscopic evidence for the formation of 1D wetting layers (WLs) during the Stransky-Krastanov (SK) growth of multi-layered InGaAs/GaAs quantum dot (QD) chains. The wire-like features of these 1D WLs were demonstrated by their 1D density of states as well as the anisotropic absorption and emission properties. Two groups of QD's were found sitting on these 1D and the traditional 2D WLs, respectively, with size-dependent polarization anisotropies of $\sim$ 6%-25% due to their elongated shapes. The previously-unexplored new SK growth mode of 1D WLs could be potentially tailored by varying the In content and barrier thickness to yield QD's and 1D WLs with expected energy level separations. This may lead to the efficient carrier transfer between QD's on top of the same 1D WL for quantum technology applications that require quantum information transfer between different nanostructures of controlled positioning.

**W36 7 Electronic and optical fine structure of GaAs nanocrystals: the role of d orbitals in a tight-binding approach** J.G. DIAZ, GARNETT W. BRYANT, *National Institute of Standards and Technology* Electronic structure and optical spectra of GaAs nanocrystals for a wide range of sizes are studied by using both $sp^3s^*$ and $sp^3s^*d^5$ nearest-neighbor tight-binding models. Our results show that the inclusion of $d$ orbitals into a minimal basis set is necessary for a proper description of the lowest electron states, especially in the strong confinement regime. For dot sizes below 2.5 nm, the ground electron state is primarily built of L-point bulk band-states, giving the nanocrystals indirect-gap character. Simpler $sp^3s^*$ models yield an incorrect description of electron states made from bulk band- states away from the Brillouin zone center. In contrast, $sp^3s^*d^5$ models are able to provide a consistent picture of the main optical features in agreement with experiments.

**16:42**
**W36 8 Neutral and charged excitons in single GaAs-based interface quantum dots** C.J. MEINING, V.R. WHITESIDE, B.D. McCOMBE, *University at Buffalo, The State University of New York, NY 14260* J.G. TISCHLER, A.S. BRACKER, D. GAMMON, *Naval Research Laboratory, Washington, D.C. 20375-5347* A.B. DZYUBENKO, *California State University at Bakersfield, CA 93311* M. BYSZEWSKI, M. POTEMSKI, *Grenoble High Magnetic Field Laboratory, France* We report circularly polarized photoluminescence (PL) in high magnetic fields ($<$ 28 T) and optically detected resonance (ODR) experiments of interface fluctuation quantum dots (IFQDs) in narrow GaAs/AlGaAs quantum wells (QWs) doped in the barriers with donors to allow creation of both neutral and negatively charged excitons. In the narrowest QW the diamagnetic shift of the trion is smaller than that of the neutral exciton. This is attributed to the larger spatial extent of the trion wavefunction in these ensembles of weakly confined QDs. Along with a careful study of the excitonic Zeeman splitting and complemented by a comparison of ensemble and single dot ODR measurements, this signature can be used to assign the narrow spectral lines observed in single dot PL studies as neutral and charged excitons. The PL of the trion is found to increase under resonant irradiation with far-infrared laser light, opposite to the behavior observed for wide QWs. Lateral carrier redistribution is believed to be the dominant mechanism that gives rise to the ODR signal in QWs with monolayer well width fluctuations. Work supported in part by NSF-DMR #0203560.

**16:54**
**W36 9 Nanostructured solar cells*** OZGUR YAVUZCETIN, CHEOL-SOO YANG, TOM RUSSELL, MARK TUOMINEN, *University of Massachusettts* In this work we investigate the use of nanofabrication technique to improve the overall efficiency of silicon solar cells. The efficiency and the durability of silicon solar cells largely depends on the quality of the anti-reflectivecoating. In this work, the change in the index of refraction on the surface of a substrate can be controlled by the amount of porosity, which is well known in effective medium theory. Also by changing the thickness of the porous layer, the medium can be fine tuned to a specific wavelength as an AR coating. We fabricate the nanoporous layer by using a self-assembled P(S-b-MMA) coating as a mask to etch into the silicon substrate using reactive ion etching. The use of different molecular weight diblock copolymer and different etching time allow us to tune the index of refraction. FT-IR and variable angle ellipsometry provide information about the transmission and reflection properties along with the index of refraction and the thickness of the coating. The investigation of the efficiencies are performed by comparing the I-V plots of conventional and nanostructured cells. Additional research is underway in order to apply this technology to other types of substrates.

**W36 10 Effects of high magnetic fields on the scattering rates of GaAs/AlGaAs and GaInAs/AlInAs quantum cascade lasers** A. WADE, G. FEDOROV, D. SMIRNOV, *National High Magnetic Field Laboratory* A. LEULIET, A. VASANELLI, C. SIRTORI, *Laboratoire Matériaux et Phénomènes Quantiques, Université, France* Using magneto-spectroscopy, we investigate the influence of a strong magnetic field on the intersubband scattering rates in MIR GaAs/AlGaAs and GaInAs/AlInAs quantum cascade

lasers (QCLs). In our experiments, we measured light-current, voltage-current and laser emission spectra as a function of magnetic field up to 40T with the magnetic field perpendicular to the 2DEG. We observed strong oscillations in the intensity and threshold current. From these, the magnetic field dependences of the intersubband lifetime of both structures were derived and compared to their calculated dependence of electron-LO phonon scattering rates.

**17:18**

**W36 11 Ultra-low threshold quantum dot microdisk laser** G.S. SOLOMON, *Ginzton and Solid-State Laboratories, Stanford University* Z.G. XIE, *Solid-State Laboratory, Stanford University* S. GOETZINGER, Y. YAMAMOTO, *Ginzton Laboratory, Stanford University* W. FANG, H. CAO, *Department of Physics and Astronomy, Northwestern University* Ultra-low threshold lasers have applications in low-power communications. These lasers are also of fundamental interest, where a full understanding of lasing based on a few discrete emitters is evolving. This is especially true in solid-state systems, for instance those with a quantum dot (QD) gain medium, where a typical spectrum of discrete emission lines observed at lower pump power is often highly modified under higher pump powers. Here we discuss a microcavity laser containing a dilute QD gain medium that has an ultra low, sub-microwatt CW lasing threshold. The structure is based on a high-quality factor microdisk cavity of GaAs with a low density of InAs-based QDs embedded in the microdisk. We estimate 250 QDs in the 1.8 $\mu$m diameter microdisk under investigation. Of these QDs approximately 60 are spatially located within the modal region of the disk, which extends inwards approximately 250 nm from the disk edge. Only a small portion of these QDs couple to the narrow cavity modes, which have a free spectral range of 45 nm and an initial linewidth of 0.06-0.07 nm. Linewidth narrowing and lifetime reduction with increasing pump are both observed. Despite the small number of QDs it is unlikely from our estimates the system lases from a single QD state.

## SESSION W37: NANOSCALE CONDUCTANCE THEORY II

**Thursday Afternoon, 16 March 2006**
**340, Baltimore Convention Center at 14:30**
**Harold Baranger, Duke University, presiding**

**14:30**

**W37 1 Variable-range cotunneling and non-Ohmic transport in a chain of one-dimensional quantum dots** MICHAEL M. FOGLER, *University of California San Diego* SERGEY V. MALININ, *Wayne State University* THOMAS NATTERMANN, *Universitat zu Koln* A 1D wire with a finite density of strong random impurities is modeled as a chain of weakly coupled quantum dots. The resistance of such a system is shown to exhibit a rich dependence on bias voltage $V$ and temperature $T$ due to the interplay of Coulomb blockade, Luttinger-liquid, and disorder effects. At low $T$ and $V$ electrons propagate through the wire by means of thermal activation and a multiple cotunneling. In this regime the resistance is limited by the ''breaks'': randomly occurring clusters of dots with a special length distribution pattern that inhibits the transport no matter how the activation and tunneling are combined. As $T$ or $V$ increases, the breaks become shorter and less resistive. The resistance can exhibit a (stretched) exponential and a quasi power-law dependence on $T$ and $V$ depending on the position at the $T$-$V$ diagram. Unlike the case of a single impurity the effect of $T$ and $eV$ is not symmetric. The Ohmic resistance of a macroscopic wire is always dictated by breaks not single impurities. Our results imply that the power-laws reported in several recent transport measurements of one-dimensional systems may reflect not only intrinsic Luttinger parameters but also impurity distribution statistics.

**14:42**

**W37 2 Pair tunneling through single molecules** JENS KOCH, *Institut für Theoretische Physik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany* MIKHAIL E. RAIKH, *Department of Physics, University of Utah, Salt Lake City, UT 84112, USA* FELIX VON OPPEN, *Institut für Theoretische Physik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany* By a polaronic energy shift, the effective charging energy of molecules can become negative, favoring ground states with even numbers of electrons. Here, we show that charge transport through such molecules near ground-state degeneracies is dominated by tunneling of electron pairs which coexists with (featureless) single-electron cotunneling. Due to the restricted phase space for pair tunneling, the current-voltage characteristics exhibits striking differences from the conventional Coulomb blockade. In asymmetric junctions, pair tunneling can be used for gate-controlled current rectification and switching. We find that pair tunneling also has interesting consequences for the shot noise.

**14:54**

**W37 3 Spin Related Effects in Transport Properties of ''Open'' Quantum Dots** YASHAR AHMADIAN, GIANLUIGI CATELANI,*IGOR ALEINER, *Columbia University* We study the interaction corrections to the transport coefficients in open quantum dots (i.e. dots connected to leads of large conductance $G \gg e^2/\pi\hbar$), via a quantum kinetic equation approach. The effects of all the channels of the universal (in the Random Matrix Theory sense) interaction Hamiltonian are accounted for at one loop approximation. For the electrical conductance we find that even though the magnitude of the triplet channel interaction is smaller than the charging energy, the differential conductance at small bias is greatly affected by this interaction. Furthermore, the application of a magnetic field can significantly change the conductance due to the Zeeman splitting, producing finite bias anomalies. For the thermal conductance we find that the Wiedemann-Franz law is violated by the interaction corrections, and we investigated the effect of magnetic field on the Lorentz ratio for contacts of finite reflection. The charge and triplet channel corrections to the electrical and thermal conductance vanish for reflectionless contacts. In the latter case the temperature and magnetic field dependence of the conductance is determined by the Maki-Thompson correction in the Cooper channel.

*Currently a postdoc at Cornell University

**15:06**

**W37 4 Numerical studies of the dynamics of interacting electrons confined in nanostructures** ROK ZITKO, *Jozef Stefan Institute, Ljubljana, Slovenia* JANEZ BONCA, ANTON RAMSAK, *FMF, University of Ljubljana, Slovenia* TOMAZ REJEC, *Ben-Gurion University, Beer Sheva, Israel* At low temperatures electrons have long phase-relaxation time. They tunnel coherently through nanostructures in a wave-like manner, which leads to vari-

ous interference effects. We presently have adequate knowledge about the transport phenomena that can be described using single-electron models. The transport in the presence of interactions is, however, still a subject of intensive research. More refined theoretical tools are required to tackle problems such as that of the transport through systems of coupled quantum dots in the Kondo regime. We present our studies using complementary methods: the quantum Monte Carlo, the variational method and the numerical renormalization group. We show the phase diagram of the triple quantum dot and explain the various regimes of enhanced conductance.

**15:18**

**W37 5 Non-equilibrium conductance of a three-terminal quantum dot in the Kondo regime: Perturbative Renormalization Group** NAYANA SHAH, ACHIM ROSCH, *University of Cologne* Motivated by recent experiments, we consider a single-electron transistor in the Kondo regime which is coupled to three leads in the presence of large bias voltages. Such a steady-state non-equilibrium system is to a large extent governed by a decoherence rate induced by the current through the dot. As the two-terminal conductance turns out to be rather insensitive to the decoherence rate, we study the conductance in a three-terminal device using perturbative renormalization group and calculate the characteristic splitting of the Kondo resonance. The interplay between potential biases and anisotropy in coupling to the three leads determines the decoherence rate and the conditions for strong coupling.

**15:30**

**W37 6 Dissipative quantum phase transition in a single electron transistor** ALFRED ZAWADOWSKI, LASZLO BORDA, GERGELY ZARAND, *Institute of Physics, TU Budapest* DAVID GOLDHABER-GORDON, *Stanford University* We study the transport properties of a single electron transistor (SET) with highly resistive gate electrodes, and show that the SET displays a quantum phase transition analogous to the famous dissipative phase transition studied by Leggett. At temperature $T = 0$, the charge on the central island of a conventional SET changes smoothly as a function of gate voltage, dueto quantum fluctuations. However, sufficiently-strong dissipation, $R_g > R_C$, can freeze out charge fluctuations on the island even at the degeneracy point, causing the charge on the island to change in sharp steps as a function of gate voltage. For $R_g < R_C$ the steps remain smeared out by quantum fluctuations. The Coulomb blockade peaks in conductance display anomalous scaling at intermediate temperatures.

**15:42**

**W37 7 The Interplay of Spin and Charge Channels in Zero Dimensional Systems*** MIKHAIL KISELEV, *Institute for Theoretical Physics, Universität Würzburg, Würzburg D-97074, Germany* YUVAL GEFEN, *Department of Condensed Matter Physics, The Weizmann Institute of Science, Rehovot 76100, Israel* We study the interplay of charge and spin (zero-mode) channels in quantum dots. The latter affects the former in the form of a distinct signature on the differential conductance. We also obtain both longitudinal and transverse spin susceptibilities. All these observables, underlain by spin fluctuations, become accentuated as one approaches the Stoner instability. The non-perturbative effects of zero-mode interaction are described in terms of the propagation of gauge bosons associated with charge (U(1)) and spin (SU(2)) fluctuations in the dot, while transverse spin fluctuations are analyzed perturbatively.

*We acknowledge support by SFB-410 grant and through the Heisenberg program of the DFG (MK), an ISF grant of the Israel Academy of Science, the EC HPRN-CT-2002-00302-RTN and the AvH Foundation (YG).

**15:54**

**W37 8 The 0.7 anomaly in quantum point contacts: a scattering approach*** CAIO LEWENKOPF, PAULO BONFIM, *Universidade do Estado do Rio de Janeiro, Brazil* The conductance steps observed in the electronic transport through quantum point contacts (QPCs) became a paradigm of the Landauer conductance formula. For this reason, the ubiquitous experimental observation of the 0.7 anomaly in the first conductance step of QPCs, that defied the single-particle scenario, raised a lot of attention. The most successful theoretical explanation of this transport feature is in terms of Kondo physics: It builds on an Anderson-like model, whose parameters, namely, the resonance position, its couplings to the reservoirs and the charging energy are adjusted to give meaningful results. Starting from a scattering approach, that uses the Feshbach projection formalism, we construct a single-particle basis that allows us to directly calculate the resonance position and its coupling to left and right reservoirs. We then include an electron-eletron interaction term and proceed as standard. This approach unveils a novel interpretation for the underlying physics of the 0.7 anomaly.

**16:06**

**W37 9 Electron transport in the presence of a magnetic field and the absence of translational invariance** TOBIAS KRAMER, ROBERT E. PARROTT, ERIC J. HELLER, *Physics Department Harvard University* Recent experimental techniques in 2DEGs using scanning probe microscope tips allow one to spatially image electron flow directly (see also the talk by Kathy Aidala). These developments motivate theoretical consideration of (localized) magnetic edge states in position space. For the case of a parabolic confinement, a semi-analytic expression of the Green function is given. The underlying physics differs from a conventional edge-state model by the absence of translational invariance. It is also possible to derive a semiclassical interpretation of the current density, which provides additional physical insight into the nature of transport in position space. For additional information, see also http://people.deas.harvard.edu/~ tkramer

**16:18**

**W37 10 Divergent beams of nonlocally entangled electrons emitted from NS structures*** FERNANDO SOLS, *Universidad Complutense de Madrid* ELSA PRADA, *Universität Karlsruhe* We propose the use of normal and Andreev resonances in normal-superconducting structures to generate divergent beams of nonlocally entangled electrons. Resonant levels are tuned to selectively transmit electrons with specific values of the perpendicular energy, thus fixing the magnitude of the exit angle. When the normal metal is a ballistic two-dimensional electron gas, the proposed scheme guarantees arbitrarily large spatial separation of the entangled electron beams emitted from a finite interface. We perform a quantitative study of the linear and nonlinear transport properties of some suitable structures, taking into account the large mismatch in

effective masses and Fermi wavelengths. Numerical estimates confirm the feasibility of the proposed beam separation method.

*Work supported by MEC, No. BFM2001-0172 and FIS2004-05120, and the Ramon Areces Foundation.

**16:30**

**W37 11 Non-equilibrium Entanglement and Noise in Coupled Double Quantum Dots** RAMON AGUADO, *Instituto de Ciencia de Materiales, CSIC* NEILL LAMBERT, *University of Tokyo, Japan* TOBIAS BRANDES, *University of Manchester, UK* We study charge entanglement in two capacitively-coupled double quantum dots in thermal equilibrium and under stationary non-equilibrium transport conditions. In the transport regime, the entanglement exhibits a clear switching threshold and various limits due to suppression of tunneling by Quantum Zeno localisation or by an interaction induced energy gap. We also calculate quantum noise spectra and discuss current cross-correlations as an indicator of the entanglement in transport experiments.

**16:42**

**W37 12 Conductance Fano lineshapes for Kondo impurities on surfaces: A numerical renormalization group description.** NANCY SANDLER, LUIS DIAS DA SILVA, SERGIO ULLOA, *Department of Physics and Astronomy, Ohio University* Scanning tunneling microscopy (STM) measurements of Kondo impurities on metallic surfaces has been an active field in recent years. For a flat density-of-states (DoS) near the Fermi energy in the host metal, the low-bias STM conductance acquires the characteristic Fano lineshape, with width proportional to the Kondo temperature $T_K$. In this work, we study how this picture is modified when a itstructured DoS (non-flat) is considered. A variety of physical effects can introduce peak/dips in the DoS, including the presence of a second impurity, hybridization between surface and bulk conduction states, and a magnetic impurity embedded in a molecule. Using numerical renormalization group techniques, we calculate the low-temperature conductance for this system. The zero-bias dip in the Fano conductance is modified by the presence of resonances or anti-resonances in the DoS near $E_F$. In particular, for DoS with pseudogaps and impurities in the mixed-valence regime, zero-bias Fano-like dips appear *even when no Kondo state has developed*, but governed by energy scales much larger than $T_K$. We further show that measurements of the scattering phase could be used as an additional probe into the Kondo regime. Supported by NFS-NIRT.

**16:54**

**W37 13 Effects of the electron-phonon interaction on the electron transport in low-dimensional disordered semiconductor structures** ANDREI SERGEEV, *University at Buffalo* MICHAEL REIZER, *5614 Naiche Road, Columbus, OH 43213* VLADIMIR MITIN, *University at Buffalo* We investigate the effects of the interference between electron-phonon scattering and elastic electron scattering in heterostructures and nanotubes. Interference strongly enhances the effective electron-phonon coupling in semiconductor structures and strengthens the electron-phonon relaxation [1]. Employing the quantum transport equitation, we calculate the interference contribution to the electrical conductivity and phonon drag thermopower. Our results show that the interference term follows to the logT-law and dominates in the temperature dependence of the conductivity. Phonon drag is also enhanced due to disorder. [1] A. Sergeev et al., Phys. Rev. Lett., 94, 136602 (2005).

**17:06**

**W37 14 Mesoscopic and nanoscopic physics of molecular-scale electronics** YONGQIANG XUE, *SUNY-Albany* Going from the mesoscopic regime of quantum semiconductor device to nanoscopic molecular device, the dominant or first-order transport mechanism remains quantum mechanical coherent transport due to the small size. A large part of the theoretical efforts in nanoelectronics is thus to recast the accumulated knowledge about mesoscopic physics into forms that are suitable for evaluating quantum transport phenomena at the atomic-scale. On the other hand, electrical conduction is intrinsically a dynamical phenomenon. Since the different degrees of freedom (electronic, mechanical, phonon . . . ) in the nanostructures can be strongly coupled to each other and to their nano-environment, the measured electrical signal is often the result of complex dynamic coupling processes without requiring ensemble average. New theoretical principles and computational techniques may be needed to unravel the rich physics involved in molecular-scale transport. In this talk, we discuss our efforts in moving from mesoscopic theory to nanoscopic theory of molecular-scale electronics.

**17:18**

**W37 15 Phonon Broadening of Spectral Lines in Scanning Tunneling Spectroscopy** J. W. GADZUK, *Electron Physics Group, NIST, Gaithersburg, MD 20899-8412* The observation and interpretation of spectral lines associated with quasi-localized states in condensed matter systems has provided a rich source of information pertaining to the transient coupling of these states to their dynamic environment.[1] While polaron/Franck-Condon models in which a transient localized potential excites the ambient phonon system have formed the basis for phonon broadening in a wide variety of core level spectroscopies, Sunjic and Lucas have put forth an elegantly simple solution to the problem in terms of driven harmonic oscillators which easily incorporates the time scales for both the switching on and the decay of the localized potential.[2] In recent STS studies of thin NaCl films on Cu substrates, Repp et al. have observed Gaussian-broadened lines that are signatures of bound electrons at Cl vacancies (F-centers).[3] These resonance tunneling line shapes are here analyzed within the context of the SL model, properly accounting for lifetime effects due to both tip-to-vacancy and also vacancy-to-substrate tunneling, thus enabling determination of the actual electron-phonon interaction. [1]J.W.Gadzuk, PRB **44**, 13466 (1991). [2]M.Sunjic and A.A.Lucas, CPL **42**, 462 (1976). [3]J.Repp et al., PRL **95**, 225503 (2005).

## SESSION W38: FLUX PINNING AND CRITICAL CURRENTS

**Thursday Afternoon, 16 March 2006**
**341, Baltimore Convention Center at 14:30**
**Judy Wu, University of Kansas, presiding**

**14:30**

**W38 1 Theory for the Dependence on Thickness Shown by the Critical Current vs. Magnetic Field in Films of PLD-YBCO*** MARTIN P. MALEY, *Los Alamos National Laboratory* JOSE P. RODRIGUEZ, *California State University at Los Angeles* The theoretical consequences of the proposal that the vortex lattice induced by perpendicular magnetic field in films of PLD-YBCO is

in a thermodynamic Bose glass state are explored. Attention is focused on the high-field regime at the extreme type-II limit, in which case only a small fraction of the vortex lines are localized at the dislocations that thread the film along the c axis, and in which case the pinning of the vortex lattice is collective. The critical current density along the film is predicted to follow an inverse square-root power law as a function of external magnetic field in the collective-pinning regime. It gives a fair account of the critical current density at kG magnetic fields in films of PLD-YBCO that are microns thick, at liquid nitrogen temperature. It fails, however, for much thinner films at lower temperature. This failure is corrected by including the effect of point pins along the interstitial vortex lines that lie in between the correlated pins. They contribute an inverse dependence on film thickness to the critical current density in magnetic field oriented near the c axis.

*Supported in part by the Department of Energy.

**14:42**

**W38 2 The growth mechanism of pinning-effective nanostructures embedded in $YBa_2Cu_3O_{7-x}$ (YBCO) superconducting thin film** A. GAPUD, A. KHAN, M. PARANTHAMAN, *Univ. of South Alabama* D. CHRISTEN, *Oak Ridge Natl. Lab.* Following up on previous success in modifying the pulsed-laser-deposition (PLD) film processing to introduce self-assembled pinning defects in films of various high-temperature superconductors (HTSC), specifically the case of self-assembled columnar arrays of oxide nanodots in $YBa_2Cu_3O_{7-x}$ (YBCO) thin film [itSuperconductor Science and Technology **18**, 1533 (2005)] using a nanodot-doped YBCO target, a careful and systematic examination of the growth mechanism is yet to be conducted on this and similar systems. This study examines (1) how the oxide nanodots retain their character during the deposition and (2) how the nanodots both influence, and are influenced by, the local potential-energy landscape that promotes spontaneous assembly into coherent stacks. This is done by growing the film subject to slight variations in the processing parameters which may influence the nature of the heterogeneity of any given layer in the film. Particular attention is paid to the influence of varying laser-pulse frequency which determines the time duration by which the potential-energy landscape of a pulsed layer is consolidated in time for the next pulsed layer. The mechanism is also tested for a system in which the embedded nanostructures are made from a non-oxide material (gold). Results consist of microstructure (cross-sectional HRTEM, XRD, surface SEM), transport properties (critical temperature and critical current), and magnetic susceptibility.

**14:54**

**W38 3 Magnetic coupling between vortices in superconductors and adjacent magnetic layers** MASAKI SUENAGA, QIANG LI, QING JIE, *Brookhaven National Laboratory* We presented a study of magnetic coupling between vortices in superconductors and adjacent magnetic layers in two systems: superconductor/magnetic multilayers and HTS films on magnetic substrates. The flux motion in superconductor and the behavior of magnetic layer (or magnetic substrate) were captured by quantitative Magneto-optical imaging (MOI) technique with an external magnetic field applied perpendicular to the sample surface and varied along a whole hysterisis loop cycle. Bulk dc SQUID magnetization, ac loss, and direct transport measurements were performed to compliment the MOI studies. It was found that magnetic substrate has limited effect on transport properties of HTS films, although some enhancement of $J_c$ was observed near $T_c$ in the multilayers due to the magnetic coupling. However, magnetic substrate did result in significant reduction of the ac losses.

**15:06**

**W38 4 Time resolved magneto-optical imaging of ac currents in YBCO conductor.** ANDREA LUCARELLI, GUNTER LUEPKE, *Department of Applied Science, The College of William and Mary, Williamsburg, VA* TIMOTHY HAUGAN, GEORGE LEVIN, PAUL BARNES, *Power Generation Branch, Air Force Research Laboratory, Wright-Patterson AFB, OH* The use of $YBa_2Cu_3O_{7-\delta}$ (YBCO) in ac applications, whether with applied ac currents or alternating magnetic fields, is strictly related to the availability of long-length ac-tolerant YBCO coated conductor. These ac applications, such as fully superconducting generators and motors or transformers, may operate with ac currents in a range of frequencies from tens of Hz up to a thousand Hz. We present a newly developed time-resolved magneto-optical imaging (MOI) technique for studying high-temperature superconductors (HTS) with applied alternating currents (AC) in the frequency range 30 – 1000 Hz. The evolution of the magnetic flux density distribution in YBCO thin films and coated conductors is studied as a function of the phase of the applied AC current. Time- and spatially-resolved images of the magnetic flux profiles are presented for a detailed series of values of the phase. A quantitative analysis of the data allows us to calculate the current density profiles at different phases. We observe for the first time that the maxima of the AC current density is shifted from the edges further inside the sample which may be caused by the higher self-induced field in that region.

**15:18**

**W38 5 Scanning Hall probe microscopy of AC losses in YBCO coated conductors** RAFAEL DINNER, KATHRYN MOLER, M. R. BEASLEY, *Stanford University* D. MATTHEW FELDMANN, DAVID LARBALESTIER, *University of Wisconsin—Madison* Magnetic imaging of current-induced vortex movement in superconducting films yields detailed information about dissipation and the path of an applied current. In our cryogenic scanning Hall probe microscope, a micro-Hall probe is rastered near the sample surface with submicron resolution and centimeter scan range. Hall probe time traces taken at each point are assembled into movies of the flux penetration as a function of time over a cycle of AC sample current. We image coated conductors—films of the high-temperature superconductor YBCO grown on metal tapes which give rise to grain boundaries. We then isolate the effects of the boundaries by imaging YBCO grown on bicrystal substrates that induce a single boundary at various angles to the current path. Current density, electric field, and dissipation distributions are reconstucted from the images.

**15:30**

**W38 6 Twins, Their Microstructure and Correlation to Critical Current Densities in Superconducting Melt-Textured Grown Y-Ba-Cu-O** SIU-WAI CHAN, *Columbia University* LIN-FENG MEI, *Columbia University* APPLIED PHYSICS TEAM, Refinement of twin microstructure in melt-textured grown (MTG) Y-Ba-Cu-O (YBCO) is engineered by annealing at different temperatures. This isothermal method exploits the temperature dependence of twin-boundary-energy. The twin boundary energy is obtained by two independent methods: (1) twin spacing and (2) twin-tip shape. The twin boundary energy measurement is

accomplished with transmission electron microscopy. Refinement of twin spacing with increasing temperature is confirmed. Twin spacing decreases from 190 nm to 54 nm as the temperature increases from 450 to 680°C. Critical current measurements support that a sample with a higher density twin density often results in a higher pinning-force i.e. 3.4 x $10^8$ N/m$^3$ versa 1.2 x $10^8$ N/m$^3$.

**15:42**

**W38 7 Scanning Hall Probe Microscope and Imaging of Vortex Penetration into Nb** A. BOVE, *Purdue University, Phys. Dpt.* N. KUNDTZ, A. M. CHANG, *Duke University, Phys. Dpt.* V. GUSIATNIKOV, *Stanford Research Systems* ART LICHTENBERGER, *U. of Virginia, ECE.* We report on the construction of a scanning Hall probe microscope with 100 nm lateral resolution and a large scan range, which exceeds 40 $\mu$m at 4.2 K. The microscope is based on the beetle design and operates between room temperature and 1.5 K. The DSP-based control electronics achieves a high (100 kHz) sampling rate and a low noise. The system is capable of simultaneous tunneling and Hall signal acquisition. The Hall sensor for measuring local magnetic fields is fabricated on a GaAs heterostructure through standard EBL and wet etching. It has an active area of 300 nm x 300 nm and a sensistivity of 0.2 Ω/Gauss. We will present (1) a description of the microscope, and (2) progress on imaging the penetration of vortices and the growth of vortex dendritic patterns into thin Nb films[1] and grid arrays[2].

**15:54**

**W38 8 Vortex Pinning in a $YBa_2Cu_3O_{7-\delta}$ Thin Film** OPHIR M. AUSLAENDER, NICHOLAS C. KOSHNICK, KATHRYN A. MOLER, *Stanford University* ROB A. HUGHES, JOHN S. PRESTON, *McMaster University* Vortices, and the nanoscale structures that pin them, are important both fundamentally and for the development of high temperature superconductor technologies. We use a home-built magnetic force microscope (MFM) to determine the depinning forces required to move individual vortices in a 200nm thick $YBa_2Cu_3O_{7-\delta}$ film. Our results indicate a wide distribution of depinning forces for different vortices. A comparison between distributions at various temperatures is underway, qualitatively showing a decrease of forces with increasing temperature.

**16:06**

**W38 9 Anomalous Slow Relaxation of the Magnetization in $Y_{1-x}Pr_xBa_2Cu_30_{7-\delta}$*** P. GYAWALI, V. SANDU,[†]C. C. ALMASAN, *Kent State University* B. J. TAYLOR, M. B. MAPLE, *University of California at San Diego* We have investigated the time $t$ evolution of the irreversible magnetization $M_{irr}$ in a series of single crystals of $Y_{1-x}Pr_xBa_2Cu_30_{7-\delta}$, $x = 0.13$ ($T_c = 82$ K), $x = 0.34$ (($T_c = 50$ K), and $x = 0.47$ (($T_c = 34$ K), all displaying a second peak in magnetization. In all cases, $M_{irr}(t)$ follows the well known law of relaxation, $M_{irr}(t) \propto [\mu k_B T/U_o ln(t/t_0)]^{-1/\mu}$. For fields/temperatures lower than the corresponding values of the second magnetization peak, $\mu$ is anomalously large, $2.5 \leqslant \mu \leqslant 4$, in contrast with theoretical predictions which gives a maximum value of 2.5, and with data reported for other cuprates. These large $\mu$ values in the vortex glass state, which give rise to a low relaxation rate, occur for all Pr doping and could be due to the presence of Pr ions. In contrast, at fields/temperatures above the second magnetization peak, $\mu$ decreases to values expected from theories of plastic vortex liquid and validated by most experimental reports.

**W38 10 Effective Action for Vortex Dynamics in Clean d-wave Superconductors** PREDRAG NIKOLIC, SUBIR SACHDEV, *Harvard University* We describe influence of gapless nodal quasiparticles on vortex dynamics in clean two-dimensional d-wave superconductors. At zero temperature, the guasiparticles give rise to a finite renormalization of vortex mass, as well as a universal sub-Ohmic damping of vortex motion. Slow vortex motion is dissipated only at finite temperatures, or when some perturbation, such as disorder, creates a finite quasiparticle density of states at the gap nodes. These results are obtained by a non-perturbative derivation of the effective vortex action, where the quasiparticles are integrated out exactly in a continuum functional formalism. Fortunately, an uncontrolled perturbative analysis reaches the same conclusions, and all findings are reflected in a simple scaling argument where the gapless Dirac quasiparticles are regarded as a quantum-critical system. Our results appear to differ from those of the semiclassical theory, which obtains singular corrections to a vortex mass appearing in transport equations.

**16:30**

**W38 11 Flux pinning and Critical current density in $La_{2-x}Sr_xCuO_{4+d}$** HASHINI MOHOTTALA, B. O. WELLS, J. I. BUDNICK, W. A. HINES, *University of Connecticut* A. R. MOODENBAUGH, *BNL* F.C. CHOU, *MIT* UNIVERSITY OF CONNECTICUT TEAM, BNL COLLABORATION, MIT COLLABORATION, We have studied the magnetic characteristics of the critical states in a series of samples of the type $La_{2-x}Sr_xCuO_{4+d}$ that is doped with both Sr and excess O incorporated using electrochemistry. These samples spontaneously phase separate and show both a superconducting phase with $T_C$ near 40 K and a magnetic phase with $T_M$ near 40 K. Our previous studies established that the superconducting phase is similar to an optimally doped sample while the magnetic phase is consistent with the static spin density wave reported for x=1/8 Sr or Ba doped samples. Magnetization data at various temperatures showed large reversibility in all the samples. The critical current densities $J_C(0)$ values were at least an order of magnitude smaller than that of the reported values for $YBa_2Cu_3O_{7-d}$and $La_{2-x}Sr_xCuO_4$. At higher fields $J_C(H)$ was smaller indicating the existence of weak flux pinning in the system. Based on our magnetization data we conclude that the vortex lattice pinning is different from non-phase separated cuprates. This work was partially supported by the US-DOE through contract DE-FG02-00ER45801 and the Cottrell Scholar Program of the Research Corporation.

**W38 12 Magnetic Pinning in Nb and YBCO Thin Films by Co/Pt Multilayers with Perpendicular Magnetic Anisotropy** X.M. CHENG, L.Y. ZHU, C.L. CHIEN, *Johns Hopkins University* MARTA Z. CIEPLAK, Z. ADAMUS, A. ABAL'OSHEV, M. BERKOWSKI, *Inst. of Physics PAS, Warsaw, Poland* Magnetic pinning of vortices has the advantage over intrinsic pinning in that the superconducting critical current can be reversibly tuned by the magnetic field (H). Magnetic pinning by Co/Pt multilayers with perpendicular magnetic anisotropy has been studied in two ferromagnetic/superconducting bilayers of Nb and YBCO with different superconducting properties (e.g. penetration depth $\lambda$). Magnetic force microscopy reveals similar magnetization (M) reversal process in the two cases, both exhibiting a large density of narrow residual domains but with different domain width w at the final reversal stage. However, the magnetic pinning, revealed by the M-H loop shape in the superconducting state, is different. The Nb film exhibits an enhancement of M with the strongest effect during the final reversal stage, while the YBCO film shows a suppression of M in the vicinity of central M peak and an enhancement of M in large magnetic fields. These different behaviors are related to the different $\lambda$/w ratio in the two cases.

**16:54**

**W38 13 Flux penetration in a ferromagnetic/superconducting bilayer utilizing perpendicular magnetic anisotropy*** MARTA Z. CIEPLAK, Z. ADAMUS, A. ABAL'OSHEV, M. BERKOWSKI, *Inst. of Physics, PAS* M. KONCZYKOWSKI, *Ecole Polytechnique, Palaiseau, France* X. M. CHENG, L. Y. ZHU, C. L. CHIEN, *Johns Hopkins University* The Hall sensor array is a useful tool for measuring local magnetic fields. An array of miniature Hall sensors has been used to study the flux penetration in a ferromagnetic/superconducting (F/S) bilayer consisting of Nb as the S layer and Co/Pt multilayer with perpendicular magnetic anisotropy as the F layer, separated by an amorphous Si layer to avoid proximity effect. The F layer is first premagnetized to different magnetization reversal stages to obtain various magnetic domain patterns. The effect of these domain patterns on the flux behavior in the S layer is then studied at various temperatures in the superconducting state. We have observed that, in addition to the vortex pinning enhancement, some domain patterns strongly increase the first penetration field and induce large thermomagnetic instabilities (flux jumps), which are not detectable by magnetometry. We also discuss the profiles of the flux distribution across these F/S bilayers.

**W39 1 Finite size scaling analysis of the helicity modulus and the inverse dielectric constant in two capacitvely coupled Ultrasmall 2D Josephson Junction Arrays*** GUILLERMO RAMIREZ-SANTIAGO, *Instituto de Fisica, UNAM (MEXICO)* JORGE JOSE, *Dept. of Physics, University at Buffalo, State University of New York* We have carried out a finite size scaling analysis of the helicity modulus $\Upsilon_i$ and the inverse dielectric constant $\epsilon_i$, $(i = 1,2)$ of two capacitively coupled Josephson junction arrays with charging energy, $E_c$, and Josephson coupling energy, $E_J$. The arrays are coupled via the capacitance, $C_{\rm inter}$, at each site of the lattices. The parameter that measures the importance of quantum fluctuations in the i-th array is, $\alpha_i \equiv E_{c_i}/E_{J_i}$. We have considered the interplay between vortex and charge dominated individual array phases by means of extensive path integral Monte Carlo simulations. It has been found that this system develops a *reentrant transition* in $\Upsilon(T,\alpha)$, at low temperatures, when one of the arrays is in the semiclassical limit (i.e. $\alpha_1 = 0.5$) and the quantum array has $2.0 \leqslant \alpha_2 \leqslant 2.5$, for $C_{\rm inter} = 0.26087, 0.52174, 0.78261, 1.04348$ and $1.30435$. Similar behavior was obtained for larger values of $\alpha_2 = 4.0$ with $C_{\rm inter} = 1.04348$ and $1.30435$.

**W39 2 RF critical current of Josephson junction** VLADIMIR MANUCHARYAN, ETIENNE BOAKNIN, MICHAEL METCALFE, R. VIJAY, *Department of Applied Physics, Yale University* IRFAN SIDDIQI, *Department of Applied Physics, Yale University, Department of Physics, University of California, Berkeley* ANDREAS WALLRAFF, R.J. SCHOELKOPF, MICHEL DEVORET, *Department of Applied Physics, Yale University* The Josephson junction is the only radio-frequency electrical element which can be both non-dissipative and non-linear at low temperatures. While the stability of the junction dynamics in presence of a DC drive has been extensively studied, the microwave drive case is relatively poorly understood, at least experimentally. It is explored by driving an increasing AC current through a Josephson junction which is effectively biased by an AC voltage generator in series with a finite linear imbedding impedance $Z(\omega)$. For small signal amplitude, the junction behaves as a linear inductor. For higher signal amplitudes, we show that there exists a critical current $I_c^{RF}$ beyond which the dynamics of the junction changes qualitatively as a result of its non-linear characteristic. This AC critical current depends strongly on the biasing impedance. We provide a detailed stability diagram from experimental measurements and show that it obeys the simple theory of nonlinear resonance.

**14:54**

**W39 3 Parametric amplification with the Cavity Josephson Amplifier** ETIENNE BOAKNIN, R. VIJAY, MICHAEL METCALFE, VLADIMIR MANUCHARYAN, *Department of Applied Physics, Yale University* IRFAN SIDDIQI, *Department of Applied Physics, Yale University; Department of Physics, University of California, Berkeley* MICHEL DEVORET, *Department of Applied Physics, Yale University* Several types of amplifiers are approaching the quantum limit, namely, the SQUID, the RF-SET (radio-frequency single electron transistor) and the QCP (quantum point contact). We investigate a new amplifier which harnesses the nonlinearity of a Josephson junction for parametric amplification. It consists of a Josephson junction placed in a high-quality on-chip superconducting cavity, pumped by microwave radiation. The high level of control over the environment provides a system which is well described by the simplest nonlinear oscillator for-

malism with no adjustable parameters. such that theoretical predictions can be compared with experimental results. The planar geometry of the device can accommodate operation over a wide range of frequencies, opening the possibility of a quantum limited amplifier for practical use. We present preliminary results on the performance of the amplifier and discuss the possibility of observing quantum noise squeezing.

**W39 4 Josephson current through a molecular transistor in a dissipative environment** TOMAS NOVOTNY, ALESSANDRA ROSSINI, KARSTEN FLENSBERG, *Nano-Science Center, Univeristy of Copenhagen, Denmark* THEORY GROUP TEAM, We study the Josephson coupling between two superconductors through a single correlated molecular level, including Coulomb interaction on the level and coupling to a bosonic environment. All calculations are done to the lowest, i.e., the fourth, order in the tunneling coupling and we find a suppression of the supercurrent due to the combined effect of the Coulomb interaction and the coupling to environmental degrees of freedom. Both analytic and numerical results are presented.

**15:18**

**W39 5 Vortex doping into finite-sized superconducting Pb networks.*** TAKEKAZU ISHIDA, HIROSHI NODA, MASARU KATO, *Osaka Prefecture University, Sakai, Osaka 599-8531* OSAMU SATO, *Osaka Prefectural College of Technology, Neyagawa, Osaka 572-8572* MASAHIKO HAYASHI, HIROMICHI EBISAWA, *Graduate School of Information Sciences, Tohoku University, Sendai980-8579* KAZUO SATOH, TSUTOMU YOTSUYA, *Technology Research Institute of Osaka Prefecture, Izumi, Osaka 594-1157* Superconducting finite-sized Pb square networks with 2x2, 3x3, 5x5 and 10x10 square holes have been fabricated by electron beam lithography of photoresist layer and a lift-off process after depositing Pb film on the resist patterns. The application of magnetic field corresponds to the particle (vortex) doping into networks. Vortex image observations were carried out by a SQUID microscope to compare with the theoretical predictions. We found the exactly reversed pattern between the vortex doping x and the anitivortex doping x into the fully occupied network (x=1/4). The Ginzburg-Landau calculations show that there are several vortex configurations with almost equivalent free energy. The complete coincidence of the two patterns might be due to residual randomness caused in the fabrication processes.

**W39 6 Nano-mechanical-resonator induced synchronization in Josephson junction arrays*** BRAD TREES, *Ohio Wesleyan University* STEFAN NATU, *Ohio Wesleyan University* DAVID STROUD, *The Ohio State University* We show that a serial array of N critical-current disordered, underdamped, Josephson junctions coupled piezoelectrically to a nanomechanical (NEM) oscillator results in phase locking (synchronization) of the junctions. We find a semi-classical solution to the coupled differential equations generated by Heisenberg operator equations, based on a Hamiltonian including the following effects: charging and Josephson energies of the junctions, junction dissipation, effect of a dc bias current, and an undamped simple harmonic oscillator representing the NEM. Synchronization of the array is signaled by a step in the current- voltage (I-V) curve. Stability analysis reveals that the phase-locked junctions are neutrally stable at the bottom and top of the step. We calculate an analytic expression for the location of the resonance step in the I-V curve. We also find it is possible to set a desired number $N_a \leqslant N$ of junctions on the resonance step, with $N_a - N$junctions in zero-voltage state.

**W39 7 Effect of Microwaves on the Current-Phase-Relation of diffusive SNS Junctions** M. FUCHSLE, J. BENTNER, P. TRANITZ, W. WEGSCHEIDER, C. STRUNK,* We investigate the current-phase-relation (CPR) of long diffusive superconductor - normal metal - superconductor (SNS) Josephson junctions under microwave irradiation. The samples consist of narrow Ag bridges with a length between 300 and 500 nm inserted into a Nb loop by shadow evaporation on top of a mesoscopic Hall cross. Our Hall-sensors are based on high mobility GaAs/AlGaAs- heterostructures. They directly detect the magnetic response of the loop to an external magnetic field, from which the full CPR can be reconstructed. The measurements are done in the high-temperature regime $E_{Th} < k_B T$, where $E_{Th}$ is the Thouless energy of the junctions and $\hbar\omega \approx E_{Th}$. We find that the CPR can be strongly affected by microwave radiation. A strong deviation of the CPR from the well-known sinusoidal $I(\Phi)$ relation is observed: depending on the applied frequency and amplitude, the supercurrent can be strongly suppressed for phase differences in the vicinity of $\phi = \pi$. At some frequencies, the sin($\Phi$) term in the CPR can be completely suppressed, resulting in a dominant second harmonic.

**W39 9 Crossover from single electron counting to Cooper pair counting** TIM DUTY, JONAS BYLANDER, PER DELSING, *Microtechnolgy and Nanoscience, Chalmers University of Technology, Sweden* We present experimental studies of charge transport in a one-dimensional array of Josephson junctions using a single charge counting device based upon a radio-frequency single-electron transistor[1]. We observe a crossover from time-correlated tunneling of single electrons to Cooper pairs as a function of an applied magnetic field. At relatively high magnetic field, single electron transport dominates and the frequency is given by f=I/e. As the magnetic field is lowered the frequency gradually shifts to f=I/2e, indicating tunneling of Cooper pairs. [1]Jonas Bylander, Tim Duty and Per Delsing, Nature 434 (2005) 285.

**W39 10 1/f Noise in Josephson Junctions** MAGDALENA CONSTANTIN, CLARE C. YU, *Department of Physics and Astronomy, University of California, Irvine* A major obstacle to the realization of Josephson junction qubits is decoherence due to noise. Our goal is to understand the microscopic mechanisms which lead to the 1/f critical current noise spectrum at low temperatures. One possible source of critical current fluctuations is the presence of defects such as two level systems in the insulating junction barrier. We present a model of the critical current noise spectrum and compare it with recent experiments.

**16:30**

**W39 11 Decoherence in Josephson Vortex Quantum Bits** JU KIM, RAMESH DHUNGANA, *University of North Dakota* KEE-SU PARK, *Pohang University of Science and Technology* We investigated decoherence of a Josephson vortex quantum bit (qubit) in dissipative and noisy environment. As the Josephson vortex qubit is fabricated by using a long Josephson junction (LJJ), we use the perturbed sine-Gordon equation to describe the phase dynamics representing a two-state system and estimate the effects of quasiparticle dissipation and weakly fluctuating critical and bias currents on the relaxation time $T_1$ and on the dephasing time $T_\phi$. We show that the critical current fluctuation does not contribute to dephasing of the qubit in the lowest order approximation. Modeling the weak current variation from magnetic field fluctuations in the LJJ by using the Gaussian colored noise with long correlation time, we show that the time $T_2$ is limited by the low frequency current noise at very low temperatures. Also, we show that a ultra-long coherence time may be obtained from the Josephson vortex qubit by using experimentally accessible value of physical parameters.

**16:42**

**W39 12 Phase-space theory for nonlinear detectors of superconducting qubits** IOANA SERBAN, *Ludwig-Maximilians-Universitaet, Munich* FRANK WILHELM, *University of Waterloo, Waterloo, ON* Superconducting circuits are envisioned as quantum bits and demonstrate quantum-coherent features i.e. Rabi oscillations and Ramsey fringes. The detector (e.g. a superconducting quantum interference device, SQUID) can itself be described by a Hamiltonian and treated quantum-mechanically.This allows more insights into the measurement process. Several experimental groups have recently realized good detectors with strong coupling to the measured system, where nonlinear dynamics plays a significant role. Motivated by the recent experiment [1], we study a nonlinear detector where the qubit couples to the square amplitude of a driven oscillator, which can be used for dispersive detection. We use a complex-environment approach treating the qubit and the oscillator exactly, expressing their full Floquet-state master equations in phase space. We investigate the backaction of the environment on the measured qubit and explore the resolution of measurement. We discuss the possibility for using the squeezing capability of the nonlinear interaction for beating the standard quantum limit and emphasize the resulting role of non-Gaussian and non-Markovian effects in the backaction including significant non-exponential shape of the coherence decay. **W39 13 Quasiparticle Poisoning in a Cooper Pair Box caused by a measuring SET*** CARLOS SANCHEZ, *Laboratory for Physical Sciences* BENJAMIN PALMER, *Laboratory for Physical Sciences* MARC MANHEIMER, *Laboratory for Physical Sciences* FRED WELLSTOOD, *University of Maryland* We have developed a model to calculate the average charge on a Cooper pair box in the presence of quasiparticle poisoning. The model uses a master equation approach to find the probabilities for the box to be in the even or odd state. The transition rates between the two states are calculated assuming a fixed number of non-equilibrium quasiparticles in the leads and island of the box. We fabricated Al/AlOx/Al devices with a Cooper pair box capacitively coupled to an SET and measured the charge on the box for SET bias currents ranging from about 1 pA to 1 nA. We find good agreement between the theory and measurements in the temperature range from 60 mK to 300 mK. For large SET bias the poisoning in the Cooper pair box increases and the charge staircase develops additional features. Our model is capable of qualitatively reproducing the features induced by the measuring SET.

**W39 14 Cavity Josephson Bifurcation Amplifier: a microwave readout for a superconducting qubit** MICHAEL METCALFE, ETIENNE BOAKNIN, VLADIMIR MANUCHARYAN, *Department of Applied Physics, Yale University, New Haven, CT, 06511* SIMON FISSETTE, *Departement de Physique, Universite de Sherbrooke, Sherbrooke, Canada* IRFAN SIDDIQI, RAJAMANI VIJAYARAGHAVAN, CHAD RIGETTI, ANDREAS WALLRAFF, ROBERT SCHOELKOPF, MICHEL DEVORET, *Department of Applied Physics, Yale University, New Haven, CT, 06511* A Josephson junction, embedded in a microwave circuit that displays a resonance, and driven near the resonance frequency by a sinusoidal signal with adequate amplitude, can adopt one of two dynamical metastable states. The transition between the two states can be triggered by a small variation in the environment of the junction. This switching phenomenon naturally lends itself to the readout of a superconducting quantum bit. We are approaching the problem of mapping the two states of a qubit onto the two dynamical states of the Josephson junction by placing it in an on-chip coplanar waveguide superconducting cavity. We present the characterization of the cavity Josephson bifurcation amplifier (CJBA) and show that it follows theoretical predictions over a wide range of operating frequencies and bandwidth. This architecture provides a calculable RF environment which can be readily optimized. We also discuss a multi-resonator chip geometry that would implement the multiplexed readout of more than 10 qubits.

**17:18**
**W39 15 Quantum dynamics and leakage of the superconducting flux qubit** EZEQUIEL POZZO, *Centro Atomico Bariloche, Argentina* DANIEL DOMINGUEZ, *Centro Atomico Bariloche, Argentina* We study the quantum dynamics of the superconducting flux qubit of Mooij et al, which consists on a SQUID with 3 Josephson junctions. We simulate the corresponding time-dependent Schrodinger equation and also eigenfunctions and eigenvalues are computed. We calculate the dynamical evolution of the qubit device after a pulse in magnetic field is applied from the operational point at half flux quantum. The system is started in the lowest energy level and we calculate the leakage into the non-computational basis after the pulse is applied, computing the change in the average population of the two lowest energy levels. The leakage is analyzed for different pulse intensities. Two different regimes are found for weak and strong pulses. We discuss the relationship of the response to strong pulses with the quantum chaoticity of the spectrum of high energy levels outside the computational space.

**W40 1 Quantum Communication via Frequency Upconversion*** AARON VANDEVENDER, PAUL KWIAT, *University of Illinois at Urbana-Champaign* We describe a method for efficiently and coherently converting photonic qubits from one frequency to another for quantum communication. The conversion is done using quasi-phase-matched up-conversion in a Periodically Poled Lithium Niobate (PPLN) crystal. We have observed 99%-efficient and 95%-coherent conversion which allows faithful conversion of ''flying'' qubits to ''stationary'' qubits for use in quantum communication. We have also used up-conversion to prepare photons in arbitrary superpositions of widely separated frequency states, enlarging the accessible Hilbert space for communication of quantum states. Finally, we have seen 56%-efficient detection of 1550-nm photons using up-conversion to the visible and silicon Avalanche Photodiodes (APD), which would enhance the performance of quantum communication protocols (e.g., BB84) based on infrared (IR) photons over what is achievable with conventional IR single-photon detectors.

**14:42**
**W40 2 Relativistic Quantum Cryptography** EVAN JEFFREY, PAUL KWIAT, *University of Illinois at Urbana-Champaign* We present results from a relativistic quantum cryptography system which uses photon storage to avoid bit sifting, in principle doubling the useful key rate. Bob stores the photon he receives from Alice in an optical delay line until she sends him the classical basis information, allowing him to measure every photon in the correct basis. Accounting for loss in our 489-ns storage cavity, we achieve a 66% increase in the BB84 key rate. The same system could be used for even greater gains in either the six-state protocol or cryptography using a larger Hilbert space. We show that the security of this protocol is equivalent to standard BB84: assuming the quantum and classical signals are space-like separated, no eavesdropper bound by special relativity can access both simultaneously.

**14:54**
**W40 3 Quantum Cryptography in Existing Telecommunications Infrastructure** DANIEL ROGERS,* JOSHUA BIENFANG, ALAN MINK, BARRY HERSHMAN, ANASTASE NAKASSIS, XIAO TANG, LIJUN MA, DAVID SU, CARL WILLIAMS, CHARLES CLARK, *National Institute of Standards and Technology* Quantum cryptography has shown the potential for ultra-secure communications. However, all systems demonstrated to date operate at speeds that make them impractical for performing continuous one-time-pad encryption of today's broadband communications. By adapting clock and data recovery techniques from modern telecommunications engineering practice, and by designing and implementing expeditious error correction and privacy amplification algorithms, we have demonstrated error-corrected and privacy-amplified key rates up to 1.0 Mbps over a free-space link with a 1.25 Gbps clock. Using new detectors with improved timing resolution, careful wavelength selection and an increased clock speed, we expect to quadruple the transmission rate over a 1.5 km free-space link. We have identified scalable solutions for delivering sustained one-time-pad encryption at 10 Mbps, thus making it possible to integrate quantum cryptography with first-generation Ethernet protocols.

**15:06**
**W40 4 Alternative Design for Quantum Cryptographic Entangling Probe** HOWARD BRANDT, *U.S. Army Research Laboratory* An alternative design is given for an optimized quantum cryptographic entangling probe for attacking the BB84 protocol of quantum key distribution [1], [2]. The initial state of the probe has a simpler analytical dependence on the set error rate to be induced by the probe than in the earlier design. The new device yields the same maximum information to the probe for a full range of induced error rates. As in the earlier design, the probe contains a single CNOT gate which produces the optimum entanglement between the BB84 signal states and the correlated probe states. [1] H. E. Brandt, Phys. Rev. A **71**, 042312 (2005). [2] H. E. Brandt, ''Design for a quantum cryptographic entangling probe,'' to appear in J. Mod. Optics (2005).

**15:18**
**W40 5 $\pi/3$ Phase-Shift Quantum Searching** LOV GROVER, *Bell Labs, Lucent Technologies* Quantum searching normally consists of an alternate sequence of selective inversion and diffusion operations. The algorithm has been extensively studied and is well understood. However, there was a surprising result that was discovered last year. According to this, if we change the selective inversions to $\pi/3$ phase shifts and adjust the sign of the phase shift in a prescribed manner, we obtain an algorithm that converges monotonically towards the solution [1]. This is in contrast to the well-known search algorithm that has an oscillatory character. This leads to a number of new and interesting applications. For example, if we consider a situation where the probability of getting a target state for a random item, is $1 - \epsilon$ (with $\epsilon$ unknown), then the probability of getting a target state after a single query in

the new algorithm, can be increased to $1 - \epsilon^3$, classically this can be increased to only $1 - \epsilon^2$. The performance of the new algorithm has recently been proved to be optimal. Another important application of this technique is in correction of systematic errors [2]. (1) L.K. Grover (2005), Fixed-point quantum search, Phys. Rev. Letters, Oct. 3, 2005. (2) B.W. Reichardt and L.K. Grover, Quantum error correction of systematic errors using a quantum search framework, Phys. Rev. A, Oct. 25, 2005

**W40 6 Relativistic Connection of Continuous and Discrete Quantum Walks** FREDERICK STRAUCH, *National Institute of Standards and Technology* Quantum algorithms, based on a quantum-mechanical generalization of random walks, have been shown to be very effective at solving local search problems. These quantum walks come in two very different forms (discrete and continuous-time) with surprisingly similar properties. An open problem has been to identify just what makes these two walks so similar. In this talk I present the analytical connection of these two walks, by way of an analogy with properties of the Dirac equation, including entanglement, zitterbewegung, and most importantly, relativistic wave-packet spreading.

**15:42**

**W40 7 Mixing and Decoherence in Continuous-Time Quantum Walks** LEONID FEDICHKIN, DMITRY SOLENOV, CHRISTINO TAMON, *Clarkson University* VLADIMIR PRIVMAN, *Clarkson University* We present analytical results showing that decoherence can be useful for speed-up of mixing in a continuous-time quantum walks on finite cycles. Our treatment of continuous-time quantum walks includes a continuous monitoring of all vertices that induces the decoherence process. We identify the dynamics of the probability distribution and observe how mixing times undergo the transition from quantum to classical behavior as our decoherence parameter grows from zero to infinity. Our results show that, for small rates of decoherence, the mixing time improves linearly with decoherence, whereas for large rates of decoherence, the mixing time deteriorates linearly towards the classical limit. In the intermediate region of decoherence rates, our numerical calculations confirm the existence of a unique optimal rate for which the mixing time is minimized.

**15:54**

**W40 8 Decoherence by Correlated Noise and Quantum Error Correction*** EDUARDO NOVAIS, HAROLD U. BARANGER, *Duke University* We study the decoherence of a quantum computer in an environment which is inherently non-Markovian and spatially correlated. We first derive the non-unitary time evolution of the computer and environment in the presence of a stabilizer error correction code. Our results demonstrate that effects of long-range correlation can be systematically reduced by suitable changes in the error correction codes. The new element that we discuss is that the periodic measurements in the QEC method separate the environmental modes into high and low frequencies. This natural ''new'' scale can then be used to better engineer quantum codes. As an example of this general discussion, we study decoherence in a quantum memory protected by Steane's three qubit code. The memory interacts with a bosonic enviroment through the spin-boson Hamiltonian. We calculate explicitly the long-range correlations in this case and demonstrate that a simple change in Steane's code reduces their effect.

**W40 9 Topological Quantum Computing with Only One Mobile Quasiparticle** STEVEN H. SIMON, *Lucent Technologies, Bell Labs* NICK BONESTEEL, *Dept Physics and NHMFL, Florida State University* MICHAEL FREEDMAN, *Microsoft Research* LAYLA HORMOZI, *Dept Physics and NHMFL, Florida State University* NADA PETROVIC, *UC Santa Barbara* In a topological quantum computer, universal quantum computation is performed by dragging quasiparticle excitations of certain two dimensional systems around each other to form braids of their world lines in 2+1 dimensional space-time. We show that any such quantum computation that can be done by braiding $n$ identical quasiparticles can also be done by moving a single quasiparticle around $n - 1$ other identical quasiparticles whose positions remain fixed. This result may greatly reduce the technological challenge of realizing topological quantum computation.

**16:18**

**W40 10 CNOT for Fibonacci anyons with only one mobile quasiparticle*** LAYLA HORMOZI, GEORGIOS ZIKOS, NICK BONESTEEL, *Dept. of Physics and NHMFL, Florida State University* STEVEN H. SIMON, *Bell Laboratories, Lucent Technologies* Certain two-dimensional systems with non-abelian quasiparticle excitations can be used for topological quantum computation (TQC). In TQC qubits are encoded using 3 or 4 quasiparticles and quantum gates are carried out by braiding quasiparticle world lines. We focus on the problem of finding explicit braiding patterns that yield a universal set of quantum gates, using Fibonacci anyons — quasiparticles which are thought to exist in an experimentally observed fractional quantum Hall state at filling fraction $\nu = 12/5$. In previous work[1] we have shown how to construct arbitrary controlled rotation gates (which together with single qubit gates provide a universal set of quantum gates) by moving a pair of quasiparticles from the control qubit around the quasiparticles in the target qubit while keeping the latter at fixed positions. In this talk we show how to take advantage of one of the structural properties of Fibonacci anyons (namely the fusion matrix) to construct a certain class of two-qubit gates (including CNOT) with only *one* mobile quasiparticle — therefore reducing the number of braiding operations by a factor of two.

*This work is supported by US DOE grant DE-FG02-97ER45639.

**16:30**

**W40 11 Quantum Phase Transitions and Typical Case, Polynomial Time Solution of Randomly Generated NP-Complete Problems via Adiabatic Quantum Computation*** WILLIAM KAMINSKY, SETH LLOYD, *MIT* We argue theoretically that adiabatic quantum computation using only polynomial resources can solve almost all members of a nontrivial randomly generated set of NP-complete problem instances, namely the problem of finding the ground states of spin glasses on 3D cubic lattices having independent, identically Gaussian-distributed couplings. The argument uses the droplet model of quantum spin glasses, particu-

larly its prediction that the paramagnet-spin glass transition is unstable to even infinitesimal longitudinal fields. We then review the ongoing debate as to how well the droplet model describes 3D spin glasses and note that those inclined to view the intractability of NP-complete problems as a guiding physical intuition could take the results presented here as justifying greater suspicion toward the droplet model. Finally, due to this uncertainty as well as uncertainty in regard to the typical case classical complexity of this random NP-complete problem, we outline work using rigorous mean-field methods on a NP-complete problem whose typical-case classical complexity on random instances is better established, namely MAX CLIQUE on random graphs.

*This work is supported in part by ARDA and DoD under the AFOSR DURINT Program. WMK gratefully acknowledges fellowship support from the Fannie and John Hertz Foundation.

**16:42**

**W40 12 Adiabatic Quantum Computing in systems with constant inter-qubit couplings** VADIM SMELYANSKIY, *NASA Ames Research Center* SERGEI KNYSH, *Mission Critical Technologies* We propose an approach suitable for solving NP-complete problems via adiabatic quantum computation with an architecture based on a lattice of interacting spins (qubits) driven by locally adjustable magnetic fields. Interactions between qubits are assumed constant and instance-independent, programming is done only by changing local magnetic fields. Implementations using qubits coupled by magnetic-dipole, electric-dipole and exchange interactions are discussed.

**16:54**

**W40 13 Quantum Phase Transition and complexity of adiabatic quantum algorithm for Constraint Satisfaction problem** SERGEI KNYSH, *Mission Critical Technologies* VADIM SMELYANSKIY, *NASA Ames Research Center* We study the dynamics of adiabatic quantum computation (AQC) for solving the problem of satisfiability of randomly chosen clauses, each with 3 Boolean variables (3sat). We map this problem to that of a diluted long-range spin glass in traverse magnetic field and derive a self-consistent equation for the order parameter. We show the existence of the first-order quantum phase transition and investigate analytically and numerically the phase diagram on the plane: strength of the transverse field $\Gamma$ vs the ratio $\gamma$=M/N of a number of clauses M to a number of variables N. We show that the phase transition line approaches $\Gamma=0$ at the point of a classical replica symmetry breaking transition $\gamma_{RSB}$. We discuss the implications of the quantum phase transition for the complexity of the AQC for the 3sat.

**17:06**

**W40 14 Computation in Finitary Quantum Processes** KAROLINE WIESNER, *University of California, Davis* JAMES P. CRUTCHFIELD, *University of California, Davis* We introduce quantum finite-state generators as a first step toward a computational description of quantum dynamical processes. We developed their mathematical foundations, establishing probability conservation, reversibility, and consistency with quantum mechanical laws, and connect the class to the existing theory of finite-state recognizers and generators. These computational models allow for a quantitative description of quantum languages generated by quantum dynamical systems. Their descriptive power is explored via several example quantum dynamical systems.

**17:18**

**W40 15 Some Thoughts Regarding Practical Quantum Computing** DEBABRATA GHOSHAL, RICHARD GOMEZ, *George Mason University* MARCO LANZAGORTA, *US Naval Research Laboratory* JEFFREY UHLMANN, *University of Missouri - Columbia* Quantum computing has become an important area of research in computer science because of its potential to provide more efficient algorithmic solutions to certain problems than are possible with classical computing. The ability of performing parallel operations over an exponentially large computational space has proved to be the main advantage of the quantum computing model. In this regard, we are particularly interested in the potential applications of quantum computers to enhance real software systems of interest to the defense, industrial, scientific and financial communities. However, while much has been written in popular and scientific literature about the benefits of the quantum computational model, several of the problems associated to the practical implementation of real-life complex software systems in quantum computers are often ignored. In this presentation we will argue that practical quantum computation is not as straightforward as commonly advertised, even if the technological problems associated to the manufacturing and engineering of large-scale quantum registers were solved overnight. We will discuss some of the frequently overlooked difficulties that plague quantum computing in the areas of memories, I/O, addressing schemes, compilers, oracles, approximate information copying, logical debugging, error correction and fault-tolerant computing protocols.

## SESSION W41: COLD FUSION
**Thursday Afternoon, 16 March 2006**
**344, Baltimore Convention Center at 14:30**
**Scott Chubb, Naval Research Laboratory, presiding**

**14:30**

**W41 1 Cold Fusion A 17 Year Retrospective** MICHAEL C. H. McKUBRE, FRANCIS L. TANZELLA, *SRI International, Menlo Park, CA.* Seventeen years after the APS voted to refute the reality of Cold Fusion in Baltimore, it is appropriate to consider what has changed. Who was right? We will review the current state of knowledge from the perspective of what we know now compared to what we knew then. Discussion will be made of various avenues of research that have followed from the original Fleischmann-Pons proposal: some failed, some unresolved and some successful.

**14:42**

**W41 2 Recent Developments in Cold Fusion / Condensed Matter Nuclear Science** STEVEN B. KRIVIT, *New Energy Times, 11664 National Blvd., Suite 142, Los Angeles, CA 90064* Krivit is recognized internationally as an expert on the subject matter of cold fusion / condensed matter nuclear science. He is the editor of *New Energy Times*, the leading source of information for the field of cold fusion. He is the author of the 2005 book, *The Rebirth of Cold Fusion* and founder of New Energy Institute, an independent nonprofit public benefit corporation dedicated to accelerating the progress of new, sustainable and environmentally friendly energy sources.

**14:54**

**W41 3 Role of Finite Size in Triggering Excess Heat: Why Nanoscale PdD Crystals Turn on Faster** SCOTT CHUBB, *Research Systems Inc, 9822 Pebble Weigh Ct., Burke, VA 22015* Two persistent questions have been: 1. Why is a finite triggering time required after the near full-loading condition ($PdD_x$, $0.85 \approx < x \rightarrow 1$) before the ExcessH eat effect[1] is observed? 2. Is it possible to identify physical properties of the materials and/or crystals that are used that might be playing a role in the length of the interval of time associated with this phenomenon? In the talk, through a generalization[2] of conventional energy band theory, as it applies to infinitely−repeating, periodic lattices to situations involving finite lattices, I have been able to address both questions. In particular, the tunneling time depends on crystal size. Crystals with dimensions $\approx$ <6nm, which have tunneling times $\approx$microseconds, either cannot provide enough momentum to initiated+d$\rightarrow$ 4He reactions or conduct ion charge so rapidly that collisions occur. Crystals with dimensions $\approx$60 nm create heat and load rapidly ($\approx$3ms). But crystals with dimensions $> \approx$60 microns have tunneling times that are longer than a month.

**15:06**

**W41 4 Resolving the Laughlin Paradox** TALBOT CHUBB, *Physicist Consultant, 5023 N. 38th St., Arlington, VA 22207* For paired Bloch electrons in a metal not subject to Pauli exclusion, the 2-electron Hamiltonian has the form $H = -\hbar^2/4m_e\Delta_{cm} + (2e)U_{lattice}(r_{cm},N_{cell}) + e^2/(N_{cell}r_{12}) - \hbar^2/3m_e\Delta_{12}$, where $r_{cm} = r_1 + r_2, r_{12} = r_1 - r_2$, and $r_1$ and $r_2$ are position vectors in configuration space, involving independent Bravais vectors $R_1$ and $R_2$, such that $R_1 - R_2 = R_{12}$ is an independent Bravais lattice vector, and $N_{cell}$ is the number of mutually shared potential wells over which the 2 electrons are coherently partitioned with entangled local density maxima. At large $N_{cell}$, the magnitude of term $3 <<$ the magnitude of term 1. When coordinate exchange symmetry is satisfied and energy minimized, term 3 cancels term 1 at $r_{12} = 0$, eliminating the singularity in the wave equation, thereby resolving Laughlin's paradox[1]

**15:18**

**W41 5 Dynamics of Non-linear Soft X-Ray Emission from a Plasma Discharge-Driven Hydride Target** GEORGE H. MILEY, YANG YANG, MICHAEL ROMER, MUNIMA HAQUE, IAN PERCEL, ANDREI LIPSON, *University of Illinois at Urbana-Champaign, Urbana, IL, 61801, USA* HEINZ HORA, *University of New S. Wales, Sydney, Australia* A high current discharge apparatus with a pulsed power supply has been constructed and successfully demonstrated an intense soft x-ray ($> 600$ eV) emission during bombardment by a 300 V deuterium plsma discharge. Emission is delayed until $\sim$ 1/2 ms into the msec voltage pulse[1]. Both electron and ion Bremsstrahlung have been ruled out as significant contibutions to the emission. A possible mechanism to explain this highly nonlinear x-ray emission is collective generation of soft x-ray quanta induced by a coherent D-diffusion process near the cathode's surface. This combined with continuous high current deuteron bombardment results in the penetration of recoil deuterons into the inner electron shell of the cathode material, generating x-ray emission.

**15:30**

**W41 6 Control of Tardive Thermal Power** MITCHELL SWARTZ, *JET Thermal Products, Wellesley, MA 02481* Previously, calorimetric improvements including thermal power analysis, dual ohmic controls, noise measurement and time-integration of multi-ring calorimetric systems with waveform reconstruction has led to the development of Phusor$^{TM}$ devices providing undeniable proof of excess heat in palladium heavy water (Pt/$D_2O$/Pd; 0.5 $cm^3$, peak excess power ratios of 2.30 $^{+/-}$ 0.84; 1). We now report improved control of tardive thermal power (TTP) which develops long after the termination of electric input power. From an engineering perspective, this is important because the effective excess power generated is further greatly increased (up to an additional $\sim$ 410% beyond that obtained without tardive thermal power operation); and because this improved means of operation can be coupled into over-unity motors and other work-producing systems. In addition, these systems have revealed further insight into the kinetics of the desired condensed matter reactions.

**15:42**

**W41 7 Progress in Excess of Power Experiments with Electrochemical Loading of Deuterium in Palladium** V. VIOLANTE, *ENEA Frascati Research Center Frascati (Italy)* M. BERTOLOTTI, E. CASTAGNA, C. SIBILIA, *University of Rome La Sapienza Dpt. Energetica Rome (Italy)* IRV DARDIK, *Energetics LLC, 7 Fieldview Lane, Califon, NJ 07830* S. LESIN, T. ZILOY, *Energetics, Ltd, Omer Industrial Park 84965, Israel* F. SARTO, *La Sapienza University, Via Scarpa, 14 00100 (Roma) Italy* F. TANZELLA, MICHAEL C. H. McKUBRE, *International 333 Ravenswood Ave, Menlo Park, CA 94025* A research activity has been carried out, during the last three years, in the field of triggering anomalous heat effects in palladium deuteride. An enhancement of the excess of power reproducibility in deuterated palladium was obtained by using HeNe laser irradiation during electrochemical loading. A preliminary correlation between excess of energy and helium-4 concentration increasing above the background was found. The continuation of the experimental program confirmed that laser triggering produces an interesting gain of reproducibility. An upgrade of the experimental set-up has been realized.

**15:54**

**W41 8 Cavitation Foil Damage** ROGER STRINGHAM, *Firstgate Energies, PO Box 1230 Kilauea, HI 96754, Phone: 808 828 2859* We have developed a much improved cavitation system for sonofusion, compared to our initial systems. The new system is a low mass 1.6 MHz unit that produces 40 watts of excess heat with an acoustic input power of 17 watts. The increase in frequency (to 1.6 MHz from 40 KHz) increases the heat, improves the performance, shows reproducible results, and indicates durability. The calorimetry is a simple in flow through system. The difference between output and input temperature ($T_{out}$ - $T_{in}$) at steady- state, times the flow gives the power (calories/s) output of the sonofusion reactor. The energy density of this system is of the order of commercial energy suppliers.

**16:06**

**W41 9 Isoperibolic Calorimetry Applied To The Pt/$D_2O$ Blank System** MARTIN FLEISCHMANN, *Fellow of the Royal Society, Bury Lodge, Duck Street, Tisbury Salisbury, Wilts, SP3 6LJ, U.K* MELVIN MILES, *Department of Chemistry, University of La Verne, La Verne, CA 91750* Doubts have often been expressed about the precision and accuracy of isoperibolic calorimeters where the heat transfer is controlled by radiation across the vacuum gap of the Dewar cells. Therefore, experiments were conducted on blank systems consisting of Pt cathodes polarized in 0.1 M LiOD/$D_2O$. Both the differential and intergral heat transfer coefficients were evaluated, and the latter based on backward integration of the data sets should be used for accurate evaluations of the experimental data. The heat transfer coefficients obtained are in agreement with values given by the product of the Stefan-Boltzmann coefficient and the radiant surface area. It is shown that the precision of this calorimetry is better than 99.99 percent while the accuracy is close to this figure. This high precision and accuracy allows the determination of the rate of enthalpy generation due to the reduction of oxygen electrogenerated in the cell. This rate was 0.0011 W for oxygen reduction whereas the input enthalpy to the cell was about 0.8 W for these experiments.

**16:18**

**W41 10 New Mechanism of Low Energy Nuclear Reactions Using Superlow** F.A. GAREEV, I.E. ZHIDKOVA, *Joint Institute for Nuclear Research, Dubna, Russia* We proposed a new mechanism of LENR (low energy nuclear reactions)[1]: cooperative processes in the whole system - nuclei+atoms+condensed matter can occur at smaller threshold than the corresponding ones assoiciated with free constituents. The cooperative processes can be induced and enhanced by (''superlow energy'') external fields. The excess heat is the emission of internal energy, and transmutations from LENR are the result of redistribution of the internal energy of the whole system. A review of possible stimulation mechanisms of LENR is presented. We have concluded that transmutation of nuclei at low energies and excess heat are possible in the framework of the known fundamental physical laws: The universal resonance synchronization principle[2], and, based on it, different enhancement mechanisms of reaction rates are responsible for these processes[3,4]. The excitation and ionization of atoms may play the role of a trigger for LENR.

**16:30**

**W41 11 Comments on Summary of Condensed Matter Nuclear Science** XING Z. LI, BIN LIU, QING M. WEI, *Department of Physics, Tsinghua University, Beijing, 100084,China.* SHU X. ZHENG, DONG X. CAO, *Department of Engineering Physics, Tsinghua University, Beijing, 100084, China* Research involving investigations of the production of tritium in electrolytic cells was a topic that was recommended by the Energy Research Advisory Board(ERAB) report of the U. S. Department of Energy (DOE) in November, 1989. Fifteen years later, the evolution of related research has proven that this was an important recommendation. In the talk, a selective resonant tunneling model is used to attempt to explain the initial discoveries of tritium production. Deuterium flux might play a key role for solving the problem of reproducibility. A further investigation is suggested, based on this model.

**16:42**

**W41 12 Excess heat observed during electrolysis of deuterated phosphoric acid with palladium electrodes and a solid state electrolyte in deuterium gas** J.-P. BIBERIAN, *CRMCN, Faculte des Sciences de Luminy,163 Avenue de Luminy, 13288 Marseille cedex 9, France* G. LONCHAMPT, *CEA-Centre D'Etudes Nucleaire, Grenoble (retired); 31 Chemin Malanot, 38700 Corenc, France* We start with the hypothesis that the production of excess heat is occurring at the recombination $H+H\rightarrow H_2$ gas. If the pressure of hydrogen at the time of recombination is high enough, nuclear reactions can occur. In the case of hydrogen $H+H\rightarrow D+e^+$ and in the case of deuterium $D+D\rightarrow He^{-4}$. The high pressure can be obtained using Nernst's law, the potential between a hydrogen electrode and the cathode is given by $E=E_o+RTln(P/P_o)$. There are two sources for the potential: the electrochemical potential which is a characteristic of the metal in the presence of the metal ions, and on the other side,the overpotential for the formation of the hydrogen molecules. In this study we use palladium anodes and cathodes, but the cathode is covered with a thin film of a metal having either a low chemical potential or a high over-voltage for hydrogen formation. When deuterium molecules form at the surface of the electrode, very high pressures can be produced during a very short period of time during which possible nuclear reactions can happen. We show that excess heat is observed with clean palladium foils, and more excess heat is produced when the cathode is covered by a thin, metallic film, constructed using one of many possible metals.

**16:54**

**W41 13 Creating an International Scientific Society as an Act of Scientific Rebellion** WILLIAM COLLIS, *International Society of Condensed Matter Nuclear Science* When a new science is born, it is often necessary to unite dispersed groups of researchers all over the world. In this talk, I intend to describe the process of constituting and managing a new international scientific society covering such diverse issues as: 1.) Rationale; 2.) Initial feelers; 3.) Achieving consensus in the international community; 4.) Choice of jurisdicition; 5.) Corporate format; 6.) Establishing international pre-eminence in law; 7.) Reducing expenses; 8.) Tax minimization; 9.) Decision making; 10.) Democracy & transparency; 11.) Raising funds; 12.) Rewarding excellence; 13.) Online publishing; 14.) Organizing meetings. These issues will be covered with reference to the history of the International Society of Condensed Matter Nuclear Science, which will celebrate its second birthday in March 2006. It currently has nearly 200 members from 23 different countries.

**SESSION W42: FOCUS SESSION: SIMULATIONS OF MATTER AT EXTREME CONDITIONS III**
**Thursday Afternoon, 16 March 2006**

*Contributed Papers*

**14:30**
**W42 1 Ab Initio Studies of High Pressure States of Crystalline Nitromethane.** FRANK ZERILLI, *Naval Surface Warfare Center* JOSEPH HOOPER, *Tulane University* MAIJA KUKLA, *National Science Foundation* We have calculated the mechanical compression curve for solid nitromethane with the ab-initio periodic structure code CRYSTAL using both Hartree-Fock and Density Functional Methods. In addition, calculations with both 6-21G and 6-31G** basis sets were performed and the effect of basis set superposition error was estimated using the counterpoise method. In each calculation the internal atomic coordinates and the crystal lattice parameters were relaxed at constant unit cell volume to the minimum energy configuration. The 6-31G** basis set was optimized by scaling the outer valence and polarization orbitals. It was found that Hartree-Fock calculations with a 6-21G basis set, uncorrected for basis set superposition error, gave the best agreement with experiment. These results may be due to the cancellation of basis set superposition error with dispersion force errors. While this result may be accidental, it appears that it extends to a number of other energetic organic molecular crystals, including beta HMX, PETN, and 1,1-diamino-2,2-dinitroethylene.

**14:42**
**W42 2 Atomistic Studies of Plastic Deformation and Dissipation in Crystalline HMX** EUGENIO JARAMILLO, THOMAS D. SEWELL, *Los Alamos National Laboratory* ALEJANDRO STRACHAN, *Purdue University* We are using large scale molecular dynamics simulations of crystalline octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine (HMX) to better understand the dominant fundamental mechanisms of inelastic deformation and other dissipative processes in anisotropic organic molecular crystals. A fully flexible force field (Smith, G. D. and Bharadwaj, R. K.; J. Phys. Chem. B 1999, 103, 3570) used in numerous preceding studies is used without modification in the present work. Our results, based on the results of simulations containing 25,000-250,000 molecules, indicate a large degree of directional anisotropy in response to compression, for both quasi-static and shock loading. Plastic deformation is observed for some loading directions whereas solid-solid phase transitions are observed for others. The emphasis of the present talk will be identifying and characterizing detailed molecular mechanisms and rate dependencies in those cases for which dislocation-induced plasticity occurs.

**14:54**
**W42 3 First-principles Study of Shock Compressed Carbon** NICHOLS ROMERO, WILLIAM MATTSON, BETSY RICE, *U.S. Army Research Laboratory* The phase diagram of carbon at high pressures and temperatures is of scientific interest to material science, geology and astrophysics. Major issues include the liquid-liquid phase transition, the melting curve of graphite and diamond, the nature of the liquid state and the nature of carbon in the interior of Uranus and Neptune. Strong shock waves generated by lasers, and even nuclear explosions have been used to study carbon at these extreme conditions. Because it is often difficult to replicate these shock-wave experiments, first-principles electronic structure calculations can play a prominent role in verifying, guiding, and interpreting these experiments. We report DFT results for the diamond Hugoniot.

**15:06**
**W42 4 Molecular dynamics simulation of shock compression of silicon** MIKHAIL LADANOV, *University of South Florida* IVAN OLEYNIK, *University of South Florida* SERGEY ZYBIN, *California Institute of Technology* MARK ELERT, *U.S. Naval Academy* CARTER WHITE, *Naval Research Laboratory* Shock compression of condensed matter is a fascinating scientific field that provides an excellent opportunity to probe the fundamental physics and chemistry of matter at extreme pressures and temperatures. In spite of substantial theoretical and experimental efforts, a full understanding of shock-induced elastic and plastic responses and polymorphic phase transitions is still far from complete. These phenomena often occur at the nanometer size and picosecond time scales, which makes molecular dynamics simulations an ideal tool for exploring nanoscale mechanisms of shock induced processes such as chemical reactions and phase transitions. We report the results of a molecular dynamics simulation of shock wave propagation in silicon in the [100], [110], and [111] directions obtained using a classical interatomic potential. Several regimes of materials response are classified as a function of shock wave intensity and crystalline orientation of shock wave propagation using calculated shock Hugoniot. The shock induced chemistry and shock wave splitting are discussed in relation to recent experimental results [1] that indicate an anomalous elastic response of the lattice at high compression ratios. [1] A. Loveridge-Smith, Phys. Rev. Let. **86**, 2349 (2001).

**15:18**
**W42 5 Molecular Dynamics Studies of Dynamical High-Pressure Phase Transitions in Rare-Gas Solids** EUGENE PECHENIK, *School of Physics and Astronomy, The Raymond and Beverly Sackler Faculty of Exact Sciences, Tel Aviv University, Tel Aviv 69978, Israel* GUY MAKOV, *Department of Physics, NRCN, P.O. Box 9001, Beer Sheva, Israel* The phase diagram of pair potential models of rare-gases was studied with respect to the effect of the choice of potential on the nature of the phase diagram. In particular the existence of a high-pressure bcc phase is shown to be potential sensitive. We show using molecular dynamics that the fcc-bcc phase transition cannot be reproduced with the Lennard-Jones (12-6) pair potential, though it is reproduced with the Buckingham pair potential. We propose a simple analytical technique, based on the Einstein theory of a harmonic solid, for predicting an fcc-bcc phase transition in a given system. Using the atomic volume and the pair potential as input, we were able to predict the transition temperature. These findings agree with an earlier work by A. B. Belonoshko et al., Phys. Rev. Lett. 87, 165505 (2001). Additionally, shock wave simulations of several model systems were conducted. The structure of shock wave in this model was examined as a function of shock strength and the existence of a dynamic phase transition was explored.

**15:30**
**W42 6 Interfacial instabilities and structure during high velocity sliding*** J.E. HAMMERBERG, T.C. GERMANN, B.L. HOLIAN, *Los Alamos National Laboratory* R. RAVELO, *University of Texas - El Paso* Interfacial sliding under high pressure loading at high velocities ($0 < v < 1$ km/s) results in a variety of mesosc ale phenomena at extreme strain rates. For ductile metal interfacial pairs, these include nano- and mesoscale dynami c strucutral transitions, local melting and amorphization, material mixing, and localization of plastic deformation. We illustrate these phenomena with large scale NonEquilibrium Molecular Dynamics (NEMD) simulations for Cu/Ag, Ta/Al, and Al/Al interfaces. These suggest universal behavior in sliding velocity for the frictional force and a scaling form for the frictional force vs. velocity at high velocities which will be discussed.

**W42 7 Simulations of Rapid Solidification in Metals at High Pressure.***
FREDERICK H. STREITZ, *Lawrence Livermore National Laboratory*

Although computer simulation has played a central role in the study of nucleation and growth since the earliest molecular dynamics simulations almost 50 years ago, confusion surrounding the effect of finite size on such simulations have limited their applicability. Modeling molten tantalum in systems ranging from 64,000 to 131,072,000 atoms on the BlueGene/L computer, I will discuss the first atomistic simulations of solidification that demonstrate independence from finite size effects during the entire nucleation and growth process, up to the onset of coarsening. Using both our new results and historical data, we show that the observed maximal grain sizes for systems smaller than about 8,000,000 atoms are functions of the simulation size, following the predictions of finite size scaling theory. For larger simulations, a crossover from finite size scaling to more physical size-independent behavior is observed.

*This work was performed under the auspices of the U.S. Department of Energy by University of California Lawrence Livermore National Laboratory under contract No. W-7405-ENG-48.

**W42 8 Properties of molten sodium under pressure from first principles theory.*** JEAN-YVES RATY, *University of Liege, Belgium* ERIC SCHWEGLER, *Lawrence Livermore National Laboratory* STANIMIR BONEV, *Dalhousie University, Canada* Recent measurements of the melting curve of sodium [1] have found a sharp decline in the melting temperatures from 1000 to 300 K in the pressure range from 30 to 120 GPa. In this study, we investigate the stability and structural properties of solid and liquid sodium at high pressure and temperature using first principles molecular dynamics. The experimental melting curve is reproduced from 0 to 120 GPa. The local structure of the liquid is found to be strongly correlated to the multiple finite temperature crystalline phases of sodium. Based on a quantitative analysis of the structural and electronic properties of the solid and liquid phases, we propose an explanation for the unusual melting curve and a new perspective on the phase diagram of sodium. [1] Gregoryantz et al., Phys. Rev. Lett. 94, 185502 (2005).

**W42 9 Melting and phase stability of high-density beryllium** ANDREA TRAVE, ERIC SCHWEGLER, *Lawrence Livermore National Laboratory* FRANCOIS GYGI, GIULIA GALLI, *University of California, Davis and Lawrence Livermore National Laboratory* First-principles Molecular Dynamics calculations have been performed to determine the liquid vs. solid phase boundary for beryllium up to 250 GPa. Shock Hugoniot curves have been calculated for both solid and liquid beryllium in this range of pressures and temperatures to determine the shock melting onset conditions and pressure range of liquid-solid coexistence. The results of these simulations also provide insights on the problem of relative stability of various crystalline forms of beryllium at high temperature. This work was performed under the auspices of the US Department of Energy by the University of California at the LLNL under contract no W- 7405-Eng-48.

**16:42**
**W42 10 Ab initio simulation of intense short-pulse laser irradiation of metals and semi-conductors** VANINA RECOULES, *CEA/DIF - Departement de Physique Theorique et Appliquee* PIERRE-MATHIEU ANGLADE, *CECAM* JEAN CLÉROUIN, *CEA/DIF* GILLES ZÉRAH, *CEA/DIF* STEPHANE MAZEVET, *Los Alamos National Laboratory* The effect of intense ultra-laser irradiation on crystal stability is not completely elucidated. Ultrashort laser pulses heat electrons to a very high temperature and leave the lattice relatively cool since the heat capacity of electrons is much smaller than that of lattice. This non-equilibrium system can be described as two subequilibrium systems : the hot electrons and a cold lattice. We studied the effect of this intense electronic excitations on the interatomic forces and the possible melting of the underlying lattice for a semi-conductor (Si) and two metals (Al and Au). We used *ab initio* linear response to compute the phonon spectrum in the Density Functional Theory framework for several electronic temperatures ranging from 1 to 6 eV. We found that semi-conductors and metals behave in an opposite ways when increasing electronic temperature. Phonon instability appears in silicon at a electronic temperature of 1.5 *eV* inducing the melting of the lattice. Gold samples become more stable. The Debye tem-

perature was deduced from the phonon spectrum and using the Linderman criterion, we showed that gold undergoes a sharp increase of its melting temperature under intense laser irradiation. The same effect is observed for aluminium.

**16:54**

**W42 11 Nonequilibrium Dynamics of Ultracold Neutral Plasmas** THOMAS POHL, *ITAMP, Harvard-Smithsonian Center for Astrophysics, Cambridge* THOMAS PATTARD, *Max-Planck-Institute for the Physics of Complex Systems, Dresden, Germany* JAN-MICHAEL ROST, *Max-Planck-Institute for the Physics of Complex Systems, Dresden, Germany* In a number of recent experiments ultracold plasmas (UNPs) have been produced by photoionizing laser-cooled atomic ensembles [1]. Their very low initial kinetic energies suggest that they are created deeply in the strongly correlated regime. Moreover, UNPs are produced far from equilibrium, leading to a complex relaxation dynamics. We present a hybrid-molecular dynamics approach [2], to describe the long-time plasma evolution while fully taking into account the strongly correlated character of the ionic motion. We demonstrate that the method yields an accurate description of recent measurements [2,3] and allows to address problems beyond present experimental capabilities [3]. It turns out that under the conditions in UNPs the commonly applied Bogoliubov assumption about a hierarchy of relaxation timescale becomes invalid, resulting in an unusual relaxation dynamics connected with a wave-like temperature evolution and an ultimate relaxation to a non-equilibrium undercorrelated state. **W42 12 Shock-Induced Polarization in Distilled Water** YURI SKRYL, *Institute of Mathematics and Computer Science, University of Latvia, Latvia* ANNA BELAK, *Virginia Polytechnic Institute and State University, Blacksburg, VA* MAIJA KUKLJA, *National Science Foundation, DMR/MPS, Arlington, VA* This study is aimed at developing a theoretical model to describe shock-induced polarization in water. The model is based on the notion that polar water molecules tend to align in the shock front due to inertial and stress forces. Analytical formulas for calculation of the shock-induced polarization charge, potential generated by this charge, and accompanied polarization current produced by the shock wave are derived. A comparison with experimental curves for polarization currents suggests that two factors contribute into the measured polarization signal: change of the polarization charge once the wave front enters the sample and change of the sample capacity while the front is progressing across the sample. Good agreement with experimental data on polarization in distilled water leads us to believe that the results obtained bring about a better understanding of mechanisms of shock induced polarization in liquids containing polar molecules.

**W42 13 Quantum Dynamics of Energy Transfer under Shock Conditions*** R.C. MOWREY, *NRL* M.L. ELERT, *U. S. Naval Academy* C.T. WHITE, *NRL* Classical molecular dynamics (MD) simulations predict efficient energy transfer from translational to vibrational modes near shock fronts in molecular solids. The validity of the classical description of collisional energy transfer under shock conditions has not been tested for extended systems. In this research effort, quantum mechanical (QM) simulations are used to study energy transfer in a system consisting of three collinear diatomic molecules and a stationary wall. A fast-moving projectile diatom collides with its neighbor initiating a collision cascade. The multiplicity of collisions precludes ita priori prediction of the detailed collision dynamics. The time dependence of the six-degrees-of-freedom wave function is determined using QM time-dependent wave packet methods. Intra- and inter-molecular interactions are described using nearest-neighbor potentials. Probabilities for vibrational excitation and bond rearrangement are predicted as a function of the collision energy of the projectile for differing interaction potentials and atomic masses.

**W43 1 Macroscopic Quantum Tunneling and Entangled States in Bose-Einstein Condensates*** LINCOLN D. CARR, DIMITRI R. DOUNAS-FRAZER, ANN M. HERMUNDSTAD, *Physics Department, Colorado School of Mines* We use a multi-band Hubbard model to study beyond-mean-field effects in macroscopic quantum tunneling of excited states in Bose-Einstein condensates. Our goal is to determine straightforward observables such as the oscillation frequency of kink-like structures between two wells or the propagation speed of such structures on a lattice. As a preliminary step, we present some surprising new results for entangled states of N bosons in two wells.

*Partial support by the National Science Foundation is very much appreciated.

**14:42**

**W43 2 Disorder-induced enhancement of phase coherence in trapped bosons on optical lattices** PINAKI SENGUPTA, ADITYA RAGHAVAN, STEPHAN HAAS, *Univ. of Southern California* Using numerical methods, we have investigated the effects of disorder on a system of interacting bosons trapped in a one-dimensional optical lattice. Our results show that there is a unique effect at small to moderate strengths of disorder if there is a Mott plateau at the center of the trap in the ordered system - long range phase coherence actually *increases* as a result of disorder. The localization effects due to correlation and disorder compete against each other which results in a partial delocalization of the particles in the Mott region leading to increased coherence. Eventually, at large disorder strengths, the phase coherence decreases. In the absence of a Mott plateau at the center, this effect is absent and the phase coherence decreases for all disorder strenghts. Fur-

ther analysis of the uniform (no trap) system shows that the disordered states belong to the Bose glass phase.

**14:54**
**W43 3 Cold Atom Optical Lattices as Quantum Analog Simulators for Aperiodic One-Dimensional Localization Without Disorder** VITO SCAROLA, SANKAR DAS SARMA, *University of Maryland* Cold atom optical lattices allow for the study of quantum localization and mobility edges in a disorder-free environment. We predict the existence of an Anderson-like insulator with sharp mobility edges in a one-dimensional nearly-periodic optical lattice. We show that the mobility edge manifests itself as the early onset of pinning in center of mass dipole oscillations in the presence of a magnetic trap which should be observable in optical lattices. This work is supported by NSA-LPS and ARO-ARDA.

**W43 4 Measuring correlation functions in interacting systems of cold atoms.***
EUGENE DEMLER, *Harvard University*

I will discuss two approaches to measuring correlation functions in experiments with cold atoms. The first approach is based on analyzing atom shot noise in the time of flight experiments. I will compare this approach to Hanburry-Brown-Twiss experiments and show that it can be used to probe novel quantum states of cold atoms including paired states of fermions and magnetically ordered states in optical lattices. The second approach relies on interference experiments between extended condensates. I will show that the interference pattern contains information about correlation functions within individual condensates and that the full distribution of the fringe contrast provides information about high order correlation functions. I will discuss possible applications of this method to study Luttinger liquid behavior in one dimensional systems and probe Kosterlitz-Thouless transition in two dimensional condensates.

**W43 5 Feshbach resonances in optical lattices** DENNIS DICKERSCHEID, *ITP Utrecht University* D. VAN OOSTEN COLLABORATION, H. T. C. STOOF COLLABORATION, In the last few years there has been much excitement in the field of ultracold atomic gases. In a large amount this is due to the use of so-called Feshbach resonances and, in addition, the use of an optical lattice for the atoms. Recently, the first steps have been made to experimentally combine these techniques, which can both be used to tune the interactions between the atoms. Motivated by these developments, we show that the physics of these systems is described by a generalized Hubbard model for which the microscopic parameters are determined by the details of the lattice and the experimentally known parameters of the Feshbach resonance in the absence of the optical lattice. As a particular application we also discuss the phasediagrams of a Bose gas and a Bose-Fermi mixture near a Feshbach resonance in an optical lattice.

**15:54**
**W43 6 Ramping Fermions in Optical Lattices across a Feshbach resonance** ANIELLO ESPOSITO, HELMUT G. KATZGRABER, MATTHIAS TROYER, *Theoretische Physik, ETH Zurich* We study the properties of ultracold Fermi gases in a three-dimensional optical lattice when crossing a Feshbach resonance. By using a zero-temperature formalism, we show that three-body processes are enhanced in a lattice system in comparison to the continuum case. This poses one possible explanation for the short molecule lifetimes found when decreasing the magnetic field across a Feshbach resonance. Effects of finite temperatures on the molecule formation rates are also discussed by computing the fraction of double-occupied sites. Our results show that current experiments are performed at temperatures considerably higher than expected: lower temperatures are required for fermionic systems to be used as quantum simulators. In addition, by relating the double occupancy of the lattice to the temperature, we provide a means for thermometry in fermionic lattice systems, previously not accessible experimentally. The effects of ramping a filled lowest band across a Feshbach resonance when increasing the magnetic field are also discussed: fermions are lifted into higher bands due to entanglement of Bloch states. Our results are in good agreement with recent experiments.

**16:06**
**W43 7 Competing phases in Bose-Fermi mixtures of ultracold atoms in optical lattices** LUDWIG MATHEY, *Harvard University* SHAN-WEN TSAI, *UC Riverside* ANTONIO CASTRO-NETO, *Boston University* We study mixtures of ultracold bosonic and fermionic atoms, confined to a two-dimensional lattice, with a numerical functional renormalization group (RG) method. The method is an extension of the RG approach to interacting fermions[1] which also takes into account couplings of the fermions to bosonic modes.[2] We obtain the phase diagram of the system for the limit of large bosonic phonon velocity in comparison to the Fermi velocity. The renormalization group method provides the value of the gaps of the various phases, as well as the subdominant orders and the short range fluctuations.

**W43 8 Vidals simulation method applied to two coupled 1D lattices** JAMES WILLIAMS, IPPEI DANSHITA, CHARLES CLARK, *NIST-Gaithersburg* Recently, a method was developed employing matrix product states to simulate the quantum dynamics of a one dimensional lattice system using an adaptive time stepping technique [G. Vidal, Phys. Rev. Lett. 91, 147902 (1993); Phys. Rev. Lett. 93, 040502 (1994)]. We use this approach to

simulate the dynamics of bosons loaded into a double-well optical lattice geometry relevant to recent experiments at NIST [I. Spielman et al., Bull. Am. Phys. Soc. (2005)]. We study a pair of coupled 1D lattices, which can be mapped into a single 1D lattice with next-nearest neighbor interactions.

**16:30**

**W43 9 The speed of sound in a Bose-Einstein condensate in optical lattices** BIAO WU, ZHAOXIN LIANG, *Institute of Physics, Chinese Academy of Sciences, Beijing, China* XI DONG, *Department of Physics, Tsinghua University, Beijing, China* We have studied the speed of sound of a Bose-Einstein condensate in optical lattices both analytically and numerically. We find that in the one-dimensional case, the speed of sound falls monotonically with increasing lattice strength. However, the trends are different in two and three dimensional cases. In these two cases, when the interaction is strong, the speed of sound also decreases monotonically with increasing lattice strength. But when the interaction is weak, the sound speed first increases then decreases when the lattice strengh increases.

**16:42**

**W43 10 Instability of a superfluid Bose gas induced by a locked thermal gas in an optical lattice** SATORU KONABE, TETSURO NIKUNI, *Tokyo University of Science* We use a dissipative Gross-Petaevskii equation derived from the Bose-Hubbard Hamiltonian to study the effect of the thermal component on the stability of a current-carrying superfluid state of a Bose gas in an optical lattice potential. We explicitly show that the superfluid state becomes unstable at certain quasi-momentum of the condensate due to a thermal component which is locked by an optical lattice potential. It is shown that this instability coincides with the Landau instability derived from the GP equation.

**16:54**

**W43 11 Imaging of diverging correlations close to a quantum phase transition in optical lattices*** A.B. KUKLOV, *Department of Physics, College of Staten Island, CUNY, NY 10314* Q. NIU, *Department of Physics, University of Texas, Austin, TX 78712* I. CARUSOTTO, *BEC-CNR-INFM and Dipartimento di Fisica, Universita di Trento, I-38050 Povo, Italy* We suggest real space determination of diverging space-time correlations close to a quantum phase transition from Bose Mott insulator to superfluid in optical lattices. The method relies on interference of either the released cloud or the outcoupled atomic beam with some reference Bose-Einstein condensate. Upon approaching the transition from the Mott phase, the resulting interference pattern represents a set of uncorrelated domains, with a typical size determined by the correlation length $\xi$ as long as it is smaller than a system size $L$. Repetition of the measurements in a progression of $L$ for $\xi > L$ provides crucial information on the critical behavior in the context of the finite size scaling approach. The Hanbury Brown & Twiss type measurements allow extracting the average spatial correlator, which is insensitive to the expansion time and decaying on distances $\approx \xi$ (for $\xi < L$). The non- destructive scheme employing two outcoupling pulses separated by some time $\tau$ can probe both the spatial and time correlations.

**17:06**

**W43 12 Attractive Bosons in Optical Lattices*** DANIEL GOLDBAUM, ERICH MUELLER, *Cornell University* We study the theory of attractive bosons in an optical lattice with a hard-core constraint, limiting on-site occupations to 0, 1, or 2 particles per site. Our goal is to investigate the Boson pairing phase transition. We describe how an off-resonant Raman photoassociation transition [C. Ryu, et. al. Cond-mat/0508201] may be used to generate this model. We explore the properties of this system through a mean-field theory that allows short-range correlations. We write a wavefunction that describes both atomic and molecular superfluid phases, and study properties of the system near the phase transition, including the structure of vortices.

*NSF PHY-0456261, Department of Education Fellowship, and Sloan Foundation

**17:18**

**W43 13 The repulsive interacting bosons in an one dimensional moving lattice ring** QI ZHOU, *Ohio State University* TIN-LUN HO, *Ohio State University* We investigate the properties of the ground state of the repulsive interacting bosons in an one dimensional moving lattice ring, and reveal that the superfluid density of the system is a periodic function of the velocity of the lattice. In the weakly interacting limit, the Umklapp process of the mutual scattering of bosons in the moving lattice provide the generation mechanism for the vortices. In the strongly interacting limit, the moving lattice can cause transitions between the Mott insulator and the different superfluid phases carrying vortex with different winding number.

## SESSION W45: SPIN STRUCTURE IN MAGNETIC MATERIALS

**W45 1 Magnetism in the diluted induced moment system $(La,Pr)_6Ni_2Si_3$*** R. W. McCALLUM, Y. JANSSEN, K. W. DENNIS, P. C. CANFIELD, *Ames Laboratory, Iowa State University, Ames IA 50011* $Pr_6Ni_2Si_3$ crystallizes in a complex hexagonal structure with two distinct Pr sites with no point symmetry, thus the $2J+1=9$ ground state levels are CEF-split into singlets. Single-crystal magnetization and specific heat measurements suggest that this splitting is large compared to the ordering temperature. As CEF-induced singlets are nonmagnetic, any ordered magnetic moment is induced by magnetic interactions. $Pr_6Ni_2Si_3$ orders with a ferromagnetic component parallel to the c-axis at $\sim$ 40K, whereas $La_6Ni_2Si_3$ appears to be nonmagnetic. Upon substitution of Pr by La the ordering temperature decreases more rapidly than predicted by a rule of mixtures. For substitutions of more than 50% La, no ordering is observed above 5 K. For 50% La, both AC and DC magnetization measurements suggest superparamagnetic or spin glass type behavior. This behavior will be discussed in terms of clusters of Pr ions with size-dependent moment and anisotropy.

*Ames Laboratory is operated for the US Department of Energy by Iowa State University under contract number W-7405-ENG-82.

**14:42**

**W45 2 Ferromagnetism in $Ba_2NaOsO_6$** ANN ERICKSON, *Stanford University and Geballe Laboratory for Advanced Materials* GORDON MILLER, *Iowa State University and Ames Laboratory* SUMOHAN MISRA, *Iowa State University* ZACK SCHLESINGER, RAJ GUPTA, *University of California, Santa Cruz* IAN FISHER, *Stanford University and Geballe Laboratory for Advanced Materials* Due to the extended nature of 5d orbitals, magnetism in systems of 5d electrons is uncommon. Here we present results of structural, thermodynamic and optical reflectivity experiments on single crystals of the novel magnetic material $Ba_2NaOsO_6$. The material has a double perovskite structure, space group Fm-3m, with full occupancy of all sites. The osmium ions have a $7^+$ valence, corresponding to a $5d^1$ electron configuration. The effective moment at high temperatures is 1.10 $\mu_B$, somewhat less than the spin-only value due to spin-orbit coupling, with no apparent anisotropy. The Weiss temperatures are -11.0 and -12.4 $\pm$ 0.4 K for fields orinted along the [100] and [111] directions respectively. At 6.8 K a sharp anomaly in the heat capacity indicates the onset of long range magnetic order. The ordered state is characterized by a small ferromagnetic moment of just 0.2 $\mu_B$ per formula unit, with only a slight anisotropy, indicative of a helical magnetic structure. Infra red reflectivitity measurements confirm that the material is an insulator.

**14:54**

**W45 3 Magnetic properties of (R, R', R'',...)$Ni_2Ge_2$ solid solutions** S.A. LAW, S.L. BUD'KO, P.C. CANFIELD, *Ames Laboratory and Dept. of Physics and Astronomy, Iowa State University* Anisotropic magnetic properties of single crystals of (R, R', R,'' ...)$Ni_2Ge_2$ (R = rare earth) solid solutions will be presented. Whereas the magnetic ordering temperatures and the paramagnetic $\Theta$'s broadly follow de Gennes scaling there are some systematic deviations from this oversimplfied trend. In this talk we will examine these deviations and also discuss the apparent absence of a spin-glass state induced by random magnetic anisotropy for the most highly mixed samples.

**15:06**

**W45 4 Temperature dependence of magnetization of hcp Gd** A. CHERNYSHEV, V. PECHARSKY, K. GSCHNEIDNER, *Department of Materials Science and Engineering, Iowa State University and Ames Laboratory, Ames, IA, 50011* V. ANTROPOV, *Condensed Matter Physics, Ames Laboratory, Ames, IA, 50011* Careful magnetization measurements of high purity Gd single crystal have been performed. Our results confirm a strong deviation from the Bloch law for the magnetization at low temperatures, and we demonstrate that this effect is even stronger than had been previously measured on less pure Gd samples. We have analyzed the physical nature of this deviation qualitatively and quantitatively using known theoretical models and the newly obtained results. However, no fully satisfactory agreement between the new experimental data and existing theories has been reached.

**15:18**

**W45 5 Magnetic phase separation in electron-doped Bi1-xCaxMnO3 systems** YUHAI QIN, TREVOR A. TYSON, *New Jersey Institute of Technology* KENJI SHIMIZU, *Toyama University* The manganite system Bi1-xCaxMnO3 possesses intriguing properties in the low bismuth doping region. In this electron doped region ($0.6< x< 1$), a ferromagnetic (FM) moment of $\sim$ 1.2 Bohr magnetons per Mn site is found for $x\sim$ 0.875. The magnetic moment per Mn site maintains a value $\sim$ 1/3 the theoretical limit even in fields a high as 60 T. The physical origin of this high moment region is not well understood. Various models including canted ferromagnetism and ferromagnetic clusters hosted by an antiferromagnetic background have been proposed. In our previous work, we have conducted small-angle neutron scattering (SANS) on Bi0.125Ca0.875MnO3 polycrystalline samples as has revealed existence of FM clusters embedded in an AFM background. New 55Mn NMR results give more evidence supporting of this heterogeneous phase model: resonance signals from both AFM and FM phases were identified. More progress from multiple-temperature Bi-L3 edge XAFS measurements will be presented as well. This work is supported by NSF DMR-0209243 and NSF DMR-0512196.

**15:30**

**W45 6 Physical Properties of Single Crystal $EuIn_2P_2$ and $EuGa_2P_2$*** NEWELL JENSEN, SAMUEL MAQUILON, PETER KLAVINS, ZACHARY FISK, *UC Davis Physics* CATHIE CONDRON, JIONG JIANG, SUSAN KAUZLARICH, *UC Davis Chemistry* PHYSICS/CHEMISTRY UC DAVIS COLLABORATION, Single crystals of $EuIn_2P_2$ and $EuGa_2P_2$ have been grown by a metal flux method. The EuIn 2P2 material crystallizes in a new hexagonal structure type and orders magnetically at 24 K. The magnetic ordering is anisotropic suggesting a possible canted ferromagnetic magnetic structure. The temperature dependent resistivity data indicate semi−metallic behavior. Negative colossal magnetoresistance is observed at the ordering temperature. The gallium metal analogue, EuGa2P2, crystallizes in a related monoclinic structure and magnetically orders at a slightly higher temperature. Magnetization, resistivity and specific heat data are presented for both compounds.

*This work is partially supported by NSF DMR−0433560 and DMR−0120990

**15:42**

**W45 7 Structural and magnetic properties of single layered manganite Pr0.5Ca1.5MnO4*** SONGXUE CHI, *University of Tennessee, Knoxville* PENGCHENG DAI, *University of Tennessee, Knoxville* FENG YE, *Oak Ridge National Laboratory* JAIME FERNANDEZ-BACA, *Oak Ridge National Laboratory* ROLAND MATHIEU, *University of Tokyo* YOSHI TOKURA, *University of Tokyo* QINGZHEN HUANG, *NIST Center for Neutron Scattering* JEFFREY LYNN, *NIST Center for Neutron Scattering* High resolution neutron powder diffraction and elastic neutron scattering have been used to determine the lattice and magnetic structure of the single layer manganite Pr0.5Ca1.5MnO4. The system becomes charge/orbital ordered (CO-OO) near 300K and antiferromagnetically ordered with a Neel temperature ($T_N$) near 125K, which has CE-type (checkerboard like) structure in the Mn-O plane. At temperatures above $T_N$ but below $T_{CO-OO}$, we discovered an anomalous lattice response around 160K. We discuss the microscopic origin of this lattice distortion and its association with competing CO-OO and antiferromagnetic states.

*The work was supported by NSF-DMR0453804 and DOE DE-FG02-05ER46202. ORNL is managed by UT-Battelle, LLC, for the U.S. Dept. of Energy under contract DE-AC05-00OR22725. This work was also performed under the US-Japan Cooperative Program on Neutron Scatteri

**15:54**

**W45 8 Magnetic structure of the Kondo lattice compound $CeZn_{0.6}Sb_2$** Y. CHEN, J. W. LYNN, *NIST Center for Neutron Research and University of Maryland* H. LEE, P. KLAVINS, Z. FISK, *Dept. of Physics, University of California at Davis* S. NAKATSUJI, *Dept. of physics, Kyoto University* W. BAO, J. THOMPSON, T. PARK, *Los Alamos National Laboratory* R. MACALUSO, J. CHAN, *Louisiana State University* B. CARTER, *National High Magnetic Field Laboratory, Florida State University* The new Kondo lattice compound $CeZn_{0.6}Sb_2$ has a tetragonal structure with space group P4/nmm and shows ferromagnetic behavior below 2.5 K. The Curie-Weiss temperature is 22 K along the tetragonal *ab* plane, indicating ferromagnetic interactions in the plane. Along the *c* axis, however, the Curie-Weiss temperature is -145 K, suggesting antiferromagnetic exchange interaction in this direction [1]. We determined the magnetic structure of $CeZn_{0.6}Sb_2$ using single crystal neutron diffraction. $(h,0,l)$ and $(h, h,l)$ scattering planes were investigated. We found $CeZn_{0.6}Sb_2$ orders ferromagnetically at $T_C$=2.5 K. The magnetic structure is collinear with a low temperature ordered Ce moment of 1.3 (1) $\mu_B$ that lies in the *ab* plane. In addition, we measured the order parameter of the ferromagnetic transition. [1] Studies of the ferromagnetic Kondo lattice system of single crystal $CeZnSb_2$, H. Lee, S. Nakatsuji, Y. Chen, W. Bao, R. Macaluso, J. Chan, T. Park, B. Carter, P. Klavins, J. Thompson, Z. Fisk, BAPS, Session L41, 2005.

**W45 9 APRES Study of Spin Spiral States in $TlCo_2Se_2$*** HAEKYUNG JEONG, *Boston University* TONICA VALLA, *Brookhaven National Lab* ROLF BERGER, *Upssla University* PETER JOHNSON, *Brookhaven National Lab* KEVIN SMITH, *Boston University* The electronic structure of $TlCo_2Se_2$ has been measured using high resolution angle resolved photoemission spectroscopy (ARPES). $TlCo_2Se_2$ is thought to be a spin spiral system, but experimental evidence from the electronic structure supporting the spin spiral states has been lacking. The original indication of a spin spiral state came from neutron powder diffraction experiments, and was confirmed in a subsequent neutron diffraction study of single crystals. However, it was not possible to distinguish between the helical structure and the sine-modulated moments since the intensity of the magnetic pattern satellites from neutron diffraction was very low. We used high resolution ARPES to study the electronic structure of single crystals of $TlCo_2Se_2$ cleaved in ultra high vacuum. Our experimental results clearly show the existence of band crossings near the Fermi level that would support spin spiral states, and reveals the predicted quasi-two dimensional electronic structure. The Boston University program is supported in part by the Department of Energy under DE-FG02-98ER45680.

**W45 10 Magnetic Ordering in Copper Pyrazine Perchlorate, a S=1/2 2D Quantum Heisenberg Antiferromagnet** F. XIAO, C. P. LANDEE, M. M. TURNBULL, *Clark University, Worcester, MA 01610* M. NOVAK, S. SORIANO, *Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brasil* Copper pyrazine perchlorate, $Cu(Pz)_2(ClO_4)_2$, consists of antiferromagnetic layers of $Cu^{2+}$ ions bridged by neutral pyrazine molecules. The exchange strength within the layers is $J/k_B$ = 17.5 K; excellent isolation between layers is provided by the bulky perchlorate ions. Specific heat studies and muon spin resonance measurements [1] show the ordering temperature to be 4.25 K, corresponding [2] to an interlayer/intralayer exchange ratio of 1 x $10^{-3}$. The specific heat data show no characteristic anomaly at $T_N$, only a broad contribution attributable to the short-range order within the layers. This result is consistent with recent theoretical predictions [3]. The excellent isolation results in the observation of field-induced XY-behavior in the magnetic susceptibility, as predicted elsewhere [4]. 1. J. Manson et al, unpublished results. 2. C. Yasuda et al, Phys. Rev. Lett. **94**, 217201 (2005). 3. P. Sengupta et al, Phys. Rev. B, **68**, 094423 (2003). 4. A. Cuccoli et al, Phys. Rev. B, **68**, 060402 (2003).

**W45 11 Magnetic field dependence of the order parameter in weakly ordered quasi-1D antiferromagnets** IGOR ZALIZNYAK, ANDREI SAVICI, *Brookhaven National Laboratory* BEATRICE GRENIER, LOUIS-PIERRE REGNAULT, SERGEI PETROV, We report neutron diffraction study of the antiferomagnetic order in two isostructural quasi-one-dimensional S=1 Heisenberg antiferromagnets, CsNiCl3 and RbNiCl3, in magnetic fields up to 15 T. These materials present model systems of Haldane spin chains with very similar in-chain exchange interaction, but coupled by the inter-chain exchange of different strengths. In both cases the inter-chain coupling is super-critical, so that the Haldane gap is suppressed and weak antiferromagnetic order appears below 4.84 K in CsNiCl3 and 11.1 K in RbNiCl3. In zero field the ordered magnetic moments in CsNiCl3 and RbNiCl3 are approximately 0.9 and 1.2 Bohr magnetons, respectively. We find that the antiferromagnetic order is enhanced by application of the magnetic field, as it is expected both for coupled Haldane chains and from the spin-wave theory arguments. However, we show that the spin-wave theory can not reproduce the observed behavior quantitatively.

**W45 12 Neutron Diffraction Study of A-site Size and Variance Effect on the Spin and Orbital Ordering in $RVO_3$ Perovskites** J.-Q. YAN, S. CHANG, J. ZARESTKY, O. GARLEA, R. MCQUEENEY, *Ames Laboratory, Neutron and X-ray Group, Ames, IA50011* A. LIOBET, *Los Alamos National Lab* Y. REN, *Argonne National Lab* J. FIERAMOSCA, *Argonne National Lab* $RVO_3$ members all exhibit an intriguing sequence of orbital and magnetic orderings below a Too and a $T_N$, respectively. Since only t-electrons are active in this system, they have been a prototype to study cooperative orbital ordering among the $\pi$-bonding t orbitals in the absence of $\sigma$-bonding e electrons and the relationship of this orbital order to long-range magnetic ordering. We have studied the A-site size and variance effect on the spin and orbital ordering in single phase (YLa)VO3 and (YLaLu)VO3 systems by magnetization, specific heat, thermal conductivity, and nenutron diffraction measurements. The results show that both A-site size and variance stabilize G-type magnetically, C-type orbitally ordered state before an electronic phase segregation takes place. The results will be presented with special emphasis on the neutron diffraction experiments for both single crystal and polycrystalline samples.

**W45 13 Soft X-ray absorption Spectroscopic Investigation on Electronic Evolutions in $SrFe_{1-x}Mo_xO_{3\pm\delta}$ ($0 \leq x \leq 1$)** B.-K. PARK, *POSTECH* J.-H. PARK, *POSTECH/PLS* J.-Y. KIM, *PLS* H.-J. LEE, J.H. SONG, Y.H. JEONG, *POSTECH* H.-J. LIN, C.T. CHEN, *NSRRC* A double perovskite $Sr_2FeMoO_6$, which an alternative mixture of $SrFeO_3$ and $SrMoO_3$, is a half-metallic ferrimagnet with a high critical temperature $T_C \sim$ 400K, although a

certain amount of anti-site disorder diminishes the half-metallicity in a real system. $SrFeO_3$ and $SrMoO_3$, which have the ionic states of $Fe^{4+}$ and $Mo^{4+}$, are known to be an antiferromagnetic insulator and a non- magnetic metal, respectively. However, as they forms the double perovskite, the ionic states primarily form $Fe^{3+}$ $(3d^5_\uparrow)$ and $Mo^{5+}$ $(4d^1_\downarrow)$, and then the Fe 3*d*-Mo4*d* hybridization makes a down spin band at the Fermi level. Hence the real ground state becomes a state with $Fe^{2+}$-$Fe^{3+}$ and $Mo^{5+}$-$Mo^{6+}$ mixed valences. It means that the valences of Fe and Mo can vary by two, i.e. from $Fe^{4+}$ to $Fe^{2+}$ and from $Mo^{4+}$ to $Mo^{6+}$ in $SrFe_{1-x}Mo_xO_{3\pm\delta}$ $(0 \leqslant x \leqslant 1)$, respectively. Here we presents the structural, electrical, and magnetic phase diagram and electronic evolutions in $SrFe_{1-x}Mo_xO_{3\pm\delta}$ $(0 \leqslant x \leqslant 1)$.

**W45 14 Electronic bandstructure of the NiMnSb(001) surface above and below the Fermi energy** JULIET CORREA, *Physikalisches Institut, Westfälische Wilhelms-Universität Münster* CHRISTIAN EIBL, GEORGI RANGELOV, JÜRGEN BRAUN, MARKUS DONATH, The predicted 100% spin polarization at the Fermi energy ($E_F$), together with the high Curie temperature (750K) of the half-Heusler alloy NiMnSb makes it interesting for technological applications. However, experimentally only 50% surface polarization has been observed. Knowledge of the electronic structure of NiMnSb is key to improving our understanding of this material. We report on surface bandstructure measurements for the (001) surface of single crystal NiMnSb. The experimental techniques used are angle resolved ultraviolet photoemission spectroscopy (ARUPS)and inverse photoemission spectroscopy (ARIPES) to probe the bandstructure both below and above $E_F$. ARUPS and ARIPES are used quasi-simultaneously in a multichamber UHV-system to ensure well defined and equal sample preparation conditions. We see both non-dispersive (ARIPES) and dispersive (ARUPS) structures in the spectra, which stem from d-like bulk states. With our normal emission UPS data, we resolve the conflict in the various contradictory reports in the literature about the position of spectral features for both polycrystal and single-crystal samples. Finally, through comparison with theoretical calculations we have identified a surface state candidate.

**W45 15 Contact-less measurements of Shubnikov-de Haas oscillations below Néel temperature in single crystals $SmAgSb_2$** M. D. VANNETTE, R. PROZOROV, S. L. BUD'KO, P. C. CANFIELD, B. N. HARMON, *Ames Laboratory and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011* Oscillations of a skin depth with magnetic field were measured in single crystals $SmAgSb_2$ by using radio-frequency resonant technique. Comparison with directly measured de Haas – van Alphen and Shubnikov – de Haas oscillations revealed additional details in the frequency spectra, probably due to high sensitivity of the measurements $\Delta\rho_{min} \approx 20$ p$\Omega \cdot$ cm. The temperature evolution of the frequency spectra was obtained. The correlation of the observed oscillations with calculated Fermi surface and possible influence of antiferromagnetic ordering are discussed.

**W46 1 Silicon-interstitials-based Benchmarking of DFT Exchange-correlation Potentials*** K. P. DRIVER, W. D. PARKER, R. G. HENNIG, J. W. WILKINS, *Ohio State U.* C. J. UMRIGAR, *Cornell U.* R. MARTIN, E. BATISTA, B. UBERUAGA, *LANL* J. HEYD, G. SCUSERIA, *Rice U.* Diffusion Monte Carlo (DMC) benchmarks DFT functionals: LDA, GGA, and HSE [1]. Extensive DFT studies on single-, di-, and tri-interstitials [2] provide stable structures and converged energies. For single-interstitial formation energies, our DMC results confirm earlier work [3], with 1.5 and 1.0 eV underpredictions for LDA and GGA, respectively. We continue to observe this trend in most di- and tri-interstitials. Additionally, we find HSE reproduces DMC results for single-interstitals. Preliminary analysis indicates that large LDA and GGA discrepancies with DMC occur for highly distorted defect configurations. [1] J. Heyd *et al.*, J.Chem.Phys. **118**, 8207 (2003). [2] D. A. Richie *et al.*, Phys. Rev. Lett. **92**, 45501 (2004). [3] W. -K. Leung *et al.*, Phys. Rev. Lett. **83**, 2351 (1999).

**W46 2 Random doping and oxide roughness induced fluctuations in nanoscale semiconductor devices*** PETRU ANDREI, *Florida State University* Random doping and oxide roughness induced fluctuations in nanoscale semiconductor devices are analyzed by using self-consistent Poisson-Schrödinger computations. A very fast and robust technique based on linearization of the transport equations is presented for the computation of fluctuations of various parameters (such as threshold voltages, terminal currents, and cutoff frequencies) of the semiconductor device. This technique is computationally much more efficient than the traditional Monte-Carlo approach and yields information on the sensitivity of device parameters fluctuations to the locations of doping and oxide thickness fluctuations. Hence, it can be used in the design of fluctuation resistant structures of semiconductor devices. Sample simulation results obtained by using the linearization technique are reported for MOSFET devices with channel lengths under 25 nm and compared with results obtained by using the Monte-Carlo technique.

**W46 3 Thermodynamics of semiconductor doping and stoichiometry from first-principles methods*** STEPHAN LANY, ALEX ZUNGER, *National Renewable Energy Laboratory, Golden, CO 80401* The theoretical investigation of semiconductor doping involves assessment of opposing physical effects: While itextrinsic doping can shift the Fermi level in the desired direction, such shifts disturb the balance between itintrinsic defects (vacan-

cies, interstitials, etc.) leading to the creation of ''killer-defects'' and, in some materials, to considerable deviation from ideal stoichiometry. We have developed a self-consistent procedure which uses first- principles calculated formation enthalpies of impurities and intrinsic defects, to predict the correlation between doping, stoichiometry, and equilibrium carrier density. With this method, we explore the deviation from ideal stoichiometry and the electrical properties of the photovoltaic materials $CuInSe_2$ and $CuGaSe_2$, sampling the entire space of thermodynamical variables. We find a systematic correlation between stoichiometry and conductivity type, which in case of $CuInSe_2$ spans the whole range from *p*- to *n*-type. Application to the case of N-doping of ZnO, identifies the narrow window for growth conditions that lead to *p*-type doping by $N_O$ acceptors.

**W46 4 Stoichiometry Driven Impurity Configurations in Compound Semiconductors*** G. CHEN, I. MIOTKOWSKI, S. RODRIGUEZ, A. K. RAMDAS, *Purdue University* Precise stoichiometry and departures therefrom in the composition of the tetrahedrally coordinated compound semiconductors allow impurity incorporation in more than one configuration. Ultra-high resolution infrared spectroscopy of CdTe:O at low temperatures reveals a unique pair of sharp lines, a non-degenerate $\nu_1 = 1096.78$ $cm^{-1}$ and a doubly degenerate $\nu_2 = 1108.35$ $cm^{-1}$ at 5 K, associated with the local vibrational modes of $O_{Te}$ in a $(O_{Te} - V_{Cd})$ complex in crystals grown with (CdTe + CdO + excess Te) or $(CdTe + TeO_2)$ which enhances the occurrence of Cd vacancy $(V_{Cd})$; in contrast, a single, triply degenerate sharp line at $\nu_0 = 349.79$ $cm^{-1}$ observed at 5 K occurs in CdTe grown with (CdTe + CdO + excess Cd) in which the appearance of $V_{Cd}$ is inhibited. In the former, oxygen, $O_{Te}$, is bonded to three nearest neighbor Cd's with a nearby $V_{Cd}$. The latter corresponds to $O_{Te}$ attached to all the four nearest neighbor Cd cations. With increasing temperature, $\nu_1$ and $\nu_2$ approach each other and behave as a single triply degenerate line at $\nu_0^*$ for temperature $T \geqslant T^* \sim 300$ K; the uniaxial $(C_{3v})$ symmetry of $(O_{Te} - V_{Cd})$ transforms to $T_d$ symmetry at T*, acquired due to an increasing rate of bond switching among the four possible $O_{Te} - V_{Cd}$ directions as T approaches T*.

**W46 5 Ab initio studies of defects in CdTe and HgTe with symmetrized basis*** YIA-CHUNG CHANG, HYEJUNG KIM, *University of Illinois at Urbana-Champaign* We have performed ab initio pseudopotential calculations of the total energies and atomic realxations of neutral and charged Cd vacancies in CdTe and Hg vacancies in HgTe. Our method takes advantage of the high point symmetry of the system, which enables us to use large supercells containing up to 64 atoms per unit cell. Supercells of 8, 16, 32, 54, and 64 atoms are employed and spin-orbit interactions are included. Considering only symmetric relaxations of neighboring atoms in CdTe system of a 64-atom supercell, we find that first-neighbor atoms around a Cd vacancy move toward the vacancy with a 9% contraction in bond length and second-neighbor atoms move toward the vacancy with a 2.5% lowering contraction in inter-atomic distance. The relaxation lowers the total energy by about 0.2eV. Similarly in HgTe, the contractions are 7% and 1.5%, respectively for first-neighbor and second-neighbor atoms. Three defect levels (with symmetry$\Gamma_6$, $\Gamma_7$, and$\Gamma_8$) are found for both CdTe and HgTe systems and one of the levels is located in the band gap while two of them are buried under the valence band maximum. Separate calculations are carried out using a full potential linearized augmented Slater-type orbital (LASTO) method and give consistent results. Self-energy corrections due to many-body effect are also estimated with the GW approach.

**W46 6 Dislocation filtering by buffer layer interfaces in $InSb/Al_xIn_{1-x}Sb$ heterostructures grown on GaAs (001) substrates*** MADHAVIE EDIRISOORIYA, TETSUYA MISHIMA, MICHAEL SANTOS, *University of Oklahoma* Recent efforts have been devoted to the development of InSb-based transport devices, including mesoscopic magnetoresistors and field-effect transistors, on GaAs (001) substrates. The small effective mass of electrons in InSb leads to a high mobility at room temperature. Remotely-doped InSb quantum wells offer the additional advantage of a conducting layer that is close to the surface. One key to maximizing the performance of such devices is the reduction of dislocation and micro-twin densities induced by the large lattice mismatch between $InSb/Al_xIn_{1-x}Sb$ and GaAs. We investigated the dislocation filtering effects of the interfaces formed between an $Al_yIn_{1-y}Sb$ interlayer and an $Al_xIn_{1-x}Sb$ matrix layer with $y > x$. Transmission electron microscopy analysis shows that the interlayer interfaces filter out threading dislocations. We improve this dislocation filtering by optimizing the interlayer thickness, the number of interlayers, and the growth conditions.

**W46 7 Thermodynamic model for the structure of the 90 degree partial dislocation in diamond cubic semiconductors.*** S. P. BECKMAN, *The University of Texas at Austin* D. C. CHRZAN, *The University of California at Berkeley* Recent studies of the 90 degree partial dislocation in diamond cubic semiconductors indicate that the structure of the core is not homogeneous, but rather is a combination of reconstructions and low energy structural excitations, such as kinks and anti-phase defects. As a result, direct investigation of the macroscopic properties of dislocation core by itab initio methods is unfeasible. A model is presented that maps the complicated structure of a dislocation core onto a one-dimensional spin lattice. At each lattice site two spins are present, one to represent the reconstructed bonds, and the other kink structures. The model is sufficiently complex to allow expression of the essential nature of the structural excitations along a dislocation line. This Ising-like model can be investigated within a Monte Carlo framework.

**W46 8 Strain relaxation and crystal quality in compositionally graded GaAsSb/GaAs metamorphic buffer layers*** BENNY PEREZ RODRIGUEZ, JOANNA MIRECKI MILLUNCHICK, *University of Michigan* We have compared linearly graded, step graded, and constant composition layers of GaAs(1-x)Sb(x)/GaAs grown by Molecular Beam Epitaxy to determine which grading

schemes result in the highest crystalline quality, while relaxing the lattice parameter most effectively. The incorporation rates used throughout the experiment for Ga and As were kept constant at 0.96 and 1.11 ML/s respectively. The Sb incorporation rate was varied from 0 to 0.63 ML/s to obtain a final composition of the topmost layers of x=0.5. The real-time stress evolution was obtained using an in situ multi-beam optical stress sensor. In our experiments, aggressive grading of the Sb flux results in decreased Sb incorporation at low x, a higher residual stress, and a bifurcation in the tilt of the sample. Less aggressive grading increases results in more uniform incorporation and lower residual stress, but the tilt remains. The tilt may be reduced by incorporating large steps in the grading, and completely eliminated when a constant composition layer of GaAs(0.5)Sb(0.5) is deposited directly on GaAs. The defect density of constant composition layers is somewhat higher than linearly graded layers with the same thickness and final composition. However, increasing the thickness of the layer reduces the defect density.

**W46 9 Mutual Passivation of Donors and Isovalent Nitrogen in GaAs** JINGBO LI, PIERRE CARRIER, SU-HUAI WEI, *National Renewable Energy Laboratory* SHU-SHEN LI, JIAN-BAI XIA, *State Key Lab for Superlattices and Microstructures, Institute of Semiconductors, CAS* Using large supercell total energy and band structure calculations, we have studied the mutual passivation mechanism of isovalent N and shallow donors in GaAs. We find that all the donor impurities, $Si_{Ga}$, $Ge_{Ga}$, $S_{As}$, and $Se_{As}$, bind to N in GaAs:N, which has a large N-induced band gap reduction relative to GaAs. For group-IV impurity such as Si, the formation of the nearest-neighbor $Si_{Ga}$-$N_{As}$ defect complex creates a deep donor level below the conduction band minimum (CBM). The coupling between this defect level with the CBM pushes the CBM upwards, thus restoring the GaAs band gap; the lowering of the defect level relative to the isolated $Si_{Ga}$ shallow donor level is responsible for the increased electrical resistivity. Therefore, Si and N mutually passivate each other's electrical and optical activities in GaAs. For group-VI shallow donors such as S, the Coulomb binding between $S_{As}$ and $N_{As}$ does not form a direct bond and a deep level inside the gap; thus, no mutual passivation exists in the GaAs:(S+N) system. We also explained the difference between the mutal passivation of Si and N and the mutal passivation of H and N in GaAs. Our study provides a deep understanding of the mutual passivation mechanism and explained some of the recent puzzling experimental observations.

**W46 10 Effect of indium on the localized vibrational mode of nitrogen in $GaN_xAs_{1-x}$*** A. M. TEWELDEBERHAN, *Tyndall National Institute, Lee Maltings, Prospect Row, Cork, Ireland* STEPHEN FAHY, *Department of Physics, University College Cork, Ireland* The effect of the substitution of nearest-neighbor gallium atoms by indium (In-N-Ga, In-N-In) on the frequency of the localized vibrational mode of substitutional nitrogen in the dilute nitride, $GaN_xAs_{1-x}$, has been studied within first-principles density functional theory, using a supercell approach. The splitting of the highly localized triply-degenerate mode into singly- and doubly-degenerate modes is obtained and compared with available Raman and FTIR spectroscopy measurements. The results are in good agreement with the experimental values.

*Work supported by Science Foundation Ireland

**16:30**

**W46 11 Effects of edge and screw dislocations on optical properties of Wurtzite GaN** JEONG HO YOU, H.T. JOHNSON, *University of Illinois at Urbana-Champaign* The wide bandgap and high temperature stability of GaN makes it a desirable material for applications such as blue light-emitting diodes, blue lasers, and high-power transistors. Despite these advantages, the large lattice mismatch in most epitaxial GaN leads to a high density of dislocations, on the order of $10^9 cm^{-2}$ for edge dislocations and $10^8 cm^{-2}$ for screw dislocations in WZ GaN. Edge dislocations are electron acceptors and take on a negative charge. Open-core screw dislocations are essentially voids, or nanopipes, in the material. The presence of these defects, plus the strain field associated with each dislocation type, change the density of states and reduce the PL intensity in typical epitaxial GaN device layers. In the present work, the effects of edge and screw dislocations in WZ GaN have been studied computationally as a function of dislocation density. Spectral properties are determined by solving a 6x6 multiband kp Hamiltonian in three-dimensions using a real-space finite element method. Results compare favorably to available experimental data.

**W46 13 Low temperature photoluminescence in the strongly disordered dilute nitride GaAsN.** IVANA BOSA, DERMOT McPEAKE, *Tyndall National Institute, University College Cork, Ireland* STEPHEN FAHY, *Tyndall National Institute and Department of Physics, University College Cork, Ireland* Photoluminescence (PL) due to the radiative recombination of excitons is used to study the structural disorder of alloys. We calculate the PL spectra at finite temperatures in the dilute nitride GaAsN. The shape of PL spectra is determined by the exciton occupation under steady-state optical excitation. Exciton energy levels and wave functions are calculated numerically in a supercell geometry with a strong random alloy potential acting on the electron. The distribution of electrons in states of the random potential is found by solving a kinetic equation, including phonon-assisted transitions between states and radiative recombination. Results are compared to the recent experiments.

**SESSION W47: QUANTUM TRANSPORT IN SEMICONDUCTORS: THEORY AND EXPERIMENT**

**W47 1 Wigner approach to quantum transport in graded semiconductors*** A.A. KISELEV, G.J. IAFRATE, *Dept. of Electrical and Computer Eng., North Carolina State Univ., Box 7911, Raleigh, NC 27695* Graded electron bandstructures have long being used to beneficially influence the performance and functionality of electronic devices. In this work, we have developed a consistent fully quantum description of electron transport in terms of the Wigner distribution function, making use of the symmetric and hermitian effective-mass-like single band Hamiltonian that can be unambiguously constructed for graded systems. The generalized Wigner equation includes contributions that, in the quasiclassical limit, can be interpreted as directly corresponding to the drift and diffusion terms, but, unlike the homogeneous materials, the velocity operator is coordinate dependent and the electron is subject to the influence of the k-dependent quasielectric fields originating from both the inhomogeneous potential profile and composition-dependent modulation of the quasiparticle inertia. The approach is useful for the analysis of a broad class of transport phenomena in graded systems, where quantum effects are important, but a full quantum treatment would be prohibitively costly.

**W47 2 Variational studies of quantum liquid crystal phases of 2DEG** EFSTRATIOS MANOUSAKIS, *MARTECH, Physics Department, FSU, Tallahassee, FL and University of Athens, Greece* QUOC DOAN, *MARTECH and Physics Department, FSU, Tallahassee, FL* The ground state of a nematic phase of the 2DEG at filling fraction $\nu = 1/2$ is studied. The pair distribution function and interaction energy are calculated for a wavefunction having the Jastrow form for the correlation part of $\Pi_{i<j}(z_i - z_j)^2$ and an elliptical Fermi surface. First, the Fermi hypernetted chain (FHNC) approximation was employed in which, as usual, the contribution of the elementary diagrams is neglected. Our HNC/FHNC results agree very well with earlier reported results for various cases studied by the same approximation. Second we used the Monte Carlo (MC) method using periodic boundary conditions for a square geometry including the contribution of the image charges. To test our correct implementation of the second method, we computed for the same square geometry the pair distribution function and the energies of $\nu = 1,1/3,1/5$ states and our results are in excellent agreement with earlier results in which the disk geometry was used. Our preliminary results indicate that there are important differences between FHNC and the MC. We find that in the FHNC calculation the nematic state is energetically favorable as compared to the isotropic state, while in the MC we find the contrary. Further work is necessary to study the role of the finite-size effects in MC, and more final results and conclusions will be presented at the meeting.

**14:54**
**W47 3 Photoconductivity in AC-driven modulated two dimensional electron gas*** MANUEL TORRES, *Instituto de Fisica, UNAM Mexico* ALEJANDRO KUNOLD, *Departamento de Ciencias Basicas, UAM Mexico* We study the photoconductivity of two-dimensional electron system in a perpendicular homogeneous magnetic field, under the influence of periodic modulation potential and microwave irradiation. The model includes the microwave and Landau contributions in a non-perturbative exact way, the periodic potential is treated perturbatively. The Landau-Floquet states provide a convenient base with respect to which the lattice potential becomes time-dependent, inducing transitions between the Landau-Floquet levels. Based on this formalism, we provide a Kubo-like formula that takes into account the oscillatory Floquet structure of the problem. The total resistivity exhibits strong oscillations, leading to negative resistance states as the electron mobility and the intensity of the microwave power increases. It is proposed that, depending on the geometry, negative conductance sates or negative resistance states may be observed in lateral superlattices fabricated in $GaAs/AlGaAs$ heterostructures.

**W47 5 Simulating the interaction of a scanning probe with the quantum Hall liquid** GARY STEELE, RAYMOND ASHOORI, NEMANJA SPASOJEVIC, *MIT* Motivated by recent experiments [1], we have developed a simulation of the interaction of a metallic scanning probe with a 2D electron system (2DES) in the quantum Hall regime. The simulation is based on an electrostatic relaxation method, modified to include the non-linear screening of the 2D electron system at high magnetic fields. Using 2D simulations with cylindrical symmetry that allow us to account for the exact shape of the tip, we predict the diameter and width of ring shaped incompressible strips (ISs) induced by DC tip biases. Extending these results to 3 dimensions, we incorporate the effect of the disorder on the shape of the IS, and predict the formation of quantum dot islands observed in [1]. Comparison of the simulation results with experimental data provides a direct and quantitative view of the disorder of a very high mobility 2DES. [1] G. A. Steele, R. C. Ashoori, L. N. Pfeiffer, and K. W. West, Phys. Rev. Lett. 95, 136804 (2005)

**W47 6 Quantum dynamics for a dissipative quantum harmonic oscillator as a model for a NEMS frequency control resonator*** ILKI KIM, GERALD J. IAFRATE, *Dept. of Electrical and Computer Eng., NC State Univ., Raleigh, NC 27695* For the simplest model of dissipation, that is, a linear oscillator coupled to an infinite number of degrees of freedom to form a dissipative bath, it is found that the Heisenberg equation of motion for the oscillator displacement takes the form of a Langevin equation with a memory dependent dissipation [Ford, Lewis, O'Connell; Phys. Rev. A 37, 004419 (1988)]. When Fourier analyzed, this leads to a complex susceptibility which gives rise to a generalized frequency dependent ''quality factor'' which relates to the dissipative environment. We explore the limits of resonator integrity, especially with regard to insights afforded by the dependence of quality factor and other observables on the microscopic connection between resonator material parameters and circuit performance.

*This work is supported by NSF.

**W47 7 Kohn localization in the quantum Hall regime** RAFFAELE RESTA, *University of Trieste, Italy* A two-dimensional electron fluid in the quantum Hall regime shows both quantized transverse conductivity and vanishing longitudinal conductivity: the latter property characterizes insulators. According to Kohn's theory of the insulating state, electron localization—defined in an appropriate sense—is the *cause* for the insulating behavior in any insulator. I show that a quantum Hall ''insulator'' is no exception; furthermore both quantization of the transverse conductivity and vanishing of the longitudinal one stem here from the same elegant formalism. Since 1999 onwards, the theory of the insulating state has been reformulated in term of a ''localization tensor'' which provides a measure of electron localization. This tensor is an intensive property, geometric in nature, having the dimensions of a squared length; it characterizes the ground wavefunction as a whole, *not* the individual states. It is finite in any insulator and divergent in any metal. A fluctuation-dissipation theorem relates this ground-state property to the system conductivity. So far, the theory has only addressed systems with time-reversal symmetry, in which case the localization tensor is real. I show that in absence of such symmetry the localization tensor is naturally endowed with an imaginary part, proportional to transverse dc conductivity, and quantized in two-dimensional systems. Therefore electron localization is the *common cause* for both vanishing of the dc conductivity and quantization of the transverse one in quantum Hall fluids.

**15:54**

**W47 8 The mass of the electron in Shubnikov-de Haas effect:Spin-charge locking** KESHAV SHRIVASTAVA, *University of Hyderabad* At low temperatures, the integration over the Fermi distribution leads to x/sinh x type expression which is called the Dingle's formula. The spin symmetry is found to modify this formula which determines the oscillation amplitude of resistivity as a function of magnetic field. The theory introduces the effective charge so that the cyclotron frequency gets fractionalized resulting into $m/\nu_{\pm}$. At a certain magnetic field 1.5m is found instead of m. The Shubnikov-de Haas effect uses quantization of Landau levels but not the flux quantization. Hence we find that there is a ''quantized S-dH effect'' which measures the $m/h^2$. We determine that when fractional values of the filling factor are taken into account, the mass of the electron, equal to the band mass is obtained. 1. K. N. Shrivastava, Phys. Lett. **W47 9 Conductance reduction without shot noise in quantum wires** MARKUS KINDERMANN, PIET W. BROUWER, *Cornell University* Shot noise can only be avoided in conductors without backscattering of conduction electrons. Such conductors without backscattering and a twofold spin-degeneracy have a minimal (nonzero) conductance of $2\ e^2/h$ in the case of weak interactions. In recent experiments, however, also conductors with a reduced conductance of $1.4\ e^2/h$ have shown a clear tendency of noise suppression in zero magnetic field. It has been argued, that these experiments point to a lifted spin-degeneracy in these wires, spin-polarizing their conductance electrons. In this talk I will describe a model of an interacting quantum wire that is able to reproduce the transport behavior observed in these experiments qualitatively: that of the ''Coulomb Tonks gas'' of impenetrable electrons. It can be realized in ultra-thin wires, such as carbon nanotubes. We have studied transport through a finite-length Coulomb Tonks gas connected to bulk leads in various exactly solvable limits, both in and out of equilibrium. While we find a reduction of the conductance of such a wire to $e^2/h$ in all cases, the current in the wire does not exhibit any fluctuations at zero temperature. Most importantly, our model demonstrates that such noise suppression does not require a spin-polarization.

**16:18**

**W47 10 Low-temperature transport in high quality strained Ge channels in SiGe** BENJAMIN ROESSNER, *Laboratory for Solid State Physics, ETH Zurich, Zurich, Switzerland* HANS VON KAENEL, *Politecnico di Milano, Como, Italy* DANIEL CHRASTINA, *Politecnico di Milano, Como, Italy* GIOVANNI ISELLA, *Politecnico di Milano, Como, Italy* BERTRAM BATLOGG, *ETH Zurich, Zurich, Switzerland* Presently, the mobility of holes in strained germanium achieved so far exceeds 100000 $cm^2/Vs$ at a carrier density of $\sim 8*10^{11}cm^{-2}$. For lower carrier density, the highest reported mobilities are roughly proportional to the carrier density. Accessing the upper left corner in the density-mobility diagram remains a challenge. Background charges, inhomogeneous strain distribution and growth defects are the main difficulties of growing strained Ge channels. We have fabricated high quality Ge channels and measured the transport parameters at temperatures down to 0.4 K. We discuss the influence of growth problems on the mobility as a whole and how these mechanisms may influence the magnetic field dependence of the sheet resistance. We explore the effects of different doping geometries, in particular backside doping and symmetrical doping on electrical transport, including the effects of dopant segregation. Our quantitative analysis shows that local charged impurities dominate the scattering rate. It also shows the effect of too low substrate temperature, leading to point defects whose existence can be detected by a pure transport measurement.

**16:30**

**W47 11 Electronic transport properties of amorphous $Sb_2Te_3$ and $Ge_2Sb_2Te_5$ films** S.A. BAILY, *Space Vehicles Directorate, Air Force Research Laboratory, Kirtland AFB, NM 87117* DAVID EMIN, *Department of Physics and Astronomy, University of New Mexico, Albuquerque, NM 87131* The electrical conductivity, Seebeck coefficient, and Hall coefficient of amorphous $Sb_2Te_3$ and $Ge_2Sb_2Te_5$ films have been measured as functions of

temperature from room temperature down to as low as 200 K. The electrical conductivities manifest an Arrhenius behavior with a larger pre-exponential factor. In $Sb_2Te_3$ the energy characterizing the p-type Seebeck coefficient's temperature dependence, about 0.10 eV, is considerably smaller than the activation energy of the electrical conductivity, about 0.28 eV. In addition, the heat-of-transport constant of the Seebeck coefficient is much larger than that of conventional semiconductors. The Hall mobility is low (near 0.1 $cm^2$/V-sec at room temperature), anomalously signed (n-type), and increases with rising temperature with an activation energy of about 0.05 eV. These results are consistent with the charge carriers being hole-like small polarons that move by thermally assisted hopping. $Ge_2Sb_2Te_5$ also has low mobility (0.7 $cm^2$/V-sec) and a high conductivity activation energy (0.41 eV), but Seebeck data is indicative of multi-band transport.

**16:42**

**W47 12 Magnetic and transport properties of $Fe_{1-x}Co_xSb_2$** RONGWEI HU, *Physics Department Brown University Providence RI 02912 and Condensed Matter Physics Brookhaven National Laboratory, Upton NY 11973* CEDOMIR PETROVIC, *Condensed Matter Physics Brookhaven National Laboratory, Upton NY 11973* VESNA MITROVIC, *Physics Department Brown University Providence RI 02912* Anisotropic magnetic and electronic transport measurements were carried out on large single crystals of $Fe_{1-x}Co_xSb_2$, grown by self flux method, in the temperature range 1.8-350K for $0 \leqslant x \leqslant 1$. The diamagnetic semiconducting state of $FeSb_2$ evolved into metallic by substitution of Fe with Co for $x < 0.5$. With further doping there was a structural transformation from orthorhombic Pnnm structure of $FeSb_2$ to monoclinic P21/c structure of $CoSb_2$. Large magnetoresistance and anisotropy in electronic transport were observed.

**W47 13 Transport Properties of Ag Nanoparticles in Carbon Matrix Prepared with a Cluster Gun*** PENG LIU, YUNHE HUANG, MICHAEL BONDER, GEORGE HADJIPANAYIS, *Department of Physics and Astronomy, University of Delaware, Newark, DE 19716* DIONISIOS VLACHOS, SOUMITRA DESHMUKH, *Department of Chemical Engineering, University of Delaware, Newark, DE 19716* The use of ''cluster guns'' with in-situ processing capabilities has been found to be suitable for the fabrication of nanoparticles in a wide range of materials, avoiding external annealing and possible surface oxidation of the nanoparticles[1, 2]. In this study, we have used our cluster gun to fabricate Ag nanoparticles and embed them in a C matrix formed by conventional sputtering. With the increased amount of Ag, the transport properties of thin films show a gradual transition from a semiconductor-like behavior to a metallic one. At cryogenic temperatures, the magnetoresistance (MR) is generally negative at low fields and becomes positive at high fields. The field at which the MR changes sign increases with increased temperature. At higher temperatures (around 20 K), only negative MR is observed. For the samples with semiconductor-like behavior, the temperature dependence of resistance follows the relation $R = R_0\exp[(T_0/T)^{1/2}]$ in the temperature range from 5 to 50 K. We are investigating the origin of this behavior and those results will be reported.

**W47 14 Controlling the Inherent Magnetoresistance in thin InSb epilayers on GaAs (001)*** T. ZHANG, J.J. HARRIS, S.K. CLOWES, W.R. BRANDFORD, L.F. COHEN, *Imperial College* S.A. SOLIN, *Washington University in St.Louis* There is great advantage to controlling the magnetoresistance (MR) in high mobility semiconductors for a number of applications which require thin active surface layers. Previously we have produced n type thin epilayers of InSb with the highest reported mobility[1] and we have used these epilayers to explore novel geometries that enhance the high field MR.[2] Here we show that by virtue of the inherent inhomogeneity in the growth direction, thin InSb epilayers can be designed to have significant MR without external geometric manipulation. The observations can be explained using a transport model that describes the electrical properties of the layers including contributions from conduction and impurity bands.[3] We will explore using the model, the possibility of maximizing or minimizing the inherent MR in these layers and we show experimentally how to create thin high mobility layers where the inherent MR is significantly reduced or enhanced without compromising the layer mobility.[4]

**W47 15 Magnetocapacitance of Semiconductors with Nonmagnetic and Magnetic Impurities** JEREMY NESBITT, ARTHUR HEBARD, *University of Florida* Positive magnetoresistance in semiconductors has been studied by previous investigators and found to have an exponential dependence on magnetic field in the regime of hopping conduction and a power law dependence at higher temperatures, due to band carriers. To our knowledge, little experimental study has been performed on the magnetocapacitance of semiconductors outside of the low temperature regime, where phenomena such as the quantum Hall effect have been studied. Here we report on the magnetocapacitance of lightly doped ($\rho > 1\ \Omega$-cm) n- and p-type silicon, using both Schottky and oxide barriers to form capacitor structures. The frequency-dependent negative magnetocapacitance can be as large as 30% at 50K and decreases to a few percent at room temperature. We attribute this effect to a field-induced localization of shallow donor impurity wavefunctions in directions transverse to the applied magnetic field. The effect can only be observed if the measurement frequency ( $\sim$ 1MHz) is comparable to or greater than the field-dependent transition rate between impurity sites. We will also contrast the differences in the magnetocapacitance effect for diluted magnetic semiconductors such as GaCrN and GaMnAs.

**SESSION Y1: ENGINEERING BIOMOLECULES AND CIRCUITS BY RATIONAL DESIGN AND GENETIC SELECTION**

**8:00**
**Y1 1 Molecular Evolution of Gene Expression in E. coli.**
TERRY HWA, *University of California San Diego*

Understanding the evolution of gene regulation is an outstanding challenge to systems biology. Here we use molecular methods to study in detail the evolution of promoter sequences needed to express gene(s) essential to the growth of E. coli cells. We quantitatively characterize changes in the genotype and phenotype of the evolving population, and study how different challenges imposed by the environment affect the dynamics and the final outcome of the evolutionary process.

**8:36**
**Y1 2 Tinkering with Genetic Networks In Vivo.**
CALIN GUET, *The University of Chicago*

Synthetic genetic networks have recently emerged as an alternative experimental framework for studying cellular networks. Biological systems have evolved through a process of blind molecular tinkering. I will present an experimental genetic system which mimics this tinkering process. This system is composed of a few well characterized genetic elements: the promoters and genes of lambda cI, LacR and TetR. Using a combinatorial synthesis method we create libraries of simple genetic networks with various connectivities that function as logical gates. We observe how new computational functions arise through one-step changes in network connectivity. The connectivity-function map is found to be many-to-many even for these small networks.

**9:12**
**Y1 3 Directed Evolution of Bacterial Chemoreceptors.**
MARK GOULIAN, *University of Pennsylvania*

The methyl-accepting chemotaxis proteins are a family of receptors in bacteria that mediate chemotaxis to diverse signals. We have developed a simple method for selecting bacteria that swim towards target attractants, which makes it possible to isolate novel chemoreceptors. The procedure is based on establishing a diffusive gradient in semi-soft agar and does not require that the attractant be metabolized or degraded. We have applied this method to evolve the itE. coli aspartate receptor, Tar, to mediate chemotaxis to new attractants. We found that Tar is quite plastic and can be readily mutated to respond to diverse compounds. The overall change in specificity depended on the target attractant. In some cases the mutated receptors still showed significant sensitivity to aspartate, indicating that the receptors had a broadened specificity relative to wild-type Tar. In other cases, however, the Tar variants showed a dramatic decrease in their response to aspartate. This occurred in the absence of any counter-selection steps. For many of the receptors, the maximal sensitivity that was obtained could not be attributed solely to substitutions within the ligand binding pocket. The receptors that we have isolated, together with additional variants that may be obtained with our technique, provide new tools for exploring the molecular mechanisms of signal transduction by chemoreceptors. Our selection method will also be useful for constructing new receptors for the development of biosensors and for engineering bacteria for applications in biotechnology.

**Y1 4 Building a cellular oscillator from metabolic and cell signaling components.**
JAMES LIAO, *UCLA*

One of the key features of cellular oscillators is their interaction with metabolism and cellular physiology. To understand such interaction and to uncover operating principles behind these networks, we designed a synthetic gene-metabolic oscillator that links metabolism with gene regulation. The conceptual design was inspired by physical and mathematical insight, but constrained by biological and chemical realities. Biological implementation was built on detailed understanding of the physiology of the organism of interest. Non-linear dynamic analysis was used to guide the search of experimental conditions and evaluate different design. Interestingly, most of the predictions were experimentally verified, suggesting that the underlying mechanisms were properly captured by the conceptual and mathematical models.

**10:24**
**Y1 5 An artificial cell based on gene expression in vesicle.**
VINCENT NOIREAUX, *University of Minnesota*

A new experimental approach is presented to build an artificial cell using the translation machinery of a cell-free expression system as the hardware and a DNA synthetic program as the software. Cytoplasmic extracts, encapsulated in phospholipid vesicles, are used to assemble custom-made genetic circuits to develop the functions of a minimal cell. The objective is to understand how a DNA algorithm can be designed to build an operating system that has some of the properties of life. We show how a long-lived bioreactor is built to carry out in vitro transcription and translation in cell-sized vesicles. To develop the synthetic membrane into an active interface, a few amphipathic peptides and an insertion mechanism of integral membrane proteins have been tested. With vesicles composed of different phospholipids, the fusion protein alpha-hemolysin-eGFP can be expressed to reveal patterns on the membrane. Finally, specific degradation mechanisms are introduced to create a sink for the synthesized messengers and proteins. Perspectives and limitations of this approach will be discussed.

## SESSION Y2: ELECTROSTATIC LEVITATION AND HIGH ENERGY X-RAYS
**Friday Morning, 17 March 2006; Ballroom III, Baltimore Convention Center at 8:00**
**Kenneth F. Kelton, Washington University, presiding**

**8:00**
**Y2 1 Floating the Ball: Advances in the technology of electrostatic levitation.**
JAN ROGERS, *NASA/Marshall Space Flight Center*

Electrostatic Levitation (ESL) is an emerging technology. The MSFC ESL is a NASA facility that supports investigations of refractory solids and melts. The facility can be used to process a wide variety of materials including metals, alloys, ceramics, glasses and semiconductors. Containerless processing via ESL provides a high-purity environment for the study of high temperature materials and access to metastable states. Scientific topics investigated in the facility include nucleation, undercooling, metastable state formation and metallic glass formation. Additionally, the MSFC ESL provides data for the determination of phase diagrams, time-temperature-transition diagrams, viscosity, surface tension, density, heat capacity and creep resistance. In order to support a diverse research community, the MSFC ESL facility has developed a number of technical capabilities, including a portable system for in situ studies of structural transformations during processing at the high-energy X-ray beamline at the Advanced Photon Source of Argonne National Laboratory. The capabilities of the MSFC ESL facilities will be discussed and selected results of materials processing and characterization studies will be presented.

**8:36**
**Y2 2 New insights into the thermophysical properties of materials using electrostatic levitation.**
ROBERT HYERS, *University of Massachusetts*

Electrostatic Levitation (ESL) allows non-contact measurement of the thermophysical properties of materials in both the solid and liquid states, from over 3500C to deep in the undercooled liquid, for a wide range of materials including metals, ceramics, and semiconductors. The combination of ESL with synchrotron x-ray structural measurements allows unprecedented insight into the relation between structure and properties in reactive and undercooled materials. Of the many different thermophysical and thermomechanical properties that have been measured using levitation techniques, four will be discussed. The density of the sample is calculated from the shape of the free surface in video images and the known mass. The surface tension and viscosity are determined from the natural frequency and damping, respectively, of free surface oscillations. Creep is measured by observing the changes in free surface shape due to centrifugal acceleration in a rapidly rotating drop. Combined with the x-ray structure measurements, these mechanical measurements can reveal the development of texture and strain-induced phase transformations. Any of these measurements may be performed on the same sample, in the same environment, at the same time as the x-ray structural measurements, allowing direct observation of the effect of changes in the structure of the sample on the thermophysical properties.

**9:12**
**Y2 3 A Deeper View of Materials: Coupling electrostatic levitation and high energy x-ray diffraction.**
ALAN GOLDMAN, *Ames Laboratory, USDOE and Department of Physics and Astronomy, Iowa State University*

The ability to measure changes in the atomic scale structure, associated with novel thermophysical properties, will lead to tremendous advances in our understanding of the underlying physics of materials. This talk will focus on the integration of electrostatic levitation (ESL) techniques and high energy x-ray diffraction. The use of high energy x-rays

($E > 100$ keV) offers several distinct advantages over conventional x-ray methods. First and foremost, high energy x-rays are required for full penetration of the levitated samples, which are typically 2-3 millimeters in diameter. This ensures that the bulk, rather than near-surface, structures are sampled in the measurement. A second important benefit of high energy x-rays lies in the fact that diffraction patterns can be collected over a relatively wide momentum transfer range for a small range of angles. The relatively small range of scattering angles required for most measurements allows the use of area detectors for fast data acquisition while the sample is either held at a constant temperature or during continuous heating/cooling cycles. The latter method is particularly suitable for continuous studies of phase transformations as the sample is heated from room temperature to the liquidus temperature and above, or cooled from high temperatures. This is, perhaps, best illustrated by recent work on the atomic scale structure of deeply undercooled liquid metals and semiconductors, such as silicon, where time resolved (100ms/frame) data have shown that, in contrast to previous structural measurements and several theoretical treatments, there is no evidence for a liquid-liquid phase transition in the undercooled regime.

**9:48**
**Y2 4 X-ray photoelectron spectroscopy in the hard x-ray regime.***
CHARLES S. FADLEY, *UC Davis & LBNL*

Photoelectron spectroscopy is by now a very widely used tool for the study of atoms, molecules, solids, surfaces, and nanoscale structures. Until very recently, the exciting radiation has been limited to the energy range below about 2 keV. However, within the past few years, a few experimental projects have been initiated in which photon energies in the 5-15 keV range are employed. By matching the characteristics of undulator beamlines at third-generation synchrotron radiation sources to the optical properties of the electron spectrometer, it has proven possible to overcome the reduced photoelectric cross sections at such high energies and to study both core and valence electronic levels with resolutions down to ca. 50 meV [1]. Such hard x-ray photoelectron spectroscopy (HXPS or HAXPES) has the advantage of being more bulk sensitive, with electron inelastic attenuation lengths in the 50-150 Angstrom range. In this talk, I will discuss the advantages and disadvantages of this new direction, including highlights from recent work, as well as suggested future avenues for HXPS studies. [1] Nuclear Instruments and Methods A 547, 24 (2005), special issue dedicated to hard x-ray photoelectron spectroscopy, edited by J. Zegenhagen and C. Kunz.

**10:24**
**Y2 5 Hard x-ray photoelectron spectroscopy and x-ray standing waves.**
TIEN-LIN LEE, *European Synchrotron Radiation Facility*

Using the brilliant undulator radiation available from the third generation synchrotron sources, hard x-ray photoelectron spectroscopy (HAXPES) has become an emerging field in the recent years. With the excitation energy used in HAXPES one can benefits from the large mean free path of fast electrons ( $\sim$ 5 nm for electrons of 6 keV kinetic energy) in probing the bulk electronic properties of materials. For high-resolution studies, photon energy bandwidth narrower than 100 meV is also readily achievable in the hard x-ray range with crystal monochromators. In addition, working with hard x-ray offers the possibility for combining photoelectron spectroscopy with x-ray standing wave (XSW) method. With the high spatial resolution from XSWs, this unique combination can provide site-specific, chemical and electronic information for studying surfaces, buried interfaces, thin films and bulk crystals. In this talk, I will briefly mention some HAXPES experiments detecting electrons up to 14.5 keV [1,2]. I will then sketch the principle of combining XSWs with HAXPES and present results from some recent applications using this combination: (1) chemical state-specific surface structure determination with core-level photoemission, (2) site-specific valence x-ray photoelectron spectroscopy and (3) XSW imaging with core-level photoemission. [1] S. Thiess, C. Kunz, B.C.C. Cowie, T.-L. Lee, M. Renier, and J. Zegenhagen. Solid State Communications 132, 589 (2004) [2] C. Kunz, S. Thiess, B.C.C. Cowie, T.-L. Lee, and J. ## SESSION Y4: HIGH TMR MGO TUNNELING AND SPIN MOMENTUM TRANSFER MATERIALS, PHYSICS, AND DEVICES

**Friday Morning, 17 March 2006; 308, Baltimore Convention Center at 8:00**
**Robert Buhrman, Cornell University, presiding**

**8:00**
**Y4 1 Giant tunneling magnetoresistance and tunneling spin polarization in magnetic tunnel junctions with MgO (100) tunnel barriers.**
STUART PARKIN, *IBM Almaden Research Center*

Recent advances in generating, manipulating and detecting spin-polarized electrons and electrical current make possible new classes of spin based sensor, memory and logic devices [1]. One key component of many such devices is the

magnetic tunneling junction (MTJ) - a sandwich of thin layers of metallic ferromagnetic electrodes separated by a tunneling barrier, typically an oxide material only a few atoms thick. The magnitude of the tunneling current passing through the barrier can be adjusted by varying the relative magnetic orientation of the adjacent ferromagnetic layers. As a result, MTJs can be used to sense the magnitude of magnetic fields or to store information. The electronic structure of the ferromagnet together with that of the insulator determines the spin polarization of the current through an MTJ – the ratio of 'up' to 'down' spin electrons. Using conventional amorphous alumina tunnel barriers tunneling spin polarization (TSP) values of up to $\sim$ 55% are found for conventional 3d ferromagnets, such as CoFe, but using highly textured crystalline MgO tunnel barriers TSP values of more than 90% can be achieved for otherwise the same ferromagnet [2]. Such TSP values rival those previously observed only with half-metallic ferromagnets. Corresponding giant values of tunneling magnetoresistance (TMR) are found, exceeding 350% at room temperature and nearly 600% at 3K. Perhaps surprisingly the MgO tunnel barrier can be quite rough: its thickness depends on the local crystalline texture of the barrier, which itself is influenced by structural defects in the underlayer. We show that the magnitude and the sign of the TMR is strongly influenced by defects in the tunnel barrier and by the detailed structure of the barrier/ferromagnet interfaces. The observation of Kondo-assisted tunneling phenomena will be discussed as well as the detailed dependence of TMR on chemical bonding at the interfaces [3]. [1].S.S.P. Parkin, X. Jiang, C. Kaiser, et al., Proc. IEEE 91, 661 (2003). [2] S. S. P. Parkin, C. Kaiser, A. Panchula, et al., Nature Mater. 3, 862 (2004). [3] C. Kaiser, S. van Dijken, S.-H. Yang, H. Yang and S.S.P. Parkin, Phys. Rev. Lett. 94, 247203 (2005).

**Y4 2 Giant TMR effect and spin momentum transfer in MgO-based magnetic tunnel junctions.***

SHINJI YUASA, *National Institute of Advanced Industrial Science and Technology (AIST)*

First-principle theories predicted an extremely high magnetoresistance (MR) ratio over 1000% in fully epitaxial Fe(001)/MgO(001)/Fe(001) MTJs [1]. This giant tunneling magnetoresistance (TMR) effect originates from a coherent spin-dependent tunneling of highly spin-polarized $\Delta_1$ electronic states. We have fabricated fully epitaxial $Fe_{1-x}Co_x$(001)/MgO(001)/Fe(001) MTJs [2,3] and CoFeB/MgO(001)/CoFeB MTJs [4] and achieved giant MR ratios above 200% at room temperature. A low resistance-area (itRA) product indispensable for magnetic sensor application has also been achieved in CoFeB/MgO(001)/CoFeB MTJs [5]. Because of the high spin polarization of tunneling electrons, the MgO-based MTJs have an advantage in spin transfer phenomena, too. Current-induced magnetization reversal due to spin transfer torque has been demonstrated using CoFeB/MgO(001)/CoFeB MTJs [6]. The MTJ was also found to act as a microwave detector [7]. When an ac current with a microwave frequency is applied to the MTJ, a dc offset voltage is generated. This phenomenon, named as spin-torque diode effect, originates from spin momentum transfer, ferromagnetic resonance and the giant TMR effect. The giant TMR effect and spin momentum transfer in MgO-based MTJs are the key for next-generation spintronic devices. References [1] W. H. Butler et al., Phys. Rev. B **63**, 054416 (2001). [2] S. **9:12**

**Y4 3 Spin torque, tunnel-current spin polarization and magnetoresistance in MgO magnetic tunnel junctions.**

GREGORY FUCHS, *Cornell University*

The ability of electron currents to transfer spin angular momentum, as well as charge, from one ferromagnetic electrode to another, and hence to exert a significant spin-torque on the electrodes, provides a powerful new tool for the study of spin transport in electronic structures, in addition to establishing new opportunities for future applications. The closely related issue of spin-dependent electron transport in magnetic tunnel junctions (MTJs) is of wide-spread interest, both fundamentally and because the importance this phenomena has for information storage. A critical aspect of MTJs is the bias dependence of the tunnel magnetoresistance (TMR), which in general, decreases as the voltage bias ($V$) increases. Currently, there is no consensus as to a microscopic model that accounts for this behavior. In this study, we employ the spin torque response of MTJs with ultra-thin MgO tunnel barrier layers to investigate the relationship between spin transfer and TMR under finite bias, and find that the spin torque per unit current exerted on the free layer decreases by $<$ 10% over a bias range where the TMR decreases by $>$ 40%. This behavior is inconsistent with a decrease in the tunnel polarization factors calculated with the Julliere formula extended to finite bias, and as predicted by free-electron tunneling models, or by surface-magnon emission models that substantially decrease the surface magnetization with increasing bias. We find, however, that magnetic-state-dependent tunneling decay lengths (effective masses) as theoretically predicted for MgO tunnel barriers, are consistent with our results. Since these results also have significant implications for spin-torque driven magnetic random access memory, we will consider these effects in addition to our work with MTJs having two polarizing magnetic layers in order to boost spin-torque as well as allow us to determine the extent of the considerable self-heating for MTJs under bias.

**Y4 4 Structure Engineering And Shape Optimization To Decrease Switching Current For Spin Transfer MRAM Application.**

YIMING HUAI, *Grandis, Inc.*

We present a systematic study of spin transfer switching in magnetic tunneling junctions (MTJs) to decrease the switching current density through material and structural engineering and MTJ element shape optimization. Data are presented for switching on MgO-based MTJs with high TMR of 170 % and low intrinsic switching current density $J_{c0} \leqslant 1\text{x}10^6$ A/cm$^2$. Micromagnetic modeling is used to study the spin transfer switching mechanism in nanosecond regime for elliptical shape of the MTJ element. The results suggest that the elliptical shape provides faster switching (lower switching current) and more reproducible switching than the conventional shapes optimized for magnetic field switched MRAM (Magnetic Random Access Memory).

**10:24**

**Y4 5 Thermal activation and switching dynamics in spin-torque-induced magnetic reversal in magnetic tunnel junctions with MgO barriers.**

JONATHAN SUN, *IBM T. J. Watson Research Center*

Spin-torque induced magnetic reversal has been unambiguously demonstrated in magnetic tunnel junctions with MgO barriers. During a quasi-static measurement, the reversal is dominated by events determined by spin-current amplified thermal activation, resulting in a measured average switching current below that of the zero-temperature dynamic threshold. Such sub-threshold switching current generally shows stronger and non-linear magnetic field dependence, following a shape determined by the magnetic field dependence of the thermal barrier height. Time-resolved measurements are usually required for adequately assessing the dynamic switching threshold current for fast (nano-second-level) deterministic switching, and for revealing the magnetic field dependence of the threshold current. The later would give direct experimental verification of the role a large easy-plane demagnetization field plays as it determines the value of the dynamic switching current threshold.

## SESSION Y5: NEW FUNCTIONALITIES IN GLASSES AND NANOMATERIALS

**Y5 1 Glasses and Ceramics as Templates for Generating Nanostructures and Novel Properties.**

DIPANKAR CHAKRAVORTY, *Indian Association for the Cultivation of Science*

Silica glasses containing substantial amounts of modifying oxides have considerable void spaces within their structure. These systems have therefore been exploited to generate different kinds of nanostructures e.g., nanoparticles,core-shell structures and nanowires. Similarly, ceramic structure like mica have well-defined crystal channels. The latter have been used to prepare nanowires or nanosheets. In this lecture the author will discuss some examples in which the above strategies of material synthesis have been applied. Copper core-copper oxide shell nanostructures with diameters $\sim$ 6 nm were grown within a gel-derived silicate glass containing copper ions[1]. Electrical conductivity of the nanocomposites was several orders of magnitude higher than that of the parent glass. An interfacial amorphous phase gave rise to this behaviour. Electrical conduction was ascribed to a small polaron hopping mechanism. Silver metal core–silver oxide shell structure with nanometer dimensions were generated in a silicate glass by first precipitating silver particles of $\sim$ 6nm diameter by an electrodeposition process and subsequently subjecting the material to an oxidation treatment[2]. Detailed analysis of the optical absorption spectra led to the conclusion that there is a metal non metal transition for particles having diameters less than $\sim$ 2.5 nm. Similar results were obtained in the case of copper core- copper oxide shell nanostructures grown within a silicate glass[3]. Core-shell structure of Fe-$Fe_3O_4$ system was also produced within a gel derived silica glass which exhibited a four order of magnitude change in electrical resistivity when the relative humidity was changed from 25%to 95% [4]. Silver and copper nanowires respectively were grown within a silicate glass by the application of an electric field. These nanowires were found to consist of arrays of metal nanoparticles. The latter gave rise to nano-junctions between large and small particles which behaved as metal–semiconductor junctions. A diode like voltage current characteristic was observed in these nanocomposites.[5] Silver nanowires were grown by electrodeposition within gel–derived silica glasses containing pores having diameters in the nanometre range. After suitable treatment to these nanowires these exhibited single electron tunnelling property[6]. Silver nanowires were grown within the channels of fluorophlogopite mica crystals precipitated within a suitably chosen glass composition. The nanocomposites exhibited giant dielectric permittivity ( $\sim 10^7$) which were explained on the basis of Gorkov-Eliashberg and Rice–Bernasconi model[7]. Na-4mica structure was used to grow CdS nanowire[8]. The former was also used to prepare films of $BaTiO_3$ with

a thickness of 1.2 nm. These films did not show any ferroelectric behaviour which was consistent with recent theoretical prediction[9]. [1] D.Das and D.Chakravorty, Appl. Phys. Lett. 76, 1273 (2000). **Y5 3 Novel polarization dependent photoinduced effects in glass.**
HIMANSHU JAIN, *Lehigh University*

For centuries oxide glasses have been used successfully in windows, thus indicating that they remain stable, unlike plastics, against exposure to sunlight. By comparison, the structure and properties of closely related chalcogenide glasses are easily altered by exposure to visible light of energy $\geqslant$ bandgap of the material. In general, such photoinduced changes may be classified into three categories depending on their stability: (a) permanent changes which cannot be recovered unless the sample is melted and prepared again, (b) metastable changes which can be reversed by heating the sample to the glass transition temperature, and (c) temporary changes which can be reversed simply by removing the light source, or exposing the specimen to another appropriate light subsequently. Among the numerous photoinduced phenomena, the photoinduced vector effects like anisotropic light transmission, mass transport, opto-mechanical effect, etc. are particularly fascinating as they depend on the direction of light polarization in spite of the isotropic glass structure. The transient 'vector' optical effects, which are produced by linearly polarized light and then erased by either unpolarized or circularly polarized light, are even more intriguing and novel. This paper will review the various observations of photoinduced vector effects. It will then focus on the origin of such effects, which we have sought by probing the changes in atomic and electronic structure under in situ laser irradiation.

**Y5 4 Polyamorphic transitions in network glasses and glass-forming liquids.**
JOHN KIEFFER, *University of Michigan*

Over the past two decades, we have witnessed increasing evidence for the occurrence of polyamorphism, i.e., the existence of more than one thermodynamically and structurally distinct non-crystalline state of a given substance. This concept is manifest predominantly through the transitions between different polyamorphic states, as we are still not able to unequivocally describe a given amorphous structure. However, if substantiated, the concept of polyamorphism should facilitate such a description, since it implies that polyamorphic states are uniquely defined and a distinctive structural character must exist for each state. We have observed polyamorphic transitions in a number of glass-forming systems, e.g., when probing their high-frequency visco-elastic response as a function of temperature,[1] or when compacting such systems at high pressures. We have carried out molecular dynamics simulations to reveal explanations for the phenomena observed in experiments.[2] In this presentation we discuss reversible and irreversible transitions in silica glass, their relation to the anomalous thermo-mechanical properties of this material, and the effects of permanent densification on structure and properties. We present an unusual transition in boron oxide glass, which is continuous upon compression and discontinuous upon decompression.[3] We show how the manifestations of polyamorphic transitions and their are related to structural transformations in the crystalline counterparts of these materials, and how this can even lead to the discovery of previously unknown metastable crystalline phases. **Y6 1 High-$T_c$ and *t-J* model: passions and disappointments.**
LEONID P. PRYADKO, *University of California, Riverside*

I will discuss the high-temperature phase diagram of the two-dimensional *t-J* and related models. Among the many numerical and analytical techniques which have been used to search for superconductivity in these models, only a few provide unbiased results. Particularly, the high-temperature series constructed for a number of thermodynamical correlation functions indicate that in the accessible range of temperatures, $T \geqslant J/2$, the superconducting fluctuations are only pronounced in the unphysical regime, $J > t$, while they are strongly suppressed in the physical regime, $J < t$. Additionally, in the physical regime, the correlation length for superconducting fluctuations is small on the scale of the lattice constant. This is suggestive evidence that high-temperature superconductivity does not occur in the *t-J* model. I will analyze the validity of these results by looking at high-temperature series for the *t-J* model on small clusters and ladders, as well as for related bosonic models, whose finite-temperature phase diagram is relatively well understood from other numerical methods.

**Y6 2 Enhanced d-wave Superconducting Fluctuations in the 2D t-J model.***
WILLIAM PUTIKKA, *Ohio State University*

I have calculated high temperature series to 12th order in inverse temperature for singlet superconducting correlation functions of the 2D *t-J* model with *s*-, $d_{x^2-y^2}$ and $d_{xy}$-symmetry pairs. The strengths of the different symmetry correlations are measured using $\mathbf{q} = 0$ correlation lengths. I find that for $J/t = 0.4$ the correlation length for $d_{x^2-y^2}$ pairing grows strongly with decreasing temperature, developing a broad peak around doping $\delta = 0.25$ when the temperature is reduced to $T/J = 0.25$. The correlation lengths for *s* and $d_{xy}$ pairs remain small and do not display peaks as a function of doping. The temperature scale for growth in the $d_{x^2-y^2}$ correlation length agrees with the temperature scale where the temperature derivative of the momentum distribution function $dn_{\mathbf{k}}/dT$ and the gradient of the momentum distribution function $|\nabla_{\mathbf{k}} n_{\mathbf{k}}|$ develop peaks on the Brillouin zone diagonal. This indicates that the low energy excitations in the 2D *t-J* model are concentrated near the zone diagonal, as would be expected for superconducting order with $d_{x^2-y^2}$-symmetry pairs. I will also discuss differences between my calculation and previous calculations for superconducting correlations in the 2D *t-J* model.

**Y6 3 *d*-wave resonating valence bond states of ultracold fermionic atoms in optical lattices.**
MATTHIAS TROYER, *ETH Zurich*

In view of the apparently exponential complexity of fermionic simulations in two and more dimensions, we consider a controlled quantum simulation to probe the ground state properties of the two-dimensional Hubbard model. We present a controlled experimental setup to adiabatically construct superfluid *d*-wave resonating valence bond (RVB) states of fermionic atoms confined in a 2D optical lattice. The key idea is to start from a pure initial state which is adiabatically transformed to *d*-wave RVB states at ultralow temperatures of a few percent of the Fermi temperature. We discuss hole doping techniques and describe a simple experimental measurement to study *d*-wave pairing.The proposed experiment can be used to effectively probe ground state properties of the repulsive Hubbard model on (coupled) plaquettes, ladders and the 2D square lattice. The proposal is within the capabilities of current technology, and shows how an adiabatic quantum simulator could answer a question that cannot currently be reliably answered by classical computational methods. **Y6 4 Superconducting correlations and thermodynamic properties in 2D square and triangular *t-J* model.***
MASAO OGATA, *Department of Physics, University of Tokyo*

Equal-time superconducting correlation functions of the two-dimensional *t-J* model on the square lattice are studied using high-temperature expansion method.[1] The sum of the pairing correlation, its spatial dependence and correlation length are obtained down to $T \simeq 0.2t$. By comparison of single-particle contributions in the correlation functions, we find effective attractive interactions between quasi-particles in $d_{x^2-y^2}$-wave channel. It is shown that *d*-wave correlation grows rapidly at low temperatures for the doping $0.1 < \delta < 0.5$. The temperature for this growth is roughly scaled by $J/2$. This is in sharp contrast to the Hubbard model in a weak or intermediate coupling region, where there are few numerical

evidences of superconductivity. We also study the possible *d*- and *f*-wave pairing in the triangular *t-J* model.[2] When $t > 0$ with hole doping, a rapid growth of effective *d*-wave paring interaction is found that indicates the resonating-valence-bond superconductivity. In contrast, when $t < 0$, where the ferromagnetic- and antiferromagnetic correlation compete, correlation lengths of the *f*-wave triplet paring tends to diverge around $\delta = 0.6$, although its effective interaction is small. This result is compared and discussed with the recently discovered superconductor, $Na_xCoO_2 \cdot yH_2O$, where Co atoms form a triangular lattice. Specific heat in low temperatures are also obtained in the high-temperature expansion method. We will discuss that the doping dependence of the specific heat coefficient, $\gamma$, agrees with experimental data.

**Y7 1 Nanowires for High-Performance Integrated Macroelectronics.**
ROBIN FRIEDMAN, *Harvard University*

Extensive electrical and optical characterization has shown that single-crystal semiconductor nanowires display physical properties that match or exceed those of their bulk counterparts. In addition, our studies have shown that it is possible to manipulate and assemble high-performance devices using low-temperature liquid based processes. These high-performance semiconductor device properties and unconventional processing advantages possible with nanowires can be readily applied in the field of macroelectronics, where integrated devices are patterned over large noncrystalline and/or flexible substrates. The separation of high temperature nanowire synthesis from subsequent ambient temperature assembly allows for electronic devices of varied functionality to be fabricated on virtually any substrate. We have fabricated p-Si nanowire transistors on glass and plastic substrates that display parameters rivaling those of single crystal silicon and exceeding those of state-of-the-art amorphous silicon and organic transistors currently used for flexible electronics on plastic substrates today. With the improved reproducibility obtained through improvements in nanowire growth and the use of multi-nanowire transistors, we have been able to demonstrate integrated logic structures with gain up to megahertz frequencies. On-chip integration of nanowire-based inverters was accomplished in a fully parallel process, and has enabled the fabrication of inverters and ring oscillators with frequencies up to 200 MHz, the highest observed for circuits based on nanoscale materials.

**Y7 2 Property of individual conducting-polymer nanowires: conductance and FET devices.***
TOMIHIRO HASHIZUME, *Advanced Research Laboratory, Hitachi, Ltd., Hatoyama, Saitama 350-0395 Japan*

Electronic devices using organic molecules and nanowires have been intensively studied in dream of a smart life utilizing charming functions of organic materials, that are thin, light, flexible and yet inexpensive and safe for environment. A key step for measuring the property of organic nanowires and evaluating the performance of the nanowire devices is how to access them by appropriate nanoscopic methods. Scanning probe microscopy (SPM) based nanofabrication (SP nanofabrication) has been used to fabricate two- or four-probe fine electrodes and several kinds of nanowires made of conducting polymers have been evaluated by SPM and the fine electrodes made with Pt thin film fabricated on SiO2/doped Si or sapphire substrates [1,2]. We have tested conductivity of single poly (3,4-ethylenedioxythiophene) / poly (styrenesulfonate) (PEDOT/PSS) nanowires. After cutting each nanowires placed on the fine electrodes, the current was checked and we were able to confirm that the conductivity was derived from the PEDOT nanowires themselves. The temperature dependence of the conductivity was explained by the quasi one-dimensional variable range hopping (VRH) model. We also will discuss on the field-effect-transistor (FET) made of a single nanowire. In collaboration with: S. Heike, M. Fujimori, Y. Suwa (ARL), H. Ichihara, S. Samitsu, A. Inomata, T. Shimomura, K. **Y7 3 Magnetic field asymmetry and high temperature magnetoresistance in single-walled carbon nanotubes.**

DAVID COBDEN, *Department of Physics, University of Washington*

The length scales and scattering processes in the one-dimensional electron system in single-walled carbon nanotubes remain only partially understood. Measuring the magnetoresistance, in both linear and nonlinear response, is a way to investigate these processes. In disordered nanotubes with ballistic paths much shorter than the length, we observe magnetoresistance in the metallic regime which at low temperatures resembles the universal fluctuations and weak localization seen in higher dimensional metals. A parabolic magnetoresistance persists at room temperature, indicating a significant role for phase coherence and/or interactions at high temperatures. While the linear resistance of a two-terminal sample must be an even function of magnetic field $B$ by Onsager's principle, the nonlinear resistance need not be. Importantly, the $B$-asymmetric nonlinear terms can in principle be used to infer the strength of electron-electron interactions in the sample [1]. We have therefore also measured in detail the lowest order $B$-asymmetric current contributions, with a focus on the $B$-linear term. This has apparently not been done before in any system. Consistent with general theory, at high temperatures the term is small and has a constant sign independent of Fermi energy. At low temperatures it grows and develops mesoscopic fluctuations. Although these result imply that interactions are involved in the transport, calculations specific to nanotubes are needed in order to extract interaction parameters. This work was done by the authors of Ref [2]. itReferences: [1] E.L. Ivchenko and B. Spivak, Phys. Rev. **Y7 4 Electrical Conductivity of Organic and Inorganic Nanowires Measured by Multi-probe Scanning Tunneling Microscopes.***

MASAKAZU AONO, *Nanomaterials Laboratory, National Institute for Materials Science (NIMS), Japan*

Since 1998 [1], the authors and co-workers have developed multi-probe scanning tunneling microscopes (MPSTMs), in which two, three or four probes are operated independently. All probes of the MPSTMs can observe STM images independently, but the main role of the multiple probes is to be used as nanoscale electrodes that can contact any points selected in an observed STM image. It is therefore possible to measure electrical conductivity at the nanoscale through the multiple probes. By using MPSTMs and related methods, we measured the electrical conductivity of organic and inorganic nanowires, i.e., single-wall carbon nanotubes (SWCNTs), erbium disilicide (ErSi2) metallic nanowires, and single polydiacetylene (PDA) molecular wires. For a SWCNT and an ErSi2 nanowire, ballistic conduction was observed at lengths less than about 500 and 20 nm, respectively, at room temperature. For a PDA molecular wire, polaron formation due to charge injection caused by applying a voltage to an STM tip placed close to the PDA molecular wire was observed, and when the voltage exceeded a critical value, the PDA molecular wire changed into a metallic state. **Y8 1 DCOMP Award Lecture (Metropolis): A 3D Spectral Anelastic Hydrodynamic Code for Shearing, Stratified Flows.***

JOSEPH BARRANCO, *Harvard University*

We have developed a three-dimensional (3D) spectral hydrodynamic code to study vortex dynamics in rotating, shearing, stratified systems (eg, the atmosphere of gas giant planets, protoplanetary disks around newly forming protostars). The time-independent background state is stably stratified in the vertical direction and has a unidirectional linear shear flow aligned with one horizontal axis. Superposed on this background state is an unsteady, subsonic flow that is evolved with the Euler equations subject to the anelastic approximation to filter acoustic phenomena. A Fourier-Fourier basis in a set of quasi-Lagrangian coordinates that advect with the background shear is used for spectral expansions in the two horizontal directions. For the vertical direction, two different sets of basis functions have been implemented: (1) Cheby-

shev polynomials on a truncated, finite domain, and (2) rational Chebyshev functions on an infinite domain. Use of this latter set is equivalent to transforming the infinite domain to a finite one with a cotangent mapping, and using cosine and sine expansions in the mapped coordinate. The nonlinear advection terms are time integrated explicitly, whereas the Coriolis force, buoyancy terms, and pressure/enthalpy gradient are integrated semi- implicitly. We show that internal gravity waves can be damped by adding new terms to the Euler equations. The code exhibits excellent parallel performance with the Message Passing Interface (MPI). As a demonstration of the code, we simulate vortex dynamics in protoplanetary disks and the Kelvin-Helmholtz instability in the dusty midplanes of protoplanetary disks.

**Y8 2 Evaporating droplets** NOUSHINE SHAHIDZADEH-BONN, *Laboratoire des Materiaux et Structures du Genie Civil (LMSGC)* SALIMA RAFAI, *WZI/University of Amsterdam* AZA AZOUNI, *LMSGC* DANIEL BONN, *LPS/Ecole Normale Superieure* LMSGC TEAM, LPS/ENS TEAM, WZI/UVA COLLABORATION, In our everyday life we are constantly confronted with evaporating drops and the consequences of it. The seemingly simple problem of an evaporating droplet has attracted a great deal of attention over the past years. The problem is complicated due to the fact that the form of the droplet during the evaporation is a priori unknown, and due to the large number of effects that have to be taken into account (temperature, convection, Marangoni effects . . . ). We consider the very simple situation of the evaporation of a perfectly wetting liquid on a molecularly smooth surface. The radius R(t) of the droplet is followed in time until it reaches zero. If the evaporation is purely diffusive, a radius that decreases as the square root of time is expected; this is indeed found for organic liquids, but water has a different exponent. We show that the difference is likely to be due to the fact that water vapor is lighter than air, and the vapor of other liquids more dense. If we carefully confine the water so that the diffusive boundary layer may develop, we retrieve the square root of time behavior. On the other hand, if we force convection for an organic liquid, we retrieve the anomalous exponent for water.

**8:48**
**Y8 3 Effect of Viscoelasticity on Drop Deformation** NISHITH AGGARWAL, *University of Delaware* KAUSIK SARKAR, *University of Delaware* Deformation of a drop is numerically investigated when one or both of the drop and continuous phases is viscoelastic. A three-dimensional front-tracking finite difference method is used to simulate the deforming drop. The viscoelasticity is modeled using the Giesekus and Oldroyd−B constitutive relations. In a shear flow, a viscoelastic drops in a Newtonian matrix deforms less than a Newtonian drop. Specifically, bounded viscoelastic drop shapes are found for capillary numbers where a Newtonian drop would break up. Matrix viscoelasticity, however is observed to cause non-monotonic change in drop deformation with increasing viscoelasticity. The effects of inertia, interfacial tension, viscosity ratio and imposed flow periodicity (in oscillatory shear) will be presented. The detailed results about transient dynamics, viscous and viscoelastic stresses and the velocity fields inside and outside the drop will be discussed and explained.

**9:00**
**Y8 4 Pressure Driven Liquid-Vapor Phase Transitions** TIANSHI LU, ROMAN SAMULYAK, *Computational Science Center, Brookhaven National Laboratory* JAMES GLIMM, *Department of Applied Mathematics and Statistics, Stony Brook University* Liquid-vapor phase transitions driven by pressure waves have been studied analytically and numerically. The Stefan problem has been extended to incorporate the compressibility of the vapor phase. Both internal heat conduction and external heat deposition (such as from electrons in tokamak fusion reactors) have been considered. The steady state and the transient waves in the phase transitions have been investigated. A numerical scheme has been developed for the simulation of compressible two-phase flows with phase transitions in the frame of front tracking. Phase boundaries can be created dynamically in regions under critical conditions. The numerical method has been applied to the simulation of boiling and cavitating processes.

**9:12**
**Y8 5 Interaction between a free boundary and thermal convection in an annulus** JIN-QIANG ZHONG, *Physics Dept., NYU* JUN ZHANG, *Physics Dept. and Courant Inst., NYU* We report an experimental study in turbulent thermal convection that has a free upper surface. The geometry of the convective system is annular with aspect ratio (girth/height) 6.8 and with periodic boundary condition. Our experiment studies the interaction between the convective flow and a freely moving floating boundary that partially covers the open surface. The floating boundary position and the corresponding convective pattern are recorded at the same time and are correlated to reveal the dynamics of the coupled system. Our experiment aims to illustrate the intricate mechanism of continental drift that is driven by mantle convection.

**9:24**
**Y8 6 The Stochastic Dynamics of an Array of Atomic Force Microscope Cantilevers in a Viscous Fluid** MATTHEW CLARK, *Virginia Tech* MARK PAUL, *Virginia Tech* The hydrodynamic coupling between micron scale atomic force microscope cantilevers in a viscous fluid is studied. Using the fluctuation-dissipation theorem, the stochastic dynamics of the cantilevers are quantified from deterministic calculations. Numerical simulations of individual cantilevers immersed in fluid are used to verify the approach. A simple harmonic oscillator model is shown to be reasonable for the description of the dynamics of a single cantilever. The fluid induced correlations in an array of cantilevers are then explored and quantified. Absolute predictions of the cross-correlations in the equilibrium fluctuations of cantilever displacement are presented. This is used to yield limits of the force and time scales of operation for a correlation detection method using multiple atomic force microscope cantilevers.

**9:36**
**Y8 7 Co-rotating Batchelor vortex merging** PAULO FERREIRA DE SOUSA, *New Mexico State University* JOSE CARLOS FERNANDES PEREIRA, *Instituto Superior Tecnico* The dynamics of co-rotating vortex pairs without axial flow has been recently thoroughly studied through theoretical, experimental and numerical studies, which revealed different instabilities contribut-

ing to the decay of the vortices. In this paper the objective is to extend the analysis to the case of co-rotating vortices with axial flow at low Reynolds numbers. A high-order incompressible Navier-Stokes flow solver is used. The momentum equations are spatially discretized on a staggered mesh by finite differences and all derivatives are evaluated with 4th order compact finite difference schemes with RK-4 temporal discretization. The initial condition is a linear superposition of two co-rotating circular Batchelor vortices with q = 1. It is found that there is an initial evolution that resembles the evolution that single q = 1 vortices go through. Azimuthal disturbances grow and result in the appearance of large-scale helical sheets of vorticity. With the development of these instability waves, the axial velocity deficit is weakened. The redistribution of both angular and axial momentum between the core and the surroundings drives the vortex core to a more stable configuration, with a higher q value. After these processes, the evolution is somewhat similar to a pair of co-rotating Lamb-Oseen vortices. A three-dimensional instability develops, with a large band of unstable modes, with the most amplified mode corresponding scaling with the vortex initial separation distance.

**Y8 8 Magnetic Body Force Sustained Temperature Gradient*** JONATHAN FRAINE, WEILI LUO, *University of Central Florida* UNIVERSITY OF CENTRAL FLORIDA TEAM, The temperature gradient was established in a magnetic fluid by controlling the rate of cycling coolant. Measurements were done to monitor temperature gradient verses time before and after the cooling was stopped in both zero and applied magnetic field. We found that the magnetic field can sustain a larger temperature gradient. The theoretical calculation shows that the effect of field on the temperature gradient is attributed to the magnetic body force that depends on the gradient of the susceptibility.

**Y8 9 Shock Interaction with a Finite Thickness Two-Gas Interface** JOHN LABENSKI, *NIST* YONG KIM, *Lehigh University* A dual-driver shock tube was used to investigate the growth rate of a finite thickness two-gas interface after shock forcing. One driver was used to create an argon-refrigerant interface as the contact surface behind a weak shock wave. The other driver, at the opposite end of the driven section, generates a stronger shock of Mach 1.1 to 1.3 to force the interface back in front of the detector station. Two schlieren systems record the density fluctuations while light scattering detectors record the density of the refrigerant as a function of position over the interface during both it's initial passage and return. A pair of digital cameras take stereo images of the interface, as mapped out by the tracer particles under illumination by a Q-switched ruby laser. The amount of time that the interface is allowed to travel up the driven section determines the interaction time as a control. Comparisons made between the schlieren signals, light scattering detector outputs, and the images quantify the fingered characteristics of the interface and its growth due to shock forcing. The results show that the interface has a distribution of thicknesses and that the interaction with a shock further broadens the interface.

**Y8 10 Investigation of Oxygen Transfer Enhancement in Thermally Driven Cavities By Lattice Boltzmann Simulation.** HUIDAN YU, *CNLS, Los Alamos National Lab* JINSUO ZHANG, *D-5, Los Alamos National Lab* NING LI, *MST-10, Los Alamos National Lab* We investigate the enhancement of mass transfer in 2D thermally driven cavities using lattice Boltzmann equation (LBE) method. The computational technique integrates three coupled LBEs for solving velocity, temperature, and concentration fields simultaneously. Simulation is performed for oxygen transfer in lead/lead-bismuth eutectic with variations of temperature boundary, Schmidt number, and field aspect ratio to investigate the effects on enhancement of oxygen transfer. Interested characteristics include oxygen concentration, Sherwood number, and velocity profiles, etc. Our results clearly indicate that oxygen transfer is dominated by convection while diffusion also plays a role on it. Comparative studies demonstrate that side heating and top cooling device is more efficient to transfer oxygen than side heating and cooling device and oxygen transfers more rapidly in square cavity than in rectangular cavity. This work establishes a reliable thermal LBE model for thermally driven heat and mass transfer.

**Y8 11 Energy from Ocean Waves, River Currents, and Wind** SHYAMAL GUHA, *Texas Southern University* The Earth we live in is surrounded by fluids, which are in perpetual motion. The air in the atmosphere and water found in lakes, ocean, and rivers form our natural environment. Much of the fluid medium is in constant motion. The kinetic energy of this moving fluid is astronomical in magnitude. Over the years, I have considered methods of converting a fraction of the vast reserve of this kinetic energy into electro-mechanical energy. I have conceived a few schemes of such conversions. The fluids whose kinetic energy can be converted into electro-mechanical energy are the following: ocean waters, river currents and atmospheric air. In a book to be published in the spring of 2006, I have described different techniques of energy conversion. In the upcoming APS meeting, I plan to discuss some of these techniques.

**10:36**

**Y8 12 Motion of Rigid Bodies in Newtonian and non-Newtonian Fluids** ASHWIN VAIDYA, *Florida State University* The properties of non-Newtonian fluids, such as normal stress effects and non-constant viscosities are known to result in flow phenomenon which are dramatically different from those of Newtonian fluids. One such interesting difference in the behavior of these kinds of fluids is in their interaction with submerged rigid bodies. In this talk, we will focus on the problem of steady motions of symmetric rigid bodies as they freefall in Newtonian and viscoelastic fluids, modeled by the Navier Stokes, Power Law, Second order and the Generalized Second order fluid models. We will examine how variations in forces and torques in these two kinds of fluids can result in remarkably different phenomenon.

**Y8 13 Particle Dynamics in Low Reynolds Number Fluidized Beds** PHIL SEGRE, *Physics Dep., Emory Univ., Atlanta Ga.* JIM McCLYMER, *Physics Dep., Univ. of Maine, Orono ME* The sedimentation dynamics of extremely low polydispersity, $\sigma_a/a \sim 1.5\%$, non-Brownian, particles are studied in a liquid fluidized bed at low Reynolds number, $Re \ll 1$. When fluidized, the system reaches a steady state in which the local velocity fluctuations and

particle concentration are found to become highly stratified with height in the column. Results are presented for the degree of stratification with normalized bed height $H/a$. We find that taller beds are more stratified than shorter beds. However, recent computer simulations have not found any measurable stratification with height. We reconcile this apparent disagreement by showing that the stratification in experiments of comparably small systems such as those studied by simulation are indeed very small. We also develop a simple advection-diffusion model that connects the velocity fluctuations to the concentration gradients, and account for the observed bed stability.

**8:00**
**Y12 1 Capacitance Investigation of the Field-Induced Resistive Switching Interface** STEPHEN TSUI, NILANJAN DAS, YAQI WANG, YUYI XUE, *Texas Center for Superconductivity at the University of Houston* C.W. CHU, *Hong Kong University of Science and Technology; Texas Center for Superconductivity at the University of Houston; Lawrence Berkeley National Laboratory* We investigate the capacitance associated with the field-induced resistive switch formed at the interface between metal and perovskite oxide, in particular Ag deposited on $Pr_{0.7}Ca_{0.3}MnO_3$ thin film. The switch is dictated by the polarity of the applied voltage pulses, which drives the interface into either a nonvolatile high or low resistance state. Different models for this phenomenon have been proposed. We verify these models by examining the changes in the capacitance. The nature of the switching is therefore investigated through the measurement of the dielectric response with respect to frequency for both high and low resistance states. As a result, we can deduce information regarding the thickness of the switching interface, the density of the defects, and the distributions of the trap potentials. These parameters signal clear changes in both the defect density and the associated trapping potential. Lattice rearrangement, therefore, may play a major role in the switching.

**8:12**
**Y12 2 Strain Relaxation in Buried $SrRuO_3$ Thin Film under a Biaxial Compression: $CaZrO_3/SrRuO_3/SrTiO_3$ System** SOO GIL KIM, YUDI WANG, I-WEI CHEN, *Deparment of Materials Science and Engineering, University of Pennsylvania* We have observed a novel strain relaxation phenomenon in the buried thin film that develops during the deposition of an overcoat layer. In $SrRuO_3/SrTiO_3$ (100) system, the $SrRuO_3$ film is initially in biaxial compression, but the strain relaxation develops after a $CaZrO_3$ overcoat is deposited, manifested as misfit dislocations at the $CaZrO_3/SrRuO_3$ interface and a cross-hatch pattern of surface corrugation on the $CaZrO_3$ surface. This arises because $CaZrO_3$ (0.4012 nm) has a larger lattice parameter than those of $SrRuO_3$ (0.393 nm) and $SrTiO_3$ (0.3905 nm), thus contributing to the strain energy. By increasing point defect population in $CaZrO_3$ to accommodate the misfit strain, this phenomenon can be avoided and atomically flat thin film stacks obtained.

**8:24**
**Y12 3 Atomically Flat $SrRuO_3$ Conductive Thin Films on $SrTiO_3$ (001) by Pulsed Laser Deposition** YUDI WANG, SOO GIL KIM, I-WEI CHEN, *Department of Materials Science and Engineering, University of Pennsylvania, Philadelphia, PA19104-6272, USA* Atomically flat surfaces are important for thin film multilayers, superlattices, and heterostructures. For $SrRuO_3$ thin films grown on perovskite substrates, higher oxygen pressure is commonly used to achieve desired stoichiometry, crystallinity and conductivity, but it can also cause step bunching, pin holes and finger-like structures which destroy film/substrate coherency. We have found the finger-like structure is due to the slow 3-layer-nucleation process that occurs on the $TiO_2$ terminated $SrTiO_3$substrate, whereas step bunching is due to excessive step mobility. Using a transition layer on $SrTiO_3$ that establishes the SrO termination, and adjusting deposition parameters and step spacing that reduce step migration time, we have obtained atomically flat $SrRuO_3$ films free of the above morphological defects. These films show a large enhancement of electrical conductivity, making them suitable for various applications.

**8:36**
**Y12 4 Growth Transient Scaling During Pulsed Laser Deposition of SrTiO3*** J.Z. TISCHLER, B.C. LARSON, GYULA ERES, C.M. ROULEAU, *Oak Ridge National Laboratory* P. ZSCHACK, *UNICAT, Univ. of Ill* Time resolved surface x-ray diffraction studies of pulsed laser deposition show that laser-pulse growth-transients nearly scale with the time between pulses, for dwell times varying by a factor of 250 (0.2s to 50s). AFM measurements show that shorter dwell times produce smoother surfaces than longer dwell times, and that the improved growth for short dwell times correlates with small but systematic changes in the observed growth-transients as the dwell time was varied from 0.2s to 50s. These results imply that the transverse length scale of surface structures in layer-by-layer growth is determined by the annealing time between laser pulses as well as the amount of material deposited per pulse. The impact of dwell time on layer-by-growth of will be discussed.

**Y12 5 Transport properties of $SrTiO_3$ / wide-gap insulator heterointerfaces** KESIUKE SHIBUYA, TSUYOSHI OHNISHI, TAKAYUKI UOZUMI, TAISUKE SATO, MIKK LIPPMAA, *University of Tokyo* HIDEOMI KOINUMA, *National Institute for Materials Science* A field-effect transistor is a sensitive probe for the investigation of interfacial electronic properties. We have demonstrated the importance of an epitaxial interface, using $SrTiO_3$ (100) single crystal field-effect transistors with amorphous and epitaxial $CaHfO_3$ layers as gate insulators. The devices with amorphous insulator layers showed n-type transistor operation with a field-effect mobility of 0.4 to 0.5 $cm^2$ / V s at room temperature. A large threshold voltage shift was observed at low temperatures and the transistor performance was temperature independent when that shift was taken into account. The device properties were greatly affected by the interface between amorphous insulator and $SrTiO_3$. To improve the quality of the channel layer-insulator interface, an ultra-thin epitaxial $CaHfO_3$ layer was grown on the $SrTiO_3$ substrate surface at high temperature, followed by room-temperature deposition of an amorphous insulator layer. The de-

vices with epitaxial interfaces exhibited a large improvement over the amorphous transistors. A field-effect mobility of around 2 $cm^2$ / V s was attained at room temperature and found to increase at low temperature, reaching 25 $cm^2$ / V s at 50 K. This result means that the carriers induced by the field effect behaved as would be expected for electron-doped $SrTiO_3$.

**Y12 6 Strain effects on the magnetic properties of epitaxial $SrRuO_3$ thin films** CHANGKUN XIE, JOSEPH BUDNICK, BARRETT WELLS, *Department of Physics, University of Connecticut, Storrs, CT 06269-3046* DEPARTMENT OF PHYSICS, UNIVERSITY OF CONNECTICUT, STORRS, CT 06269-3046 TEAM, We study the effects of lattice strain on the magnetic behavior of epitaxial $SrRuO_3$ thin films grown by pulsed laser deposition. Most films have been grown on $SrTiO_3$ and $KTaO_3$ substrates that provide compressive and tensile strain, respectively. The Curie temperature (Tc) is reduced compared to the corresponding bulk for compressively strained $SrRuO_3$ films. This is consistent with previous results. Tc is enhanced an almost equal amount for films under tension. The transition temperature shows a fairly large change between the films with different types of strain (compressive and tensile), but further variation of strain produces only small changes in Tc. The rise in Tc with tensile strain is unique as far as we know. We present the temperature-strain phase diagram of $SrRuO_3$ thin films and discuss possible mechanisms for the strain dependent changes in magnetic properties. This work is supported through NSF DMR-0239667. Some data was taken at the National Synchrotron Light Source, Brookhaven National Laboratory, which is supported by the U.S. Department of Energy, Division of Materials Sciences and Division of Chemical Sciences, under Contract No. DE-AC02-98CH10886.

**Y12 8 Effect of polarization on the surface reactivity of ferroelectric materials** JOHN GARRA, *University of Pennsylvania* DAWN BONNELL, *University of Pennsylvania* JOHN VOHS, *University of Pennsylvania* ANDREW RAPPE, *University of Pennsylvania* Temperature programmed desorption (TPD) has been used to study the effect of polarization on the surface reactivity of ferroelectric materials including single crystal lithium niobate (0001) and barium titanate (001). In the case of barium titanate, the polarization state of the crystal is controlled by electrical poling in UHV. Several suitable probe molecules have been identified including methanol, water, carbon dioxide, and pyridine. By comparing the desorption spectra of these molecules for the positive and negative surfaces of the crystal, one can determine the effect of polarization on the surface-adsorbate interaction.

**9:36**

**Y12 9 Structure of Hydrated $\alpha$-$Fe_2O_3$ (0001) and (1$\bar{1}$02)*** CYNTHIA LO, *National Institute of Standards and Technology, Chemical Science and Technology Laboratory* ANNE CHAKA, *National Institute of Standards and Technology, Chemical Science and Technology Laboratory* THOMAS TRAINOR, *University of Alaska Fairbanks, Department of Chemistry and Biochemistry* The structure and reactivity of $\alpha$-$Fe_2O_3$ depends on several factors, including the composition of the bulk material, crystallographic orientation, and local coordination of the surface atoms. As an example, the adsorption and dissociation of water on $\alpha$-$Fe_2O_3$ and other metal oxide surfaces is not well understood, since the oxide surface has largely been characterized under ultra-high vacuum or clean conditions. However, interactions at the solid-liquid and solid-solid interface play major roles in environmental processes, including contaminant sequestration, mobility, and bioavailability. In this work, we present density functional theory results on the structure of clean and hydrated $\alpha$-$Fe_2O_3$ (0001) and (1$\bar{1}$02), and show the changes in surface structure upon heterolytic water dissociation and water physisorption.

**Y12 10 Dopant induced surface reconstruction in N-doped rutile $TiO_2$(110)** MATTHIAS BATZILL, *Tulane University* ERIE MORALES, ULRIKE DIEBOLD, Recently N-doping of $TiO_2$ has attracted some attention because it has been demonstrated to shift the photocatalytic activity of $TiO_2$ from the UV-region to the visible light. Here we examine the impact of N-doping on the electronic structure and surface morphology of single crystal $TiO_2$ surfaces.* Often it is assumed that bulk dopants have little influence on the surface properties. In the case of rutile $TiO_2$(110) it is, however, well established that intrinsic O-vacancies cause the surface to reconstruct to form a 1x2 superstructure. We find that N-doping reduces the formation energy of O-vacancies in $TiO_2$ and as a consequence destabilizes the surface to cause a 1x2 reconstruction. Similar surface effects may be expected for other bulk dopants that are know to induce oxygen vacancies in $TiO_2$. * M. Batzill, E.H. Morales, U. Diebold, Phys. Rev. Lett. accepted

**Y12 11 Electron-stimulated desorption ion angular distribution (ESDIAD) investigations of the rutile $TiO_2$(011)-(2x1) surface*** SERGEY SOLOVEV, *Rutgers State University* MATTHIAS BATZILL, ULRIKE DIEBOLD, *Tulane University* THEODORE MADEY, *Rutgers State University* A wide variety of potential applications have stimulated investigations of the atomic-scale properties of $TiO_2$surfaces. In a combined experimental and theoretical study it was shown recently that the rutile $TiO_2$(011)-(2x1) reconstruction is distinct from other $TiO_2$ surfaces: a model was proposed based on onefold coordinated (titanyl) oxygen atoms, giving rise to double-bonded Ti=O species at the surface [T. J. Beck et al., PRL 93 (2004) 036104]. These species may play a significant role in the enhanced photocatalytic activity of $TiO_2$(011). The present work is an attempt to provide a direct experimental test of the model. The ESDIAD method com-

bined with LEED is used to determine the orientation of Ti-O bonds relative to the (2x1) surface. The ESDIAD data for $O^+$ exhibit two beams along [100] azimuths, each tilted $>$ 20 degrees from the surface normal; the data provide supporting evidence for the proposed model. *supported in part by NSF

**Y12 12 Structure and energetics of step edges on anatase $TiO_2$(101)** XUE-QING GONG, *Princeton University* ANNABELLA SELLONI, *Princeton University* MATTHIAS BATZILL, *Tulane University* ULRIKE DIEBOLD, *Tulane University* PRINCETON UNIVERSITY COLLABORATION, TULANE UNIVERSITY COLLABORATION, Defects, such as step edges, are of paramount importance to the physical and chemical properties of metal and metal oxide surfaces. However, while steps on metal surfaces have been extensively investigated both experimentally and theoretically, much less is known about the structure and properties of steps on metal oxide surfaces. Recent STM work examined the step structure of the (101) surface of anatase $TiO_2$, which is the most stable and widely exposed surface of this interesting $TiO_2$ polymorph. Steps were found to exhibit a few preferred orientations, giving rise to islands with identical shape on the surface. Motivated by these observations, we have carried out extensive density functional theory calculations to determine the formation energies of steps along various orientations and with different structures. A procedure based on systematic calculations of related vicinal anatase $TiO_2$ surfaces has been used, which yields step edge energies with remarkable accuracy. The electronic structures of the stepped surfaces and adsorption of prototype molecules have been also investigated. The present results allow us to obtain a very detailed and complete understanding of the experimental observations.

**10:24**

**Y12 13 Atomic structure of a Ultrathin $TiO_2$ film on Mo(112) surface*** RUQIAN WU, *Department of Physics and Astronomy, UCI, CA* Materials with reduced dimensions attract much interest because their properties are often significantly different from the properties of bulk materials. Additionally, thin oxide films represent model systems well suited for studying structure reactivity relationships on oxides and oxide supported metal particles considered as models for heterogeneous catalysts. Recently, gold clusters on titania/Mo(112) surface are found to be high catalytic activity, attributing to the structural effects. Despite extensive experimental and theoretical studies the detailed atomic structure of $TiO_2$ films on Mo(112) substrate remain unknown. The geometrical and electronic structures of a ultrathin $TiO_2$ film expitaxially grown on a Mo(112) substrate have been determined by first principles density-functional theory calculations. The results show that the $TiO_2$ perfer to the $8\times 2$ surface structure on the Mo(112) surface, which is well agreement with the experiments.

**Y12 14 Thin oxide films: analysis of finite-size effects** C. FREYSOLDT, P. RINKE, M. SCHEFFLER, *Fritz-Haber-Institut, Berlin, Germany* Oxide surfaces have attracted considerable interest over the last years. In order to employ surface science tools, oxides are often grown epitaxially on metals. Recent findings for $SiO_2$ on Mo(112) indicate that well-ordered films are only 2-3 atomic layers thick – less than previously thought[1,2]. But is the surface of the films characteristic for the surface of a bulk oxide? Not only the structure may differ from any known bulk structure, but also the metal might alter the electronic structure. Also, sizeable quantum effects are expected at these dimensions. We present DFT simulations for oxide films of various thicknesses for $SiO_2$, $Al_2O_3$, and $HfO_2$. In order to separate the thickness from the substrate dependence, free-standing films are considered. We find that the electronic structure at the DFT level becomes bulk-like for very few atomic layers. The case of silica is discussed in detail. The film structure on Mo(112) corresponds to the most stable quartz(0001) surface. The electronic structure is essentially bulk-like and independent of the film thickness. The presence of the substrate does not alter these findings. For the electronic response of the thin film, however, the quasiparticle picture predicts a thickness-dependent band gap due to the dielectric discontinuity at the interface. Likewise, the chemistry and stability of defects is expected to be influenced by the substrate.

**Y12 15 Surface and Interface Structures of Crystalline Oxides on Silicon (COS)** FRED WALKER, *Oak Ridge National Laboratory* MARCO BUONGIORNO-NARDELLI, *North Carolina State University* RODNEY McKEE, *Oak Ridge National Laboratory* The structure of the Sr-covered Si(001) surface (the precursor to COS heteroepitaxy) is a matter of on-going scientific debate with experiment and theory casting opposing views. Real space Z-contrast imaging shows that half of the silicon atoms on the (001) surface are absent, and this has presented us with the intriguing question – ''Where does the silicon go?'' A metallic surface termination of silicon was required in the layer-sequenced heteroepitaxy of COS. What has been common to all experimental realizations of the layer-sequenced COS structure, is the presence of hydrogen evolving from the metal sources during the film growth. We report here that this hydrogen has inadvertently played a pivotal role in defining the silicon termination and thus the evolution of the interface structure for COS. We will describe the thermodynamic basis for this hydrogen effect along with experimental and theoretical characterization of the structural details. Research sponsored jointly by the Division of Materials Sciences and Engineering, Office of Basic Energy Sciences, U.S. Department of Energy at Oak Ridge National Laboratory under contract DE-AC05-00OR22725 with UT-Battelle, LLC and at the University of Tennessee under contract DE-FG02-01ER45937. Calculations have been performed on CCS supercomputers at Oak Ridge National Laboratory.

## SESSION Y16: OPTICS AND OPTOELECTRONICS

**Stuart A Solin, Washington University, presiding**

**8:00**

**Y16 1 Investigations of Carbon Nanotube Networks for use as Transparent Conductors** MARK TOPINKA, *Stanford University* Recently there has been increasing interest in the physics of conduction through carbon nanotube networks and the possibility of using carbon nanotube networks as transparent conducting lay-

ers for solar cells and other optoelectronic applications(1). Conductivities as high as 30 ohm/square with transparencies of about 80% have been reported(2). Here we present results of our work on understanding the underlying physics behind the real-world behavior of these systems and identifying the bottlenecks which are currently limiting their performance. We focus in particular on their possible use in solar cells as a low-cost alternative to more expensive transparent conductor technologies such as Indium Tin Oxide (ITO). We include numerical simulations of conduction through nanotube networks and scanning probe microscopy studies of transport through these systems. **Y16 2 Theoretical model of extraordinary optoconductance in GaAs-In hybrid structures*** A.M. GIRGIS, L.R. RAMMOHAN, *Worcester Polytechnic Institute* K.A. WIELAND, YUN WANG, S.A. SOLIN, *Washington University in St. Louis* We have recently demonstrated extraordinary optoconductance (EOC) of order 500% in GaAs-In metal semiconductor hybrid structures (MSHs).[1] This is the third example of a geometry driven ''EXX'' phenomenon, the first example of which was extraordinary magnetoresistance (EMR).[2] However, EOC is the first example of an EXX effect in which the bulk properties of the semiconductor and not the interfacial properties are modified by the external perturbation. Here we describe a Gaussian broadened point charge theoretical model which quantititavely accounts for the dependence of the optocondutance on the position of a focussed Ar laser beam. We also account quantitatively for the temperature dependence of the EOC. Our theoretical model incorporates the Dember effect[3] directly via the differential mobilities of the electrons and holes. Using these mobilities and a third variable corresponding to the net charge, a good fit to the positional dependence of the voltage is achieved. The strengths and limitations of this theory will be highlighted.

**Y16 3 Extraordinary optoconductance in InSb-In hybrid structures*** K.A. WIELAND, YUN WANG, S.A. SOLIN, *Washington University in St. Louis* A.M. GIRGIS, L.R. RAMMOHAN, *Worcester Polytechnic Institute* Previously reported extraordinary optoconductance (EOC)[1] in degenerate Si-doped ($n \sim 1 \times 10^{18}$ cm$^{-3}$) GaAs-In metal-semiconductor hybrid structures (MSHs) is compared to new experimental results on intrinsic Te-doped ($n \sim 4 \times 10^{14}$cm$^{-3}$) InSb-In MSHs. Using a shunted van der Pauw plate, DC and AC voltage measurements of InSb MSHs were acquired. The sample was illuminated with a focused Ar ion laser and studied as a function of wavelength (457 $-$ 526nm), bias current ( $\pm$ 100mA), lateral position (transverse to the beam), and at 300K and 10K. Whereas the optimal room temperature position sensitivity in the case of GaAs is 137 mV/mm for 100mW of 488.0 nm illumination, the corresponding sensitivity of InSb is found to be 1.2 mV/mm for 10 mW of 514.5 nm illumination. The magnitude of the InSb result is surprisingly large given the relative values of band gaps, mobility, carrier concentration, and laser illumination.[2] The origin of this large position sensitive photovoltage will be discussed.

**Y16 4 All-Epitaxial Microcavity for Cavity-QED with Quantum Dots** ANDREAS MULLER, *University of Texas at Austin, Dept. of Physics* DINGYUAN LU, JAEMIN AHN, DEEPA GAZULA, SONIA QUADERY, SABINE FREISEM, DENNIS DEPPE, *University of Texas at Austin, Dept. of Electrical and Computer Engineering* CHIH-KANG SHIH, *University of Texas at Austin, Dept. of Physics* We report on the optical characterization of a novel type of optical microcavity that forms a fully-buried semiconductor heterostructure and offers numerous technological advantages such as chemical/mechanical stability, good thermal heat-sinking, and compatibility with electrical injection. Based on epitaxial re-growth over a lithographically-defined, quantum dot-containing mesa, this approach leads to self-alignment of single dots with the field anti-node while simultaneously providing quality factors exceeding 10,000 that support lasing with only a single quantum dot layer. Time-resolved measurements reveal the most basic cavity-QED effect in this structure, namely the Purcell spontaneous emission enhancement. A strong spectral and spatial dependence of this effect is observed using photoluminescence imaging, highlighting in particular the importance of the spatial overlap.

**8:48**

**Y16 5 Ultra-high-Q Microcavities for $D_2O$ Detection*** ANDREA ARMANI, DENIZ ARMANI, *California Institute of Technology* SEAN SPILLANE, *Hewlett-Packard Laboratories* KERRY VAHALA, *California Institute of Technology* Ultra high Q optical microcavities ($Q > 10^6$) provide a method for boosting detection sensitivity over conventional detection methods. In a recently published work, the difference between quality factors (Q) of microcavities immersed in $D_2O$ and $H_2O$ was measured and calculated. Due to the higher absorption of $H_2O$, resonators immersed in $H_2O$ have lower Q's than those immersed in $D_2O$. This difference in absorption can be exploited to use the resonator as a $D_2O$ detector. The effect on Q is most noticeable at 1300nm, where the Q in water is $10^6$ and the Q in $D_2O$ is $10^7$. At longer wavelengths, both $Q(D_2O)$ and $Q(H_2O)$ are further degraded, reducing the efficacy of detection, and at shorter wavelengths, $Q(D_2O)$ and $Q(H_2O)$ become similar, reducing the effect that the presence of $D_2O$ alone has on Q. By monitoring the quality factor,01 M concentration of $D_2O$ in water ($10^{17}$ molecules of $D_2O$) has been detected; however, the actual sensitivity limit is far better than this concentration value. Detection has also been demonstrated by cyclic introduction and flushing of $D_2O$, leading to cyclic degradation and improvement of the Q, thereby demonstrating reversible detection.

**Y16 6 Radiation-pressure-induced regenerative mechanical oscillations in optical microcavities** HOSSEIN ROKHSARI, MANI HOSSEIN-ZADEH, TOBIAS KIPPENBERG, TAL CARMON, KERRY VAHALA, *California Institute of Technology* VAHALA RESEARCH GROUP TEAM, A silica microcavity is shown to allow both circulation of long lived cavity photons as well as mechanical vibrations at characteristic radio frequencies. Radiation pressure or the force due to impact of photons can couple the mechanical modes of an optical cavity structure to its optical modes, leading to regenerative RF mechanical oscillations of the micro structure with only micro-Watts of optical threshold power. Embodied within a microscale, chip-based device, this mechanism can benefit both research into macroscale quantum mechanical phenomena and improve the understanding of the mechanism within the context of Laser interferometer gravitational-wave observatory (LIGO). This novel class of oscillators that acquire gain directly from CW optical fields may also find applications in all-optical photonic systems. Through a detailed study of the short-term stability of these optomechanical oscillators we demonstrate that thermo-mechanical noise also referred to as Brownian noise, is the dominant noise mechanism at room temperatures. Preliminary calculations show that lowering the temperature in a vacuum environment may enable the observation of quantum back action noise in microtoroidal resonators.

**Y16 7 Optimizing planar waveguide design for multi-wavelength and nonlinear quantum cascade lasers** SCOTT HOWARD, FATIMA TOOR, ANTHONY HOFFMAN, CLAIRE GMACHL, *Princeton University* DEBORAH SIVCO, *Lucent Technologies* High performance and novel multi-wavelength quantum cascade (QC) lasers present unique challenges in designing waveguides. We present a computational approach that uses the projected threshold current densities and mode overlaps to iteratively optimize the waveguide design. This program has been used to solve three specific problems by designing: (1) two dual wavelength QC laser structures (a 7.5 and 13.5 $\mu$m, and a 9.5 and 11.5 $\mu$m structure) with the goal of minimizing the threshold current of each pair of lasers simultaneously below the continuous wave threshold while maintaining an operating voltage less than 10 V; (2) a waveguide for high performance QC lasers with the goal of minimizing input electrical power at high operating temperatures; and (3) waveguides for nonlinear QC lasers designed for difference frequency generation with the goal of minimizing the threshold currents of the two integrated pump lasers, maximizing the overlap of the pump light with the monolithically-integrated nonlinear mixing region, and reducing the loss of the non-linear guided mode.

**Y16 8 Distributed Bragg reflectors on quantum cascade lasers fabricated by focused ion beam milling** AFUSAT DIRISU, CLAIRE GMACHL, *Princeton University* DEBORAH SIVCO, *Lucent Technologies* The use of Focused Ion Beam (FIB) milling to fabricate custom gratings on Quantum Cascade (QC) lasers for single mode operation is reported. Using the FIB, gratings that fit specific laser wavelength requirements can be fabricated after all other laser processing is completed. This has the advantage that the processed lasers can be fully characterized before milling to determine the laser gain spectrum and its alignment with the desired emission wavelength, hence allowing the proper choice of the grating parameters, such as period and strength to be tailored to the final device. We have been able to mill gratings onto QC laser ridges using the FIB method to significantly narrow the emission spectrum without compromising other properties, such as output power or threshold, of the working device. We fabricated distributed Bragg reflector gratings approximately 1.2 $\mu$m deep, 250 $\mu$m long, with square profile, and with a period of 1.2 $\mu$m; these were processed on top of 2.7-3 mm long QC laser ridges emitting at 7.7 $\mu$m. We observed single mode operation with a side mode suppression ratio of about 12dB.

**9:36**

**Y16 9 Light propagation in random colloidal films with varying coordination number** XIAOTAO PENG, ANTHONY DINSMORE, *University of Massachusetts, Amherst* We measure the propagation of light through a random film of strongly-scattering microspheres as a function of the mean number of contacts per particle (the coordination number, Z). Decreasing Z reduces the local average refractive index and enhances the optical contrast of each scattering sphere with the effective background. In our experiments, we mix two kinds of colloidal spheres and prepare a dried film with random structure. Latex spheres coated with a high-index ZnS and poly(methylmethacrylate) spheres are used, as well as $SnS_2$ core-shell spheres for the near infrared. The transport mean-free path is then extracted from measurements of coherent backscattering of light from the films; its value is sensitive to Z. The results may guide our understanding of the propagation of waves in random media in general and may lead to new photonic materials. This work is supported by the NSF-sponsored UMass MRSEC. **Y16 10 Calculations of the Photonic Properties of Two Dimensional QuasiCrystals** WEINING MAN, ORION CRISAFULLI, PAUL STEINHARDT, *Princeton University* PAUL CHAIKIN, *New York University* PRINCETON UNIV. TEAM, NYU COLLABORATION, Quasicrystals have higher point group symmetry than ordinary crystals, and hence are good candidates for complete photonic bandgaps. Our model system consists of infinite long cylinder dielectric (or air) rods at each Penrose lattice point We took three different approaches in using periodic approximants for these calculations. Our first approach uses a rectangular section of a Penrose tiling of different sizes and at different positions. In the second set of calculations, we generate a series of periodic approximants of the Penrose lattice via an inflation method. Our third approach, a rational number approximation, has the fewest number of defects. The rational number approximant is the best since there are no modes localized along the defects and no artificial modes appear in the gap frequency region. In each case we increased the approximant size until the results converged. Our calculations on 2-D Penrose quasicrystals show very isotropic sizeable complete photonic bandgaps which can be identified with known Bragg scattering peaks. We predict the best Bragg scattering spot and optimize the cylinder size for the widest over all band gap for a given dielectric contrast. We also discuss experimental results on 3D icosahedral quasicrystals in the microwave regime and show that 3D icosahedral quasicrystals are better photonic bandgap candidates than crystalline structures.

**Y16 11 A Magnus Expansion Analysis of Frequency-Dependent Mueller Matrices** MICHAEL REIMER, DAVID YEVICK, *University of Waterloo* We have recently demonstrated that, for any physical system characterized by a non-singular, frequency dependent Jones matrix, the frequency evolution of the corresponding Mueller matrix is described by a differential equation whose general solution can be compactly formulated through the Magnus expansion [M. Reimer, D. Yevick, and D. Dumas, submitted to J. Opt. Soc. Am. A, Photon. Technol. Lett.]. [D. Yevick, T. Lu, W. Huang and W. Bardyszewski to be published in J. Opt. Soc. Am. A]. We subsequently applied our analytic results to optical compensators for communications networks and to the estimation of a system's frequency dependent Mueller matrix based on repeated measurements of the output state of polarization for randomly generated input polarization states [M. Reimer, D. Yevick and D. Dumas, submitted to Photon. Technol. Lett.]. We have also incorporated the Magnus expansion into a Clifford algebra description of polarization evolution. This procedure reformulates numerous physical transformations in a simple and transparent manner [M. Reimer and D. Yevick, submitted to Photon. Technol. Lett.].

**Y16 12 Nanoscale Motion Detection by Diffraction of Evanescent Waves** P. SCOTT CARNEY, *Dept. of Electrical and Computer Eng., University of Illinois at Urbana-Champaign* DEVREZ KARABACAK, *Dept. of Aerospace and Mechanical Eng., Boston University* STEPHEN B. IPPOLITO, M. SELIM UNLU, *Dept. of Electrical and Computer Eng., Boston University* KAMIL L. EKINCI, *Dept. of Aerospace and Mechanical Eng., Boston University* Conventional optical techniques such as Michelson interferometry and Fabry-Perot interferometry have been widely used for ultrasensitive motion detection in micro- and nanoscale mechanical devices. Here, we propose a novel motion detection scheme based upon the diffraction of evanescent waves. In this scheme, an evanescent field is formed within the vicinity of a moving device surface. The motion of the surface results in an enhanced scattering of the evanescent field into propagating states. This novel detection scheme appears to have several advantages over conventional techniques: it lowers the background optical signal; if implemented using a solid immersion lens, the effective spot size is reduced. We shall describe a possible implementation of a dark-field microscope for motion detection in a nanomechanical resonator and present numerical analyses.

**Y16 13 High Sensitivity Electro-Optic Field Sensors** ANTHONY GARZARELLA, DONG HO WU, TERENCE WIETING, SYED QADRI, *Naval Research Lab* RANDAL HINTON, *Temple University* The use of electro-optic (EO) crystals for electric field detection has recently gained considerable interest, due to their nonperturbative method of detecting both field amplitude and phase over a wide range of frequencies. One of the technical challenges facing this detection technique is to improve the detection sensitivity. Since the sensor responsivity is proportional to the EO coefficient of the crystal ($r_{33}$), utilizing materials with a large $r_{33}$ values, such as $Sr_{0.75}Ba_{0.25}Nb_2O_6$ (SBN-75), is the most straightforward approach. However, it was found that in spite of its large EO coefficient, sensors utilizing SBN-75 ($r_{33}^{expt} \sim 700$ pm/V) showed similar or weaker responsivities than sensors utilizing $LiNbO_3$ ($r_{33}^{expt} \sim 30$ pm/V). The detailed data indicate that the responsivity losses in SBN-75 are produced by optically-induced incoherence in the birefringence of the crystal. In this report, we measure this incoherence, and demonstrate its direct impact on the sensitivity and stability of the EO sensor.

**Y16 14 Characterization of triangular-structured two-dimensional photonic crystals designed for visible wavelengths.** JEFFREY CLARK, MICHAEL MARCINIAK, ROBERT NELSON, *Air Force Research Laboratory* JAMES LOTT, *Air Force Institute of Technology* The growing number of fabrication techniques of photonic crystals (PhC) is increasing the number of applications for these devices. This work focuses on the fabrication and characterization of triangular-structured, two-dimensional PhC designed for visible wavelengths. The fabrication processes studied for this PhC are focused ion beam, electron lithography, photolithography, and holographic photopolymerization/lithography. The fabrication techniques and materials used to create the PhC in part determine the characterization technique required to investigate the PBG. Techniques examined here include the coupling of a beam by means of a prism into a wave-guiding medium in which the PhC has been fabricated, and the guiding of a beam to a PhC through a cylindrical glass container filled with an index matching medium. Analyses of the transmission and reflectance properties of a PhC for various incident angles confirm the presence of a PBG. The design of the PhC was based on a program created to display gap maps for triangular structures. The PBG of the structure, designed from the gap maps, was modeled using another program created to display band diagrams for triangular structures. Finally, FDTD modeling and simulation results are compared to the experimental results.

**Y18 1 Adhesion of single functional groups to individual carbon nanotubes: electronic effects probed by itab-initio**

**calculations*** JEFFREY GROSSMAN, *University of California, Berkeley* GIANCARLO CICERO, *INFM, Torino Polytechnic* GIULIA GALLI, *University of California, Davis* The interfacial interaction of simple functional groups (-$NH_2$, -CN, -$CH_3$ -$CHOCH_2$) with single wall carbon nanotubes (SWCNT) was investigated using itab-initio calculations. Binding energies and attachment forces were computed using Density Functional Theory (DFT) in the local density approximation, and Quantum Monte Carlo calculations were employed to test DFT accuracy in describing weak interactions for the controversial case of an oxygen molecule. We find that computed energies and forces are very sensitive to small variations of the electronic charge on the nanotube. In particular, the presence of a solvent (polar or non-polar), and thus of a small charge transfer from or to the tube, may alter the relative strength of adhesion forces for different functional groups, as compared to vacuum.

**Y18 2 Tunable Nanoresonators Constructed from Telescoping Nanotubes** KENNETH JENSEN, *U.C. Berkeley* CAGLAR GIRIT, *U.C. Berkeley* WILLIAM MICKELSON, *U.C. Berkeley* ALEX ZETTL, *U.C. Berkeley* We have created a tunable mechanical nanoscale resonator with potential applications in precise mass, force, position, and frequency measurement. The device consists of a specially prepared multiwalled carbon nanotube (MWNT) suspended between a metal electrode and a mobile, piezo-controlled contact. By exploiting the unique telescoping ability of MWNTs, we controllably slide an inner nanotube core from its outer nanotube casing, effectively changing its length and tuning its flexural resonance frequency.

**8:24**

**Y18 3 Interlayer forces in telescoping nanotubes** ANDRAS KIS, KENNETH JENSEN, *University of California, Berkeley* SHAUL ALONI, *Materials Sciences Division, Lawrence Berkeley National Laboratory* WILLIAM MICKELSON, ALEX ZETTL, *University of California, Berkeley* The ability to fabricate low-friction surfaces and lubricants is one of the key requirements for the miniaturization of mechanical systems, especially on the nanoscale where friction and surface adhesion often dominate over gravity and even electrostatic attraction. In this context, multi-walled carbon nanotubes (MWNT) have been proposed as the ideal nanobearing because of their inert, ultra-smooth surfaces and the narrow separation between their neighboring shells that prevents the accumulation of contaminant particles between sliding parts. In analogy with graphite, the weak van der Waals interaction between nanotube shells could provide the equivalent of lubrication, allowing easy relative sliding of nanotube layers. We have externally induced telescoping motion in MWNTs while measuring the force acting between the two layers involved in this motion. The restoring van der Waals force is comparable with theoretically predicted values. Defects are found to modulate this force and can lead to jamming.

**8:36**

**Y18 4 Registry-dependent interlayer potential for graphitic systems** ALEKSEY KOLMOGOROV, *Duke University* VINCENT CRESPI, *Pennsylvania State University* Standard applications of density functional theory (the local density approximation (LDA) and the generalized gradient approximation (GGA)) without nonlocal corrections do not adequately describe the exfoliation energy of graphite. The GGA, in particular, does not show any binding at physically meaningful interlayer distances. However, the *variation* in the energy under interlayer shifts, defined predominantly by the overlap of $\pi$ orbitals, is nearly identical in the two approximations and appears to be much more sound than previously suspected. We combine these results with experimental information on the exfoliation energy to create an improved registry-dependent classical potential for the interlayer interaction in graphitic structures.

**Y18 5 Adsorption of simple aromatic molecules on single-wall carbon nanotubes** LILIA M. WOODS, *Univ of South Florida, Tampa FL* STEFAN C. BADESCU, *NRL, Washington DC* THOMAS L. REINECKE, *NRL, Washington DC* Understanding the adsorption of aromatic molecules on carbon nanotubes is important for nanotube functionalization. We perform ab-initio plane-wave calculations for the adsorption of benzene derivatives such as nitrobenzene, aniline and toluene, using pseudopotentials in the local density approximation. We find that the minimum energy configurations of the molecules are flat along the nanotube, in agreement with experiments on polar molecules [1], and that the dominant part of the binding is physisorbtion. The physisorbed benzene used for reference lies in a graphite-stacking configuration, whereas benzene derivatives have small deviations from this perfect alignment. The deviation from ideal $\pi - \pi$ stacking is a complex process that involves the hybridization between molecular and nanotube levels, a small charge redistribution, and in some cases the formation of narrow conduction bands in the energy gap of semiconductor nanotubes. We trace the differences between derivatives to the properties of the molecular fragments attached to the benzene ring. [1] Snow E.S. et al, Science 307 (5717), 1942 (2005)

**Y18 6 DNA-CNT Interaction - A Density Functional Approach** RALPH SCHEICHER, S. GOWTHAM, RAJEEV AHUJA, *Fysiska Institutionen, Uppsala Universitet, Sweden* RAVINDRA PANDEY, *Michigan Technological University, USA* Standing at the intersection of the biological regime and the nanomaterials world, DNA-coated carbon nanotubes (CNT) possess features which can make them attractive for a range of applications, e.g., as highly specific nanosensors [1], or as a method to efficiently separate CNTs according to their structure [2]. It is therefore certainly worthwhile to obtain a detailed understanding of the binding between the bases in DNA and the surface of CNTs, preferably from first principles. To this end, we have studied the interaction between single-stranded DNA and single-walled CNTs (SWCNTs) using density functional theory. More specifically, we were interested in assessing the differences in the interaction of the four different bases in DNA, and how important the underlying structure of the CNT is for the orientation of the bases relative to the tube axis. We will report our results on the binding energy, the charge density, and the respective distortion in the electronic structure of the constituents of this hybrid system, depending on the geometrical properties of the CNT and the relative positioning of the DNA. **Y18 7 Molecular hydrogen adsorption on the boron-doped graphene sheet in presence of magnesium and transition metal**

ZHAOHUI HUANG, VNICENT CRESPI, *Dept. of Physics, Penn State University* Adsorption of hydrogen molecules onto a boron-doped graphene sheet in the simultaneous presence of magnesium and a transition metal has been studied using density functional methods. This setup is inspired by magnesium dihydride. We obersve that there form bonds between metal and boron atoms, which suggest a potential way to prevent metal from aggregating. Macroscopic aggregation of metal atoms makes this structure useless to adsorb hydrogen. We present results for different combination of transition metal and magnesium, and compare the binding energy of hydrogen molecule adorbed onto those structures.

**Y18 8 Controlled Confinement and Release of Gases in Single-Walled Carbon Nanotube Bundles** CHRISTOPHER MATRANGA, BRADLEY BOCKRATH, *U. S. Dept. of Energy, National Energy Technology Laboratory* A simple procedure is described which locks small quantities of $SF_6$, $CO_2$, and $^{13}CO_2$ into opened single-walled carbon nanotube (SWNT) bundles and keeps the gas inside the SWNTs above the desorption temperature of these molecules. The confinement technique involves opening the SWNTs with ozonolysis at 300 K followed by vacuum annealing at 700 K. Gases are then cryogenically adsorbed into the opened SWNTs and a locked into the SWNT pores by functionalizing the sample with a low temperature ozone treatment. The low temperature ozone treatment functionalizes the entry ports into the SWNT pores which in turn create a physical barrier for gases trying to desorb through these functionalized ports. The samples are stable under vacuum for periods of at least 24 hours and the trapped gases can be released by vacuum heating to 700 K. Reduced quantities of the trapped gases remain in the SWNTs even after exposure to room air. Fourier Transform Infrared Spectroscopy is used to monitor the functionalities resulting from the ozone treatment and to detect the trapped gas species.

**Y18 9 Physisorption Kinetics in Carbon Nanotube Bundles** JARED BURDE, M. MERCEDES CALBI, *Southern Illinois Univesity, Carbondale* The possibility of adsorbing gases in the interstitial channels that lie between nanotubes in a bundle is still the subject of much discussion because experimental observations do not seem to confirm the existence of adsorbed gases on this site as it has been predicted by several theoretical studies (that assume infinitely long tubes). After exploring the potential energy surfaces near the ends of the tubes, we have recently shown how the presence of a high binding energy site right before the entrance of the channel slows down the adsorption rate of $H_2$ dramatically [1]. Using a Kinetic Monte Carlo scheme, we present here a comprehensive study of the adsorption kinetics in the channels modeling the transport of various gases through the ends of the bundle. In order to facilitate the comparison with adsorption experiments, the results are given in terms of the equilibration time as a function of coverage, for different temperatures. In addition, the effect of cluster formation at the end of the bundle is analyzed. [1] M. Mercedes Calbi and J. L. Riccardo, ''Energy barriers at the ends of carbon nanotube bundles: Effects on interstitial adsorption kinetics,'' Phys. Rev. Lett. **94**, 246103 1-4 (2005).

**Y18 10 Adsorption of TCNQ on the inside and outside surface of single-wall carbon nanohorn aggregates*** RYOTA YUGE, *NEC* MASAKO YUDASAKA, *NEC, SORST-JST* JIN MIYAWAKI, *SORST-JST* TOSHINARI ICHIHASHI, *NEC* HIDETO IMAI, *NEC* YOSHIMI KUBO, *NEC* SUMIO IIJIMA, *NEC, SORST-JST, Meijo University* Storage and release of various materials into/from single-wall carbon nanohorns (SWNH), a type of single-wall carbon nanotubes, have been studied well, thus SWNHs have become potentially useful in many fields. However, not much is known about the mechanism of adsorption on the walls of SWNHs, which we have investigated using Tetracyano-*p*-quinodimethane (TCNQ). SWNHs were pretreated with $O_2$ at $550^oC$ to open holes, followed by the treatment with $H_2$ at $1200^oC$ to remove functional groups (SWNHh). Thermogravimetric analysis revealed that the quantities of TCNQ inside and outside were estimated to be about 0.07 and 0.11 g per 1 g of SWNHh, respectively, which did not increase even for the TCNQ overdosing. Raman spectra of TCNQ adsorbed on SWNHh (TCNQ/SWNHh) showed red shifts of several vibration modes of TCNQ, while the C=C ring stretching (CCr) showed the large blue-shift. This indicates that the quinoid ring of TCNQ strongly interacted with graphene sheets of SWNHh. The blue-shift of CCr Raman-peak is not observed for the charge transfer complexes such ash TTF/TCNQ, Cu/TCNQ, and so on. We will discuss the reason for the large-blue shift of CCr peak of TCNQ adsorbed on SWNHs in the talk.

**Y18 11 Investigation of Fluorinated and Hydrogenated Carbon Nanotubes by STM** DHARMPAL TAKHAR, Z. GU, A. A. PEERA, W. E. BILLUPS, J. L. MARGRAVE, K. F. KELLY, *Department of Electrical and Computer Engineering, Rice University, Houston, Texas* There is a great deal of interest in the functionalization, in particular fluorination, of carbon nanotubes for the purposes of solvation and subsequent chemical reaction. Towards this end, we report the investigation of fluorinated nanotubes by variable-temperature STM. The atomic-scale fluorine coverage on the fluorotubes with composition was observed as a function of annealing temperature. Upon heating of the fluorotubes, we observe the subsequent desorption of the fluorine initiated around $240\ ^oC$ and proceeding up to $650\ ^oC$. At higher temperatures, all the fluorine desorbs revealing a number of small defects. Further heating leads to cutting of the fluorotubes which is initiated at these defect locations. We compare these results to our recent investigation of dihydrogen functionalized carbon nanotubes.

**10:12**

**Y18 12 Fast Mass Transport through Sub-2nm Carbon Nanotubes*** JASON K. HOLT, *LLNL* HYUNG GYU PARK, *LLNL & UC Berkeley* YINMIN WANG, MICHAEL STADERMANN, ALEXANDER B. ARTYUKHIN, *LLNL* COSTAS P. GRIGOROPOULOS, *UC Berkeley* ALEKSANDR NOY, OLGICA BAKAJIN, *LLNL* We report gas and water flow measurements through microfabricated membranes with sub-2nm aligned carbon nanotubes as pores. The measured gas flow exceeds predictions of the Knudsen diffusion model by at least an order of magnitude. The measured water flow rate exceeds values calculated from continuum hydrodynamics models by two to three orders of magnitude and agrees with flow rates extrapolated from molecular dynamics simulations. The gas and water permeabilities

of these nanotube-based membranes are orders of magnitude higher than those of commercial polycarbonate membranes, despite having an order of magnitude smaller pore sizes. These properties should enable more energy-efficient nanoscale filtration, as well as fundamental studies of mass transport in confined environments.

**Y18 13 STM Investigation of Functionalized Carbon Nanotube Self-Assembly on Gold** JUN ZHANG, *Rice University, Department of Electrical and Computer Engineering* LEI ZHANG, *Rice Univeresity, Department of Chemistry* VALERY KHABASHESKU, *Rice Univeresity, Department of Chemistry* ANDREW BARRON, *Rice Univeresity, Department of Chemistry* KEVIN KELLY, *Rice University, Department of Electrical and Computer Engineering* Self-assembly has proven a powerful technique for patterning and building devices at the nanometer level. Scanning tunneling microscopy (STM) is the ideal tool for probing the chemistry and physics of these types of nanostructures. Building upon on our previous carbon nanotube research, we have investigated thiol- and thiophene-functionalized nanotubes. The motivation is to use these functional groups as a means to self-assemble tubes on surfaces by exploiting the well-established Au-S chemistry. Thiol and thiophene substituted nanotubes were assembled on bare gold surfaces as well as inserted into hexanethiol self-assembled monolayers and imaged by STM. The thiol and thiophene functional groups work as anchors, strongly binding the SWNTs to the gold. Additionally, we have measured the size and spatial distribution of the functional groups along the nanotube sidewalls.

**Y19 1 Mn dopant distribution and magnetic ordering in Mn-doped Ge ferromagnetic semiconductor** AN-PING LI, K. VON BENTHEM, M.F. CHISHOLM, K. VARGA, J. SHEN, *Oak Ridge National Laboratory* N. RAO, S.K. DIXIT, L.C. FELDMAN, *Vanderbilt University* H.H. WEITERING, *The University of Tennessee* We report the spatial distribution of Mn dopant atoms in germanium, grown with molecular-beam epitaxy. Cross-sectional transmission electron microscopy shows the stripe-shaped nanostructures with 2 nm in diameter, which arise from the chemical phase separation of the Mn dopants. Electron energy loss spectroscopy and ion-channeling spectroscopy indicate that these nano-stripes have $\sim$ 5 times higher Mn concentration than in the dilute doped Ge host. Only about 20% of total Mn atoms are incorporated in Ge lattice sites. Ferromagnetism in the doped Ge is characterized by two different ordering temperatures. A critical temperature $T_C$* is obtained as ferromagnetic spin clusters form, and a second transition occurs at much lower temperature itTc at the onset of global ferromagnetic ordering. Both transition temperatures can be enhanced significantly by an appropriate post-annealing process. The Mn aggregated clusters provide seeds of magnetic spin clusters, these spin clusters expand in size with lowering temperature and percolate eventually to form infinite magnetic clusters at low temperature. [1] A. P. Li, et al., Appl. Phys. Lett. **86**, 152507 (2005). [2] A. P. Li, et al., Phys. Rev. B 72, 195205 (2005).

**Y19 2 Epitaxial Growth and Properties of Fe and Co Co-doped Ge (100) Magnetic Semiconductor Films** LIANG HE, BRIAN COLLINS, FRANK TSUI, *University of North Carolina* YUNCHENG ZHONG, STEFAN VOGT, YONG CHU, *Advanced Photon Source* Structural, magnetic and electronic properties of Fe and Co co-doped Ge (100) epitaxial films, grown by combinatorial molecular beam epitaxy techniques, have been studied systematically using diffraction, magnetometry, magnetotransport techniques. These experiments reveal that this epitaxial ternary system can be grown coherently on Ge (100) substrates for total doping concentrations of the transition metal dopants as high as 14 at. %, where high quality p-type magnetic semiconductor films have been synthesized with Curie temperature as high as 270 K. Above this concentration rough disordered growth occurs, which is characterized by a large number of stacking faults along the $< 111 >$ directions; no phase separation has been detected for doping concentrations as high as 20 at. %. The observed magnetotransport properties exhibit large anomalous Hall coefficients and large magnetoresistance (MR) with MR ratios $> 100$. They also indicate the presence of an acceptor level at $\sim$ 70 meV above the valence band with the resulting hole concentrations that can be controlled up to $10^{19}$ $cm^{-3}$by the doping concentrations. Ferromagnetic ordering, specifically the Curie temperature is shown to depend on the carrier concentration.

**8:24**

**Y19 3 Optimal doping control of magnetic semiconductors** CHANGGAN ZENG, ZHENYU ZHANG, KLAUS VAN BENTHEM, MATTHEW CHISHOLM, HANNO WEITERING, Dilute magnetic semiconductors (DMS) with high ferromagnetic ordering temperatures ($T_C$)have vast potential for advancing spin-based electronics or ''spintronics.'' To date, achieving high-$T_C$ DMS typically required doping levels of order 5%. Such high doping levels inevitably compromise the structural homogeneity and carrier mobility of the DMS. Here, we establish ''itsubsurfactant epitaxy'' as a novel kinetic pathway for synthesizing Mn-doped germanium with $T_C$ much higher than room temperature, at dramatically reduced doping levels. This is accomplished by optimal control of the diffusion kinetics of the dopant atoms near the growth front in two separate deposition steps. The first involves a submonolayer dose of Mn on Ge(100) at low temperature, which populates subsurface interstitial sites with Mn while suppressing lateral Mn diffusion and clustering. The second step involves epitaxial growth of Ge at elevated temperature, taking advantage of the strong floating ability of the interstitial Mn dopants towards the newly defined subsurface sites at the growth front. Most remarkably, the Mn dopants trapped inside the film are uniformly distributed at substitutional sites, and the resulting film exhibits ferromagnetism above 400 K at the nominal doping level of only 0.2%.

**Y19 4 Room-temperature ferromagnetism in (Zn,Cr)Te.**
HIDEKAZU SAITO, *Nanoelectronics Research Institute, National Institute of Advanced Industrial Science and Technology*

Ferromagnetic diluted magnetic semiconductors (DMSs) are the key material to developing semiconductor spintronic devices. One of the most characteristics physical phenomena in DMS is a strong interaction between itsp-carriers and localized *d*-spins (itsp-*d* exchange interaction) [1]. Confirmation of this interaction is essential to prove a synthesis of real DMS, and can be done directly by the magneto-optical studies such as a magnetic circular dichroism (MCD) measurement [2]. Here, we report room-temperature (RT) ferromagnetism with the itsp-*d* exchange interaction in $Zn_{1-x}Cr_xTe$ (x=0.20) [3]. $Zn_{1-x}Cr_xTe$ films with $x \leqslant 0.20$ were grown on GaAs (001) substrates by a molecular beam epitaxy method. No sign of a secondary phase was detected in any films by the reflection high-energy electron and X-ray diffractions. MCD spectra were measured in a transmission mode. Magnetization ($M$) measurements were carried out using a SQUID. The $M - H$curves of $Zn_{1-x}Cr_xTe$ (x=0.20) showed a ferromagnetic behavior up to about RT. Curie temperature $T_C$ was estimated to be $300 \pm 10$ K by the Arrott plot analysis. A strong enhancement of the MCD signal at the optical transition energies of critical points of host ZnTe was observed in $Zn_{1-x}Cr_xTe$, indicating a strong itsp-*d* exchange interaction. The MCD spectra of $Zn_{1-x}Cr_xTe$ at any magnetic field could be superposed upon a single spectrum, indicating that the observed MCD signals come from a single material, that is, $Zn_{1-x}Cr_xTe$. The magnetic field dependence of MCD intensity showed the ferromagnetic feature, which coincides with the $M - H$ curves measured using a SQUID. Furthermore, the MCD data showed the same $T_C$ as that obtained from magnetization data. These results indicate that $Zn_{1-x}Cr_xTe$ (x=0.20) is an intrinsic DMS with RT ferromagnetism. **Y19 5 Room-Temperature Femtosecond Faraday Effect in Cd-MnTe Single Crystals** D. WANG, R. SOBOLEWSKI, *University of Rochester, Rochester, NY 14627* M. MIKULICS, *Technical University Carolo-Wilhelmina, D-38106 Braunschweig, and Research Center Juelich, D-52425 Juelich, Germany* A. MYCIELSKI, *Polish Academy of Sciences, PL-02668 Warszawa, Poland* We report the subpicosecond Faraday effect, measured in high quality $Cd_{1-x}Mn_xTe$ ($x = 0.12$ and $x = 0.09$) single crystals at room temperature. Using a femtosecond pump-probe technique, we were able to generate sub-picosecond current pulses by illuminating a free-standing LT-GaAs photoswitch, couple those pulses to the CdMnTe probe crystal using a coplanar transmission line, and, finally, optically sample the temporal evolution of the resulting magnetic transients with subpicosecond resolution and the excellent signal-to-noise ratio. The ultrafast (below 600 fs) Faraday rotation, responsible for the observed magneto-optical effect, has been attributed to the ultrafast spin dynamics of holes in our p-type CdMnTe crystals. The observed femtosecond Faraday effect can be the basis for a development of a magneto-optical sampling system for ultrafast, time-resolved characterization of current transients in novel electronic and spintronic devices.

**Y19 6 Spin-Polarization of a 2DEG in $Cd_{1-x}Mn_xTe$ Quantum Wells** C. AKU-LEH,*F. PEREZ, B. JUSSERAND, *INSP, UMR 7588, CNRS/Paris VI et VII, France* D. RICHARDS, *Dept. of Physics, King's College London, UK* G. KARCZEWSKI, *Polish Academy of Sciences, Warsaw, Poland* Low energy excitations of a spin-polarized electron gas embedded in $Cd_{1-x}Mn_xTe$ quantum wells are studied by magneto-resonant Raman scattering and magneto-photoluminescence at superfluid helium temperature in the Voigt geometry. From Raman, we measured the one electron spin flip energy as a function of the bare Zeeman splitting originating from exchange interaction between *s* electrons and localized Mn d electrons. The ratio between the spin flip energy and the bare Zeeman splitting shows a strong dependence on the electron density. From photoluminescence measurements, we extract the spin flip energy and the spin-polarization rate. Comparison of the measured spin flip energy with our theoretical model [1] shows that the Raman values are in better agreement with the theory. The photoluminescence lineshape, however, gives estimation of the spin-polarization rate that is in good agreement with our model. [1] F. Perez et al. ACTA Physics Polonica A, **106**, 311 (2004).

**Y19 7 Theory of the spin EPR shift and application to $Pb_{1-x}Mn_xTe$** PRASANTA MISRA, *University of Houston* R.K. DAS, *Gopalpur College, India* GOURI TRIPATHI, *Berhampur University, India* We consider a system with a periodic potential, spin-orbit interaction, conduction electron-local moment interaction and an applied magnetic field. We derive a theory for the spin-contribution to the electron-paramagnetic resonance shift ($P_s$) by considering an effective equation of motion of the Green's function in a representation defined by the periodic part of the Bloch function. The spin-EPR shift is expressed as a function of the matrix elements of the momentum, Pauli spin-operators, and conduction electron-local moment interactions. We apply the theory to calculate $P_s$ at $Mn^{2+}$ ion in the diluted magnetic semiconductor $Pb_{1-x}Mn_xTe$, as a function of the carrier concentration. Contributions from band-edge interactions as well as from far bands are included and their relative strengths are analyzed. $P_s$ is found to be anisotropic arising mainly due to spin-orbit interactions. Our results of $P_s$ for two typical hole densities agree fairly well with the recent experimental results for p-$Pb_{1-x}Mn_xTe$.

**Y19 8 Density functional study of manganese doped bulk silicon*** BHAGAWAN SAHU, *Microelectronics Research Center, University of Texas at Austin, Austin, TX 78758* LEONARD KLEINMAN, *Department of Physics, University of Texas at Austin, Austin, TX 78712* SANJAY BANERJEE, *Microelectronics Research Center, University of Texas at Austin, Austin, TX 78758* Using a 250 atom Si supercell with two manganese impurities at the substitutional and tetrahedral interstitial positions, we find, using the density functional projector-augmented wave method, that the ferromagnetic arrangement of manganese atoms at the tetrahedral interstitial position is energetically more stable compared to that at the substitutional position. We find a half-metallic density of states (integer spin magnetic moment over the supercell) for both the interstitial and substitutional manganese. However, the total energy difference (or magnetic energy difference) between interstitial manganese in the ferro and anti-ferro spin-alignments are not large enough to conclude whether ferromagnetic or antiferro-magnetic stability is preferred in the pure Si samples doped with manganese.

**Y19 9 Static and dynamic magnetic response in Mn-doped InP diluted magnetic semiconductor (DMS) nanoparticles** H. SRIKANTH, P. PODDAR, S. SRINATH, *Department of Physics, University of South Florida, Tampa, FL* Y. SAHOO, P.N. PRASAD, *IPLB, University at Buffalo, Buffalo, NY* Soft chemical synthesis of nanostructured diluted magnetic semiconductor (DMS) materials is promising for achieving single phase, ferromagnetic materials. We report the first observation of ferromagnetic ordering at 25K in Mn-doped InP nanoparticles of average size 3 nm. A hot colloidal method without any external surfactant was used to synthesize the nanoparticles. Structural and elemental characterizations established the occurrence of the zinc-blende phase of the DMS without any impurity phases. DC, AC and RF susceptibility measurements were done over a wide range in temperature and magnetic fields to probe the static and dynamic magnetic response. The samples showed a ferromagnetic transition at 25K and frozen spin state below 15K. Transverse susceptibility experiments done using a resonant radio-frequency method revealed a strong temperature-dependent effective anisotropy. Frequency dependence observed in the AC susceptibility was reminiscent of spin-glass characteristics.

**Y20 1 Nodal quasiparticle in pseudogapped colossal magnetoresistive manganites** N. MANNELLA, W. L. YANG, X. J. ZHOU, K. TANAKA, H. ZHENG, J. F. MITCHELL, J. ZAANEN, T. P. DEVEREAUX, N. NAGAOSA, Z. HUSSAIN, Z. X. SHEN, In this talk, the result of a recent angle-resolved photoemission spectroscopy (ARPES) investigation which allowed elucidating the controversial nature of the ferromagnetic metallic groundstate in the prototypical colossal magnetoresistive manganite bilayer compound $La_{1.2}Sr_{1.8}Mn_2O_7$ will be discussed [1]. The distribution of spectral weight in momentum space exhibits a nodal–antinodal dichotomous character. Quasiparticle excitations have been detected for the first time along the nodal direction (i.e. diagonal), and they are found to determine the metallic transport properties of this compound. The weight of the quasiparticle peak diminishes rapidly while crossing over to the antinodal (i.e. parallel to the Mn–O bonds) parallel sections of the Fermi surface, with the spectra strongly resembling those found in heavily underdoped cuprates high temperature superconductors (HTSC) such as $Ca_{2-x}Na_xCuO_2Cl_2$ [2]. This dichotomy between the electronic excitations along the nodal and antinodal directions in momentum space was so far considered a characteristic unique feature of the copper oxide HTSC. These findings therefore cast doubt on the assumption that the pseudogap state in the cuprate HTSC and the nodal-antinodal dichotomy are hallmarks of the superconductivity state. [1] N. Mannella et al., Nature 438, 474 (2005) [2] K. M Shen et al., Science 307, 901 (2005).

**Y20 3 First-order metal-insulator transitions in manganites: Are they universal?*** KENNETH GRAY, QING'AN LI, STINE KLAUSEN, HONG ZHENG, STEPHAN ROSENKRANZ, RAY OSBORN, JOHN MITCHELL, *Argonne National Laboratory* Conductivity data for $La_{2-2x}Sr_{1+2x}Mn_2O_7$ ($x=0.6$) show a first-order transition from an orbital/charge-ordered insulator to a metal as the temperature falls below $\sim$ 160 K. The change in conductivity of $\sim$ 10000 is 100 times larger than that seen previously in any single-phase manganite in zero field. The metallic low-temperature state is similar to that found at $x=0.58$, but $x=0.58$ shows no evidence of orbital/charge order. This result, and further analysis, supports a conclusion that strongly coupled magnetic/conductive transitions are universally of first order.

**Y20 4 Topotactic Reduction of Complex Manganese Oxides.**
MICHAEL HAYWARD, *University of Oxford*

Mixed-valent manganese (III/IV) perovskite and Ruddlesden-Popper oxides have received considerable attention due to the observation of strong coupling between spin, charge and lattice degrees of freedom in these materials. Little attention however has been focused on the analogous Mn (II/III) oxides due to the difficulty of their synthesis. The topotactic reduction of the Mn(III/IV) perovskites $La_{1-x}Sr_xMnO_3$ ($0.2 < x < 0.4$) results in the formation of the corresponding $La_{1-x}Sr_xMnO_{2.5}$ brownmillerite phases. The $x = 0.25$ and 0.2 phases adopt structures with an unusual ordered L-R-L-R alternation of twisted chains of Mn(II) tetrahedra which is accompanied by Mn(II)/(III) charge ordering within the remaining $MnO_6$ octahedral layers. In contrast the $x = 0.4$ phase adopts a structure in which the twisted chains of tetrahedra are disordered. Temperature dependant magnetization data collected from similarly reduced $n = 2$ Ruddlesden-Popper phases of composition $YSr_2Mn_2O_{7-x}$ ($0 < x < 1.5$) indicate strong antiferromagnetic coupling interactions in all samples. Long range magnetic order is suppressed by structural and/or charge disorder in all samples except $YSr_2Mn_2O_{5.5}$ which adopts a G-type antiferromagnetic ordering scheme.

**Y20 5 Tunneling evidence for weak localization in layered manganites*** DANIEL MAZUR, *Illinois Institute of Technology* KEN E. GRAY, *Argonne National Laboratory* JOHN F. ZASADZINSKI, *Illinois Institute of Technology* HONG ZHENG, JOHN MITCHELL, *Argonne National Laboratory* Our point contact tunneling experiments on $La_{1.28}Sr_{1.72}Mn_2O_7$ (bi-layered LSMO $x=0.36$) at low temperatures reveals a $\sqrt{V}$ low bias anomaly in the tunneling conductance. This anomally qualitatively matches the $\sqrt{E}$ predictions of the weak localization effect on the electronic DOS. The data could provide an important corroboration of the weak localization hypothesis, which was concluded previously from low-temperature conductivity and magnetoresistance data.

**Y20 6 Doping Dependence of Polaron Correlations in Bilayer Manganites*** RAYMOND OSBORN, STINE KLAUSEN, STEPHAN ROSENKRANZ, PETER CHUPAS, JOHN MITCHELL, *Materials Science Division, Argonne National Laboratory, Argonne, IL 60439* It is now well established that colossal magnetoresistance (CMR) in manganite compounds is strongly enhanced by competing interactions close to the magnetic phase transitions. In the paramagnetic phase of the bilayer manganites, diffuse x-ray scattering data has shown evidence of polaron correlations that grow with decreasing temperature and coexist with the critical magnetic fluctuations down to the ferromagnetic phase transition, before collapsing below $T_C$. These correlations, which have a length scale of about 20Å, are in the form of longitudinal Jahn-Teller stripes within the bilayers, characterized by an incommensurate wavevector. There have been proposals that these nanoscale correlations are evidence of an incipient charge density wave, whose wavevector corresponds to nesting features in the Fermi surface. We report new measurements of the doping dependence of these correlations that show that the wavevector increases from 0.26 at a hole doping of $x = 0.32$ to about 0.3 at $x = 0.46$, which is inconsistent with the anticipated change in the Fermi surface volume, and will discuss alternate models of the short-range order.

**Y20 7 Magneto-optical investigation of the field-induced transition in bilayer manganese oxide $(La_{0.4}Pr_{0.6})_{1.2}Sr_{1.8}Mn_2O_7$*** J. CAO, J.T. HARALDSEN, R.C. RAI, S. BROWN, J.L. MUSFELDT, *University of Tennessee* X. WEI, Y.J. WANG, *National High Magnetic Field Laboratory* M. APOSTU, R. SURYANARAYANAN, A. REVCOLEVSCHI, *Université Paris-Sud* We measured the magneto-optical response of PrLSMO in order to investigate the microscopic aspects of the magnetic field driven paramagnetic insulator to ferromagnetic metal transition. With applied magnetic field, optical weight transfers to lower energy and develops a clear signature of ferromagnetic domains. Mn-O stretching and bending modes soften through the phase transition as well, demonstrating precisely how the lattice is coupled to the transition. We also extract the H-T optical phase diagram and compare it with that from resistivity, magnetization, and magnetostriction to show that the lattice responds more slowly than charge and spin at low temperature. Color rendering allows visualization of the thermochromic and magnetochromic effect.

**Y20 8 Is CE-type orbital order the true ground state for $LaSr_2Mn_2O_7$?*** HELMUT CLAUS, QING'AN LI, HONG ZHENG, KENNETH GRAY, STINE KAUSEN, STEPHAN ROSENKRANZ, RAY OSBORN, JOHN MITCHELL, *Argonne National Laboratory* Previous scattering and conductivity data for $La_{2-2x}Sr_{1+2x}Mn_2O_7$ ($x=0.5$) indicate the CE phase, predicted by Goodenough 50 years ago, is only stable between $\sim$ 100 and 200 K and below $\sim$ 100 K an A-type antiferromagnet is the ground state. We present scattering, magnetization and transport evidence that the CE phase is the ground state, but only in a very narrow composition range, presumably at exactly $x=0.5$. The vitally important roles of crystal homogeneity and methodology of transport measurements will be demonstrated for this conclusion as well as for the field of layered manganites in general.

**Y20 9 Polarons and polaron correlations in 40% doped bilayer manganite.*** S. N. KLAUSEN, S. ROSENKRANZ, R. OSBORN, P. J. CHUPAS, J. F. MITCHELL, *Materials Science Division, Argonne National Laboratory, Argonne, IL 606439* Among the compounds exhibiting colossal magnetoresistance, the bilayer manganites, $La_{2-2x}Sr_{1+2x}Mn_2O_7$, where $x$ is the hole doping in the $MnO_2$ layers, are advantageous to study because the reduced dimensionality strongly enhances the spin and charge fluctuations. For the intermediate doping regime ($32\% \leqslant x \leqslant 42\%$), the magnetoresistance is strongly enhanced near the combined metal-insulator and ferromagnetic transition. Here, we report on our detailed x-ray scattering investigation of the diffuse scattering associated with lattice distortions around localized charges (polarons) as well as short-ranged polaron correlations present in the paramagnetic phase of the $x = 40\%$ doped compound, both collapsing at $T_C = 112$ K. We have studied in detail the temperature dependence to high temperatures ($T = 50$ K - 500 K) and are able to directly extract a polaron activation energy from the data.

**Y20 10 A Polaronic Picture of Bilayer Colossal Magnetoresistive Manganites in Angle Resolved Photoemission Spectroscopy** C. JOZWIAK, G.-H. GWEON, *Department of Physics, UC Berkeley* J. GRAFF, *Materials Science Division, LBNL* S.Y. ZHOU, *Department of Physics, UC Berkeley* H. ZHENG, J. F. MITCHELL, *Material Sciences Division, ANL* A. LANZARA, *Department of Physics, UC Berkeley and Material Sciences Division, LBNL* It is becoming generally recognized that the presence of a strong electron-lattice interaction, in the limit of polaronic coupling, is a common feature to transition metal oxides such as cuprate superconductors and colossal magnetoresistive manganites. Angle resolved photoemission spectroscopy (ARPES) is the ideal tool to address and gain insight on the polaronic nature of the electron-lattice interaction through a direct study of the ARPES single particle spectral function. Here we present a detailed momentum dependent study of the ARPES single particle spectral function in double layer manganites $La_{1.2}Sr_{1.8}Mn_2O_7$,and Bi2212 and LSCO cuprates. A direct comparison between the two classes of materials and the peculiar momentum dependence of the ARPES lineshapes, also known as nodal-antinodal dichotomy, will be discussed in terms of a polaronic picture.

**Y20 11 Order/Disorder Effects in Perovskite Manganites** B. DABROWSKI, *Argonne National Laboratory* S. KOLESNIK, *Dept. of Physics, Northern Illinois University* O. CHMAISSEM, *ANL* E.N. CASPI, *Nuclear Research Centre-Negev, Beer-Sheva, Israel* J. MAIS, *Dept. of Physics, Northern Illinois University* J.D. JORGENSEN, *ANL* Indirect magnetic interactions between transition metals in perovskites $ABO_3$ are commonly described in terms of superexchange and double-exchange interactions that depend on the bond angle B-O-B. By useing the tolerance factor parameterization procedure we have designed and obtained new substituted manganites with randomly-mixed and layer-ordered structures having identical chemical compositions. The order/disorder effects on magnetic properties have been investigated as a function of the bond angle disorder for both the A- and Mn-sites. By comparing ordered (containing planes of the $RO_2$ and $BaO_2$) and disordered ferromagnetic compounds $La_{1-x}Ba_{1+x}Mn_2O_6$, we have demonstrated that by decreasing local structural and charge disorder, an increase of $T_c$ of over 100 K can be achieved. Similar effects have been demonstrated for $Sr_2MnGaO_{6-d}$ where transitions from spin-glass seen for the disordered compound to antiferromagnetic behavior seen for the ordered material (containing planes of the $MnO_2$ and $GaO_{2-d}$), have been observed. Supported by NSF (DMR-0302617) and U.S. Department of Energy, BES – Materials Sciences (W-31-109-ENG-38)

**Y22 2 Magnetic properties of $L1_0$ FePtCu:Au films for high-density perpendicular recording*** M.L. YAN, Y.F. XU, Y.C. SUI, R. SKOMSKI, D.J. SELLMYER, *University of Nebraska* We present fabrication methods for tunable magnetic properties of non-epitaxially grown, nanocomposite $L1_0$ FePtCu:Au films including a coupled FePt continuous gradient layer (CGL) for the application of high-density perpendicular recording media. The films are deposited with the structure FePt(x)/[FePtCuAu] on a thermally oxidized Si wafer and subsequently annealed. [FePtCuAu] is a nanocomposite layer (NL) with a fixed layer thickness, 12nm, and FePt(x) is the continuous gradient layer, with the thickness x varying from 0 to 10 nm, which is coupled to the NL. X-ray diffraction patterns show an enhanced degree of orientation for FePtCu:Au films with an increase of the CGL thickness. SQUID measurements show that magnetic properties of the films are tunable by changing the CGL layer thickness. When the CGL thickness is 10 nm, the magnetic properties of the film are $M_s \cong 600$ emu/cc, slope $\alpha$ ($= 4\pi d\mathrm{M}/d\mathrm{H}$) at the coercivity $\cong 1$ and $H_c \cong 6$ kOe. These results are discussed in terms of exchange-coupled layers with differing properties, and demonstrate the

possibility of fabricating FePt-based nanocomposite media with properties suitable for high-density perpendicular recording.

**Y22 3 Parallel and anti-parallel coupling of CoPt/Ru/CoFe trilayers investigated with magnetometry and ferromagnetic resonance** MICHAEL PECHAN, CHENGTAO YU, *Miami University, Oxford, OH* STEFAN MAAT, *Hitachi Global Storage Technologies, San Jose, CA* Due to their low resistivity ( $\sim$ 30 $\mu\Omega$-cm) and critical thickness $CoPt_x$ ($16 \leqslant x \leqslant 24$ at %) thin films are interesting pinning materials for current perpendicular to the plane (CPP) spin-valve sensors [1]. These properties help to minimize serial resistance and thus enhance the magnetoresistance. 4 nm thick CoPt films deposited on Cr were shown to exhibit coercivities up to 1.5 kOe. One requirement for using CoPt as a pinned layer in a CPP spin-valve is that anti-parallel (AP) coupling to a reference layer can be demonstrated to minimize magnetostatic coupling to the free layer to keep the free layer magnetically soft. Here we investigate the parallel (P) and AP coupling of $CoPt_{18}(50)/Ru(x)/CoFe_{16}(36)$ trilayers with $0 \leqslant x \leqslant 2.1$ nm with magnetometry and ferromagnetic resonance (FMR). We found the coupling to be oscillatory with peaks at x = 0.7 nm (AP) 1.4 nm (P) and 2.0 nm (AP), respectively. These peaks were also observed using 35 GHz FMR in saturation. From the FMR technique the coupling strengths were determined to be 1150 (AP), 250 (P) and 660 (AP) Oe respectively. Variable temperature magnetometry reveals the exchange, coercivity and saturation fields increase monotonically with decreasing temperature. Supported at Miami by U.S. Dept. of Energy [1] S. Maat et al. J. Appl. Phys. Dec. 1 issue (2005)

**8:36**

**Y22 4 X-ray reflectivity of ruthenium nano-oxide layer in a CoFe-Ru-CoFe trilayer system** SAEID ASGHARI ZADEH, MARK SUTTON, ZAVEN ALTONIAN, *Physics Department and Centre for the Physics of Materials, McGill University, 3600 University street, Montreal, Quebec* MING MAO, CHIH-LING LEE, *Veeco Instruments Fremont, Fremont, CA 94538* A grazing incidence X-ray reflectivity technique is used to determine electron density profile(EDP) as a function of depth in CoFe-Ru-CoFe and CoFe-Ru nano oxide layer(NOL)-CoFe trilayers. Four trilayers with ruthenium thicknesses of 8,8.5 and 9 Å and one with Ru8.5 NOL, prepared by a dc planetary sputtering system, were investigated. For all samples, EDP shows a central peak which is related to the Ru layer. Natural oxidation in all samples introduces a graded EDP of the top CoFe layer that decreases gradually to zero. The large surface resistivity of Ru8.5 Å NOL compared to Ru 8.5Å can be related to the remarkable difference between their EDP.

**8:48**

**Y22 5 Systematic Investigation of Exchange Coupled $Fe_xCo_{1-x}$/CoPt Magnetic Bilayers Using the High-Throughput Approach** H. OGUCHI, *Univ. of MD* M. YU, *Univ. of New Orleans* J. HATTRICK-SIMPERS, *Univ. of MD* A. ZAMBANO, I. TAKEUCHI, *Univ. of MD* S. LOFLAND, *Rowan Univ.* D. JOSELL, L.A. BENDERSKY, *NIST* J.P. LI, *Univ. of Texas at Arlington* Exchange-coupled magnetic nanocomposites are being pursued for future permanent magnets with high energy products. To gain better understanding of the exchange coupling behavior between the soft and hard magnetic layers, we are using the high-throughput approach. $Fe_xCo_{1-x}$/CoPt magnetic bilayers are grown on MgO(110) substrates using the combinatorial electron-beam deposition. CoPt hard magnetic layer is epitaxially grown at 600° C. The $Fe_xCo_{1-x}$ soft layer is deposited at 200° C. To study the effect of changing soft phase parameters on exchange coupling, we have fabricated libraries where in one direction the composition of the soft-phase is continuously changing from Fe to Co and the thickness of the soft layer is changing in the other direction. The magnetic hysteresis loop for each soft layer composition and the thickness is measured using a magneto-optical Kerr effect system. From systematically changing hysteresis loops, we calculate the exchange field ($H_{ex}$) as a function of anisotropy and magnetization of the soft phase. Observed dependence of $H_{ex}$ on soft phase parameters are directly compared against theoretical models of the exchange mechanism. ONR N00014-05-1-0497, NSF DMR -0520471.

**Y22 6 Molecular Beam Epitaxial Growth and Magnetic properties of Fe(001)/$Mn_3N_2$(010) Thin Films** RONG YANG, *Ohio University* ERDONG LU, *Ohio University* MUHAMMAD HAIDER, *Ohio University* ARTHUR SMITH, *Ohio University* DIANA LEITNER, *Oberlin College* YUMI IJIRI, *Oberlin College* Exchange bias systems have attracted considerable attention due to their importance to magnetic sensor technology. Considering that $T_{Neel}$ of $Mn_3N_2$ ($T_N$=652°C) is less than $T_{Curie}$ of Fe ($T_C$=770 °C), and also since Mn-Mn spacing of $Mn_3N_2$(010) ( $\simeq$ 2.86 angstrom) is closely matched to the Fe-Fe spacing of Fe(001)(2.87 angstrom), it is therefore of great interest to explore Fe epitaxy on Mn3N2(010). We have grown thin Fe films on $Mn_3N_2$(010)/MgO(001) using molecular beam epitaxy at 150°C, and then following by annealing at 450°C for 10 minutes. The growth is monitored by reflection high-energy electron diffraction, which shows c(2x2) reconstructed surface for the as-grown sample, and a change to (1x1) after annealing. Annealing leads to a smoothening of the film surface.The epitaxial orientation have been determined to be Fe [100] (001)// Mn3N2[101] (010)// MgO[110](001). Annealed samples are transferred to the in situ analysis chamber for scanning tunneling microscopy studies. Images show smooth terraces and atomic-height steps. Vibrating sample magnetometry measurements found in-plane anisotropy and hysteresis loop shifting after field cooling. The work is supported by NSF9983816 and 0304314.

**Y22 7 Novel materials and media concepts for thermally assisted magnetic recording.**
JAN-ULRICH THIELE, *Hitachi Global Storage Technologies*

Magnetic media using materials with high uniaxial magneto-crystalline anisotropy, $K_U$, combined with a thermal assist to overcome thermal stability and write field limitations are widely seen as a potential extension of current magnetic recording technology. Here we present an overview of recent work on adapting the thermo-magnetic properties of FePt-based high-$K_U$ materials for the requirements of such a recording system. In [1] we recently proposed a novel media

structure consisting of two exchange coupled films, a high anisotropy film like, e.g., FePt, and a FeRh film. At close to equiatomic compositions FeRh is an antiferromagnet at low temperatures. Interestingly, upon heating beyond a critical temperature, $T_{AF-FM}$, FeRh becomes ferromagnetic for temperatures $T_{AF-FM} < T < T_C$. This opens interesting possibilities for media applications for thermally assisted recording: at a storage temperature, $T_S < T_{AF-FM}$, the magnetic information is stored in the high-$K_U$ FePt layer. For writing at increased temperature, $T_{AF-FM} < T_W < T_{C-FeRh}$, the FeRh becomes ferromagnetic, effectively lowering $K_U$ and increasing the total magnetic moment of the bilayer, thus lowering its coercivity via an exchange spring mechanism and helping magnetization reversal at temperatures well below $T_C$ of the FePt layer. A related area of great interest is the magnetization dynamics upon rapid heating and cooling of FeRh films using itfs-laser pump-probe techniques. First results indicate that the AF-FM transition can be driven on a timescale below 1 itps [2], yielding interesting insight into the interaction of the spin, electron and lattice subsystems. **Y22 8 Uncompensated Fe moments in positively exchange biased Ni/$FeF_2$ bilayers** ELKE ARENHOLZ, *LBNL* KAI LIU, *University of California, Davis, CA* ZHI-PAN LI, I.K. SCHULLER, *University of California San Diego, La Jolla, CA* The magnetization reversal of uncompensated Fe moments in exchange biased Ni/$FeF_2$ bilayers was determined using soft x-ray magnetic circular dichroism. Hysteresis loops resulting from Fe moments oriented parallel and perpendicular to the external field are almost identical to those of the ferromagnetic Ni layer. However, a small vertical loop shift indicates that some Fe moments are pinned antiparallel to small cooling fields leading to negative exchange bias but parallel to large cooling fields resulting in positive exchange bias. For intermediate cooling fields, loop bifurcation is observed. This is attributed to a coexistence of domains with uncompensated Fe moments pinned parallel and antiparallel to the cooling field. Furthermore, x-ray magnetic linear dichroism was employed to characterize the spin structure of the antiferromagnetically ordered $FeF_2$ but no indication for the formation of a parallel antiferromagnetic domain wall upon magnetization reversal in the ferromagnetic layer was found. The ALS at LBNL and work at UCSD are supported by DOE and work at UCD by ACS-PRF and Sloan Foundation.

**Y22 9 On the method of exchange bias measurement** ONDREJ HOVORKA (*), ANDREAS BERGER, *San Jose Research Center, Hitachi Global Storage Technologies, San Jose, CA 95120* GARY FRIEDMAN (*), *Electrical and Computer Engineering Department, Drexel University, Philadelphia, PA 19104* Exchange bias is the observation of a hysteresis loop shift in ferromagnetic-antiferromagnetic compound structures [1]. Recently, such a shift was also observed in all ferromagnetic bilayer systems [2]. Conventionally, exchange bias fields are measured by determining the average coercive field of a hysteresis loop (two-point method). However, hysteresis loops in exchange biased systems can also change in shape and even exhibit asymmetrical reversal [3], which can affect the estimate of the exchange bias field significantly. A different method for measuring the exchange bias based on obtaining the ''center of mass'' for exchange biased hysteresis loops is proposed and analyzed in this work. The method is validated by numerical simulation, using a realistic model system composed of soft and hard ferromagnetic layers coupled antiferromagnetically. Our calculations allow us to determine the laterally averaged bias field $< Hbias >$ created by the hard layer grains. We find that $< Hbias >$ is in excellent quantitative agreement with the proposed ''center of mass'' measurement, but not with the conventional two-point method. [1] A. Berkowitz, K. Takano, J. Magn. **Y22 10 Magnetic anisotropy in $CrO_2$ and $CrO_2/Cr_2O_3$ bilayer thin films** N.A. FREY, S. SRINATH, H. SRIKANTH, *Physics Department, University of South Florida, Tampa, FL 33620, USA* G. MIAO, A. GUPTA, *MINT Center, University of Alabama, Tuscaloosa, AL,35487, USA* We have investigated the effective magnetic anisotropy in CVD-grown epitaxial $CrO_2$ films and $Cr_2O_3/CrO_2$ bilayers using a resonant RF transverse susceptibility (TS) technique. These materials are of interest due to their high spin polarization and the potential for exhibiting interesting magnetoelectric (ME) effects. In $CrO_2$, the measured values for the room temperature anisotropy constant for the films scaled with the film thickness and the data is influenced by magnetoelastic contributions at low temperature. TS in $CrO_2/Cr_2O_3$ bilayers revealed features associated with both the ferromagnetic and antiferromagnetic phases. In addition, a considerable broadening of the anisotropy fields and large $K_{eff}$ values were observed depending on the amount of $Cr_2O_3$. These anomalously large $K_{eff}$ values observed with $Cr_2O_3$ content cannot be accounted for by the variable thickness of $CrO_2$alone and is indicative of intimate coupling between the two phases that has a significant effect on the magnetic properties.

## SESSION Y23: SINGLE MOLECULE MAGNETS
**Friday Morning, 17 March 2006**
**320, Baltimore Convention Center at 8:00**
**Mark Pederson, Naval Research Laboratory, presiding**

**8:00**

**Y23 1 Pulsed-Radiation-Induced Magnetization Relaxation in Single-Molecule Magnets** M. BAL, J. R. FRIEDMAN, *Dept. of Physics, Amherst College* W. CHEN, *Physics Dept., Stony Brook University* M.T. TUOMINEN, *Dept. of Physics, Univeristy of Massachusetts at Amherst* S. SHAH, E.M. RUMBERGER, D.N. HENDRICKSON, *Dept. of Chemistry and Biochemistry, UC San Diego* N. AVRAHAM, Y. MYASOEDOV, H. SHTRIKMAN, E. ZELDOV, *Dept. of Condensed Matter Physics, The Weizmann Institute of Science* Millimeter-wave radiation induces large dips in the magnetization of a single crystal of the $Fe_8$ single-molecule magnet (SMM) when the radiation is on resonance with transitions

between energy levels. In our recent studies, we pulsed the radiation with the goal of determining $T_1$, the lifetime of the first excited state. We found that during a 0.2-ms pulse of intense radiation the spin system and the lattice are driven out of thermal equilibrium. Experiments at shorter time scales, carried out with the use of an inductive thin-film pick-up loop, revealed a surprisingly long relaxation time for magnetization on the order of $\sim 10$ $\mu$s. A poor signal-to-noise (S/N) ratio required averaging of $\sim 4 \times 10^5$ individual traces to obtain acceptable data. Incorporating a superconducting interference device (SQUID) as a low-noise voltmeter into our experimental setup improves the S/N ratio, allowing us to explore the origin of the observed long relaxation time. The results of these experiments on $Fe_8$ as well as other SMMs will be presented.

**8:12**

**Y23 2 Control of quantum magnetic deflagration in Mn12 acetate.** ALBERTO HERNANDEZ-MINGUEZ, JOAN MANEL HERNANDEZ, FERRAN MACIA, ANTONIO GARCIA-SANTIAGO, JAVIER TEJADA, *Universitat de Barcelona* PAULO SANTOS, *Paul Drude Institut* EXPERIMENTAL MAGNETISM TEAM, SEMICONDUCTOR SPECTROSCOPY COLLABORATION, Magnetic avalanches in Mn12-ac involve spin tunneling through an energy barrier which is controlled by the applied magnetic field. The reversal proceeds through the propagation of a narrow magnetic reversal front at constant velocity through the crystal [1]. In this contribution, we demonstrate that the ignition of the deflagration can be controlled in a deterministic way using surface acoustic waves (SAWs). For that purpose, the Mn12 crystal was mounted on the surface of a piezoelectric LiNbO3 substrate containing an interdigital transducer (IDT) for the excitation of SAWs. In the super-paramagnetic regime (above 3 K), the Mn12 magnetization shows pronounced changes when the IDT is excited at its resonant frequencies, thus proving that the crystals can be used as very sensitive acoustic detectors. At low temperatures (below 3 K), both the ignition rate and the velocity of the deflagration front present peaks for the values of the magnetic fields that bring the spin levels on both sides of the tunneling barrier into resonance, thus demonstrating the occurrence of both quantum magnetic ignition and quantum magnetic deflagration [2]. [1] Y. Suzuki et. al., Phys. Rev. Lett. 95, 147201 (2005). [2] A. Hernández-Mínguez et. al., Phys. Rev. Lett. 95, 217205 (2005).

**8:24**

**Y23 3 Pressure-dependence of the zero-field splittings for the $Fe_8$ single-molecule magnet** S. TAKAHASHI, E. THOMPSON, S. HILL, *Physics, University of Florida* S. W. TOZER, *NHMFL, Florida State University* A. G. HARTER, N. S. DALAL, *Chemistry and Biochemistry and NHMFL, Florida State Univerisity* We present a study of the pressure-dependent electron paramagnetic resonance (EPR) spectrum for the $Fe_8$ single-molecule magnet (SMM). The biaxial $[Fe_8O_2(OH)_{12}(tacn)_6]Br_8 \cdot 9H_2O$ ($Fe_8$) SMM has recently been studied extensively because its low-temperature magnetization dynamics are dominated by quantum tunneling of its spin $S = 10$ magnetic moment through a sizeable anisotropy barrier. To date, chemical methods have usually been employed in order to control the magnetic quantum tunneling (MQT) behavior of a SMM, e.g. by varying the magnetic ions in the molecular core, or the ligand/solvent environment. The advantage of this approach is that many different SMMs can be realized in this way, with widely varying MQT behavior. However, controllable variation of MQT is difficult. As an alternative approach for manipulation of the MQT, we have recently studied the effect of physical pressure on the $Fe_8$ SMM. In this presentation, we show the pressure dependence of the zero-field splittings of $Fe_8$, as studied by an angle and pressure-dependent high-frequency EPR technique.

**8:36**

**Y23 4 Alignment of $Mn_{12}$-acetate in Suspension*** D. SEO, W. TEIZER, *Department of Physics, Texas A&M University, College Station, TX 77843-4242* The magnetization of $Mn_{12}$-acetate single molecule magnets has been studied in an oriented $Mn_{12}$-acetate suspension that, unlike in prior work [1, 2], exceeds the solution saturation. We observe magnetic properties of the frozen suspension similar to large oriented single crystals, specifically several sharp steps in the low temperature hysteresis loop, indicating alignment. The surface morphology of a film made from this suspension, which was studied by atomic force microscopy, indicates micron-size crystals are likely the main source of the magnetization signal. The greater the external magnetic field during alignment, the sharper the steps in the low temperature hysteresis loops. Experimental data showed that $\sim$ 5000 Oe was sufficient to orient the micro crystals in the organic solvent to a degree comparable to a single crystal. [1] D. M. Seo et al., J. Mag. Magn. Mater. in press (2005), doi:10.1016/j.jmmm.2005.06.005 [2] K. Kim et al., Appl. Phys. Lett. **85,** 3872 (2004).

**8:48**

**Y23 5 V, C, and N soft x-ray absorption and MCD of molecular magnet $V[TCNE]_{x\sim2}$ films*** JEFF KORTRIGHT, *LBNL* R. SHIMA EDELSTEIN, D.M. LINCOLN, J.W. YOO, A.J. EPSTEIN, *The Ohio State University* CVD films of $V[TCNE]_{x\sim2}$ are magnetic room temperature and of interest as prototypes in functional organic magnetic systems. In addition to potential technological interest, fundamental questions regarding the electronic structure and spin distribution in $V[TCNE]_{x\sim2}$ films remain, and motivate these measurements of x-ray absorption (XAS) and magnetic circular dichroism (MCD) spectra at the vanadium L, carbon K, and nitrogen K edges. XAS spectra reveal strong multiplet splitting at the V edge and strong $\pi^*$ features at the C and N edges. The registry of these features at different edges indicates a distinct molecular orbital structure involving all constituents. That this molecular orbital structure supports magnetism is indicated by vanadium MCD spectrum and by the loss of specific XAS and MCD features for oxidized samples. Results are interpreted in the context of prior neutron scattering [1] and EXAFS [2] studies, multiplet calculations of V XAS and MCD, and established C and N XAS features. [1] A. Zheludev, et al., J. Am. Chem. Soc. 116, 7243 (1994). [2] D. Haskel, et al., Phys. Rev. B 70, 054422 (2004).

*Measurements were made at the ALS and work was supported by DOE (DE-AC03-76SF00098, DE-FG02-86ER45271, and DE-FG02-01ER45931), NSF-DMR (0114098), and AFOSR (F49620-03-1-0175).

**9:00**

**Y23 6 Understanding the Gap in Polyoxovanadate Molecular-Based Magnets** A. BARBOUR, R.D. LUTTRELL, J. CHOI, J.L. MUSFELDT, *University of Tennessee* D. ZIPSE, N.S. DALAL, *Florida State University* D.W. BOUKHVALOV, *Russian Academy of Sciences Ural Division* V.V. DOBROVITSKI, *Ames Laboratory* M.I. KATSNELSON, *Radboud University* A.I. LICHTENSTEIN, *Universität Hamburg* B.N. HARMON, P. KÖGERLER, *Ames Laboratory* We report a joint experimental and theoretical investigation of the transport gap, optical properties, and electronic structure of two chemically similar, inhomogeneously mixed-valent polyoxavanadate molecule-based magnets. We attribute the substantial gap in $[NHEt_3]_4\ [V_8^{IV}V_4^{V}As_8O_{40}(H_2O))]\cdot H_2O$ to weak *p-d* hybridization and a large on-site Coulomb repulsion ($U = 5$ eV). The reduced gap in $[NHEt_3]_3\ [V_6^{IV}V_6^{V}As_8O_{40}(HCO_2)] \cdot 2H_2O$ is associated with a smaller value of $U$, at least from a molecular point of view, although the transport properties also reflect subtle organization of the molecular structure and the difference between direct and indirect intermolecular charge transfer. A detailed analysis of the vibrational response supports the important role of local molecular distortion and hydrogen bonding in the intramolecular and intermolecular charge transport in $[NHEt_3]_4\ [V_8^{IV}V_4^{V}As_8O_{40}(H_2O))]\cdot H_2O$. This work is supported by PRF and the U.S. Department of Energy.

**9:12**

**Y23 7 High-frequency Infrared Studies of Manganese-based Single-molecule Magnets*** JIUFENG TU, *The City College of New York* YOKO SUZUKI, S. McHUGH, D. GRAYBILL, M.P. SARACHIK, *CCNY* L. MIHALY, *SUNY-Stony Brook* G.L. CARR, *BNL* N.E. CHAKOV, G. CHRISTOU, *University of Florida* High-resolution far-infrared transmission studies of $Mn_{12}$ single crystals (both aligned crystal assemblies and randomly oriented samples) have been carried out as a function of temperature and magnetic field over a wide frequency region (7 - 100 $cm^{-1}$). Several absorption lines corresponding to different transitions within the S = 10 manifold can be observed as a function of temperature. Our previous low frequency studies have shown that the sum of absorption coefficients of these absorption lines does not seem to conserve as a function of temperature. The new high-frequency measurements indicate that the oscillator strength is recovered at higher frequencies with the appearance of new absorption bands. The origin and the frequency dependence of these new absorption bands will be discussed.

*Supported by NSF grant DMR-0451605, DOE-AC02-98CH10886, DMR-0103290 and CHE-0123603.

**9:24**

**Y23 8 Field-dependent magnetic parameters in $\{Ni_4Mo_{12}\}$: Magnetostriction at the molecular level?*** R. C. RAI, J. CAO, J. L. MUSFELDT, *University of Tennessee* X. WEI, *National High Magnetic Field Laboratory* J. SCHNACK, M. BRÜGER, *Universität Osnabrück* M. LUBAN, P. KÖGERLER, E. MOROSAN, R. FUCHS, *Ames Laboratory & Iowa State University* R. MODLER, *Johann Modler GmbH* H. NOJIRI, *Tohoku University* We present the optical and magneto-optical properties (0 - 32 T) of $Mo_{12}^{V}O_{30}(\mu_2\text{-}OH)_{10}H_2\{Ni^{II}(H_2O)_3\}_4$, a magnetic molecule with antiferromagnetically coupled tetrahedral $Ni^{II}$ in a diamagnetic molybdenum matrix. A magnetochromic effect, centered at $\sim$ 1.9 eV, is observed at 4.2 K, and it is attributed to a change in the Ni $d \rightarrow d$ on-site excitation. The low-temperature magnetization exhibits steps at irregular field intervals, a result that cannot be explained using a Heisenberg model even if it is augmented by magnetic anisotropy and biquadratic terms. Field-dependent exchange parameter, however, provides the best fit to magnetization, suggesting that the molecular structure (and thus the interactions between spins) may be changing with applied magnetic field. The magneto-optical response of $Mo_{12}^{V}O_{30}(\mu_2\text{-}OH)_{10}H_2\{Ni^{II}(H_2O)_3\}_4$ supports a small change in the $NiO_6$ coordination geometry and the associated electronic single-ion properties.

*This work is supported by the U.S. Department of Energy.

**9:36**

**Y23 9 Numerical Analysis of the EPR Spectrum of a $Ni_4$ Single-Molecule Magnet through Direct Diagonalization of the Four-Spin Hamiltonian** ANTHONY WILSON, *University of Florida, Department of Physics* STEVE HILL, *University of Florida, Department of Physics* EPR studies have established the Giant Spin (GS) Hamiltonian parameters, $D$, $B_4^0$ and $B_4^4$, for members of the $[Ni(hmp)(ROH)X]_4$ (R = Me, Et, etc., and X = Cl and Br) family of single-molecule magnets.[1] Four $S = 1$ $Ni^{II}$ ions, aligned on corners of a cubic core, couple ferromagnetically creating a spin $S = 4$ ground state. Experiments on an isostructural Ni/Zn alloy established single-ion $d_i$ and $e_i$ parameters, as well as the orientations of the local magnetic axes.[1] A numerical model utilizing matrix diagonalization has simulated EPR spectra for the coupled $S = 1$ $Ni^{II}$ ions using parameters from the Ni/Zn studies. Fourth order anisotropy parameters in the giant spin model arise from the isotropic Heisenberg coupling, $itJS_1 \cdot S_2$, and quadratic single-ion anisotropy in the four-spin Hamiltonian. Heisenberg coupling causes higher energy states to influence the $S = 4$ ground state addressed in the GS model. Matching the lowest nine energies of the four-spin model to those of the GS model allows direct spectroscopic determination of $J$. [1]E.-C. Yang et al., Inorg. Chem. **44**, 3827-3836 (2005).

**9:48**

**Y23 10 Magnetic Quantum Tunneling in a $Mn_{12}$ Single-Molecule Magnet Measured With High Frequency Electron Paramagnetic Resonance** JON LAWRENCE, SUNG-SU KIM, STEVE HILL, *University of Florida, Physics* MURALEE MURUGESU, *University of California at Berkeley, Chemistry* GEORGE CHRISTOU, *University of Florida, Chemistry* The low temperature spin dynamics of the single-molecule magnet $[Mn_{12}O_{12}(CH_3COOH)_{16}(H_2O)_4] \cdot 2CH_3COOH \cdot 4H_2O$, were studied using High Frequency Electron Paramagnetic Resonance (HFEPR) in order to demonstrate magnetic quantum tunneling between resonant spin projection states. We prepare the spins such that they populate only one side of the axial potential energy barrier and, using a magnetic field, we cause tunneling of the magnetic moment between resonant spin projection states. We then use HFEPR to monitor the populations on each side of the potential energy barrier. We show that, in addition to measuring the ensemble average of the relaxation, these HFEPR experiments demonstrate that one can separately monitor the relaxation from different parts of the inhomogeneous distribution of spin environments. This technique, therefore, provides an alternative method for performing hole-digging experiments for measuring spin relaxation dynamics.

**10:00**

**Y23 11 Acoustomagnetic pulse experiments in LiNbO3/Mn12 hybrids** JOAN MANEL HERNANDEZ, FERRAN MACIA, ALBERTO HERNANDEZ-MINGUEZ, ANTONIO GARCIA-SANTIAGO, JAVIER TEJADA, *Universitat de Barcelona* PAULO SANTOS, *Paul Drude Institut* EXPERIMENTAL MAGNETISM TEAM, SEMICONDUCTOR SPECTROSCOPY COLLABORATION, We report here that single crystals of molecular magnets like Mn12 and Fe8 mounted on the surface of piezoelectric LiNbO3 can be used as very sensitive detectors for surface acoustic waves (SAW). These SAWs are generated by sending microwave pulses in the time range between 1 $\mu$s and several tens of ms to an interdigital transducer mounted on the LiNbO3. Our experiments were carried at low temperatures and in the presence of external magnetic fields, and the analysis of the magnetization variations was done using an SQUID magnetometer with time resolution of 1 $\mu$s that allows us to study the quantum properties of these nanomagnets. The results obtained show that the variation of magnetization depends: 1) on the intensity and quality factor of the SAW at the different frequencies, 2) on whether the temperature of the experiment is above or below the magnetic blocking temperature of the molecular clusters. Furthermore, the heat released by the scattering of the coherent phonons forming the SAW contributes to the generation of the so-called magnetic avalanches. J.M. Hernandez et. al., App. Phys. Lett., (accepted).

**10:12**

**Y23 12 Magnetism in Metal Clusters** FORREST PAYNE, WEI JIANG, L.A. BLOOFIELD, *University of Virginia* We have measured the magnetic moments of clusters of Cobalt, Niobium, and Chromium, ranging in size from $<$ 20 to 200 atoms. Improvements to our cluster source have allowed us to produce smaller and colder ( $\sim$ 60K) clusters than we were able to study in previous work and to study each cluster size individually. We will present measured values for the magnetic moments of these clusters as functions of size, temperature, and applied field. We have also investigated superparamagnetic behaviors of these clusters, looking for deviations from that behavior. This presentation is based upon work supported by the National Science Foundation under Grant No. DMR-0405203.

**10:24**

**Y23 13 STM differential conductance of a pair of magnetic adatoms*** BRIAN LANE, KEVIN INGERSENT, *University of Florida Department of Physics* Competition between screening of local moments through the Kondo effect and magnetic ordering of those moments through direct or induced (RKKY) exchange interactions is a key feature of heavy-fermion systems and of metals containing dilute magnetic impurities. It should be possible to probe this competition in its purest form through scanning tunneling microscopy (STM) studies of pairs of magnetic adatoms on metallic surfaces. However, in order to interpret the STM differential conductance through a pair of nearby adatoms, it is necessary to understand the effects of Fano-like interference between different tunneling paths from the STM tip into the substrate. We report preliminary results of numerical renormalization-group calculations of the impurity spectral function and the differential tunneling conductance for the two-impurity Anderson model, and compare our results with those for the well-studied one-impurity case.

**10:36**

**Y23 14 Electronic Structure of Magnetic Titanocene Dimer Molecules at a Metal Surface Measured by Scanning Tunneling Microscopy** XINGHUA LU, YAYU WANG, R. YAMACHIKA, A. WACHOWIAK, M. F. CROMMIE, *Department of Physics, University of California, Berkeley, and Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley* L. BELTRAN, J. R. LONG, *Department of Chemistry, University of California, Berkeley* The titanocene dimer ($[Cp_2TiCl]_2$, where $Cp = C_5H_5$) is an interesting magnetic molecule because it incorporates two spin-1/2 Ti atoms in an antiferromagnetic configuration. We have used cryogenic scanning tunneling microscopy to study the local electronic properties of titanocene dimer molecules adsorbed onto metal surfaces. Ordered patterns of titanocene dimmers have been observed for submonolayer coverage on Au(111). Scanning tunneling spectroscopy of the molecules shows sharp features near the Fermi energy that may be magnetic in origin.

## SESSION Y24: POLYMER MELTS & SOLUTIONS: STRUCTURE & SOLUBILITY

**Friday Morning, 17 March 2006**
**321, Baltimore Convention Center at 8:00**
**Ferenc Horkay, National Institutes of Health, presiding**

**8:00**

**Y24 1 Why Good Solvents Are Seldom All That Good** S. T. MILNER, *ExxonMobil* M.-D. LACASSE, *ExxonMobil* W. W. GRAESSLEY, The strength of interactions between polymers and solvents is most commonly summarized in a chi parameter. Chi greater than 0.5 leads to phase separation, while a value of zero indicates an ''ideal'' solvent. In fact, chi values less than 0.25 are quite rare, even among so-called ''good solvents'' for a given polymer. Why should this be? The origin of energetic interactions between nonpolar polymers and solvents is primarily dispersive forces, which are proportional to the square of the difference in solubility parameter; hence it should be possible to choose polymer and solvent with matched solubility parameters to achieve an ideal solvent. We shall argue that there is also a generic entropic contribution to chi. One way of describing it is to say that polymer and solvent have a different propensity to explore free volume; when obliged to mix, there is an entropic penalty resulting from the necessary compromise in free volume per mer. One may also say that the solvent molecules induce a depletion attraction between chain segments, analogous to the attraction between colloidal particles induced by micellar solutions. This effect can be observed in simulations of hard-sphere chains in identical hard sphere solvent. There one finds that the radius of gyration of such chains in solvent are significantly smaller than in vacuum, though still scaling as self-avoiding walks. From this result, a chi value of about 0.3 may be inferred.

**8:12**

**Y24 2 Re-examination of the slow mode in semidilute solutions** CHI WU, *The Chinese University of Hong Kong* Dynamics of semidilute solutions has been well described by two different motions, respectively, related to the ''blobs'' and the reptation of an entire chain. In the past, dynamic LLS results revealed that besides the fast relaxation related to the ''blobs,'' there existed an addi-

tional slow relaxation. In the earlier time, such a slow mode was wrongly identified as the reptation. Later, this slow mode was attributed to possible problems in the sample preparation, such as dust particles or a concentration gradient. Whether this slow mode is real has remained a challenging problem since 80's. Recently, we found that it appears only when the solvent quality is less good. To avoid problems in the sample preparation, we, respectively, used the coil-to-globule transition of long polystyrene chains, the high-vacuum anionic polymerization of styrene in cyclohexane, and the living bulk polymerization of MMA to alternate the size of polymer chains (i.e., the overlap concentration) to induce an itin-situ dilute-semidilute transition. Our results confirm that this slow mode is real with no ambiguity. In theory, we can demonstrate that this slow mode appears whenever segments (monomers) in different ''blobs'' start to interact with each other and its characteristic relaxation time is related to the correlation length of these interacting ''blobs.''

**8:24**

**Y24 3 On Fluctuations in Polymer Systems: Field Theoretic Simulations** KIRILL KATSOV, *Materials Research Lab, UCSB* ERIN LENNON, *Chemical Engineering, UCSB* GLENN FREDRICKSON, *Materials Research Lab, UCSB* We use variety of approaches to sample equilibrium fluctuations in polymersystems within a field theoretic framework. Comparison of (complex) Langevin and (smart) Monte Carlo sampling techniques is presented with special attention paid to their efficient implementation. We apply these methods to study effect of fluctuations on phase behavior in diblock copolymer melts and correlations in semidilute polymer solutions.

**8:36**

**Y24 4 Molecular Dynamics Simulations of a Dendritic Polyelectrolyte with Flexible Spacers in Salt-free Solution** QI LIAO, YONG LIN, XIGAO JIN, CHARLES C. HAN, *PPCL, Joint Lab. of Polymer Science and Materials,Institute of Chemistry, Chinese Academy of Science, Beijing 100080, China* We present the results of molecular dynamics simulation of a dendritic polyelectrolyte in a dilute salt–free solution. The dendritic polyelectrolyte is modeled as an ensemble of bead spring regular-branched chain of charged Lernard-Jones particles with explicit counterions. The simulations were performed covering a wide range of molecular variables of the dendritic polyelectrolyte such as generation number, spacer length, and charge density. The relaxation time of dendrimer size, the conformation of spacers, the size depend of dendrimer on the generation and charge density are discussed and compared with a Flory-type theory. We determined the osmotic coefficients of the dilute dendritic polyelectrolyte solution, and compared with the prediction of cell model of charged sphere.

**8:48**

**Y24 5 Solution and Melt Rheology of Polypropylene Comb and Star Polymers** ARNAV GHOSH, RALPH H. COLBY, *Department of Materials Science and Engineering, Penn State University* JEFFREY M. ROSE, ANNA E. CHERIAN, GEOFFREY W. COATES, *Department of Chemistry, Cornell University* Syndiotactic polypropylene macromonomer arms have been prepared by coordination-insertion polymerization. These arms have been made into polypropylene star polymers by the homopolymerization of the syndiotactic arms with a living alkene polymerization catalyst. The macromonomer arms have also been randomly copolymerized with propylene using rac-dimethylsilyl(2-methyl-4-phenylindenyl) zirconium dichloride catalysts to make polypropylene combs. Consequently we have star polymers and a series of comb polymers with different backbone lengths that are all made from the same macromonomer arms. We compare linear viscoelastic data on star and comb polypropylene melts and solutions in squalane to predictions of the tube dilation model and the tube model without tube dilation. The ratio of comb terminal relaxation time to star terminal relaxation time eliminates the friction coefficient and allows determination of the extent of tube dilation the backbone experiences when it relaxes. The concentration dependence of the comb/star terminal relaxation time ratio can be described by either model, owing to adjustable parameters that are not known itapriori, so independent means to evaluate those parameters will be discussed.

**9:00**

**Y24 6 Watching nucleation and growth of chain disentanglement in large-amplitude oscillatory shear of entangled polymer solutions** P. TAPADIA, A. PHILIPS, SHI-QING WANG, *Department of Polymer Science, The University of Akron* Our recent stress-controlled measurements show that a sufficient yet moderate level of chain deformation due to shear can produce spatial topological rearrangement to free chains from mutual dynamic constraint [1]. The chain disentanglement seems to occur catastrophically, resulting in an inhomogeneously sheared sample during rate-controlled shear [2]. Thus, chain disentanglement is also expected to take place during large amplitude oscillatory shear (LAOS) at frequencies higher than the overall chain relaxation rate. We applied our particle-tracking velocimetric technique to probe the state of chain entanglement during LAOS. We found that the chain orientation produced by LAOS led to a new environment in which the initially well-entangled chains managed to disentangle inhomogeneously in space. A layer free of chain entanglement developed to take the load of the imposed strain. As a result of this nonlinearity, the rest of the sample avoided significant deformation and its chain entanglement remained intact. [1] Tapadia, P.; Wang, S. Q. Phys Rev. Lett, **91**, 198301 (2003); Tapadia, P.; Wang, S. Q. Macromolecules **37**, 9083 (2004). [2] Tapadia, P.; Wang, S. Q. Phys. Rev. Lett., in press (2005).

**9:12**

**Y24 7 Anomalous Sorption of Carbon Dioxide in Polymer Thin Films** XIAOCHU WANG, ISAAC SANCHEZ, *University of Texas* Unusual sorption has been reported in thin polymer films exposed to near-critical CO2. When the supercritical fluid approaches the critical point the film appears to thicken, but it is not clear whether the film swells or if there is adsorption on the film surface A combination of the gradient model of inhomogeneous systems and the lattice fluid model have been used to investigate this phenomenon. It is shown that gas surface adsorption on an attractive surface is proportional to the compressibility of the fluid. We have also investigated numerically the sorption of supercritical CO2 on PDMS and PIB, and supercritical 1,1-difluorethane on PS. By calculating the Gibbs adsorption and adsorption layer thickness of the supercritical fluids, we found in all cases that maximum adsorption occurred when the supercritical fluid was near its compressibility maximum.

**9:24**

**Y24 8 Gas Diffusion in Polyethylene Terepthalate By Molecular Dynamics*** SIMON BUTLER, DAVID ADOLF, *School of Physics & Astronomy, University of Leeds, Leeds, LS2 9JT, UK*

Molecular dynamics simulations of the diffusion of small penetrants through PET have been performed utilising the anisotropic united atom model [1] and a virtual liquid technique. [2] The accuracy and reliability of these two approaches has been assessed in terms of the improvement in equation of state behaviour and of diffusion co-efficients and solubilities. The effect of the diffusion of nitrogen, carbon dioxide, and oxygen on the local dynamics of PET have been investigated as a result. Attention has been focused on the dual mode effect [3] observed during mixed gas diffusion. [1] Molecular dynamics calculation of the equation of state of alkanes, J. Chem. Phys. 93, 6 (1990) [2] Kikuchi, Kuwajima, Fukada, Novel method to estimate the solubility of small molecules in cis-polyisoprene by molecular dynamics simulations, J. Chem. Phys, 115, 13 (2001) [3] Lewis, Duckett, Ward, Fairclough, Ryan, The barrier properties of polyethylene terephthalate to mixtures of oxygen, carbon dioxide and nitrogen, Polymer, 1631, 44 (2003)

**Y24 9 Overcoming the difficulty in performing large step-strain experiments: A first reliable comparison with Doi-Edwards tube model** PAULA X. WANG, SHI-QING WANG, *Department of Polymer Science, The University of Akron* Large step shear has been a popular way to interrogate nonlinear viscoelastic responses of polymeric materials. In absence of any severe interfacial failure, the experimental data [1] were found to agree with the Doi-Edwards model of entangled chains. A separate set of experimental studies [2-4] produced strain-softening and showed disagreement with the D-E model. We have successfully prevented interfacial breakdown for the first time to show that the strain-softening is an interfacial artifact [5] and that the stress relaxation behavior of entangled melts and solutions can be reliably depicted experimentally and accounted for within the D-E model. **Y24 10 Simulations of the dynamics of polymer solutions in unidirectional flows*** BERK USTA, *University of Florida* JASON BUTLER, TONY LADD, We investigate migration and dispersion of polymer chains in unidirectional channel flows by numerical simulation. The algorithm combines the fluctuating lattice-Boltzmann equation with a bead-spring model of a flexible polymer. The method has been shown to be very efficient, capable of simulating polymers in excess of 1000 beads with Oseen level hydrodynamic interactions. The grid-based solution of the fluid equations makes it straightforward to incorporate complex confining boundaries, but here we examine flows in a narrow channel. We observe lateral migration of a single polymer chain in both shear and Poiseuille flows. The direction and extent of migration depend on the degree of confinement as well as the Peclet number, contrary to previous reports. Numerical results show that the longitudinal dispersion deviates from the Taylor dispersion theory at high Peclet numbers, resulting in smaller dispersion coefficients. We will discuss the underlying mechanisms for the reduced dispersion, and also the possibility of improved separation scenarios.

**Y24 11 Heat Capacity of Liquid Poly(vinyl methyl ether) With and Without Water*** MAREK PYDA, *Department of Chemistry, The University of Technology, Rzeszow, 35959 Rzeszow, Poland* B. WUNDERLICH, *Dept. of Chemistry, The Univ. of Tenn., and Chemical Sciences Div., ORNL* K. VAN DURME, B. VAN MELE, *Dept. of Physical Chem. and Polymer Science, Vrije Universiteit, Belgium* The liquid heat capacities at constant pressure Cp, of amorphous poly(vinyl methyl ether), PVME, without and with water have been computed as the sum of vibrational, external, and conformational contributions. The vibrational contribution was calculated from the heat capacity arising from group and skeletal vibrations. The external contribution was estimated from experimental data of the thermal expansivity and compressibility in the liquid state. The conformational heat capacity was evaluated from a fit of experimental part to a one-dimensional Ising model for two discrete states, characterized by parameters linked to stiffness, cooperativity, and degeneracy. For the PVME-water system the additional changes in the conformational heat capacity arising from the interaction of the PVME chains with water. The experimental liquid Cp agrees with these calculations to better than 3%. The calculated liquid Cp was employed in the interpretation of the thermal analysis of the apparent Cp in the region of the melting, demixing, remixing, and crystallization within the PVME-water system.

**Y24 12 Thermodynamically Constrained Inverse Monte Carlo Determination of Effective Pair Interactions** HENRY ASHBAUGH, *Tulane University* LU YANG, *Tulane* SHEKHAR GARDE, *RPI* SANAT KUMAR, *RPI* TULANE COLLABORATION, RPI COLLABORATION, Bridging length scales with molecular simulations requires the development of effective interactions in which degrees of freedom are integrated out to reduce computational expense. Such coarse graining strategies often lose critical thermodynamic information as molecular detail is washed out. Inverse Monte Carlo methods which focus on the reproduction of fluid structure, for example, typically have heats of vaporization and vapor pressures which are significantly greater than experiment. We propose a new method, Thermodynamically Constrained Inverse Monte Carlo (TCIMC), which systematically constrains empirical potential functions to reproduce known energetics and pressures while minimizing the difference between experimental and model pair correlations. We demonstrate the application of TCIMC to the recovery of model pair interactions for the Lennard Jones fluid. This method is subsequently extended to the development of united atom potentials for the alkanes from more complex all atom descriptions. The development of thermodynamically consistent coarse grained potentials for the modeling of polymers is discussed.

**10:24**
**Y24 13 Equivalence of particle and field representation of coarse-grained polymer models** KIRILL TITIEVSKY, KENNETH BEERS, *Massachusetts Institute of Technology* Particle-based and field theoretic coarse-grained models of heterogeneous polymer melts have been difficult to compare quantitatively because of the differences in state variables and simulation parameters. We reconcile the two approaches by noting that assumptions involved in discretizing a polymer field theory allow each molecule to be treated as several particles connected by spring bonds. In effect, these particles are the grid points on which the fields are discretized. The interaction potentials of the points, therefore, are obtained directly from the energy model (e.g. Flory) used in the field theory. The equilibrium phase behavior of a melt of such coarse-grained chains is calculated by stochastic dynamics or Monte Carlo simulations. Unlike field theory which becomes infeasible away from the mean field limit due to complex terms in the Hamiltonian, our simulations converge for realistic chain lengths because the potentials are smooth and real. Also, unlike in existing particle-based methods, all parameters in our model are explicitly related to experimentally measurable quantities. Our simulations of diblock copolymers, furthermore, are quantitatively consistent with experimental and field theoretic results.

**10:36**
**Y24 14 Coarse-graining and dynamics of complex macromolecular liquids: melts and blends** MARINA GUENZA, *University of Oregon* Processes of scientific interest in macromolecular liquids can involve more than ten orders of magnitude in space and time variables, impairing our ability of performing atomic-level simulations in the long-time regime. A way to overcome this problem is to resort to multiscale modeling procedures. Here the challenge is to have a formally rigorous, possible analytical, coarse-graining procedure that enables accurate transfer of information between different lengthscales of interest. Starting from the Ornstein-Zernike equation we derived (G.Yatsenko et al. PRL 93, 257803 (2004)) an analytical procedure to coarse-grain structure and dynamics of macromolecular liquids (homo- and diblockcopolymers) and their mixtures. Our procedure maps macromolecules into interacting soft-colloidal particles and provides the effective soft-core potentials input to mesoscale simulations of the coarse-grained systems. Because analytical, our procedure provides a universal formalism easily implemented to treat different systems of interest. Our procedure efficiently extends the range of length- and timescales accessible in simulations of macromolecular liquids. The soft-core mean-force potential enters the Langevin Equation for Cooperative Dynamics (M.Guenza PRL 88, 025901 (2002)), which predicts anomalous subdiffusive center-of-mass motion in excellent agreement with simulations and recent experimental data.

**10:48**
**Y24 15 Kac-Dirac propagators modeling crossover between entangled and unentangled conformations in polymer melts** YITZHAK SHNIDMAN, *College of Staten Island, City University of New York* We will discuss the advantages of using the Kac stochastic process on a lattice for modeling the statistics of chain conformations in polymers melts. Certain projections of the master equation governing such a process assume the form of the telegrapher's equation in the continuum limit, while other projections assume the form of Dirac's equation for free fermions that can also be recast as the Klein-Gordon equation. The statistics of ideal chain conformations and the onset of entanglement in a dense polymer melt will be related to the finite path statistics and the onset of quantum entanglement in a system of free fermions. A persistence length above the Kuhn length scale emerges naturally in the entangled regime without assuming a confining tube as in the Doi-Edwards theory. Kac-Dirac propagators may also provide a better description than Wiener-Schroedinger propagators for conformations of interacting chains across interfaces in inhomogeneous polymer fluids.

## SESSION Y25: CHARGED AND ION-CONTAINING POLYMERS: COMPUTATION
**Friday Morning, 17 March 2006**
**322, Baltimore Convention Center at 8:00**
**Cameron Abrams, Drexel University, presiding**

**8:00**
**Y25 1 A New Necklace Model** ANDREY DOBRYNIN, *University of Connecticut* MICHAEL RUBINSTEIN, *University of North Carolina* QI LIAO, *Institute of Chemistry, China* We have developed a necklace model of hydrophobic polyelectrolytes in which the necklace structure consisting of polymeric globules (beads) connected by extended sections of the chain (strings of monomers) appears as a result of the counterion condensation and is caused by the balance of the correlation-induced attraction of condensed counterions to charged monomers and electrostatic repulsion between uncompensated charges. The size of the beads increases with polymer concentration while their number per chain decreases. We predict coexistence of necklaces with different number of beads on a polymer backbone at any polymer concentration. To test this necklace model we performed molecular dynamics simulations of polyelectrolyte chains with degree of polymerization N varying from 25 to 373 and with fraction of charged monomers f=1/3, 1/2 and 1 in poor solvent conditions for polymer backbone. The observed concentration dependence of the bead size supports the assumption of the counterion condensation origin of the necklace structure. The overlap concentration is almost independent of the degree of polymerization for weakly charged chains (f=1/3). For strongly charged chains with f=1 the overlap concentration follows the normal N-dependence observed for polyelectrolyte solutions in q and good solvent regimes for polymer backbone. In semidilute solutions the correlation length of fully charged chains is inversely proportional to square root of polymer concentration.

**8:12**
**Y25 2 Electrostatic Complexation between Membrane and Colloid** JIAFANG WANG, *University of Massachusetts, Amherst* M. MUTHUKUMAR, *University of Massachusetts, Amherst* As a primary model of endocytosis, the electrostatic complexation between membrane and colloid is studied. Using a simple approximation, the membrane shape can be determined easily without solving the nonlinear differential shape equation, which facilitates the consideration of electrostatic effects. The phase diagram for the electrostatic complexes can be constructed in terms of the rescaled stretching tension, adhesion strength, and the screening length. By referring to the phase diagram, the possible phase transitions due to the variations of the electrostatic factors (including the charge density, and the screening length) are discussed.

**8:24**

**Y25 3 Molecular Dynamics Simulations of Multilayer Polyelectrolyte Films** PRITESH PATEL, *Macromolecular Science and Engineering, Case Western Reserve University* JUNHWAN JEON, *Polymer Program, Institute of Materials Science, University of Connecticut* PATRICK MATHER, *Macromolecular Science and Engineering, Case Western Reserve University* ANDREY DOBRYNIN, *Polymer Program, Institute of Materials Science and Department of Physics, University of Connecticut* We have performed molecular dynamics simulations of multilayer assembly of oppositely charged polyelectrolytes at charged surfaces. The multilayer build-up was achieved through sequential adsorption of charged polymers in a layer-by-layer fashion from dilute polyelectrolyte solutions. The strong electrostatic attraction between oppositely charged polyelectrolytes at each deposition step is a driving force behind the nanometer-scale multilayer growth. Our simulations have shown that a charge reversal after each deposition step is critical for steady multilayer growth and that there is a linear increase in amount of polymer adsorbed after the first few deposition steps. There is substantial intermixing between chains adsorbed during different deposition steps within multilayer film. Despite significant chain intermixing, however, there are almost perfect periodic oscillations in local composition of positively and negatively charged polymers in the adsorbed film. We show that the film thickness, polymer surface coverage exhibit strong correlation with the strength of electrostatic and short-range interactions.

**8:36**

**Y25 4 Langevin dynamics simulations of dsDNA translocation through synthetic nanopores** CHRISTOPHER FORREY, MURUGAPPAN MUTHUKUMAR, *University of Massachusetts, Amherst* We have modeled dsDNA using a coarse-grained bead-spring method to study its behavior as it is driven by a potential gradient through a nanoscopic pore located in a rigid membrane. Using the Poisson-Nernst-Plank formalism, we calculate traces of the ionic current corresponding to the translocation process and compare our findings with experimental results. In agreement with recent experiments, we find that the dsDNA frequently translocates in a folded configuration. We explore the role of chain length, potential difference and pore diameter on the frequency of translocation events, average residence time, electrophoretic mobility and percentage of unfolded events.

**8:48**

**Y25 5 Modeling Layer-by-Layer Assembly of Flexible Polyelectrolytes** QIANG WANG, *Department of Chemical and Biological Engineering, Colorado State University* Using a continuum self-consistent field theory, we have modelled the sequential process of layer-by-layer assembly of flexible polyelectrolytes on flat surfaces as a series of kinetically trapped states. Up to 60 depositions of oppositely charged polyelectrolytes are performed, each followed by a washing step. The multilayer has a three-zone structure. An exponential growth is found for the first several layers, followed by a linear growth for subsequent layers evolving towards a steady state. Each layer inverts the total charge of the multilayer film (including the bare substrate charge). While adjacent layers are highly interpenetrating, stratification can be seen for every four or more layers. We have also examined the effects of surface charge density, bulk salt concentration, and solvent quality on the thickness and internal structure of the multilayer. Our results agree with most experimental findings on polyelectrolyte layer-by-layer assembly.

**9:00**

**Y25 6 Simulations of comb polyelectrolytes** ZHAOYANG OU, M. MUTHUKUMAR, *University of Massachusetts, Amherst* Using Langevin dynamics, we have characterized the effects on backbone stretching by systematically varying grafting density, grafted-chain length, and backbone length. Chain persistence length, conformational asphericity, and counterion and monomer density profiles were determined. We have found that increasing grafting density leads to increases in both chain persistence length and overall asphericity. Increasing the length of side chains also creates a stiffer backbone, but overall asphericity is decreased. Simulation results will be compared with theory.

**9:12**

**Y25 7 Spanning the gap between strong and weak-coupling electrostatics for charged rods*** CHRISTIAN SANTANGELO, *University of Pennsylvania* I present a method to compute the distribution of counterions near a charged macromolecule at intermediate coupling. The procedure involves decomposing the Coulomb interaction into a separate short and long distance piece. The long distance piece is treated within mean-field theory and a strong-coupling expansion is performed for the long distance part. The theory recovers both the strong and weak coupling results in the appropriate limit for charged surfaces. Furthermore, it is accurate for describing the density at intermediate coupling. I derive from this a two-fluid model for a charged rod with discrete charges along its center axis, making contact with previous models of discretely-charged rods.

**9:24**

**Y25 8 Electrostatic attraction between cationic-anionic assemblies with surface compositional heterogeneities** YURY VELICHKO, MONICA OLVERA DE LA CRUZ, *Northwestern University* Biological assemblies of heterogenous cationic and anionic molecules with hydrophobic groups have important functional properties controlled by interdependencies of the architectures and the intermolecular interactions. The net incompatibility among chemically different charged components, which in water can be due to different degrees of hydrophobicity, promotes macroscopic segregation, while electrostatics promotes mixing of the charges into ionic crystal structure. This competition results in formation of surface charge domains. We analyze attractions among two cylindrical assemblies with surface charge heterogeneities. The compositional heterogeneities are correlated and strongly polarized in the presence of the second assembly. This leads to a strong attraction. The strength of the effective attraction is studied as a function of the distance for different values of the net incompatibility. We compare results of computer simulations and theory.

**9:36**

**Y25 9 Relevance of Solvent Characteristics on Ion-Binding and the Structure Formation of Neutral Polymers in Electrolyte Solutions** ILHEM FAIZA HAKEM, *Carnegie Mellon University* JYOTSANA LAL, *IPNS, Argonne National Laboratory* MICHAEL BOCKSTALLER, *Carnegie Mellon University* Polymers carrying functional groups constituted of heteroatoms are omnipresent in biology and polymer technology, for example in the development of solid state polymer electrolytes. When dissolved in polar solvents, these polymers can coordinate ions that result in an effective transformation of the neutral polymer into a

weakly charged polyelectrolyte as indicated by the characteristic changes in the polymers solution characteristics. In our contribution we discuss the implications of solvent characteristics – i.e. dielectric constant and hydrogen bonding capacity – and the ion-strength of the added electrolyte on the polymer-ion coordination as well as polymer solution characteristics. A mean-field model to predict the amount of ion-coordination is presented and validated for the particular case of poly(oxy ethylene)/salt solutions. The Random Phase Approximation (RPA) is applied to extract quantitative information about the coordination of ions to the polymer in solution from small-angle neutron scattering (SANS) data.

**9:48**

**Y25 10 Conformational Properties and Phase Behavior of Mixed Brushes between Charged and Neutral Polymers: SCF Modeling Using the Edwards Hamiltonian Approach** KEVIN WITTE, YOU-YEON WON, *Purdue University* We present a theoretical study of the single-chain statistics and two-dimensional (2-D) phase behavior of mixed brushes composed of charged and non-charged polymers. We extend the Edwards Hamiltonian formulation for the Green function to investigation of mixed brushes containing a polyelectrolyte species through the incorporation of the combined electrostatic effects as an additional external field which can be self-consistently computed by a corresponding Poisson-Boltzmann-like equation. The resultant SCF equations were numerically analyzed to achieve results that are exact within the assumption of mean field. The 2-D phase behavior of the mixed brushes (assuming that the brushes are laterally mobile) was examined using the conventional free energy of mixing analysis. The predictions on the effects of such control variables as the brush hydrophilicity/hydrophobicity, surface grafting density, charge content of the polyelectrolyte species, and ionic strength of the medium on the conformation properties and phase behavior of the mixed brushes will be discussed.

**10:00**

**Y25 11 Electrostatic Origin of Single-Stranded Genome Packing in Viruses** VLADIMIR BELYI, M. MUTHUKUMAR, *University of Massachusetts, Amherst* We develop an electrostatic model for single-stranded RNA/DNA viruses that bind their genome via highly basic semiflexible peptide arms. We show that genome-capsid binding is dominated by non-specific electrostatic interactions, rather than actual amino-acid content. Proposed model explains many universal features of the viral genome. Good agreement is found with wide range of qualified wild-type and mutant viruses.

**10:12**

**Y25 12 Regimes of Conformational Transitions of Diblock Polyampholytes** ZUOWEI WANG, MICHAEL RUBINSTEIN, *Department of Chemistry, University of North Carolina at Chapel Hill* Regimes of electrostatically-driven conformational transitions of diblock polyampholytes are investigated by scaling theory and molecular dynamics simulations. The coil-globule transition of a symmetric diblock polyampholyte is found to consist of three regimes identified with increasing interaction strength: (i) the folding regime where the electrostatic attraction causes the diblock chain to to fold through the overlap of the two blocks, while each block is slightly stretched by self-repulsion; (ii) the weak association regime which is the classical collapse of the chain into a globule dominated by the fluctuation-induced attractions between oppositely charged chain sections; (iii) the strong association regime that starts with direct binding of oppositely charged monomers (dipole formation), followed by a cascade of multipole formation leading to multiplets. The conformation of a charge-asymmetric diblock polyampholyte changes from extended polyelectrolyte structure, to tadpole-shape with a globular head and a polyelectrolyte tail, and then to polyelectrolyte structure with the variation of the ratio between the charges of the two blocks.

**10:24**

**Y25 13 Polyelectrolyte condensation by linear molecules of variable length: a grand-canonical Monte Carlo study** CAMILO GUAQUETA, ERIK LUIJTEN, *University of Illinois at Urbana-Champaign* The condensation of like-charged polyelectrolytes has been observed to occur under the addition of a variety of oppositely-charged species, such as multivalent counterions, charged globular proteins, and even short chain molecules with monovalent end groups. Inspired by the latter, we study via computer simulations a prototypical polyelectrolyte bundle where condensation is induced by dumbbell-like charged molecules of variable length. We present results from a systematic investigation into the effects of the concentration of bundling agent on the stability of the system. We also consider the effect of changing the length of the dumbbells, as well as the surface charge density of the polyelectrolytes. Recent work[1] has illustrated the important role of the osmotic pressure exerted by the excess solution. In order to take this effect directly into account, we perform simulations in the grand-canonical ensemble, which allows us to equilibrate the bundle with an excess solution of dumbbell molecules at fixed chemical potential.

**Y26 1 Electrical Wave Propagation in a Minimally Realistic Fiber Architecture Model of the Left Ventricle** XIANFENG SONG, SIMA SETAYESHGAR, *Department of Physics, Indiana University, Bloomington, IN* Experimental results indicate a nested, layered geometry for the fiber surfaces of the left ventricle, where fiber directions are approximately aligned in each surface and gradually rotate through the thickness of the ventricle. Numerical and analytical results have highlighted the importance of this rotating anisotropy and its possible destabilizing role on the dynamics of scroll waves in excitable media with application to the heart. Based on the work of Peskin[1] and Peskin and McQueen[2], we present a minimally realistic model of the left ventricle that adequately captures the geometry and anisotropic properties of the heart as a conducting medium while being easily parallelizable, and computationally more tractable than fully realistic anatomical models. Complementary to fully realistic and anatomically-based computational approaches, studies using such

a minimal model with the addition of successively realistic features, such as excitation-contraction coupling, should provide unique insight into the basic mechanisms of formation and obliteration of electrical wave instabilities. We describe our construction, implementation and validation of this model. [1] C. S. Peskin, Communications on Pure and Applied Mathematics **42**, 79 (1989). [2] C. S. Peskin and D. M. McQueen, in Case Studies in Mathematical Modeling: Ecology, Physiology, and Cell Biology, 309(1996)

**8:12**

**Y26 2 Scaling behavior and a Markov model for ventricular fibrillation generated by ectopic beats*** HAROLD HASTINGS, *Hofstra University* STEVEN EVANS, ALEX ZAHARAKIS, CHRISTIAN HILAIRE, Sudden cardiac death is a major cause of death in the industrialized world, responsible for 300,000 deaths per year in the US. Although the cardiac electrical system normally produces one ventricular activation in response to each stimulus from the sinus node, ''spontaneous'' activations, called premature ventricular contractions (PVCs), can arise in the ventricles themselves, and propagate through the ventricles. Although usually harmless in the absence of underlying disease, PVCs can generate broken wavefronts when they meet gradients of refractoriness generated by other beats. These broken wavefronts may generate spiral waves producing ventricular tachycardia and ultimately degenerate into ventricular fibrillation (VF), causing sudden cardiac death. When does a PVC lead to ventricular fibrillation? This is a stiff problem, involving time scales from milliseconds to many years. We overcome this problem by developing universal scaling properties and using these rules to drive a Markov process. We find two significant ''amplifiers'' and discuss consequences for variability of VF rates in human populations. We thank Elizabeth Cherry, Flavio Fenton, Anna Gelzer and James Glimm for helpful discussions.

**Y26 3 Indeterminacy and Image Improvement in Snake Infrared ''Vision''*** J. LEO VAN HEMMEN, *Physik Department, TU Munich* Many snake species have infrared sense organs located on their head that can detect warm-blooded prey even in total darkness. The physical mechanism underlying this sense is that of a pinhole camera. The infrared image is projected onto a sensory 'pit membrane' of small size (of order $mm^2$). To get a neuronal response the energy flux per unit time has to exceed a minimum threshold; furthermore, the source of this energy, the prey, is moving at a finite speed so the pinhole substituting for a lens has to be rather large ( $\sim$ 1 mm). Accordingly the image is totally blurred. We have therefore done two things. First, we have determined the precise optical resolution that a snake can achieve for a given input. Second, in view of known, though still restricted, precision one may ask whether, and how, a snake can reconstruct the original image. The point is that the information needed to reconstruct the original temperature distribution in space is still available. We present an explicit mathematical model [1] allowing even high-quality reconstruction from the low-quality image on the pit membrane and indicate how a neuronal implementation might be realized. Ref: [1] A.B. Sichert, P. Friedel, and J.L. van Hemmen, TU Munich preprint (2005).

**8:36**

**Y26 4 Diffusion Weighted MRI and MRS to Differentiate Radiation Necrosis and Recurrent Disease in Gliomas** LARS EWELL, *Medical Physics* A difficulty encountered in the diagnosis of patients with gliomas is the differentiation between recurrent disease and Radiation Induced Necrosis (RIN). Both can appear as enhancing lesions on a typical T2 weighted MRI scan. Magnetic Resonance Spectroscopy (MRS) and Diffusion Weighted MRI (DWMRI) have the potential to be helpful regarding this differentiation. MRS has the ability to measure the concentration of brain metabolites, such as Choline, Creatin and N- Acetyl Aspartate, the ratios of which have been shown to discriminate between RIN and recurrent disease. DWMRI has been linked via a rise in the Apparent Diffusion Coefficient (ADC) to successful treatment of disease. Using both of these complimentary non-invasive imaging modalities, we intend to initiate an imaging protocol whereby we will study how best to combine metabolite ratios and ADC values to obtain the most useful information in the least amount of scan time. We will look for correlations over time between ADC values, and MRS, among different sized voxels.

**Y26 5 Modeling the statistics of elementary calcium release events*** GHANIM ULLAH, PETER JUNG, *Ohio University* Elementary $Ca^{2+}$ signals, such as '$Ca^{2+}$ puffs', which arise from the release of $Ca^{2+}$ from Endoplasmic Reticulum through small clusters of inositol 1,4,5-trisphosphate receptors, are the building blocks for intracellular $Ca^{2+}$ - signaling. The small number of release channels involved during a $Ca^{2+}$ puff renders the puffs stochastic with distributed amplitudes, durations and frequency, well characterized experimentally. We present a stochastic model that accurately describes simultaneously the statistical properties of the duration, amplitudes, frequencies, and spatial spread with a single set of parameters.

**Y26 6 Calcium Signaling enhancement during oocyte maturation** PETER JUNG, *Department of Physics and Astronomy, Ohio university* GHANIM ULLAH, *Ohio University* KHALED MACHACA, *Department of Physiology and Biophysics, University of Arkansas for Medical Sciences* A Ca2+ signal with a special spatial and temporal characteristic universally removes cell-cycle arrest after fertilization of a mature egg cell. The Ca2+ signal is characterized by a fast rise of intracellular Ca2+ and a slow decay on the time scale of minutes. We use computational modeling of Ca2+ release on the microscale (Ca2+ puffs) and cell-scale in conjunction with experimental knowledge of the changes in the Ca2+ signaling apparatus during oocyte maturation and changing signaling patterns to explore the relationship between organization and sensitivity of IP3 receptors and SERCA pumps and the resulting signaling patterns. We hypothesize that potentiation of the IP3 receptors during oocyte maturation is the main cause for the differentiation in the signaling patterns.

**Y26 7 Functional Complexity of Biological Networks.**
ESHEL BEN-JACOB, *Tel Aviv University*

It is now widely accepted that the complexity of the dynamical behavior of task-performing biological networks affords the latter adaptability to perform a wide variety of different tasks. Hence, understanding complexity is crucial for understanding the activity of biological systems. However, even in the context of simpler, man-made systems, complexity is still largely an intuitive blurry concept with no agreed-upon definition. In this lecture I will present new quantified observables of regularity and structural complexity that were first developed in the context of neural networks activity. I will then address the challenge of the complexity-function relationship via the introduction of a new quantified observable of functional complexity and will demonstrate that for neural networks this observable is connected with the capacity for information storage.

**Y26 8 A model for the volume regulatory mechanism of the Airway Surface Layer** MICHAEL LANG, MICHAEL RUBINSTEIN, *Department of Chemistry, University of North Carolina at Chapel Hill, N.C.* C. WILLIAM DAVIS, ROBERT TARRAN, *Department of Cell and Molecular Physiology, University of North Carolina at Chapel Hill, N.C.* RICHARD BOUCHER, *Department of Pulmonary and Critical Care Medicine, University of North Carolina at Chapel Hill, N.C.* VIRTUAL LUNG PROJECT COLLABORATION, The airway surface layer (ASL) of a lung consists of two parts: a mucus layer with thickness of about 30 $\mu$m in contact with air and a periciliary layer (PCL) of about 7 $\mu$m below. Mucus collects dust and bacteria and is swept to throat by beating cilia, while riding on top of PCL. It is important that the thickness of PCL is matched with the length of cilia in order to optimize clearance of mucus. Decrease of PCL thickness would finally lead to an occlusion of the respiratory system. Experiments show that the height of PCL stays constant after removing mucus. When modifying height or composition of this open PCL by removing fluid or adding isotonic solution leads to the same final height of PCL. Thus, there must be a regulatory mechanism, that controls height, i.e. ASL volume. Additional experiments show that mechanical stimulus of the cells like shear leads to an increase of ASL volume, thus, the cell is able to actively adjust this volume. Based on these observations a class of models is introduced that describes the experiments and a specific minimum model for the given problem is proposed.

**Y26 9 Development of dielectric biosensors for diagnostic applications** CHRISTOPHER BASSEY, *Western Kentucky University, Bowling Green, KY 42101* Dielectric biosensors utilize the intrinsic electrical properties (permittivity and conductivity) of materials to determine their dielectric characterization. Dielectric measurements, both in vivo and in vitro, provide information on the electrical properties of biomaterials (tissues and organs) as a function of frequency. This information can be used to determine the state of health of the subject since diseased and healthy tissues show significantly different dielectric characteristics. The dielectric properties of tissues depend largely on their water contents, hence dielectric data can provide information on the level of dehydration. In this work, the development of instrumentation and methods for determining dielectric properties of biomaterials is proposed. The principle of using dielectric data for diagnostic purposes is discussed.

**Y26 10 Analytical model of induced transmembrane potentials in cells and organelles** VIJAYANAND VAJRALA, *Department of Physics and Texas Center for Superconductivity, University of Houston* JAMES CLAYCOMB, *Department of Mathematics and Physics, Houston Baptist University* JOHN H. MILLER, JR., *Department of Physics and Texas Center for Superconductivity, University of Houston* Oscillatory electric fields cause morphological and functional changes in biological cells by perturbing the resting potentials across the cell and organelle membranes. Although much work has been reported on ac field induced transmembrane voltages in cells, this has mainly been limited to the plasma membrane. We have developed a three-membrane analytical model describing the plasma membrane surrounding inner and outer mitochondrial membranes. Frequency dependent induced plasma and mitochondrial membrane potentials are calculated with mobile interfacial charges on either side of the membranes. The dependence of the induced membrane potentials on the membrane conductivity and permittivity is also calculated. A finite element electromagnetic model is used to calculate the induced mitochondrial membrane potentials for arbitrary geometries with axial symmetry. Modeling results are compared to nonlinear harmonic response measurements of cells and isolated mitochondria exposed to ac electric fields.

**10:24**
**Y26 11 Phase locking in driven integrate-and-fire neuron models** CHRISTOPHER BEDELL, *Boston College* JAN R. ENGELBRECHT, *Boston College* We investigate phase locking between a particular non-linear oscillator and a periodic drive. The nonlinear equation we study is a reduced version of the celebrated Hodgkin-Huxley equations, which we couple to a cosine drive representing an EEG Rhythm. This model is motivated by the growing interest in the role of the exact timing of action potentials in neurons. For instance, electro-physiology experiments indicate that the phase differences between action potential times and large-scale oscillatory neuron activity (EEG rhythms) carry reliable information. We study various thresholds for phase locking and the delicate interplay between coherence and decoherence leading to chaos near these phase-locking thresholds.

**Y26 12 The Influence of Environment Geometry on Injury Outcome: I. Cervical Spine** SAAMI J. SHAIBANI, *Independent Modeling, Algorithms & Analytical Studies (IMAAS)* Previous studies with some 500 patients have indicated that the forces at particular injury sites of occupants in motor-vehicle accidents can-

not be simply related to parameters for the occupant or the impact.[1-2] Another factor that might play a role is assessed in this research, namely passenger compartment geometry, which in most low-severity insults involves the seating arrangement and the restraint system. Analysis of the former is achieved here by considering the heights, lengths and angles of the seat cushion and seat back. The separate effect of geometric environment on the potential for neck injury is then found from studying only those cases with isometric occupants in isokinetic impacts. Such stringent constraints require the matching of numerous data fields, thus reducing the number of suitable candidates quite significantly. However, enough cases remain from the large population available for a proper evaluation to be undertaken. 1. Effect of occupant and impact factors on forces within neck, Bull Am Phys Soc, 45, 1018 (2000). 2. within low back, Bull Am Phys Soc, 46, 1174 (2001).

**Y26 13 Flux Analysis of Hypoxia Response Network.** YIHAI YU, *Department of Physics, George Washington University* RAHUL SIMHA, *Department of Computer Science, George Washington University* FRANK TURANO, *Department of Biological Sciences, George Washington University* CHEN ZENG, *Department of Physics, George Washington University* The availability of cellular oxygen regulates many physiological processes. Oxygen deficiency, i.e., hypoxia, induces expression of a set of genes that are involved in angiogenesis and metabolism. Here we report a detailed flux analysis on a theoretical model on hypoxia response network proposed by Kohn et al. The network is decomposed into smaller underlying pathways which are amenable to direct analytical calculations and capture the essence of the original larger network as observed in numerical simulations. Our analysis elucidates a generic mechanism for the switch-like response of gene up-regulation to hypoxia.

## SESSION Y28: FOCUS SESSION: MAGNETIC AND DOPING EFFECTS IN COJUGATED ORGANICS

**Y28 1 Anomalous Magnetoresistance Phenomena in Organic Semiconductors*** JEREMY D. BERGESON, DEREK M. LINCOLN, RUTH SHIMA EDELSTEIN, VLADIMIR N. PRIGODIN, ARTHUR J. EPSTEIN, *The Ohio State University, Columbus, OH 43210-1117* We report magnetoresistance (MR) phenomena with temperature and bias dependence in organic semiconductor thin films with either nonmagnetic or magnetic contacts through high field reaching 9T. For nonmagnetic organic thin films such as $Alq_3$ we find a low field MR up to 15%. A similar magnetic field effect has been reported earlier[1] but, as noted, the mechanism remains unclear. We propose a model of the anomalous MR where charge transport is space-charge limited. The current is determined by the e-h recombination rate. The recombination rate is field dependent, analogous to the chemical yield for radical pairs[2]. Using an organic- based magnetic semiconductor[3], $V[TCNE]_x$, and Co as magnetic contacts, with a nonmagnetic organic semiconductor ($\alpha$-6T) leads to an order-of-magnitude broader zero-centered MR peak superimposed on a spin-valve effect. Possible origins of this broader MR will be discussed. 1. Francis, et al., New J. Phys. **6** 185 (2004); Frankevich, et al., Phys. Rev. B **53** 4498 (1996) 2. Steiner and Ulrich, Chem. **Y28 2 Preparation, Magnetism, and Applications of Thin Films of the Organic Semiconductor $V[TCNE]_{x\sim2}$** R. SHIMA EDELSTEIN, D.M. LINCOLN, J.-W. YOO, N.P. RAJU, J.D. BERGESON, A.J. EPSTEIN, *The Ohio State University, Columbus, OH, 43210* J.B. KORTRIGHT, *Lawrence Berkeley National Lab, Berkeley, CA, 94720* Different aspects of the room-temperature ($T_c > 350K$) molecular magnet vanadium tetracyanoethylene ($V[TCNE]_{x\sim2}$) remain only partially understood, including its intra- and inter-molecular bonding and spin distribution, degradation mechanisms, and mesoscopic magnetic and chemical order. Previous studies have shown that control of the local order, structure, spin, and chemical composition determines the magnetic state achieved and its charge transport and dynamic properties[1]. In this study, we focus on thin films ( $\sim$ 0.05-0.5 $\mu$m) prepared by CVD[2,3] (room temperature conductivity $10^{-4}$-$10^{-3}$S/cm). Soft x-ray absorption and Magnetic Circular Dichroism (MCD) spectra of the atomic edges are presented, together with XPS, SQUID magnetometry, and EPR spectroscopy. The knowledge gained enables successful demonstration of spin valve devices and photoinduced magnetism in this molecule-based magnetic semiconductor. 1. Pokhodnya, et al, PRB **63**, 174408 (2001) 2. **Y28 3 Magnetoresistance and Ferrimagnetic Resonance (FMR) on Thin Films of Organic-based Magnetic Semiconductor $V[TCNE]_{x\sim2}$ with $T_c$ above 350 K.*** N.P. RAJU, R. SHIMA EDELSTEIN, A.J. EPSTEIN, *The Ohio State University, Columbus, OH 43210* We present magnetoresistance and ferrimagnetic resonance (FMR) results on a CVD-prepared [1] thin films (about 0.5 micron thick) [2] of ferrimagnetic semiconductor $V(TCNE)_{x\sim2}$. The temperature dependence of resistance, and the magnetoresistance variation with magnetic field and temperature show similar to the trends reported earlier. [3] FMR spectra reported here show marked differences from the earlier studies on thicker samples (up to 2 microns). [4] Earlier reported FMR shows several sharp peaks compared to only two in the present study. We report temperature dependence of linewidth and integrated intensity for each of these two peaks. The earlier study suggested that the porosity of the sample as one of the possible origins for many peaks. It appears that absence of many sharp FMR peaks in the present sample may reflect less porosity of the thin film which is important for the development of spin-valve devices. 1. K.I. Pokhodnya et. al., Adv. Mater **12**, 410 (2000). 2. Shima et. al., MRS Proc. **871E**, I7.3 (2005) 3. N.P. Raju et. al., J. Applied

Physics **93**, 6799 (2003). 4. R. Plachy et. al., Phys. Rev. B **70**, 064411 (2004).

**Y28 4 Semiconducting Organic Thin Film Devices with Large Magnetoresistance** Y. SHENG, Ö. MERMER, *Dept. of Phys. & Astr., Univ. of Iowa* G. VEERARAGHAVAN, *Dept of Elec. & Comp. Engr., Univ. of Iowa* T.D. NGUYEN, *Dept. of Phys. & Astr., Univ. of Iowa* T.L. FRANCIS, *OMR Sensors Inc., Dubuque, Iowa* M. WOHLGENANNT, *Dept. of Phys. & Astr., Univ. of Iowa* A comprehensive study on a recently discovered, large magnetoresistance (MR) effect in sandwich devices comprised of nonmagnetic electrodes and organic thin films is performed. Devices were fabricated from pi-conjugated polymers and small molecular weight compounds in combination with different electrode materials, and characterized extensively at different voltages, temperatures, and at weak magnetic fields from DC up to 100 kHz in frequency. The MR effect shows only weak temperature dependence and is independent of the sign and direction of the magnetic field. The effect reaches up to 10% in a magnetic field of 10 mT at room temperature. To illustrate a potential application of the effect, we demonstrate a prototype organic LED (OLED) touchscreen using the MR effect. To the best of our knowledge, the discovered effect is not adequately described by any of the MR mechanisms known to date.

**8:48**

**Y28 5 Structure-property relationships of water-dispersible, conductive PANI-PAMPSA** JOUNG EUN YOO, KWANG SEOK LEE, JAMES NORMAN, *University of Texas at Austin* MATTHEW ESPE, *University of Akron* YUEH-LIN LOO, *University of Texas at Austin* Polyaniline (PANI) is an attractive candidate for organic and polymer electronics because of its high electrical conductivity when doped with molecular acids. Its utility as functional components in electrical devices, however, has been severely restricted by processing and patterning limitations because molecular acid-doped PANI does not dissolve in any common solvents. To overcome this barrier, we have investigated polyaniline that is template polymerized in the presence of a polymer acid, poly(2-acrylamino-2-methyl-1-propanesulfonic acid), PAMPSA. In addition to doping polyaniline, the sulfonic acid groups along the polymer acid chain render water- dispersability to PANI-PAMPSA. The doped polymer is therefore not only electrically conductive, it can be easily processed and patterned from an aqueous medium. Solid-State NMR indicates that template polymerization results in linear, defect-free polyaniline. Both X-ray diffraction and electron microscopy experiments on PANI-PAMPSA synthesized at varying PAMPSA molecular weights reveal that PANI-PAMPSA crystallinity increases with decreasing PAMPSA molecular weight. The conductivities of PANI-PAMPSA increase accordingly with crystallinity. These results are corroborated by UV-vis-NIR experiments where the polaron peaks become progressively broader and red-shifted with decreasing PAMPSA molecular weights.

**Y28 6 The Optical Conductivity and Dielectric Constant of Polyaniline Nanofiber-based Film** OLUDUROTIMI O. ADETUNJI, NAN-RONG CHIOU, ARTHUR J. EPSTEIN, *The Ohio State University, Columbus, OH 43210-1117* We report the optical properties of polyaniline/HCl nanofiber (PANN) films with interconnecting nanofibers of average diameter 100 nm. The room temperature dc conductivity is in the range of 2-4 S/cm in the insulating regime of the disorder induced metal- insulator (M-I) transition [1]. PANN films were probed by reflectance spectroscopy at room temperature over a broad energy range 2meV-6eV. The reflectance ( $< 4200 cm^{-1}$) increases monotonically as the frequency is lowered but has no indication of a plasma edge. Optical constants such as frequency dependent dielectric constant and frequency dependent conductivity have been derived via Kramers-Kronig (K-K) analysis of the reflectance data using appropriate extrapolations. The resulting optical conductivity extrapolated to near-zero frequency scales is in agreement with the measured dc conductivity of 2-4 S/cm [2]. A maximum of the frequency dependent conductivity is found at $\sim 2400 cm^{-1}$ while the K-K analysis shows no zero crossing of the dielectric constant between 40-50000$cm^{-1}$. We discuss these results in terms of roles of disorder and localization. This leads us to the conclusion that PANN films are on the insulating side of the disorder induced metal- insulator transition. [1]R.S. Kohlman, et al., PRL 77, 13 (1996) [2]N.-R. Chiou and A.J. Epstein, Adv. Mater. 17, 1679 (2005) Supported in part by NSF-IGERT Grant No DGE-0221678.

**Y28 7 Charge transport in conducting polymer nanofibers** NATALYA ZIMBOVSKAYA, *University of Puerto Rico - Humacao* Here, we present theoretical analysis of electron transport in polyaniline based (PANi) nanofibers assuming the metalic state of the material. To build up this theory we treat conducting polymers as a special kind of granular metals, and we apply the quantum theory of conduction in mesoscopic systems to describe the transport between metallic-like granules. Our results show that the concept of resonance electron tunneling as the predominating mechanism providing charge transport between the grains is supported with recent experiments on the electrical characterization of single PANi nanofibers. By contacting the proposed theory with the experimental data we estimate some important parameters characterizing the electron transport in these materials [1]. Using the Buttiker dephasing model within the scattering matrix formalism we analyze dephasing effects, and we show that these effects could be reduced enough to allow the structure of the electron transmission function to be exposed in the experiments on the electronic transport through fibers [2]. Also, we discuss the origin of rectifying features observed in current-voltage characteristics of fibers with varying cross-sectional areas. 1. N. A. Zimbovskaya, A. T. Johnson, Jr., and N. J. Pinto, Phys. Rev. B 72, 024213 (2005). 2. N. A. Zimbovskaya, J. Chem. Phys. 123, 114708 (2005).

**Y28 8 Effects of confinement on the transport properties of CSA doped polyaniline** RAUL PEREZ, NELIZA LEON, IDALIA RAMOS, NICHOLAS PINTO, *Department of Phys. and Electr., University of Puerto Rico - Humacao* PAWAN KAHOL, *Dept. of Physics, Astronomy and Materials Science, Missouri State University* Polyaniline doped with camphor sulfonic acid (CSA) and cast from *m*-cresol can exhibit metallic behavior depending on the conditions of preparation. Under standard methods

of preparation the transport properties of cast films generally lie on the insulating side of the metal-insulator transition. We have confined CSA doped PANi into the cylindrical pores of a dielectrically inert porous matrix and measured the temperature dependence of the resistance. The resistance of the confined polymer is seen to have a weaker dependence at low temperatures than that of the cast film. Further analysis of the results show that the charge transport of the confined polymer has moved into the metallic regime while that of the cast film lies in the insulating regime. Reduced barriers to charge transport that result from the suppression of microphase separation of the non-dopable forms of polyaniline due to extreme confinement in the porous matrix are believed to be responsible for this crossover.

**Y28 9 Gas sensing using the microwave conductivity of conducting polymer nanofiber thin films.** ALEXEY KOVALEV, LINTAO CAI, THERESA MAYER, *Pennsilvania State University, University Park, PA, 16802.* There are a variety of chemoresistive sensors based on conducting polymer thin films, and studies of conducting polymer nanofiber thin films and single nanofibers sensors are an active area of research because of their enhanced sensitivity. Traditional chemoresistive sensors monitor a change in DC resistance that arises when a low concentration of a chemical vapor is present. In this talk, we will discuss the use of conducting polymer nanofiber thin films as gas sensors that operate in the microwave frequency range. Polyaniline nanofiber films that were 1 - 10 $\mu$m thick were characterized measuring DC conductivity (four-point) and microwave conductivity in the range of 4 - 8 GHz. We found a direct correlation between changes in the DC and microwave conductivity during exposure to ammonia and hydrochloric acid at concentrations of 10 - 1000 ppm. These films show a significant response over this range of concentrations, thus opening the possibility of using conducting polymers thin films as remote wireless gas sensors.

**Y28 10 Anomalous transmission through a periodic subwavelength hole array in heavily doped conducting polymer films*** TATSUNOSUKE MATSUI, Z. VALY VARDENY, *Physics Department, University of Utah* AMIT AGRAWAL, AJAY NAHATA, *Department of Electrical and Computer Engineering, University of Utah* REGHU MENON, *Department of Physics, Indian Institute of Science* PHYSICS DEPARTMENT, UNIVERSITY OF UTAH COLLABORATION, DEPARTMENT OF ELECTRICAL AND COMPUTER ENGINEERING, UNIVERSITY OF UTAH COLLABORATION, DEPARTMENT OF PHYSICS, INDIAN INSTITUTE OF SCIENCE COLLABORATION, Since Ebbesen et al. reported the phenomenon of ''anomalous transmission'' through optically thick metallic films perforated with two-dimensional (2D) subwavelength hole array, numerous studies have been carried out to explore both fundamental issues and potential device applications. So far, studies on ''anomalous transmission'' were carried out using metals and semiconductors. We report here the observation of ''anomalous transmission'' in 2D hole array on films of another, more exotic class of conductors, namely heavily-doped organic conducting polymers. Specifically, the conductivity of conducting polymers can be controlled in situ by changing doping level using an electrochemical technique, so that we could tune the transmission characteristics by applied voltage. With this goal in mind we will report the ''anomalous transmission'' spectra of conducting polymer films at various doping levels. *supported in part by ARO.

**Y29 1 How stability can lead to variability: An example from eukaryotic gene expression** GABOR BALAZSI, WILLIAM BLAKE, *Applied BioDynamics Laboratory, Boston University* FARREN ISAACS, *Genetics Department, Harvard Medical School* KEVIN MURPHY, JAMES J. COLLINS, *Applied BioDynamics Laboratory, Boston University* Eukaryotic genes have the potential for transcriptional reinitiation, resulting in repeated rounds of transcription from a scaffold of proteins assembled near the promoter region. We use stochastic simulations and mathematics to analyze the effect of the promoter-scaffold stability on gene expression noise for various steady-state levels of induction. In agreement with experimental observations, we find that decreasing transcription scaffold stability results in lower levels of noise at the protein level. We track the cause of this decrease through mRNA expression down to the level of an engineered GAL1 promoter.

**8:12**

**Y29 2 How stability can lead to variability: Induction timecourse of a eukaryotic gene** WILLIAM BLAKE, GABOR BALAZSI, *Applied BioDynamics Laboratory, Boston University* FARREN ISAACS, *Genetics Department, Harvard Medical School* KEVIN MURPHY, *Applied BioDynamics Laboratory, Boston University* YINA KUANG, DAVID R. WALT, *Department of Chemistry, Tufts University* JAMES J. COLLINS, *Applied BioDynamics Laboratory, Boston University* Using an engineered GAL1 promoter as a model, we study the effect of the promoter-scaffold stability on the mean and noise of gene expression during an induction timecourse. In agreement with experimental observations, we find that decreasing transcription scaffold stability results in slower buildup of protein product and lower levels of noise at the protein level. This is a consequence of ''transcriptional bursting,'' observed in the simulations as well as experiment, where optical fiber-based technology was used to monitor induction timecourses in individual cells.

**8:24**

**Y29 3 Origins of extrinsic variability in eukaryotic gene expression** DMITRI VOLFSON, JENNIFER MARCINIAK, *UC San Diego* WILLIAM J. BLAKE, *Boston University* NATALIE OSTROFF, LEV S. TSIMRING, JEFF HASTY, *UC San Diego* Variable gene expression within a clonal population of cells has been implicated in a number of important processes including mutation and evolution, determination of cell fates and the development of genetic disease. Recent studies have demonstrated that a significant component of expression variability arises from extrinsic factors thought to influence multiple genes in concert, yet the biological origins of this extrinsic variability have received little attention. Here we combine computational modeling with fluorescence data generated from multiple promoter-gene inserts in *Saccharomyces cerevisiae* to identify two major sources of extrinsic variability. One unavoidable source arising from the cou-

pling of gene expression with population dynamics leads to a ubiquitous noise floor in expression variability. A second source which is modeled as originating from a common upstream transcription factor exemplifies how regulatory networks can convert noise in upstream regulator expression into extrinsic noise at the output of a target gene. Our results highlight the importance of the interplay of gene regulatory networks with population heterogeneity for understanding the origins of cellular diversity.

**Y29 5 Absolute Rate Theories of Epigenetic Stability** ALEKSANDRA M. WALCZAK, JOSE N. ONUCHIC, PETER G. WOLYNES, *Center for Theoretical Biological Physics, UCSD* Spontaneous switching events in most characterized genetic switches are rare, resulting in extremely stable epigenetic properties. We show how simple arguments lead to theories of the rate of such events much like the absolute rate theory of chemical reactions corrected by a transmission factor. Both the probability of the rare cellular states that allow epigenetic escape, and the transmission factor, depend on the rates of DNA binding and unbinding events and on the rates of protein synthesis and degradation. Different mechanisms of escape from the stable attractors occur in the nonadiabatic, weakly adiabatic and strictly adiabatic regimes, characterized by the relative values of those input rates.

**9:24**
**Y29 6 Noise and correlations in genes silenced by small RNA.** TERENCE HWA, EREL LEVINE, *Center for Theoretical Biological Physics, UCSD* Many small regulatory RNAs have been identified in prokaryotes and eukaryotes in recent years. In many cases, RNA regulation is found in critical pathways. These include stress response and quorum sensing pathways in bacteria, and cell differentiation and programmed cell death in eukaryotes. In many cases, regulation by small RNA is used in switching off a response program as long as it is not required, allowing for a fast switching on when necessary. Clearly, accidental execution of such a program may bare grave consequences on the cell, and should be avoided. Here we analyze a stochastic model for gene regulation by the most abundant class of small RNA in bacteria. This class of small RNAs acts by base pairing with target mRNAs, silencing its translation and actively promoting its degradation. Importantly, the small RNA molecule is not recycled. Our model suggests that genes silenced by sRNA exhibits smooth noise, as opposed to the bursty noise characteristic to genes repressed at the level of transcription, with coupling between intrinsic noise and global, extrinsic fluctuations. In addition, we investigate how noise propagates through the indirect coupling between different targets of the same sRNA. These features are discussed in the context of circuits exhibiting multi-stability, where protein bursts have strong implications on spontaneous switching.

**9:36**
**Y29 7 A model for codon position bias in RNA editing*** RALF BUNDSCHUH, TSUNGLIN LIU, *The Ohio State University* RNA editing can be crucial for the expression of genetic information via inserting, deleting, or substituting a few nucleotides at specific positions in an RNA sequence. Within coding regions in an RNA sequence, editing usually occurs with a certain bias in choosing the positions of the editing sites. In the mitochondrial genes of *Physarum polycephalum*, many more editing events have been observed at the third codon position than at the first and second, while in some plant mitochondria the second codon position dominates. Here we propose an evolutionary model that explains this bias as the basis of selection at the protein level. The model predicts a distribution of the three positions rather close to the experimental observation in *Physarum*. This suggests that the codon position bias in *Physarum* is mainly a consequence of selection at the protein level.

**Y29 8 From Asymmetric Exclusion Processes to Protein Synthesis*** JIAJIA DONG, BEATE SCHMITTMANN, ROYCE K.P. ZIA, *Department of Physics, Virginia Tech* Protein production rates are clearly vital for all biological systems. Thus, there is considerable interest in understanding the origins of these rates, as well as in manipulating them, especially for physiological and pharmaceutical applications. Since some codons are ''fast'' and others ''slow,'' we propose to exploit these differences and modify the production rate for any specific protein by replacing codons in the associated mRNA by their synonymous counterparts. As an illustration, we study a simple model of protein production: the one-dimensional driven lattice gas, also known as the totally asymmetric simple exclusion process (TASEP). We investigate systematically the effects on the overall current (the protein production rate) of having one or two slow/fast sites (i.e., codons) in an otherwise homogeneous lattice. The currents show a nontrivial dependence on the location of a single ''defect'' as well as on the separation between two defects. We discuss the implications for more realistic models of protein production.

**Y29 9 Intrinsic Fluctuations, Robustness and Tunability in Signaling Cycles.** JOSEPH LEVINE, *Caltech* HAO YUAN KUEH, *Harvard Univ.* LEONID MIRNY, *MIT* Covalent modification cycles (e.g. phosphorylation) underlie most cellular

signaling. Low molecular copy number, arising from compartmental segregation and slow diffusion between compartments, potentially renders these cycles vulnerable to intrinsic chemical fluctuations. How can a cell operate reliably in the presence of this inherent stochasticity? How do changes in extrinsic parameters lead to variability of response? Can cells exploit these parameters to tune cycles to different ranges of stimuli? We study the dynamics of an isolated phosphorylation cycle. Our model shows that the cycle transmits information reliably if it is tuned to an optimal parameter range, in spite of intrinsic fluctuations and even for small input signal amplitudes. At the same time, the cycle is sensitive to changes in the concentration and activity of kinases and phosphatases. This sensitivity can lead to significant cell-to-cell response variability Our results show that signaling cycles possess a surprising combination of robustness and tunability. This combination makes them ubiquitous in eukaryotic signaling, optimizing signaling in the presence of fluctuations using their inherent flexibility. On the other hand, cycles tuned to suppress intrinsic fluctuations can be fragile to changes in the number and activity of kinases and phosphatases. Such trade-offs in robustness to fluctuations can influence the evolution of signaling cascades, making them the weakest links in cellular circuits.

**Y29 10 The Nature of Memory Objects in the Brain.**
PIERRE-GILLES DE GENNES, *Physico-Chime Institut Curie*

Our minds keep a huge number of memories. We discuss here the number $M$ of neurons which must be implied in one primal memory object (the smell of a rose). We find that (in a storage area which is not genetically designed) spatial and connectivity requirements impose that $M$ be *very small* (of the order of 3). We then extend these considerations to associative memories (where the smell of a rose evokes the color of a rose).

**Y29 11 Resource allocation in neural networks for motor control** J. MILTON, *Claremont Colleges, USA* J. CUMMINS, *Claremont McKenna College, USA* J. GUNNOE, M. TOLLEFSON, *Scripps College, USA* J.L. CABRERA, *IVIC, Venezuela* T. OHIRA, *Sony Computer Science Lab, Japan* Multiplicative noise plays an important part of a non-predictive control mechanism for stick balancing at the fingertip. However, intentionally-directed movements are also used in stick balancing, particularly by beginners. The interplay between intentional and non-predictive control mechanisms for stick balancing was assessed using two dual task paradigms: the subject was asked to either move one of their legs rhythmically or to imagine moving their leg while balancing a stick (55.4 cm, 35 g) at their fingertip. Performance was measured by determining the stick survival function, i.e. the fraction of trials (total $\geqslant 25$) for which the stick remained balanced at time t as a function of t. Performance was increased by concurrent rhythmic leg movements (50% survival time shifted from 8-9s to 15s in a typical subject). Imagined movements resulted in a similar improvement (50% survival time of 20s for the above subject) suggesting that this enhancement is not simply related to mechanical vibrations of the fingertip induced by leg movement. These observations emphasize the importance of the development of mathematical models for neural control of skilled motor movements that take into resource allocation of limited resources, such as intention.

**Y30 1 Temperature and Pressure effects on folding/unfolding of proteins.**
ANGEL GARCIA, *Department of Physics and Astronomy*

High hydrostatic pressures change the energy landscape of proteins, affecting the thermodynamics and kinetics of folding. Proteins denature at high hydrostatic pressures, implying that the unfolded proteins in aqueous solution have lower volume than the folded state. A model that explains pressure unfolding requires water to penetrate the protein interior and disrupt the protein hydrophobic core. I will explore the energetics of water penetration and the effect of pressure on hydrophobic interactions. I will also describe molecular simulations of the reversible folding/unfolding equilibrium as a function of density and temperature of solvated peptides that can form alpha helices (the AK peptide) and beta hairpins (the C terminal domain of protein G). I will characterize the structural, thermodynamic and hydration changes as a function of temperature and pressure. To study protein folding equilibrium thermodynamics we use an extension of the replica exchange molecular dynamics (REMD) method that allows for density and temperature Monte Carlo exchange moves.

**8:36**
**Y30 2 The energy landscape for folding and function.***
JOSE ONUCHIC, *Center for Theoretical Biological Physics, UCSD*

Globally the energy landscape of a folding protein resembles a partially rough funnel. The local roughness of the funnel reflects transient trapping of the protein configurations in local free energy minima. The kinetics of folding is best considered as a progressive organization of an ensemble of partially folded structures through which the protein passes through on its way to the folded structure. The folding mechanisms for several fast-folding proteins can be described using an energy landscape theory to set up the correspondence with simulations of protein minimalist models. Using these simulations together with analytical theory, we can learn about good (minimally frustrated) folding sequences and non-folding (frustrated) sequences. An important idea that emerges from this theory is that subtle features of the protein landscape can profoundly affect the apparent mechanism of folding. Experiments on the dependence of the folding/unfolding times, and the stability of these proteins to denaturant concentration and site-directed mutagenesis, and on the early events of folding allow to infer the global characteristics of the landscape. In addition to need to minimize energetic frustration, the topology of the native fold also plays a major role in the folding mechanism. Some folding motifs are easier to design than others suggesting the possibility that evolution not only selected sequences with sufficiently small energetic frustration but also selected more easily designable native structures. Several proteins (such as CI2 and SH3) have sufficiently reduced energetic frustration) that much of the heterogeneity observed in their transition state ensemble (TSE) is determined by topology. Topological effects go beyond the structure of the TSE. The overall structure of the on-route and off-route (traps) intermediates for the folding of more complex proteins is also influenced by topology. Utilizing this theoretical framework, simulations of minimalist models and computationally-expensive all-atom simulations, we are now obtaining a quantitative understanding of the folding problem, which allows for a direct comparison to a new generation of folding experiments. Connections between the folding landscape and protein function will also be discussed.

**Y30 3 RNA folding inside a virus capsid and dimensional reduction.** ROUZBEH GHAFOURI, *Department of Physics, UCLA* ROBIJN BRUINSMA, *Department of Physics, UCLA* JOSEPH RUDNICK, *Department of Physics, UCLA* As RNA folds on itself, in certain conditions, it takes the form of a branched polymer. So the problem of RNA folding in a virus capsid is essentially the problem of a branched polymer in a confined environment. In this paper we attack the problem using the technique of dimensional reduction which relates a branched polymer with self interation in D dimension to a hardcore classical gas in (D-2) dimension. We look for phase transitions and intersting physical quantities such as pressure.

**9:24**
**Y30 4 On the Melting Transition of RNA** DAVID SCHWAB, *Deparment of Physics, UCLA* ROBIJN BRUINSMA, *Deparment of Physics, UCLA* The secondary structure of RNA can undergo a phase transition from a designed native state to a branched molten-globule. This melting transition is continuous, neglecting excluded volume. We study the effect of excluded volume interactions in good solvent on the melting transition. First, we calculate the effect of a constant external tension on the melting transition in the ideal polymer case and then, in the context of Flory theory, equate the tension with what would be generated by excluded volume. We find that, with excluded volume, the continuous melting transition is still second order but with a different exponent.

**9:36**
**Y30 5 Trapping and Condensing DNA at the Air/Water Interface** JAIME RUIZ-GARCIA, *Instituo de Fisica – UASLP* DNA is a highly charged polyelectrolite and as such it is considered to be completely soluble in pure water. Surprisingly, we found that DNA can be trapped at the air/water interface and does not go back into a pure water subphase. Once at the interface, DNA molecules condense to form different two-dimensional mesostructures such as foams, giant rings, disks and rods at low density. This condensation occurs without the presence of multivalent cationic ions, as it is required in bulk, for example in condensing DNA toroids. At high density, the molecules form a regular monomolecular network. At the interface, DNA is only partially immersed in water, which originates that the chains get only partially charged, but the charges are of the same sign. Therefore, this can be considered another case of like-charge attraction, similar to those found in colloids trapped between glass plates and at the air/water interface. However, the origin of the attractive part of the interaction potential is unknown. In addition, we found that DNA at the air/water interface can form 2D smectic-like domains tens of microns in size, which are interesting from a theoretical and application standpoints.

**9:48**
**Y30 6 Insight into the Helix-to-Coil Transition in DNA** BOUALEM HAMMOUDA, *National Institute of Standards and Technology* Dissolved DNA is known to undergo a helix-to-coil transition when temperature is increased. For a solution of 4% DNA in water, the transition temperature is around 94$^o$C. UV absorption spectroscopy was performed to characterize such a transition. The 260 nm absorption line is a good monitor of the un-stacking of the DNA amine bases. Small-Angle Neutron Scattering was also performed to investigate structural changes that accompany the transition. A characteristic DNA cross section correlation length was found to increase from 9A to 15A and the Porod exponent was found to decrease from close to 4 to around 2 across the transition. The average sugar-sugar inter-distance is larger in the open molecule coil phase. The helix phase is characterized by a cylindrical structure with well-defined interface whereas melted DNA macromolecules behave like Gaussian coils. Jump in the scattered (solvation) intensity was also observed across the transition. A hysteresis cycle was observed upon a sub-

sequent temperature decrease. Once DNA melts, it does not reform the helix phase easily. DNA solvation (interaction of DNA and solvent molecules) has also been investigated. When solvent mixtures (for example water/alcohol mixtures) are used, ideal solvent mixing is observed for the helix phase but a highly non-ideal mixing behavior is observed for the coil phase.

**10:00**

**Y30 7 Diffusion of Isolated DNA molecules: dependence on length and topology** RAE M. ROBERTSON, STEPHAN LAIB, DOUGLAS E. SMITH, *University of California at San Diego* Diffusion coefficients (D) for relaxed circular and linear DNA molecules ranging in length (L) from 5.9 to 287.1 kilobasepairs were measured by tracking the Brownian motion of single molecules. A topology independent scaling law, $D\sim L^{-0.58+/-0.016}$, was observed, in good agreement with the –0.588 exponent predicted by renormalization group theory. The measured ratio $D_{Circular}/D_{Linear}$ = 1.32+/-0.014 fell between predictions of 1.18 for Kirkwood hydrodynamic theory and 1.45 for renormalization group theory and agreed best with a value 1.31 predicted using the Zimm model and an expression for the radius of gyration proposed by Bensafi, Maschke, and Benmouna. Measurements on supercoiled DNA molecules were also made and qualitatively compared to theoretical predictions.

**10:12**

**Y30 8 Mobility of DNA on supported lipid bilayers** CHAKRADHAR PADALA, *Rensselaer Polytechnic Institute* RICHARD COLE, *Wadsworth Center* SANAT KUMAR, RAVI KANE, *Rensselaer Polytechnic Institute* Extensive theoretical ideas have been developed to understand the transport properties of transmembrane proteins in the lipid bilayer. However, of late, there has been a rising interest in understanding the transport properties of non-compact macromolecules strongly adsorbed ''on'' and not incorporated into lipid bilayers in light of the relevance for designing improved DNA separation strategies and for gene therapy. Previously, researchers like Radler itet al. have suggested that such strongly adsorbed polymers can be treated similar to a polymer in a two-dimensional fluid, but there exists no experimental proof to date. In order to test this hypothesis and also to gain a better understanding of polymer dynamics in two dimensions, we studied the lateral transport of a short, single stranded DNA oligonucleotide adsorbed on a supported cationic lipid bilayer. Fluorescence Recovery After Photobleaching (FRAP) analysis reveals that diffusivity of the adsorbed DNA quantitatively tracks that of the underlying lipid. These results, along with the comparison between our results for short, non-compact adsorbed biopolymers and those reported for globular proteins incorporated into the lipid bilayer will be discussed.

**10:24**

**Y30 9 Electrophoresis of DNA on a disordered two-dimensional substrate** CYNTHIA J. OLSON REICHHARDT, CHARLES REICHHARDT, *Theoretical Division and Center for Nonlinear Studies, Los Alamos National Laboratory* We propose a new method for electrophoretic separation of DNA in which adsorbed polymers are driven over a disordreed two-dimensional substrate which contains attractive sites for the polymers. Using simulations of a model for long polymer chains, we show that the mobility increases with polymer length, in contrast to gel electrophoresis techniques, and that separation can be achieved for a range of length scales. We demonstrate that the separation mechanism relies on excluded volume interactions between polymer segments.

**10:36**

**Y30 10 Kinetic Modeling of Designed Signaling DNA Aptamers** ISSEI NAKAMURA, RAZVAN NUTIU, JASMINE YU, YINGFU LI, AN-CHANG SHI, *McMaster University* Aptamers are recently developed molecular biosensors made of single functionalized DNA molecules. They can bind a protein target specifically or a complementary DNA sequence. The binding kinetics can be studied based on the principle of fluorescence quenching, which in turn provides an understanding of the binding mechanism and the conformational structure of DNA during the binding reaction. Despite many experimental studies, an understanding of the binding reaction is still lacking. In our study, we constructed kinetic models for the aptamer binding reaction, and showed that the theoretical models can be studied to describe experimental observations. Determined parameters for the rate constant for the reaction provided us with an understanding of the binding mechanism of aptamers. We will discuss the numerical solutions to them in comparison with the experiment and show how the binding reaction of aptamers occurs as time proceeds.

**10:48**

**Y30 11 AFM Imaging of Counterion-Induced Phase Transition of Biological Polyelectrolyte Network on a Photopolymer Containing Azo-Dye*** TAIJI IKAWA, OSAMU WATANABE, *Toyota CRDL, Inc., Japan* YOULI LI, CYRUS SAFINYA, *UC, Santa Barbara* We present a new method for direct imaging of protein assembly based on atomic force microscopy and a protein immobilization technique using a nonionic photopolymer containing azo-dye; the photopolymer was found to be capable of holding proteins in an aqueous solution by exposure to blue-wavelength light. As a model system, we examine the association of actin filament in the presence of divalentcation. We find the method clearly represents phase transitions of the filament network as a function of both cation concentration and filament length. Longer filaments (up to 10 $\mu$m) shows an isolated single filament phase (0 mM of $Mg^{2+}$) transforms to a web-like network phase (5-10 mM) and finally condenses into a close-packed bundled phase (20-80 mM). Meanwhile, shorter filaments (up to 200 nm) form a co-existing nematic-like raft phase at intermediate cation concentration (5-40 mM), coinciding with the previous result obtained by small-angle x-ray scattering study. From angular analysis, the longer filament is shown to prefer wider angular configuration, suggesting the interaction between filaments is dependent on their length such that longer filaments are more repulsive than shorter one.

**Y31 1 Magnetism in $Fe_4Al_{13}$ and related FeAl intermetallics** JI CHI, YANG LI, WEIPING GOU, V. GORUGANTI, K. D. D. RATHNAYAKA, JOSEPH H. ROSS, JR., *Department of Physics, Texas A&M University* We report the results of an experimental study of FeAl alloys, including $Fe_4Al_{13}$, $FeAl_2$ and $Fe_2Al_5$. By using NMR, dc magnetic susceptibility, and specific heat, we found that $Fe_4Al_{13}$ and $Fe_2Al_5$ are non-magnetic with some dilute magnetic moments, while $FeAl_2$ can be characterized as a concentrated local moment system. $Fe_4Al_{13}$ is a decagonal quasicrystal approximant with 102 atoms in its unit cell. The $^{27}$Al NMR spin-lattice relaxation indicates a very narrow pseudogap in the electronic density of states $[g(E)]$ in the vicinity of the Fermi energy. The observations could be fit assuming a parabolic variation of $g(E)$, consistent with observations in other quasicrystals and approximants. NMR lineshape measurements also agree with this analysis, and show that the system is dilute-magnetic, in strong contrast to the $FeAl_2$ ordered intermetallic. We use specific heat to analyze the dilute moment density. This work was supported by the Robert A. Welch Foundation, Grant No. A-1526, by the National Science Foundation (DMR-0103455), and by Texas A&M University through the Telecommunications and Informatics Task Force.

**8:12**
**Y31 2 3D octagonal quasicrystals fabricated by phase mask lithography** TAEYI CHOI, ION BITA, EDWIN THOMAS, *Massachusetts Institute of Technology* Quasicrystals were discovered in 1984 and have shown unusual physical and mechanical properties. Artificially patterned quasicrystalline structures have attracted a lot of attention due to their promise as photonic and phononic crystals. A challenge is to create 3D quasicrystalline patterns on the 100nm scale. Using phase mask lithography, we successfully fabricated in photopolymer films 3D quasicrystals having eight-fold rotation axes on a submicron length scale. Conformable phase masks of eight-fold rotation symmetry were first made with multiple interference lithography on a silicone substrate. Light at normal incidence to the phase mask generates a 3D distribution of intensity with quasicrystalline eight-fold symmetry. This intensity distribution is then transferred into a photosensitive material, SU8, generating 3D quasiperiodic structures that we further characterize both structurally and optically.

**8:24**
**Y31 3 Band Structure, Density Waves, and the Third Invariant*** DAVID RABSON, JOHN HUESMAN, *University of South Florida* There are three types of invariants in crystals. The first two, corresponding to electronic degeneracies, are well known, but the third is novel, realized in incommensurate crystals of non-minimal rank. Since the first two invariants have consequences in band structure, it is natural to look there for the third type as well. Rather than developing an atomic or tiling model with the third type of symmetry, we introduce a tight-binding approach based on a density-wave pattern, which is easy to generate from the Rokhsar-Wright-Mermin phase functions.

**Y31 4 Epitaxial orientations and temperature dependence of the 5- to 6-fold ordering transition** STEFANO CURTAROLO, WAHYU SETYAWAN, *Duke University* NICOLA FERRALIS, MILTON W. COLE, RENEE DIEHL, *Penn State University* The ordering of Xe films on an $Al_{73}Ni_{10}Co_{17}$ quasicrystalline surface is studied using grand canonical Monte Carlo simulations with an empirical adsorption potential based on Lennard-Jones interatomic potentials. At all temperatures studied (20-140K), there is a continuous 5- to 6-fold ordering transition in the monolayer [1]. The ordering transition shows interesting temperature-dependent phenomena [2]. At intermediate $T$ ($40K < T < 130K$), the transition occurs before the second layer forms. Moreover, this T-dependent transition shows a non-monotonic dependence on coverage, completing earliest at $T \sim 70K$. At low $T$ ($< 40K$), the transition does not complete, whereas at high $T$ ($> 130K$), the transition completes by the transfer of atoms from the second layer to the first layer. At all temperatures, after the transition completes, the orientations of the monolayer domains are along the 5-fold axes of the quasicrystal. The existence of pentagonal defects gives rise to domains that are rotated by n*60°/5 with n = 1, 2, 3, 4, or 5. The defect density increases with T, suggesting that entropy plays the major role in defect formation [2]. Research sponsored by NSF. [1] S. Curtarolo et al., Phys. Rev. Lett. **95**, 136104 (2005). **Y31 5 Evolution of noble gas films on a decagonal Al-Ni-Co quasicrystal surface.** WAHYU SETYAWAN, *Duke University* NICOLA FERRALIS, RENEE D. DIEHL, MILTON W. COLE, *Penn State University* STEFANO CURTAROLO, *Duke University* The evolution of Ne, Ar, Kr, and Xe films on an $Al_{73}Ni_{10}Co_{17}$ quasicrystalline surface is studied using grand canonical Monte Carlo simulations with an empirical adsorption potential based on Lennard-Jones interatomic potentials. Layer by layer growth is observed for all the studied noble gases. The monolayer of Ar, Kr, and Xe grows abruptly, where as the monolayer of Ne grows gradually. The next layers of all gases grow step wise. At a comparable range of temperatures, the evolution of the monolayer density profiles shows a continuous commensurate 5-fold to incommensurate 6-fold ordering transition for all gases. However, the degree of completeness of the transition varies and shows an increase from Ne, Ar, Kr, to Xe. Research sponsored by NSF.

**Y31 6 Argon adsorption on a microporous metal organic framework, $Cu_3(BTC)_2(H_2O)_3$(Benzene-1,3,5-tricarboxylate)*** K. LASK, V. KRUNGLEVICIUTE, L. HEROUX, A. D. MIGONE, *Southern Illinois University* J.-Y. LEE, J. LI, *Rutgers University* We will present results for argon adsorbed on $Cu_3(BTC)_2(H_2O)_3$(Benzene-1,3,5-tricarboxylate) metal-organic frameworks. Full adsorption isotherms (up to saturation) were measured at four temperatures between 66 and 92 K. We

observe three distinct sub-steps in the data, indicating that there are at least three different types of binding sites available for argon. We have calculated isosteric heats of adsorption as a function of coverage for this system. We have also measured four isotherms at low coverage for temperatures between 112 and 143 K in order to determine the binding energy for argon on the strongest binding sites available on this microporous metal organic framework. Our results will be compared to previous experimental and computer simulations for this system.

**Y31 7 Microstructure of a phase-separating liquid mixture confined in mesoporous Controlled Pore Glass – A study combining SANS, NSE and adsorption measurements*** GERNOT ROTHER, *Oak Ridge National Laboratory* SEBASTIAN SCHEMMEL, *TU Berlin* DIRK WOYWOD, *TU Berlin* MARTIN SCHOEN, *TU Berlin* GERHARD H. FINDENEGG, *TU Berlin* The physical properties of liquid mixtures with miscibility gap in pores of mesoscopic size are drastically altered from their bulk states, due to adsorption on the pore walls and confinement effects, and it is highly desirable to gain knowledge in the adsorption and separation processes, due to the widescale use of such media in chromatography and other applications [1]. In this work, three complementary techniques were used to address this issue, including both elastic (SANS) and inelastic (neutron- spin-echo) techniques, backed up by physical adsorption measurements of binary liquid mixtures with a miscibility gap [i.e. iso-butyric acid and heavy water] [2,3]. We found a shift in the phase separation temperature by $\sim$ 10 K towards the two-phase region and a drastical slowing down of the dynamics in the two-phase region. [1] K. Binder and E. Luijten, Phys. Reports 344, 179 (2001) [2] S. Schemmel et al., J. Chem. Phys. **122**, 244718 (2005) [3] T. Hellweg et al., Eur. Phys. J. E **12**, s01 (2003) 001

**Y31 8 Time dependent diffusion in a disordered medium with partially absorbing walls** JIANG QIANG, *Harvard University* PABITRA N. SEN, *Schlumberger-Doll Research* We present an analytical and numerical study of time dependent diffusion coefficient in systems with partially absorbing boundary condition. We obtain a perturbative expansion for time dependent propagator in terms of volume fraction $f$ of spheres in a dilute suspension of spheres. Exact single sphere $t$-operator for partially absorbing boundary condition is used to obtain a time-dependent diffusion coefficient $D(t)$ for a random distribution of spheres, accurate to the lowest order of volume fraction $f$. Short and long time limits of $D(t)$ are obtained and compared to the known exact results. We then present a significantly improved numerical method for dealing with random walk with partially absorbing boundary on curved surfaces. The method is applied to the dilute suspension of spheres to obtain $D(t)$ and compared with the analytical solution. Numerical simulation on a random closed packed (Finney pack) is used to study correlation between time-dependent relaxation and diffusion.

**9:36**

**Y31 9 Percolation and diffusion in two dimensional random media** BONG JUNE SUNG, ARUN YETHIRAJ, *Department of Chemistry, University of Wisconsin-Madison* The diffusion of hard disc fluids in two dimensional porous media (composed of immobile hard discs) is studied using discontinuous molecular dynamics (DMD) simulations and analyzed using a Voronoi tessellation procedure. A pore is defined as a circle tangential to three neighbor matrix discs with a pore center at a Voronoi vertex. If an edge of Voronoi diagram connecting two pores is too narrow for a fluid particle to move along, the edge is considered disconnected. This procedure maps the system onto a lattice model with diffusion possible in the bond percolation limit. The percolation threshold, $p_c$ of edges connecting pores is found to be 0.526, where p is the fraction of connected edges. $p_c$ is significantly different from $p_r = 2/3$ of random bond percolation theory where the edge connectivity of the same Voronoi diagram is determined randomly. This suggests that the edge connectivity is strongly correlated even for randomly distributed medium particles. DMD simulations show normal diffusion for $p > p_r$, confined dynamics for $p < p_c$, and anomalous diffusion for $p_c < p < p_r$.

**9:48**

**Y31 10 Well defined arrays of silica nanotubes for the study of processes at nanoscale: example of one-dimensional diffusion** YAROSLAV KIEVSKY, BRENT CAREY, DANIEL BEN-AVRAHAM, IGOR SOKOLOV, *Clarkson University, Potsdam, NY 13699* Using organic templating synthesis of inorganic precursor, silica, we synthesized well defined fibers of $\sim$ 2 microns in diameter and 5 microns in length. Structurally these fibers are parallel arrays of closely packed silica nanotubes (ASNT). BET, SAXS, SEM, TEM, and light scattering techniques were used to characterize these ASNT. Each nanotube is $\sim$ 3nm in diameter, and extends to the full length of the fiber, 5 microns. Thus, each array has about a quarter of a million of nanotubes in parallel. We expect these ASNT to be a popular system for the study of processes at nanoscale confined space. Signals from the processes that happen inside each silica nanotube will be amplified by the number of nanotubes, i.e., a few hundred thousand times for each fiber. High monodespersity of the fibers ( $\sim$ 10% standard deviation in the length distribution) allows for amplifying the signals even more. To demonstrate the proposed method, we study diffusion of a dye from a single silica nanotube. Due to the size of the dye molecule, one can treat this process as truly one-dimensional diffusion. Experimental data are compared with a diffusion model. Apart from just pure demonstration, these data show the potential of ASNT in the controlled drug release.

**Y31 11 A Two-dimensional Porphyrin-based Porous Network Featuring Communicating Cavities** A. KIEBELE, H. SPILLMANN, M. STOEHR, N. WINTJES, *University of Basel* T. JUNG, *Paul Scherrer Institute* D. BONIFAZI, F. CHENG, F. DIEDERICH, *ETH-Zurich* Metallo-porphyrins and their derivatives have been shown to be exceedingly useful building blocks for the construction of 3D supramolecular functional networks due to their excellent thermal and chemical stability and synthetic versatility. Nonetheless, no 2D analogon has been reported so far, although these could be interesting for various potential applications such as molecular sieves or chemical sensors. Herein we report on an unprecedented 2D porphyrin network featuring pores capable of hosting fullerenes following a bottom-up approach at a

single crystal silver surface. Surface- and porphyrin-driven long-range interactions between the $C_{60}$ guest molecules and porphyrin layer resulted in the formation of exceptionally large supramolecular hybrid chains and islands as evidenced by Scanning Tunneling Microscopy.

**10:12**
**Y31 12 Analysis of the Complex Dielectric Permittivity Behavior of Porous $Al_2O_3$-SiC Composites in the 1 MHz − 18GHz Frequency Range*** JACOB BATTAT, JEFFREY CALAME, *Naval Research Laboratory* The complex dielectric permittivity of electrically lossy, porous $Al_2O_3$-SiC composites was measured as a function of frequency over the range of 0.001-18 GHz (broadband). These composites were fabricated by an infusion method of incorporating SiC polymer precursor into porous alumina discs. Repeat polymer infusions and pyrolysis steps to $1000^oC$ were carried out, with some samples undergoing an additional air-fire prior to each subsequent step. Generally, it was found that for non-air-fired samples, moderate, controllable losses were attainable over a broad frequency range with $\log\varepsilon''$ being inversely proportional to $\log f$. By contrast, the dielectric loss attainable for air-fired samples was generally very low. For all samples, various aspects of the variation of permittivity components $\varepsilon'$ and $\varepsilon''$ with frequency were analyzed, with a view to determine the various factors contributing to dielectric response. In addition, the ramifications of this behavior on the properties of the material as a lossy composite were addressed.

**Y31 13 Low field NMR study of the pre-asymptotic Stokes flow in porous rocks.** PHILIP SINGER, *Schlumberger-Doll-Research* GABRIELA LEU, EDMUND FORDHAM, PABITRA SEN, Dispersion in porous media is a powerful tool for probing the microgeometry of porous media and the topology of flow fields. Pulsed field gradient nuclear magnetic resonance (PFG-NMR) methods are emerging as very powerful techniques for measuring fluid propagation and dispersion. However, high magnetic field techniques have proven limited since the susceptibility contrast between fluid components and solid interfaces can give rise to strong internal field gradients which corrupt the measurement, and which cannot be easily corrected for. Here for the first time we present PFG-NMR data on a variety of rocks (Bentheimer and Berea sandstones, Portland carbonate) using an unusually low applied magnetic field (2 MHz for protons) to limit these internal field artifacts. We find remarkable differences with the high field data, and we quantify these differences as a function of the mean flow velocity and the interrogation time.

**10:36**
**Y31 14 Influence of Local Field Effects on the Radiative Properties of Nd:YAG Nanoparticles in a Liquid Suspension** KSENIA DOLGALEVA, ROBERT BOYD, *Institute of Optics, University of Rochester* Local field effects can significantly modify the optical properties of laser materials. Neodymium-doped yttrium-aluminum garnet (Nd:YAG) nanopowder with particle sizes on the order of 50 nm was suspended in different organic and inorganic liquids to produce Maxwell-Garnett-type composite materials. The fluorescence decay time of Nd:YAG nanocomposites was experimentally investigated as functions of the refractive index of the liquid, Nd:YAG filling fraction, and the pump-radiation wavelength. The results of these measurements were compared to the predictions of various theoretical models that include in influence of local field effects in nanocomposite materials.

**10:48**
**Y31 15 Thermodynamic studies of one and two dimensional Neon adsorbed on single walled carbon nanotube bundles*** SUBRAMANIAN RAMACHANDRAN, GREGORY DASH, OSCAR VILCHES, *University of Washington* In this study we report heat capacity measurements between 2 and 20 K for films of Neon adsorbed on single-walled closed end carbon nanotube bundles. The heat capacity of the adsorbed layer is measured from $1/60^{th}$ (2 scc) of a monolayer to $\sim$ 1.2 monolayer (155 scc). The heat capacity is used to identify if the phases are solid, liquid or gaseous. The heat capacity at a fixed coverage (less than 12 scc) as a function of temperature reveals some agreement with the values predicted from a 1D solid model by Kostov et.al **(**Phys. Rev. B **68,** 245403 (2003)**)** between 2 and 4 K. For coverage higher than 24 scc, the heat capacity at low temperature shows a clear $T^2$ dependence. The calculated 2D Debye Temperatures are in the range of 50-60K and are in good agreement with what has been measured by G.B. Huff and J. G. Dash **(**JLTP **24,** 1 / 2, 1976**)** for Neon adsorbed on Grafoil. The specific heat values are greater than 2 for temperatures greater than $\sim$ 14 K. There is no evidence of first order phase transition due to melting.

**Y33 1 Higher Order Phase Transitions and Tachyon Condensation** PRADEEP KUMAR, *University of Florida* AVADH SAXENA, *Los Alamos National Lab* AVINASH KHARE, *Institute of Physics, India* We discuss the similarities (and the differences) between the models which describe a $p$'th order phase transition (in the Ehrenfest sense) and that which describes tachyon condensation in string theory. Using the appropriate free energy for the two systems, we obtain exact domain wall solutions and study their stability for some cases. Extrapolating this analogy, we suggest that the tachyon condensation is analogous to the celebrated Kosterlitz-Thouless transition. It has been suggested that the superconducting transition in BKBO may be of order four. Similarly, the Ising ferromagnet on a Cayley tree and a model by Gross and Witten in particle physics are believed to be order three.

**8:12**
**Y33 2 Analysis of the long-range random field quantum antiferromagnetic Ising model : Some exact results*** JUN-ICHI INOUE, *Hokkaido University* ARNAB DAS, *SINP* BIKAS K. CHAKRABARTI, *SINP* With the realization in the mid last century, that the Neel state cannot be the ground state of a quantum Heisenberg anti-ferromagnet (AF), considerable effort has gone in

search of and in understanding the nature of the ground stateof such and similar quantum AF. Since early 1960s, quantum spin systems described by Ising model in a transverse tunneling field was investigated, particularly because of easy mapping of the quantum system to its equivalent classical system and some cases of exact solubility. However, there has, so far, been very few models with AF interactions. It is well-known, the transverse Ising model with long range interactions is solved exactly, even if the system has some special kind of quenched disorder, like in spin glasses. However, it is not so easy to consider the AF version of the model due to a lack of sub-lattice to capture the Neel ordering at low temperature. In this paper, we introduce and study a solvable quantum AF model. In our model system each spin is influenced by the infinite range AF interactions in a transverse field. We also consider the case under the random fields. By introducing two sub-groups of the spin system, we describe the system by means of the effective single spin Hamiltonian and solve it exactly.

**Y33 3 Lattice dimers and the tilting transition*** ERCAN KAMBER, JANÉ KONDEV, *Martin A. Fisher School of Physics Brandeis University* We study the statistics of dimer coverings of the honeycomb lattice by Monte Carlo simulations. Dimer configurations are given by placing dimers on adjacent sites with the constraint that every site is covered by one and only one dimer. We implement the pocket algorithm [1], which is believed to be ergodic on the space of dimer coverings. The pocket algorithm enables global updates of dimer configurations without violating the packing constraint. Dimer configurations can be mapped to a height model [2], which associates a discrete interface with every dimer covering. If the dimers are aligned along one direction of the honeycomb lattice, the height interface will be tilted. We investigate the fluctuations of the associated height model, when the system undergoes a transition from an untilted rough interface to a tilted smooth interface. We impose a fixed tilt of the interface and measure fluctuations of the height. For a tilted surface the height fluctuations are anisotropic with a variance that increases logarithmically with system size. We compute the effective stiffness of the interface and find that it increases with increasing tilt. [1] W. Krauth, R. Moessner, Phys. Rev. B 67, 2003. [2] H.W.J. Blote, H.J. Hilhorst, J. Phys. A 15, 1982.

**Y33 4 A non-Hermitian analysis of strongly correlated quantum systems** YUICHI NAKAMURA, *Dept. of Phys., Univ. of Tokyo, Japan* NAOMICHI HATANO, *IIS. Univ. of Tokyo* We study a non-Hermitian generalization of strongly correlated quantum systems in which the transfer energy of electrons is asymmetric. Hatano and Nelson[1] applied this technique to non-interacting random electron systems. They related a non-Hermitian critical point to the inverse localization length of the Hermitian systems. We here conjecture that we can obtain in the same way the correlation length of Hermitian interacting non-random systems[2]. We show for the Hubbard model and the antiferromagnetic XXZ model in one dimension that the non-Hermitian critical point of the ground state, where the energy gap vanishes, is equal to the inverse correlation length. We also show that the conjecture is consistent with numerical results for $S=1/2$ frustrated quantum spin chains with the nearest- and next-nearest-neighbor interactions including the Majumdar-Ghosh model[3]. [1] N. Hatano and D. R. Nelson, PRL 77 (1996) 570; PRB 56 (1997) 8651. [2] Y. Nakamura and N. Hatano, Physica B, accepted. [3] C. K. Majumdar and D. K. Ghosh, J. Phys. C3 (1970) 911; J. Math. **Y33 5 Spectrum of superintegrable chiral Potts model and $L(sl_2)$ symmetry in associated XXZ-type spin chain** AKINORI NISHINO, *Institute of Industrial Science, The University of Tokyo* TETSUO DEGUCHI, *Department of Physics, Ochanomizu University* We study the correspondence between the Ising-like spectra of superintegrable N-state chiral Potts (SCP) model [1,2] and the energy degenerate subspaces of XXZ-type spin chain, called nilpotent Bazhanov-Stroganov (NBS) model [3], whose transfer matrix commutes with the SCP transfer matrix. We show that, if the number of sites is a multiple of N, the NBS model has a loop algebra $L(sl_2)$ symmetry in the subspace with $Z_N$-charge $Q=0$. Applying the approach [4] to the case, we obtain the dimension of $L(sl_2)$-degenerate subspaces through the calculation of Drinfeld polynomials. The Drinfeld polynomials are in fact identified with Baxter's polynomials [2] characterizing the SCP's Ising-like spectra, which shows that each subspace with the Ising-like spectra have the same dimension as the corresponding $L(sl_2)$-degenerate subspace of NBS model. **Y33 6 Alignment of Rods and Partition of Integers, an Exact Solution** ELI BEN-NAIM, *Los Alamos National Laboratory* We study dynamical alignment of rods, a process in which rods become parallel by pairwise interactions, and also, wiggle in a diffusive manner. With strong diffusion, the system is disordered, but with weak diffusion, the system is ordered. We present an exact solution for the nonlinear and nonlocal kinetic theory of this alignment process, at the steady-state. The Fourier transform is expressed as a function of the order parameter, and generally, the Fourier modes decay exponentially with the wave number. The order parameter is found as a root of a closed equation. This solution involves iterated partitions of the integer numbers.

**9:12**

**Y33 7 Integrable Chiral Potts Model Alive and Well** JACQUES H.H. PERK, *Oklahoma State University* HELEN AU-YANG, *Oklahoma State University* About two decades have passed since the introduction of the integrable chiral Potts model, parametrized by a high-genus curve [1,2]. In spite of this mathematical complication, several exact results have been obtained since, culminating in Baxter's proof [3,4] of the conjecture for the order parameters. Here we shall discuss several other results. First we shall show how the model fits in the phase diagram of a more general non-integrable chiral Potts model and what we have learned about critical exponents and scaling behavior. Next, we shall mention some mathematical implications. Finally, we shall discuss our preliminary work on the pair correlation functions.

**Y33 8 Statistics of work done by flow on a polymer** MICHAEL CHERTKOV, *LANL* We study polymer immersed in a flow and subjected to thermal fluctuations. Shear flow as well as chaotic flows are considered. Flow does work on the polymer while the polymer in its turn releases access of energy into heat. Statistics of work/heat production is analyzed in this non-equilibrium (off detailed balance) but steady problem theoretically and numerically. Analogs of fluctuation theorem and Jarzynski equality for annealed/quenched averaging procedures applied to the system are established. We also discuss possible generalization of this approach/study to more complex non-equilibrium problems, like turbulence. This is a joint work with A. Puliafito (INLN, Nice) and K. Turitsyn (Landau Inst., Moscow).

**9:36**

**Y33 9 On Harmonic Measure of Critical Curves** ILIA RUSHKIN, *University of Chicago* ELDAD BETTELHEIM, *University of Chicago* ILYA GRUZBERG, *University of Chicago* PAUL WIEGMANN, *University of Chicago* Fractal geometry of critical curves appearing in 2D critical systems is characterized by their harmonic measure. For systems described by conformal field theories with central charge $c \leqslant 1$ the scaling exponents of the harmonic measure have been computed by B. Duplantier [Phys. Rev. Lett. **84**, 1363 (2000)] by relating the problem to boundary two-dimensional gravity. We present a simple argument connecting the harmonic measure of critical curves to operators obtained by fusion of primary fields, and compute characteristics of the fractal geometry by means of regular methods of conformal field theory. The method is not limited to theories with $c \leqslant 1$.

**9:48**

**Y33 10 Methods of calculating Ruelle-Pollicott resonances** ELIZABETH KELLER, MARK SREDNICKI, *University of California, Santa Barbara* We develop a method to compute the Ruelle-Pollicott resonances for the classical perturbed cat map. Using sine and cosine basis states, we calculate the matrix elements of the Frobenius-Perron operator and find the eigenvalues of the resulting matrix. Because the matrix is sparse, we are able to reach sufficiently large matrix dimensions to obtain stable, convergent values for the Ruelle-Pollicott resonances.

**Y33 11 Phase Transition of a Dynamical System with a Bi-Directional, Instantaneous Coupling to a Virtual System** VADAS GINTAUTAS, ALFRED HUBLER, *University of Illinois at Urbana-Champaign* As worldwide computer resources increase in power and decrease in cost, real-time simulations of physical systems are becoming increasingly prevalent, from laboratory models to stock market projections and entire ''virtual worlds'' in computer games. Often, these systems are meticulously designed to match real-world systems as closely as possible. We study the limiting behavior of a virtual horizontally driven pendulum coupled to its real-world counterpart, where the interaction occurs on a time scale that is much shorter than the time scale of the dynamical system. We find that if the physical parameters of the virtual system match those of the real system within a certain tolerance, there is a qualitative change in the behavior of the two-pendulum system as the strength of the coupling is increased. Applications include a new method to measure the physical parameters of a real system and the use of resonance spectroscopy to refine a computer model. As virtual systems better approximate real ones, even very weak interactions may produce unexpected and dramatic behavior. The research is supported by the National Science Foundation Grant No. NSF PHY 01-40179, NSF DMS 03-25939 ITR, and NSF DGE 03-38215.

**Y33 12 Wave stability on one-dimensional non-linear lattices** CHIA-CHEN CHANG, *Department of Physics, The Pennsylvania State University* GERALD D. MAHAN, *Department of Physics, The Pennsylvania State University* We report the results of our stability analysis of exact travling wave solutions for two non-linear mono-atomic lattices in one dimension. One lattice has nearest-neighbor potential energy containg quadratic and quartic terms (Fermi-Pasta-Ulam model). The other lattice has potential energy which goes as $cosh(q)$, a generalization of the Toda lattice. These exact traveling wave solutions have wave lengths that are commensurate with the lattice constant. It is found that on the quadratic-quartic lattice, the traveling wave solutions are unstable. For the $cosh(q)$ lattice, on the other hand, the solutions are stable.

**Y37 1 Highly Ordered Graphene for Two Dimensional Electronics*** RUI FENG, J.R. HASS, E.H. CONRAD, X LI, C. BERGER, W.A. DE HEER, T. LI, P.N. FIRST, *School of Physics, Georgia Institute of Technology* C.A. JEFFREY, *Dept. of Physics and Astronomy, University of Missouri-Columbia* Many of the same electrical properties of carbon nanotubes can be realized by confining grapheme sheets to nano-dimensions. Scalability issues of nanotube devices can therefore be overcome by lithographic patterning of graphene films if thin well ordered graphene films can be grown. We have been able to grow ultrathin epitaxial graphite films that show remarkable 2D electron gas (2DEG) be-

havior by thermal decomposition of both Si-face and C-face 4H-SiC. Early studies of the structure of both surfaces of 4H-SiC showed that graphite grown on the C- face was rotationally disordered compared to the Si-face. For this reason the C-face graphite was ignored as a potential substrate for graphitic devices. However, our surface X-ray scattering measurements show that while the orientational order is reduced, the coherent film size of the C-face graphite is more than three time greater than the Si-face. Part of the reason is that the Si-face step density increases dramatically with graphitization while the C-face shows little change in step structure. These observations are consistent with the improved 2D conductivity measurement on the C-face graphite films.

*Research funding is supported by NSF-NIRT and Intel.

**Y37 2 2d electronic gas properties of epitaxial graphene** CLAIRE BERGER, *GATECH / CNRS* CECILE NAUD, *CNRS* ZHIMIN SONG, *GATECH* XUEBIN LI, *GATECH* WALT DE HEER, *GATECH* We present transport measurement on multilayered epitaxial graphene grown on SiC. The films, a few to a few dozen layers thick, can be lithographically patterned and show remarkable 2d electron gas properties. In high mobility samples (up to $10^4$ $cm^2/Vs$) perpendicular magnetoresistance measurements indicate micrometer long electronic phase coherence lengths at 4K, comparable to the sample size. Pronounced Shubnikov –de Haas oscillations are consistent with graphene-like electronic dispersion relation. A novel low temperature electronic phase transition was also observed. Most recent development of his ongoing research will be presented.

**8:24**
**Y37 3 STM studies of graphite microdevices** ELENA POLYAKOVA, *Chemistry Department, Columbia University* GEORGE FLYNN, *Chemistry Department, Columbia University* YUANBO ZHANG, *Physics Department, Columbia University* MINA FAZLOLLAHI, *Physics Department, Columbia University* PHILIP KIM, *Physics Department, Columbia University* A novel scanning tunneling microscope (STM) has been designed and built to study transport phenomena in mesoscopic conductive films, self-assembled monolayers, and nanostructures on insulating substrates under ambient conditions. In this work we present experimental STM studies of monocrystalline ultrathin graphite films including single graphite sheets (graphene) at the atomic scale. Electronic transport is possible only in the lateral direction for graphene. Graphite microscopic devices ( $\sim$ 10 $\mu$m) have been prepared by mechanical exfoliation followed by deposition of macroscopic gold electrodes over the graphite film and its surrounding insulator. Evolution of STM images during the transition from multilayer to single graphene sheets as well as the dependence of STM images on tunneling conditions near the Fermi energy will be discussed.

**Y37 4 Low temperature scanning tunneling microscopy of metallic and organic nanostructures.***
STEFAN FÖLSCH, *Paul Drude Institute for Solid-State Electronics, 10117 Berlin, Germany*

Low temperature scanning tunneling microscopy (LT-STM) is capable of both characterizing and manipulating atomic-scale structures at surfaces. It thus provides a powerful experimental tool to gain fundamental insight into how electronic properties evolve when controlling size, geometry, and composition of nanometric model systems at the level of single atoms and molecules. The experiments discussed in this talk employ a Cu(111) surface onto which perfect nanostructures are assembled from native adatoms and organic molecules. Using single Cu adatoms as building blocks, we obtain zero-, one-, and two-dimensional quantum objects (corresponding to the discrete adatom, monatomic adatom chains, and compact adatom assemblies) with intriguing electronic properties. Depending on the structure shape and the number of incorporated atoms we observe the formation of characteristic quantum levels which merge into the sp-derived Shockley surface state in the limit of extended 2D islands; this state exists on many surfaces, such as Cu(111). Our results reveal the natural linkage between this traditional surface property, the quantum confinement in compact adatom structures, and the quasi-atomic state associated with the single adatom. In a second step, we study the interaction of pentacene ($C_{22}H_{14}$) with Cu adatom chains serving as model quantum wires. We find that STM-based manipulation is capable of connecting single molecules to the chain ends in a defined way, and that the molecule-chain interaction shifts the chain-localized quantum states to higher binding energies. The present system provides an instructive model case to study single organic molecules interacting with metallic nanostructures. The microscopic nature of such composite structures is of importance for any future molecular-based device realization since it determines the contact conductance between the molecular unit and its metal ''contact pad.''

**Y37 6 Probing Single-Electron Charging and Dissipation of Au Nanocrystals with Electric Force Microscopy** J. ZHU, M. BRINK, P. L. McEUEN, *LASSP, Cornell University, Ithaca, NY 14853* We synthesize and link Au nanocrystals to carbon nanotube (CNT) field effect transistors through thiol and aromatic ring bifunctionalized molecules. AFM images taken at room temperature using tapping mode and at 77 K using force microscopy both show specific binding of Au nanocrystals onto the CNTs. At 77 K, the small size of the Au nanocrystals (d $\sim$ 12 nm) leads to quantum dot phenomena. A metalized AFM tip perturbs the electrostatic potential of the dot and brings electrons onto the dot one by one. The CNT serves as a charge transfer line and a reservoir. We study the force, frequency shift, and dissipation generated by this single-electron motion using AFM-based electric force microscopies. We observe Coulomb oscillations of the Au nanocrystal and derive its capacitances to the gates, i.e. the backgate, the AFM tip, and the anchoring CNT, through charge addition spectra. The total capacitance of the Au nanocrystals was found to be approximately 1.6 aF, corresponding to a charging energy of 100 meV. Most interestingly, we observe a typical power dissipation of $\sim$ 10 aW, extracted from the decrease of the quality factor Q of the AFM cantilever, for many charging events. We discuss the possible origins of the observed dissipation.

**9:36**

**Y37 7 Quantitative Investigation of Quantum Dots Using Frequency Shift Microscopy at Low Temperatures.** MARKUS BRINK, JUN ZHU, PAUL L. McEUEN, *LASSP, Cornell University, Ithaca, NY 14853* We use frequency shift microscopy (FSM), an AFM-based scanned probe technique, to study quantum dots formed in carbon nanotubes at 4K. FSM requires the quantum dot to be coupled to only one charge reservoir, allowing us to probe quantum dots in single-terminal geometries; furthermore, FSM requires only weak coupling between the quantum dot and the charge reservoir, permitting measurements in poorly conducting regimes that are inaccessible to transport measurements. Charging events of individual quantum dots are detected with single-electron sensitivity down to the few electron regime. We describe a general method to extract the charging energy of a quantum dot from frequency shift measurements. Coupled dots show avoided crossings in FSM charge addition spectra, from which we extract their mutual capacitance.

**9:48**

**Y37 8 Measurements of electron-in-a-box level spectra in chemically-synthesized metal nanoparticles** FERDINAND KUEMMETH, K.I. BOLOTIN, D.C. RALPH, *Laboratory of Atomic and Solid State Physics, Cornell University, Ithaca, NY 14853* We incorporate chemically-synthesized metal nanoparticles into a single electron transistor geometry such that tunneling spectroscopy can be used to measure the electron energy levels within a single nanoparticle at dilution refrigerator temperatures. This technique gives better control over the size and shape of the nanoparticle than previous studies of level spectra in metals. We use a monolayer of dithiols or propylamines as a self-assembled tunnel barrier on top of a back-gated pair of gold electrodes, separated by a nm-sized gap. Into the gap we trap gold nanospheres 5 to 15 nm in diameter from a citrate based colloid solution, with control provided by adjusting the pH. Previous experiments on gold nanoparticles found a wide range of g-factors for Zeeman splitting in an applied magnetic field, with some values inconsistent with expected orbital contributions. Our measurements clarify the relationship between g-factors and level spacing through systematic variation of the particle's size and composition.

**10:00**

**Y37 9 Single-electron transport through a $Mn_{12}$ (2-thiophenecarboxylate) single-molecule magnet** CHRISTOPHER M. RAMSEY, ENRIQUE DEL BARCO, EDUARDO MUCCIOLO, *Department of Physics, University of Central Florida, Orlando, FL* FIROZE HAQUE, SAIFUL KHONDAKER, MICHAEL LEUENBERGER, *Nanoscience Technology Center, University of Central Florida, Orlando, FL* ABHUDAYA MISHRA, GEORGE CHRISTOU, *Department of Chemistry, University of Florida, Gainesville, FL* We report single-electron transport measurements on $Mn_{12}$ based single-molecule magnet, which has been functionalized with 2-thiophenecarboxylate ligands that bind to gold. The self-assembly of these molecules was confirmed by scanning probe microscopy and XPS measurements. Because it is well known that the molecule's environment within the crystal can have a profound influence on the quantum properties of the system, it is important to study the quantum spin dynamics in individual isolated molecules. Single electron transistor devices have been prepared for this purpose by electron beam lithography and electromigration. The transport properties of a single, isolated $Mn_{12}$(2-thiophenecarboxylate) molecule were measured down to mK temperatures in a 3-D superconducting vector magnet with arbitrary field direction. The data are characteristic of a molecular single-electron transistor device where the SMM bridges the gap between two gold nanoelectrodes. Magnetic field and temperature dependence as well as theoretical aspects will be discussed.

**10:12**

**Y37 10 Local electronic structure of a quantum point contact observed with STM** KATSUMI NAGAOKA, SNIN YAGINUMA, TADAAKI NAGAO, TOMONOBU NAKAYAMA, *National Institute for Materials Science* A quantum point contact (QPC) is realized when a width of an electron conduction channel is comparable to the Fermi wavelength of electrons in a material. Since the first observation that QPCs show the conductance quantization in units of $G_0 = 2e^2/h$, QPCs have been mainly used in transport measurements. But the quantized states of confined electrons, which are the origin of the quantized conductance in the transport measurements, have not been observed directly so far. We report the direct observation of electronic structures of QPCs using an STM spectroscopy at 77K. The QPCs are formed across boundary gaps between a multi-domain Bi film on a Si(111)-$\beta\sqrt{3}$x$\sqrt{3}$-Bi substrate. Since the QPCs are formed in the direction parallel to the substrate, the direct observations of the atomic and the local electronic structures by using STM are possible. The electronic structure of the QPCs is neither sensitive to the external electric field induced by the STM tip nor to the length of the bridging part, and is well-explained by electronic confinement in a one-dimensional cylindrical potential well.

**10:24**

**Y37 11 Spectral diffusion in the tunneling spectra of ligand-stabilized undecagold clusters** THOMAS P. PEARL, *North Carolina State University* RACHEL K. SMITH, SANJINI U. NANAYAKKARA, PAUL S. WEISS, *The Pennsylvania State University* GERD H. WOEHRLE,*JAMES E. HUTCHISON, *University of Oregon* Electronic properties of isolated, solution-derived, and ligand-stabilized undecagold clusters ($Au_{11}L_{10}$) in both cryogenic (4 K, UHV) and ambient conditions were measured using scanning tunneling microscopy and spectroscopy. Clusters were immobilized on alkanethiolate self-assembled monolayer matrices with inserted dithiol tethers. At low temperature, $Au_{11}L_{10}$ clusters demonstrated Coulomb blockade, with zero-conductance gaps resulting from quantum size effects, and spectral hopping. While these clusters were immobilized for probing, we hypothesize that these assemblies may be dynamic and influence their charge transport significantly. Diffusion in the conductance resonances of the tunneling spectra of $Au_{11}L_{10}$ clusters is observed for a itsingle cluster, as well as across multiple clusters. The observed spectral diffusion is independent of tunneling conditions and varies significantly for spectra recorded with identical setpoint/tunneling junction conditions.

**10:36**

**Y37 12 Influence of Linker Molecules on Charge Transport through Self-Assembled Single-Nanoparticle Devices.** AL-AMIN DHIRANI, AMIR ZABET-KHOSOUSI, YOSHINORI SUGANUMA, KENNETH LOPATA, PAUL-EMILE TRUDEAU, *Department of Chemistry, University of Toronto* We investigate electrical characteristics of single-electron electrode/nanoisland/electrode devices formed by alkanedithiol assisted self-assembly. Contrary to predictions of the orthodox model for double tunnel junction devices, we find a significant ( $\sim$ five fold) discrepancy in single-electron charging energies determined by Coulomb blockade (CB) voltage thresholds in current-voltage measurements versus those determined by an Arrhenius analysis of conductance in the CB region. The energies do, however, scale with particle sizes, consistent with single-electron charging phenomena. We propose that the discrepancy is caused by a multi-barrier junction potential that leads to a voltage divider effect. Temperature and voltage dependent conductance measurements performed outside the blockade region are consistent with this picture. We simulated our data using a suitably modified orthodox model.

**10:48**

**Y37 13 Absence of Even-Odd Effect in Kondo Resonance in Single-Molecule Transistors** DONG-HUN CHAE, ZHEN YAO, *Department of Physics, The University of Texas at Austin, Austin, TX 78712* JEONG T. LEE, JONATHAN L. SESSLER, *Department of Chemistry and Biochemistry, The University of Texas at Austin, Austin, TX78712* We have observed the Kondo effect in single-electron transistors incorporating individual cyclo[*n*]pyrrole molecules. In contrast to the usual spin-1/2 Kondo effect, the zero-bias Kondo resonance in these devices appears for both even and odd number of electrons. We suggest a model in which instead of alternate spin filling, two successive electrons are added to the molecule with parallel spins due to strong exchange interaction within the molecule.

**Y38 1 Vortex-lattices in quasiperiodic pinning potentials*** JAVIER E. VILLEGAS, MARIA I. MONTERO, CHANG-PENG LI, IVAN K. SCHULLER, *Physics Department, University of California-San Diego, 9500 Gilman Drive, La Jolla CA 92093-0319, USA* We have investigated vortex-lattice dynamics in superconducting Nb thin films with different types of quasiperiodic arrays of magnetic pinning centers. The mixed-state magnetoresistance show minima for particular applied fields, which reveal matching effects between the vortex-lattice and the quasiperiodic array. These minima are as sharp and well defined as those found with periodic pinning arrays. Moreover, a larger number of minima are observed for quasiperiodic arrays, which in some cases indicate a high ratio of vortices per pinning site. These results suggest that matching between the vortex-lattice and the array of magnetic dots takes place on a very local scale, indicating a short local correlation-length of the vortex-lattice.

**Y38 2 Resistance anomaly in superconducting films containing disordered arrays of holes** Z.L. XIAO,*J. HUA, U. PATEL, D. ROSENMANN, U. WELP, W.K. KWOK, G.W. CRABTREE, *Argonne National Laboratory* Anomalous resistive peaks with values larger than the normal-state resistance has been observed in the resistance versus temperature and magnetic field curves of superconducting nanostructures of Al nanowires, nanoloops and nanodiscs. The excess resistance in these systems is believed to originate at the normal-superconducting ($N - S$) interface and induced by dynamic phase slip centers or by different critical temperatures ($Tc$) in the neighboring parts. Here we report on a new type of resistance anomaly which occurs only at high driving currents in disordered superconducting films. The samples were formed by sputtering niobium onto substrates containing arrays of irregularly distributed nanoscale holes. Resistance peaks appear as a function of temperature or magnetic field in the superconducting transition, with peak values up to 2% above the typical normal-state value. We attribute the observed resistance peak effect to dissipation-induced granularity which enhances contributions from the fluctuation-induced decrease of the quasiparticle density of states. The granularity of the superconducting film arises from inhomogeneous heat-transfer due to the size variation of the Nb sections between the nanoholes.

**Y38 3 Origin of the resistance and critical current oscillations in superconducting films with hole arrays** U. PATEL,* *Argonne National Laboratory* Z.L. XIAO, J. HUA, T. XU, D. ROSENMANN, V. NOVOSAD, U. WELP, W.K. KWOK, G.W. CRABTREE, The resistance and critical current of a superconducting film containing a regular array of microscale or nanoscale holes are found to oscillate with magnetic field. These oscillations are

generally interpreted as commensurate pinning. On the other hand, oscillations of the critical temperature of such films with magnetic field due to the Little-Parks effect can also induce oscillations of the resistance and critical current. We present a new method to separate the contributions of commensurate pinning from the Little-Parks effect in superconducting niobium films containing triangular lattices of holes with diameter of tens of nanometers. Remarkably, we find the oscillations of the resistance and critical current with respect to field and temperature to originate purely from the Little-Parks effect. Details on sample preparation, morphological characterization and transport measurements of the critical temperature, the resistance and critical current will be reported.

**8:36**

**Y38 4 Stochastic resonance in a periodic superconducting array** MAXIM MARCHEVSKY, MICHAEL DEFEO, *Syrcause University* VITALI METLUSHKO, *University of Illinois at Chicago* Magnetic fluxon dynamics was studied in superconducting Nb films patterned with a periodic array of holes. A sum of weak harmonic and Gaussian white noise magnetic fields is applied to the sample at $T \ll T_c$ and the local magnetic response is measured with a scanning Hall sensor. We find that the fluxon jump rate in the array exhibits locking with the half-period of the harmonic magnetic drive at a certain quotedblleft optimalquotedblright nonzero amplitude of the white noise. Peaks in the resident time distribution and formation of the quasi-periodic flux patterns is observed. We explain our observations with the phenomenon of array enhanced stochastic resonance earlier seen in various driven non-linear systems with dynamic threshold. Implications of our results for the fluxon-based superconducting devices will be discussed.

**8:48**

**Y38 5 Vortex Rectification in Thickness Modulated Films*** YAOHUA LIU, DANIEL H. REICH, *The Johns Hopkins University* CALEB D. BLISSETT, STUART B. FIELD, *Colorado State University* Rectification effects of Abrikosov vortices have been addressed theoretically in both one-dimensional (1D) and two-dimensional (2D) asymmetric potentials. However, experimentally, vortex ratchets have typically been realized in 2D arrays of asymmetric micropatterned features in superconducting films. Here we report vortex rectification in a smooth, 1D modulation potential fabricated by a novel method. Low- pinning granular Al films were deposited on sinusoidal glass gratings by angle evaporation to achieve an asymmetrical thickness modulation with a period $\sim 2\mu m$. The varying thickness yields a 1D periodic pinning potential for the vortices, which is confirmed experimentally by observation of matching field effects in magneto-transport measurements. A rectified longitudinal DC voltage is generated when the sample is driven by a zero-biased AC current at $T < T_C$, which implies a unidirectional mean motion of the vortices. Weak frequency dependence up to 10 KHz signifies that the system is in the adiabatic regime. The maximum rectified voltage decreases as the applied field increases, but is detectable far above the first matching field. In some cases, a sign reversal in the DC voltage is observed, implying that the preferred direction for vortex motion can change.

**Y38 6 Interacting particles ratchet effect: Experiments and theoretical simulations.*** JOSE L. VICENT, NURIA O. NUNEZ, *Departamento Fisica Materiales, Universidad Complutense, 28040 Madrid (Spain)* LUIS DINIS, JUAN M. R. PARRONDO, *Departamento Fisica Atomica, Molecular y Nuclear, Universidad Complutense, 28040 Madrid (Spain)* JOSE V. ANGUITA, *Instituto Microelectronica Madrid, CSIC, 28670 Madrid (Spain)* Ratchet effect occurs when out of equilibrium particles move on asymmetric potentials. The outcome is a net motion without the need of being driven by non-zero average forces or temperatures gradients. This effect spans in Nature for example from molecular motors to particles separation. Most of the theoretical models have dealt with non-interacting particles. From the experimental point of view superconducting vortices are a powerful tool to study ratchet effect on interacting particles. We will present the experimental behavior of vortex lattice motion on asymmetric pinning potentials, when the asymmetric potentials are modified and extensive simulations of a two-dimensional gas of vortices in an asymmetric substrate. We simulate the vortices as Langevin particles interacting by means of a repulsive potential. The defects in the substrate are simulated as potential wells for the Langevin particles. We will analyse the experimental data in comparison with the simulations when the shape and periodicity of the asymmetric potentials are varied.

**Y38 7 Direct experimental visualization of magnetic flux guidance in artificially patterned $YBa_2Cu_3O_{7-x}$ thin films.** V.V. YURCHENKO, *Department of Physics, University of Oslo, Norway* R. WOERDENWEBER, *Research Centre of Juelich, Germany* J.I. VESTGAARDEN, YU.M. GALPERIN, D.V. SHANTSEV, T.H. JOHANSEN, *Department of Physics, University of Oslo, Norway* Development of new 'fluxonic' devices, based on controlled motion of magnetic vortices, requires understanding of the principles of magnetic flux distribution and its dynamics in patterned superconductors. We investigated $YBa_2Cu_3O_{7-x}$ thin films equipped with various arrangements of antidots (holes of 1 $\mu$m radius) by means of real-time magneto-optical imaging. We demosntrate that 1D antidot arrays facilitate propagation of magnetic flux: each antidot concentrates the flux and tends to pass it on to the next antidot. Some flux from the antidot enters the superconductor creating a characteristic parabolic pattern. At high fields a whole line of antidots represents a cascade of parabolas with the centres in the holes. Flux 'channels' and 'reservoirs' were created in a superconducting strip by combining antidots of different size. We demonstrate that transfer of magnetic flux between two 'reservoirs' lying parallel to the edge of the strip can be realized without applying additional transverse currents. At alternating magnetic field dynamics of the flux can be localized inside the 'reservoirs'.

**Y38 8 Induced in-plane order in vortex liquid by regular holes array in $Bi_2Sr_2CaCu_2O_{8+y}$*** SHUUICHI OOI, TAKASHI MOCHIKU, SATOSHI ISHII, SHAN YU, KAZUTO HIRATA, *National Institute for Materials Science* SUPERCONDUCTING MATERIALS RESEARCH CENTER COLLABORATION, To study the influence of artificial hole defects on the vortex matter in high-$T_c$ superconductors, we have measured electrical transport properties in the vortex state of $Bi_2Sr_2CaCu_2O_{8+y}$ single-crystal

thin films which have holes configurations with different symmetries. In samples with triangular and square holes arrays, the flow resistance of pancake vortices exhibits dips at multiples of the matching fields, while it is absent in a random hole configuration. Such matching effect occurs even in a vortex liquid phase, suggesting that the periodicity in holes configuration induces in-plane order in liquid flow.

**Y38 9 Niobium superconducting networks and its anisotropy** J. HUA,*Z.L. XIAO, U. PATEL, T. XU, D. ROSENMANN, V. NOVOSAD, U. WELP, W.K. KWOK, G.W. CRABTREE, *Argonne National Laboratory* Novel properties such as an oscillating phase boundary in the magnetic field – temperature (H-T) diagram have been reported in superconducting films containing a regular hole array where the interhole separation is comparable to the superconducting coherence length – the superconducting networks. Aluminum is the most common material used in fabricating such superconducting networks due to its large coherence length. However, they require low $He^3$ refrigeration temperatures due to aluminum's low critical temperature of about 1 K. Here, we report on the fabrication of Nb superconducting networks with interhole separation down to tens of nanometers and critical temperatures up to 9K. In addition, we present results on angular dependence of the critical temperature and magnetoresistance of the superconducting networks.

**Y38 10 Anisotropic model for plastic flow with pinning: 3D simulations** B. ELIZABETH RODRIGUEZ-MILLA, A. ALAN MIDDLETON, M. CRISTINA MARCHETTI, *Syracuse University* Switching and macroscopic hysteresis are seen in the driven transport of flux liquids (and in charge density waves). Such effects are ruled out for purely elastic models of flux array transport. Results are presented for a coarse-grained model of flux arrays which generically incorporates both elastic coupling and plastic viscous coupling. This anisotropic model, describing elastic channels interacting in a plastic fashion, has a complex phase diagram with many interesting features that have been found in exact mean-field calculations, including a tricritical point which separates the non-hysteretic region from the region where there is coexistence of stuck and moving states. Our most recent work examines this coarse-grained model in finite dimensions in detail, for distinct models of couplings between the elastic channels. Strong evidence for the existence of a tricritical point has been found. The shape of the phase diagram has a shape significantly different from the mean-field calculations. Results for the critical behavior in finite dimensions will be presented.

**Y38 11 Flux Quantization in Thick Mesoscopic Pb Superconductors.*** WAI-KWONG KWOK, ANDREAS RYDH,†RUOBING XIE, ULRICH WELP, MICHAEL ZACH, GEORGE CRABTREE, *Materials Science Division, Argonne National Laboratory* ZHILI XIAO, *Dept. of Physics, Northern Illinois University* SIMON BENDING, *School of Physics, University of Bath, U.K.* We present studies of novel vortex behavior on a thick triangular-shaped mesoscopic Pb crystal using ballistic micro-Hall probe magnetometry. The Pb single crystal with dimensions of 2 microns on each edge and 0.7 $\mu$m thick was placed on a 2DEG Hall sensor with a detection area of 1 $\mu m^2$ and the magnetization was studied as a function of applied magnetic field and temperature. The critical field was found to be $H_c = 78$ mT and $T_c = 7.20$ K, in good agreement with values of clean, bulk Pb. Above $T_x = 6.6$ K, we observe a stable Meissner state for increasing field and a remarkable quantized flux entry behavior with decreasing field. Below $T_x$, we observe quantized flux entry (removal) with increasing (decreasing) field. These behaviors indicate that thick mesoscopic Pb superconductors can be tuned with temperature to exhibit type I or type II superconducting behavior.

**Y38 12 SANS Study of Edge-Contaminated Vortex States in a $V_{21at\%}Ti$ Superconducting Alloy*** X.S. LING, N.D. DANIILIDIS, I.K. DIMITROV, *Brown University* In this talk, we report the first direct observation of edge-contaminated vortex matter using small angle neutron scattering (SANS). The vortex structures of Zero Field Cooled and Field Cooled states in a high-$\kappa$ superconducting alloy have been studied using SANS. In this sample FC states are partially ordered as shown by the coexistence of a diffuse scattering ring with two Bragg peaks. ZFC states are disordered at low fields and more disordered than FC states at all fields. For example, the ZFC vortex state at H=6 kOe gives a diffuse ring indicating an amorphous state. Upon further increasing the field, Bragg peaks emerge from the ring, indicating ordering. On increasing temperature from the disordered structure at 6 kOe, the ring gradually transforms into distinct peaks. The experiments were performed at the NIST Center For High Resolution Neutron Scattering (CHRNS).

**Y38 13 AC-Susceptibility and SANS Studies of the Vortex States in $V_{-21at.\%}Ti$*** I.K. DIMITROV, N.D. DANIILIDIS, V. MITROVIC, C. ELBAUM, *Brown University* J.W. LYNN, *NIST* Y. SHAPIRA, *Tufts University* X.S. LING, *Brown University* The vortex matter phase diagram of a binary alloy ($V_{-21at.\%}Ti$) has been mapped out using mutual-inductance ac susceptometry, and explored using small angle neutron scattering (SANS). In this sample, a peak effect (PE) appears at high fields, but disappears at low fields. The phase diagram shows a trend remarkably similar to that of a single-crystal itNb, despite the vast differences in their respective values of $\kappa$ and $H_{c2}$. SANS measurements of the vortex states in this sample shows the survival of quasi-long range order, suggesting the existence of a Bragg glass phase in this system. The SANS experiments were performed at the NIST Center For High Resolution Neutron Scattering (CHRNS).

**10:36**

**Y38 14 Vortex Fractionalization in a Josephson Ladder*** DAVID STROUD, IVAN TORNES, *Ohio State University* We show numerically that in a Josephson ladder with periodic boundary conditions and subject to a suitable transverse magnetic field, a vortex excitation can break up into two or more fractional excitations. If the ladder has N plaquettes, and N is divisible by an integer q, then in an applied field of 1/q flux quanta per plaquette, the ground state is a regular lattice of one fluxon every q plaquettes. When an additional fluxon is added, it spontaneously breaks up into q fractional fluxons, each carrying 1/q units of vorticity. The fractional fluxons are basically walls between different domains of the underlying 1/q lattice. The fractional fluxons are all depinned at the same applied current and move as a unit. For certain applied fields and ladder lengths, we show that there are isolated fractional fluxons. The fractional fluxons produce a time-averaged voltage related in a characteristic way to the ac voltage frequency.

**Y39 1 Superconductivity in Yttrium Metal at 17 K*** JAMES J. HAMLIN, *Department of Physics, Washington University, St. Louis, MO* VLADIMIR G. TISSEN, *Institute of Solid State Physics, Chernogolovka, Russia* JAMES S. SCHILLING, *Department of Physics, Washington University, St. Louis, MO* Many of the known elemental superconductors only become superconducting if high pressure is applied. In 1970 J. Wittig [1] discovered superconductivity in yttrium metal at 1.2 K under 11 GPa pressure, $T_c$ increasing to 2.7 K at 16 GPa. Using a diamond-anvil cell with dense helium pressure medium, we have extended this pressure range to 89 GPa. We find that $T_c$ for yttrium metal reaches values as high as 17 K (ac susceptibility midpoint), one of the highest transition temperatures ever observed for an elemental superconductor. [1] J. Wittig, Phys. Rev. Lett. 24, 812 (1970).

**Y39 3 Correlation of superconductivity with the apical oxygen ordering.*** C. Q. JIN, Q. Q. LIU, H. YANG, R.C. YU, X.M. QIN, L. X. YANG, Y. YU, F.Y. LI, *Institute of Physics, Chinese Academy of Sciences* We discuss the evolution of superconducting transition temperature (Tc) with the ordering state at the apical oxygen layer of a high temperature superconductor (HTS). This study became available in $Sr_2CuO_{3+\delta}$ superconductor with K2NiF4 structure showing so far rarely formed partially occupied apical oxygen which also acts as the dopant. With observation of a series of modulation structures at apical oxygen layer, we found a well-defined links between Tc (from 75 to 95 K) and modulated structures. We address that the distribution geometry of dopant such as the partially occupied apical oxygen here can be an additional route to reach further higher Tc.

**Y39 4 Oxygen isotope effect in layered cuprate superconductors** XIAOJIA CHEN, VIKTOR V. STRUZHKIN, ZHIGANG WU, RUSSELL J. HEMLEY, HO-KWANG MAO, *Geophysical Laboratory, Carnegie Institution of Washington,Washington, DC 20015, USA* BING LIANG, *Center for Superconductivity Research, University of Maryland, College Park, MD 20742, USA* CLEMENS ULRICH, CHENGTIAN LIN, *Max-Planck-Institut für Festkörperforschung, D-70569 Stuttgart, Germany* HAI-QING LIN, *Department of Physics, The Chinese University of Hong Kong, Hong Kong, China* The isotope effect has generally been believed to be important in providing information about the high-temperature superconductivity. We report systematic studies of the oxygen isotope effect in nearly optimally doped $Bi_2Sr_2Ca_{n-1}Cu_nO_{2n+4+\delta}$ (n=1,2,3) single crystals. We find that $\alpha$ decreases monotonically with increasing the number of $CuO_2$ layers in this series, which is considered as a result of the interlayer coupling effect. Our results suggest that a *d*-wave BCS equation with a phonon cutoff is able to provide a self-consistent explanation for both the Tc and $\alpha$ behaviors of cuprates covering the parameters of doping, $CuO_2$ layer, and compound. The proposed theoretical model is also used to predict the pressure dependence of the oxygen isotope exponent in the optimally doped $YBa_2Cu_3O_{7-\delta}$ based on our measured Tc and Raman data. We find that $\alpha$ decreases with increasing pressure and becomes negative at some pressure. Such prediction is waiting for direct isotope measurements under high pressures.

**8:48**

**Y39 5 The effect of process gas pressure, target composition, Ar:$O_2$ ratio and substrate bias on the preparation of thin films of the superconductor $Bi_2Sr_2CaCu_2O_{8+\delta}$*** ROBERT J. SANDERSON, KEVIN C. HEWITT, *Dalhousie University* Thin films prepared by DC magnetron sputtering of single targets of the well known superconductor $Bi_2Sr_2CaCu_2O_{8+\delta}$ and an enriched target of composition $Bi_{2.2}Sr_2Ca_{1.1}Cu_2O_{8+\delta}$ were studied to determine the effect of deposition conditions on the resulting film. The targets were both sputtered at a power of 60 Watts for 83.3 minutes, at a base pressure of $(5\pm 1)\times10^{-7}$ Torr. Films were deposited onto

Al foil using a comprehensive range of deposition pressures (3.96 to 27.3 mTorr), Ar:$O_2$ gas ratios (1:1, 1:2, 1:3 and 2:1) and substrate biases (-5, -20, and -30 V). Elemental analysis using energy dispersive spectroscopy allows us to determine the effect of these variables on each individual element in the deposited film. The proportion of Bi increases linearly with increasing process gas pressure. Changing the Ar:$O_2$ ratio does not have a major effect on the composition, but it does slightly vary the Sr and Ca concentrations. Resputtering was present in the film which had a -5 V bias, the -30 V bias also showed a reduced elemental composition, while the -20 V bias produced the best composition. The results of this study show the fickle nature of depositing films from multi-element oxide targets, and the need to optimize conditions to produce the desired film.

**Y39 6 Large Single Crystal growth of Bi-2212 superconducting oxide** GENDA GU, GANGYONG XU, *Condensed Matter Physics and Materials Science, BNL, USA* JOHN TRANQUADA, *BNL* A floating zone method was used to study the effects of the growth velocity and starting composition of the feed rod on the crystal growth behaviour of Bi-2212 superconducting materials. It shows that a necessary condition for large single crystal growth is that the solid-liquid interface of a rod maintains a planar interface during crystal growth. The planar solid-liquid interface tends to break down into the cellular interface while increasing the velocity from 0.3 mm/h, or while deviating from the optimum starting composition of the feed rod $Bi_{2.1}Sr_{1.9}Ca_{1.0}Cu_{2.0}O_x$. The single crystals up to $100_*7_*3.8$ mm$^3$along the *a*-, the *b*- and the *c*-axis have been grown in a itΦ7mm rod with optimum growth conditions. The single crystals of up to 50*7*3.8 mm$^3$ have been picked up from the cut section of the as-grown rod. The neutron measurements show that the quality of the single crystals is good. The superconducting transition temperature $Tc_{onset}$ by SQUID is 91K for as-grown crystals.

**Y39 7 A Search for Novel Superconductors: A Study of the Lithium-Boron System** MICHAEL BLEIWEISS, *Naval Academy Preparatory School, Newport, RI* JAFAR AMIRZADEH, *Morris College, Sumter, SC* MING YIN, *Benedict College, Columbia, SC* DOUGLAS KIRVEN, *Sigma-K Corp, Durham, NC* ED SHARP, TIMIR DATTA, *University of South Carolina, Columbia, SC* A rapid solid-state reaction was used to synthesize a class of novel lithium-boron based ceramics. The resulting multiphase ceramic materials were investigated by XRD, electron microscopy (SEM) and EDAX. Efforts were taken to avoid contamination by magnesium diboride; $MgB_2$ was not detectable by XRD or EDAX. A number of the samples were electrically conducting and some were found to be superconducting in the 30-40 K range. Superconducting transitions were confirmed by SQUID magnetometry. Efforts are in progress to identify and isolate the superconducting phase. Influence of preparation on the electrical conductivity and superconductivity will be reported.

**9:24**

**Y39 8 A Novel Method to Detect Oxygen Vacancies in the Grain Boundaries of High-Tc Superconductors*** TAKAHIRO TOMITA, JAMES S. SCHILLING, *Department of Physics, Washington University, St. Louis, MO* LIHUA CHEN, BOYD W. VEAL, HELMUT CLAUS, *Materials Science Division, Argonne National Labs* A new diagnostic method is introduced (pressure-induced $J_c$ relaxation) which is capable of detecting oxygen vacancies in the grain boundaries of oxide superconductors. A series of bicrystalline rings of $YBa_2Cu_3O_x$ containing single [001]-tilt grain boundaries with mismatch angles from 0 to 31 degrees are studied. Even for samples with nearly optimal doping in the bulk, a significant oxygen deficiency in the grain boundary region is revealed. In addition, compressing the grain boundary region is found to lead to a considerable enhancement of the critical current density $J_c$.

**Y39 9 Crystal Growth and Electrical Transport Properties of Low Dimensional Nb-Se Superconducting Phases** CEDOMIR PETROVIC, *Condensed Matter Physics, Brookhaven National Laboratory, Upton NY 11973* RONGWEI HU, *Physics Department, Brown University, Providence RI 02912* VESNA MITROVIC, *Physics Department Brown University Providence RI 02912* Single crystals of $NbSe_2$ and $Nb_2Se_3$ have been grown by molten metallic flux technique. Powder x-ray diffraction confirms phase purity. Superconducting transitions have been observed for both materials. Electronic transport properties and comparison with samples made with conventional chemical vapor transport method will be discussed.

**9:48**

**Y39 10 Epitaxial thin films of the superconducting spinel oxide $LiTi_2O_4$** RAJESH CHOPDEKAR, *Applied Physics, Cornell University* YURI SUZUKI, *Materials Science, UC Berkeley* Lithium titanate is the only superconducting spinel oxide documented in literature. Related oxide spinels[1] such as the heavy fermion system $LiV_2O_4$ and charge-ordered $LiMn_2O_4$ indicate that electron correlations are strong in these systems. We have fabricated epitaxial films of $LiTi_2O_4$ on $MgAl_2O_4$ and MgO single crystalline substrates to explore such behavior in thin film form. Atomic force microscopy indicates $<$ 1nm RMS surface roughness, and 2- and 4-circle x-ray diffraction confirms film epitaxy. Films on $MgAl_2O_4$ have a critical temperature $T_c$ of up to 11.3K with a resistivity transition width of 0.25K, while films on MgO have lower $T_c$ with broader transitions. Magnetization vs. magnetic field of a zero-field cooled sample shows Meissner shielding consistent with Type II superconductors. Such films can be used in spin-polarization measurements of complex oxide half-metallic thin films, as well as fundamental studies of the effect of epitaxial strain, microstructure, and cation disorder/substitution on the superconducting properties of $LiTi_2O_4$. [1] M. Lauer et al, Phys Rev B 69, 075117 (2004).

**10:00**

**Y39 11 The annealing process and its relationship to superconductivity in the electron-doped superconductors** HYE JUNG KANG, *NIST, University of MD* PENGCHENG DAI, *University of Tennessee, ORNL* BRANTON CAMPBELL, *Brigham Young University* STEPHAN ROSENKRANZ, PETER CHUPUS, *ANL* SHILIANG LI, *University of Tennessee* Y. KURITA, SEIKI KOMIYA, YOICHI ANDO, *CRIEPI, Japan* Superconductivity in the high transition temperature superconductors can be achieved when the antiferromagnetic insulating parent compounds are doped with holes or electrons. The discovery of the electron-doped superconductors has obtained special attention because of the symmetry with doped charge carriers. The electron-doped superconductors can provide important clues in the mechanism of high temperature superconductivity by finding fundamental features seen in the hole-doped superconductors. Unlike hole-doped superconductors, the electron-doped compounds require the annealing process to achieve superconductivity. The role and effects of the annealing process on superconductivity have been one of the unresolved problems in the electron-doped superconductors. To investigate how the annealing process is associated to superconductivity, we performed X-ray measurement on an as-grown, an annealed superconducting, an oxygenated nonsuperconducting, and a reannealed Pr0.88LaCe0.12CuO4 samples.

**10:12**

**Y39 12 Pressure Dependence Transport Studies of the Possible Charge Kondo Effect in Tl-doped PbTe** YOSUKE KUROSAKI, JUN SHINAGAWA, *Dept. Physics and Astronomy, UCLA* YANA MATSUSHITA, *Dept. Materials Science and Engineering, Stanford Univ.* TED GEBALLE, IAN FISHER, *Dept. Applied Physics, Stanford Univ.* STUART BROWN, *Dept. Physics and Astronomy, UCLA* $Pb_{1-x}Tl_xTe$ is noteworthy for a high superconducting transition temperature relative to carrier concentration, as well as normal state properties consistent with a charge-Kondo effect. Recent experiments also demonstrate that the onset of an observable superconducting $T_c$ with Tl concentration at x$\sim$ 0.3% coincides with features characteristic of charge Kondo [1], including $d\rho/dT < 0$ at low temperatures and an unusual linear variation of the resistivity $\rho(T)=\rho_0+AT$ at higher temperatures. Together, these observations are consistent with an association between the two phenomena [2]. We report the effect of applied pressures up to P$\sim$ 1.5GPa on $\rho(T)$, $T_c$, and the Hall number $p_H \equiv R_H^{-1}$ for x= 0.3%, 0.8%, and 1.3%. $T_c$ is reduced sharply with pressure, $dT_c/dP$=400-500mK/GPa as the low temperature Kondo- like upturn in $\rho(T)$ is weakened. Also, $dA/dP < 0$ and $dp_H/dP > 0$. These observations are discussed in the context of the proposed charge-Kondo model for $Pb_{1-x}Tl_xTe$. [1] Y. Matsushita, H. Bluhm, T.H. Geballe and I.R. Fisher, Phys.Rev.Lett. 94, 157002(2005).[2] M. Dzero and J. Schmalian, Phys.Rev.Lett. 94, 157003 (2005). This work is supported by NSF frant DMR-0520552.

**Y39 13 Superconductivity and anomalous transport in PbTe:Tl** ELIHU ABRAHAMS, PIERS COLEMAN, *Rutgers University* MAXIM DZERO, JOERG SCHMALIAN, *Iowa State University/Ames Lab* We analyze the transport properties of Tl-doped PbTe. We show that upon doping, Tl has degenerate valence states 1+ and 3+. Quantum valence fluctuations lead to the superconductivity and a charge Kondo effect at low-temperatures and cause linear temperature dependence of resistivity at high temperatures.

**10:36**

**Y39 14 Superconducting Properties of Tl-Doped PbTe** Y. MATSUSHITA, P. A. WIANECKI, *Department of Materials Science and Engineering, Stanford University* T. H. GEBALLE, I. R. FISHER, *Department of Applied Physics, Stanford University* R. J. ORMENO, P. J. BAKER, C. E. GOUGH, *School of Physics and Astronomy, University of Birmingham* Tl-doped PbTe ($Pb_{1-x}Tl_xTe$) has a remarkably high $T_c$ given its relatively low carrier concentration and also exhibits unusual electronic properties [1–2]. For Tl concentrations $x$ beyond a critical value $x_c \sim 0.3\%$, it is observed to superconduct with $T_c$ rapidly increasing with $x$ up to a maximum doping of 1.5% and a maximum $T_c$ of 1.5 K. Here we present results of heat capacity, transport, and microwave conductivity experiments for single crystal samples. We extract estimates of superconducting parameters including $\Delta C/\gamma T_c$, $H_{c2}$, coherence length, and penetration depth. For the highest Tl concentrations, we find that the heat capacity anomaly and the temperature dependence of the superfluid density are consistent with BCS predictions and that the material is in the dirty limit. [1] Y. Matsushita, H. Bluhm, T. H. Geballe, and I. R. Fisher, Phys. Rev. Lett. **94**, 157002 (2005). [2] M. Dzero and J. Schmalian, Phys. Rev. Lett. **94**, 157003 (2005).

**Y40 1 Landau-Zener interferometry in a Cooper pair box** MIKA SILLANPÄÄ, TEIJO LEHTINEN, ANTTI PAILA, *Low Temperature Laboratory, Helsinki University of Technology, Finland* YURIY MAKHLIN, *The Landau Institute of Theoretical Physics, Moscow, Russia* PERTTI HAKONEN, *Low Temperature Laboratory, Helsinki University of Technology, Finland* Quantum-mechanical systems having two crossing energy levels are ubiquitous in nature. The rate $v = d(E_1 - E_0)/dt$ at which such levels in a driven system approach each other determines the probability $P_{LZ}$ of a Landau-Zener (LZ) tunneling between them. The traditional treatment of the LZ process, however, ignores quantum-mechanical interference. Here we report an observation of phase-sensitive interference between consecutive LZ tunneling attempts in an artificial two-state system, a superconducting charge qubit. We interpret the experiment in terms of a multi-pass analog to the optical Mach- Zehnder interferometer: The beam splitting occurs by LZ tunneling at the charge degeneracy, while the arms of the Mach- Zehnder interferometer in energy space are represented by the ground and excited state. In accord with theory, we observe constructive interference when the Stokes phase $\phi_S$ picked up during the LZ interaction, and the dynamical phase of one drive period $\phi = \int(E_1 - E_0)dt$ satisfy the condition: $(\phi - 2\phi_S) = m \cdot 2\pi$. Our LZ interferometer can be used as a high-resolution detector for phase and charge owing to interferometric sensitivity- enhancement.

**Y40 2 Measuring the environmental impedance of the Cooper-pair box** BENJAMIN TUREK, JOHANNES MAJER, JOHN TEUFEL, *Yale University* AASHISH CLERK, *McGill University* STEVEN GIRVIN, ROBERT SCHOELKOPF, *Yale University* The Cooper-pair box qubit measured by the SET can have long decoherence times that are limited by the quantum noise of the environment. Qubits fabricated at Yale are designed with 50 ohm transmission lines that control this environmental impedance to very high frequencies. We use the AC Josephson effect of a hysteretic DC-Squid to measure the frequency dependence of this impedance. At frequencies where the real part of the environmental impedance is large, the AC Josephson effect causes the small-junction analogue of self-induced Shapiro steps in the IV curves of a DC Squid [T. Holst et al., PRL 73, 3455 (1994)]. We determine that the environmental impedance of our qubit is well behaved at frequencies less than 20 GHz.

**8:24**

**Y40 3 Anomalously low tunneling escape rates from the excited states of an inductively−isolated current−biased Josephson junction phase qubit*** R.M. LEWIS, T.A. PALOMAKI, HANHEE PAIK, S.K. DUTTA, A. PRZYBYSZ, B.K. COOPER, J.R. ANDERSON, A.J. DRAGT, C.J. LOBB, F.C. WELLSTOOD, *University of Maryland* We present measurements of an inductively-isolated current-biased Nb/AlOx/Nb Josephson junction quantum bit at 20 mK. Density matrix fits of Rabi oscillations in our system suggest that the tunneling rate ($\Gamma_1$) from the first excited state is an order of magnitude lower than expected from a single current-biased junction. Furthermore, measurements of the energy relaxation time, $T_1$, through both pulse/decay and thermal population[1] techniques only agree if $\Gamma_1$ is approximately an order of magnitude lower than our single junction model predicts. To test for low $\Gamma_1$, we use a fast-ramp technique ($\alpha = d(ln\Gamma)/dt > 1/T_1$) to directly measure $\Gamma_1$. We propose that an increase in the Josephson inductance of the qubit junction when in the excited state causes this effective reduction in $\Gamma_1$.

*Supported by NSF grant #EIA0323261, the NSA, and the Center for Superconductivity Research

**Y40 4 Variable coupling between the inductively isolated current-biased Josephson junction qubit and the current bias leads*** HANHEE PAIK, S. K. DUTTA, R. M. LEWIS, R. C. RAMOS, H. XU, T. A. PALOMAKI, B. K. COOPER, A. J. PRZYBYSZ, A. J. DRAGT, J. R. ANDERSON, C. J. LOBB, F. C. WELLSTOOD, *Center for superconductivity Research, Department of Physics, University of Maryland* We examined the behavior of inductively isolated Josephson junction qubits in which the coupling to the bias leads could be varied in situ. The variable coupling was achieved by using a second Josephson junction and an inductor that act as an inductive current divider. The coupling between the current bias leads and the qubit was varied by changing the current through the second junction, altering its Josephson inductance. We measured the tunneling escape rates of Al/Al$O_x$/Al and Nb/Al$O_x$/Nb junctions with continuous or pulsed microwave power, showing the allowed energy transitions and coherent Rabi oscillations. We found that $T_2$, $T_2^*$ and $T_1$ did not change significantly as the coupling to the current bias leads was varied.

**8:48**

**Y40 5 Analysis of Rabi Oscillations of a Josephson Phase Qubit*** S. K. DUTTA, H. XU, FREDERICK W. STRAUCH, PHILIP R. JOHNSON, R. C. RAMOS, HANHEE PAIK, T. A. PALOMAKI, R. M. LEWIS, J. R. ANDERSON, ALEX J. DRAGT, C. J. LOBB, F. C. WELLSTOOD, *Department of Physics, University of Maryland* We have experimentally studied asymmetric Nb/AlOx/Nb dc SQUID qubits at 25 mK. The two lowest metastable levels localized within a single well of the complex two-dimensional potential of the device can serve as qubit states, if they are not unduly perturbed by resonant coupling to higher states of the full potential. Rabi oscillations between the qubit states can be driven with a microwave bias current. State readout is performed by measuring the tunneling rate from all energy levels with non-zero occupation probability to the finite voltage state. To interpret the results of our Rabi oscillation measurements, we have used a multi-level density matrix simulation to extract the populations of the individual quantum states from this total rate. We can then calculate the visibility of the oscillations and determine the effects of the higher levels and multi-photon transitions.

**Y40 6 Two Coupled Inductively-Isolated Josephson Junction Qubits*** TAUNO PALOMAKI, SUDEEP DUTTA, HANHEE PAIK, RUPERT LEWIS, ROBERTO RAMOS, HUIZHONG XU, BOB ANDERSON, CHRIS LOBB, FRED WELLSTOOD, *University of Maryland* We report experimental measurements on coherent quantum oscillations and entangled macroscopic quantum states in two capacitively-coupled inductively-isolated Nb/$Al_2O_3$/Nb Josephson qubits at 25mK. The interaction between the two qubits is controlled by tuning the energy level spacings of the junctions using the bias current and applied flux. We discuss transitions to various states of the coupled device, show Rabi oscillations, and analyze the spectroscopy of the system when the junctions are in and out of resonance with each other.

**9:12**

**Y40 7 Flux Noise in an Inductively Isolated Josephson Junction Qubit*** B. K. COOPER, HANHEE PAIK, R. M. LEWIS, S. K. DUTTA, T. A. PALOMAKI, A. J. PRZYBYSZ, J. R. ANDERSON, ALEX J. DRAGT, C. J. LOBB, F. C. WELLSTOOD, *Department of Physics, University of Maryland* Martinis et al. [1] first proposed a technique for inductively isolating a Josephson junction qubit from the bias leads. It involves using one junction of a dc SQUID as a qubit, and the SQUID inductance and second junction of the SQUID as an inductance divider. This arrangement allows for isolation from current bias lines but potentially introduces greater sensitivity to flux noise. By introducing counter-wound inductors on the qubit arm of the SQUID, we can reduce spatially uniform flux noise. We compare experimental coherence

times for a $Nb/Al_2O_3/Nb$ qubit in such gradiometer designs to similar devices lacking the counterwound inductors. No significant difference is seen, suggesting that uniform flux noise is not the major source of decoherence in our system. [1] J. M. Martinis et al., PRL **89**, 117901

**9:24**

**Y40 8 Measurement of Microwave Resonators for Improved $T_1$ in Josephson Qubits** MATTHEW NEELEY, M. ANSMANN, R. BIALCZAK, N. KATZ, E. LUCERO, R. McDERMOTT, M. STEFFEN, E. WEIG, A. CLELAND, J. M. MARTINIS, *UC Santa Barbara* To realize a quantum computer with Josephson qubits, the energy relaxation time $T_1$ must be increased by an order of magnitude or more over current qubits. One of the dominant sources of energy decoherence is dielectric loss due to two-level defect states in the Josephson junction and in wiring cross-overs. Easily-fabricated microwave resonators provide a convenient way to measure the dielectric loss of candidate materials before incorporating them into qubits. We describe the measurement process and the results for several candidate dielectric materials. The loss tangents have been observed to vary with applied magnetic field. This variation is explained by a simple model of flux vortex trapping in the type I superconducting aluminum films of the resonators.

**9:36**

**Y40 9 High Q Dielectrics for Josephson Phase Qubits** E. M. WEIG, M. ANSMANN, R. BIALCZAK, N. KATZ, E. LUCERO, R. McDERMOTT, M. NEELEY, M. STEFFEN, J. M. MARTINIS, A. N. CLELAND, *California NanoSystems Institute & Department of Physics, UC Santa Barbara* Dielectric loss in the bulk insulating material surrounding a superconducting phase qubit has recently attracted attention as a major source of decoherence. Dissipation arises from the excitation of a bath of two-level defects that is unsaturated in the limit of low microwave power and low temperature. This gives rise to much lower intrinsic Q factors than expected from material characterization typically performed in the saturated higher power or temperature regime. The density of these two-level systems in the insulator can be distinctively reduced by carefully choosing and engineering the dielectric material. We have investigated LC resonators fabricated using various amorphous dielectrics ranging from silicon dioxide or silicon nitride to silicon hydride (a-Si:H). The intrinsic Q factors of the materials have been measured at microwave frequencies in the unsaturated regime. The data demonstrates that by proper choice of material the dielectric loss tangent can be dramatically reduced, thus allowing for long coherence time phase qubits.

**9:48**

**Y40 10 Fabrication and Testing of AlN Josephson Junction Qubits** RADOSLAW BIALCZAK, *University of California, Santa Barbara* MARKUS ANSMANN, NADAV KATZ, ERIK LUCERO, ROBERT McDERMOTT, MATTHEW NEELEY, MATTHIAS STEFFEN, EWA WEIG, ANDREW CLELAND, JOHN MARTINIS, Recently, it has been shown that a major source of decoherence in Josephson junction (JJ) qubits comes from coupling to two-level systems (TLS) in the dielectric materials used to construct these qubits. These TLS's result from defects in the dielectric material. In our previous work we have shown that the energy relaxation times of our JJ phase qubits improve 20-fold when we substitute SiO2 with SiN as the dielectric material used for cross-over wiring. This shows that nitride based dielectrics might be less prone to defects and suggests that the next logical step would be to replace the Al2O3 tunnel barrier dielectric of the JJ with AlN. We have used atomic nitrogen to successfully fabricate a JJ phase qubit with AlN as the JJ tunnel barrier material. Through spectroscopy measurements, we have found that qubits made with AlN as the tunnel barrier material have only slightly lower concentrations of defects compared with previously studied qubits made with Al2O3 grown by natural oxidation. Also, the measured T1 times for these AlN qubits were low ( $\sim$ 15ns). This agrees with theoretical predictions of Ioffe et al. which state that piezoelectric materials, such as AlN, might have other loss mechanisms due to phonon radiation.

**10:00**

**Y40 11 Evolution and decay of a superconducting Josephson junction qubit due to partial measurement** N. KATZ, M. ANSMANN, R. BIALCZEK, E. LUCERO, R. McDERMOTT, M. NEELEY, M. STEFFEN, E. WEIG, A. CLELAND, J. M. MARTINIS, *California NanoSystems Institute and Physics Dept., University of California, Santa Barbara* A. KOROTKOV, *Electrical Engineering Dept., University of California, Riverside* Superconducting Josephson phase qubits have been shown to be a promising candidate for scalable quantum computing. In many such quantum computing algorithms, partial measurement of the quantum state is used to project the system into a required subspace. We experimentally study the effect of a partial measurement on our Josephson phase qubit using state tomography and high fidelity measurement capabilities. We also explore related multi-photon effects which appear naturally in such a system during state preparation, evolution and measurement.

**10:12**

**Y40 12 Quantized Rabi oscillation observed in the superconducting flux qubit LC-harmonic oscillator system** K. SEMBA, J. JOHANSSON, S. SAITO, *NTT Basic Research Labs, NTT Corp. and CREST Japan Science and Technology Agency* T. MENO, *NTT Advanced Technology* H. NAKANO, *NTT Basic Research Labs, NTT Corp. and CREST JSTA* M. UEDA, *NTT Basic Research Labs, NTT Corp., CREST JSTA, Dept. of Physics, Tokyo Inst. of Tech.* H. TAKAYANAGI, *NTT Basic Research Labs, NTT Corp. and CREST JSTA* Superconducting circuit containing Josephson junctions is one of the promising candidates as a quantum bit (qubit) which is an essential building block for quantum computation. A flux qubit is represented by energetically lowest two collective states of macroscopic numbers of Cooper pairs which are linear combination of clockwise and counterclockwise persistent-current states. By replacing an atom with a flux qubit (artificial atom), and a high-Q cavity with an LC-circuit, quantum optics type experiments are possible on a superconductor chip. We have observed, for the first time, the vacuum Rabi oscillations in a superconducting flux qubit LC-oscillator coupled system [1]. We have also obtained evidence of level quantization of the LC circuit by observing the change in quantum oscillation frequency when the LC circuit was not initially in the vacuum state. Sharing a single superconducting LC-circuit with many flux qubits as a quantum information bus, spatially separated multiple qubits can be controlled by a set of microwave pulses. [1] J. Johansson et al., arXiv:cond-mat/0510457, http://www.brl.ntt.co.jp/group/shitsuryo-g/index.html

**10:24**

**Y40 13 Quantum Computing Architectural Design** JACOB WEST, GEOFFREY SIMMS, MARK GYURE, *HRL Laboratories, LLC. Malibu, CA* Large scale quantum computers will invariably require scalable architectures in addition to high fidelity gate operations. Quantum computing architectural design (QCAD) addresses the problems of actually implementing fault-tolerant algorithms given physical and architectural constraints beyond those of basic gate-level fidelity. Here we introduce a unified framework for QCAD that enables the scientist to study the impact of varying error correction schemes, architectural parameters including layout and scheduling, and physical operations native to a given architecture. Our software package, aptly named QCAD, provides compilation, manipulation/transformation, multi-paradigm simulation, and visualization tools. We demonstrate various features of the QCAD software package through several examples.

**10:36**

**Y40 14 Threshold calculation and optimization for measurementless quantum error correction** GEOFFREY SIMMS, MARK GYURE, JACOB WEST, *HRL Laboratories, LLC. Malibu, California* General-purpose quantum computing will rely on measurement as a primitive operation, but the operations of measurement and classical feed-forward are not necessary to perform certain useful computations, including quantum error correction. Measurementless quantum computation is appealing because it reduces the classical control system to an automaton, having no conditional operations. Measurementless, fault-tolerant quantum error correction (MFTQEC) of Calderbank-Shor-Steane (CSS) encoded logical qubits requires logical zero states to be prepared with high fidelity as an initial step, and this logical zero preparation has a threshold of its own, analogous to, but not identical to, the threshold of the entire error correction algorithm. In this talk, we present the results of mapping the MFTQEC algorithm onto a specific semiconductor-based qubit system using the Quantum Computing Architectural Design (QCAD) program, discussed in another talk in this session. The algorithm is translated from the set of ''design gates'' to the set of accessible ''physical gates,'' and the resulting quantum circuit is optimized to improve the threshold. Limited 2-dimensional connectivity is assumed, making this well suited to the ''enhancement mode'' quantum dot qubits described in other talks in this session.

**10:48**

**Y40 15 Shift register in a SQUID architecture with untunable couplings*** PREETHIKA GAGNEBIN, STEVEN SKINNER, *Department of Electrical and Computer Engineering, Wichita State University* ELIZABETH BEHRMAN, *Department of Physics, Wichita State University* JAMES STECK, *Department of Aerospace Engineering, Wichita State University* A scheme to implement a qubit shift register in a one-dimensional series of superconducting quantum interference devices (SQUIDs), using a sequence of pulsed biases, is described. Each SQUID is coupled to its neighbors through an untunable coupling parameter. The only variable parameter of the system is the bias on each SQUID, which is pulsed low during a shift operation. Our design requires only two bias control signals for any size of shift register, with an additional one on the output qubit to shift out the data. The shift register operation is realized by copying the state of one qubit onto another, in the direction of the shift, during the bias pulse. As the no-cloning theorem prohibits the cloning of an unknown arbitrary quantum state, this device works as a classical shift register or, in other words, a binary wire. We show here how to find the time duration of the bias pulse and the minimum value of the bias during the pulse given the fixed physical parameters of the system.

## SESSION Y45: MAGNETIC PHASE TRANSITIONS

**Friday Morning, 17 March 2006**
**348, Baltimore Convention Center at 8:00**
**Julie Borchers, National Institute of Standards and Technology Center for Neutron Research, presiding**

**8:00**

**Y45 1 Discovery of remarkably high magnetic ordering temperatures in dilute rare earth intermetallic compounds** S. JIA, G.D. SAMOLYUK, NI NI, E-D. MUN, S.L. BUD'KO, P.C. CANFIELD, *Ames Laboratory and Dept. of Physics and Astronomy, Iowa State University* Dilute, rare earth intermetallic compounds are ordered structures in which the rare earth comprises less than 5% atomic of the compound, but still fully occupies a unique crystallographic site. When none of the other elements are moment bearing, it is generally anticipated that such a compound will have magnetic ordering temperatures near 10 K for the R = Gd member of the series and systematically lower temperatures for heavier R members. In this talk we will present a series of dilute rare earth intermetallic compounds that have ferromagnetic ordering temperatures that range from $T_C \sim 90$ K for R = Gd to $T_C \sim 5$ K for R = Tm. The origin of this high ordering temperature as well as systematic trends across the series will be discussed.

**8:12**

**Y45 2 The effects of pressure and chemical substitution on the transition temperature and groundstate of Gd-based dilute rare earth intermetallic compounds** P.C. CANFIELD, S. JIA, G.M. SAMOLYUK, S.L. BUD'KO, *Ames Laboratory and Dept. of Physics and Astronomy, Iowa State University* Dilute, rare earth intermetallic compounds are ordered structures in which the rare earth comprises less than 5% atomic of the compound, but still fully occupies a unique crystallographic site. We have investigated a family of Gd-based, ternary, dilute, rare earth intermetallic compounds in an attempt to understand the remarkably high ferromagnetic ordering found for some of the members ($T_C$ as high as 90 K). By studies of the thermodynamic and transport properties as a function of temperature, field and hydrostatic pressure and combining these results with band-structure calculations we have been able to determine that some of these compounds have an enhanced DOS at the Fermi level that may be correlated with the enhanced ordering temperatures.

**8:24**

**Y45 3 Paramagnetic Semiconductor to itinerant Ferromagnet in $Fe_{1-x}Co_xS_2$** SONG GUO, *Dept. of Physics and Astronomy, Louisiana State University* JOHN DITUSA, *Dept. of Physics and Astronomy, Louisiana State University* DAVID YOUNG, *Dept. of Physics and Astronomy, Louisiana State University* ROBIN MACALUSO, *Dept. of Chemistry, Louisiana State University* DANA BROWNE, *Dept. of Physics and Astronomy, Louisiana State University* NATHAN HENDERSON, *Dept. of Chemistry, Louisiana State University* JULIA CHAN, *Dept. of Chemistry, Louisiana State University* Carrier doping of ''fool's gold,'' the paramagnetic insulator $FeS_2$ by partial substitution of Co for Fe, results in an insulator-to-metal transition at $x \leqslant 0.001$. Magnetization and susceptibility measurements for samples with Co substitution beyond $x0.01$ reveal the emergence of a highly itinerant ferromagnet with no discontinuous changes with $x$, field, or temperature ($T$) suggesting either a continuous crossover or quantum phase transition to ferromagnetism. For $x \leqslant 0.01$ and low-$T$, the conductivity decreases with smaller $T$ and displays a positive magnetoconductance. Samples which order magnetically show similar magnetoconductance, but with a minimum in conductivity near $T_c$. We conclude that either Kondo or magnetic polaron effects are responsible for these low-$T$ anomalies. Specific heat measurements display extraordinarily large carrier masses that diverge logarithmically or with a small power law at low-$T$ close to the ferromagnetic critical concentration, similar to the behavior near quantum critical points.

**8:36**

**Y45 4 Ferromagnetic Transition in Heusler Alloys** ANKE HUSMANN, *Toshiba Research Europe Ltd* MARK C. HICKEY,* *University of Cambridge* MINHYEA LEE, *Princeton University* TOSHIBA RESEARCH EUROPE LTD COLLABORATION, UNIVERSITY OF CAMBRIDGE COLLABORATION, PRINCETON UNIVERSITY COLLABORATION, The transition from a magnetically disordered (paramagnetic) to a magnetically ordered (ferromagnetic) state at finite temperature in zero magnetic field has long been regarded as one of *the* text book examples for a second order phase transition. However, this mean field Weiss model leaves out some of the physics that can become crucial for itinerant magnets when approaching the transition temperature. $Co_2TiSn$ and $Co_2CrAl$ are two Heusler alloys with Curie temperatures just above room temperature. Theoretical band structure calculations, ours as well as by others, predict them to be close to half metals. Magnetisation data as a function of temperature and magnetic field show deviations from the mean field Weiss model which we argue are due to band structure properties.

*also Toshiba Research Europe Ltd

**8:48**

**Y45 5 Field and temperature dependence of the first order antiferromagnetic to ferromagnetic phase transition in FeRh thin films** STEFAN MAAT, JAN-ULRICH THIELE, ERIC E. FULLERTON, *Hitachi Global Storage Technologies* Chemically ordered FeRh exhibits a first order antiferromagnetic (AF) to a ferromagnetic (F) phase transition upon heating from room temperature to above a transition temperature of approximately 370 K. This transition is accompanied by a volume increase of $\sim$ 1%, a change in resistivity, and a large change in entropy. The phase transition occurs within a few ps allowing it to be used in thermal assisted recording. For example, it was recently proposed to use exchange coupled FeRh/FePt bilayers for thermally assisted magnetic recording media. Here we studied the thermodynamics of the transition in thin FeRh films epitaxially grown onto MgO and sapphire substrates. A shift to lower transition temperatures is observed in external magnetic fields and supercooling is easily observed by cycling either the temperature or the magnetic field. A temperature-field phase diagram was constructed revealing a linear -8 K/ Tesla temperature-field relationship. The observed field dependence of the shift in transition temperature is modeled with an Ising spin type model utilizing a mean field approach. The computational results are in excellent agreement with the experimental data.

**9:00**

**Y45 6 Vector-magnetometry determination of magnetization processes in $Pr_6Ni_2Si_3$ and $Nd_6Ni_2Si_3$*** Y. JANSSEN, K. W. DENNIS, R. PROZOROV, P. C. CANFIELD, R. W. McCALLUM, *Ames Laboratory, Iowa State University, Ames, IA 50011* Hexagonal $Pr_6Ni_2Si_3$ and $Nd_6Ni_2Si_3$ order magnetically at 40 and 85 K, repectively. At 5 K, the magnetic order of both compounds appears to have a ferromagnetic component parallel to the hexagonal c-axis, and an antiferromagnetic component perpendicular to it. In both compounds, at 5 K and in a magnetic field of $\sim$ 2-3 T, applied perpendicular to the c-axis, a magnetic transition occurs. Using a QD-MPMS equipped with a transverse pickup coil system, we have studied the behavior of the magnetization vector in single-crystal samples during this transition. In both cases, the magnetization vector becomes anomalously itlonger during the transition. This indicates the transition may be related to an antiferromagnetic component of the magnetic order, which is consistent with the magnetic order having both antiferro and ferromagnetic components.

*Ames Laboratory is operated for the US Department of Energy by Iowa State University under contract number W-7405-ENG-82.

**9:12**

**Y45 7 Observation of two distinct energy scales in the magnetization measurements of the anisotropic antiferromagnet TmAgGe** ANA LIMA, *NHMFL - LANL* PAUL GODDARD, *Clarendon Laboratory, Oxford University, Oxford, UK* JOHN SINGLETON, *NHMFL - LANL* EMILIA MOROSAN, SERGEY BUD'KO, PAUL CANFIELD, *Dept. of Phys. & Astronomy, ISU and Ames Laboratory* TmAgGe is an antiferromagnet ($T_N = 4.2$ K) that crystallizes in a variant of the hexagonal $Fe_2P$ structure (three Tm atoms per unit cell). We have studied the magnetization of the TmAgGe single crystals in fields $\mu_0 H$ of up to 65 T as a function of the field orientation and the temperature $T$. With **H** in the basal **ab**-plane, a number of metamagnetic transitions are observed for $\mu_0 H < 5$ T and $T < T_N$. However, when $\mathbf{H}||\mathbf{c}$, three steps in the magnetization occur between 30 and 35 T, persisting to $T \cong 60$ K. On tilting **H** away from **c,** both sets of features (high-field steps and low-field metamagnetism transitions) are seen, showing that they arise from two distinct mechanisms. The dependence of the high-field steps on $T$ and field orientation suggests that they are associated with crystalline electric field (CEF) level crossing; the CEF confines the moments to the **ab**-plane. By contrast, it is the rearrangement of the moments within the basal plane that gives to the low-field metamagnetic transitions. To the best of our knowledge, TmAgGe is the first intermetallic system in which these two energy scales (CEF and in-plane exchange) can be unambiguously distinguished in this way.

**9:24**

**Y45 8 Anomalous Magnetic Properties near the Spin-Flop Bicritical Point in $Mn_2AS_4$ ($A$ = Si and Ge)** KENYA OHGUSHI, YUTAKA UEDA, *ISSP, Univ. of Tokyo* The magnetic properties of the single crystalline $Mn_2AS_4$ ($A$ = Si and Ge) with an olivine structure, which are the uniaxially anisotropic antiferromagnets (the $b$-axis as an easy axis), were investigated. Near the Néel temperature, both compounds exhibit the contrastive magnetic responses along the $c$-axis, namely, the spontaneous weak ferromagnetism in $A$ = Si and the significant enhancement of the differential susceptibility (itdM/dH) under the small magnetic field in $A$ = Ge. When $A$ = Ge, we also observed the evolution of itdM/dH along the $a$-axis at low temperatures. We discuss these phenomena on the basis of the magnetic field-temperature ($H - T$) phase diagram with the spin-flop bicritical point ($H_{BP}$, $T_{BP}$). The role of the thermal or quantum fluctuation was stressed. (Ref.) K. Ohgushi and Y. Ueda, Phys. Rev. Lett. **95**, 217202 (2005)

**9:36**

**Y45 9 Composition dependent properties of mixed magnetic Fe/Ni dichloride dihydrate*** G.C. DEFOTIS, M.G. KIM, D.G. CHAN, Z.D. REED, A.T. HOPKINSON, Y. MATSUYAMA, *College of William and Mary* This mixed magnet is composed of two approximate 3D-Ising antiferromagnets ordering at 22.3 K (Fe component) and 7.3 K (Ni component). The pure substances also display metamagnetic transitions at low temperature near 39 kG (Fe) and 19 kG (Ni). Ferromagnetically coupled metal-dichloride-metal . . . chemical and structural chains occur in each component, with predominantly antiferromagnetic interchain interactions. Homogeneous mixtures have been obtained and examined by dc susceptibility and magnetization measurements over the entire composition range. Curie and Weiss constants are obtained from fits to high temperature data. In many mixtures two magnetic transitions at different temperatures are observed. In several mixtures marked nonlinearities in magnetization vs field appear, with signficant temperature dependence, and suggestive of metamagnetic transitions with associated hysteresis. Most interestingly, the inferred transition fields are lower than those of either component. The overall behavior can be compared with that in the previously studied and closely related Co/Ni mixed system. Some similarities appear, but also notable differences.

**9:48**

**Y45 10 Hysteresis effect in $^{55}Mn$ NMR of $TbMn_2O_5$** SEUNG-HO BAEK, ANDREW HARTER, ARNEIL REYES, *National High Magnetic Field Lab* SANG-WOOK CHEONG, N. HUR, *Rutgers University* $^{55}Mn$ zero-field NMR has been performed on antiferromagnetic magnetoelectric multiferroic compound $TbMnO_5$ from 60 K to 1.8 K. The broad and complex spectrum is distributed between 240 MHz and 280 MHz implying a superposition of NMR lines arising from the several inequivalent Mn ions due to the amplitude-modulated spin structure. When external perturbing field up to 3 T is applied, a dramatic change in the first moment and the signal enhancement is observed which are hysteretic in nature. The behavior is attributed to antiferromagnetic domain walls which are coupled to ferroelectric domains similar to that observed in weakly ferromagnetic $\alpha$-$Fe_2O_3$. The nature of strong coupling of magnetic and electric ordering and its subsequent effect on its multiferroic behavior are discussed.

**10:00**

**Y45 11 Magnetic Field Induced Phases in the Quantum Antiferromagnet $Cs_2CuCl_4$ as revealed by NMR.** M.-A. VACHON, V.F. MITROVIC, O. MA, J.B. MARSTON, *Brown University* A.P. REYES, P. KUHNS, *NHMFL* R. COLDEA, *University of Bristol* We report nuclear magnetic resonance (NMR) measurements on the 2D frustrated quantum antiferromagnet $Cs_2CuCl_4$. $^{133}Cs$ spectra at temperatures down to 60 mK and in external magnetic field up to 15 T are presented. At the lowest temperature we observe multiple field induced quantum phase transitions in a magnetic field applied within the spin plane. The phases are distinguished by their local spin textures. The possible nature of these phases and their underlying spin structure are discussed. Furthermore, simulations of spectra are presented.

**10:12**

**Y45 12 Phase Transitions at the $Cr_{1-x}V_x$/W(110) System** OLEG KRUPIN, *Department of Physics, University of Oregon, Eugene, Oregon* ELI ROTENBERG, *Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, California* STEVE KEVAN, *Department of Physics, University of Oregon, Eugene, Oregon* The rich phase diagram of thin films of chromium-vanadium ($Cr_{1-x}V_x$) alloys offers a unique possibility to study the phenomena associated with the spin-density wave (SDW) ground state and quantum phase transition (QPT). Using angular-resolved photoemission (ARP) we have studied the periodicity of SDW in the region of commensurate-incommensurate phase transition followed by quantum phase transition as a function of two non-thermal parameters: film thickness and vanadium concentration. That allows probing the interplay between spatial confinement and Fermi surface topology change resulting from modification of chromium electron structure by vanadium doping.

**10:24**

**Y45 13 The spin state transition in $LaCoO_3$; revising a revision** L. H. TJENG, M. W. HAVERKORT, Z. HU, T. BURNUS, C. ZOBEL, M. REUTHER, H. HARTMANN, T. LORENZ, *II. Physikalisches Institut, Universität zu Köln, Germany* J. C. CEZAR, N. B. BROOKES, *European Synchrotron Radiation Facility, Grenoble, France* A. TANAKA, *Department of Quantum Matter, ADSM, Hiroshima University, Japan* H. H. HSIEH, *Chung Cheng Institute of Technology, National Defense University, Taoyuan, Taiwan* H.-J. LIN, C. T. CHEN, *National Synchrotron Radiation Research Center, Hsinchu, Taiwan* Using soft x-ray absorption spectroscopy and magnetic circular dichroism at the Co-$L_{2,3}$ edge we demonstrate that the spin state transition in $LaCoO_3$ can be well described by a low-spin ground state and a high-spin first excited state which becomes populated at elevated temperatures. From the temperature dependence of the spectral lineshapes we find that $LaCoO_3$ at finite temperatures is an inhomogeneous mixed-spin-state system. Crucial is that the magnetic circular dichroism signal in the paramagnetic state carries a large orbital momentum. This directly shows that the currently accepted low-/intermediate-spin picture is at variance, and that instead the original low-/high-spin scenario is the better itansatz.

**10:36**

**Y45 14 Transport and Magnetic Properties of $Nd_2Ni_2Pb$ and NdNiPb** V. GORUGANTI, YANG LI, JOSEPH H. ROSS, JR., K.D.D. RATHNAYAKA, *Department of Physics, Texas A&M University* Y. ÖNER, *Deparment of Physics, Istanbul Technical University* We report magnetic, transport and thermodynamic measurements for $Nd_2Ni_2Pb$ and NdNiPb, members of recently-discovered $R$-Ni-Pb families of intermetallics. In $Nd_2Ni_2Pb$ a

λ-type specific heat jump was observed at 19 K corresponding to an antiferromagnetic transition. Magnetization measurements show this phase to have a canted structure, with a metamagnetic transition in $H = 3$ T at low temperatures. We have further explored the metamagnetic transition using field dependent specific heat, concluding that the metamagnetic phase is a fully aligned phase. The single antiferromagnetic phase stands in contrast to the more complex magnetic structures observed in the heavy-rare-earth members of this family. Nd is the lightest RE forming this type strucure. At high temperatures the magnetization obeys a Curie law and the magnetic moment agrees with the free ion moment of Nd. Resistivity measurements showed metallic behavior with a kink at 19 K. We performed similar measurements on NdNiPb and observed an antiferromagnetic transition at 4 K. Specific heat indicated rather different critical behavior, with magnetic fluctuations extending well above the transition. This work was supported by the Robert A. Welch Foundation (grant A-1526), the National Science Foundation (DMR-0103455), and by the Texas A&M University Telecommunications and Informatics Task Force.

**10:48**

**Y45 15 Magnetic Susceptibility Experiments on the Heavy Lanthanides Using Designer Diamond Anvils** DAMON JACKSON, VINCE MALBA, SAMUEL WEIR, *Lawrence Livermore National Laboratory* PAUL BAKER, YOGESH VOHRA, *University of Alabama, Birmingham* The high pressure magnetic properties of the heavy lanthanide elements Gd, Tb, Dy, Ho, Er, and Tm have been investigated by ac magnetic susceptibility using designer diamond anvils. It is found that the magnetic transition temperatures monotonically decrease with increasing pressure. In addition, the amplitudes of the magnetic transition signals decrease with increasing pressure, with the signals all eventually disappearing at pressures by 20 GPa. The transition temperatures, $T_{Crit}$ are all found to drop at a rate proportional to their de Gennes factor, and the values of $T_{Crit}/T_{Crit}(P = 0)$ vs $P/P_{Crit}$, where $P_{Crit}$ is the pressure where the magnetic transition disappears, all sit on a single phase diagram.

## SESSION Y46: BILAYERS, WIGNER CRYSTALS

**Friday Morning, 17 March 2006**
**349, Baltimore Convention Center at 8:00**
**Alan Dorsey, University of Florida, presiding**

**8:00**

**Y46 1 Coulomb frustrated phase separation in bilayer electronic systems** REZA JAMEI, STEVEN KIVELSON, *Stanford University* BORIS SPIVAK, *University of Washington* We have previously proven that in clean two dimensional electronic systems, long range Coulomb interactions convert what might otherwise have been a first order transition between a high density liquid and a low density insulating electron crystalline phase into a sequence of continuous phase transitions between various sorts of intermediate ''electronic microemulsion phases.'' Here, we consider the electronic micromemulsion phases in a bilayer system, with Coulomb interactions both within and between the layers. At mean-field level, we find infinite families of modulated phases, with a subtle interplay of the period and magnitude of the density oscillations in the two layers.

**Y46 2 Interlayer CF Pairing in a Symmetric $\nu_T = 1$ Quantum Hall Bilayer** GUNNAR MOLLER, *LPTMS Orsay/France* STEVEN H. SIMON, *Lucent Technologies* EDWARD REZAYI, *California State University Los Angeles* In bilayer quantum Hall systems at filling fractions near $\nu = \frac{1}{2} + \frac{1}{2}$, as the spacing $d$ between the layers is continuously decreased, intra-layer correlations must be replaced by inter-layer correlations, and the composite fermion (CF) Fermi seas at large $d$ must eventually be replaced by a composite boson (CB) condensate at small $d$. In recent work [1], trial wave functions were constructed that can describe how composite fermion-like intra-layer correlations can be continuously replaced by 111-like inter-layer correlations using a picture of two classes of quasi particles: composite bosons and composite fermions. Here, we present how to extend this approach both qualitatively and quantitatively, introducing a new way of writing the previously introduced wave functions, which allows for the introduction of composite fermion inter-layer positive p-wave pairing. These wave functions depend on a small number of variational parameters related to the momentum distribution of $(\mathbf{k},\uparrow; -\mathbf{k},\downarrow)$ CF pairs. Comparison of energies and correlation functions to results from exact diagonalizations for small systems shows close to perfect agreement, thus giving evidence for inter layer CF pairing in QH bilayer systems [2]. This work was supported by the DOE. [1] S. H. Simon, E. H. Rezayi, and M. V. Milovanovic, Phys.Rev.Lett. **91**, 046803 (2003). [2] G. Möller, S. H. Simon, to be published, G. Möller, S. H. Simon, E. **Y46 3 Excitonic codensation in quantum Hall electron-hole bilayers** YOGESH JOGLEKAR, *IUPUI* ALEXANDER BALATSKY, *LANL* Bose-Einstein condensation of excitons in bilayers has been explored increasingly over the past decade. We present an effective theory of excitonic condensate phase in electron-hole systems in the quantum Hall regime and its derivation from a microscopic Hamiltonian using mean-field analysis. We present results for the critical layer separation $d$ as a function of electron-layer filling factor $\nu_e$, hole-layer filling factor $\nu_h$, and interlayer bias voltage $\Delta_v$. We extend our analysis to singlet and triplet excitons. We point out the salient differences between these systems and the (electron-electron) quantum Hall bilayers near total filling factor $\nu = 1$ which have been investigated experimentally in recent years.

**8:36**

**Y46 4 Development of the excitonic state of bilayer quantum Hall system at total filling one** DAIJIRO YOSHIOKA, *The University of Tokyo* NAOKAZU SHIBATA, *Tohoku University* Excitonic phase, namely Haplerin's $\Psi_{1,1,1}$ state, is realized in bilayer quantum Hall systems at $\nu = 1$ at small layer separation $d$ as evidenced by various experiments. This phase vanishes as $d$ is increased, and at large enough separation, composite-fermion Fermi-liquid states are realized in each layer. How the excitonic state develops into independent Fermi-liquid states has not been fully understood. We investigated this development by the density matrix renormalization group method (DMRG). We calculated the ground state wave function and energy gap for various values of $d$

for systems with up to 24 electrons. From the ground state wave function, two-particle distribution function $g(r)$ and excitonic correlation function have been calculated. The results indicate that the transition between the two limits is continuous. There is a smooth crossover of the ground state at around $d/l \simeq 1.6$ from the excitonic character at small $d/l$ to independent Fermi-liquid character at large $d/l$, where $l$ is the magnetic length.

**8:48**

**Y46 5 Spin-pseudospin textures in a strongly correlated bilayer quantum Hall system near $\nu = 1$** RENE COTE, JEROME BOURASSA, *Universite de Sherbrooke* BAHMAN ROOSTAEI, *University of Oklahoma* HERB A. FERTIG, *University of Indiana* KIERAN MULLEN, *University of Oklahoma* Recent experiments on strongly correlated bilayer quantum Hall systems [1,2] strongly suggest that contrary to the usual assumption, the electron spin degree of freedom is not completely frozen either in the quantum Hall or the compressibles states that occur near filling factor $\nu = 1$. These experiments imply that the quasiparticles near $\nu = 1$ could have both spin and pseudospin textures i.e. they could be CP3 skyrmions. Assuming that these skyrmions crystallize at very low temperature, we use a microscopic unrestricted Hartree-Fock calculation to compute the energy of these excitations as well as the number of flipped spins and pseudospins for various values of the separation between the well and of potential biais. We compare our results to previous calculations based on a field-theoretical description and discuss their relevance for the experiments of Refs. [1,2]. (1) I. B. Spielman, L. A. Tracy, J. P. Eisenstein, L. N. Pfeiffer, and K. W. West, Phys. Rev. Lett. 94, 76803 (2005). (2) N. Kumada, K. Muraki, K. Hashimoto, and Y. Hirayama, Phys. Rev. Lett. 94, 96802 (2005).

**Y46 6 Pseudospin Vortex-Antivortex States with Interwoven Spin Texture in Double Layer Quantum Hall Systems*** B. ROOSTAEI, *U. of Oklahoma* J. BOURASSA, *U. of Sherbrooke* H. FERTIG, *U. of Indiana* K. MULLEN, *U. of Oklahoma* R. COTE, *U. of Sherbrooke* Enhanced nuclear spin relaxation rates have been observed in recent experiments[1] on double layer quantum Hall systems near total filling factor $\nu_T = 1$. The effect is analogous to what happens in single layer systems, where a possible explanation lies in the development of a Skyrme crystal with low energy spin wave modes as the system is doped away from integer filling. Double layer systems are thought to support bimeron excitations, analogous to skyrmions but with layer indices playing the role of spin states. We demonstrate,within the Hartree-Fock approximation, that for low interlayer tunneling and large separations the bimerons reorganize into a vortex-antivortex lattice with an interwoven real spin texture. These states are most stable at large layer separation, where the introduction of the spin degree of freedom can relax an interlayer charge imbalance at the cores of the merons. The presence of the real spin texture produces a true spontaneously broken symmetry whose Goldstone modes can explain the enhancement of the nuclear spin relaxation. [1]I.B. Spielman et al., Phys. Rev. Lett. 94, 076803 (2005).

**Y46 7 Correlated Jumps in Magnetotransport of Imbalanced Bilayer Two Dimensional Hole Systems** NATHANIEL C. BISHOP, *Princeton University* SHASHANK MISRA, *Princeton University* EMANUEL TUTUC, *IBM/ T.J. Watson Research Center* MANSOUR SHAYEGAN, *Princeton University* A pair of dilute two-dimensional hole layers can interact to produce correlated electronic states unique to the bilayer geometry. Here, we examine the nonequilibrium resistivity of one layer when the other layer is tuned to the $\nu = 1$ quantum Hall state. Previous studies have shown that the longitudinal resistivity of the detuned layer jumps with a slow ($\tau \approx 100s$) relaxation.[1] Surprisingly, we find that both the longitudinal and Hall resistivities of the detuned layer jump at the same time for contacts located hundreds of microns apart. This suggests either that the instabilities in charge distribution of the two layers occur over domains of macroscopic size, or that some novel quantum correlation manifests itself over similarly large length scales. [1] E. Tutuc *et al.*, PRB **68**, 201308 (2003).

**9:24**

**Y46 8 Time Dependent Magnetotransport of Imbalanced Bilayer Two Dimensional Hole Systems** SHASHANK MISRA, *Princeton University* NATHANIEL C. BISHOP, *Princeton University* EMANUEL TUTUC, *IBM/ T.J. Watson Research Center* MANSOUR SHAYEGAN, *Princeton University* The magnetotransport of a two dimensional hole layer in close proximity to a second layer tuned to the $\nu = 1$ quantum Hall state exhibits correlations novel to the bilayer geometry. Previous experiments have shown the resistivity of the detuned layer to be hysteretic when sweeping the magnetic field, and to exhibit jumps as a function of time when staying at a fixed field.[1] We find that allowing the system to relax in middle of taking a hysteresis loop results in the magnetoresistance following a curve in between the two branches of the hysteresis loop, a hallmark of a glassy system. We further find that the seemingly random resistance jumps occur at similar times in separate measurements, each performed upon resetting the bilayer state. Work performed with support from the NSF and DOE. [1] E. Tutuc *et al.*, PRB **68**, 201308 (2003).

**Y46 9 Electron Drag in Intermediate Magnetic Fields** SANGHUN AN, GOKUL GOPALAKRISHNAN, YUKO SHIROYANAGI, SARAH PARKS, DONGKYUN KO, THOMAS GRAMILA, *Ohio State University, Physics Dept.* LOREN PFEIFFER, KEN WEST, *Bell Labs, Lucent Technologies* We report measurements of electron drag on the bilayer two-dimensional electron gas (2DEG) in intermediate magnetic fields, for which anomalous temperature-dependence and field-dependence of the drag resistivity have been previously observed. In this regime, drag resistivity shows surprisingly little temperature dependence, as well as a highly unusual field dependence which varies roughly as the cube of magnetic field. To our knowledge, no theoretical works have predicted such behavior. We have continued investigation of drag in this regime, therefore, in an attempt to understand the source of this anomalous behavior. We report detailed measurements exploring the potential role of spin in the process via application of an in-plane magnetic field, as well as examination of possible correlation effects, and a careful study of the temperature dependence.

**9:48**

**Y46 10 Plasmon Enhanced Drag Measurements at Low Densities** YUKO SHIROYANAGI, GOKUL GOPALAKRISHNAN, SANGHUN AN, SARAH PARKS, THOMAS GRAMILA, *Ohio State University* LOREN PFEIFFER, KEN WEST, *Bell Labs, Lucent Technologies* The plasmons of the two-dimensional electron gas(2DEG) can provide valuable information about electronic many-body correlation effects, while electron drag provides a unique method to probe electron-electron scattering processes in a double layer 2DEG system. An enhancement of electron drag by plasmons was predicted[1] and subsequently observed[2,3]. Experimental studies of the strength of the plasmon enhancement as a function of relative density, however, revealed that the maximum enhancement occurred for mis-matched layer densities, in disagreement with theoretical expectation. It has been argued that this results from correlation effects, in particular the presence of multi-particle excitations. We report new measurements of plasmon enhanced drag, which examine lower overall electron densities than had been reported earlier. Since correlation effects are stronger for lower densities, these measurements provide a means to test the role of correlations in determining the dependence of plasmon enhanced drag on relative densities. **Y46 11 A Physical Picture for the Negative Drag in High Landau Levels** ADY STERN, RAFI BISTRITZER, *Weizmann* Experimental investigation of the longitudinal drag resistivity, $\rho^D$, of a bi-layer subjected to a strong magnetic field in the regime of large filling factors found an anomalous behavior at low temperatures $T$: $\rho^D$ depends non monotonously on $T$ and becomes negative when the filling factors of the two layers differ by an odd number. A calculation of $\rho_D$ within the framework of the self consistent Born approximation was generally consistent with the experiment; nevertheless, it left the physical picture obscure. We employ the exact eigenstates method to unravel that picture. We find the oscillating sign of $\rho^D$ to originate from the effect of disorder on the relation between an adiabatic momentum transfer to an electron and the displacement of its position. For localized states a momentum transfer $\mathbf{q}$ implies a displacement of $ql_H^2$, with $l_H$ being the magnetic length. For extended states, the combined effect of a short range disorder and a rapidly oscillating wave function at high Landau levels results in an additional, potentially larger, displacement whose sign depends on the electron's energy.

**10:12**

**Y46 12 Pinned Bilayer Wigner Crystals with Pseudospin Magnetism** YONG CHEN, *Princeton University and National High Magnetic Field Lab* We study a model of itpinned bilayer Wigner crystals (WC) and focus on the effects of interlayer coherence (IC) on pinning. We consider both a pseudospin ferromagnetic WC (FMWC) with IC and a pseudospin antiferromagnetic WC (AFMWC) without IC. Our central finding is that a FMWC can be pinned more strongly due to the presence of IC. One specific mechanism is through the disorder induced interlayer tunneling, which effectively manifests as an extra pinning in a FMWC. We also construct a general ''effective disorder'' model and effective pinning Hamiltonian for the case of FMWC and AFMWC respectively. Under this framework, pinning in the presence of IC involves itinterlayer spatial correlation of disorder in addition to intralayer correlation, leading to itenhanced pinning in the FMWC. The pinning mode frequency ($\omega_{pk}$) of a FMWC is found to decease with the effective layer separation, whereas for an AFMWC the opposite behavior is expected. An abrupt drop of $\omega_{pk}$ is predicted at a transition from a FMWC to AFMWC. Possible effects of in-plane magnetic fields and finite temperatures are addressed. Finally we discuss some other possible ramifications of the FMWC as an electronic supersolid- like phase. [1] Yong P. Chen, cond-mat/0507124

**Y46 13 Effect of vertical confinement on pinning mode of electron solids** G. SAMBANDAMURTHY, *NHMFL and Princeton University* YONG P. CHEN, *Princeton University and NHMFL* LLOYD ENGEL, *NHMFL* D.C. TSUI, *Princeton University* L.N. PFEIFFER, K.W. WEST, *Bell Labs, Lucent Technologies* We present the results from a study of the electron solid regime that terminates the fractional quantum Hall series in very clean two-dimensional electron systems (2DES). The disorder-induced pinning mode of the electron solid appears as a resonance in the microwave conductivity spectrum. In the present study, we compare results from two quantum well samples that were grown in the same way, with the only difference being the well widths (15 and 65 nm), allowing us to observe the effect of vertical confinement of electrons on the pinning mode of electron solids. We find that the narrower well (15 nm width) has a resonance with peak frequency ($f_{pk}$) $\sim$ 6-8 GHz, whereas the wider well (65 nm width) has $f_{pk} \sim$ 100-200 MHz. Moreover, $f_{pk}$ vs. $B$ for the two samples show markedly different behaviors. Our results suggest that the disorder that dominates the pinning of electron solids is from the interface roughness associated with the quantum well.

**Y46 15 Remote sensing of the radiation induced zero-resistance state in the high mobility GaAs/AlGaAs system** RAMESH MANI, *Harvard University* The possibility of inducing novel zero-resistance states by photo-exciting a high mobility GaAs/AlGaAs device, with radiation from the microwave and Terahertz parts of the electromagnetic wave spectrum, has recently motivated a broad theoretical examination of the photoexcited steady states of the low dimensional electron system. Present theory suggests that radiation- induced resistance oscillations originate from a field dependent scattering at impurities and/or a steady state change in the electronic distribution function. In these theoretical scenarios, the amplitude of the magnetoresistance oscillations increases with the radiation intensity such that the resistivity/conductivity is able to take on negative values at the minima of the oscillatory magnetoresistivity (or magnetoconductivity) for sufficiently large radiation intensities. The negative resistivity/conductivity state is believed to give way, however, to a zero-resistance state as a result of domain formation, providing for

the experimentally observed phenomenon. Here, we report the results of experiments which sought to find signatures of the radiation-induced zero-resistance states in microwave transmission and reflection measurements of the high mobility 2DES. Remarkable changes are observed in the remotely observed photoresponse as a function of both the frequency and intensity. From the results, we deduce that the remote sensing of the radiation-induced zero-resistance state lies within the realm of possibility.

**Z1 1 Controlling a Singlet-Triplet Spin Qubit.***
JASON PETTA, *Harvard University*

An attractive candidate for a solid-state quantum bit is based on semiconductor quantum dots, which allow controlled coupling of one or more electrons, using rapidly switchable voltages applied to electrostatic gates [1]. Due to tight confinement and the high degree of isolation from the environment, spin relaxation times in quantum dots can approach millisecond timescales [2]. In this talk I will describe how fast electrical control of the exchange interaction can be used to coherently manipulate two-electron spin states [3]. By separating a spin singlet state on-chip, we measure an ensemble averaged spin dephasing time $T_2^*$ of 10 ns, limited by the contact hyperfine interaction with the GaAs host nuclei. We develop quantum control techniques based on the exchange interaction to correct for hyperfine dephasing. Coherent spin state rotations are achieved, including spin SWAP. By using a spin-echo pulse sequence based on the exchange interaction we extend the spin coherence time, $T_2$ beyond 1.2 microseconds. The quantum control techniques demonstrated here are general and may be used to manipulate singlet-triplet spin qubits in carbon nanotubes, electrons on helium, and semiconducting nanowires.

**Z1 2 Conductance of a quantum wire at low electron density.**
KONSTANTIN MATVEEV, *Argonne National Laboratory*

We study the transport of electrons through a long quantum wire connecting two bulk leads. As the electron density in the wire is lowered, the Coulomb interactions lead to short-range crystalline ordering of electrons. In this Wigner crystal state the spins of electrons form an antiferromagnetic Heisenberg spin chain with exponentially small exchange coupling $J$. Inhomogeneity of the electron density due to the coupling of the wire to the leads results in violation of spin-charge separation in the device. As a result the spins affect the conductance of the wire. At zero temperature the low-energy spin excitations propagate freely through the wire, and its conductance remains $2e^2/h$. At finite temperature some of the spin excitations are reflected by the wire and contribute to its resistance. Since the energy of the elementary excitations in the spin chain (spinons) cannot exceed $\pi J/2$, the conductance of the wire acquires an exponentially small negative correction $\delta G \propto -\exp(-\pi J/2T)$ at low temperatures $T \ll J$. At higher temperatures, $T \gg J$, most of the spin excitations in the leads are reflected by the wire, and the conductance levels off at a new universal value $e^2/h$. This result is consistent with experimental observations of a mini-plateau of conductance at $e^2/h$ in quantum wires in the absence of magnetic field.

**12:27**
**Z1 3 Localization Transition in a Ballistic Quantum Wire.**
HADAR STEINBERG, *Weizmann Institute of Science*

We report measurements probing the many-body wave-function of localized states in one dimension. We utilize tunneling between two long, clean, parallel quantum wires in a GaAs/AlGaAs heterostructure, where one of the two wires is driven into the localized regime using a density tuning gate, and the other wire, still in the regime of extended electronic states, serves as a momentum spectrometer. Our measurements show that as the electron density is lowered to a critical value, the many-body state abruptly changes from an extended state with a well-defined momentum to a localized state with a

wide range of momentum components. The signature of the localized states appears as discrete tunneling features at resonant gate-voltages, corresponding to the depletion of single electrons from the localized region and showing Coulomb-blockade behavior. Typically 5 - 10 such features appear, where the one-electron state has a single-lobed momentum distribution, and the few-electron states have double-lobed distributions with peaks at the Fermi momenta.

**13:03**
**Z1 4 Spin incoherent effects in momentum resolved tunneling, transport, and Coulomb drag in Luttinger liquids.***
GREGORY FIETE, *Kavli Institute for Theoretical Physics, UC Santa Barbara*

In a one dimensional electron gas at low enough density the magnetic exchange energy $J$ between neighboring electrons is exponentially suppressed relative to the Fermi energy, $E_F$. At finite temperature $T$, the energy hierarchy $J << T << E_F$ can be reached, and we refer to this as the spin incoherent (SI) Luttinger liquid state. By using a model of a fluctuating Wigner solid, we theoretically explore the signatures of spin incoherence in the single particle Greens function[1], momentum resolved tunneling[2], transport[3], and Coulomb drag[4]. In the SI Greens function the spin modes of a Luttinger liquid (LL) are thermally washed out leaving only singular behavior from the charge modes. The charge modes are broadened in momentum space by an amount of order $k_F$ and the energy dependence of the tunneling density of states qualitatively changes from the low energy suppression of the LL regime to a possible low energy divergence in the SI regime. Such a state may be probed directly in momentum resolved tunneling between parallel quantum wires. Deep in the SI regime, the physics of transport and Coulomb drag can be mapped onto spinless electrons. Various crossovers in temperature and for finite systems connected to Fermi liquid leads are discussed. Both transport and Coulomb drag may exhibit interesting non-monotonic temperature dependence. **Z1 5 Dephasing of mesoscopic interferences from Electron Fractionalization.***
KARYN LEHUR, *Université de Sherbrooke*

The understanding of dephasing processes (the physical causes of supressed interference effects) constitutes a topics of perpetual interest in mesoscopic systems. Phase-breaking mechanisms in ballistic systems of dimensionality less than two are presently not completely understood and therefore deserve intensive theoretical and experimental endeavors. In this talk, we investigate the dephasing of mesoscopic interferences by electron-electron interactions in a well-defined geometry composed of two tunnel-coupled wires embodied by a Luttinger liquid. We thoroughly demonstrate that interactions can produce a visible attenuation of Aharonov-Bohm oscillations [1]. Moreover, in our geometry, we firmly emphasize that the emerging dephasing time results from the electron factionalization phenomenon that is known to produce an electron life-time in 1/T with T being the temperature [2]. A dephasing time in 1/T has been reported in one-dimensional GaAs rings. [1] Karyn Le Hur, Phys. Rev. Lett. 95, 076801 (2005). [2] Karyn Le Hur, Phys. Rev. B 65, 233314 (2002).

**Z2 1 Resonant Inelastic X-ray Scattering in Correlated Electron Systems.***
YOUNG-JUNE KIM, *University of Toronto*

Extremely bright photons generated at the new generation of synchrotron light sources have made a huge impact on various scientific disciplines ranging from biology to materials science. One of the exciting new developments is the use of x-rays in the field of solid-state spectroscopy. Inelastic x-ray scattering, analogous to the well-known inelastic neutron scattering, is a powerful tool for studying momentum-dependent electronic excitations and phonons. In particular, resonant inelastic x-ray scattering in the hard x-ray regime has been widely utilized to study the momentum dependence of various electronic excitations in strongly correlated electron systems. For example, by tuning the incident photon energy to the Cu K-edge, one can gain a large intensity enhancement as well as element specific knowledge of the electronic excitations in various copper oxide compounds. Most of the work to date has been focused on the charge-

transfer excitation between the bonding and antibonding molecular orbitals, the excitation across the Mott gap, and crystal field excitations between the d-orbitals. Recent improvements in instrumentation have allowed us to observe a new mode in the mid-infrared frequency region. We will discuss the momentum dependence of these excitations in prototypical cuprate superconductors, $La_{2-x}Sr_xCuO_4$, and also examine the evolution of such excitations as charge carriers are doped into the system.

**Z2 2 Intermediate-Energy Charge-Transfer Excitations in the Cuprate Superconductors and the Photon Energy Dependence of the RIXS process.***
JASON HANCOCK, *Stanford University*

We present a study of the charge-transfer excitations of the structurally simple high-Tc superconductor $HgBa_2CuO_4 + \delta$ and of the Mott insulator $La_2CuO_4$ using the burgeoning experimental technique of resonant inelastic X-ray scattering (RIXS). Our measurements address the 1-7 eV spectral range and place particular emphasis on the incident photon energy dependence of the cross section. Our results reveal clear evidence for a group of weakly-dispersing excitations[12]. Collectively, these results call for the use of a multi-band theoretical approach for the description of the charge dynamics of high-Tc cuprate superconductors in this intermediate-energy regime.

**Z2 3 Momentum Dependence of Charge Excitations in $YBa_2Cu_3O_{7-\delta}$ and $Nd_{2-x}Ce_xCuO_4$.**
KENJI ISHII, *SPring-8, Japan Atomic Energy Agency*

Resonant inelastic x-ray scattering (RIXS) studies at Cu *K*-edge on high-$T_c$ superconducting cuprates, $YBa_2Cu_3O_{7-\delta}$ and $Nd_{2-x}Ce_xCuO_4$ are presented. The superconductivity occurs in the vicinity of the Mott insulating state and it is important to clarify the nature of the Mott gap and its doping dependence. Because RIXS has an advantage that we can measure charge excitation in a wide energy-momentum space, it gives a unique opportunity to study the electronic structure of materials. We apply this technique to high-$T_c$ superconducting cuprates. In particular the electronic structure of strongly correlated metals is in the focus of our RIXS study. The experiments were performed at BL11XU of SPring-8, Japan, where a specially designed spectrometer for inelastic x-ray scattering is installed. In optimally doped $YBa_2Cu_3O_{7-\delta}$, anisotropic spectra are observed in the ab plane of a twin-free crystal. The Mott gap excitation from the one-dimensional CuO chain is enhanced at 2 eV near the zone boundary of the chain direction, while the excitation from the $CuO_2$ plane is broad at 1.5-4 eV and almost independent of momentum. Theoretical calculation based on the one-dimensional and two-dimensional Hubbard model reproduces the observed features in the RIXS spectra when smaller values of the on-site Coulomb energy of the chain than that of the plane are assumed. This means that the charge transfer gap of the chain is smaller than that of the plane. On the other hand, both interband excitation across the Mott gap and intraband excitation in the upper Hubbard band are observed in the electron-doped $Nd_{2-x}Ce_xCuO_4$. The intensity of the interband excitation is concentrated at $\sim$ 2 eV near the zone boundary while a dispersion relation with a momentum-dependent width emerges in the intraband excitation. The author would like to acknowledge to his collaborators, K. Tsutsui, Y. Endoh, T. Tohyama, K. Kuzushita, T. Inami, K. Ohwada, M. Hoesch, M. Tsubota, Y. Murakami, J. Mizuki, S. Maekawa, T. Masui, S. Tajima, and K. Yamada. The crystal growth of $YBa_2Cu_3O_{7-\delta}$ was supported by the New Energy and Industrial Technology Development Organization (NEDO) as the Collaborative Research and Development of Fundamental Technologies for Superconductivity Applications.

**Z2 4 Low-Energy Electronic Excitations in the Layered Cuprates Studied by Copper $L_3$ Resonant Inelastic X-Ray Scattering.***
GIACOMO GHIRINGHELLI, *Politecnico di Milano*

Resonant inelastic x-ray scattering (RIXS) can be effectively used to measure the energy and symmetry of neutral electronic excitations in solids. In the soft x-ray range it is particularly powerful for strongly correlated electron systems based on 3*d* transition metals, because at the $L_{2,3}$ edges it involves directly the 3*d* states. In those systems it can be considered as a chemically selective, bulk sensitive alternative to optical absorption and electron energy loss spectroscopy in the study of low energy electronic excitations. The reduced intensity and the instrumental energy resolution usually hinder the detection of very detailed spectral features, but the recent progress in the energy resolving power of our RIXS apparatus has opened new exciting possibilities in the 400-1000 eV range. We present spectra measured using the AXES spectrometer, installed at the beam line ID08 of the ESRF, France. The combined resolution ranges from 240 meV to 650 meV going from the Ti to the Cu $L_3$ edges. We have measured the itdd excitations in cuprates [1,2,3,4] and other

interesting systems where electronic correlation plays a central role [5]. In the specific case of cuprate superconductors, $L_3$ RIXS can be used to estimate the energy of the itxy, ityz, itzx and $z^2$ excited states. We report the examples of $La_2CuO_4$, $CaCuO_2$, Tl2212 and $Nd_{1.2}Ba_{1.8}Cu_3O_7$, where the different coordination and Cu-O distances result in a variety of itdd excitation spectra. [1] G. **Z2 5 Asymmetric evolution of low-energy electron-hole pair modes and the Mott pseudogap in doped cuprates.***
YINWAN LI, *Princeton University & Argonne Lab*

A central issue in the universal Mott behavior in a variety of complex systems is to understand the nature of the electron-hole pair excitation modes. Using high resolution resonant x- ray scattering we resolve the momentum dependence of low-energy electron-hole pair modes in two major classes of doped copper oxides which reveals the momentum structure of the Mott pseudogap over the entire phase diagram including the superconducting states. The pair bandwidth and zone-boundary velocity renormalize on either sides of the phase diagram at different rates indicating strong doping asymmetries observed in the momentum resolved particle-hole collective channels for the first time. The measured asymmetry of modes is qualitatively consistent with Hubbard model.

**Z4 1 Bonds that strengthen under force.**
VIOLA VOGEL, *Swiss Federal Institute of Technology, ETH*

While the adhesive strength of most receptor-ligand interactions is exponentially reduced if strained, some receptor-ligand complexes exist that strengthen under force which is the hallmark of catch bonds. Although the existence of catch bonds was theoretically predicted, the first experimental demonstrations of their existence were given only recently, i.e. for the bacterial adhesin FimH that is located at the tip of type I fimbriae of itE. coli and for p-selectin. In a major collaborative effort, we studied the structural origin by which the FimH-mannose bond is switched by force to a high binding state. Mutational studies were thereby combined with steered molecular dynamic simulations to decipher how force might affect protein conformation. Force-activation of FimH leads to a complex 'stick-and-roll' bacterial adhesion behavior in which itE. coli preferentially rolls over mannosylated surfaces at low shear but increasingly sticks firmly as the shear is increased. Interesting similarities are further seen if comparing the structural mechanisms by which liganded FimH and liganded integrins are switched to a high binding state. This comparison was made possible by docking fibronectin's $10^{th}$ type III module ($fnIII_{10}$) to $\alpha_V\beta_3$ integrin. $\alpha_V\beta_3$ can switch from the ''closed'' $\alpha_V\beta_3$ integrin headpiece to the ''open'' conformation by opening the hinge angle between the $\beta$A domain and the hybrid domain of the $\beta$-integrin. The ''open'' state has been implicated by many experimental laboratories to correspond to the activated state of integrins. W. E. Thomas, E. Trintchina, M. Forero, V. Vogel, E. **Z4 2 Cellular Force, and Geometry Sensing (Over Time) Can Detect Matrix Rigidity: Local Modules Produce Global Signals.**
MICHAEL SHEETZ, *Columbia University*

The shape and behavior of mammalian cells is defined by an interplay between extracellular signals and the cellular responses. Although the chemical nature of the external signals is important, there is a growing realization that the physical aspects of the external environment are equally important. In particular, the stresses, rigidity and form of the external environment have major effects on cell behavior. Of particular importance is rigidity since cancerous cells can often grow on soft agar or in a fluid phase without force production. For most mammalian cells there are relatively few types of motility that are evident from quantitative analyses of rapidly spreading fibroblasts (Dubin-Thaler et al., Biophys. J. 86:1794-1806, 2004). One motile phase that we have studied extensively involves periodic contractions (24 s period) in local regions of the leading edge of the cell (Giannone et al., Cell, 116:431-443, 2004). The periodic signal is carried radially from the cell edge toward the center and is part of a general mechanism for rigidity-directed movement and pathfinding. Another motile phase involves the movement of individual collagen fibers in a hand-over-hand fashion (Meshel et al., Nature Cell Biol. 7:157-164, 2005) where the form of the fiber is being sensed. Rigidity and form sensing in these systems is dependent upon the cytoskeleton and force-dependent tyrosine phosphorylation through oncogenes (Sawada and Sheetz, J Cell Biol. 156:609-15, 2002; Tamada et al., Developmental Cell, 7:706-718, 2004). Recent studies indicate that the cell rigidity sensing occurs preferentially at the leading edges of moving cells and involves forces of 10-20 pN generated by displacements of 50-100 nm (Jiang et al., Biophys J. In Press). We will discuss how cells organize motility tools in motile phases (Döbereiner et al., Phys. Rev. Letters. 93:108105-1-4, 2004) in a dialogue with the environment to define cell morphology and behavior over time.

**12:27**
**Z4 3 Looking for steps of individual enzymes moving along DNA.**
THOMAS PERKINS, *JILA, NIST and CU-Boulder*

Understanding the molecular mechanism of any motor activity involves determining the elementary step size with which it moves. RecBCD is a processive, DNA-based motor with both helicase and nuclease activities. To directly measure RecBCD's putative step size of 4 base pairs (1.4 nm), several technical advances were incorporated in a new high-resolution optical trapping instrument capable of resolving 0.1 nm motion. First, mechanical drift was eliminated by developing a differential measurement system based upon improved laser beam-pointing stability and the introduction of a fiducial mark attached to a microscope coverslip (e.g., a stuck bead). To generalize this technique to measure subnanometer vertical motion, we intensity stabilized the detection laser and differentially amplified the vertical signal. We further enhanced this process by actively stabilizing the sample in 3D. In the presence of substantial thermal heating, 3D differential measurements with active stabilization achieved short term (1 s) stabilities of 0.13, 0.08 and 0.22 nm (RMS) in x, y, and z, respectively. Positional stability, as demonstrated by our differential subtraction, does not guarantee subnanometer resolution of an optically trapped bead itunder load. We therefore intensity stabilized our trapping laser to $\sim$ 0.1% at 100 Hz. Finally, our technique requires a DNA tether to be within a small distance (3 $\mu$m) of a fiducial mark. If the stuck bead is too close or directly along one of the primary axes of the stage motion, it interferes with the measurement. Since the location of stuck beads and DNA tethers is random, this leads to only a few stuck bead/DNA tether pairs that can be successfully used. To overcome these limitations, we developed a regular grid of nanoposts. We will present our progress on integrating these technological advances to measure individual steps of RecBCD.

**13:03**
**Z4 4 Thermodynamics and Structure of Polymerizing Actin.**
SANDRA GREER, *University of Maryland College Park*

The polymerization of the globular protein G-actin to form filamentary F-actin is an important cellular process, serving major functions in cell structure and cell motility. This transition from monomeric G-actin to polymeric F-actin can be initiated by the variation of thermodynamic variables such as temperature, pressure, and compositions of G-actin and salts. We use fluorescence spectroscopy to obtain the fraction of monomer converted to polymer, and model these data using a Flory-Huggins type of theory. We measure the size and shape of the actin species by small angle neutron scattering, and find an unexpected spherical shape for G-actin in salt buffer.

**13:39**
**Z4 5 Synthetic and Biopolymer Gels - Similarities and Difference.**
FERENC HORKAY

Ion exchange plays a central role in a variety of physiological processes, such as nerve excitation, muscle contraction and cell locomotion. Hydrogels can be used as model systems for identifying fundamental chemical and physical interactions that govern structure formation, phase transition, etc. in biopolymer systems. Polyelectrolyte gels are particularly well-suited to study ion-polymer interactions because their structure and physical-chemical properties (charge density, crosslink density, etc) can be carefully controlled. They are sensitive to different external stimuli such as temperature,

ionic composition and pH. Surprisingly few investigations have been made on polyelectrolyte gels in salt solutions containing both monovalent and multivalent cations. We have developed an experimental approach that combines small angle neutron scattering and osmotic swelling pressure measurements. The osmotic pressure exerted on a macroscopic scale is a consequence of changes occurring at a molecular level. The intensity of the neutron scattering signal, which provides structural information as a function of spatial resolution, is directly related to the osmotic pressure. We have found a striking similarity in the scattering and osmotic behavior of polyacrylic acid gels and DNA gels swollen in nearly physiological salt solutions. Addition of calcium ions to both systems causes a sudden volume change. This volume transition, which occurs when the majority of the sodium counterions are replaced by calcium ions, is reversible. Such reversibility implies that the calcium ions are not strongly bound by the polyanion, but are free to move along the polymer chain, which allows these ions to form temporary bridges between negative charges on adjacent chains. Mechanical measurements reveal that the elastic modulus is practically unchanged in the calcium-containing gels, i.e., ion bridging is qualitatively different from covalent crosslinks.

## SESSION Z7: SYNCHRONY AND COMPLEXITY IN BRAIN ACTIVITY AND FUNCTION

**Z7 1 Analysis of Direct Recordings from the Surface of the Human Brain.**
VERNON L. TOWLE, *University of Chicago*

Recording electrophysiologic signals directly from the cortex of patients with chronically implanted subdural electrodes provides an opportunity to map the functional organization of human cortex. In addition to using direct cortical stimulation, sensory evoked potentials, and electrocorticography (ECoG) can also be used. The analysis of ECoG power spectrums and inter-electrode lateral coherence patterns may be helpful in identifying important eloquent cortical areas and epileptogenic regions in cortical multifocal epilepsy. Analysis of interictal ECoG coherence can reveal pathological cortical areas that are functionally distinct from patent cortex. Subdural ECoGs have been analyzed from 50 medically refractive pediatric epileptic patients as part of their routine surgical work-up. Recording arrays were implanted over the frontal, parietal, occipital or temporal lobes for 4-10 days, depending on the patient's seizure semiology and imaging studies. Segments of interictal ECoG ranging in duration from 5 sec to 45 min were examined to identify areas of increased local coherence. Ictal records were examined to identify the stages and spread of the seizures. Immediately before a seizure began, lateral coherence values decreased, reorganized, and then increased during the late ictal and post-ictal periods. When computed over relatively long interictal periods (45 min) coherence patterns were found to be highly stable ($r = 0.97$, $p < .001$), and only changed gradually over days. On the other hand, when calculated over short periods of time (5 sec) coherence patterns were highly dynamic. Coherence patterns revealed a rich topography, with reduced coherence across sulci and major fissures. Areas that participate in receptive and expressive speech can be mapped through event-related potentials and analysis of task-specific changes in power spectrums. Information processing is associated with local increases in high frequency activity, with concomitant changes in coherence, suggestive of a transiently active language network. Our findings suggest that analysis of coherence patterns can supplement visual inspection of conventional records to help identify pathological regions of cortex. With further study, it is hoped that analysis of single channel dynamics, along with analysis of multichannel lateral coherence patterns, and the functional holographic technique may allow determination of the boundaries of epileptic foci based on brief interictal recordings, possibly obviating the current need for extended monitoring of seizures.

**Z7 2 Astrocytes, Synapses and Brain Function: A Computational Approach.***
SUHITA NADKARNI, *Center for Theoretical Biological Physics, University of California, San Diego*

Modulation of synaptic reliability is one of the leading mechanisms involved in long- term potentiation (LTP) and long-term depression (LTD) and therefore has implications in information processing in the brain. A recently discovered mechanism for modulating synaptic reliability critically involves recruitments of astrocytes - star- shaped cells that outnumber the neurons in most parts of the central nervous system. Astrocytes until recently were thought to be subordinate cells merely participating in supporting neuronal functions. New evidence, however, made available by advances in imaging technology has changed the way we envision the role of these cells in synaptic transmission and as modulator of neuronal excitability. We put forward a novel mathematical framework based on the biophysics of the bidirectional neuron-astrocyte interactions that quantitatively accounts for two distinct experimental manifestation of recruitment of astrocytes in synaptic transmission: a) transformation of a low fidelity synapse transforms into a high

fidelity synapse and b) enhanced postsynaptic spontaneous currents when astrocytes are activated. Such a framework is not only useful for modeling neuronal dynamics in a realistic environment but also provides a conceptual basis for interpreting experiments. Based on this modeling framework, we explore the role of astrocytes for neuronal network behavior such as synchrony and correlations and compare with experimental data from cultured networks.

**Z7 3 Neuronal Spatiotemporal Pattern Discrimination: The Dynamical Evolution of Seizures.**
STEVEN SCHIFF, *George Mason University*

We developed a modern numerical approach to the multivariate linear discrimination of Fisher from 1936 based upon singular value decomposition that is sufficiently stable to permit widespread application to spatiotemporal neuronal patterns. We demonstrate this approach on an old problem in neuroscience – whether seizures have distinct dynamical states as they evolve with time. A practical result was the first demonstration that human seizures have distinct initiation and termination dynamics, an important characterization as we seek to better understand how seizures start and stop. Such strategies are also useful in defining the onset of a seizure dynamically, and whether there is a dynamically distinct preseizure state. A proper orthogonal decomposition helps illustrate the changing coherent structures that underlie such activities. Our approach is broadly applicable to a wide variety of spatiotemporal dynamical data, from multichannel EEG or MEG, to sequentially acquired optical imaging data or fMRI.

**Z7 4 Measuring complexity and synchronization phenomena in the human epileptic brain.***
KLAUS LEHNERTZ, *Dept. of Epileptology, Neurophysics Group and Helmholtz-Institute for Radiation and Nuclear Physics, University of Bonn, Bonn, Germany*

The framework of the theory of nonlinear dynamics provides new concepts and powerful algorithms to study complicated dynamics such as the human electroencephalogram (EEG). Although different influencing factors render the use of nonlinear measures (such as measures for complexity, synchronization, or interdependencies) in a strict sense problematic, converging evidence from various investigations now indicates that nonlinear EEG analysis provides a means to reliably characterize different states of normal and pathological brain function and thus, promises to be important for clinical practice. This talk will focus on applications of nonlinear EEG analysis in epileptology. Epilepsy affects more than 50 million individuals worldwide - approximately 1 % of the world's population. The disease is characterized by a recurrent and sudden malfunction of the brain that is termed seizure. Epileptic seizures are the clinical manifestation of an excessive and hypersynchronous activity of neurons in the brain. It is assumed that seizure activity will be induced when a critical mass of neurons is progressively involved in closely time-linked high frequency discharging. Recent investigations of intracranially recorded EEG involving nonlinear time series analysis techniques indicate that this build up of a critical mass can indeed be tracked over time scales lasting minutes to hours. Future real-time analysis devices may enable both investigations of basic mechanisms leading to seizure initiation in humans and the development of adequate seizure warning and prevention strategies.

**Z7 5 Detection of phase and lag synchrony as an adaptive measure of asymmetric neuronal interactions.**
MICHAL ZOCHOWSKI, *University of Michigan*

Asymmetric temporal interdependencies between individual neurons and their populations are though to underlie learning and memory formation and can provide information about direction of information transfer in neural systems. We have developed an adaptive measure that detects asymmetries in phase and lag synchrony between activities of individual neurons of synchronized networks. In the first part of the talk I will discuss the properties of the measure on network models of coupled non-linear oscillators and show progression of rapid transitions in temporal patterning in such networks as a function of their topology. In the second part of the talk I will present its application in analysis of normal and pathological neural activity: detection of evolving asymmetry in interactions of hippocampal neurons in freely behaving rats, and characterization of dynamical progression of synchronous seizure-like activity recorded from intact rat hippocampus.

**Z18 1 Tube-tube interaction and high curvature effects in double wall carbon nanotubes.***
HANS KUZMANY,† *Universitaet Wien, Austria*

Recent results will be reported on the consequences of the interaction between peapod grown inner shell carbon nanotubes and the corresponding outer shell tubes in double wall carbon nanotubes (DWCNTs). The results were obtained from resonance Raman experiments on natural and $^{13}C$ isotope substituted nanotubes, from time resolved NMR experiments and from calculations which include tube-tube interaction and high curvature effects of the inner tubes. The Raman analysis of the radial breathing mode of the inner tubes exhibits extremely narrow line widths which indicates unusual long phonon life times. It also confirms family behaviour of the tubes and the large number of observed lines is a consequence of pair spectrum response between inner shell and outer shell tube pairs. The response from the RBM is used to demonstrate reversible filling and release of the fullerenes from the tubes. Measurements of the longitudinal relaxation time $T_1$ in NMR experiments from $^{13}C$ substituted inner tubes reveal a Korringa behaviour for temperatures above 150 K. This indicates a metallic character of the inner tubes. Below 20 K the metallicity is lost and a gap of about 4 meV opens up. The properties of the inner tubes will be discussed in the frame of a inner shell-outer shell orbital hybridization and curvature enhanced electron-phonon interaction.

**Z18 2 Density Functional Calculations of the $^{13}C$ NMR Chemical Shifts in Single-Walled Carbon Nanotubes** JOCHEN AUTSCHBACH, *Department of Chemistry, State University of New York at Buffalo, Buffalo, NY 14260-3000* EVA ZUREK, *Max Planck Institut für Festkörperforschung, Stuttgart, Germany* Nuclear Magnetic Resonance (NMR) chemical shifts of single–walled carbon nanotubes were computed for capped finite–sized tube fragments and for infinite–length tubes. Molecular density functional calculations using atom–centered basis sets have been performed for the electronic structure and $^{13}C$ NMR chemical shifts of (5,0), (9,0) and (10,0) single-walled carbon nanotube (SWNT) fragments. For the (9,0) tube, a $C_{30}$-capped fragment appeared to be a more suitable model to represent an infinite tube then a fragment capped with hydrogens. Thus, the study of the finite (5,0) and (10,0) tubes were restricted to the systems capped with carbon hemispheres. The chemical shift for the (9,0) system [1] is in good agreement with experimental data that were recently obtained from a solution of functionalized nanotubes. Further, we have calculated the $^{13}C$ chemical shift for a number of infinite small-radius SWNTs using a plane–wave approach. Here, the effect of inter-tube interactions upon the chemical shift was also considered. The results will be compared with those obtained for the finite systems. We believe that our computations may be useful in determining new experimental methods which rely upon NMR to characterize a nanotube sample. [1] E. Zurek, J. Autschbach, J. Am. Chem. Soc.**126**, 13079 (2004).

**Z18 3 Comparative Raman spectroscopy study of Single-Wall and Double-Wall carbon nanotube systems doped with $H_2SO_4$** EDUARDO BARROS, ANTONIO G. SOUZA FILHO, *Universidade Federal do Ceara* YOONG-AHM KIM, HIROYUKI MURAMATSU, TAKUYA HAYASHI, MORINOBU ENDO, *Shinshu University* MILDRED DRESSELHAUS, *Massachusetts Institute of Technology* In this work, we performed Raman experiments on a mixture of Single-wall and Double-wall carbon nanotubes for different relative concentrations and using different laser energies. Two sets of samples were analyzed, one which was exposed to $H_2SO_4$ for 5*s* and one which is pristine. The $H_2SO_4$ is known to act as an acceptor for the electrons of graphitic materials. The effect of the hole doping on the vibrational and electronic properties of the double and single-wall carbon nanotubes is probed using Resonant Raman scattering with different excitation energies probing different nanotubes. The inner and outer walls of double-wall nanotubes can also be studied at the same time for selected excitation energies. A detailed analysis of the charge transfer in single wall and double wall nanotubes and its effects on the nanotube properties is obtained.

**12:15**
**Z18 4 Spectroscopy of Functionalized Double-Walled Carbon Nanotubes** J. SHAVER, *Rice University, Houston TX* J. KONO, F. LIANG, W.E. BILLUPS, R.H. HAUGE, *Rice University, Houston TX* E. FLAHAUT, *Universite Paul Sabatier, CIRIMAT/LCMIE, Toulouse France* Double walled nanotubes are of recent interest for spectroscopic study partly due to the protected nature of the inner tubes. Functionalization of single walled nanotubes has been used to increase solubility, though this comes at the expense of disrupting the electronic properties. We present spectroscopy of DWNTs functionalized with various organic and inorganic compounds. Photoluminescence, Raman, and coherent phonon oscillations are utilized to determine the effect of sidewall modification of outer tubes on the DWNT spectra.

**12:27**

**Z18 5 Defects in single and double wall carbon nanotubes*** JIAN-MIN ZUO, T.K. KIM, *Dept. Mat. Sci. Eng., University of Illinois, Urbana* We show that single and double wall carbon nanotubes grown by catalytic chemical vapor deposition can change its chirality and create junctions along the tube direction. These tubes often appear straight (perfect) in electron images. The change in structure is often subtle and only detectable by electron diffraction. The experimental evidence of defects, structure determination and consequence on tube transport properties will be presented and discussed.

**12:39**

**Z18 6 Resonant Raman scattering in Br2-adsorbed double wall carbon nanotubes*** ANTONIO SOUZA FILHO, *Univ. Federal do Ceara - Frotaleza - Brazil* MORINOBU ENDO, HIROYUKI MURAMATSU, YOONG A. KIM, TAKUYA HAYASHI, *Shinshu University - Nagano - Japan* N. AKUZAWA, *Tokyo National College of Technology - Japan* RIICHIRO SAITO, *Tohoku University - Japan* MILDRED S. DRESSELHAUS, *MIT - USA* The vibrational and electronic properties of Br2-adsorbed double-wall carbon nanotubes (DWNTs) were investigated by resonance Raman scattering. We have found that Br2 molecules interact with the DWNTs and their intercalation characteristics are completely reversible upon thermal annealing. Upshifts in the Raman frequencies for the tangential modes and depression of their Raman intensities indicate that electrons are transferred from the nanotubes to the Br2 molecules. Metallic nanotubes are specially sensitive to the adsorption of Br2 molecules, even when they are the inner tubes of DWNTs. The vibrational spectra of the bromine dopant also provide information about the intercalation process.

**Z18 7 Growth transition from single wall- to double walled-carbon nanotubes by using acetylene gas*** VIJAYA KAYASTHA, *Michigan Tech University* YOKE KHIN YAP, *Michigan Tech University* Based on a growth model that we have proposed for multiwalled carbon nanotubes (CNTs) [1, 2], we found that similar mechanism is applied for the growth of single wall- and double walled- CNTs by acetylene gas. This model combines disociative adsorption of acetylene molecules on Fe catalyst and the vapor-liquid-solid mechanism. Basically, the growth is the consequence of optimization of decomposition rate of acetylene molecules as referred to the diffusion rate and segregation rate of carbon into and from the catalyst. For the growth of single wall- and double walled- CNTs, catalytic film consists of layers of aluminum, iron, and molybdenum were used. We found that samples grown at $\sim$ 600-700 $^{o}$C contained more than 80% double walled CNTs with diameters in the range 3-5nm and length 15 $\mu$m. These CNTs are vertically aligned on substrates. As the temperature increased to 1000 $^{o}$C the growth of single wall CNTs are detected. [1]. **Z18 8 Electronic structure of a linear carbon-atom chain inside single-walled carbon nanotubes*** ROMEO DE COSS, ALEJANDRO TAPIA, CESAR CAB, *Department of Applied Physics, CINVESTAV-Merida, Mexico* JORGE MEDINA, GABRIEL CANTO, *CCMC-UNAM, Ensenada, Mexico* CESAR ACOSTA, *FI-UADY, Yucatan, Mexico.* Recently has been reported a new type of one-dimensional carbon structures. Carbon nanowires formed by a linear carbon-atom chain inside an armchair (5,5) carbon nanotube has been observed using high-resolution transmission electron microscopy. In the present work we have studied the electronic structure of a linear carbon-atom chain inside the (5,5) and (8,0) single-walled carbon nanotubes (SWCN) using the Density Functional Theory. The calculations where performed with the pseudopotentials LCAO method (SIESTA code) and the Generalized Gradient Approximation (GGA) for the exchange-correlation potential. We have analyzed the band structure, the local density of states (LDOS), and the local orbital population. We find charge transfer from the nanotube to the linear chain in both systems chain@(5,5) and chain@(8,0). However, the electronic character of the chain and nanotube sub-systems in chain@SWCN is the same that in the corresponding isolated chain or SWCN systems.

**Z18 9 Optical Anisotropy of Aligned Single Wall Carbon Nanotubes** JEFFREY A. FAGAN, BARRY J. BAUER, IDAN MANDELBAUM, MATTHEW L. BECKER, ERIK K. HOBBIE, *NIST* The optical properties of single wall carbon nanotubes (SWCNTs) are of significant importance for a variety of applications, particularly for fractions containing well defined tube lengths and chiralities. In this work, stable suspensions of DNA wrapped SWCNTs were mechanically aligned by dispersing them in amorphous polymer films, and their intrinsic optical anisotropy measured through a combination of polarized light spectroscopy, polarized Raman spectroscopy, and small-angle neutron scattering (SANS). Conventional measures of nematic alignment in the stretched polymer films typically varied from 0.7 to 0.9. The quality of the nanotube dispersion within the centimeter scale polymer film samples was also directly investigated by means of atomic force and electron microscopy. We obtain the intrinsic optical anisotropy of the SWCNTs over a broad range of photon energies, with a number of well-resolved absorption peaks corresponding to specific SWCNT chiralities.

**13:27**

**Z18 10 Boron Nanotubes and Boron Sheets – New Perspectives for Nanotechnology** JENS KUNSTMANN, *Max Planck Institute for Solid State Research, Heisenbergstrasse 1, 70569 Stuttgart, Germany* ALEXANDER QUANDT, *Institut fuer Physik der Universitaet Greifswald, Domstrasse 10a, 17489 Greifswald, Germany* We report about a recent ab initio study of boron nanotubes (BNTs). The latter were first predicted by theory, and have recently been synthesized experimentally. To understand the basic properties of BNTs, we have derived a structure model for an extended boron sheet (i.e. a boron analogue of a single graphene sheet) as a possible structural precursor of boron nanotubes. This sheet has a puckered structure, high stiffness, and anisotropic bonding properties. Puckering turns out to be the key mechanism for stabilizing sp sigma bonds lying along the armchair direction

of the sheet. The BNTs have puckered surfaces as well, and their chiral angles are defined in a range from 0 to 90 degree. We show that all ideal boron nanotubes are metallic, irrespective of their radii and chiral angles, and discuss the possible existence of helical currents in chiral BNTs. Furthermore we show that strain energies of BNTs depend on their radii AND on their chiral angles. This unique property could be the basis of a new structure control mechanism in nanotechnology that permits to make nanotubes of a specified type, only. Zigzag nanotubes for example seem to have very little strain energy, if any. Therefore they should be highly susceptible to structural collapses, and might not exist at all.

**Z19 1 Single electron Transport in diluted magnetic semiconductor quantum dots** J. FERNANDEZ-ROSSIER, *Universidad de Alicante* R. AGUADO, *Instituto de Ciencia de Materiales, CSIC* We consider a single electron transistor based upon a II-VI semiconductor quantum dot doped with a few Mn atoms.Our proposal is motivated by the recent fabrication and optical probing of single CdTe quantum dots doped with a single Mn [1]. The numerical diagonalization of the quantum dot Hamiltonian is possible in the case of small number of both carriers and Mn [2],[3],[4]. Our calculations [5] reveal that the magnetic ions behave like a quantum nanomagnet whose the total spin and magnetic anisotropy depend dramatically both on the number of carriers and their orbital nature. We show that single electron transport spectroscopy permits a complete characterization of electronic excitations of the dot. A protocol of gate voltage pulses that permits the preparation and detection of the quantum state of a single Mn spin is presented. (1) L. Besombes, et al. Phys. Rev. **Z19 2 Optimizing g-factor tuning with electric fields in self-assembled InAs/GaAs quantum dots** JOSEPH PINGENOT, CRAIG E. PRYOR, MICHAEL E. FLATTÉ, *Dept. of Physics and Astronomy, The University of Iowa* Single-spin manipulation in quantum dots can be achieved without a time-dependent magnetic field by modulating the electron g tensor in the dots with an electric field. Using a recently-developed envelope-function formalism for quantum dot g factor calculations[1], we have studied the dependence of the electron g tensor tuning range on quantum dot size and shape. The electric field is applied in the growth direction of the dot, assumed to be along [001]. We find that larger percentage changes in the g factors along the principal axes can be achieved in taller dots (more extended along the growth direction) and also, surprisingly, in more elliptical dots. The [110] and $[1\bar{1}0]$ g factors change sign as a function of dot height and lateral extent. Tuning ranges are of the order of $\Delta$ g 0.02 for electric fields changing from 0 to $\pm$ 100 kV/cm. By choosing a dot with a g factor near 0 we identify dots whose g factors should change sign along one principal axis as a function of electric field. This should generate very rapid spin manipulation using g tensor modulation resonance[2]. This work supported by DARPA/ARO DAAD19-01-1-0490. [1] C. E. Pryor and M. E. Flatté, Phys. Rev. **Z19 3 Calculations of Landé g-factors in III-V nanowhisker quantum dots** A. DE, *Dept. of Physics and Astronomy, University of Iowa* C. E. PRYOR, *Dept. of Physics and Astronomy, University of Iowa* We present detailed numerical calculations of Landé g-factors in semiconductor nanowire based quantum dots. We consider 111 oriented InAs nanowires with InP double barriers forming the dot, for which transport properties have recently been investigated[1]. We find that compared to recent calculations of self-assembled InAs/GaAs quantum dots[2], typical nanowire dots have larger, and negative, g-factors. We attribute this to the nanowire dots being larger than self-assembled dots, resulting in less angular momentum quenching. For nanowire sizes typical of those that have been fabricated to date, we find $g \approx -3.1$. M. T. Björk et al., Nano Letters, **4**, 1621 (2004).2. C. E. Pryor, M. E. Flatte, Phys. Rev. **Z19 4 Control and manipulation of charge and spin in single and coupled quantum dots.**
GERHARD ABSTREITER

I will discuss measurements of the spin lifetime in self-assembled InGaAs dots in GaAs. The spin relaxation time ($T_1$) is found to be extremely long (e.g. $>$ 25ms at T=1K, B=4T) decreasing with magnetic field according roughly to a clear $B^{-4}$ power law [1]. Furthermore, $T_1$ is found to reduce linearly with lattice temperature and be very strongly sensitive to the motional quantisation (s-p shell splitting). Another topic is the the coherent quantum coupling of a vertically stacked pair of quantum dots. The interaction can be tuned in such quantum dot molecule devices using an applied voltage as external parameter [2]. At the resonance the electron component of the exciton wave function hybridizes, giving rise

to a quantum coupling energy in the excitonic spectrum. This work is supported financially by Deutsche Forschungsgemeinschaft via collaborative research center 631 and by German Federal Ministry of Research via NanoQuit. [1] M. Kroutvar, Y. Ducommun, D. **Z19 5 Anisotropic phonon-assisted spin relaxation in elliptical quantum dots*** OLEG OLENDSKI, TIGRAN V. SHAHBAZYAN, *Jackson State University* We study theoretically phonon-assisted spin relaxation of an electron confined in elliptical quantum dot subjected to a tilted magnetic field. We show that in the presence of both Rashba and Dresselhaus spin-orbit terms the relaxation rate exhibits anisotropy with respect to the in-plane field orientation. This anisotropy originates from the interference, at non-zero tilt angle, between the two spin-orbit terms that couple adjacent spin-split energy levels. The variation of the relaxation rate for different azimuthal angles is determined by the quantum dot geometry and by the relative strengths of the Rashba and Dresselhaus coupling constants. The effect is strongest when adjacent spin-split levels are brought into resonance by tuning the total field magnitude and tilt angle. In this case, for certain values of tilt angle, the relaxation rate can be drastically reduced by varying the in-plane field orientation. Calculations were performed for InSb quantum dots.

**Z19 6 Spin Relaxation in Spherical CdS Quantum Dots** P. NAHALKOVA, *Charles University in Prague, Ke Karlovu 3, 121 16 Prague, Czech Republic and Universiteit Antwerpen, Universiteitsplein 1, B-2610 Antwerpen, Belgium* D. SPRINZL, P. NEMEC, P. MALY, *Charles University in Prague, Ke Karlovu 3, 121 16 Prague, Czech Republic* V. N. GLADILIN, J. T. DEVREESE, *Universiteit Antwerpen, Universiteitsplein 1, B-2610 Antwerpen, Belgium* We present results of the time-resolved spin-sensitive differential transmission experiments and the quantitative theoretical analysis of the spin relaxation mechanism in quasi-spherical CdS quantum dots (QD) in a glass matrix. The measured decay of the degree of circular polarization (DCP) on ns timescale can be explained well by intralevel exciton transitions with electron spin flip, driven by the electron-hole exchange interaction and assisted by two LO phonons. The predicted spin relaxation rates for different QD sizes and temperatures are in line with experimentally determined values. The developed theoretical model provides also a qualitative understanding of the observed behavior of DCP as a function of central energy of pump and probe pulses. **Z19 7 Theory of spin-orbit effects and spin relaxation in single and coupled quantum dots.*** PETER STANO, *University of Regensburg* JAROSLAV FABIAN, Spin-orbit effects and phonon-induced spin relaxation in laterally coupled quantum dots in the presence of magnetic field are investigated by exact numerical diagonalization. Both Bychkov-Rashba and Dresselhaus spin-orbit couplings are included. Several new phenomena are predicted. In particular, we shown that coherent tunneling between the dots depend on the spin, enabling a scheme for spin-to-charge conversion by spin separation in a *homogeneous* magnetic field. Furthermore, we show that spin relaxation is highly anisotropic, both in terms of the direction of the double-dot axis as well as the direction of the magnetic field. The anisotropy comes from spin-orbit coupling. Calculated spin relaxation rates of GaAs single dots agree with a recent experiment.

**Z19 8 Asymmetric electron-electron exchange in a single quantum dot** STEFAN C. BADESCU, *NRL, Washington DC* YULI B. LYANDA-GELLER, *Purdue Univ, West Lafayette IN* THOMAS L. REINECKE, *NRL, Washington DC* Recent photoluminescence experiments on negative trions in a self-assembled quantum dot [1] reveal a high dephasing rate inconsistent with the electron-hole exchange mechanism. We find, however, that this rate can be explained by the asymmetric electron-electron exchange due to electron spin-orbit coupling in the excited singlet and triplet states. The necessary and sufficient condition for the existence of asymmetric exchange is the lack of inversion symmetry in the plane transverse to the growth direction. We develop a model that describes the two relevant cases of this asymmetry: when the system has a single reflection plane along the growth axis, and when the system has no reflection plane along the growth axis. These asymmetries are characteristic for shapes of self-assembled quantum dots. We find typical values for the dephasing part of the asymmetric exchange that are $\sim 10^{-1}$ of the symmetric exchange. We also find that the asymmetric exchange is important for electron spin relaxation when the triplet states with non-zero projection of spin are brought into resonance with the singlet. **Z19 9 Spin Dynamics in InAs Quantum Dots** JANICA WHITAKER, ALLAN BRACKER, DANIEL GAMMON, THOMAS KENNEDY, *Naval Research Laboratory* Spin coherence in InAs Self-Assemble Quantum Dots (SAQD's) could be useful for optical delay lines and quantum information technology. Very uniform dots and a very accurate measurement of dephasing processes are required to realize these possibilities. To this effect we report decoherence times in InAs SAQD. Here we describe measurements of spin dynamics from a 17 layered nominally undoped wafer of InAs SAQDs with a varying dot-size. We used Time Resolved Kerr Rotation (TRKR) for a wavelength resonant with the 3D InAs Stranski-Krastanow strain mediated quantum dots. Response is observed from 0 to 5 T that corresponds to a freely precessing spin with $g = 0.45$, a 1.2 ns lifetime at $B=0$ that decreases with B, and a sine-like phase. We attribute this spin to an electron from either the ground state of a negative trion or the excited state of a positive trion. The dots are dots unintentionally doped from background doping in the MBE chamber. Work supported in part by ONR, NSA/ARO, and DARPA/QUIST. JW is an NRC/NRL Postdoctoral Research Associate.

**Z19 11 Dynamics of Coupled Qubits Interacting with an Off-Resonant Cavity*** OLIVER GYWAT, FLORIAN MEIER, DANIEL LOSS, DAVID D. AWSCHALOM, *Center for Spintronics and Quantum Computation, University of California, Santa Barbara, California 93106, USA* We study a model for a pair of qubits which interact with a single off-resonant cavity mode and, in addition, exhibit a direct inter-qubit coupling[1]. Possible realizations for such a system include coupled superconducting qubits in a line resonator as well as exciton states or electron spin states of quantum dots in a cavity. The emergent dynamical phenomena are strongly dependent on the relative energy scales of the inter-qubit coupling strength, the coupling strength between qubits and cavity mode, and the cavity mode detuning. We show that the cavity mode dispersion enables a measurement of the state of the coupled-qubit system in the perturbative regime. We discuss the effect of the direct inter-qubit interaction on a cavity-mediated two-qubit gate. Further, we show that for asymmetric coupling of the two qubits to the cavity, the direct inter-qubit coupling can be controlled optically via the ac Stark effect.

*We acknowledge support from DARPA SPINS, DARPA QUIST, CNID, ARO, ONR, NCCR Nanoscience, and the Swiss NSF.

**Z19 12 Cavity Enhanced Faraday Rotation in Semiconductor Quantum Dots*** D.W. STEUERMAN, Y.Q. LI, J. BEREZOVSKY, D.S. SEFEROS, G.C. BAZAN, D.D. AWSCHALOM, *Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106* The promise of quantum computation is helping fuel the development of single spin manipulation and measurement techniques. Photonic cavities provide an intriguing platform to increase the sensitivity of optical measurements, as well as the possibility to explore emergent light-matter interactions. The flexibility of a dielectric vertical cavity is exploited to study the spin dynamics within molecularly self-assembled CdSe quantum dots (QDs). Through the integration of QDs in microcavities, a twenty-fold enhancement of Faraday rotation is observed, which scales with the quality factor of the cavity. In this weak coupling regime, the amplified rotation is attributed to optically generated excited spins and multiple passes of the probe photons in the cavity. By applying this general planar cavity motif to Faraday rotation, dynamical measurements are accessible at extremely low powers on relatively small numbers of quantum confined states. In CdSe QDs, low power measurements reveal that contributions from both exciton and electron spin precession are largely dependent upon the power of excitation. This scheme is amenable to both soft and hard systems as a means to increase detection sensitivity.

**Z19 13 Optical manipulation of electron spin in quantum dot systems*** JOSE VILLAS-BOAS, SERGIO ULLOA, ALEXANDER GOVOROV, *Ohio University* Self-assembled quantum dots (QDs) are of particular interest for fundamental physics because of their similarity with atoms. Coupling two of such dots and addressing them with polarized laser light pulses is perhaps even more interesting. In this paper we use a multi-exciton density matrix formalism to model the spin dynamics of a system with single or double layers of QDs. Our model includes the anisotropic electron-hole exchange in the dots, the presence of wetting layer states, and interdot tunneling [1]. Our results show that it is possible to *switch* the spin polarization of a single self-assembled quantum dot under elliptically polarized light by increasing the laser intensity. In the nonlinear mechanism described here, intense elliptically polarized light creates an effective exchange channel between the exciton spin states through biexciton states, as we demonstrate by numerical and analytical methods. We further show that the effect persists in realistic ensembles of dots, and we propose alternative ways to detect it. We also extend our study to a double layer of quantum dots, where we find a competition between Rabi frequency and tunneling oscillations. [1] J. M. Villas-Boas, S. E. Ulloa, and A. O. Govorov, Phys. Rev. Lett. 94, 057404 (2005); Phys. Rev. B 69, 125342 (2004).

**Z20 1 Defect-induced Ferromagnetism in Insulators without Magnetic Ions: The Case of Cation Vacancy in CaO*** JORGE OSORIO-GUILLEN, S. LANY, S.V. BARABASH, ALEX ZUNGER, *National Renewable Energy Laboratory* We have investigated by means of first-principle supercell calculations the posibility of ferromagnetism being induced by cation vacancies in non-magnetic oxides in four steps: (*i*) A single neutral Ca vacancy $V_{Ca}^{0}$ is found to have a magnetic moment of 1.9 $\mu_B$ due to its electronic configuration: $(a_1^2\, t_{1+}^3\, e_+^2) t_{1-}^p\, e_-^q$ where, the $e_-$ state is partially occupied ($q \approx 0.5$), leading to a transfer of some hole density to the $t_{1-}$ valence band states ($p \approx 2.5$). (*ii*) The ferro-

magnetic interaction between two vacancies is found to extend only to four neighbors or less. (*iii*) To achieve magnetic percolation on a fcc lattice with such an interaction range one needs a minimum vacancy concentration of $1.8 \times 10^{21}$ $cm^{-3}$ (4.9 %). However, (*iv*) due to the high vacancy formation energy even under the most favorable growth conditions one can not obtain at equilibrium more than $10^{18}$ $cm^{-3}$ vacancies. Thus, a non-equilibrium vacancy-enhancement factor of $10^3$ is needed to achieve ferromagnetism in such systems. Comparison with other non-magnetic oxides will be also discussed.

**11:27**

**Z20 2 Ferromagnetism in Transparent ZnO:xCu Sputter Deposited Thin Films** CHANDRAN SUDAKAR, R. NAIK, *Wayne State University, Detroit* G. MOHAN RAO, *ISU, IISc, Bangalore, India* V.M. NAIK, *University of Michigan-Dearborn* K.V. RAO, *Tmfy-MSE, KTH, Stockholm, Sweden* Currently, detailed understanding on the intrinsic or extrinsic nature of the diluted magnetic oxides when doped with cations (magnetic or nonmagnetic) is an intricate issue. We report a systematic study of ferromagnetism (FM) above room temperature in transparent ZnO:xCu (x in at.%) films deposited by reactive magnetron sputtering. $Cu^{2+}$ ions are found to be in wurtzite structure for $x < 3$, whereas CuO phase is deciphered for $x > 3$, and located within the ZnO lattice with the associated stacking faults or at grain boundary regions. An anomalous large magnetic moment (**itM**) of $\approx 1.76 \pm 0.2$ $\mu_B$/Cu is observed for $x \approx 0.6$. **itM** decreases drastically ( $< < 0.4$ $\mu_B$/Cu) for $x > 1$ due to increased Cu-O-Cu anti-FM interactions. Micro-Raman spectral studies reveal plausible Cu-O clusters of few Å in ZnO lattice giving rise to anomalous high **itM** even at low concentrations ($x < 1$) in ZnO lattice. Detailed discussion will be presented on related results.

**11:39**

**Z20 3 Measurement of the spin polarization of the magnetic semiconductor EuS with zero-field and Zeeman-split Andreev reflection spectroscopy*** CONG REN, J. TRBOVIC, J.G. BRADEN, R.L. KALLAHER, J.S. PARKER, P. SCHLOTTMANN, S. VON MOLNAR, P. XIONG, DEPARTMENT OF PHYSICS/MARTECH, FLORIDA STATE UNIVERSITY TEAM, Measurements of the spin polarization (**itP**) of doped EuS using zero-field and Zeeman-split Andreev reflection spectroscopy (ARS) on EuS/Al planar junctions are reported. EuS films (100nm thick) of different conductivities were grown via UHV electron-beam deposition at various substrate temperatures. A thin (7nm) Al film was used as the counterelectrode. The zero-field ARS spectra can be fit straightforwardly, with itzero spectral broadening and expected gap values, to the spin-polarized BTK model. The fits consistently yield **itP** on the order of 80% regardless of the barrier strength. Moreover, we performed ARS in the presence of a Zeeman-splitting of the quasiparticle density of states in Al. The Zeeman-split ARS spectra are well described theoretically by combining the solution to the Maki-Fulde equations with the spin-polarized BTK analysis. The results have provided an independent verification of the validity of the zero-field ARS, and demonstrated the utility of field-split superconducting spectroscopy on Andreev junctions of arbitrary barrier strengths.

**Z20 4 Observation of the Temperature driven Insulator to Semiconductor (Ferromagnetic) Phase** HANGIL LEE, *Beamline Research Division, Pohang Accelerator Laboratory (PAL)* K.-J RHO, *Electron Spectroscopy Laboratory, Department of Physics, POSTECH* J.-Y KIM, *Beamline Research Division, Pohang Accelerator Laboratory (PAL)* J.-H PARK, *Electron Spectroscopy Laboratory, Department of Physics, POSTECH* PAL TEAM, POSTECH TEAM, We investigated the changes of magnetic properties (para to ferromagnetic) and phase transitions (insulator to semiconductor) in films of EuO grown on a MgO(100) single crystal as a function of temperature. In between 70 K, we found a clear phase transition and magnetic transition using the spin-summed and spin-resolved photoemission spectra, as well as the low energy electron diffraction. We will elucidate the temperature driven electronic and magnetic property in EuO on MgO(100) substrate.

**12:03**

**Z20 5 Critical behavior and spin polarization of a single crystal $Mn_5Ge_3$.** T.Y. CHEN, J. VALENTINE, C.L. CHIEN, *The Johns Hopkins University* C. PETROVIC, *Brookhaven National Laboratory* Despite difficulties of injecting spin into semiconductor using ferromagnetic metals, spin injection into semiconductor is essential for spintronics in order to take advantage of the silicon-based electronics. The intermetallic compound $Mn_5Ge_3$ is a promising candidate as a spin injector for semiconductor because of its relatively high Curie temperature and good lattice match with semiconductors. Recent theoretical calculations show that $Mn_5Ge_3$ has a spin polarization of as much as 70% in the purely diffusive region. In this work, we have determined the critical exponents of a single crystal $Mn_5Ge_3$ using magnetometry. The critical temperature has been determined to be $T_C = 283.68 \pm 0.02$ K from spontaneous magnetization with the critical exponents of $\beta = 0.358 \pm 0.005$ and $\gamma = 1.367 \pm 0.005$. The spin polarization of the crystal determined using point contact Andreev reflection (PCAR) is $54 \pm 2\%$, indicating that it is a good spin injector with a substantial spin polarization compared with ordinary ferromagnetic metals such as Fe, Co and Ni. Work supported by NSF grant No. DMR05-20491 and DMR04-03849.

**12:15**

**Z20 6 Epitaxial Ferromagnet on Ge(111) : $Mn_5Ge_3$** MICHAEL HOCHSTRASSER, DANILO PESCIA, *ETH Zurich* ROY WILLIS, *The Pennsylvania State University* IVANA VOBORNIK, GIANCARLO PANACCIONE, GIORGIO ROSSI, *TASC, INFM-CNR* Magnetic materials used for recording and reading information involve the use of the electron spin, while semiconducting devices normally take advantage of the electron charge. Recently, a big effort has been made in adding the spin degree of freedom to conventional semiconductors. A good potential candidate for spin injection in a silicon- compatible semiconductor are $Mn_5Ge_3$ thin films on Ge(111) [1]. To further gain information on the usefulness of possible spintronics applications of $Mn_5Ge_3$/Ge(111) multilayers angle resolved photoemission spectroscopy (ARPES) was employed to map the band dispersion of

$Mn_5Ge_3$ films on Ge(111) above and below the Curie temperature. Furthermore, we performed temperature dependent x-ray magnetic dichroism measurements of $Mn_5Ge_3$ films on Ge(111) to probe the magnetic properties of $Mn_5Ge_3$. [1] C. Zeng et al., Appl. Phys. Lett. **83**, 5002 (2003).

**12:27**

**Z20 7 Growth and magnetization dynamics of thin film tetradymite-type diluted magnetic semiconductors based on Sb2-xTMxTe3 (M = V, Cr)** ZHENHUA ZHOU, YI-JIUNN CHIEN, CTIRAD UHER, *Department of Physics, University of Michigan* Recently we reported on a new MBE-grown thin film ferromagnetic semiconductor based on Sb2-xVxTe3 with a Curie temperature of 177 K when x = 0.35 [1]. Ferromagnetism was confirmed by magnetization measurements and anomalous Hall effect. We have now extended our investigations to thin films of Sb2-xCrxTe3 and we observed ferromagnetism in this system through magnetic measurements. The Curie temperature increases with the increasing concentration of Cr. Ferromagnetic resonance (FMR) was detected in both Sb2-xVxTe3 and Sb2-xCrxTe3 thin films at low temperatures using an electron paramagnetic resonance (EPR) spectrometer. Optical ultrafast spin dynamics investigations in both Sb2-xVxTe3 and Sb2-xCrxTe3 thin films reveal the existence of spin waves in these diluted magnetic semiconductors. The spin wave parameters are obtained based on the FMR and optical methods. [1] Z. Zhou, Y.-J. Chien and C. Uher, Thin film ferromagnetic semiconductors Sb2-xVxTe3 with TC of 177 K, Applied Physics Letters, vol.87, 112503 (2005).

**12:39**

**Z20 8 A Study of Magnetoresistance of $Yb_{14-x}La_xMnSb_{11}$ : an Ordered Dilute Magnetic Semiconductor*** DAVID MANDRUS, RONGYING JIN, ZHIXIAN ZHOU, BRIAN SALES, *Oak Ridge National Laboratory* LUIS BALICAS COLLABORATION,† $Yb_{14-x}La_xMnSb_{11}$is an ordered dilute magnetic semiconductor, showing evidence for partial screening of the Mn magnetic moments and mass renormalization from 2 $m_e$ near room temperature to 20 $m_e$ at 5 K. We have measured both the transverse (I⊥ H) and longitudinal (I//H) magnetoresistance (MR) of $Yb_{14-x}La_xMnSb_{11}$(x=0, 0.7) single crystals above and below the ferromagnetic (FM) transition temperature $T_c$ = 53 K (x=0) and 39 K (x=0.7). While it is negative in a wide temperature range, the MR becomes positive below $T_c/2$ and increases with decreasing temperature. Strikingly, the positive MR increases linearly with applied field, showing no sign of saturation up to 32 tesla. Quantitative analysis and implications of the data will be reported.

**Z20 9 Observation of a new magnetic anomaly in low field ac and dc magnetic measurements in $Yb_{14}MnSb_{11}$** S. SRINATH, P. PANKAJ, H. SRIKANTH, *Department of Physics, University of South Florida, Tampa FL 33620* B.C. SALES, D. MANDRUS, *Condensed Matter Sciences Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831* $Yb_{14}MnSb_{11}$ is the first known example of a ferromagnetic Kondo lattice compound in the underscreened limit. Recent optical, Hall, magnetic, and thermodynamic measurements indicate that $Yb_{14}MnSb_{11}$ may be a rare example of an underscreened Kondo lattice. This heavily doped magnetic semiconductor is ferromagnetic below 52 ± 1 K. We report the first experimental observation of a new magnetic anomaly in this system at around 47 K, a few degrees below the Curie temperature. Systematic investigations of the AC and DC susceptibilities of $Yb_{14}MnSb_{11}$ single crystals reveal features associated with possible spin re-orientation at this temperature. This new anomaly is extremely sensitive to the applied field and is absent in DC magnetization measurements for fields above 50 Oe. The origin of this could be related to a change in magnetic anisotropy caused by the decoupling of energetically close FM and AFM sub-lattices.

**13:03**

**Z20 10 Transport and magnetic properties of rare-earth nitrides** JOE TRODAHL, SIMON GRANVILLE, BEN RUCK, FELIX BUDDE, *Victoria University of Wellington, Wellington, New Zealand* TONY BITTAR, GRANT WILLIAMS, *Industrial Research Ltd., Lower Hutt, New Zealand* There is controversy about the conducting character of the rare-earth nitrides, with reports existing from metallic to moderately wide band-gap semiconductors. In a programme intended to clarify that issue we have grown thin films of the rare-earth mononitrides GdN, SmN, DyN and ErN by ion assisted deposition (IAD). Their stoichiometry and nanocrystalline structure have been characterised by RBS, SIMS, XRD, TEM, and EXAFS. The as-prepared materials are very reactive in the atmosphere, but they are effectively passivated by capping layers of either $MgF_2$ or IAD GaN. Their magnetic properties have been studied from ambient temperature to 5 K and found to be in agreement with reported behaviour in the literature. The conductivity is typical of semiconductors, as regards both its magnitude and its temperature dependence.

**Z22 2 Novel Chemical Synthesis of FePt and CoPt Magnetic Nanoclusters** YUCHENG SUI, YAO ZHAO, MINGLANG YAN, DAVID SELLMYER, *Department of Physics & CMRA, University of Nebraska* $L1_0$ ordered FePt and CoPt clusters are very promising candidates for ultrahigh magnetic recording media applications due to their large magnetocrystalline anisotropies and chemical stability. We report simple and highly efficient approaches for synthesizing FePt and CoPt nanoclusters by the pyrolysis of corresponding Fe, Co and Pt compounds in organic solvents. A mixture of Fe and Pt acetylacetonates was heated in trioctylamine, producing FePt clusters with average size about 4.2 nm and with a narrow size distribution. When the clusters with equal Fe and Pt atomic ratio were dispersed onto a silicon wafer and heated in forming gas, high- anisotropy magnetic FePt clusters with $L1_0$ chemical order were obtained. Coercivity values as high as 23 kOe were realized after annealing at 750$^o$C for 5 min. When the pyrolysis of Co and Pt acetylacetonates mixture was carried out in trioctylamine, CoPt clusters about 4 nm and narrow size distribution also were produced. The atomic ratio of CoPt clusters can be tuned by the addition of proper reducing agents. The chemical reaction mechanism, the phase transformation and the magnetic properties will be discussed. This research is supported by DOE, NSF-MRSEC, INSIC, NRI and CMRA.

**Z22 3 Size Effect on Chemical Ordering in Face-Centered Tetragonal FePt Nanoparticles*** DAREN LI, NARAYAN POUDYAL, VIKAS NANDWANA, J.PING LIU, *Department of Physics, University of Texas - Arlington* Monodisperse face-centered tetragonal (fct) FePt nanoparticles with high magnetocrystalline anisotropy have been obtained by means of the salt-matrix annealing technique. The as-synthesized face-centred cubic (fcc) FePt nanoparticles of different sizes were mixed with NaCl powder particles and the mixture was annealed at temperatures up to 750 $^o$C for several hours. X-ray diffraction (XRD) and transmission electronic microscopy (TEM) analyses showed that the annealed particles transfered to the fct structure without sintering and agglomeration. Magnetization measurements gave the coercivity of the nanoparticles increasing with the particle size. Extended annealing does not change the size dependence of the coercivity. Further XRD analysis revealed that the size dependence of the coercivity is related to the particle size dependance of long-range chemical ordering degree. The long-range order parameter S is 0.78, 0.92, 0.98 and 0.94 for the 4 nm, 6 nm, 8 nm and 15 nm particles, respetively. This trend is consistent with that of the coercivity measured from the nanoparticles. The relatively low ordering parameter of the 15 nm particles may be related to the polycrystalline morphology as shown by the high resolution TEM.

**Z22 4 Chemically Synthesized FePt Binary Alloy Nanoparticles with Different Shapes*** L. COLAK, Y. HUANG, M.J. BONDER, G.C. HADJIPANAYIS, *Dept. of Physics and Astronomy, U of Delaware, Newark,DE,USA* D. WELLER, *Seagate Technology, Pittsburg, PA,USA* Chemically synthesized FePt nanoparticles are promising candidates for future high density magnetic recording media. In this work, FePt and $FePt_3$ binary alloy nanoparticles have been synthesized by thermal decomposition of iron pentacarbonyl ($Fe(CO)_5$) and reduction of platinum acetylacetonate (Pt $(acac)_2$) in the presence of oleic acid (OA) and oleyl amine (OY) surfactants at low refluxing temperatures. $FePt_3$ and FePt nanoparticles were obtained by varying the Fe:Pt molar ratio in the range of 1.4-1.7. With control of the heating rate to the refluxing temperature, nanoparticles with a size of $\sim$ 5 nm and with different shapes were obtained for both compositions. The particles showed very little agglomeration to an annealing temperature of 650$^o$C, as observed using X-Ray Diffraction (XRD) and Transmission Electron Microscopy (TEM). Magnetic measurements show that annealing at 700$^o$C partially transforms the FePt and $FePt_3$ nanoparticles from the disordered fcc phase to the ordered $L1_0$ and $L1_2$ phases, respectively. HRTEM and Mossbauer studies will be discussed in terms of the temperature and time dependent evolution of microstructure with annealing.

**Z22 5 Variability in the extent of ordering for individual FePt $L1_0$ nanoparticles** RUMYANA V. PETROVA, BO YAO, VU LAM, K.R. COFFEY, *University of Central Florida, Orlando, FL 32815 USA* R.R. VANFLEET, *Brigham Young University, Provo, Utah 84602, USA* $L1_0$ordered phase FePt nanoparticles are of interest as high-density magnetic recording media due to the large uniaxial magnetocrystalline anisotropy,$K_u$ observed in bulk and thin film samples. Similarly high itKu values have not yet been achieved for small ( $<$ 10nm) FePt nanoparticles. Mixtures of ordered and disordered nanoparticles are often observed and have been attributed to nucleation barriers for the ordering transformation in individual small nanoparticles. For FePt, $K_u$ is known to depend strongly on the extent of long-range chemical order. In this work we report on the variability of the extent of order amongst ordered $L1_0$ FePt particles. Well-isolated, small FePt nanoparticles were prepared from discontinuous FePt films, using ultra high vacuum dc magnetron sputtering. A Tecnai F30 analytical transmission electron microscope was used to characterize the FePt nanoparticles. Convergent beam electron diffraction patterns from individual nanoparticles were compared to multislice simulations to determine the extent of order of single nanoparticles.

**12:39**

**Z22 6 Direct Fabrication and Magnetic Characterization of Highly Ordered $L1_0$ FePt Nanoparticles** JIAO-MING QIU, JIAN-PING WANG, *MINT & Department of Electrical and Computer Engineering,University of Minnesota* Future advanced magnetic recording media require the grains to be small and uniform with sufficient anisotropy to sustain thermal fluctuation. $L1_0$ phase FePt nanoparticles fit these requirements but their fabrication turns out to be difficult. Conventional methods were reported to be able to make monodispersed FePt nanoparticles with disordered structure[1]. The inevitable phase transformation process is believed to be kinetically limited[2] and such issues as agglomeration and twinning are to be addressed. Here we report a novel technique that can fabricate monodispersed highly ordered FePt nanoparticles with no need for phase transformation process. In this technique, particle nucleation and growth processes happened in the gas phase and they were separated in space. Modified sputtering plasma made the ordering and particle growth processes proceed simultaneously. Uniform $L1_0$ FePt nanoparticles with room temperature coercivity of 8.25 kOe were achieved for particle randomly assembled film. HRTEM analysis shows that these particles have perfect octahedron shape with only {111} surfaces exposed. Ref: 1. Sun, S, et al, Science, 287, 1989, 2000 2. Ding, Y. et al, Appl. Phys. Lett. 87, 022508, 2005

**Z22 7 Effects of Annealing on the Magnetic and Structural Properties of FePt Nanoparticles by Chemical Synthesis*** HONGLI WANG, Y. HUANG, Y. ZHANG, G. HADJIPANAYIS, *Department of physics, University of Delaware, Newark, DE 19716, USA* D. WELLER, *Seagate Technology, Pittsburgh, PA 15203, USA* A. SIMOPOULOS, *IMS, NCSR ''DEMOKRITOS,'' Ag. Paraskevi, Athens 15310, Greece* In this paper, we have studied the effects of annealing atmospheres on the particle size, the degree of ordering, and the magnetic properties of FePt nanoparticles made by chemical synthesis. Measurements were made on particle assemblies with controlled dimension and thickness. Annealing was done under forming gas and vacuum atmospheres. Particles did not grow much after annealing at 550 $^{o}$C for 30 min under forming gas, resulting in an average particle size D $\approx$ 5 nm and a coercivity of 4 kOe. After annealing under vacuum using the same annealing temperature and time, the morphology of particles is similar to that of particles annealed under forming gas but with a coercivity less than 1 kOe. We believe that this large difference in coercivity is due to the fact that the forming gas not only assists the transformation from the chemically disordered fcc phase to the chemically ordered $L1_0$ phase but also makes the atomic composition of FePt nanoparticles more uniform. Mössbauer studies showed a higher percentage of $L1_0$phase in the sample annealed under forming gas than that under vacuum, which further confirms the hypothesis stated above.

**Z22 8 Enhanced orbital magnetism in oxide free Fe50Pt50 nanoparticles probed by x-ray magnetic circular dichroism*** MICHAEL FARLE, *Universitaet Duisburg-Essen* X-ray absorption spectra at both the Fe and Pt L3,2 edges were measured on wet-chemically synthesized Fe50Pt50 particles with a mean diameter of 6.3 nm. The organic ligands and the oxide shell covering the particles in the as prepared state were removed by soft hydrogen plasma. After thermal treatment under hydrogen atmosphere of 5 Pa, the coercive field increased by a factor of 6. This indicates the formation of the chemically ordered L10 phase and is accompanied by an enhancement of the orbital magnetic moment at the Fe site by 275%. Changes in the frequency of oscillations in the extended x-ray absorption fine structure at the Pt L3,2 edges provide additional crystallographic evidence for the formation of the L10 phase.

**Z22 9 FePt-Si Nanoparticles With Perpendicular Anisotropy*** J. WAN, Y. ZHANG, Y. HUANG, M. BONDER, G.C. HADJIPANAYIS, *Department of Physics and Astronomy, University of Delaware, Newark DE 19711* C. NI, *Department of Materials Science and Engineering, University of Delaware, Newark DE 19711* D. WELLER, *Seagate Technology, Pittsburgh, PA 15203* FePt Nanoparticles are attractive for applications in magnetic recording media because of their high magnetocrystalline anisotropy. In this work, FePt-Si nanoparticles were fabricated by sputtering an FePt-Si target onto heated MgO substrates. The deposition temperature varied from 350$^{o}$ to 500$^{o}$C. The ratio of FePt to Si in the films was changed by varying the amount of Si in the target. XRD results show that the lattice parameters of L10 phase changed in the FePt-Si nanoparticles from 3.71 to 3.61 Å for the c parameter and from 3.85 to 3.87 Å for the a parameter. Higher amounts of Si led to a larger change in lattice parameters. The change of lattice parameters in FePt nanoparticles affected the magnetic properties as indicated by the decrease of the coercivity in the FePt-Si samples. TEM images show that the FePt/Si nanoparticles have a better size distribution than the FePt/C nanoparticles. Selected area electron diffraction patterns show that the FePt-Si nanoparticles deposited on MgO have a (001) texture due to the lattice matching between FePt and MgO. The FePt-Si nanoparticles have properties that can be tailored for applications in magnetic recording media.

**Z22 10 Magnetic force microscopy (MFM) study of FePt nanocrystals overcoated with silica*** ALEX DE LOZANNE, CHANGBAE HYUN, *Department of Physics, University of Texas at Austin, Austin, TX 78712* DOH C. LEE, BRIAN A. KORGEL, *Department of Chemical Engineering, University of Texas at Austin, Austin, TX 78712* Chemically-synthesized FePt nanocrystals must be annealed at $\sim$ 550C to induce the hard magnetic L10 phase. Sintering of nanocrystal films occurs at these temperatures, resulting in the loss of control over nanocrystal size and separation in the film. We have developed a silica overcoating strategy to prevent nanocrystal sintering. In this study, 6 nm diameter FePt nanocrystals were coated with 20 nm thick shells of silica using an inverse micelle process. Magnetization measurements of the annealed FePt@SiO2 nanocrystals indicate ferromagnetism at room temperature. The micromagnetic properties of thin films of these nanocrystals were studied using MFM.

**Z22 11 Enhancement of $L1_0$Order in FePt Thin Films and X-ray Rapid Thermal Annealing (XRTA)*** ROSA ALEJANDRA LUKASZEW, JONATHAN SKUZA,† *University of Toledo* ERIC DUFRESNE, *Argonne National Laboratory* CODRIN CIONCA, *University of Michigan* ALFONSO CEBOLLADA, *IMM-Spain* CESAR CLAVERO, *IMM-Spain* CORA LIND, *University of Toledo* Highly ordered $L1_0$ FePt thin films and nanostructures are important for magneto-recording applications because this ordered phase exhibits very large magnetic anisotropy. One possibility to achieve high degree of chemical order in epitaxial, but somewhat chemically disordered films is to perform annealing treatments. One variation of such treatments is rapid thermal annealing (RTA). Here we describe an innovative application of x-ray undulator radiation to simultaneously perform RTA and probe structural changes that occur itduring annealing. In our studies, we have used XRTA to enhance chemical order in epitaxial (001) FePt thin films. We observed the enhancement of the itfcc-fct transition with 30 ms temporal resolution in Bragg geometry. The results demonstrate that undulator radiation offers unique possibilities for materials processing, particularly the ability to use the itsame beam for heating and probing.

**Z23 1 Yb- and Ce- based, dilute rare earth intermetallic compounds: Fully ordered compounds that approach the single Kondo-impurity limit** M.S. TORIKACHVILI, *Dept. of Physics, San Diego State University* S. JIA, *Ames Laboratory and Dept of Physics and Astronomy, Iowa State University* S.T. HANNAHS, *NHMFL-Florida State University, Tallahassee* NI NI, E-D. MUN, S.L. BUD'KO, P.C. CANFIELD, *Ames Laboratory and Dept of Physics and Astronomy, Iowa State University* Dilute, rare earth intermetallic compounds are ordered structures in which the rare earth comprises less than 5% atomic of the compound, but still fully occupies a unique crystallographic site. Whereas for local moment bearing R-members these series offer the possibility of studying the RKKY interaction for relatively large R R spacing, the R = Yb and Ce members offer a unique opportunity to study the Kondo lattice for concentrations that start to approach the single ion limit. In this talk we will present data on six Yb-based, and two Ce-based, dilute rare earth intermetallic compounds. Despite the rather different behavior of the analogous Gd-based members, the thermodynamic and transport properties of the Yb-based materials are rather similar. This new family of heavy Fermion materials promises to be a fruitful testing ground for current theories of correlated electron physics.

**11:27**
**Z23 2 The low temperature thermodynamic properties and Hall effect in YbAgGe close to the field-induced quantum** Y. TOKIWA, A. PIKUL, P. GEGENWART, F. STEGLICH, *Max-Planck Institute for Chemical Physics of Solids, Dresden* V.S. ZAPF, *NHMFL - Los Alamos* S.L. BUD'KO, P.C. CANFIELD, *Ames Laboratory and Department of Physics and Astronomy, Iowa State University* We present temperature and field dependent heat capacity and magnetization data ($T \geqslant 50$ mK, $H \leqslant 11.5$ T) as well as field dependent Hall effect data ($T \geqslant 50$ mK, $H \leqslant 18$ T) for YbAgGe, a heavy-fermion compound with a field induced quantum critical point. These data clearly indicate that the same electronic degrees of freedom are responsible for the features seen in both specific heat and magnetization data. In addition, they further refine the different boundaries suggested for the $H - T$ phase diagram of YbAgGe through previous, magneto-transport measurements, and allow for further understanding of different phases on the $H - T$ phase diagram, in particular, clearly disconnecting the field-induced quantum critical point in YbAgGe from any sort of saturation of the Yb moment in higher applied magnetic field.

**Z23 4 Rare-earth nitrides: an LSDA+U study** PAUL LARSON, WALTER LAMBRECHT, *Case Western Reserve University* MARK VAN SCHILFGAARDE, *Arizona State University* The class of rare-earth (Ce-Lu) nitrides all form in the rocksalt crystal structure. One member in particular, GdN, has received considerable theoretical and experimental interest because it appears to be a bulk ferromagnetic semiconductor. The other members of this class of compounds have received much less attention. Electronic structure calculations for the entire series are presented here using a full-potential linear muffin-tin orbital (FP-LMTO) method within the LSDA+U approach. In this approach the localized orbitals have their Coulomb interactions treated in a screened Hartree-Fock mean field approximation while the remaining orbitals are treated in the standard local spin density approximation. $U$ terms were also added to the rare-earth 5$d$ states to correct for the underestimation of the band gap in LSDA. In a cubic field, the 4$f$ states split into triply degenerate $t_{1u}$ and $t_{2u}$ states and a singly degenerate $a_{2u}$ state. The large Hubbard $U$ is found to dominate crystal field splitting to determine the order of minority and majority spins. Avoiding partially filled states at the Fermi level is the dominant principle, yielding narrow gap semiconducting or semimetallic band structures. In a few cases, namely those which correspond to configurations deviating by 2 electrons from a completely empty, completely full, or half-full configuration, however, an $f$-band is forced to cross the Fermi level, possibly resulting in heavy-fermion metallic behavior.

**12:03**
**Z23 5 Electronic structure of CrN: a Mott insulator** ADITI HERWADKAR, WALTER R.L. LAMBRECHT, *Case Western Reserve* MARK VAN SCHILFGAARDE, *Arizona State University* It was recently reported by D. Gall et al. [J. Appl. Phys. 91, 5882, 2002] that CrN in the rocksalt structure has an optical band gap of about 0.7 eV, though in local spin density approximation, this materials is predicted to be metallic. We examine this possibility using the LSDA+U approach in the fully localized limit implemented in our full-potential muffin-tin orbital method. Slater integral $F^0 = U$ is screened such that the position of the occupied 3$d$ levels agrees well with the photoelectron spectra of CrN. We find that a band gap opens in the band structure. The actual value of the gap obviously depends on the choice of $U$. To understand the origin of the gap it is essential to study how the $d$ states split in cubic symmetry and what their filling is. Cr in forming CrN is

trivalent and hence has three $3d$ electrons. The Cr $e_g$, form antibonding states in the conduction band. Adding $U$ tends to push these empty states further up for both spins. The $t_{2g}$ on the other hand form weaker $\pi$ bonds with N $2p$, which in LSDA occur near the Fermi energy. Adding a Hubbard $U$ now shift the majority spin electrons by $-U/2$ and the minority spin ones by $U/2$ and remove them from the Fermi level. This works because the three fold degenerate majority spin state $t_{2g\uparrow}$ becomes completely filled while the minority $t_{2g\downarrow}$ becomes empty. The valence band maximum then has predominantly N$2p$ character, which makes CrN a charge transfer type Mott-insulator.

**12:15**

**Z23 6 Free Magnetic Moments in Disordered Metals*** EDUARDO R. MUCCIOLO, *University of Central Florida* STEFAN KETTEMANN, *Institut für Theoretische Physik, Universit at Hamburg, Germany, and Max-Planck Institute for Physics of Complex Systems, Dresden, Germany* The screening of magnetic moments in metals, the Kondo effect, is found to be quenched with a finite probability in the presence of nonmagnetic disorder. Numerical results for a disordered electron system show that the distribution of Kondo temperatures deviates strongly from the result expected from random matrix theory even in the diffusive regime. A pronounced second peak emerges for small Kondo temperatures, showing that the probability that magnetic moments remain unscreened at low temperatures increases with disorder. Analytical calculations, taking into account correlations between eigenfunction intensities yield a finite width for the distribution that survives the thermodynamic limit. Experimental consequences for the electron dephasing in disordered mesoscopic metals and the thermodynamic properties of heavy-fermion compounds are discussed.

*This research was supported by the German Research Council (DFG) and the EU TMR-network

**12:27**

**Z23 7 d-wave Kondo liquids** POUYAN GHAEMI MOHAMMADI, *Massachusetts Institute of Technology* T. SENTHIL, *Massachusetts Institute of Technology & Center for Condenced matter theory, Indian Institute of Science* Conventional heavy Fermi liquid phases of Kondo lattices involve the formation of a ''Kondo singlet'' between the local moments and the conduction electrons. This Kondo singlet is usually taken to be in an internal s-wave angular momentum state. Here we explore the possibility of Fermi liquid phases where the Kondo singlet has internal angular momentum that is d- wave. Such states are readily acessed in a slave boson mean field formulation, and are energetically favorable when the Kondo interaction is between a local moment and an electron at a nearest neighbor site. The properties of the d- wave Kondo lattice are studied. Effective mass and quasiparticle residue show large angle dependence on the Fermi surface. We suggest that such d-wave Kondo pairing may provide a useful route to thinking about correlated Fermi liquids with strong anisotropy along the Fermi surface.

**12:39**

**Z23 8 Randomly Depleted Kondo Lattices** RIBHU KAUL, *Duke U. and TKM Uni-Karlsruhe* MATTHIAS VOJTA, *TKM Uni-Karlsruhe* How is the ''heavy Fermi liquid'' of the Kondo lattice connected to the Kondo impurity ''local Fermi liquid'' as the concentration of f-moments is varied? We study the ensuing interplay of strong correlations and disorder within an $SU(N)$ model in a $N \to \infty$ limit. Although normal Fermi liquid behavior is well defined close to the two limits of Kondo-lattice and Kondo-impurity, we find that in between them there are strongly inhomogeneous phases with large fractions of quasi-free moments that result in a violation of the usual Fermi-liquid behavior. The full spatial dependence of the mean field solutions allows us to study the depletion driven evolution of inhomogeneities in local quantities like the local susceptibility and the local spectral function in detail. We describe the relevance of our results to recent experiments on $Ce_{1-x}La_xCoIn_5$.

**12:51**

**Z23 9 Multipole properties of one-dimensional *f*-electron systems** HIROAKI ONISHI, TAKASHI HOTTA, *Advanced Science Research Center, Japan Atomic Energy Agency* By exploiting a density matrix renormalization group method, we investigate the ground-state properties of a one-dimensional three-orbital Hubbard model on the basis of a *j-j* coupling scheme. Here we focus on the case where the *f*-electron number per site is one ($f^1$). When three orbitals are degenerate, we observe a peak at $q=0$ in $\Gamma_{3g}$ quadrupole correlation, indicating a ferro-orbital state. Namely, $f$ electron occupies an itinerant $\Gamma_8^b$ orbital to gain kinetic energy, while localized $\Gamma_8^a$ and $\Gamma_7$ orbitals are found to be almost empty. Furthermore, we find a peak at $q=\pi$ in $\Gamma_{4u}$ dipole correlation, suggesting an antiferromagnetic state. On the other hand, when we take account of the level splitting between $\Gamma_8$ and $\Gamma_7$ orbitals, due to the competition between itinerant and localized orbitals, we observe a characteristic change of $\Gamma_{3g}$ quadrupole correlation into an incommensurate structure in accordance with the change of the orbital structure. We will also discuss a key role of multipole degrees of freedom in $f^2$- and $f^3$-electron systems.

**13:03**

**Z23 10 Correlation Behavior in Nanoassembled Spin Lattices*** LAILA S. MATTOS, *Stanford University* G.A. FIETE, *UC Santa Barbara* B.A. JONES, C.P. LUTZ, D.M. EIGLER, *IBM Almaden* H.C. MANOHARAN, *Stanford University* The single-impurity Kondo problem, in which an isolated magnetic impurity in a nonmagnetic metallic host has its spin screened by that of the conduction electrons, has been extensively studied both theoretically and through bulk experiments. Only recently, however, have new methods allowed detailed experimental probing of single-impurity Kondo effect of individual magnetic atoms. When many magnetic impurities are present in a bulk conductor or on its surface, the interactions between them may engender novel collective effects. Using a scanning tunneling microscope (STM) we assembled and studied atomically precise periodic arrangements of (magnetic) Co atoms and (non-magnetic) CO molecules on the Cu(111) surface. We observe signs of spin correlation effects when the lattice row spacing for the Co lattices approached half of the Fermi wavelength for the Cu(111) surface electrons. Removing the central atom in each lattice and directly probing the energetics of the resulting hole provides a novel method to search for global spin correlations and investigate Kondo hole behavior in these systems.

**Z23 11 Studies on Single Crystal CeCo3B2** LONG PHAM, *Department of Physics, University of California, Davis, California,*

*95616* VLADIMIR SIDOROV, *Vereshchagin Institute of High Pressure Physics, 142190 Troitsk, Russia* JASON LASHLEY, JOE THOMPSON, *Los Alamos National Laboratory, Los Alamos, New Mexico 87545* HANOH LEE, ZACH FISK, *Department of Physics, University of California, Davis, California, 95616* Magnetization, resisitivity, and specific heat measurements, under pressure, on weak ferromagnet CeCo3B2 are reported. This hexagonal structure with space group P6/mmm ($D^1_{6h}$), and one formula unit per unit cell, forms in the $CaCu_5$-type structure. At ambient pressure, dc and ac susceptibility displayed an ordering below a $T_{curie}$ of $\sim$ 210K, with the highly anisotropic ordering along the c axis, which is weakly suppressed with the application of pressure(- 4 K/GPa). Along the ordering axis, the saturation moment, taking into account the linear behavior at higher fields, reaches only $\sim 0.01\mu_B$ at 2K. This work was supported by NSF-DMR 0433560.

**13:27**
**Z23 12 Evolving Magnetism from self damage in $\alpha$ and $\delta$-Pu** SCOTT McCALL, *LLNL* MICHEAL FLUSS, BRANDON CHUNG, MICHEAL McELFRESH, DAMON JACKSON, As a consequence of the unusual nature of plutonium's electronic structure, point- and extended-defects are expected to, and do exhibit extraordinary properties. Low temperature magnetic susceptibility measurements on Pu and fcc-Pu(Ga) show that the magnetic susceptibility increases as a function of time, yet upon annealing the specimen returns to its initial magnetic susceptibility. This excess magnetic susceptibility (EMS) arises from the $\alpha$-decay and U recoil damage cascades which produce vacancy and interstitials as point and extended defects. The time dependence of the EMS leads to an estimate of the number of atoms influenced by each $\alpha$-decay, as well as a temperature dependence well described by a Curie-Weiss law. These results will be described in context of recent time dependent studies of the elastic modulus in delta Pu. Work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract W-7405-Eng-48.

**Z24 1 Predicting the Positions and Breadths of the Glass Transitions in Polymer-Diluent Mixtures** J.E.G. LIPSON, *Dartmouth College* S.T. MILNER, *ExxonMobil* When a plasticizer is added to a polymer the effect is to lower and broaden the glass transition of the polymer. Less frequently studied is the opposite range of the concentration scale, which presumably raises and broadens the diluent glass transition. In fact, although the default assumption is that this miscible combination will exhibit only one transition, we expect two transitions on theoretical grounds, one for the polymer and one for the diluent. Both should be visible at intermediate compositions unless the pure component glass temperatures are rather close. The development of our theory has been stimulated by the appearance of recent experimental data on polystyrene dibutylphthalate; the results presented in the talk will focus on its application to a series of polystyrene-diluent mixtures. Finally, the ability of our approach to predict both the transition temperatures and breadths, as well as the conditions under which two transitions may be observed, will be discussed.

**11:27**
**Z24 2 A Novel Technique to Measure Enthalpy Recovery for Polymer Glasses Subsequent to Temperature and Plasticizer Concentration Jumps.*** LAMECK BANDA, *Dept. of Chemical Engr., Texas Tech University* MATAZ ALCOUTLABI, *Dept. of Chemical Engr., University of Utah* GREGORY McKENNA, *Dept. of Chemical Engr., Texas Tech University* We report results of the enthalpy recovery of polymer glasses subsequent to temperature jumps and carbon dioxide pressure jumps in the isothermal mode. The results were performed on a novel system that was built in our laboratory. The system is a Setaram C80 calvet calorimeter that we modified to include pressure capabilities. The system also offers the advantage of large bore chambers that facilitate the use of large samples. Additionally, experiments of enthalpy recovery subsequent to plasticizer concentration histories in the isothermal mode are feasible. Enthalpy recovery results show qualitative similarities with volumetric measurements reported in our previous work. Particularly, the three signatures of structural recovery; intrinsic isopiestics, asymmetry and the memory effect are observed. Further, consistent with the volumetric observations, enthalpy recovery results also show that equilibration times for the polymer glass are longer when the glass transition is traversed

through a plasticizer jump than when traversed through a temperature jump.

**Z24 3 Glass Transition Temperature of Polyetherimide: Relationship between Thin Films and Nanoporous Materials*** RAHMI OZISIK, TONG LIU, RICHARD W. SIEGEL, *Materials Science and Engineering Department, Rensselaer Nanotechnology Center; Rensselaer Polytechnic Institute* The glass transition temperature ($T_g$) of nanoporous polyetherimide (PEI) was investigated using differential scanning calorimetry. Nanosized pores were created by spin coating a solution of PEI and polycaprolactone-diol (PCLD) in their common solvent dichloromethane. The nanoporous structure was created by fast phase separation during spin coating and subsequent removal of PCLD with acetone. Atomic force microscopy, scanning electron microscopy and statistical methods were used to characterize the pore structure. The glass transition temperatures of both the thin PEI films and nanoporous PEI samples were lower than that of bulk PEI. The $T_g$ of nanoporous PEI was found to depend strongly on pore volume fraction. A Monte Carlo simulation was performed to investigate the relationship between thin films and nanoporous systems. The distribution of nearest neighbor distances (ith) were obtained from the Monte Carlo simulation, which was biased to create the pore size distribution obtained from experiments. Various moments of ith was calculated and used to compare the findings to thin film data.

**Z24 4 Dynamics of Polyethylene, Studied by Monte-Carlo Simulations*** E. VON MEERWALL, H. LIN, W.L. MATTICE, *Univ. Akron* To compare with our diffusion (D) measurements in polyethylene (PE) melts and blends we have performed Monte-Carlo simulations on the second-nearest-neighbor diamond lattice, exploring static and dynamic properties of PE from C40 to C324 (molecular weights M from 584 to 4538) at 180 deg. C. The bridging method is based on beads combining neighboring moieties and now incorporates two-bead moves; it permits detailed reconstruction of the PE chain at any stage. It uses the short-range rotational isomeric state model and long-range intra- and interchain Lennard-Jones potentials as discretized. Reliable results depend on extended prior equilibration. In static properties, chain statistics is non-Gaussian for all but the longest chains, evidenced by an anomalous non-Rouse scaling of Rg with M; at low M chain-end effects become important. But the autocorrelation functions of the end-to-end vectors still adhere to Rouse and reptation theories for chains longer than C82. Above C100 the relaxation times scale with M in keeping with reptation theory. Center-of-mass D, converted from Monte-Carlo steps to time units according to D measured at a single M, is in excellent agreement with experiment at all M. D of five n-alkanes in M=33k PE extrapolated to trace concentration conforms to the pure Rouse 1/M prediction in the absence of chain-end free-volume enhancements, in good agreement with current experiment.

**Z24 5 Molecular dynamics studies of slow relaxation phenomena in glassy polymeric systems.** SANAT KUMAR, SERGEI SHENOGIN, *Rensselaer Polytechnic Institute* ARUN YETHIRAJ, *University of Wisconsin, Madison* JACK F. DOUGLAS, *Polymer Division, NIST, Gaithersburg, MD.* Molecular dynamics simulations were used to study long-time structural relaxations in glass-forming polymeric systems. The model system was composed of identical hard spherical beads linked into the chains by the bonds. The minimum length of each bond was limited to 1.05 of the bead diameter to prohibit crystallization at higher densities and create completely amorphous structures. The packing volume fraction ranges from 0.45 to 0.62, with glass transition at volume fraction around 0.565. It was shown that for glassy structures the distribution of mean-squared displacements deviates from Fickian form, showing the presence of ''mobile'' particles with caged (hop-like) mechanism of mobility. As the result, dynamic heterogeneity emerges in glassy structures with two distinct distributions of ''mobile'' and ''immobile'' particles relative to the Brownian motion. Structural relaxation, shear viscosity and their relationship to particle mobility was studied for systems with different densities. These results provide the evidence that the excessive mobility of ''hopping'' particles is the reason of breakdown of Stokes-Einstein relationship in glassy systems.

**12:15**

**Z24 6 On the determination of primitive paths in entangled polymer melts and networks** MICHAEL LANG, MICHAEL RUBINSTEIN, *Department of Chemistry, University of North Carolina at Chapel Hill, N.C.* The primitive path of a polymer chain in a melt or a network can be understood as the center line for the minima of a constraining potential, which describes the essence of the entanglement interactions of neighboring chains with a given polymer. Thus, the conformation of the primitive path plays a key role for the determination of tube parameters or the shape of the tube potential. In recent years, different methods and models for the determination of the primitive paths in entangled polymer melts and networks have been proposed leading to different results for the primitive path. In this contribution, the differences of these models as well as their assumptions on systems, calculations, or simulations will be compared and discussed in order to determine the optimal method for finding a primitive path.

**12:27**

**Z24 7 Properties of Well-Defined Elastomeric Poly(alkylnorbornene)s and Their Hydrogenated Derivatives** RICHARD REGISTER, JOHN HATJOPOULOS, JOHN BISHOP, *Princeton University* Narrow-distribution homopolymers of various 5-n-alkylnorbornenes were synthesized by living ring-opening metathesis polymerization (ROMP), and subsequently hydrogenated to yield materials with the good thermooxidative stability of polyolefins. The unsubstituted hydrogenated polynorbornene is highly crystalline, with Tm = 140-150C, but all the substituted norbornenes (before and after hydrogenation) are amorphous. Hydrogenation reduces the glass transition temperature (Tg) modestly; polymers with butyl or longer substituents have Tg below ambient due to internal plasticization by the alkyl sidechains (Tg = -40C for hydrogenated polydecylnorbornene). The fractional decrease in Tg with increasing sidechain length is in good quantitative agreement with that for polyolefins, polymethacrylates, and poly(alkylstyrene)s, when the sidechain length is normalized by the number of backbone carbons per mer. The rubbery plateau moduli

for these hydrogenated products are typical for elastomers, and tunable through the length of the alkyl sidechain; lengthening the sidechain from butyl to decyl increases the entanglement molecular weight by nearly a factor of three. These materials show promise as the midblocks in ROMP thermoplastic elastomers with crystalline endblocks. [work supported by NSF Polymers Program, DMR-0505940]

**12:39**

**Z24 8 The viscoelastic properties of ultrathin polymer films as measured with a novel nanobubble inflation technique** PAUL OCONNELL, GREGORY MCKENNA, *Texas Tech University* Using a novel microbubble inflation technique developed within our laboratory, we are able to measure the absolute biaxial compliance of polymer films as thin as 13 nm. Experiments performed on both poly(vinyl acetate) (PVAc) and polystyrene (PS) films show that large reductions in the glass transition temperature at the nano-scale are non-universal, viz., the PVAc shows no reduction even for the thinnest films while the PS shows a significant reduction at a thickness below approximately 80nm. More surprisingly, the rubbery plateau region for both materials shows dramatic stiffening as the thickness is reduced (by up to 300 times), perhaps due to surface pinning of the entanglement network. The compliance increases as approximately the square of film thickness until the bulk values are achieved at a thickness of the order of 300nm.

**12:51**

**Z24 9 Viscoelastic Properties of Metathesis Synthesized Linear and Cyclic Macromolecules** JIAN WANG, GREGORY MCKENNA, *Texas Tech University* IRINA GORODETSKAYA, ROBERT GRUBBS, *California Institute of Technology* A novel method of synthesis[1] now permits the creation of closed, uncatenated rings in relatively large amounts ( $>$ 1g). The metathesis synthesis route results in samples with relatively low polydispersities of $<$ 2. Here we report on a series of experiments on poly(octenamer) and polyethylene rings made by hydrogenating the poly(octenamer). The samples are being characterized for molecular weight, radius of gyration and intrinsic viscosity to assure their ring-like nature. Then, using conventional methods of rheometry, we are obtaining the dynamic moduli and zero shear rate (zero frequency) viscosities of the materials and comparing them to their linear analogues. Results for polymers having molecular weights between $1x10^5$ and $5x10^5$ g/mol, which is between 80 and 400 entanglements per chain assuming the linear entanglement molecular weight, will be discussed. Finally, in spite of the relatively low polydispersity of these samples, additional work is ongoing to fractionate them in order to obtain narrow fractions ($M_w/M_n < 1.1$) in order that the plateau modulus and the steady state rubbery plateau modulus can be obtained. Initial work suggests that $G_N^0$ for the rings and for the linear chains is similar.

**13:03**

**Z24 10 Observation of high viscous stress of oriented polyolefin under uniaxial tensile** QIANG FU, BING NA, HAO ZOU, KE WANG, QIN ZHANG, *Department of Polymer Science & Materials, Sichuan University, State Key Laboratory of Polymer Materials Engineering, Chengdu, 610065, China* CHARLES C. HAN, *PPCL, Joint Lab. of Polymer Science and Materials, Institute of Chemistry, Chinese Academy of Science, Beijing 100080, China* In this work, by means of stress relaxation experiments, the viscous stress at various strains during tensile deformation of oriented polyolefin samples, including high density polyethylene (HDPE), linear low density polyethylene (LLDPE) and isotactic polypropylene (iPP), has been determined. The viscous stress in the oriented samples takes up to 50 -70% of the total stress, which is unusually high, compared with their isotropic counterparts. More over, the enhanced modulus of oriented polyolefin was found not mainly caused by the existence of shish-kebab structure, but mainly come from the contribution of viscous stress. The result is new and provides deep understanding of the origin of high modulus for oriented polymers.

**13:15**

**Z24 11 Probing the breakdown of chain entanglement in simple shear: The effect of molecular weight distribution** POUYAN BOUKANY, SHI-QING WANG, *Department of Polymer Science, University of Akron* Our latest particle-tracking velocimetric (PTV) observations indicate [1] that a shear rate gradient develops across the gap in cone-plate shear cell when a fairly polydisperse entangled polymer solution is subjected to a velocity-controlled shear. The co-existence of a continuous spectrum of shear rates in the different layers is inconsistent with any theoretical description of shear banding (where only two values of shear rate would coexist). Could the smooth shear rate gradient be an artifact of the cone-plate shear cell? The present study applies the PTV measurements for a linearly-displaced shear cell that is free of any stress gradient. By examining a highly monodisperse sample and comparing its behavior with that of the polydisperse sample, we aim to explore the origin of the shear rate gradient and find out whether shear banding occurs in the monodisperse sample instead of a gradient of shear rate. [1] Tapadia, P.; Wang, S. Q. Phys. Rev. Lett., in press (2005).

**Z24 12 Short-Range Helical Ordering of Isotactic Vinyl Polymers in the Liquid State*** JOHN G. CURRO, *Sandia National Laboratories* A. HABENSCHUSS, *Oak Ridge National Laboratory* GUSTAVO A. CARRI, *The University of Akron* Wide-angle x-ray scattering measurements on various vinyl polymer melts show that the main amorphous peak (at $k\sim 1.5\ A^{-1}$) in the structure factor initially broadens, and then forms a ''pre-peak'' that shifts to lower k as the size of the pendant group increases. To investigate this behavior we performed self-consistent PRISM calculations on isotactic polypropylene and polystyrene liquids. Good qualitative agreement was seen for the theoretical structure factors with scattering data. Analysis of the torsional angle distribution shows a significant amount of short-range helical content in the iPP and iPS melts. At $450^oK$ the average number of consecutive trans/gauche pairs along the chain backbone was significantly higher than for a random distribution of torsional angles. The theory indicates that the location of the pre-peak is a measure of the helix-helix correlation distance or helix ''thickness.''

**Z24 13 Concurrent Physical Aging and Polymer Degradation during Weathering of Coatings*** STUART CROLL, DILHAN FERNANDO, *North Dakota State University* A polyester-urethane coating system was subjected to ''accelerated'' weathering cycles under UV light, elevated temperature and moisture (in a Q-Sun 1000 chamber). Cross-link density values obtained from high temperature modulus data demonstrated chain scission with increased exposure. However, increasing Tg and tensile modulus with weathering require an additional explanation to chemical degradation. Physical aging was explored to explain the behavior. Regular and modulated DSC analysis of the coating clearly shows increasing enthalpy recovery with increased weathering of the coating. Enthalpy recovery rate in degraded polymer films was much larger than in films that had only undergone the thermal component of exposure. An effort was also made to characterize the concurrent physical-chemical aging effects by tracking the changes in the non-linearity of the molecular relaxation times and the distribution of molecular relaxation times of the weathered coating. Understanding the physical relaxation properties of polymers subjected to accelerated weathering may help in resolving differences between natural weathering and accelerated weathering cycles, and also may be used to refine models for lifetime prediction of coatings.

**13:51**

**Z24 14 Statics and Dynamics in model Dendrimer Melts*** KOSTAS KARATASOS, *Aristotle University of Thessaloniki, Thessaloniki, Greece* Molecular Dynamics simulations were employed in order to explore the static and dynamic response of model AB2 dendrimer melts of generations 3 to 6. This study was performed in a temperature range covering the states of enhanced mobility, as well as the states where a significant dynamic slowdown led to the freezing-in of the dendrimer motion. Particular emphasis was given to the investigation of the effects of the dendritic geometry and the dendrimer size to local polymer dynamics associated with the glass transition phenomena.

## SESSION Z25: MOLECULAR DYNAMICS: THEORY AND SIMULATION

**Friday Morning, 17 March 2006**
**322, Baltimore Convention Center at 11:15**
**Eric Cochran, Iowa State University, presiding**

**11:15**

**Z25 1 Application of a Semi-Grand Canonical Monte Carlo (SGMC) Method for the Simulation of Non-Equilibrium Systems** FREDERICK BERNARDIN, GREGORY RUTLEDGE, *Massachusetts Institute of Technology* The use of the SGMC as a generalized descriptive tool for interpreting experimental data obtained from non-equilibrium systems will be summarized. The usefulness of the method will be demonstrated specifically by interpreting the orientation distribution functions (odf's) of polymer melts which have been uniaxially oriented. Using SGMC, we identify the thermodynamic variables that serve as chemical potentials in a polydisperse system of orientations, and then generate the ensemble of configurations that minimizes the free energy subject to the constraints set by the odf. In this demonstration, the axial symmetry leads to the use of Legendre polynomials as the basis set for the odf. We apply our approach to obtain molecular ensembles corresponding to different values of $P_2$ (the first non-zero Legendre term), which are obtainable through measurements by light scattering or birefringence. Comparisons will be made to a related method by Mavrantzas and Theodorou (Macromolecules, 31, 6310 1998).

**11:27**

**Z25 2 Multiscale modeling of polystyrene dynamics in different environments** ROLAND FALLER, QI SUN, FLORENCE PON, *UC Davis* Polystyrene is a very abundant and industrially important polymer. We are modeling its dynamical behavior on multiple length scales and different environments. We start with pure PS where we develop a mesoscale polystyrene model based on atomistic simulations. The non-bonded effective potential is optimized against the atomistic simulation until the radial distribution function generated from the mesoscale model is consistent with the atomistic simulation. The mesoscale model allows understanding the polymer dynamics of long chains in reasonable computer time. The dynamics of polystyrene melts are investigated at various chain lengths ranging from 15 to 240 monomers and the crossover to entangled dynamics is observed. As computer simulations cannot only address average properties of the system under study but also the distribution over any observable of interest we are study mixtures of polystyrene and polyisoprene by atomistic molecular dynamics and calculate correlation times for all segments in the system. We then identify fast and slow segments and can correlate the segment speed with the local neighborhood and obtain that fast segments have a surplus of the faster component in their neighborhood and vice versa. A coarse grained mixture model will be presented as well.

**11:39**

**Z25 3 Polymer dynamics within a harmonic confinement potential** JEREMY SCHMIT, JOSHUA MARTIN, BULBUL CHAKRABORTY, JANÉ KONDEV, *Brandeis University* We study the effects of confinement on the Rouse dynamics of polymers inspired by the question of chromosome confinement in the nucleus. We propose a simple model of a polymer diffusing within a three-dimensional harmonic potential. Within this model, the Rouse modes relax as independent particles within the harmonic potential so that the inverse relaxation times increase linearly with the confinement strength. This linear regime is also seen in simulations of phantom chains trapped within a hollow sphere. We also address the effect of self-avoidance using a self-consistent variational approximation to the propagator and compare the results to simulation.

**11:51**

**Z25 4 Monte Carlo simulations of polymer translocation through a nanopore*** TAPIO ALA-NISSILA, KAIFU LUO, ILKKA HUOPANIEMI, *Laboratory of Physics, Helsinki University of Technology, P.O. Box 1100, FIN-02015 HUT, Espoo, Finland* SEE-CHEN YING, *Department of Physics, Box 1843, Brown University, Providence, RI 02912-1843, U.S.A.* HELSINKI UNIVERSITY OF TECHNOLOGY TEAM, BROWN UNIVERSITY COLLABORATION, We investigate the problem of polymer translocation through a nanopore using the fluctuating bond model with single-segment Monte Carlo moves. For non-driven case we study the escape time $\tau_e$ required for a polymer, which is initially placed in the middle of the pore, to completely exit the pore on either end. We find $\tau_e \sim N^{1+2\nu}$, where $N$ is the chain length and $\nu$ is the Flory exponent. We also examine the interplay between the pore length $L$ and the radius of gyration $R_g$. For driven case we find a crossover scaling for the translocation time $\tau$ with $N$ from $\tau \sim N^{2\nu}$ for relatively short polymers to $\tau \sim N^{1+\nu}$ for longer chains. This crossover is due to the change of the translocation velocity v from $v \sim N^{-\nu}$ for relatively short chains to $v \sim N^{-1}$ for long polymers. The reason is that a high density of segments near the exit of the pore for long polymer slows down the translocation process due to slow relaxation of the chain.

*This work has been supported in part by a Center of Excellence grant from the Academy of Finland.

**12:03**

**Z25 5 Calculating probability distributions for knot sizes and locations** PETER VIRNAU, *MIT* YACOV KANTOR, *Tel Aviv University* MEHRAN KARDAR, *MIT* We generate three dimensional random walks and loops with Monte Carlo simulations, and analyze them using various operational definitions of knot sizes and locations. We find that the size of a knot follows a power-law distribution with an exponent of approximately -1.5. As a consequence, knots in open chains are on the average larger when they are located close to the center.

**12:15**

**Z25 6 The Role of Quenched Randomness in the Stereochemical Sequences of Atactic Vinyl Polymers** NUMAN WAHEED, WAYNE L. MATTICE, *Institute of Polymer Science, University of Akron* The influence of quenched randomness on the mean square unperturbed end-to-end distance, $\langle r^2 \rangle_0$, is assessed in polystyrene, using a rotational isomeric state (RIS) model based on virtual bonds between the centers of mass of the $C_6$ rings. This coarse-grained model is derived from a conventional RIS model expressed in terms of the C-C bonds in the main chain and contains bond lengths, angles, and torsions determined by the stereochemistry and conformations of the underlying tetrad. The zeroth approximation virtual bond model, which retains only the most probable conformation(s) of the six stereochemically unique tetrads, correctly finds $\langle r^2 \rangle_0 \sim n$ in the limit as $n \to \infty$ if the probability for a itmeso diad, $p_m$, is $0 < p_m < 1$, although the same zeroth approximation model yields $\langle r^2 \rangle_0 \sim n^2$ if $p_m$ is either 0 or 1. The values of $\langle r^2 \rangle_0$ at intermediate $p_m$ are surprisingly close to those obtained from a full, C-C bond based RIS model. This achievement of the zeroth approximation model demonstrates the important role of quenched randomness in determining the unperturbed dimensions of atactic chains. Excellent agreement with the $\langle r^2 \rangle_0$ from the full RIS model over the entire range of stereochemical composition, $0 \leqslant p_m \leqslant 1$, can be achieved in a first-approximation virtual bond model, which includes the next most probable conformations at each tetrad and refines slightly some of the conformations by minor adjustments in soft degrees of freedom.

**12:27**

**Z25 7 Effects of Confinement on Tethered Chains** JOHN MCCOY, TITUS ISPIRESCU, *New Mexico Tech* JOHN CURRO, *Sandia National Laboratories* Density Functional Theory (DFT) is used to analyze tethered Bead-Spring Chains. Previous work has demonstrated the ability of DFT to accurately predict both the density profiles of and colloidal force generated by such chains as compared to the results of computer simulation. In addition, the chains are found to display a collapse transition as a function of either surface coverage or temperature. In the current work, we explore the additional effect of confinement on the collapse transition, and the ability of simple scaling models to describe the behavior.

**12:39**

**Z25 8 Mixtures of Monomer and Dimer Square-well Fluids** JAMES PORTER, JANE LIPSON, *Dartmouth College* In previous work, we have used the continuum version of Born-Green-Yvon (BGY) theory, in conjunction with the square-well potential, to model structural and thermodynamic properties of alkanes and, in the case of one-component fluids, have also suggested mappings between the continuum and lattice versions of the theory. Having applied the lattice description to numerous mixtures, we are now interested in determining whether an analogous mapping is possible between the lattice and continuum descriptions when both are used to study mixtures. Towards this end, we present in this talk the first continuum BGY results for monomer/dimer square-well fluid mixtures. Thermodynamic and structural properties are compared with available simulation data, and the effect of changing both monomer diameters and square-well interaction strengths is examined.

**12:51**

**Z25 9 Field-Theoretic Models for Supramolecular Polymers** EDWARD FENG, *Miller Institute, UC Berkeley* WON BO LEE, *UC Santa Barbara* GLENN FREDRICKSON, *UC Santa Barbara* Supramolecular polymer systems consist of polymers with bonding groups that can form reversible inter-polymer linkages. These materials have great technological potential since one can use temperature to tune the material properties such as viscosity. Moreover, new methods in synthesizing bonding groups point the way to making supramolecular polymer systems that self-assemble into inhomogeneous phases. To understand these materials, we develop a field-theoretic model for a system in which an A and B homopolymer can reversibly bond to form a diblock copolymer. An energy of bonding governs the strength of this reversible bond. Using computational methods, we calculate a mean-field phase diagram for the symmetric case in which the A and B parts of the system consist of polymers of the same length and occupy the same volume. At low temperatures, we find either a lamellar phase or macrophase separation depending on the strength of the bonding reaction. We are collaborating with experimental groups interested in synthesizing and characterizing these systems.

**13:03**

**Z25 10 Hybrid Two-Chain Simulation and Integral Equation Theory: Application to Polyethylene Liquids** HUIMIN LI, *Dept. of Chemical Engr., Colorado School of Mines, Golden, CO 80401* DAVID T. WU, *Dept. of Chemical Engr. and Chemistry, Colorado School of Mines, Golden, CO 80401* JOHN G. CURRO, *Sandia National Laboratories, Albuquerque, NM 87185* JOHN D. McCOY, *Dept. of Materials Engr., New Mexico Technology, Socorro, NM 87801* We present results from a hybrid simulation and integral equation approach to the calculation of polymer melt properties. The simulation consists of explicit Monte Carlo (MC) sampling of two polymer molecules, where the effect of the surrounding chains is accounted for by an HNC solvation potential. The solvation potential is determined from the Polymer Reference Interaction Site Model (PRISM) as a functional of the pair correlation function from simulation. This hybrid two-chain MC-PRISM approach was carried out on liquids of polyethylene chains of 24 and 66 $CH_2$ units. The results are compared with MD simulation and self-consistent PRISM-PY theory under the same conditions, revealing that the two-chain calculation is close to MD, and able to overcome the defects of the PRISM-PY closure and predict more accurate structures of the liquid at both short and long range. The direct correlation function, for instance, has a tail at longer range which is consistent with MD simulation and avoids the short-range assumptions in PRISM-PY theory. As a result, the self-consistent two-chain MC-PRISM calculation predicts an isothermal compressibility closer to the MD results.

**13:15**

**Z25 11 Phase coherence in LDOT diblock copolymer films** KWANWOO SHIN, *Gwangju Institute of Science and Technology* JUNHAN CHO, *Dankook University* KWANGSOO CHO, *Kyungpook National University* JI HYUK KIM, *Gwangju Institute of Science and Technology* SUSHIL K. SATIJA, *National Institute of Standards and Technology* DU YEOL RYU, *Yonsei University* JIN KON KIM, *Pohang University of Science and Technology* Theoretical and experimental studies of the thin films of LDOT (lower disorder-order transition) diblock copolymers have been studied. The recently developed compressible Landau analysis has been applied to the copolymer films to interpret phase-coherent decaying profiles and other thermodynamic aspects of the LDOT films. Specific interactions and finite compressibility were considered in a unified way in this compressible Landau approach. The linearized and then nonlinear solutions of the minimized free energy functional under proper constraints were discussed. The neutron reflectivity and the surface topography measurements on the copolymer films were reported here to compare them with the theoretical analysis.

**13:27**

**Z25 12 Relation between cyclization of polymers with different initial conditions** CHUCK YEUNG, *School of Science, Penn State Erie, Erie, PA* BARRY FRIEDMAN, *Dept. of Physics, Sam Houston State Univ, Huntsville, TX* We study cyclization of polymer chains in which the reactive ends of the chains are initially in close proximity (ring initial conditions). We find a surprising general relation between cyclization with ring and equilibrium initial conditions, namely that $\Phi_{ring}(t) \propto d\Phi/dt_{eq}$ where $\Phi(t)$ is the survival fraction. We show that this proportionality is exact for a special type of non-generic ring initial conditions and use an approximate argument to motivate the proportionality for more general ring initial condition. Our analytic results are confirmed by Langevin simulations of Gaussian chains. Earlier work for very long Rouse chains with equilibrium initial conditions show that $d\Phi/dt_{eq} \sim t^{-1/4}$ for times less than the longest polymer relaxation time. Therefore our relation shows that $d\Phi/dt_{ring} \sim t^{-5/4}$ for a ring initial distribution under the same conditions.

## SESSION Z26: RADIATION THERAPY AND MEDICAL IMAGING TECHNIQUES

**Friday Morning, 17 March 2006**
**323, Baltimore Convention Center at 11:15**
**Paul Gueye, Hampton University, presiding**

**11:15**

**Z26 1 Monte Carlo study of interseed attenuation and tissue composition effect for clinical cases of prostate permanent implants.** JEAN-FRANCOIS CARRIER, *Hopital Notre-Dame du CHUM* LUC BEAULIEU, *CHUQ, Pavillon Hotel-Dieu de Quebec* Monte Carlo simulations were used to study the interseed attenuation and the effect of tissue composition on prostate implant dosimetry. Using computed tomography images of postimplant analysis, the precise anatomy of the patient was considered voxel by voxel. The physical density of each voxel was set according to the Hounsfield Unit and the specific elemental composition of each voxel was set depending on the radiation-oncologist organ contours and the local density. Mixes of different tissues were available: muscle, prostate tissue, rectum tissue, adipose tissue, bone and prostate calcification. Typically, more than 300 combinations of elemental composition and density were used for each patient. The Monte Carlo dosimetry results were compared to the clinically approved TG43-based calculations for 30 patients. The results show an interseed attenuation of about 4.5% for the $D_{90}$parameter (minimal dose received by 90% of the target volume). The effect of the tissue composition varies from one patient to the other. Globally, the difference between the TG43-based calculations and the Monte Carlo results can reach more than 10 Gy for the $D_{90}$ values. From a clinical perspective, the difference level can be non-negligible for the target volume and for the surrounding organs at risk.

**11:27**

**Z26 2 Effects Of The Inhomogeneity of Brachytherapy Sources In Cancer Treatments** NNENNA ONUMAH, *Hampton University* FOR CAMI COLLABORATION, Uniformity of radioactive sources is vital in delivering accurate doses in Brachytherapy. The International Atomic Energy Agency (IAEA) defines source uniformity as no more than a 20 % deviation from the average value of the dose along a transverse region. Brachytherapy induced cell damages occur at the microdosimetric levels, and as such, small deviations in dose delivered from different geometrical positions on the source can lead to huge deviations in proper treatment. A Geant4 simulation of a uniform source and a non-uniform source was simulated to check the validity of IAEA's proposed definition. A realistic source of non-uniformity, air bubbles of differing diameters (from 20 to 80 microns) were simulated and their uniformity checked against the model suggested by IAEA in two ways: (1) using the average obtained from the non-

uniform source (2) using that obtained from the uniform source. Significant deviations of up to 50% were observed. These results validate the need for the scintillating fiber based detector currently in development within our research group.

**11:39**

**Z26 3 Absolute Dose Distribution Measurements Of Beta Sources Using A Scintillating Fiber Based Detector** LAWRENCE TYNES, *Hampton University* FOR CAMI COLLABORATION, Brachytherapy using catheter based high dose rate $\beta$ sources has taken nowadays an important role in out-patient cancer treatments. At the present time, there is no detector system which can record accurate quantitative doses and spatial information for Brachytherapy sources. This is partly because of the short-range of the low energy beta emission of these sources (having typically an average energy of a few hundreds of keV), and the resolution limitation of existing extrapolation chambers and radiochromatic-dye films (currently the preferred method used). For the latter, transfer of data from one method to the other can lead to a loss of accuracy as high as 7%, well beyond the required 2% limits of current protocols. We have developed a scintillating fiber based beta detector prototype which will provide solution to this problem. It is composed of an array of 0.5 $mm^2$ and 1 $mm^2$ fibers optically coupled to photo-multiplier tubes for photon-to-current conversion. Preliminary results from high dose rate $^{90}Sr/^{90}Y$ and $^{32}Ru$ sources comparing film dosimetry, well chambers, and our scintillating fiber based detector will be presented.

**11:51**

**Z26 4 An Active Mammosite For Breast Brachytherapy** THOMAS CUDJOE, *Hampton University* FOR CAMI COLLABORATION, Brachytherapy is an advanced cancer treatment that uses radioactive sources inside or in close proximity to cancerous tumors, thus minimizing exposure to neighboring healthy cells. This radiation oncology treatment unlike many others is localized and precise. The latest involvement of the Brachytherapy research group of the medical physics program at Hampton University is in the development of a scintillator fiber based detector for the breast cancer specific Mammosite (balloon device) from Cytyc Inc. Radioactive sources are inserted into a small plastic catheter (shaft) and pushed at the end of the tube. At that location, a water filled balloon surrounds the source and allow uniform gamma emission into cancer tumors. There is presently no capability for this device to provide measurements of the location of the source, as well as the radiation emitted from the source. Recent data were acquired to evaluate the possibility of measuring the dose distribution during breast Brachytherapy cancer treatments with this device. A high activity $^{192}Ir$ radioactive source and a 0.5 and 1 $mm^2$ scintillating fibers were used. Results will be presented and discussed.

**12:03**

**Z26 5 Calibration Of An Active Mammosite Using A Low Activity Sr-90 Radioactive Source** JACQUELYN WINSTON, *Morgan State University* FOR CAMI COLLABORATION, The latest involvement of the Brachytherapy research group of the medical physics program at Hampton University is in the development of a scintillator fiber based detector for the breast cancer specific Mammosite (balloon device) from Cytyc Inc. Recent data were acquired at a local hospital to evaluate the possibility of measuring the dose distribution during breast Brachytherapy cancer treatments with this device. Since sub-millimeter accuracy in position is required, precision of the device relies on the accurate calibration of the scintillating fiber element. As part of a collaboration work, data were acquired for that purpose at Hampton University and subsequently analyzed at Morgan State University. An 8 mm diameter strontium-90 radioactive field source with a low activity of 25 $\mu$Ci was used along with a dedicated LabView data acquisition system. We will discuss the data collected and address some of the features of this novel system.

**12:15**

**Z26 6 Modelization For Electromagnetic Electron Scattering at Low Energies for Radiotherapy applications.*** VAHAGN NAZARYAN, *Hampton University, The College of William and Mary* PAUL GUEYE, *Hampton University* Since release of the GEANT4 particle simulation toolkit in 2003, there has been a growing interest in its applications to medical physics. The applicability of GEANT4 to radiotherapy has been a subject of several investigations in recent years, and it was found to be of great use. Its low-energy model allows for electromagnetic interaction simulations down to 250 eV. The electron physics data are obtained from the Lawrence Livermore National Laboratory's Evaluated Electron Data Library (EEDL). At very lower energies (below 10 MeV), some of the tabulated data in EEDL have big uncertainties (more than 50%), and rely on various extrapolations to energy regions where there is no experimental data. We have investigated the variations of these cross-section data to radiotherapy applications. Our study suggests a strong need for better theoretical models of electron interactions with matter at these energies, and the necessity of new and more reliable experimental data. The progress towards such theoretical model will be presented.

**12:27**

**Z26 7 Fully Complex Magnetoencephalography*** JONATHAN SIMON, YADONG WANG, *University of Maryland* Complex numbers appear naturally in biology whenever a system can be analyzed in the frequency domain, such as physiological data from magnetoencephalography (MEG). For example, the MEG steady state response to a modulated auditory stimulus generates a complex magnetic field measurement at each MEG channel, equal to the response's Fourier transform at the stimulus modulation frequency. The complex nature of these data sets, often not taken advantage of, is fully exploited here with new methods. Whole-head, complex magnetic data can be used to estimate complex neural current sources, and standard methods of source estimation naturally generalize for complex sources. We show that a general complex neural vector source, e.g. a current dipole, is described by its location, magnitude, and direction, but also by a phase and by an additional two-dimensional perpendicular component. We give natural interpretations of all the parameters for the complex equivalent-current dipole by linking them to the underlying neurophysiology. We demonstrate biologically generated complex magnetic fields, and their equivalent fully complex current sources, with both simulations and experimental data.

**12:39**

**Z26 8 Multi-Active Catheters For Real Time Dose Distribution Measurements In Prostate Brachytherapy Treatments** CARLOS VELASCO, *Hampton University* FOR CAMI COLLABORATION, We have performed real time 3D dose distribution measurements of high dose rate brachytherapy sources. These data demonstrate the possibility of in-vivo dosimetry monitoring of the dose rate while treating patients with particle radiation therapy. The prototype used for these experiments is made out of 16 scintillating fibers, 30 cm long and with a 1 $mm^2$ transverse cross section. Each fiber was coupled to a 16 channel Hamamatsu photo-multiplier tube for photon to current conversion. Millimeter accuracy in position was attained with sub-seconds timing scale. No correction was done from Cherenkov radiation background. The (over)estimated systematic uncertainty is 10% and includes electronic and computer dead times, channel-to-channel efficiency, and signal attenuation. We will discuss the impact of such device to clinical prostate cancer treatments and treatment planning softwares.

**12:51**

**Z26 9 Speckle Patterns in Coherence Domain Biomedical Imaging** PING YU, *Department of Physics and Astronomy, University of Missouri-Columbia* We have shown previously that coherence domain biomedical imaging can be used for optically sectioning small tumors such as rat osteogenic sarcoma (bone tumors). Speckle patterns of such small tumors provided quantitative measures of the health, necrotic, and poisoned tissues. However, the origins of these speckle patterns are not clear. Although the nuclei, mitochondria and other organelles inside cells are responsible for the speckle under the illumination of low coherence light source, these patterns at the imaging plane are related to the photon pathways both inside and outside the tissue. We report systematic experiments and simulation of the speckle patterns from coherence domain imaging of small tumors. The image frames are acquired at different depths inside the tumor tissue and analyzed by using a turbid medium model. The results reveal that the speckle patterns are dominated by the scattering properties of the tissue, which is characterized by the mean free path of the photons, and the collection geometry of the backscattered light photons. This work was supported by a University of Missouri Research Board grant URB-04-072 and NIH grant P50-CA-103130.

**13:03**

**Z26 10 Clinical implementation of proton Monte Carlo dose calculation.*** HARALD PAGANETTI, *Massachusetts General Hospital* HONGYU JIANG, SHASHIDHAR KOLLIPARA, HANNE KOOY, Goal was the clinical implementation of Monte Carlo dose calculation for use in parallel to a commercial planning system. Treatment heads were modeled in detail. To describe the patient anatomy, Hounsfield Units were converted into materials with explicit element composition and density. We developed a method to dynamically assign the mass density to the materials during particle transport. Memory for CT voxels is assigned dynamically. A software link was created between the commercial planning system, the treatment machine control system and the Monte Carlo program. The prescribed range and modulation are automatically translated into the corresponding settings of the treatment head. For broad beam modulation treatment, the Monte Carlo code simulates apertures and compensators based on the milling machine files. Treatment information, like prescribed dose per field, size of the air gap, couch angle and gantry angle, is read from the departmental patient database. For absolute dosimetry, the dose delivered to the patient per monitor unit is calculated based on the simulation of the reading of a segmented transmission ionization chamber. Dose calculations are done on the CT grid resolution and have been performed for various treatment sites. Monte Carlo results can be imported into the planning system.

**Z26 11 A Universal Scaling of Proton Energy Deposition in Biological Materials*** DAN FRY, WILFRED SEWCHAND, JOHN O'CONNELL, *Walter Reed Army Medical Center, Radiation Oncology, Washington, DC 20307* We have used GEANT 4.7.0 to simulate the dosimetric properties of various materials. Bragg curves for monoenergetic pencil beams with incident energies ranging from 70 MeV to 250 MeV have been characterized by the width (90%-10%) of distal and lateral edges, peak-to- entrance dose ratio, and FWHM. In all materials ionization by primary protons is the dominant energy loss channel. Energy loss by electrons and secondary protons is approximately an order of magnitude lower and dose from all other secondary particles is three orders of magnitude lower. We have found that a single scaling factor (material density) is most inadequate for fully defining the characteristics of the percent depth- dose distribution. However, the distal and lateral edge widths and FWHM can be universally scaled by scaling the proton beam energy by a material dependent factor. In addition, when the peak-to- entrance dose ratio is scaled by the stopping power ratio $S_w$ relative to water, energy deposition properties of all materials appear to behave alike. Our results suggest that knowledge of the incident proton energy and effective $Z$ of the target are sufficient to fully predict the depth-dose distribution irrespective of material type.

**13:27**

**Z26 12 Feasibility Study Of Kaon Therapy** SOLOMON SAHLE, *Hampton University* FOR CAMI COLLABORATION, Proton therapy is a new emerging radiation modality that supersedes electron machines for cancer treatments. The strength of these beams lies in their Bragg peak distribution that allows sparing healthy tissues while depositing the majority of the dose at the (targeted) tumor location. Although promising, there are still unresolved issues with this technique due to the impossibility of viewing the beam within a patient and the production of low energy neutrons at the end of the distribution. Simulation studies on the use of kaon beams were made using the Geant4 toolkit. The strangeness content of these particles permits to extract the spatial beam information in-vivo, as well as providing a similar Bragg distribution as protons. We will discuss the impact of such beams for hadron therapy in cancer treatments.

**13:39**

**Z26 13 Low Energy Experimental Elastic Cross Sections for Medical Physics Application** MICHAEL EPPS, *Hampton University* FOR CAMI COLLABORATION, Elastic cross sections for electron energies below 10 MeV are fundamental quantities needed in treatment planning systems used at hospitals and health facilities. To date, there is very little if not no data within that energy regime. In collaboration with the high current, high energy resolution continuous electron beam of the Department of Energy's Jefferson Lab accelerator, we have performed a first stage of dedicated experiments with energies of 100-150 keV to collect data for this type of reactions. The targets used were gold, copper and silver. A Mott scattering chamber was used to detect the outgoing electrons. We will present the first results of this program that aims at performing a wide range of measurements including the use of polarization data for spin studies.

**13:51**

**Z26 14 Wavelet assessment of cerebrospinal compensatory reserve and cerebrovascular pressure reactivity** M. LATKA, M. TURALSKA, *Wroclaw University of Technology* W. KOLODZIEJ, D. LATKA, *Opole Regional Medical Center* B. WEST, *Army Research Office* We employ complex continuous wavelet transforms to develop a consistent mathematical framework capable of quantifying both cerebrospinal compensatory reserve and cerebrovascular pressure–reactivity. The wavelet gain, defined as the frequency dependent ratio of time averaged wavelet coefficients of intracranial (ICP) and arterial blood pressure (ABP) fluctuations, characterizes the dampening of spontaneous arterial blood oscillations. This gain is introduced as a novel measure of cerebrospinal compensatory reserve. For a group of 10 patients who died as a result of head trauma (Glasgow Outcome Scale GOS =1) the average gain is 0.45 calculated at 0.05 Hz significantly exceeds that of 16 patients with favorable outcome (GOS=2): with gain of 0.24 with $p = 4 \times 10^{-5}$. We also study the dynamics of instantaneous phase difference between the fluctuations of the ABP and ICP time series. The time-averaged synchronization index, which depends upon frequency, yields the information about the stability of the phase difference and is used as a cerebrovascular pressure–reactivity index. The average phase difference for GOS=1 is close to zero in sharp contrast to the mean value of $30^o$ for patients with GOS=2. We hypothesize that in patients who died the impairment of cerebral autoregulation is followed by the break down of residual pressure reactivity.

**14:03**

**Z26 15 Convolution Product And Lyapunov Stability In Medical Imaging** LESLIE UPTON, *Hampton University* FOR CAMI COLLABORATION, Resolution is one of the most important aspects of any apparatus used in medical imaging. Several mathematical algorithms have been developed to best extract anatomical features and tumors within patients suffering from cancer diseases. Distortions of images are a result of blood flow, breathing, apparatus efficiency etc. This problem is also inherent to other disciplines in physics, like nuclear physics. Here, study of the electromagnetic nuclear structure relies in the extraction of the form factors from the nuclear medium (nucleus or nucleons). Data collected depend on a number of different variables. A new approach which consists of using the mathematical convolution product combined with the (entropy equivalent) Lyapunov stability was tested in this area of physics, since easier to implement. A deconvolution technique allowed isolating the individual dependencies of the differential cross section and extracting meson form factors of interest (pion and kaon). Preliminary results will be presented, as well as a discussion on the application of this technique to medical imaging.

## SESSION Z28: METHODS OF STATISTICAL PHYSICS, POPULATION DYNAMICS AND EPIDEMIOLOGY

**Friday Morning, 17 March 2006**

**Z28 1 Mathematical Modeling of the Dynamics of Salmonella Cerro Infection in a US Dairy Herd** PREM CHAPAGAIN, *Department of Population Medicine and Diagnostic Sciences, Cornell University, Ithaca, NY 14853, USA* JO ANN VAN KESSEL, JEFFREY KARNS, *Environmental Microbial Safety Laboratory, Agricultural Research Service, USDA, Beltsville, MD 20705, USA* DAVID WOLFGANG, *Animal Diagnostic Laboratory, Pennsylvania State University, PA 16802, USA* YNTE SCHUKKEN, YRJO GROHN, *Department of Population Medicine and Diagnostic Sciences, Cornell University, Ithaca, NY 14853, USA* Salmonellosis has been one of the major causes of human foodborne illness in the US. The high prevalence of infections makes transmission dynamics of Salmonella in a farm environment of interest both from animal and human health perspectives. Mathematical modeling approaches are increasingly being applied to understand the dynamics of various infectious diseases in dairy herds. Here, we describe the transmission dynamics of Salmonella infection in a dairy herd with a set of non-linear differential equations. Although the infection dynamics of different serotypes of Salmonella in cattle are likely to be different, we find that a relatively simple SIR-type model can describe the observed dynamics of the Salmonella enterica serotype Cerro infection in the herd.

**11:27**

**Z28 2 Desynchronization and spatial effects in multistrain diseases** LEAH SHAW, *Naval Research Lab* LORA BILLINGS, *Montclair University* IRA SCHWARTZ, *Naval Research Lab* Dengue fever, a multistrain disease, has four distinct co- existing serotypes (strains). The serotypes interact by antibody- dependent enhancement (ADE), in which infection with a single serotype is asymptomatic, but contact with a second serotype leads to serious illness accompanied by greater infectivity. We present a compartmental model for multiple serotypes with ADE, and consider autonomous, seasonally driven, and stochastic versions of the model. Spatial effects are included in a multipatch model. We observe desynchronization between outbreaks of the different serotypes, as well as desynchronization between spatially distinct regions.

**11:39**

**Z28 3 Improved Epidemic Path Predictability in Complex Networks*** MARKUS LOECHER, *APS* JIM KADTKE, *NSI* We apply recent results on random walkers to the analysis of idealized epidemic outbreaks in scale-free networks. By replacing the node degree with the *random walk centrality* we observe a refined hierarchical cascade leading to a greatly enhanced predictability for the order of infected nodes. We confirm our model results on data from real-world Internet maps at the autonomous system level. The present results are highly relevant for the advancement of dynamic and adaptive strategies that aim to mitigate network attacks.

**Z28 4 The scaling laws of human travel—A message from George.**
DIRK BROCKMANN, *Max Planck Institute for Dynamics and Self-Organization*

In the light of increasing international trade, intensified human mobility and an imminent influenza A epidemic the knowledge of dynamical and statistical properties of human travel is of fundamental importance. Despite its crucial role, a quantitative assessment of these properties on geographical scales remains elusive and the assumption that humans disperse diffusively still prevails in models. I will report on a solid and quantitative assessment of human travelling statistics by analysing the circulation of bank notes in the United States. Based on a comprehensive dataset of over a million individual displacements we find that dispersal is anomalous in two ways. First, the distribution of travelling distances decays as a power law, indicating that trajectories of bank notes are reminiscent of scale free random walks known as Lévy flights. Secondly, the probability of remaining in a small, spatially confined region for a time $T$ is dominated by algebraic tails which attenuate the superdiffusive spread. We show that human travel can be described mathematically on many spatiotemporal scales by a two parameter continuous time random walk model to a surprising accuracy and conclude that human travel on geographical scales is an ambivalent effectively superdiffusive process.

**12:27**

**Z28 5 Prediction and predictability of global epidemics: the role of the airline transportation network** VITTORIA COLIZZA, *School of Informatics and Center for Biocomplexity - Indiana University, Bloomington IN, USA* ALAIN BARRAT, *Unite' Mixte de Recherche (UMR 8627) du CNRS, Universite' de Paris-Sud. ORSAY* MARC BARTHELEMY, ALESSANDRO VESPIGNANI, *School of Informatics and Center for Biocomplexity - Indiana University, Bloomington IN, USA* The systematic study of large-scale networks has unveiled the ubiquitous presence of connectivity patterns characterized by large scale heterogeneities and unbounded statistical fluctuations. These features affect dramatically the behavior of the diffusion processes occurring on networks, determining the ensuing statistical properties of their evolution pattern and dynamics. We present a stochastic computational framework for the forecast of global epidemics that considers the complete world-wide air travel infrastructure complemented with census population data. We address two basic issues in global epidemic modeling: i) We study the role of the large scale properties of the airline transportation network in determining the global diffusion pattern of emerging diseases; ii) We evaluate the reliability of forecasts and outbreak scenarios with respect to the intrinsic stochasticity of disease transmission and traffic flows. In order to address these issues we define a set of novel quantitative measures able to characterize the level of heterogeneity and predictability of the epidemic pattern. These measures may be used for the analysis of containment policies and epidemic risk assessment.

**12:39**

**Z28 6 Success of mutants in an evolutionary game in finite populations** TIBOR ANTAL, *Boston University* ISTVAN SCHEURING, *Eotvos University, Budapest, Hungary* A stochastic evolutionary dynamics of two strategies given by $2 \times 2$ matrix games is studied in finite populations. We focus on stochastic properties of fixation: how a strategy represented by a single individual wins over the entire population. The process is discussed in the framework of a random walk with site dependent hopping rates. The time of fixation is found to be identical for both strategies in any particular game. The asymptotic behavior of the fixation time and fixation probabilities in the large population size limit is also discussed. We show that fixation is fast when there is at least one pure evolutionary stable strategy (ESS) in the infinite population size limit, while fixation is slow when the ESS is the coexistence of the two strategies.

**12:51**

**Z28 7 Invasion of mutants in an evolutionary process on a graph.** VISHAL SOOD, TIBOR ANTAL, We study the Moran process (MP) on an undirected graph. The MP has been studied on the complete graph and lattices extensively. Remarkably the fixation probability of the mutants is the same for all undirected degree-regular graphs. However, this is not true for degree-heterogeneous graphs. Some graphs can enhance the fixation probabilities over the degree-regular graphs. We derive fixation probabilities for general graphs when the mutants have a small advantage over the resident population. For the general bias case, we derive exact results for the bipartite graphs and discuss the structure of graphs where such a result can be applicable.

**13:03**

**Z28 8 Seeing beyond invisible with noise: application to populational biology** DMITRY LUCHINSKY, *Mission Critical Technologies, Inc* VADIM SMELYANSKIY, *NASA Ames Research Center* The problem of determining dynamical models and trajectories that describe observed timeseries data (dynamical inference) allowing for the understanding, prediction and possibly control of complex systems in nature is of great interest in a variety of fields. Often, however, in multidimensional systems only part of the systems dynamical variables can be measured directly. The measure-

ments are usually corrupted by noise and the dynamics is complicated by interplay of nonlinearity and random perturbations. We solve the problem of dynamical inference in these general settings by applying a path-integral approach to fuctuational dynamics, and show that, given the measurements, the most probable system trajectory can be obtained from the solution of the certain auxiliary Hamiltonian problem in which measured data act effectively as a control force driving algorithm towards the most probable solution. We illustrate the efficiency of the approach by solving an intensively studied problem from the population dynamics of a predator-prey system where the prey populations may be observed while the number of predators is difficult or impossible to estimate. We apply our approach to recover both the unknown dynamics of predators and model parameters (including parameters that are traditionally very difficult to estimate) directly from real data measurements of the prey dynamics.

**13:15**

**Z28 9 Eigen model with general fitness functions and degradation rates*** CHIN-KUN HU, *Institute of Physics, Academia Sinica, Taipei* DAVID B. SAAKIAN, *Academia Sinica, Taipei and Yerevan Physics Institute, Armenia* We present an exact solution of Eigen's quasispecies model with a general degradation rate and fitness functions, including a square root decrease of fitness with increasing Hamming distance from the wild type. The found behavior of the model with a degradation rate is analogous to a viral quasi-species under attack by the immune system of the host. Our exact solutions also revise the known results of neutral networks in quasispecies theory. To explain the existence of mutants with large Hamming distances from the wild type, we propose three different modifications of the Eigen model: mutation landscape, multiple adjacent mutations, and frequency-dependent fitness in which the steady state solution shows a multi-center behavior.

**Z28 10 Combining a total cell population growth and cell population dynamics in the presence of anti-cancer agents** MITRA SHOJANIA FEIZABADI, *Canisius College* A two-compartment Webb-Gyllenberg model describes the population dynamics of proliferating and quiescent cancer cells. Combination of the total cell growth curve and the two-compartment model yields an analytical solution for the behavior of proliferating subpopulation and the net transition rate between proliferating and quiescent cells as a function of time. This work presents a qualitative model for drug interaction with cancer cells in the Webb-Gyllenberg model. The drug is assumed to kill all cell types, each at a specific rate. Considering the total cell population growth in the presence of the drug, the behavior and the size of proliferating and quiescence subpopulations, as well as the related transition rates have been investigated.

## SESSION Z31: COMPLEXED STRUCTURED MATERIALS, GLASSES AND CLATHRATES

**Z31 1 Electronic structure of interfaces between insulating $LaAlO_3$ and $SrTiO_3$ perovskite oxides*** MIN SIK PARK, S.H. RHIM, A.J. FREEMAN, *Northwestern University* Since heteroepitaxial structures of perovskite oxides are potent candidates for multifunctional devices, understanding their interface properties is very important for applications, because they often show completely different properties from bulk. Recently, interfaces between the wide-band gap insulators of $LaAlO_3$ and $SrTiO_3$, were found to be insulating when hole-doped, and conducting when electron-doped[1]. First-principles calculations with the highly precise full-potential linearized augmented plane wave (FLAPW) method[2] for the stoichiometric compounds on [001] superlattices composed of perovskite unit cells of $LaAlO_3$ and $SrTiO_3$, show metallicity in both the hole-doped $AlO_2$/SrO and electron-doped $LaO/TiO_2$ interfaces, even with inclusion of geometry relaxation. Only by considering oxygen vacancies is the experimental result of insulating behavior in the hole-doped $AlO_2$/SrO interface obtained.

**Z31 2 Local atomic ordering in nanocrystalline $ZrO_2$ and $Zr_xCe_{1-x}O_2$ studied with the Atomic Pair Distribution Technique.*** MILEN GATESHKI, VALERI PETKOV, *Dept. of Physics, Central Michigan University* A number of $ZrO_2$ and $Zr_xCe_{1-x}O_2$ nanocrystalline samples have been prepared using different techniques, such as ball-milling ($ZrO_2$) and soft chemistry ($ZrO_2$ and $Zr_xCe_{1-x}O_2$). The atomic-scale structure of these samples has been studied using high-energy x-ray diffraction and the atomic pair distribution function technique. For the ball-milled materials, the studies show that the parent crystalline material, monoclinic $ZrO_2$, evolves into a nanocrystalline phase that is locally similar to monoclinic zirconia but shows a cubic-type ordering at nanometer-range distances. The atomic-scale structure of the $ZrO_2$ samples obtained by soft chemistry techniques varies depending on the preparation method and the degree of structural coherence. The studies reveal that all samples show Zr-O distances typical for monoclinic-like local atomic ordering, while the Zr-Zr distances depend on the morphology of the samples. For the $Zr_xCe_{1-x}O_2$ samples, interatomic distances typical for both monoclinic $ZrO_2$ and cubic $CeO_2$ are observed up to 5Å, while the longer interatomic distances are attributed solely to a cubic-type structure. The result underlines the importance of local structural disorder and the medium-range order in stabilizing the technologically important cubic zirconia at room temperature.

**Z31 3 Atomic PDF study of size and structure of CdSe nanoparticles** A. S. MASADEH, G. PAGLIA, E. S. BOZIN, S. J. L. BILLINGE, *Department of Physics and Astronomy, Michigan State University, East Lansing, Michigan 48824-1116* A. KARKAMKAR, M. G. KANATZIDIS, *Department of Chemistry, Michigan State University, East Lansing, Michigan 48824-1116.* The atomic pair distribution function (PDF) is used to address the size and structure of series of CdSe nanoparticles prepared by the method of distribution focusing [1]. Due to their limiting structure coherence conventional crystallographic methods, such as Rietveld can't be used to assess quantitative size or structural information. Total scattering techniques, such PDF have been successfully applied recently on some similar systems [2, 3]. The PDF includes both Bragg and diffuse scattering and provides quantitative information about the local structure of the materials at different length scales. We report on results of the PDF analysis of synchrotron x-ray diffraction on series of CdSe nanoparticles, data were collected using the rapid acquisition PDF (RA-PDF) technique [4]. [1] X. G. Peng, J. Wickham, A. P. Alivisatos, J. Am. Chem. Soc. **1998**, 120, 5343-5344 [2] B. Gilbert, F. Huang,H. Zhang, G. A. Waychunas, J. F. Banfield.Science, 305, 651–654 (2004). [3]R. B. Neder, V. I. **Z31 4 Interactions of $Ga_nAs_n$ Clusters with CGaAs Cages: Possible Nanostructures** A.S. HIRA, E. ALLISON, M.F. FERNANDEZ, J. SHIPMAN, E.R. VELARDE, *Northern New Mexico College* Extending our work on fullerene-alkali complexes[1], we now examine the interactions of small $Ga_nAs_n$ clusters (n = 1 thru 10) with mixed CGaAs cage clusters. First, we derive the physical and chemical properties of the GaAs clusters, including their binding energies, bondlengths, ionization potentials and charge distributions. The geometries of the small gallium arsenide clusters are based on full optimizations. Electron correlation effects are included for binding energies and optimal intermolecular bondlengths. Next we focus on the physical and chemical properties of 60-atom mixed CGaAs cages. The optimization of the cages is subject to symmetry constraints. The third phase of the investigation examines the interactions of the small GaAs clusters with the CGaAs cages. For these complexes various properties, including dissociation channels and dissociation energies, are tabulated. We also explore the implications of this research for the design of nanostructures. 1. Daniel Bulnes, Nichole Moya-Leyba, Erica Velarde and Ajit Hira, '' Theoretical Study of $Na_3C_{60}$ and $Na_4C_{60}$Clusters: Pathways to Nanoscale Contacts,'' Bull. Am. Phys. Soc. 50, 1475 (March 2005).

**12:03**

**Z31 5 Statistical Mechanics for Linking Length Scales in Complex Solids** YING HU, SOKRATES T. PANTELIDES, *Department of Physics and Astronomy, Vanderbilt University, Nashville, TN* Linking scales is usually pursued by computational means, either by passing information from calculations at one scale to another or by constructing a composite simulation with different features treated at different length scales. Here we report on a formulation that is based on the principles of statistical mechanics, applied to a complex solid. Two new concepts, 'lattice space' and 'atom space', are introduced. The deformed state of a crystal is described in terms of deformations of the lattice space and atom space. The distribution function is decomposed in a Born-Oppenheimer-like fashion into slow and fast components. Phonons are integrated out to give a driving force to the lattice deformation. Interplay between the two spaces leads to the formation of defects and such phenomena as elastic deformation, thermal expansion, creep, and dislocation motion. New distribution functions are constructed by adapting the method of local integrals of motion from the theory of liquids. Simulations can be implemented at different mesoscopic length scales, tracking fluxes of point defects, impurities, dislocations, etc.

**12:15**

**Z31 6 Study of structure and thermophysical properties of molten BaGe by using electrostatic levitation technique** AKIKO ISHIKURA, *Gakushuin University* TADAHIKO MASAKI, TAKEHIKO ISHIKAWA, *Japan Aerospace Exploration Agency* NORIYUKI KOIKE, *Chiba Institute of Technology* SHINJI KOHARA, *Japan Synchrotron Radiation Research Institute (SPring-8/JASRI)* AKITOSHI MIZUNO, MASAHITO WATANABE, *Gakushuin University* BaGe alloys with two compositions around their eutectic point form open framework structures called clathrate structure. However, the formation mechanism of clathrate structure has not yet been clarified due to lack of study and understanding of their liquid state structure and properties. Therefore, in order to clarify the formation mechanism of the clathrate structure, thermophysical properties (density, surface tension, and viscosity) of BaGe alloys melts around eutectic compositions were measured by using the electrostatic levitation (ESL) technique and also the structure of them was observed by using the high-energy X-ray diffraction method combined with the ESL. We found that from experimental results, the short range order based on the clathrate structure would exist even in the liquid state at the clathrate forming compositions.

**Z31 7 Localized probe of dielectric response of polymer free surface near the glass transition*** PHILIP CRIDER, NATHAN ISRAELOFF, *Northeastern University* Experimental study of length scales in glassy systems can give new insights into the glassy dynamics. Finite size effects are studied in a polymer (PVAc) utilizing UHV non-contact atomic force microscopy (NCAFM) methods. Localized dielectric susceptibility is probed using the electrostatic interaction of a metal-coated AFM tip with a thick polymer film on a metal substrate. The depth probed below the free surface of the polymer is as small as 10 nm. A lockin amplifier is utilized to measure response from the surface in the second harmonic to extract the Tan(delta) (C/C) response over frequencies of 0.1 - 100 Hz. Preliminary results for the smallest probed depths show an increase in the frequency of the alpha relaxation peak in Tan(delta) as compared with macroscopic measurements. Results for various probed depths will be discussed.

**12:39**

**Z31 8 Spatio-temporal imaging of polarization fluctuations near the glass transition*** NATHAN ISRAELOFF, PHILIP CRIDER, HASSAN OUKRIS, *Northeastern University* Mesoscopic scale spatio-temporal fluctuations are mapped using novel non-contact atomic force microscopy (NCAFM)-based methods in polymer (PVAc) films near the glass transition. Utilizing the localized electrostatic interaction of a NCAFM conducting tip, we

measure polarization fluctuations within depths as small as 10nm. Applying a sinusoidal bias voltage between the AFM tip and sample results in a response in the AFM cantilever frequency that is offset by surface potential due to thermally induced local polarizations. The measured fluctuations agree quantitatively with predictions. Measurements of these spontaneous fluctuations along a single space-dimension as a function of time yield space-time maps of the dynamics. Spatial and temporal correlation functions were studied as a function of temperature. Results show the expected slowing of the dynamics with decreasing temperature, and hints of spatially varying dynamics. Space-time maps will be compared with recent model simulations which show foam-like space-time trajectories.

**12:51**

**Z31 9 Raman scattering and modulated-DSC experiments on Potassium Germanate glasses*** N. WANG, D. NOVITA, P. BOOLCHAND, *University of Cincinnati* We have synthesized titled glasses in the $0 < x < 0.16$ range by traditional melt-quenching, and have examined them in Raman scattering and modulated-DSC (MDSC) experiments. Raman lineshapes observed in the present work are quite similar to those reported by Henderson and Wang [1]. Preliminary MDSC experiments reveal glass transition temperatures, $T_g(x)$, starting from a value of 570[r]C at $x = 0$, to decrease to 508[r]C near $x = 0.06$, and to increase thereafter almost linearly to 552[r]C as x increases to 0.15. On the other hand, the non-reversing enthalpy associated with $T_g$ provides evidence of a global minimum in the $0.08 < x < 0.10$ range, the reversibility window[2]. These results are consistent with glasses at $x < 0.08$ as Stressed-Rigid, those at $x > 0.10$ as Floppy, while those in the reversibility window as representing the Intermediate Phase[2]. The space filling nature of the Intermediate Phase is, independently, corroborated by trends in molar volumes which show a broad global minimum in the 9-11% range. Identification of the three elastic phases provides a physical basis to understand the origin of the Germanate anomaly, and the electrical conductivity threshold when glasses become mechanically floppy. *Supported by NSF grant DMR 04-56472. **Z31 10 Damped elastic relaxation seen in glassy colloidal suspensions*** ERIC R. WEEKS, DOUGLAS ANDERSON, *Physics Dept., Emory University* PIOTR HABDAS, *Physics Dept., St. Joseph's University* We study concentrated colloidal suspensions, a model system which has a glass transition when the particle concentration is high. We use an optical confocal microscope to view the motion of these colloidal particles in three dimensions. We add small magnetic particles to locally ''poke'' the colloidal samples. We find a yield force (below which the magnetic particles are unable to move through the sample), which grows as the glass transition is approached. When a force is applied below this yield force, the sample deforms elastically, but with relaxation seen after the force is removed. This relaxation seems to behave in a nonexponential fashion. We characterize this elastic response and relaxation and study how both change as the glass transition is approached.

**13:15**

**Z31 11 Cohesion in clathrates I; covalencies and ionicity** KAZUO TSUMURAYA, *Meiji University* HARUKI EGUCHI, *Ishikawajima Harima Heavy Industry (IHI)* HIDEKAZU TOMONO, *Meiji University* We present the roles of endohedral atoms in the cohesion of group 14 clathrates I. Taking a view that the clathrate I consists of a sheaf of one-dimensional connections of $Na@Si_{24}$ cages interleaved in three perpendicular directions, we calculate the electronic structures with an itab initio method and find that 30% of the $3s^1$ charge of each endohedral sodium atom transfers to the frame and the remaining charge forms a bonding state between the endohedral atoms: the roles of cohesion is the covalent bonds between the endohedral atoms in the cages and between the frame atoms, together with the ionic bond between the host and the endohedral atoms.

**13:27**

**Z31 12 Stabilities of earlier row atoms in group 1 and 2 for encapsulation in silicon clathrates I** TOSHIHIKO OGURA, KAZUO TSUMURAYA, *Meiji University* Group 14 clathrates consisting of Si, Ge, or Sn atoms have been synthesized only when they contain some specific endohedral atoms. They are Na, K, Rb, or Cs atoms in group 1, Sr or Ba atoms in group 2, and Cl, Br, or I atoms in group 17.[K.A.Kovnir, et al. Russian Chem. Rev.73,923(2004).] No experiment has been reported on the encapsulation of the earlier row atoms than the atoms mentioned above. We predict the stability of the encapsulation of these atoms using ab initio methods. We evaluate the stability of the guest atom in double caged M2@Si42H36 cluster in the clathrate I, where M is group 1, 2, or 17 atom. The encapsulation of two lithium atoms into one cage and the other is vacant is more stable than the separate encapsulation of lithium atoms into each cage by 0.436eV. The Be2 is the same case and by 0.0859 eV. For sodium case, the separate encapsulation into each cage is more stable by 1.473eV. The strong dimer formation prevents the stabilization of the cage structure. We also evaluate the stabilities in the crystalline states.

**13:39**

**Z31 13 Electronic structures and displacements of endohedral sodium atoms in silicon clathrate II** HIROYUKI TAKENAKA, KAZUO TSUMURAYA, *Meiji University* Since group 14 clathrates encapsulate specific atoms in their cages, the atoms give rise to rattling motion in the cages leading to low thermal conductivity. The clathrate II consists of $Si_{28}$ and $Si_{20}$ cages and the $Si_{28}$ cage is the largest among the cages in the clathrates. We investigate the displacements and the charge densities between the endohedral sodium atoms in the clathrate II using ab initio methods. First we present the displacements of the guest sodium atoms in double caged $Na_2@Si_{50}H_{44}$ cluster, which is a piece of clathrate II being hydrogenated in order to terminate the dangling bonds. Although in a single $Si_{28}H_{28}$ cage the endohedral sodium atom is the most the most stable at the center of the cage, the sodium atoms in each of the double cage cluster displace about 0.06 nm away from each center of the cages to shorten the distance of the sodium atoms. The displacements are attributed to the formation of covalent bond between the sodium atoms and the ionic bonding between the sodium atoms and the cage silicon atoms. Secondly we present the bonding charge densities between the sodium atoms in the clathrate II.

**13:51**

**Z31 14 Stabilities of Al or Ga atoms for encapsulation in silicon clathrates I** HIDEKAZU TOMONO, KAZUO TSUMURAYA, *Meiji University* Clathrates are cagelike compounds and encapsulate endohedral atoms inside the cages of the host network. On the one hand, the clathrates with host atoms silicon, germanium, or tin have been synthesized only when group 1 alkali metal atoms or group 2 alkaline earth metal atoms coexist as electron donors or group 17 halogen atoms coexist as electron acceptors. On the other hand, the group 13 atoms such as Al, Ga, In atoms are substituted for the host frame atoms. There has been no explanation of the mechanism of the solution of these atoms into the frame or insoluble into the cages. We investigate this through calculating the enthalpies of solution of these atoms into silicon clathrate I by use of an itab initio method. We discuss the energies of solution of group 13 atoms into the cages with those into frame structure.

**14:03**

**Z31 15 Vacancy defect formation energies in Ba8@Ge46 clathrates** KATSUHITO SAKAI, KAZUO TSUMURAYA, *Meiji University* The clathrates I Ba8@Ge46 have been found experimentally to have vacancy defects in the framework and to form Ba8Ge43. This has been explained by the Zintl-Klemn empirical concept: the inclusion of the barium atoms leads to increase the valence electrons in the framework of the clathrates and the introduction of vacancy defects relaxes the hypervalence of the electrons. We clarify the process of the defect formation by analyzing the electric structure with the first-principle method. We calculate formation energy of a single vacancy in the clathrates in which we use Ceperley-Alder with LDA exchange correlation functional for the pseudopotential of barium atom.[J. Junquera et al. Phys.Rev.B 67,155327(2003)] The energies are 0.09eV for 6c, 0.39eV for 24k, and 0.74eV for 16i sites in the clathrate Ba8@Ge45, although 1.15eV for 6c, 1.31eV for 24k, and 1.70eV for 16i sites in the clathrate Ba8@Si45. The small energy of the 6c site is due to the small binding energy of Ge clathrate. We will present the reason why vacancy defects are introduced at the 6c sites.

## SESSION Z33: STATISTICAL AND NONLINEAR PHYSICS

**Friday Morning, 17 March 2006**
**336, Baltimore Convention Center at 11:15**
**Kurt Wiesenfeld, Georgia Institute of Technology, presiding**

**11:15**

**Z33 1 Synchronization of phase oscillators in large complex networks** JUAN RESTREPO, EDWARD OTT, *IREAP, University of Maryland* BRIAN HUNT, *IPST, University of Maryland* It has been shown in recent years that many real world networks have a complex structure (e.g., scale-free networks). The effect of a complex interaction network on the dyamics of coupled dynamical systems is, therefore, of interest. An important aspect of the dynamics is the synchronization of coupled oscillators. I will present a generalization of the classical Kuramoto model of all-to-all coupled oscillators to the case of a general topology of the network of interactions. We find that for a large class of networks, there is still a transition from incoherence to coherent behavior at a critical coupling strength that depends on the largest eigenvalue of the adjacency matrix of the network. I will discuss the application of our theory to study the effect of heterogeneity in the degree distribution and degree-degree correlations in the network. Finally, I will comment on generalizations to more realistic dynamical systems.

**11:27**

**Z33 2 Weak Dynamic Links for Synchronizing Oscillator Arrays.*** DENIS TSYGANKOV, *University of Maryland, IPST* KURT WIESENFELD, *Georgia Institute of Technology, CNS* A novel synchronization mechanism observed in a model of coupled fiber laser arrays is explained [1]. The arrays can operate in a highly coherent way if some elements are driven more strongly than others. The synchronized state of such an inhomogeneous array, although sub-optimal relative to a uniformly pumped array, is far more robust with respect to parameter mismatch among the individual elements. Similar dynamical behavior might be useful for synchronizing more general coupled oscillator systems when amplitude dynamics is crucial.

*1. D. Tsygankov and K. Wiesenfeld, Weak Link Synchronization, submitted.

**11:39**

**Z33 3 Competing Synchronization of Nonlinear Oscillators*** EPAMINONDAS ROSA, *Department of Physics, Illinois State University* Coupled nonlinear oscillators abound in nature and in man-made devices. Think for example of two neurons in the brain competing to get the attention of a third neuron, and eventually developing some sort of synchronization process. This is a common feature involving oscillators in general, and can be studied using numerical simulations and/or experimental setups. In this talk, results involving electronic circuits and plasma discharges will be presented showing interesting features related to the types of oscillators and to the types of couplings. In particular, for the case of two oscillators competing for synchronization with a third one, the target oscillator synchronizes alternately to one or the other of the competing oscillators. The time intervals of synchronous states vary in a random-like manner. Numerical and experimental results will be presented and the consistency between them will be discussed.

*The author acknowledges financial support from Research Corporation.

**11:51**

**Z33 4 Complexity, Parallel Computation and Statistical Physics** JONATHAN MACHTA, *University of Massachusetts Amherst* The intuition that a long history is required for the emergence of complexity in natural systems is formalized using the notion of *depth* (related to Bennett's *logical depth*). The depth of a system is defined in terms of the number of parallel computational steps needed to simulate it. Depth provides an objective, irreducible measure of history applicable to systems of the kind studied in statistical physics. The talk will review concepts of parallel computational complexity theory and then present results for the depth of several well-known model systems in non-equilibrium statistical physics. It is argued that physical complexity cannot occur in the absence of substantial depth and that depth is a useful proxy for physical complexity.

**12:03**

**Z33 5 Vortex-Phonon Interaction in the Kosterlitz-Thouless Theory** EVGENY KOZIK, NIKOLAY PROKOF'EV, BORIS SVISTUNOV, *University of Massachusetts Amherst* The ''canonical'' variables of the Kosterlitz-Thouless theory– fields $\Phi_0(\mathbf{r})$ and $\phi(\mathbf{r})$, generally believed to stand for vortices and phonons (or their XY equivalents, like spin waves, etc.) turn out to be neither vortices and phonons, nor, strictly speaking, *canonical* variables. The latter fact explains paradoxes of (i) absence of interaction between $\Phi_0$ and $\phi$, and (ii) non-physical contribution of small vortex pairs to long-range phase correlations. We resolve the paradoxes by explicitly relating $\Phi_0$ and $\phi$ to canonical vortex-pair and phonon variables.

**12:15**

**Z33 6 Sticky Random Walks** TORU OHIRA, *Sony Computer Science Laboratories, Japan* TADAAKI HOSAKA, *National Institute of Advanced Industrial Science and Technology, Japan* Entangled strings is something we commonly observe. For example, wires for electrical appliances or communication network cords sometimes require us to disentangle them. We describe here a concept of sticky random walks to gain some insight into this phenomenon. The strings are represented by the trajectory of a random walker. This random walker leaves sticks or marks at certain time intervals. Therefore, a string is represented by this trajectory with these marks on it. By sending out multiple sticky random walkers, we obtained multiple sticky strings. Furthermore, a string is considered as entangled with another when these marks overlap at the same site in space, and not when they are simply crossed. Thus, the string is considered more sticky when there are more marks on it. We tested a situation having multiple sticky strings in a bounded two-dimensional square grid by sending out sticky random walks in this space. We found that in certain situations, the optimal balance between stickiness and number of strings gives most entangled situation.

**12:27**

**Z33 7 Finite-Connectivity Spin-Glass Phase Diagrams and Low Density Parity Check Codes** GABRIELE MIGLIORINI, *Aston University* DAVID SAAD, *Aston University* We present phase diagrams of finite connectivity spin-glasses. We firstly compare the properties of the phase diagrams with the performance of low density parity check codes (LDPC) within the Replica Symmetric (RS) ansatz. We study the location of the dynamical and critical transition points within the one step Replica Symmetry Breaking theory (RSB), extending similar calculations that have been performed in the past for the Bethe spin-glass. The location of the dynamical transition line *does* change within the RSB theory, when comparing with the results obtained in the RS case. For LDPC decoding of messages transmitted over the binary erasure channel (BEC) we find, at zero temperature and rate $R = 1/4$ an RSB transition point located at $p_c \simeq 0.7450 \pm 0.0050$, to be compared with the corresponding Shannon bound $1 - R$. For the binary symmetric channel (BSC) we show that the low temperature reentrant dynamical transition boundary occurs at higher values of the channel noise when comparing with the RS case. Possible practical implications to improve the performance of the state-of-the-art error correcting codes are discussed.

**12:39**

**Z33 8 Novel Approach in Statistical Physics for Accurate Multiscale Materials Investigation** UDUZEI EDGAL, *North Carolina Agricultural and Technical State University* This paper discusses a novel scheme recently developed by the author [(i)Edgal, U. F., J. Chem. Phys. **94**, 8179, 1991; (ii)Edgal, U. F. and Huber, D. L., J. Phys. Chem. B, **108**, 13777, 2004; (iii)Edgal, U. F. and Huber, D. L., accepted for publication in the journal ''Physica A,'' 2005] for **accurately** determining the free energy of arbitrary equilibrium classical and quantum (material) systems at arbitrary densities, temperatures, and interaction potentials. Nearest neighbor probability density functions are formulated. The scheme allows us avert the ''sign'' problem usually encountered in Fermion calculations. Extension to mixed systems, as well as a novel ensemble, the ''Nearest Neighbor'' ensemble, used to effect the computational component of the novel approach are briefly discussed.

**12:51**

**Z33 9 Reversal of motion induced by mechanical coupling in Brownian motors** ERIN CRAIG, *University of Oregon* MARTIN ZUCKERMANN, *Simon Fraser University* HEINER LINKE, *University of Oregon* Many studies of Brownian ratchets have dealt with the asymmetric pumping of individual point-like particles. Here, we consider the transport of objects with internal structure in a flashing ratchet potential by investigating the overdamped behavior of a rod-like chain of evenly spaced point particles. In 1D, analytical arguments show that the current can reverse direction multiple times in response to changing the size of the chain or the temperature of the heat bath. However, if the rods are allowed to rotate freely in 3D, or if their length is much less than the spatial period of the ratchet potential, current reversal is no longer observed, and the qualitative behavior of single particle motion is recovered. All analytical predictions are confirmed by Brownian dynamics simulations. These results are relevant to the design of novel particle separation technology, and may provide the basis for simple, coarse-grained models of molecular motor transport that incorporate an object's size and internal degrees of freedom into the mechanism of transport.

**13:03**

**Z33 10 Optimal Resonance Forcing of Nonlinear Systems** GLENN FOSTER, ALFRED HUBLER, *Center for Complex Systems Research, Department of Physics, University of Illinois at Urbana-Champaign* We study the response of dynamical systems to additive forcing and find that, for a broad class of systems, the response is maximized by a pattern of forcing that mimics the time-reversed dynamics of the unforced system. Applying these results, we numerically construct families of optimal inputs and successfully perform spectroscopic system identification on our modeled systems.

**13:15**

**Z33 11 Quantum wave packets in hard-disk and hard-sphere billiards** ARSENI GOUSSEV, *University of Regensburg* J. ROBERT DORFMAN, *University of Maryland* Analysis of quantum dynamics in systems with classically chaotic analogs constitutes one of the main objectives for the field of *Quantum Chaos*. The quantum dynamics is known to be determined, to a large extent, by chaotic features of counterpart classical systems. We address time evolution of wave packets in open chaotic billiards, in which a quantum particle travels among a collection of fixed scatterers taken to be hard disks or hard spheres in two or three spatial

dimensions respectively. By studying the autocorrelation function for the wave packets we provide a detailed analysis of the phenomenon of wave packet partial reconstruction in the course of the time evolution, and discuss a close connection between the reconstruction dynamics and such important properties of the counterpart classical systems as the Lyapunov exponents, the Kolmogorov-Sinai and the topological entropies.

**13:27**

**Z33 12 Universal Impedance, Admittance and Scattering Fluctuations in Quantum-chaotic Systems.** SAMEER HEMMADY, XING ZHENG, THOMAS ANTONSEN, EDWARD OTT, STEVEN M. ANLAGE, *Univ. of MD-College Park, USA.* We experimentally investigate fluctuations in the eigenvalues of the impedance, admittance and scattering matrices of wave chaotic systems using a microwave analog of a quantum chaotic infinite square well potential. We consider a 2-D, time-reversal symmetric chaotic microwave resonator driven by two non-ideally coupled ports. The system-specific coupling effects are removed using the measured radiation impedance matrix ($\vec{Z}_{Rad}$) [1] of the two ports. A normalized impedance matrix ($\vec{z}$) is thus obtained, and the Probability Density Function (PDF) of its eigenvalues is predicted to be universal depending only on the cavity loss. We observe remarkable agreement between the statistical properties of $\vec{z}$ and $\vec{y} = \vec{z}^{-1}$ for all degrees of loss, which is in accordance with [1, 2] and Random Matrix Theory (RMT). We compare the joint PDF of the eigenphases of the normalized scattering matrix ($\vec{s}$) with that obtained from RMT for varying degrees of loss. We study the joint PDF of the eigenvalues of $\vec{s}\vec{s}^{\dagger}$ and find good agreement with [3]. [1] X. Zheng, itet al., – Electromagnetics (in press); condmat/0408317; S. Hemmady, *et al.*, Phys. Rev. Lett. **94**, 014102 (2005).[2] Y. V. Fyodorov, *et al.*, –condmat/0507016.[3] P. W. Brouwer and C. W. J Beenakker–PRB **55**, 4695 (1997). **13:39**

**Z33 13 Controlling transitions in a Duffing oscillator by sweeping the driving frequency.** OLEG KOGAN, *Caltech* BARUCH MEERSON, *Hebrew University of Jerusalem* We consider a high-$Q$ Duffing oscillator in a weakly non-linear regime with the driving frequency $\sigma$ varying in time between $\sigma_i$ and $\sigma_f$ at a characteristic rate $r$. We found that the frequency sweep can cause controlled transitions between two stable states of the system. Moreover, these transitions are accomplished via a transient that lingers for a long time around the third, unstable fixed point of saddle type. We propose a simple explanation for this phenomenon and find the transient life-time to scale as $-(\ln|r - r_c|)/\lambda_r$ where $r_c$ is the critical rate necessary to induce a transition and $\lambda_r$ is the repulsive eigenvalue of the saddle. The same type of phenomena is expected to hold for a large class of driven nonlinear oscillators which are describable by a two-basin model.

**13:51**

**Z33 14 Structure and Complexity in Rule Ensemble Cellular Automata** ALEXANDER WISSNER-GROSS, *Harvard University, Department of Physics* Individual elementary cellular automata (ECA) rules are attractive models for a range of non-equilibrium physical systems, but rule ensembles remain poorly understood. This paper presents the first known analysis of the equally weighted ensemble of all ECA rules. Ensemble dynamics reveal persistent, localized, non-interacting structures strongly correlated by velocity and reminiscent of solitons, instead of equilibration. Dispersion from a single initial site generates peaks traveling at low-denominator fractional velocities, some of which are not discernable in individual rules, implying collective excitation. Principal component analysis of the rule space shows the ECA are dense (with $\sim$ 111 eigenrules out of 128 ECA rules, up to symmetry), but can be transformed to a simple basis set that is quasi-linear in initial conditions. These results suggest that the ECA, often considered to be the simplest nontrivial set of ''short program'' models for self-assembly, might be approximated well by computationally simpler models. This work also shows, surprisingly, that structure can develop without favoring a single evolution rule.

**14:03**

**Z33 15 Universality away from Critical Points: Collapse of Observables in a Thermostatistical Model** CINTIA LAPILLI, PETER PFEIFER, CARLOS WEXLER, *Department of Physics and Astronomy, University of Missouri-Columbia, Columbia, Missouri 65211, USA* The $p$-state clock model in two dimensions is a discrete model exhibiting, for $p > 4$, a quasi-liquid phase in a region $T_1 < T < T_2$. We show that above a temperature $T_{\rm eu}$ the model exhibits *extended universality* in which, for $p > 4$ and all $T > T_{\rm eu}$, all thermal averages become identical to those of the continuous, planar rotor model ($p = \infty$). This *collapse of thermodynamic observables* amounts to an emergent symmetry, not present in the Hamiltonian. For $p \geqslant 8$, the collapse starts in the quasi-liquid phase and makes the transition at $T_2$ indistinguishable from the Berezinskii-Kosterlitz-Thouless (BKT) transition of the planar rotor. For $p \leqslant 6$, we find $T_{\rm eu} > T_2$, and the transition at $T_2$ is no longer BKT. The results include a detailed analysis of the critical properties at $T_1$ and $T_2$. Broader implications are discussed.

**SESSION Z37: FOCUS SESSION: NANOSCALE CONDUCTANCE THEORY III**
**Friday Morning, 17 March 2006**
**340, Baltimore Convention Center at 11:15**
**Jeffrey Neaton, Lawrence Berkeley National Laboratory, presiding**

**11:15**

**Z37 1 First-principles studies of the electronic structure of cyclopentene on Si(100)*** SU YING QUEK, *Division of Engineering and Applied Sciences, Harvard University* JEFFREY NEATON, *The Molecular Foundry, Materials Sciences Division, Lawrence Berkeley National Laboratory* MARK HYBERTSEN, *Department of Applied Physics and Center for Transport in Molecular Nanostructures* EFTHIMIOS KAXIRAS, *Department of Physics and Division of Engineering and Applied Sciences, Harvard University* STEVEN LOUIE, *Department of Physics, University of California, Berkeley & The Molecular Foundry, Materials Sciences Division,Lawrence Berkeley National Laboratory* Small organic molecules on silicon surfaces are promising candidates for active elements in nanoelectronic devices. The interplay between electronic states of the molecule and the silicon surface can change the molecular HOMO-LUMO gap, as well as result in interesting transport properties that depend sensitively on the alignment of molecular frontier orbitals with the silicon band

structure. In this work, we determine this alignment quantitatively using the GW method for cyclopentene on Si(100), a prototypical organic-molecule/silicon junction of interest in molecular electronics. We will discuss our results in the context of recent STM experiments that observed negative differential resistance in this system.

**11:27**

**Z37 2 Hydrodynamical approach to transport in nanostructures** ROBERTO D'AGOSTA, MASSIMILIANO DI VENTRA, *Department of Physics, University of California - San Diego* The electrical resistance induced by the viscous properties of the electron liquid has been recently derived.[1] In addition, it is known that the geometric constriction experienced by electrons flowing in a nanostructure gives rise to a fast ''collisional'' process.[2] These facts allow us to derive Navier-Stokes-type of equations, and therefore describe the electron flow on a par with a viscous and compressible liquid. By using this hydrodynamical approach we study electron transport in nanoscale systems and derive the conditions for the transition from laminar to turbulent flow in quantum point contacts. We also discuss possible experimental tests of these predictions. [1] N. Sai, M. Zwolak, G. Vignale, and M. Di Ventra, Phys. Rev. Lett. **94**, 186810 (2005). [2] M. Di Ventra and T.N. Todorov, J. Phys. Cond. Matt. **16**, 8025 (2004); N. Bushong, N. Sai and, M. Di Ventra, Nano Lett. (in press). Work supported by the Department of Energy (DE-FG02-05ER46204)

**11:39**

**Z37 3 Source and sink approach to calculate transport properties of nanostructures** KALMAN VARGA, SOKRATES PANTELIDES, *Vanderbilt University* We have calculated the transport properties of single molecule and carbon nanotube devices using the the Source and Sink method. We have carefully tested the convergence of the current by enlarging the basis. The fully converged current-voltage characteristics presented in this paper can serve as benchmark for transport calculations. We also compare our results to those obtained by other approaches and analyze the source of disagreements.

**11:51**

**Z37 4 Theory of the Conductance of a Single Molecule Connected to Metallic Single Wall Carbon Nanotube Electrodes*** LEI ZHANG, YIING-REI CHEN, *Chemistry Dept., Columbia University* MARK S. HYBERTSEN, *Applied Physics and Applied Math Dept, Columbia University* Metallic single wall carbon nanotubes intuitively are expected to be ideal electrodes for making contact to small, conjugated organic molecules. In this work, the conductance of ideal junctions consisting of armchair nanotube electrodes connected by conjugated carbon chains is studied. A pi-electron tight binding model is used with a Greens function formulation of the electronic states in the junction and the conductance. Key factors that influence the conductance of these junctions include molecule length, electrode attachment topology, and even versus odd length. This study delimits the maximum conductance that can be ideally expected using metallic nanotube electrodes.

*This work is supported by the NSF under award numbers CHE-0117752 and DMR-0213574, the DOE under grant number DE-FG0290ER14162, and by NYSTAR

**12:03**

**Z37 5 Role of the evanescent states in the elastic quantum transport*** ARANTZAZU GARCIA-LEKUE, *Chemical Science Division, Lawrence Berkeley National Laboratory, Berkeley, California 94720, USA* LIN-WANG WANG, *Computational Research Division, Lawrence Berkeley National Laboratory, Berkeley, California 94720, USA* The role of evanescent states is always an issue in electronic transport, especially when the energy of the propagating electron is close to a band structure minimum. In this work, we investigate the effects of exact evanescent states on the calculation of the elastic quantum transport through a molecule connected by two quantum wires, based on the method presented in Ref. [1]. An exact treatment of evanescent (decaying) states involves the calculation of the complex band structure of the electrodes with imaginary parts of the k vectors. We have calculated the complex band structure under the plane-wave pseudopotential approach. The exact evanescent states are used in the transport calculations with auxiliary boundary condition as described in Ref. [1]. The results are exact numerical solutions of the scattering states under a plane-wave pseudopotential formalism. [1] L.W. Wang, Phys. Rev. B. **72**, 045417 (2005).

**Z37 6 First-principles investigation of electronic coupling effects between organic molecules and transition metal electrodes on conduction** GUNN KIM, MARCO BUONGIORNO NARDELLI, J. BERNHOLC, *North Carolina State University, Raleigh* We investigate electronic transport in long chain molecules sandwiched between metallic electrodes. The calculations are carried out using the non-equilibrium Green function method and a basis set of localized orbitals, which are optimized to minimize the DFT total energy of the system. The optimization is performed on a grid, using multigrid techniques to accelerate convergence. Our model systems consist of saturated hydrocarbon (alkane) chains having thiol (-SH) and amino ($-NO_2$) end groups attached to transition metal electrodes. We show that the current-voltage characteristics strongly depend on the coupling between the molecule and the metal electrodes.

**12:27**

**Z37 7 Effect of doping and molecular coverage on the I-V characteristics of organic molecules on silicon surfaces** WEN-CHANG LU, *N.C. State University* V. MEUNIER, *ORNL* S. WANG, Q. ZHAO, J. BERNHOLC, *N.C. State University* Quantum transport properties of organic molecules on the silicon (001) surface have been studied by ab initio non- equilibrium Green function calculations in a basis of optimal localized orbitals. Our calculated results provide a qualitative picture and quantitative understanding of the importance of self-consistent screening and broadening of quasi- molecular orbitals under a large bias. Negative Differential Resistance (NDR) is found to be a general feature of organic molecules on Si surfaces [1]. By comparing the I-V characteristics of a monolayer of cyclopentene molecules with that of a single molecule, we show that interactions between the molecules attenuate the NDR, as seen in experiments. We have also investigated the effects of proximal dopant atoms on the NDR in a large unit cell. [1]. W. Lu, V. Meunier, J. Bernholc, Phys. Rev. Lett. 95, 206805 (2005).

**12:39**

**Z37 8 Calculation of Single-Electron Transport Through Molecules** JINGBIN LI, NIKITA SIMONIAN, KONSTANTIN LIKHAREV, *Department of Physics and Astronomy, Stony Brook University* We have carried out numerical calculations of electron transport through OPE terminated with isocyanide groups. The electron spectra and orbitals are calculated using the NRLMOL DFT package (http://cst-www.nrl.navy.mil/~ nrlmol/). The wave functions are then used to calculate the transmission of the interface energy barriers, within the Bardeen approximation. If the transmission is high, we calculate the current using the standard methods of the theory of ballistic field effect transistors, while if it is sufficiently low, we use the general theory of single-electron tunneling in systems with discrete energy spectrum [1]. (In order to understand the best way of resolving the problems due to the intrinsic limitations of the DFT approach, initial calculations have been carried out for a simple model: a Na atom sandwiched between two Au electrodes.) Our results yield I-V curves with substantial negative differential resistance (NDR) of conducting branches, due to a new mechanism: the enhancement of one of the tunnel barriers of the system by the applied electric field. The work is supported in part by AFOSR and NSF. [1]. D. V. Averin, A. N. Korotkov, and K. K. Likharev, Phys. Rev. B, 44, 6199 (1991).

**Z37 9 Contact Effects on Transport Properties through Single Molecules — ab initio RTM/NEGF method study** KENJI HIROSE, *Fund.Res.Labs., NEC Corporation* NOBUHIKO KOBAYASHI, *NRI, National Institute of AIST* Recently much attention has been focused on the transport properties of single molecules sandwiched between electrodes, aiming at construction of ultimate functional devices with molecular electronics. Since the transfer of an electron through single molecules attached to electrodes is sensitivily affected by the atomic-scale contacts and also it is difficult at present to construct well-characterized nanostructures and to directly observe their atomic structures, theoretical approaches based on the ab inito calculations is indispensable to study the transport properties of molecular-scale devices. Using the ab initio RTM/NEGF method developed recently, we study the the transport properties through single molecules attached to electrodes. This method is based on the plane-wave basis sets and thus not dependent on the atomic positions, which enables us to treat accurate tails of wavefunctions in the tunneling regimes as well as those in the ballistic regimes on the same footing. We investigate especially atomic-scale contact effects on the I-V characteristics through single molecules, changing the distance to electrodes. We find strong non-linear behaviors appear in the I-V characteristics at some distances with and even without single molecules connected to electrodes. We clarify the relationship between electronic states of single molecules and the contact effect at the electrodes for the transport properties.

**13:03**

**Z37 10 All Electron Calculations of IV Characteristics For Molecular Junctions** JOHN LAWSON, CHARLES BAUSCHLICHER, *NASA Ames Research Center* We present current-voltage (I-V) characteristics computed using all-electron basis sets on the conducting molecule. We consider benzene dithiol with gold contacts as our model system. The all-electron results are very similar to previous results obtained using effective core potentials (ECP). A hybrid integration scheme is used that keeps the all-electron calculations cost competitive with the ECP calculations. By neglecting the coupling of states to the contacts below a fixed energy cutoff, the density matrix for the core electrons can be evaluated analytically. The full density matrix is formed by adding this core contribution to the valence part that is evaluated numerically. Expanding the definition of the core in the all-electron calculations significantly reduces the computational effort and, up to biases of about 2 V, the results are very similar to those obtained using more rigorous approaches. The convergence of the I-V curve and the transmission function with respect to basis set is discussed.

**13:15**

**Z37 11 Spin-polarized electron transport in a molecular wire: tuning the conductivity through conformational changes** L. SENAPATI, S.C. ERWIN, *Center for Computational Materials Science, Naval Research Lab, Washington DC* R. PATI, *Department of Physics, Michigan Technological University, Houghton MI* We investigate theoretically the electrical conductivity of a molecular wire consisting of three linked benzene molecules. By using magnetic electrodes the conductivity becomes spin-dependent, the degree of this dependence varying with the relative spin-alignment of the two electrodes. Of particular interest is how the the conductivity depends on the geometrical conformation of the benzene wire. Here we use density-functional theory and the Landauer-Büttiker method to calculate this dependence from first principles. We find that the current depends sensitively on the conformation, with a near-planar configuration of the three benzene rings giving significantly higher current (by ~ 30%) than the ground-state non-planar structure.

**13:27**

**Z37 12 Ab initio modeling of molecular spintronics** DEREK WALDRON, VLADIMIR TIMOCHEVSKI, *Dept. of Physics, McGill University* BRIAN LARADE, *QuantuModeling Inc.* HONG GUO, *Department of Physics, McGill University* We report on theoretical studies of spin polarized quantum transport through molecular scale magnetic tunnel junctions. Our theoretical formalism is based on carrying out density functional theory (DFT) analysis within the Keldysh nonequilibrium Green's function (NEGF) formalism. The NEGF-DFT technique allows one to calculate nonlinear quantum transport features from atomic point of view. We will report these features for systems such as Ni-bezenedithiol(BDT)-Ni molecular magnetic tunnel junction, conventional Fe-MgO-Fe device, and spin injection through Fe-GaAs interfaces, including all the microscopic material properties.

**13:39**

**Z37 13 Theory of electron-vibration coupling in the electron transport of molecular bridges** MASARU TSUKADA, *Waseda University* KUNIHIRO MITSUTAKE, *Canon Research Center, Canon Inc.* Electron transport through molecules connecting nano-electrodes is the key issue for molecular devices. The competition and coexistence of the coherent and dissipative transport are unresolved issue, in spite of its importance. In this work, this problem is investigated by a novel theoretical approach of an itab initio molecular orbital model with combining polaron effect. When carriers are injected into molecules from electrodes, the structure of the molecule changes, which leads the coupling term of the electron/hole and the molecular vibration. The model Hamiltonian for the thiophene oligomer is solved by a variational approach, and a mixed states of dressed polaron with molecular orbital states mediated by the phonon cloud is found. The former and latter are predominant for small or large transfer integral, respectively. The excited states can be calculated in the same framework as the

ground state. The overall carrier transport properties can be analyzed by solving the master equation with the transition rate estimated by the golden rule including the phonon degrees of freedom. In this theoretical approach, the coherent and dissipative electron transport through molecular bridges can be described in a uniform systematic way.

**13:51**

**Z37 14 Inter-strand coupling and base pairing sequences in DNA charge transport.*** EFTA YUDIARSAH, *Ohio University* SERGIO ULLOA, *Ohio University* The electronic transport properties of double-stranded DNA are studied using a tight-binding Hamiltonian. Transfer and scattering matrix methods for double strands are employed simultaneously in the calculation, guaranteeing numerical stability. Realistic on-site energies [1] and hopping constants are used in the model [2]. The role of inter-strand coupling is shown to be extremely important for random sequences typical of genetic DNA. In contrast, inter-strand coupling only changes slightly the charge transport properties for more periodic sequences. The effect of base-pairing across strands and details of the sequences were investigated. Our model shows that the resistance of DNA depends on the sequences and the ratio of the bases. This agrees with previous results by Roche [3]. The resistance is also shown to increase with the concentration of different bases in a homogenous strand, and we find that for certain sequences only short-range electronic transport is possible. **Z37 15 Rabi-assisted transport in diatomic molecules*** EDSON VERNEK, ENRIQUE V. ANDA, *Pontifícia Universidade Católica do Rio de Janeiro* SERGIO E. ULLOA, NANCY SANDLER, *Ohio University* Electronic transport through few atoms, molecules and quantum dots has captured much attention recently among physicists. The confinement of electrons going alongin these systems gives rise to strong Coulomb repulsion that produces a very rich phenomenology. Electrons also interact with phonons, which affect transport characteristics under resonant conditions. We have modeled electronic transport in a diatomic molecule by a system composed of two orbital sites coupled in parallel between two leads [1]. We studied the regime where both electron- electron and electron-phonon interactions are important and have shown dramatic effects on the conductance. Using Green's functions and equation of motion techniques we found new conducting channels in the presence of Coulomb interactions when the energy of phonons matches the energy difference between quasei-particle levels. We call this phenomenon Rabi-assisted tunneling. We now present a detailed study that includes the super-exchange interaction between the atoms in the molecules (indirectly coupled through the leads), which was not included in the previous work. We describe how the indirect coupling affects resonance conditions and the conductance of the system. [1] E. Vernek, et al., Phys. Rev. B (R) **72**, 121405 (2005). (Rapid comm.)

**Z38 1 From Fermi Arcs to Nodal Metal: Scaling of the Pseudogap with Temperature and Doping** AMIT KANIGEL, *Univ. of Illinois at Chicago* M.R. NORAMN, *Materials Science Div., ANL* M. RANDERIA, *Dept. of Physics, Ohio State Univ.* U. CHATERJEE, *Dept. of Physics, Univ. of Illinois at Chicago* A. KAMINSKI, H.M. FRETWELL, *Ames Laboratory and Dept. of Physics and Astronomy, Iowa State Univ.* S. ROSENKRANZ, *Materials Science Div., ANL* M. SHI, *Dept. of Physics, Univ. of Illinois at Chicago* T. SATO, T. TAKAHASHI, *Dept. of Physics, Tohoku Univ., Japan* Z.Z. LI, H. RAFFY, *Laboratorie de Physique des Solides, Universite Paris-Sud, France* K. KADWAKI, *Inst. of Materials Science, Univ. of Tsukuba, Japan* J.C. CAMPUZANO, *Dept. of Physics, Univ. of Illinois at Chicago* The pseudogap phase in the cuprates is a most unusual state of matter[1–4]: it is a metal, but its Fermi surface is broken up into disconnected segments known as Fermi arcs[5]. Using angle resolved photoemission spectroscopy, we show that the anisotropy of the pseudogap in momentum space and the resulting arcs depend only on the ratio itT/T*(x), where itT*(x) is the temperature below which the pseudogap first develops at a given hole doping, itx. In particular, the arcs, which extend at itT* to the hot spots where the antiferromagnetic zone boundary crosses the Fermi surface, collapse linearly with itT/T* and extrapolate to zero extent as itT 0. This suggests that the itT = 0 state is a nodal liquid, a strange metallic state whose gapless excitations are located only at points in momentum space, just as for a itd-wave superconductor.

**11:27**

**Z38 2 Pseudogap and Superconducting Gap in $(La_{2-x}Sr_x)CuO_4$** X.J. ZHOU, *Stanford University and Lawrence Berkeley National Lab* T. YOSHIDA, *University of Tokyo* W.L. YANG, *Stanford University and LBNL* SEIKI KOMIYA, YOICHI ANDO, *Central Research Institute of Electric Power Industry, Japan* T. SASAGAWA, *University of Tokyo* F. ZHOU, W.X. TI, J.W. XIONG, Z.X. ZHAO, *Institute of Physics, Chinese Academy of Sciences* T. KAKESHITA, H. EISAKI, S. UCHIDA, *University of Tokyo* A. FUJIMORI, *University of Tokyo* Z. HUSSAIN, *Lawrence Berkeley National Lab* Z.-X. SHEN, *Stanford University* We have carried out high resolution angle-resolved photoemission measurements on $(La_{2-x}Sr_x)CuO_4$ (LSCO) over the entire doping range (x=0~ 0.3). We will present doping-dependence and momentum-dependence of the pseudogap and superconducting gap in the LSCO system.

**11:39**

**Z38 3 ARPES Study of Nodal Quasiparticles of $Bi_2Sr_{1.6}La_{0.4}CuO_{6+\delta}$ Using Low-Energy Excitation Photons** T. KAMO, K. YAMAZAKI, T. YAMASAKI, H. ANZAI, A. INO, M. ARITA, H. NAMATAME, M. TANIGUICHI, *Graduate School of Science and Hiroshima Synchrotron Radiation Center, Hiroshima University* A. FUJIMORI, *University of Tokyo* Z.-X. SHEN, *Stanford University* K. FUJITA, S. UCHIDA, *Department of Physics, University of Tokyo* Using low-energy synchrotron radiation ($h\nu$ = 7.75 eV) as excitation photons, the quasiparticle-momentum resolution has been dramatically improved ($\Delta k$

$\sim 0.01\text{Å}^{-1}$) in the angle-resolved photoemission (ARPES) study of single-layer high-$T_c$ cuprate $Bi_2Sr_{1.6}La_{0.4}CuO_{6+\delta}$ (Bi2201). We report the new experimental result on the nodal quasiparticle dispersion and scattering rate of optimally doped Bi2201 ($T_c = 33$ K) over an extended temperature range. Since only a single quasiparticle band is involved for the single-layer cuprate, the high-resolution quasiparticle images have provided us the direct information on fine quasiparticle structures. In comparison to the result on the bilayer cuprate Bi2212, we will discuss the character of the multiple excitation modes coupled with the electrons.

**11:51**

**Z38 4 Nodal Quasiparticle Life Time in High-Tc Cuprates** Z.H. PAN, H.B. YANG, P. RICHARD, J.H. MA, M. NEUPANE, Y.M. XU, A. SHEKHARAN, H. DING, G. GU, T. VALLA, P.D. JOHNSON, *Department of Physics, Boston College, MA* Angle-Resolved Photoemission Spectroscopy (ARPES) are used to study the temperature dependence of nodal quasiparticle life time of $Bi_2Sr_2CaCu_2O_8$ (Bi2212) with different doping levels. For optimally doped (OP) and overdoped (OD) samples, a sudden change is observed in the temperature dependence of the scattering rate at Tc, however this change is not obvious in the underdoped (UD) samples.

**12:03**

**Z38 5 A reexamination of the oxygen isotope effect in ARPES spectra of BSCCO** FRASER DOUGLAS, Z. SUN, D.S. DESSAU, *University of Colorado at Boulder* A.V. FEDOROV, *Advanced Light Source* H. EISAKI, *AIST* H. IWASAWA, *AIST* Y. AIURA, *AIST* T. MASUI, S. TAJIMA, *Osaka University* High resolution angle-resolved photoemission spectroscopy (ARPES) has been utilized to further explore the effects of oxygen isotope substitution in Bi2212 and Bi2201 high temperature superconductors. First presented as evidence for the importance of phonons in the nodal dispersion of 2212, the use of several synchrotron beamlines with many different photon energies suggests an alternate explanation for the observed effect.

**12:15**

**Z38 6 Selective Observation of Bilayer-Split Nodal Quasiparticles in $Bi_2Sr_2CaCu_2O_{8+\delta}$ by ARPES Using Low-Energy Tunable Photons** T. YAMASAKI, T. KAMO, H. ANZAI, A. INO, M. ARITA, H. NAMATAME, M. TANIGUCHI, *Graduate School of Science and Hiroshima Synchrotron Radiation Center, Hiroshima University* A. FUJIMORI, *Department of Complexity Science and Engineering, University of Tokyo* Z.-X. SHEN, *Department of Applied Physics and SSRL, Stanford University* M. ISHIKADO, S. UCHIDA, *Department of Physics, University of Tokyo* Doubling the $CuO_2$ layer is considered to enhance the transition temperature of cuprate superconductors. However, since a recent breakthrough in angle-resolved-photoemission spectroscopy (ARPES) using low-energy excitation photons, it has been controversial whether the nodal bilayer splitting is resolvable or not. We have performed the photon-energy-dependent ARPES study of bilayer cuprate $Bi_2Sr_2CaCu_2O_{8+\delta}$ using low-energy synchrotron radiation ($h\nu = 7$-8 eV). While the bonding and antibonding band are consistently resolved by a constant splitting width of $\Delta k \cong 0.008\text{A}^{-1}$, the spectral weight drastically transfers between them with changing photon energy. The tunable photons enabled us to control the bonding-to-antibonding ratio from 0% to 162%. We will discuss the nodal quasiparticle properties using this bilayer-selective probe.

**12:27**

**Z38 7 Impurity-effect on the electronic structure in $Bi_2Sr_2CaCu_2O_{8+\delta}$ studied by angle-resolved photoemission spectroscopy** KENSEI TERASHIMA, HIROAKI MATSUI, DAISUKE HASHIMOTO, TAKAFUMI SATO, TAKASHI TAKAHASHI, *Department of Physics, Tohoku University* HONG DING, *Department of Physics, Boston College* TAKASHI YAMAMOTO, KAZUO KADOWAKI, *Institute of Materials Science, University of Tsukuba* We studied the impurity effect on the electronic structure near the Fermi level in $Bi_2Sr_2CaCu_2O_{8+\delta}$ by high-resolution angle-resolved photoemission spectroscopy to clarify the origin of dispersion kink in high-$T_c$ superconductors. We found that the dispersion kink at the off-nodal region is significantly suppressed by Zn or Ni impurity while that at the node is less affected. The impurity-induced change of the self-energy and its temperature dependence show a good correspondence to those of the magnetic excitation of $Q = (\pi, \pi)$, suggesting that electrons are strongly coupled to the spin fluctuation at the antinodal region.

**12:39**

**Z38 8 Laser ARPES on the cuprate superconductor Bi2212** JAKE KORALEK, *University of Colorado and NIST* FRASER DOUGLAS, NICK PLUMB, *University of Colorado* ZHE SUN, *University of Colorado and the Advanced Light Source* MARGARET MURNANE, HENRY KAPTEYN, STEVE CUNDIFF, *University of Colorado and NIST* Y. AIURA, K. OKA, H. EISAKI, *AIST* DAN DESSAU, *University of Colorado and NIST* We use 6 eV photons from the fourth harmonic of a Ti:Sapphire laser to perform ARPES on the cuprate superconductor Bi2212. The very low photon energy improves momentum resolution and reduces extrinsic background, offering the clearest picture yet of the single electron spectral function. We will present detailed analysis of the temperature dependence of the nodal spectral lineshapes and compare the predictions of Fermi liquid theory and marginal Fermi liquid theory to what is seen in the data. We will also discuss recent laser ARPES results for overdoped and underdoped Bi2212.

**12:51**

**Z38 9 ARPES investigation of deeply underdoped BISCO 2212** K. TANAKA, W. S. LEE, D. H. LU, T. FUJII, A. FUJIMORI, Z. HUSSAIN, Z. X. SHEN, We present ARPES results from deeply underdoped BISCO 2212 with Tc ranging from 30 to 50 K. The improved sample quality with Y subsitution enables the detection of much sharper spectral features. We uncovered experimental evidence for two distinct energy gaps in these deeply underdoped samples. The theoretical implications of these findings will de discussed in conjunction with ARPES and RAMAN data.

**13:03**

**Z38 10 APRES study of the High temperature cuprates with high superconducting transition temperature ($T_c > 90$K)** WEI-SHENG LEE, WORAWAT MEEVASANA, DONGHUI LU, KYLE SHEN, GUICHUAN YU, XUDONG ZHAO, MARTIN GREVEN, ZHI-XUN SHEN, *Department of Physics and Stanford Synchrotron Radiation Laboratory, Stanford University, Stanford, California, US* WANLI YANG, *Advanced Light Source, Lawrence Berkeley Lab, Berkeley, California, US* AKIRA IYO, HIROSHI EISAKI, *AIST, Japan* The curprates with high superconducting transition temperature, nearly optimally doped $HgBa_2CuO_{4+\delta}$ system ( Hg1201, $T_c$=96K) and nearly optimally-doped $TlBa2Ca_2Cu_3\ O_{8+\delta}$ ( Tl1223, $T_c$=120K), were studied by the Angle Resolved Photoemission Spectroscopy (ARPES). These

materials provide us an opportunity to examine the universal properties of the cuprates and their material dependence trend. Although they are not easy to be cleaved, we managed to measure the band dispersions and the Fermi surfaces of these materials. Interestingly, in Hg1201 system, we found the existence of a quasi-particle peak along (0,0) to ($\pi$, $\pi$) direction (nodal direction); whereas no structure was observed near the zone boundary. Contrarily, in Tl1223 system, a well-defined peak in EDCs was observed near the zone boundary; whereas no peak was observed in the nodal region. A comparison to other most studied cuprates will also be presented.

**13:15**

**Z38 11 Doping dependence study by ARPES on four layered cuprate superconductor $Ba_2Ca_3Cu_4O_8(O_\delta F_{1-\delta})_2$** YULIN CHEN, AKIRA IYO, WANLI YANG, XINGJIANG ZHOU, DONGHUI LU, HIROSHI EISAKI, THOMAS DEVEREAUX, ZAHID HUSSAIN, ZHI-XUN SHEN, An interesting phenomenon in various families of cuprate superconductors is that with the increase of the number of $CuO_2$ layers (which are believed to be responsible for the superconducting phenomenon) within a unit cell of the crystal, the superconducting transition temperature ($T_c$) increases first with the layer number n when n$<$ =3, then decreases when n$>$ 3 and reaches the maximum at n=3. To understand this phenomenon, we investigate a four layered cuprate family $Ba_2Ca_3Cu_4O_8(O_\delta F_{1-\delta})_2$ by Angular Resolved Photoemission Spectroscopy (ARPES). We find that the electronic band structure of this four layered system exhibits clear difference from the previously studied cuprate superconductors with less layers where layers are doped uniformly when n$<$ =2. Our doing ($\delta$) dependence study reveals the band structure, Fermi surface and superconducting gap evolution, with insights on important microscopic process.

**13:27**

**Z38 12 Dimensional crossover in the electronic structure of $(Bi,Pb)_2(Sr,La)_2CuO_{6+\delta}$** T. KONDO, T. TAKEUCHI, *EcoTopia Science Institute, Nagoya Univ., Japan* H. YANG, H. DING, *Dept. of Physics, Boston College* A. KAMINSKI, *Dept. of Physics and Astronomy, Ames Lab.* J.C. CAMPUZANO, *Materials Sciences Division, Argonne National Lab.* The hole-concentration ($p$) dependence of the 3D energy- momentum ($\varepsilon - \boldsymbol{k}$) dispersion in Bi2201 was investigated by ARPES. We observe a significant $\varepsilon - k_z$ dispersion ( $\sim$ 10 meV wide) around ($\pi$,0) in a heavily overdoped sample ($T_c \leq$ 0.5 K). This $\varepsilon - k_z$ dispersion shrinks with decreasing $p$, and is not observed in lightly overdoped and optimally doped samples ($T_c$ = 21 K and 35 K, respectively) indicating a crossover from a 3D to 2D electronic structure.

**13:39**

**11:27**

**Z39 2 Interaction of Zhang-Rice singlets with the buckling phonons in Cuprates** EHSAN KHATAMI, ALEXANDRU MACRIDIN, MARK JARRELL, *University of Cincinnati* THOMAS DEVEREAUX, *University of Waterloo* Starting from a fully interacting three-band model we derive an effective single-band Hamiltonian which describes the interaction of Zhang-Rice (ZR) singlets[1] with the buckling phonons. Our approach is based on exact diagonalization of small clusters which contain both Cu and O atoms[2]. We study the parametric dependence of the electron-phonon coupling. The coupling to the phonon mode with $B_{1g}$ symmetry is one order of magnitude stronger than the coupling to the $A_{1g}$ phonon mode and there is an anisotropy in the interaction. For the $B_{1g}$ phonon, the antinodes contribute to the interaction more than the nodes, in agreement with weak coupling approaches[3]. By increasing the O-O hopping, the coupling amplitude becomes smaller in antinodal points. We also find that a simpler model, which considers the modulation of the ZR hopping

by the corresponding bond phonons, captures the symmetry of the electron-phonon interaction. Reference: [1] F. C. Zhang and T. M. Rice, PRB **37**, 3759 (1988) [2] H. Eskes *et.al.*, Physica C **160**, 424 (1989) [3] T. P. Devereaux *et.al.*, PRL **93**, 117004 (2004)

**Z39 3 Anisotropic electron-phonon coupling in Bi2212 and Bi2223*** STEVEN JOHNSTON, *University of Waterloo* THOMAS DEVEREAUX, *University of Waterloo* In this talk we present calculations of self energy effects due to anisotropic electron-phonon coupling in the Bi-family of cuprates. The specific anisotropy of a number of phonon modes yields momentum-dependent signatures in the spectral function and renormalizations in the tunneling density of states both above and below Tc. The spectral functions are compared to angle-resolved photoemission and SIS break junction measurements and renormalizations at specific wavevectors and energies are in accordance with coupling primarily to the B1g phonon. Self-consistent treatment of the electron-phonon interaction is shown to display band renormalizations at energies well above that of the characteristic phonon energy.

**Z39 4 Numerical study of the isotope effect of underdoped high-temperature superconductors** ANDREI MISHCHENKO, *CREST, JST* NAOTO NAGAOSA, *CREST, The University of Tokyo* RRC KURCHATOV INSTITUTE TEAM, CERC, AIST TEAM, ERATO-SSH TEAM, We present a numerical study of the isotope effect on the angle resolved photoemission spectra (ARPES) in the undoped cuprates. By the systematic-error-free Diagrammatic Monte Carlo method, the Lehman spectral function of a single hole in the $tt't'' - J$ model in the regime of intermediate and strong couplings to optical phonons is calculated for normal and isotope substituted systems. We found that the isotope effect is strongly energy-momentum dependent, and is anomalously enhanced in the intermediate coupling regime while it approaches to that of the localized hole model in the strong coupling regime. We predict the strengths of effect as well as the fine details of the ARPES lineshape change. Implications to the doped case are also discussed.

**Z39 6 Transport and thermodynamic properties of cuprate superconductors: E(k) dispersion, pseudogap and isotope effects.** JAMES STOREY, *MacDiarmid Institute, Victoria University* JEFFERY TALLON, *MacDiarmid Institute, Industrial Research Ltd and Victoria University* GRANT WILLIAMS, SURESH NARAYANASWAMY, *MacDiarmid Institute, Industrial Research Ltd* We have calculated the thermoelectric power, susceptibility and entropy of Bi-2212 and Bi-2201 using the ARPES-derived energy dispersion, a model scattering rate and including a normal-state pseudogap. The doping and temperature dependence is found to closely mimic the experimentally measured data. We have used this approach to examine isotope effects and in particular note that the kink in the dispersion near $E_F$ (including its isotope effect) can be probed through the high temperature thermoelectric power.

**12:27**

**Z39 7 Renormalization Group Study of the Electron-phonon Interaction in High $T_c$ Cuprates** HENRY FU, *University of California, Berkeley* CARSTEN HONERKAMP, *Institute for Theoretical Physics, Universitat Wuerzburg* DUNG-HAI LEE, *University of California, Berkeley* We apply a numerical renormalization group scheme to study the phonon-mediated retarded interactions in the high $T_c$ cuprates. We find that three sets of phonon-mediated retarded quasiparticle scatterings grow under RG flow. These scatterings share the following common features: 1) the initial and final quasiparticle momenta are in the antinodal regions, and 2) the scattering amplitudes have a $x^2 - y^2$ symmetry. All three sets of retarded interactions are driven to strong coupling by the magnetic fluctuations around $(\pi, \pi)$. After growing strong, these retarded interactions can trigger density wave orders with d-wave symmetry. However, due to the d-wave form factor they will leave the nodal quasiparticle unaffected. We conclude that the main effect of electron-phonon coupling in the cuprates is to promote these density wave orders.

**Z39 8 Phonon renormalization reflecting dynamic charge inhomogeneity in copper-oxide superconductors** D. REZNIK, L. PINTSCHOVIUS, *Forschungszentrum Karlsruhe, Institut für Festkörperphysik, P.O.B. 3640, D-76021 Karlsruhe, Germany* M. ITO, S. IIKUBO, M. SATO, *Department of Physics, Division of Materials Science, Nagoya University, Furo-cho, Chikusa-ku, Nagoya 464-8602, Japan* H. GOKA, M. FUJUTA, K. YAMADA, *Institute for Material Research, Tohoku University, Katahira, Aoba-ku, Sendai, 980-8577, Japan.* G. GU, J. TRANQUADA, *Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, Upton, New York 11973-5000, USA* Our inelastic neutron scattering measurements show that there is a strong anomaly in the Cu-O bond-stretching phonon in cup rate superconductors $La_{2-x}Sr_xCuO_4$ (x=0.07,0.15). This behavior also appears in superconducting $YBa_2Cu_3O_{6+x}$, however it is completely absent in undoped and overdoped LSCO. $InLa_{1.875}Ba_{0.125}CuO_4$ and $La_{1.48}Nd_{0.4}Sr_{0.12}LCuO_4$, compounds that exhibit spatially modulated charge and magnetic order, often called stripe order, the anomaly occurs at a wave vector corresponding to the charge order. The results suggest that this giant electron−phonon anomaly, which is absent in LDA calculations, is associated with charge inhomogeneity induced by strong electronic correlations. It follows that electron−phonon coupling may be important to understanding the superconductivity although its contribution to the mechanism is probably non−BCS−like.

**12:51**

**Z39 9 Is room-temperature superconductivity with phonons possible?** MANUEL DE LLANO, *Instituto de Investigaciones en Materiales, UNAM, Mexico City* By recognizing the vital importance of two-hole Cooper pairs in addition to the usual two-electron ones in a strongly-interacting many-electron system, the concept of Cooper pairing was re-examined with striking conclusions, namely gapped and linearly-dispersive resonances with a finite lifetime. Based on this, Bose-Einstein condensation (BEC) theory has been generalized to include not boson-boson interactions (also neglected in BCS theory) but rather boson-fermion interaction vertices reminiscent of the Froehlich electron-phonon interaction in metals. Instead of phonons, the bosons in the generalized BEC (GBEC) theory are now both particle and hole Cooper pairs. Each kind is responsible for half the condensation energy. The GBEC reduces to all the old known statistical theories as special cases—including the so-called ''BCS-Bose crossover'' picture which in turn generalizes BCS theory. With no adjustable parameters, the GBEC theory yields superconducting transition temperatures substantially higher than the BCS limitation of around 45K [including room-temperature superconductivity (RTSC)] without relying on non-phononic dynamics involving excitons, plasmons, magnons or otherwise purely-electronic mechanisms. The results are expected to shed light in the experimental search for RTSCs.

**13:03**

**Z39 10 Duality and normal modes in a Cooper pair Wigner crystal** TAMAR PEREG-BARNEA, *University of Texas* MARCEL FRANZ, *University of British Columbia* A duality transformation from a phase fluctuating d-wave superconductor to a condensed state of vortices shows that Cooper pairs may form a Wigner crystal once the phase fluctuations destroy the superconducting long range order [1]. The lattice constant and the basis of this crystal are consistent with the charge modulations seen by the STM experiments in strongly underdoped cuprates [2]. Based on this vortex-boson duality we suggest a theoretical picture to relate the charge modulations seen by STM and the mysterious increase in the thermal conductivity [3] recently observed in the underdoped non-superconducting state. This addition to the thermal conductivity has bosonic temperature dependence and is attributed within our picture to the vibrational modes of the pair Wigner crystal. We analyze the spectrum of these modes and find it qualitatively consistent with the experimental observations. 1. Z. Tesanovic, Phys. Rev. Lett. 93, 217004 (2004). 2. J. E. Hoffman et al., Science 295, 466 (2002). 3. L. Taillefer (unpublished).

**Z39 11 Cooper-Pair Molasses: Cooling a nanomechanical resonator with quantum backaction** A.K. NAIK, O. BUU, M.D. LAHAYE, K.C. SCHWAB, *Laboratory for Physical Science* A.D. ARMOUR, *School of Physics and Astronomy, University of Nottingham, Nottingham, United Kingdom* A.A. CLERK, *Department of Physics, McGill University, Montreal, QC Canada* M.P. BLENCOWE, *Department of Physics and Astronomy, Dartmouth College, Hanover, NH USA* We have measured the back-action of a superconducting single electron transistor using a radio frequency nanomechanical resonator. The backaction forces are a factor of 15 above the intensity required by the Heisenberg uncertainty principle: $\sqrt{S_x S_f} = 15\hbar/2$. This system has also shown a record position and force sensitivity of $0.4fm/\sqrt{Hz}$ and $0.5aN/\sqrt{Hz}$, and the closest approach to the quantum ground state of a mechanical system (N=25) (1). In addition, we have discovered a novel cooling mechanism, analogous to optical molasses, which is a result of resonant Josephson effects in the transistor (2,3). Using devices of similar design and performance, we are anticipating the observation of squeezed, superposition, and entangled states of a mechanical device. 1. M.LaHaye, O. Buu, B. Camarota, K. Schwab, Science 304, 74 (2004). 2. M. P. Blencowe, J. Imbers and A. D. Armour, xxx.lanl.gov/ cond-mat/0507645. 3. A. A. Clerk, S. Bennett, xxx.lanl.gov/ cond-mat/0507646.

**Z39 12 Real-Space Picture of the Cooper Pair** ALAN M. KADIN, *Princeton Junction, NJ 08550* The Cooper pair is generally analyzed in momentum space, but its real-space structure also follows directly from the BCS theory. From this viewpoint [1], a Cooper pair consists of a spherical quasi-atomic wavefunction of radius $\sim \pi\xi_0$ for both electrons, with radial nodes separated by $\pi/k_F$. An induced commensurate quasi-static charge modulation in the underlying lattice provides the interaction potential, similar to that in the simple BCS approximation, which leads to a bound state. This picture can be generalized for alternative pairing symmetries (p or d-wave) as well as alternative pairing mechanisms (excitonic or spin-based) and extended to disordered superconductors. While it does not derive essentially new physics, this real-space approach may provide a more heuristic picture for developing and understanding new phenomena in superconductivity. [1] A.M. Kadin, http://www.arxiv.org/abs/cond-mat/0510279

**Z39 13 Cooper pairs on a spherical surface*** JACQUES TEMPERE, VLADIMIR GLADILIN, *Universiteit Antwerpen* ISAAC SILVERA, *Harvard University* JOZEF DEVREESE, *Universiteit Antwerpen* Superconductivity has been widely studied for flat, two-dimensional electron systems, such as electrons in copper-oxide planes or electron films on helium. In this contribution, we investigate how Cooper pairing is affected by curvature. In particular we investigate the pairing correlations of a spherical, two-dimensional electron gas. This system is realized in for example multielectron bubbles, and in metallic nanoshells. For the case of multielectron bubbles, the pairing Hamiltonian can be solved exactly using Richardson's method. This reveals not only the structure of the ground state, but also the density of states of the excited states. We find that in the ground state, a redistribution of the electrons over the angular momentum levels occur, and that in the density of states a pseudogap appears. These results are put in the context of multielectron bubbles in helium, and compared to those for a flat 2D electron system.

**Z39 14 Cooper Pair Wavefunction Approach to the AC Josephson Effect** YONG-JIHN KIM, *University of Puerto Rico - Mayaguez* Recently, we have proposed Cooper pair wavefunction approach to the DC Josephson effect, which shows the threshold resistance of SIS Josephson junctions (in the high tunneling resistance regime). In the $MgB_2$case, since the threshold resistance is so small for the big gap, $MgB_2$break junctions and SIS tunnel junctions display the Josephson supercurrent only for the small gap. We apply this approach to the AC Josephson effect. The amplitude of the oscillating supercurrent in the presence of the electric field is calculated, using the Cooper pair wavefunctions formed by the Airy functions. We also discuss the sign problem of the pair-quasi-particle interference term.

**Z40 1 Double quantum dot coupled to a superconducting single-electron transistor for measurement of back action** MADHU THALAKULAM, *Rice University, Houston, TX 77005* JOEL STETTENHEIM, A. J. RIMBERG, *Dartmouth College, Hanover, NH 03755* L.N. PFEIFFER, K. W. WEST, *Bell Laboratories, Lucent Technologies Inc., Murray Hill, NJ 079745* The superconducting single electron transistor SET is a highly sensitive electrometer operating near the quantum limit. The back action current noise of the SET has been a topic of interest ever since the SET was proposed as a readout device for charge or spin based qubits [1]. We study the back-action noise of a superconducting SET by means of an electrostatically coupled double quantum dot (DQD) system. Inelastic current through the DQD is sensitive to the spectral density of voltage fluctuation in its electromagnetic environment [2,3]. By properly choosing the dot size and inter-dot tunnel barrier, one can cause inelastic processes to dominate the transport. A measurement of the inelastic current through the double dot system can then be used to calculate the spectral density of quantum noise associated with the RF-SET and hence its back-action. We have fabricated samples consisting of a DQD formed in a GaAs/AlGaAs heterostructure and strongly coupled to an Al/$AlO_x$/Al SET@. Recent results of measurements on such devices will be discussed. **Z40 2 Quantum Capacitance for Quantum Computation** C.M. WILSON, T. DUTY, F. PERSSON, M. SANDBERG, G. JOHANSSON, L. TORNBERG, J. BYLANDER, P. DELSING, *Chalmers University* We present measurements of superconducting quantum bit (qubit) circuits utilizing the quantum capacitance (QC) of a single cooper-pair box (SCB). The QC is essentially the curvature of the SCB energy bands near the charge degeneracy point, and has recently been measured by our group and others. The curvature arises from the avoided level crossing induced by the Josephson coupling of the SCB. The QC can be much larger than the geometric capacitance, and changes sign between the ground and excited states. We present a qubit with integrated readout that embeds a SCB in a resonant circuit and detects changes in the QC as changes in the phase of a reflected microwave signal. We have calculated that this readout method is strictly quantum limited independent of the quality factor (Q) of the the resonator. This allows great flexibility in the design and optimization of the readout. Calculations show that the method should be able to achieve single-shot discrimination of the qubit state under realistic experimental conditions. We also present preliminary measurements of coupled qubit circuits, with both fixed coupling and a variable coupling scheme based on the ground-state QC.

**Z40 4 Macroscopic Quantum Coherence in a Multi-Level Nb Persistent-Current Qubit*** YANG YU, *MIT* W. D. OLIVER, *MIT Lincoln Laboratory* J. C. LEE, K.K. BERGGREN, L.S. LEVITOV, T.P. ORLANDO, *MIT* We drove a niobium persistent-current qubit with strong microwaves and observed single-, two-, and three-photon transitions between its macroscopic quantum states. A multi- level energy-band diagram was extracted by mapping the frequency of the induced transitions as a function of applied magnetic flux to the qubit, and the anti-crossing caused by the superposition between the third and fourth excited states were directly measured. The energy relaxation time T1 between two states connected by multi-photon transitions ranged from 30 to 100 ms. In addition, three-photon coherent temporal oscillations between the ground state and fourth excited state were observed with a decoherence time of approximately 50 ns.

**Z40 5 Electronic control and readout of qubit states in Si:Li-based quantum computing system** V.V. OSIPOV, V.N. SMELYANSKIY, *NASA Ames Research Center, Moffett Field, CA* A.G. PETUKHOV, *Physics Department, South Dakota School of Mines and Technology* In our previous work (V. N. Smelyanskiy *et al.* Phys. Rev. B **72**, 081304 (2005)) we predicted a gigantically long lifetime of the first excited state of an interstitial lithium donor in silicon. The nature of this effect roots in the anomalous level structure of the 1*s* Li manifold under external stress. Namely, the coupling between the lowest two states of the opposite parity is very weak and occurs via intervalley phonon transitions only. We proposed to use these states under the controlled ac and dc stress to process quantum information. In this work we consider some practical aspects of the proposed scheme such as formation of heavily doped semiconductor electrodes for electrical control of the qubit states and single-qubit readout by means of the resonant tunneling stimulated by polarized infrared radiation. We propose a proof-of-the principle experiment on photo-stimulated time-dependent resonant tunneling in a $\delta$-doped layer of Li donors in Si placed between two $n^+$ Si electrodes. The effect will be characterized by a high sensitivity of the signal to the polarization of photons and by long-term relaxation of the resonant tunneling photocurrent.

**12:15**

**Z40 6 Single electron tunneling in a controllable electromagnetic environment** Z. JI, *Rice University* W. XUE, A.J. RIMBERG, *Dartmouth College* L.N. PFEIFFER, K.W. WEST, *Bell Laboratories* Real-time counting of single electrons is the most fundamental means of measuring current [1]. Direct observation of single electron tunneling oscillations requires embedding a tunnel barrier in a high-impedance electromagnetic environment. Beginning with a two dimensional electron gas in a GaAs heterostructure we first etch a narrow mesa to serve as a conducting channel. We fabricate two staggered arrays of quantum point contacts (QPCs) across the mesa to serve as ballistic resistors controlled by tuning the QPC gate voltage. An additional QPC placed between the arrays serves as the tunnel barrier and a nearby radio-frequency single electron transistor (RF-SET) serves as an electrometer. We have fabricated several such samples. Typically the conductance G versus gate voltage of such an array of 10 QPCs shows plateau-like structures at fractions of the conductance quantum, $G_0 = 2e^2/h$. The first plateau, below which the conductance drops rapidly to zero, is the preferred working point corresponding to one open channel in each QPC. When the arrays are at their working points and the central barrier is formed, the samples show a large gap in their I-V characteristics corresponding to dynamical Coulomb blockade. Recent measurements of such samples will be presented, and the use of the RF-SET to directly observe single electron tunneling will be discussed. [1] J. Bylander, T. Duty and P. Delsing, Nature **434**, 361 (2005).

**12:27**

**Z40 7 Calculated tunneling rates for single electron charging events in Vertical ''Enhancement Mode'' quantum dot devices.** RICHARD ROSS, MARK GYURE, *HRL Laboratories, LLC* CHRIS ANDERSON, *Dep't of Mathematics, UCLA* We report on calculations of tunneling rates associated with single electron charging events in vertical ''enhancement mode'' quantum dot device structures. These devices consist of two vertically stacked quantum well layers. A pair of surface depletion gates define a Quantum Point Contact (QPC) and a single localized enhancement gate creates a quantum dot (QD) in the upper quantum well. Single electron charging events in this device occur via tunneling between the vertically separated QD and QPC states. Tunneling rates are computed using Fermi's Golden Rule based on numerical eigenstates derived from fully 3-dimensional self-consistent Poisson-Schroedinger calculations. The effects of coulomb interaction on the quantum dot states and hence tunneling rates will be considered. Additionally, a comparison of these numerical results with experimental estimates of tunneling rates derived from random telegraph signals will be presented.

**12:39**

**Z40 8 Observation of Sequential Single Electron Charging in Vertical ''Enhancement Mode'' Quantum Dot Devices*** EDWARD CROKE, GEOFFREY SIMMS, MARK GYURE, *HRL Laboratories, LLC* The vast majority of devices currently being explored for quantum information processing with semiconductor quantum dots rely on multiple surface gates operating in reverse bias (depletion mode) to constrict a buried 2D electron gas to the few electron regime. Although successful in demonstrating one and two qubit operations, they are unlikely to scale to large arrays that are needed to perform practical quantum information processing. In this talk, we present the first experimental results from a new type of ''enhancement mode'' device that requires only a single gate electrode operating in forward bias to create a few electron quantum dot. We observe random telegraph signals in several well defined regions of gate voltage, indicative of single electrons tunneling between states of the quantum dot and the readout channel. The absence of these signatures below a particular gate voltage suggests that these quantum dots are in the few electron regime and can be easily depleted to contain only one electron.

**12:51**

**Z40 9 Analysis of Random Telegraph Signals from Vertical ''Enhancement Mode'' Qunatum Dot Devices** MARK GYURE, GEOFFREY SIMMS, RICHARD ROSS, EDWARD CROKE, *HRL Laboratories, LLC* Clear signatures of single electron tunneling in vertical ''enhancement mode'' semiconductor quantum dot devices have recently been observed. These devices hold great promise for future scalability of semiconductor-based quantum information processing because they require only a single gate electrode to create the quantum dot. In this talk, we present a detailed analysis of the random telegraph signals observed in these devices as various N to N+1 electron transitions are swept through by varying the gate voltage and magnetic field. This analysis allows us to extract a variety of information about the transitions and further supports our conclusion that electrons are tunneling between the gate-induced quantum dot and the readout channel below. Results of self-consistent Schrodinger-Poisson simulations of these devices are presented that also support this interpretation of the experimental results.

**Z40 10 MOSFET-like single electron transistor built in pure silicon** G.M. JONES, B.H. HU, C.H. YANG, *Department of Electrical and Computer Engineering, University of Maryland at College Park* M.J. YANG, *Naval Research Laboratory* Solid state implementations of qubits offer the advantage of being scalable, and, in particular, those based on semiconductors can be integrated by existing technologies. The two Zeeman states of an electron spin in a quantum dot (QD) provide a promising candidate for a qubit, and lateral quantum dots provide the best opportunity for scaling. Spins in lateral QDs in the GaAs/AlGaAs single electron transistors (SETs) have been intensively investigated. In contrast, Si provides a number of advantages, including long spin coherence time, large g-factor, and small spin-orbit coupling effect. However, isolation of a single electron in a Si QD has not yet been achieved. We will report a fabrication technique that utilizes the established MOSFET concept on highly resistive Si substrates in order to minimize the potential disorder resulting from impurities. In our approach, 2D (or 1D) electrons are induced by a top gate, which laterally overlaps with the ion-implanted source/drain, but vertically separated by SiO2. Several side gates buried in the SiO2 help define the tunneling barriers and control the number of electrons in the island. We will discuss the operating principle, computer simulation, and experimental results that confirm the validity of the design concept.

**Z40 11 Proposal to stabilize and detect half-quantum vortices in strontium ruthenate thin films: Non-Abelian braiding statistics of vortex matter in a $p_x + ip_y$ superconductor*** SUMANTA TEWARI, SANKAR DAS SARMA, *Condensed Matter Theory Center, Department of Physics, University of*

*Maryland, College Park, MD 20742* CHETAN NAYAK, *Microsoft Research, Project Q, Kohn Hall, University of California, Santa Barbara, CA 93108* We propose a simple way to stabilize half-quantum vortices in superconducting strontium ruthenate, assuming the order parameter is of chiral $p_x + ip_y$ symmetry, as is suggested by recent experiments. The method, first given by Salomaa and Volovik in the context of Helium-3, is very naturally suited for strontium ruthenate, which has a layered, quasi-two-dimensional, perovskite crystal structure. We propose possible experiments to detect their non-abelian braiding statistics. These experiments are of potential importance for topological quantum computation.

**Z40 12 Measurement errors for phase qubits*** QIN ZHANG, ABRAHAM KOFMAN, ALEXANDER KOROTKOV, *University of California, Riverside* We analyze error mechanisms in measurement of superconducting phase qubits, including measurement cross-talk for two coupled phase qubits and effect of nonadiabaticity during the measurement pulse. Each qubit is represented by a fictitious particle moving in an asymmetric double-well potential. A measurement, e.g., of the state $|10\rangle$ perturbs the second qubit which may result in a wrong measurement result $|11\rangle$. In the study of this cross-talk the first qubit is described classically, since it is highly excited, whereas the second qubit can be treated either classically or quantum- mechanically. We obtain conditions for minimizing the cross- talk. We also study the nonadiabatic errors for different shapes and durations of the measurement pulse and discuss optimal conditions for fast and reliable measurements.

*Supported by NSA/ARDA/ARO grant

**Z40 13 Entanglement distillation by adiabatic passage in coupled quantum dots*** JAROSLAV FABIAN, *University of Regensburg* ULRICH HOHENESTER, *University of Graz* Adiabatic passage of two correlated electrons in three coupled quantum dots is shown to provide a robust and controlled way of distilling, transporting and detecting spin entanglement, as well as of measuring the rate of spin disentanglement. Employing tunable interdot coupling the scheme creates, from an unentangled two-electron state, a superposition of spatially separated singlet and triplet states. A single measurement of a dot population (charge) collapses the wave function to either of these states, realizing entanglement to charge conversion. The scheme is robust, with the efficiency close to 100%, for a large range of realistic spectral parameters.

**Z45 1 $Ba_2CoO_4$: Crystal Growth, Structure Refinement, and Physical Properties*** RONGYING JIN, *Oak Ridge National Laboratory* HAO SHA, *Florida International University* PETER KHALIFAH, *Oak Ridge National Laboratory and University of Massachusetts* RICHARD SYKORA, BRIAN SALES, DAVID MANDRUS, *Oak Ridge National Laboratory* JIANDI ZHANG, *Florida International University* Single crystalline $Ba_2CoO_4$ is grown for the first time using the floating-zone technique. Single-crystal refinement of X-ray diffraction data indicates that $Ba_2CoO_4$ has a monoclinic structure with $a = 5.9176(13)$ Å, $b = 7.6192(16)$ Å, $c = 10.3790(22)$ Å, and ß $= 91.734(4)^o$ at room temperature. Magnetic susceptibility, specific heat, and thermal conductivity show anomalies at $T_N = 25$ K, due to antiferromagnetic ordering. However, the magnitude of the Néel temperature $T_N$ is significantly lower than the Curie-Weiss temperature ($|\Theta| \sim 110$ K), suggesting either reduced-dimensional magnetic interactions and/or the existence of magnetic frustration. The latter may be induced by disorder evident from the variable-range-hopping behavior in electrical resistivity, non-zero T term in specific heat and $T^2$ dependence in thermal conductivity at low temperatures.

**Z45 3 Incommensurate spin correlations in a spin-1 triangular lattice antiferromagnet** SETH JONAS, CHRIS STOCK, COLLIN BROHOLM, *Department of Physics and Astronomy, Johns Hopkins University, Baltimore, MD 21218, USA* SATORU NAKATSUJI, YUSUKE NAMBU, HIROSHI TONOMURA, OSAMU SAKAI, YOSHITERU MAENO, *Department of Physics, Kyoto University, Kyoto 606-8502, Japan* Spin correlations in the triangular lattice antiferromagnet NiGa2S4 were investigated as a function of temperature and magnetic field through neutron scattering. At T=1.5 K the in plane correlations are incommensurate with a wave vector $(\frac{1}{6} - \delta, \frac{1}{6} - \delta, 0)$ where $\delta = 0.00866$. The in-plane correlation length is 6.9(8) lattice spacings while inter-plane correlations cannot be detected beyond the second nearest plane. These correlations persist on a time scale that exceeds 0.3 ns. Application of an in-plane magnetic field of 10 Tesla only slightly reduces the inter-plane correlations with no appreciable effect on intra-plane correlations, while heating reduces the frozen moment, the in-plane correlation length, and the correlation time. We shall discuss what can be inferred about the spin Hamiltonian for NiGa2S4 as well as the spin-1 triangular lattice antiferromagnet from these data.

**Z45 4 Nonmagnetic impurity effects of the spin disordered state in $NiGa_2S_4$*** YUSUKE NAMBU, SATORU NAKATSUJI, YOSHITERU MAENO, *Department of Physics, Kyoto University* Nonmagnetic impurity effects of the spin disordered state in the triangular antiferromagnet $NiGa_2S_4$ [1] was studied through magnetic and thermal measurements for Zn substituted insulating materials $Ni_{1-x}Zn_xGa_2S_4$ $(0.0 \leqslant x \leqslant 0.3)$[2]. Only 1 % Zn substitution is enough to strongly suppress the coherence observed in the spin disordered state. However, suppression is not complete and the robust feature of the quadratic temperature dependent specific heat and its scaling behavior with the Weiss temperature indicate the existence of a coherent Nambu-Goldstone mode. Absence of either conventional magnetic long-range order or bulk spin freezing suggests a novel symmetry breaking of the ground state. **Z45 5 Novel spin structures in Mn and Co chromite** THOMAS KAPLAN, *Michigan State University* The ferrimagnetic or conical spiral (FS), a variational approximation to the ground state of the classical Heisenberg model with competing AB and BB interactions in cubic spinels[1], is in qualitative to quantitative agreement with neutron diffraction (ND) results for $MnCr_2O_4$ and $CoCr_2O_4$. [2] This despite its local instability for the experimental parameter values.[1] It also was used to interpret related NMR studies.[3] Understanding recent ND experiments[4] on both materials again was generally based on the FS. However, these measurements, done on single crystals, and with highly improved resolution, uncovered a subtle but important modification of the FS: while the fundamental Bragg peaks (originating from the spin components along the cone axes) are typical, the satellite peaks (coming from the transverse or spiral components) are broadened.[4] Efforts to understand this based on the classical spin model will be discussed. 1. **Z45 6 Competing phases in a frustrated magnet: a study with neutron scattering.*** DAVID HSIEH, *Princeton University* YINWAN LI, ZHIMING TAN, ROBERT CAVA, ZAHID HASAN, *Princeton University* YIMING QIU, JAE-HO CHUNG, JEFFREY LYNN, *NIST* Zero-field magnetic neutron diffraction on the pyrochlore magnet $ZnCr_2S_4$ reveals successive phase transitions from a paramagnet into a helical ($T_{N1} = 13$ K) then collinear ($T_{N2} = 8$ K) spin ordered state as the system is cooled. This occurs as the system crosses a critical line in $J_1$-$J_2$ space, where $J_1$ and $J_2$ are the first and second nearest neighbor exchange constants respectively. We report the magnetic field dependence of the dc susceptibility and neutron scattering of $ZnCr_2S_4$ in the form of a temperature-field phase diagram. We also study the low energy excitation spectrum of $ZnCr_2S_4$ which was found to be consistent with the $J_1$-$J_2$ model.

**Z45 7 Quantum effects in a half-polarized pyrochlore antiferromagnet** DORON BERGMAN, RYUICHI SHINDOU, *Department of Physics, UC Santa Barbara* GREGORY FIETE, *Kavli Institute for Theoretical Physics, UC Santa* LEON BALENTS, *Department of Physics, UC Santa Barbara* We study quantum effects in a spin-3/2 antiferromagnet on the pyrochlore lattice in an external magnetic field, focusing on the vicinity of a plateau in the magnetization at half the saturation value, observed in $CdCr_2O_4$ and $HgCr_2O_4$. Our theory, based on quantum fluctuations, results in an effective quantum dimer model of the dynamics. We predict the existence of a symmetry-broken ground state on the plateau, even with only nearest-neighbor microscopic exchange. This symmetry broken state consists of a particular arrangement of spins polarized parallel and antiparallel to the field in a 3:1 ratio on each tetrahedron. It quadruples the lattice unit cell, and reduces the space group from $Fd\bar{3}m$ to $P4_332$. We also predict that for fields just above the plateau, the low temperature phase has transverse spin order, describable as a Bose-Einstein condensate of magnons. Other comparisons to and suggestions for experiments are discussed.

**Z45 8 Ordering in a frustrated pyrochlore antiferromagnet proximate to a spin liquid** GREGORY A. FIETE, *Kavli Institute for Theoretical Physics, UC Santa Barbara* DORON L. BERGMAN, LEON BALENTS, *Department of Physics, UC Santa Barbara* We perform a general study of spin ordering on the pyrochlore lattice with a 3:1 proportionality of two spin polarizations[1]. Equivalently, this describes valence bond solid conformations of a quantum dimer model on the diamond lattice. We determine the set of likely low temperature ordered phases, on

the assumption that the ordering is weak, i.e the system is close to a ''U(1)'' quantum spin liquid in which the 3:1 proportionality is maintained but the spins are strongly fluctuating. The nature of the 9 ordered states we find is determined by a ''projective symmetry'' analysis. All the phases exhibit translational and rotational symmetry breaking, with an enlarged unit cell containing 4 to 64 primitive cells of the underlying pyrochlore. The simplest of the 9 phases is the same ''R'' state found earlier in a theoretical study[2] of the ordering on the magnetization plateau in the $S = 3/2$ materials $CdCr_20_4$ and $HgCr_20_4$. We suggest that the spin/ dimer model proposed therein undergoes a direct transition from the spin liquid to the R state, and describe a field theory for the universal properties of this critical point, at zero and non-zero temperatures. **Z45 9 Nature of magnetic structure in a geometrically frustrated manganite spinel** KAZUYA KAMAZAWA, ZHE ZHANG, DESPINA LOUCA, *Dept. of Physics, University of Virginia* Unlike the pyrochlore geometrically frustrated magnets, several normal spinels such as $ZnCr_2O_4$ and $ZnV_2O_4$ undergo magnetic long-range order as well as cubic to tetragonal structural transitions at low temperatures. By comparison, $ZnMn_2O_4$, although tetragonal at room temperature, does not undergo a magnetic transition in spite of the rather large Curie-Weiss temperature of $\sim$ -800K indicative of strong antiferromagnetic fluctuations. The absence of an antiferromagnetic transition is surprising considering the nature of the $Mn^{3+}$ ion that is Jahn-Teller active and its effect on the ground state degeneracy. With the orbital degree of freedom active and a crystal anisotropy created by the Jahn-Teller octahedral distortions the system is tetragonally distorted just as in the vanadates where the V ion is orbitally active, but no magnetic transition is observed. Using neutron scattering we investigated how the magnetic structure changes as a function of temperature. We observed the presence of incommensurate magnetic peaks close to nuclear Bragg peaks that exhibit a first order phase transition. The FWHM of the magnetic peaks is much wider than that of nuclear peaks that indicates that the magnetic order is short range. Considering the 1-dimensional Boner-Fisher like behavior of the bulk susceptibility, it is proposed that the spin structure is helical and one-dimensional.

**Z45 10 Local structural disorder by chemical pressure in geometrically frustrated magnets, $Cd_{1-x}Zn_xV2O4$** ZHE ZHANG, DESPINA LOUCA, ALINA VISINOIU,*SEUNGH-HUN LEE, *University of Virginia* The orbital degree of freedom plays an important role in the physics of frustration in $Cd_xZn_{1-x}V2O4$ spinels. The magnetic and structural properties for $0 < =x < =1$ compounds were investigated using neutron scattering. While the end members, x = 0 and 1, are magnetically frustrated in the high temperature cubic phase, the frustration is relieved with the transformation to the tetragonal Néel state through a spin-orbital coupling mechanism. In the doped compounds, both macroscopic transitions are absent due to the local randomness induced by the difference in the chemical pressure imposed by Zn and Cd ions. This leads to the loss of cooperative orbital ordering and suppression of any long range antiferromagnetic coupling. However, from the local atomic structure it is deduced that in the mixed compounds the local environments around Zn and Cd ions correspond to ZnV2O4 and CdV2O4, respectively. Thus locally short-range orbital ordering is possible that explains why the magnetic exchange interactions remain largely unchanged with doping.

**Z45 11 Magnetic ordering in $EuNiO_3$ and $NdNiO_3$** JOCHEN LITTERST, *TU Braunschweig, Germany* ELISA BAGGIO-SAITOVITCH, ALEXANDER CAYTUERO, *CBPF, Rio de Janeiro, Brazil* MOHSEN ABDELMEGUID, HANS MICKLITZ, *University of Cologne, Germany* J.A. ALONSO, *CSIC, Madrid, Spain* We report Mössbauer and magnetization studies on $^{57}Fe$:$EuNiO_3$ and $^{57}Fe$:$NdNiO_3$ between 1.5 K and 300 K. Below $T_N \approx$ 190 K and 132 K for the Eu and the Nd compound, resp., the Mössbauer spectra reveal two magnetically inequivalent Ni (Fe) sites. Roughly 50% of the spectral area split into a sextet (A) with a well defined magnetic hyperfine field. The spectra A are due to the antiferromagnetically ordered Ni sublattices. The other 50% of the spectral area remain unsplit and only gradually broaden on decreasing temperature (spectra B). The observation of two kinds of magnetically inequivalent Ni(Fe) sites is both compatible with charge ordering or orbital ordering leaving 50% of Ni sites frustrated. Spectrum B is typical for a slowing down magnetic fluctuations. A best approach is yielded by a model allowing for stochastic jumps of the hyperfine field in random directions. Both compounds yield nearly identical fluctuation rates with a roughly linear temperature dependence indicating that the influence of the magnetic moment of the rare earth on Ni is negligible.

**Z45 12 Ultrasonic Study of Critical Behavior in the Magnetic Phase Diagram of $CsNiCl_3$*** G. QUIRION, X. HAN, M. L. PLUMER, *Department of Physics, Memorial University, St.-John's, NL, Canada* M. POIRIER, *Department of Physics, Sherbrooke University, Sherbrooke, Qc, Canada* It is now well established that many quasi-one-dimensional frustrated triangular antiferromagnets of the $ABX_3$ family exhibit exotic magnetic phase diagrams with new types of multicritical points [1]. Nevertheless, investigations into the nature of some phase boundaries remain controversial. While some theoretical and numerical studies suggest new chiral universality classes, others conclude these transitions are weakly first order [2]. Results are presented here of a systematic investigation of the critical behavior associated with the magnetic field - temperature phase diagram of $CsNiCl_3$ using high resolution ultrasonic measurements of the elastic constants, along with analysis based on a Landau-type model of magneto-elastic coupling [3]. In particularly, we will show how it is possible to obtain very reliable values for the critical exponents associated with the transitions to elliptical and the spin-flop ordered states. Exponent estimates very close to the multicritical point are also presented. [1] M.L. Plumer et al, in Magnetic Systems with Competing Interactions, Ed. H.T. Diep (World Scientific, Singapore, 1994). **Z46 1 Observation of Inter-valley Gap Anomaly in Two Dimensional Electrons in Si** K. LAI, T.M. LU, D.C. TSUI, S.A. LYON, *Princeton University* W. PAN, *Sandia National Laboratories* M. MUHLBERGER, F. SCHAFFLER, *University of Linz* J. LIU, Y.H. XIE, *UCLA* We report a systematic study of the energy gaps at the odd-integer quantum Hall states $\nu=3$ and 5 under tilted magnetic (B) fields in the two-dimensional electron system (2DES) in $Si/Si_{1-x}Ge_x$ heterostructures [1]. Consistent with previous studies, we find that out of the coincidence region, the valley splitting is independent of the in-plane B-field. However, the $\nu=3$ valley gap appears to be highly asymmetric and differs significantly on different sides of the coincidence. Similar behaviors were observed in both high ($20m^2/Vs$) and low ($6m^2/Vs$) mobility samples. More surprisingly, instead of reducing to zero at coincidence, as expected in the independent-electron model, the inter-valley gaps at $\nu=3$ and 5 rise rapidly towards the coincidence angles. We will discuss our results in the framework of two known models, level coupling with random-matrix elements and quantum Hall ferromagnetism, and show that the anomaly is related to the strong couplings of the Landau levels close in energy in the coincidence region. [1] K. Lai *et al.*, cond-mat/0510599.

**11:27**
**Z46 2 Integer quantum Hall effect and valley splitting on a H-Si(111) surface** KEVIN ENG, ROBERT N. McFARLAND, BRUCE E. KANE, *Laboratory for Physical Sciences, University of Maryland at College Park* We have recently developed a high mobility two-dimensional electron system, where an electric field is applied through an encapsulated vacuum cavity and induces electrons on a clean and atomically flat hydrogen-passivated Si surface. Low temperature magneto-transport measurements ($0< B < 12T$) made on such an inversion layer has led us to the first observation of the integer quantum Hall effect on a Si(111) surface. With a mobility of $\sim$ 10,000 $cm^2/Vs$ at T=150 mK and $n_s=6.75 \times 10^{11}\ cm^{-2}$, we observed filling factors $\nu=6$, 4, 3, and 2. This is particularly interesting, because Si(111) is expected to have a six-fold valley degeneracy. Activation energy measurements within filling factors 6 and 2 coupled with analysis of Shubnikov-de Haas oscillations suggests that the six-fold valley degeneracy is broken asymmetrically into 2-fold and 4-fold at B=0. In addition, the observation of $\nu=3$ indicates that individual valleys are splitting at higher fields. We will discuss these results along with the possible origins of the breaking of the six-fold valley degeneracy at B=0.

**11:39**
**Z46 3 Valley Dynamics on H-Si(111) in Tilted Magnetic Fields** ROBERT N. McFARLAND, KEVIN ENG, BRUCE E. KANE, *Laboratory for Physical Sciences, University of Maryland, College Park* Because of the predicted sixfold valley degeneracy of the Si(111) surface and the numerous mechanisms that can lift this degeneracy, 2D electron transport on this surface displays complex and interesting behavior. To explore this behavior, we have performed low temperature ( $\sim$ 150 mK) tilted-field magneto-transport measurements ($0< B_{tot} < 12$ T) on H-passivated Si(111) surfaces encapsulated in a vacuum cavity. We find a strong dependence of the longitudinal magneto-resistance on the in-plane B field. At low fields ( $< 2$ T) this manifests as an amplification of the Shubnikov-de Hass amplitudes without a significant effect on the phase or frequency. At high fields ( $> 6$ T, $\nu < 6$) the valley degeneracy is lifted, and we observe energy gaps at $\nu=4$ and $\nu=3$ which are strongly affected by small in-plane fields. Since in neither case are the observed effects linear in total B field, the results are inconsistent with Zeeman-like effects. We present measurements of the activation energies for the gaps at $\nu=4$ and 3 as a function of tilt angle. Finally, we consider possible mechanisms for this field-dependent splitting and propose future experiments that may shed further light on the matter.

**11:51**
**Z46 4 The spin susceptibility in Si-MOSFETs.** MARIAPIA MARCHI, *Democritos-INFM and Universita' di Trieste* DE PALO STEFANIA, *Democritos-INFM* SAVERIO MORONI, *Democritos-INFM* GAETANO SENATORE, *Democritos-INFM and Universita' di Trieste* We have performed for the first time DMC simulations of a symmetric two-valley electron gas with variable spin polarization, both in the strictly 2D limit and with a thickness appropriate to Si-MOSFETs. We find that valley degeneracy substantially reduces the spin susceptibility enhancement $\alpha$, with respect to the conventional 2DEG. The farther reduction of $\alpha$, caused by thickness, brings our prediction in excellent agreement with the available experimental data on Si-MOSFETs[1] up to $r_s \approx 5$. The agreement extends to the full experimental range ($r_s \leqslant 8$) when weak disorder is kept into account within a response function formalism, generalizing to the two valley system the approach previously employed for the conventional 2DEG [2]. [1] See, e.g, S.V. Kravchenko and M.P.Sarachik, Rep. Prog. Phys. **67**, 1 (2004) and references therein. [2] S. De Palo et. al., Phys. Rev. Lett. **94**, 226405 (2005).

**Z46 5 Valley susceptibility of an interacting two-dimensional electron system.** YAKOV SHKOLNIKOV,*OKI GUNAWAN, KAMRAN VAKILI, TAYFUN GOKMEN, ETIENNE DE POORTERE,†MANSOUR SHAYEGAN, *Princeton University* In a wide AlAs quantum well grown on a (001) GaAs substrate, 2D electrons occupy two elliptical conduction band minima (valleys), whose major axes lie along the two in-plane $<100>$ directions. Strain-induced energy splitting between these valleys results in an inter-valley charge transfer and consequently in a change of the system's valley polarization. We parameterize this strain-induced change of the valley polarization using valley susceptibility $\chi_v$, in analogy to the spin-susceptibility traditionally used to characterize the magnetic field induced spin-polarization. We find that $\chi_v$ dramatically increases relative to its band value as the electron density is reduced, reflecting the dominant role of electron-electron interaction.

**Z46 6 Selective occupation of conduction band valleys in AlAs quantum wells.** MEDINI PADMANABHAN, K. VAKILI, Y.P. SHKOLNIKOV, O. GUNAWAN, T. GOKMEN, E. TUTUC, E.P. DE POORTERE, M. SHAYEGAN, We report our progress in the controlled and selective occupation of various conduction band minima in AlAs quantum wells and the corresponding magnetotransport behaviors. AlAs has three conduction band minima, or valleys, located at the X-points of the Brillouin zone. By a suitable choice of well width and in-plane stress, these minima can be occupied by two-dimensional electrons singly or in various combinations. We review the factors that determine the valley occupation and show how we have used them to produce a variety of systems with different valley occupations. In particular, we will discuss two methods that we have successfully used: (a) using a piezoelectric material to impart uniaxial strain and, (b) using a material with a different thermal expansion coefficient than our samples to impart biaxial tensile strain.

**12:27**

**Z46 7 Landau level crossings in imbalanced, two-valley two-dimensional electron systems** KAMRAN VAKILI, TAYFUN GOKMEN, MEDINI PADMANABHAN, OKI GUNAWAN, YAKOV P. SHKOLNIKOV, EMANUEL TUTUC, MANSOUR SHAYEGAN, *Department of Electrical Engineering, Princeton University, Princeton, NJ 08544* We report results of magnetotransport measurements performed on two-dimensional electron systems in AlAs quantum wells with highly imbalanced valley occupation. We observe spikes in the diagonal resistance that signal the crossing of Landau levels originating from each of the occupied valleys. From the positions of these spikes and their dependence on tilt angle, we can extract the valley splitting as well as the ratios of the effective electron masses and g-factors for the two-valleys. We find that the mass ratio is unchanged from the band value and the g-factors are equal between the two valleys despite the high degree of density imbalance. We have also explored the interaction-induced finite gaps that persist at avoided crossings between Landau levels and discuss some of our results.

**12:39**

**Z46 8 Parallel magnetic field induced valley splitting** T. GOKMEN, O. GUNAWAN, K. VAKILI, E. P. DE POORTERE, M. SHAYEGAN, *Department of Electrical Engineering, Princeton University, Princeton, NJ 08544* In an 11nm-wide thick AlAs quantum well grown on a GaAs (001) substrate, the two-dimensional electrons occupy two in-plane conduction-band valleys. The Fermi contours for these two valleys are ellipses whose major axes are rotated by 90 degrees. The energy separation between these two valleys at zero magnetic field is normally controlled via the application of in-plane strain along the major axis of one of the valleys. In this talk, through a combination of experimental results and calculations, we demonstrate a novel method for tuning of the valley splitting. Namely, we show that the application of a magnetic field parallel to the major axis of one the ellipses leads to a lifting of the valley degeneracy. This is because the parallel field which, thanks to the finite thickness of the electron layer couples to the electrons' orbital motion modifies the effective masses of the two valleys (in the direction perpendicular to the field direction) by different amounts.

**12:51**

**Z46 9 Multiple Phases with the Same Quantized Hall Conductance in a Two-Subband System** XINCHANG ZHANG, DONALD RICHARD FAULHABER, HONGWEN JIANG, *UCLA* In a GaAs/AlGaAs two-dimensional electron system with two occupied subbands, the experimentally determined phase diagram exhibits rich topological features. Ring-like structures are observed at even integer filling factors. Even with the identical quantized Hall resistance values as those given rise by the ordinary integer quantum Hall effect due to the Landau level quantization; the activation energies of these states within the rings are much smaller. These ring structures cannot account for by the simple single particle picture. We argue that ferromagnetic quantum Hall states, due to the interaction of two energy levels with opposite spin and different subband indices, are responsible for these unusual structures.

**13:03**

**Z46 10 Anomalous magnetoresistance peaks: Evidence for Landau level spin-anticrossing in (110) GaAs two-dimensional hole systems*** M. GRAYSON, S. F. ROTH, Y. XIANG, F. FISCHER, M. BICHLER, D. SCHUH,† *Walter Schottky Institut, TU-Muenchen, 85748 Garching, Germany* R. WINKLER,‡ *Inst. fuer Festkoerperphysik, U. Hannover, 30167 Hannover, Germany* We report anomalous peaks in the longitudinal resistance of (110) GaAs two-dimensional hole systems (2DHS), which we associate with an anticrossing of spin split Landau levels. GaAs hole systems are of research interest due to their heavy mass and strong spin-orbit coupling. With modulated growth conditions, Si can be used as an acceptor for high mobility 2DHS on (110) wafers with mobilities up to $7 \times 10^5$ cm$^2$/Vs at a hole density of $1.2 \times 10^{11}$cm$^{-2}$. Resistance peaks within the $\nu = 1$ minimum of the quantum Hall effect are observed in various samples. We propose that these anomalous peaks arise from an anticrossing of Landau levels with magnetic field. The position of the anticrossing field is independent of top-gate voltage, but can be tuned by illumination. This behaviour is in agreement with self- consistent calculations of the valence band mixing, assuming an illumination dependent background charge in the substrate. Band calculations predict a spin-flip at the anticrossing, which might be exploited to test new spin based device concepts.

**Z46 11 Monitoring the Motion of Charge Carriers in the Integer Quantum Hall Bulk with a Single Electron Transistor** LEE FARINA, ÇAGLIYAN KURDAK, *Physics Department, University of Michigan, Ann Arbor, MI* MANSOUR SHAYEGAN, *Department of Electrical Engineering, Princeton University, Princeton, NJ* Using an Al/AlO$_x$/Al single electron transistor on top of an antidot etched into a GaAs/AlGaAs heterostructure containing a two-dimensional electron gas, we studied the quantum Hall system in the middle of the $\nu=2$ plateau. In this highly insulating regime, oscillations in single electron transistor resistance indicate that the charges in the system adjust slowly ( $\sim$ 1 hour) to changes in the back gate voltage or magnetic field. We find that after a small increase in magnetic field an excess of electrons leave the bulk. Moreover, the presence of the etched antidot under the SET creates a small but clear discrepancy between behavior after a change in magnetic field and change in back gate voltage indicating charging of the antidot after a change

in magnetic field. When the antidot is accounted for we find the expected ratio of 2 electrons/flux quanta at $\nu=2$. We also present the time dependence of the charge equilibration for 18 mK to 280 mK. Bulk conductivities in the range of $10^{-18}$-$10^{-18}$ /$\Omega$ are obtained from this measurement and compared to conductivies obtained from lock-in measurements at high temperatures (1-10 K).

**13:27**

**Z46 12 Frozen Charges, Persistent Eddy Currents, and Nearly Perfect Diamagnetism in Stacked Integer Quantum Hall Layers** CAGLIYAN KURDAK, *University of Michigan* LEE A. FARINA, *University of Michigan* Faraday's law of induction for an integer quantum Hall liquid dictates that after the application of a small additional magnetic field an integer number of electrons for each additional magnetic flux quanta must enter the 2DEG. Since the diagonal conductivity is close to zero, these charges are nearly frozen. The electric field associated with these charges leads to a persistent eddy current flowing in the bulk of the 2DEG. The magnetic field generated by the persistent eddy currents is much smaller than the additional magnetic field applied. However, the magnetic field generated by the persistent eddy currents can be greatly enhanced in closed stacked layers of integer quantum disks. In fact, we find that when the number of layers is much greater than inverse fine structure constant, these persistent eddy currents can perfectly screen the applied additional magnetic field at zero temperature.

**13:39**

**Z46 13 Spin and Valley Splitting of Two-Dimensional Electrons in Graphene in the High Magnetic Field Limit** YUANBO ZHANG, ZHIGANG JIANG, JOSHUA SMALL, *Department of Physics, Columbia University* MENINDER PUREWAL, *Department of Applied Physics, Columbia University* YAN-WEN TAN, MINA FAZLOLLAHI, JOEL CHUDOW, *Department of Physics, Columbia University* JOHN JASZCZAK, *Department of Physics, Michigan Technological University* HORST STORMER, PHILIP KIM, *Department of Physics, Columbia University* The quantum Hall effect in high quality graphene, a sinlge atomic layer of graphite, is studied in strong magnetic fields up to 45 Tesla. The splitting of Landau levels $n = 0$ and $\pm$ 1, caused by the lifting of the spin and valley degeneracies in strong magnetic fields, is observed at T $<$ 5 K. In particular, the quantum Hall state $\nu = \pm 4$ is found to arise from the spin splitting of Landau level n = $\pm$ 1. The effective Lande g-factor measured at this state is close to 2. The spin origin of $\nu = \pm 4$ is further confirmed in magnetotransport experiments performed in the presence of an in-plane magnetic field. While the exact origin of the valley degeneracy lifting is not yet clear, we propose several possibilities.

**13:51**

**Z46 14 Quantized conductance in an AlAs 2D electron system quantum point contact** M. SHAYEGAN, O. GUNAWAN, B. HABIB, E.P.D. POORTERE, *Princeton University* We report experimental results on a quantum point contact (QPC) device fabricated in a wide AlAs quantum well where the electrons occupy two conduction-band valleys with in-plane, elliptical Fermi contours. To probe the closely-spaced, one-dimensional, electric subbands (channels), we fabricated a QPC structure where the point contact is defined by a split-etched region covered by a global top gate. The conductance versus top gate bias trace shows a series of weak plateaus at every $2e^2/h$, consistent with the fact that the one-dimensional confinement and the anisotropy of the Fermi contours break the valley degeneracy for the QPC channels. Moreover, we observe a ''0.7 structure'' which is much better developed than the $2e^2/h$ plateaus, possibly reflecting the stronger electron-electron interaction in this system because of the larger electron effective mass.

**14:03**

**Z46 15 Nonlinearities in Strongly Coupled Lateral Quantum Hall Droplets** P. JIANG, C. CHIEN, I. YANG, W. KANG, *James Franck Institute and Department of Physics, University of Chicago* L.N. PFEIFFER, K.W. BALDWIN, K.W. WEST, *Bell Laboratories, Lucent Technologies* We report on conductance characteristics of a lateral quantum Hall line junction with an aperture in a thin tunnel barrier (width = 8.8 nm). Due to the small opening inside the barrier, the charge distribution in the junction resembles that around a narrow split gate. In the presence of a magnetic field, the edge states of the two- dimensional electron systems across these particular junctions are strongly coupled compared to those with pristine barriers. In the integer quantum Hall effect (IQHE) regime, a strong resonance in conductance is detected at zero bias, while it evolves into an anomalous suppression as the system enters the fractional quantum Hall effect (FQHE) regime. The dramatic suppression of the conductance in the FQHE regime is consistent with the presence of strong repulsive interaction in the lowest Landau levels, while the enhanced conductance in the IQHE regime supports the prediction of softened Coulomb interaction. The contrasting conductance behaviors in the IQHE and the FQHE regimes clearly distinguish the effects of electron-electron interaction in the inter-edge transport in these two regimes.

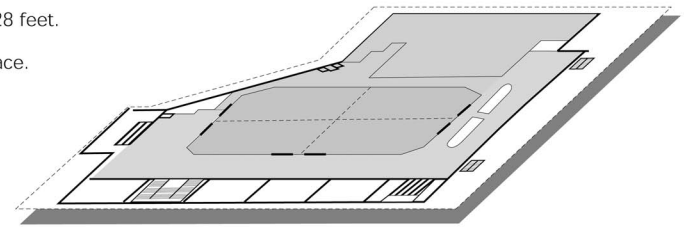
# The Baltimore Convention Center Overview

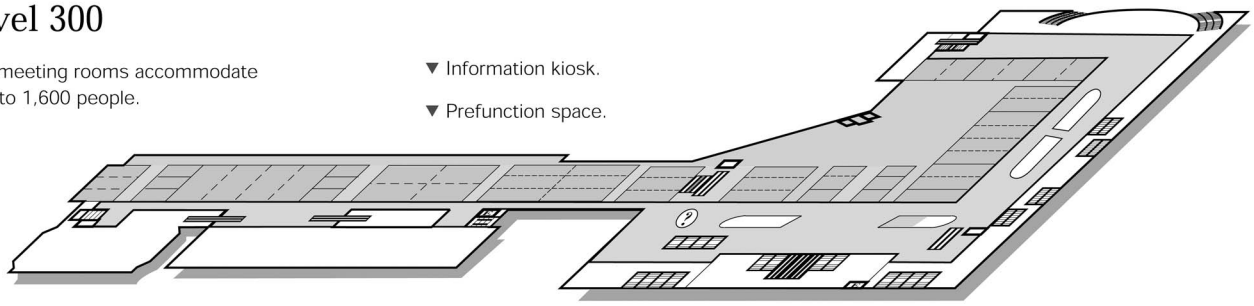
## Level 400

- 36,672 square foot ballroom.
- Divides into 4 sections.
- Ceiling height 28 feet.
- Prefunction space.



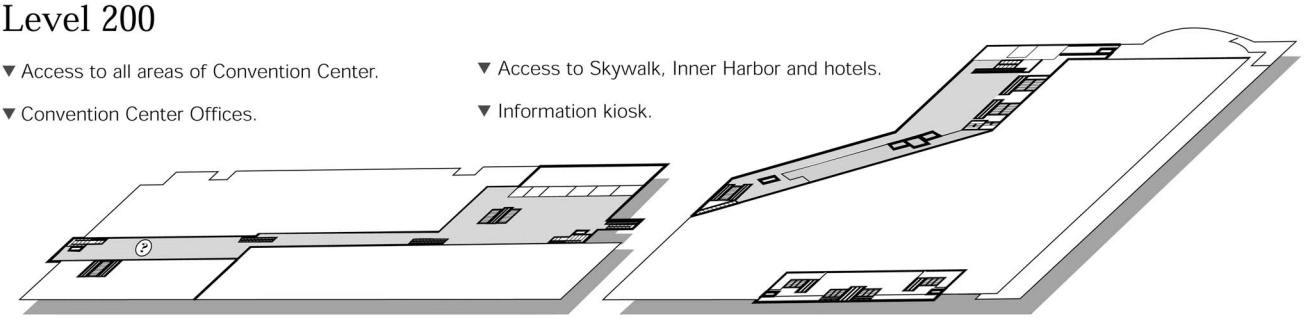
## Level 300

- 50 meeting rooms accommodate 85 to 1,600 people.
- Information kiosk.
- Prefunction space.



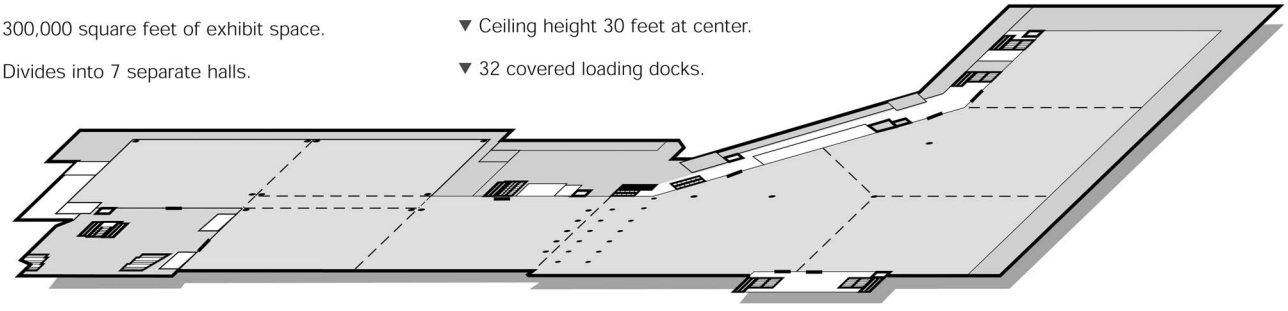
## Level 200

- Access to all areas of Convention Center.
- Convention Center Offices.
- Access to Skywalk, Inner Harbor and hotels.
- Information kiosk.



## Level 100

- 300,000 square feet of exhibit space.
- Divides into 7 separate halls.
- Ceiling height 30 feet at center.
- 32 covered loading docks.



# The Baltimore Convention Center

## Level 100

- 300,000 square foot exhibit space divides into 7 sections.
- Ceiling height 30 feet at center.
- 120/208V and 277/480V electrical services at approximately 30-foot spacing on the floor.
- Cold water, sanitary drain, compressed air available.
- Direct drive-in access for vehicles through 15'x18' overhead doors.
- 32 covered loading docks.
- All halls have available public address system and telephone outlets.
- Complimentary show offices come with exhibition halls.
- VIP Suite available in Charles Lobby.
- The entire exhibition space is relatively column-free.

# The Baltimore Convention Center

## Level 200

- Includes Otterbein and Sharp Street Lobbies, Pratt Street Entrance and Convention Center Offices.
- Access to Skywalk, Inner Harbor, and hotels. Access to Baltimore's Light Rail System providing a direct route to BWI Airport. Walking distance to the MARC train system with service to Washington, D.C.
- Prefunction space.
- Visitor information kiosk.
