# APS MARCH MEETING 2006

March 13–17, 2006
Baltimore Convention Center
Baltimore, MD

## General Information

Welcome to the Annual March Meeting of the American Physical Society. All scientific sessions and some APS-sponsored sessions will be held at the Baltimore Convention Center (BCC). APS affiliated meetings and satellite meetings will be held at the Marriott Waterfront Hotel, headquarters hotel for the meeting. Consult the schedule of APS affiliated and satellite meetings, in this Bulletin for exact locations.

An outstanding scientific program has been planned by the March Meeting Program Committee. The five-day program consists of approximately 6,900 papers to be presented in invited, contributed, focus and poster sessions. A larger, enhanced exhibit show will complement the scientific program. Attendees are encouraged to visit with exhibitors who will be displaying the latest products, instruments and equipment, computer software, as well as science publications related to the research and application of physics.

## Participating APS Units

**Divisions:** Condensed Matter Physics (DCMP); Materials Physics (DMP); Polymer Physics (DPOLY); Chemical Physics (DCP); Biological Physics (DBP); Fluid Dynamics (DFD); Computational Physics (DCOMP); Atomic, Molecular and Optical Physics (DAMOP); Laser Science (DLS).

**Topical** Groups: Instrument and Measurement Science (GIMS); Magnetism and Its Applications (GMAG); Quantum Information, Concepts, and Computation (GQI); Shock Compression of Condensed Matter (SCCM); Statistical and Nonlinear Physics (GSNP).

**Forums:** Industrial and Applied Physics (FIAP); Physics and Society (FPS); History of Physics (FHP); International Physics (FIP); Education (FEd); Graduate Student Affairs (FGSA).

## Registration Location/Hour

Pratt Street Lobby
Baltimore Convention Center (BCC)

The APS Registration Desk will open and close at the following times.

| | |
|---|---|
| Sunday, March 12 | • 1:00pm –7:00pm |
| Monday, March 13 | • 7:00am – 5:00pm |
| Tuesday, March 14 | • 7:00am – 5:00pm |
| Wednesday, March 15 | • 7:00am – 4:00pm |
| Thursday, March 16 | • 7:30am – 3:00pm |
| Friday, March 17 | • 7:30am – 10:00am |

## Badge Monitoring

All attendees must register for the meeting. Attendees must wear their badges at all times. Security personnel will be checking for badges before allowing admission to the sessions. Attendees without badges will not be admitted to sessions or exhibits. If you have lost your badge, please go to the APS registration desk for a new one. We will give you one replacement badge free. After that replacement badges will be charged $10.00.

## Wireless Connection at the Convention Center

The Baltimore Convention Center has wireless internet connection available free of charge, sponsored by the American Physical Society.

## APS Job Fair

Whether you are looking for a job or recruiting, the American Physical Society Annual March Meeting Job Fair is the place to be! The Job Fair will provide job seekers and hiring managers with unsurpassed recruitment and networking opportunities. Last year, we assisted hundreds of job seekers and more than 50 employers.

*March 12 –16*
*Job Fair Schedule*

| | |
|---|---|
| *March 12* • | Employer/Job Seeker on-site pre-registration and check-in 1:00pm – 4:00pm |
| March 13 • | Job Fair hours of operation 10:00am – 5:00pm |
| March 14 • | Job Fair hours of operation 10:00am – 5:00pm |
| March 15 • | Job Fair hours of operation 10:00am – 4:00pm |
| March 16 • | Last day to view/search jobs and résumés online |

Join in with hundreds of individuals specializing in the following areas:

*Computational Physics*
*Insulators and Detectors*
*Polymeric and Organic Materials*
*Metals History and Physics*
*Statistical and Nonlinear Physics*
*Phase Transitions and Strongly Correlated Systems*
*Artificially Structured Materials*
*Surface, Interfaces and Thin Films*
*Physics and Society Magnetism*

*International Physics Instrumentation and Measurement*
*Quantum Information, Concepts and Computation*
*Education Chemical Physics*
*Biological Physics*
*Superconductivity*
*Fluids*
*Complex Structured Materials*
*Industrial and Applied Physics*

## Job Seekers utilize the Job Fair services to:

- Network with technical staff and human resource recruiters
- Post your résumé and search open positions
- Interview for positions

## Employers utilize the Job Fair services to:

- Showcase your company with a Recruitment Booth
- Advertise open positions
- Interview qualified job seekers
- Search résumés specific to this meeting

*For more information contact abrice@aip.org*

## APS Store

| | |
|---|---|
| Monday – Wednesday | • 9:30am – 5:00pm |
| Thursday | • 9:30am – 1:00pm |

Come browse our t-shirts, bumper stickers, and more.

## APS Exhibit Show/APS Lounge

*Exhibit Hall E*

| | |
|---|---|
| Monday, March 13 | • 10:00am – 5:00pm |
| Tuesday, March 14 | • 10:00am – 5:00pm |
| Wednesday, March 15 | • 10:00am – 4:00pm |

The annual exhibit show days are Monday through Wednesday. The exhibits are an important adjunct to the meeting, offering information on a wide variety of physics-related products and services. In addition, book and periodical publishers will be participating as exhibitors. The poster sessions, and food concessions will be located in the exhibit hall, as will the E-mail Pavilion. A wine and cheese reception will be held in the exhibit hall on Monday and Tuesday from 4:00pm – 5:00pm. Plan to stop by to visit the exhibits, view the posters and enjoy the refreshments. **NOTE:** *You must wear your badge to be admitted to the exhibit hall.*

## APS Membership Booth

The APS Membership Booth is located near APS Registration in the Pratt Street Lobby. Membership Department staff will be on hand to answer questions about APS Membership and journal subscriptions.

## E-mail Service

E-mail service will be available on Monday, Tuesday and Wednesday in the Exhibit Hall during exhibit hours only. E-mail will be available on Thursday and Friday in the Pratt Street Lobby. Email stations will be available for your use during the following hours:

| | |
|---|---|
| Monday, March 13 | • 10:00am – 5:00pm (exhibit hall) |
| Tuesday, March 14 | • 10:00am – 5:00pm (exhibit hall) |
| Wednesday, March 15 | • 10:00am – 4:00pm (exhibit hall) |
| Thursday, March 16 | • 7:00am – 6:00pm (Pratt Street Lobby) |
| Friday, March 17 | • 7:00am – 12:00noon (Pratt Street Lobby) |

Please be advised that e-mail access is provided as a service to attendees, and that we cannot provide unlimited access to e-mail stations, both in terms of the number of stations provided and the length of time that they are available.

## Speaker-Ready Room

*BCC/Room 330*

The speaker-ready room will be open as follows:

| | |
|---|---|
| Sunday, March 12 | • 1:00pm – 7:00pm |
| Monday, March 13 | • 7:00am – 5:00pm |
| Tuesday, March 14 | • 7:00am – 5:00pm |
| Wednesday, March 15 | • 7:00am – 5:00pm |
| Thursday, March 16 | • 7:00am – 5:00pm |
| Friday, March 17 | • 7:00am – 12:00noon |

## Press Room

*Press Room: BCC/Room 334*
*News Conference Room: BCC/Room 333*

| | |
|---|---|
| Monday through Thursday | • 8:00am – 5:00pm |
| Friday | • 8:00am – 12:00noon |

Phone: 410–649–6498
Fax: 410–649–6494

## Press Conference Room

*BCC/Room 333*

A schedule of news conferences can be obtained from the Press Room (Room 334).

## City Information Desk

The Baltimore Convention and Visitors Bureau will host an information desk in the BCC/Pratt Street Lobby:

| | |
|---|---|
| Sunday, March 12 | • 2:00pm – 6:00pm |
| Monday, March 13 | • 11:00am – 5:00pm |
| Tuesday, March 14 | • 11:00am – 5:00pm |

Stop by to inquire about restaurants in the city and sightseeing.

## Business Center

The Baltimore Convention Center business center is located off the Pratt Street Lobby across from Room 333. The business center offers a full range of services and is open Monday through Friday 8:30am – 4:30pm.

## Hotel List - March Meeting

- Marriott Waterfront Hotel (HQ)
  700 Aliceanna Street
  *Bussing provided to and from Convention Center*
- Sheraton Inner Harbor
  300 South Charles Street
  *Within walking distance*
- Days Inn
  100 Hopkins Place
  *Within walking distance*
- Renaissance Harborplace Hotel
  202 East Pratt Street
  *Within walking distance*
- Hyatt Regency Baltimore
  300 Light Street
  *Connected to Center*
- Holiday Inn
  301 West Lombard Street
  *Within walking distance*
- Wyndham Inner Harbor
  101 West Fayette Street
  *Within walking distance*

# PRE-MEETING PROGRAMS

**DPOLY Short Course – Baltimore Convention Center (BCC)**
Polymers in Existing and Emerging Patterning Technologies (no on-site registration – you must be pre-registered to attend this course)
**Room 304**
Saturday March 11 • 8:30am – 5:00pm
Sunday March 12 • 8:30am – 3:00pm

**Tutorials – Baltimore Convention Center (BCC)**
*(No on-site registration – you must be pre-registered to attend a tutorial)*
**Sunday, March 12**
**Baltimore Convention Center**
**Morning Tutorials #1–4**
*8:30am –12:30pm*
T1 Spintronics: What's New – Room 307
T2 Molecular Magnetics – Room 301
T3 Current Interpretations of Quantum Mechanics – Room 302
T4 Thermoelectric Energy Conversion – Room 303

**Afternoon Tutorials #5–8**
*1:30pm – 5:30pm*
T5 Solid State Implementations of Cavity QED – Room 301
T6 Spallation Neutron Sources – Room 302
T7 Forefront Methods and Limits of Lithography – Room 303
T8 Polymeric Templating – Room 305

**Professional Skills Development for Women Physicists**
**Sunday, March 12**
*8:00am – 5:00pm*
*Reception 5:00pm – 6:30pm*
Marriott Waterfront Hotel/Dover A (workshop)
Marriott Waterfront Hotel/Grand Salon I (reception)
This one-day workshop will offer training on persuasive negotiation and communication skills for tenure track and newly-tenured women physicists. Workshop will be led by professional facilitators using an interactive format that encourages highly personal learning. Lunch will be provided and a reception for participants will follow the workshop. Limited to 30 participants. Pre-registration required.

**Workshop on Opportunities in Biology for Physicists**
**Organized by APS Division of Biological Physics**
**Sunday, March 12**
*8:00am – 5:00pm*
Lunch break on your own.
BCC/Room 310
Biology is a rapidly changing field that has been making tremendous strides forward in recent years. Biology is changing from a descriptive to a quantitative and conceptually profound field. This workshop will showcase a sample of the rich opportunities in biology for physicists. It is aimed at physicists, especially graduate students and postdocs, who are curious about how a background in physics can provide a unique perspective of biological systems. We believe that physicists will make a substantial contribution to this revolution by working together with biologists.

**Invited speakers include:**
- William Bialek (Princeton)
- Steven Block (Stanford) (tentative)
- Robijn Bruinsma (UCLA)
- Hans Frauenfelder (Los Alamos)
- Klaus Lehnertz (Bonn)
- Yale Goldman (Penn)
- Boris Shraiman (Santa Barbara) (tentative)
- Charles Stevens (Salk Institute)
- Zuzanna Siwy (Irvine)
- Sunney Xie (Harvard)

Co-chairs of Organizing Committee:
Dean Astumian, DBP Vice Chair, astumian@maine.edu
Clare Yu, cyu@uci.edu

On-site registration is available but payable in cash only – no credit cards or checks.
Students: $50
Post Docs: $75
Regular Members: $100

**Special Workshop: Quantum Mechanics with Interactive Computer-based Tutorials**
Sponsored by the APS Forum on Education
**Sunday, March 12**
1:30pm – 5:30pm
BCC/Room 306
• No cost to attend the workshop - all are welcome.
Although quantum mechanics is one of the most widely taught topics on the college/university level in the physical sciences, the teaching of quantum mechanics has not changed significantly since the 1940s. This workshop will present recently developed computer-based curricular material that has shown to improve understanding of traditional quantum topics and that makes many heretofore inaccessible topics in quantum mechanics accessible to undergraduate and graduate students. Participants will receive a CD containing curricular material from the Quantum Interactive Learning Tutorials (QUILT) project as well as a collection of ready to run Java programs from the Open Source Physics (OSP) project. All programs are freely distributable under the GNU GPL license.
This workshop will benefit anyone teaching or planning to teach quantum mechanics as well as computational physicists wishing to adopt the OSP Java libraries for their own teaching and research. We will discuss the general pedagogical and technical issues in the design of interactive computer-based tutorials as well as how OSP programs can be adapted to your local situation. Additional information can be obtained at www.opensourcephysics.org

**Speakers:**
- Chandralekha Singh, University of Pittsburgh
- Wolfgang Christian, Davidson College
- Mario Belloni, Davidson College

**Career Workshop**
**Sunday, March 12**
*3:00pm – 7:00pm*
BCC/Room 308

Attendance is free. All are welcome.

# PRE-MEETING PROGRAMS

**NRC/NAS Town Meeting**
**Sunday, March 12**
*7:30pm – 9:30pm*
Marriott Waterfront Hotel, Grand Ballroom Salon V

**Condensed Matter and Materials Physics In the Next Decade**

M. A. Kastner, Chair, Solid State Sciences Committee of the National Research Council and Department of Physics, MIT

• The National Research Council (NRC) will soon appoint a committee to carry out a decadal study of condensed-matter and materials physics called CMMP2010. The study, which will result in an NRC report, is supported by the NSF and DOE. The committee will assess the current and future opportunities of our field. It will identify the most important fundamental scientific problems, as well as problems whose solutions are likely to help meet national or societal needs. It will also examine the current status and future needs for resources that will be necessary to solve these problems, such as small and large facilities, individual and multi-investigator research support, as well as university, national and industrial laboratories. After a brief introduction to the work done so far, under the auspices of the Solid State Sciences Committee, attendees will be invited to offer their views about issues to which the panel should pay special attention.

# APS MEETINGS / EVENTS

***(In chronological order)***

**Contact Congress**
**Mon-Thurs 9:00am–6:00pm**
Sponsored by DCMP and DMP
BCC/Pratt Street Lobby

Worried about the slashing of NSF, DOE and NASA funding? Concerned about the dearth of science literacy in our high-schoolers? Anxious about where the country's security is heading? YOU can have an impact on national science policy! Come write your representatives in Congress to let them know how you feel about science issues of interest to you. The most important letters that a Member of Congress receives are the ones from his or her constituents – you elect them, and you matter. The American Physical Society feels that it is incumbent on all of us to interact with the government, to offer technical assistance where we can, and to remind our Members of Congress that scientists have much to offer the country, in areas of basic science R&D funding, education, and energy policy. We have set up computers in the entrance area where you can send a letter to your Senators and Representatives - you can use our template or write your own letter on issues that matter to you. If the state of affairs in Washington, DC, interests you, we have another way for you to get involved: the APS "Physics and Government Network," a group of APS members who volunteer to contact their representatives in Congress a few times a year at critical junctures. PGNet signup fliers will be available at the registration desk and at the "Contact Congress" computers. Come help make science more visible in Congress!

**Awards Program**
**Monday, March 13**
*5:45pm – 6:30pm*
BCC/Room 309
Prizes and awards will be bestowed on individuals for outstanding contributions to physics. Please plan on attending the Awards Program and join us in honoring these individuals. See page 13 for a list of award and prize winners. The Awards Program will be followed by the Welcome Reception at 6:45pm.

**Welcome Reception**
**Monday, March 13**
*6:45pm – 8:00pm*
BCC/Ballroom II

All Attendees welcome.

### *Special Symposium:*

**Emerging Emergent Phenomena (Session F50)**
**Monday, March 13**
Sponsored by DCMP
*8:00pm – 10:00pm*
Marriott Waterfront Hotel, Grand Ballroom Salons V-VI

Session Chair: Leo Kadanoff, University of Chicago
*Speakers:*

- Edward Witten: Emergent Phenomena In Particle Physics
- Susan J. Lolle: Revisiting Mendel and the Paradox of Gene Restoration
- Albert Laszlo Barabas: Complex Networks: From the Internet to Biology
- Bernard Sadoulet: Condensed Matter Physics and the Nature of Dark Matter in the Universe

**Wine and Cheese Reception**
**Monday and Tuesday • 4:00pm – 5:00pm**
BCC/Exhibit Hall E

**APS Journal Editors Panel Discussion**
**Tuesday, March 14**
*2:30pm – 3:30pm*
BCC/Room 337
All are invited to a panel discussion with the Editors of the American Physical Society journals. The panel will include Editors from Physical Review Letters, Physical Review B, and Physical Review E. They will briefly discuss some current issues facing the journals such as how to express appreciation for good refereeing, possible inclusion of popular abstracts in PRL to make Letters accessible to physicists in all fields, the challenge posed by open access, etc. The Editors look forward to hearing opinions on these and other issues. They will also respond to questions and comments. The Panel Discussion will be followed by the Meet the Editors Reception.

**Meet the Journal Editors of AIP and APS**
**Tuesday, March 14**
*3:30pm – 5:30pm*
BCC/Camden Lobby

The Editors of the AIP and APS journals cordially invite you to join them for conversation and refreshments. Your questions, criticisms, compliments, and suggestions about the journals are welcome. We hope you will be able to join us.

**Journals of the American Institute of Physics:**
- Applied Physics Letters
- Chaos
- Journal of Applied Physics
- The Journal of Chemical Physics
- Journal of Mathematical Physics
- Physics of Fluids
- Physics of Plasmas
- Review of Scientific Instruments

**Journals of the American Physical Society:**
- Physical Review A
- Physical Review B
- Physical Review E
- Physical Review Focus
- Physical Review Letters
- Reviews of Modern Physics

# APS MEETINGS / EVENTS
***(In chronological order)***

### *Special Symposium:*

**Intelligent Design: Its Impact and Responses to It**
**Tuesday, March 14**
*7:30pm – 9:30pm*
Marriott Waterfront Hotel/Grand Ballroom Salon V

Session Chair: Robert Eisenstein
Speakers:

- Jeremy Gunn, ACLU - Dover, PA Case
- Marshall Berman - Action at the Local Level
- Cory Dean, New York Times - Media Coverage
- Francis Slakey, APS Office of Public Affairs - APS Activities

**Congressional Visits during March Meeting 2006**
**Congressional Visits Office –**
**BCC/East Pratt Show Office, Lower Level**

The APS Office of Public Affairs (OPA) is organizing Congressional visits during the 2006 APS March Meeting in Baltimore. The advantageous location of this year's Meeting provides an exciting opportunity to have attendees from as many districts and states as possible travel down to Washington, DC to educate Congress on the importance of science research funding. The visit days are scheduled for Wednesday, March 15th and Thursday March 16th.

Carrying the message to individual offices remains one of the best means of influencing a Member of Congress. The timing of these visits is excellent since Congress will have just started its considerations of the appropriations for the next fiscal year. In addition to influencing Congress, we hope that participants see first-hand the importance of informing their elected officials about what physicists do. While our members are getting more active in this regard and more APS meeting attendees write letters at the Contact Congress computers, there is much more to do.

OPA will assist the participants in all aspects of the congressional visits from scheduling to follow up. Leading up to the meeting, OPA will contact participants to inform them of the organizational logistics of the visits and provide a means of coordination of their meetings on the Hill with other participants in their state or district. During the March Meeting, briefings will be held in Baltimore in the evenings preceding the visits to outline a common message, offer advice on how to conduct an effective meeting, and cover the logistics of a congressional visit. We will also provide materials to be left with each office that will present useful talking points and have state specific information. Shuttle bus transportation to and from the Meeting and Washington, DC will be provided for participants.

We would like you and all APS members to view Congressional visits as part of developing a relationship with an office rather than a one-time event. We would hope that you would follow up with the Congressional office at opportune times, make visits to the home offices and perhaps invite staff or Members of Congress to visit their labs. You may also become resources for a Member's office.
For more information visit the Congressional Visits office as noted above.

**Session on Refereeing**
**Wednesday, March 15**
*9:30am – 11:00am*
BCC/Room 337

Editors from Physical Review Letters and the Physical Review will provide useful information and tips for referees. Following short presentations from the editors, there will be a moderated discussion where questions relevant to refereeing will be addressed. Refreshments will be served.

**Estate Planning Seminar**
**Wednesday, March 15**
*1:00pm – 2:00pm*
BCC/Room 301

### *Special Symposium:*

**Perspectives on our Energy Future**
**Wednesday, March 15**
*7:30pm – 9:00pm*
Marriott Waterfront Hotel/Grand Ballroom Salon V

Session Chair: George Crabtree, Argonne National Laboratory
Speakers:

- Steven E. Koonin, Chief Scientist, BP
- Patricia Dehmer, Office of Basic Energy Sciences, DOE

**Physics Sing-a-Long/Listen-a-Long**
**Wednesday, March 15**
9:00pm – 10:00pm
Grand Salon II, Marriott Waterfront Hotel

**Changing Dynamics of Industrial Research as a Consequence of Global Trends (Session V19)**
Sponsored by APS and AIP
**Thursday, March 16**
BCC/Room 316

Session Chair: Mark Bernius, The Dow Chemical Company
Speakers:

- **Alan Taub**: General Motors' R&D: Managing Innovation Globally
- **Hans Stork**: Not Only Texas is Flat …
- **Mark Durcan**: Micron R&D: Global Scope and Nano-Scale in N-Dimensions
- **Abel Weinrib**: Leap Ahead: Global R&D at Intel
- **Thomas Feist**: Sustaining Breakthrough Research in a Changing Global Environment

# APS EVENTS FOR SPECIAL GROUPS

***(In chronological order)***

**Companions Breakfast**
**Monday, March 13**
*8:00am – 9:30am*
Marriott Waterfront Hotel/Dover A

Companions of the attendees of the March Meeting are invited to a complimentary breakfast to meet other companions and learn about the city of Baltimore. Presentations will be made by a representative of the Baltimore Convention and Visitors Bureau. At the breakfast you will receive information about the sites and attractions in the city.

**SPS Undergraduates and Mentors Gathering**
**Monday, March 13**
*1:50pm – 2:20pm*
BCC/Room 345

Undergraduates and their mentors, as well as graduate school representatives, are especially invited to hear the student presentations and mingle with the presenters during this gathering. The event is sandwiched between two exciting undergraduate research sessions - B42 and D42 in room 345. Light refreshments will be available for those attending the talks.

**CSWP/FIAP Networking Breakfast for Women in Physics**
**Tuesday, March 14**
*7:30am – 9:30am*
Marriott Waterfront Hotel, Grand Ballroom Salon VII
$20 (pre-registration only)

The Committee on the Status of Women in Physics (CSWP) and the Forum on Industrial and Applied Physics (FIAP) will host a networking breakfast for women in physics. All are welcome, both men and women. Thanks to the generosity of FIAP, the breakfast is free for physics students who pre-register. Only a limited number of walk-ins can be accepted.

**High School Physics Teachers Day**
**Tuesday, March 14**
*8:00am – 2:30pm*
Marriott Waterfront Hotel, Grand Ballroom Salons II–III

In conjunction with the 2006 March Meeting, the APS Department of Education & Outreach is sponsoring a High School Physics Teachers' Day for teachers in the Baltimore region. For more information contact Ed Lee: lee@aps.org

*The day's program includes:*

- Hands-on workshops presenting innovative, class room-ready activities
- Research talks on cutting-edge physics
- A welcoming breakfast, and a chance to network with fellow teachers
- Lunch with a physicist

**Congressional Visits Meeting**
**Tuesday, March 14**
*5:00pm – 6:30pm*
BCC/Room 337

**DCMP/DMP/DCOMP Fellows & Awards Reception**
**Tuesday, March 14**
*5:30pm – 7:00pm*
Marriott Waterfront Hotel/Grand Salon VI

**FIP Reception**
**Tuesday, March 14**
*6:30pm – 8:00pm*
Marriott Waterfront Hotel/Dover C

**Students Lunch with the Experts**
**Wednesday, March 15**
*1:00pm – 2:30pm*
BCC/Ballroom II

Students can sign up on-site to enjoy a complimentary box-lunch while participating in an informal discussion with an expert on a topic of interest to them. Sign-up will take place beginning on Monday, March 13 at 1:00pm at the APS registration desk, and will be on a first-come, first-served basis. Attendance is limited to eight students per topic. See page 12 for list of topics and experts.

**Congressional Visits Meeting**
**Wednesday, March 15**
*5:00pm – 6:30pm*
BCC/Room 311

**Status of Funding Opportunities in NSF's Division of Materials Research**
**Wednesday, March 15**
*5:00pm – 7:00pm*
BCC/Room 338

**Student Reception**
**Wednesday, March 15**
*5:30pm – 6:30pm*
BCC/Ballroom II
Sponsored by the Forum on Graduate Student Affairs (FGSA)

All students are welcome. Plan to attend and socialize with your fellows and enjoy the refreshments. The Forum on Graduate Student Affairs (FGSA) will present a short program.

# APS EVENTS FOR SPECIAL GROUPS

***(In chronological order)***

## APS Unit Business Meetings

### SUNDAY, MARCH 12

**GSCCM Business Meeting**
*3:00pm – 4:00pm*
Falkland Room, Marriott Waterfront Hotel

### TUESDAY, MARCH 14
### 5:30pm – 6:30pm

**DPOLY Business Meeting**
BCC/Room 315

**FIAP Business Meeting**
BCC/Room 312

**FIP Business Meeting**
Marriott Waterfront Hotel, Galena

**DCP Business Meeting**
BCC/302

**GSNP Business Meeting**
BCC/Room 336

**GMAG Business Meeting**
BCC/Room 320

**GQI Business Meeting**
BCC/Room 343

**GIMS Business Meeting**
BCC/Room 301

### TUESDAY, MARCH 14
### 7:00pm–8:00pm

**DCMP Business Meeting**
Marriott Waterfront Hotel/Dover A

**DMP Business Meeting**
Marriott Waterfront Hotel/Dover B

### WEDNESDAY, MARCH 15

**FED Business Meeting and Reception**
*5:30pm – 7:00pm*
Marriott Waterfront Hotel/Grand Ballroom Salon III

**DCOMP Business Meeting**
*6:30pm – 730pm*
Marriott Waterfront Hotel, Dover C

# SATELLITE MEETINGS

***(ancillary events sponsored by non-APS groups)***

**Sunday, March 12**
**High Magnetic Field Laboratory Users Group**
*5:00pm – 9:00pm*
Marriott Waterfront Hotel/Grand Ballroom Salon X

**Sunday, March 12**
**Socialize with Science - Oxford Instruments**
*7:00pm – 9:00pm*
Marriott Waterfront Hotel/Grand Salons VIII–IX

**Monday, March 13**
**Discussions and Updates on the Nanoscale Ordered Materials Diffractometer at the Spallation Neutron Source (NOMAD)**
11:00am – 2:00pm
Marriott Waterfront Hotel/Dover C

**Tuesday, March 14**
**Research Corporation Reception**
*5:00pm – 7:00pm*
Marriott Waterfront Hotel/Grand Ballroom Salon I

**Tuesday, March 14**
**Alumni Reunions**
*6:00pm – 8:00pm*
Marriott Waterfront Hotel
- Cornell University, Grand Ballroom Salons IX–X
- University of Illinois, Grand Ballroom Salons II–III
- Michigan State University, Bristol
- IBM, Grand Salon VIII
- Brown University, Falkland
- State of Florida Universities, Harborside Ballrooms AB
- Sigma Pi Sigma, Essex B
- Brandeis Alumni Reunion, Essex C

**Tuesday, March 14**
**Chinese Academy of Sciences Reception**
*6:00pm–8:00pm*
Marriott Waterfront Hotel/Essex A

**Tuesday, March 14**
**American Chapter of the Indian Physics Association**
*7:30pm – 9:30pm*
Marriott Waterfront Hotel/Grand Ballroom Salon IV

**Wednesday, March 15**
**RSI Editorial Board Meeting**
*12:00noon – 2:00pm*
Marriott Waterfront Hotel/Grand Salon IX

**Wednesday, March 15**
**Status of Funding Opportunities in NSF's Division of Materials Research**
*5:00pm – 7:00pm*
BCC/Room 338

**Wednesday, March 15**
**MRFM Workshop**
**(Magnetic Resonance Force Microscopy)**
*6:30pm – 10:30pm*
Marriott Waterfront Hotel/Atlantic Room

# STUDENTS LUNCH WITH THE EXPERTS

**Wednesday, March 15**
*1:00pm – 2:30pm*
Ballroom II

Students can sign up on-site to enjoy a complimentary box-lunch while participating in an informal discussion with an expert on a topic of interest to them. Topics are listed below. Sign-up will take place beginning on Monday, March 13 at 1:00pm at the APS registration desk, and will be on a first-come, first-served basis. Attendance is limited to eight students per topic/expert. You must show your ticket and badge at the door, and sit at the table for which you have a ticket.

Lunch topics

# 2006 PRIZES AND AWARDS

**Award Session (Session E5)**
**Monday, March 13**
*5:45pm – 6:45pm*
*BCC/309*

## Biological Physics Prize

**Alfred G. Redfield**
*Brandeis University*

"For his seminal contributions to the theory and technical development of nuclear magnetic resonance spectroscopy, and for pioneering applications of this technique to the study of biological molecules."

## Lars Onsager Prize

**Rodney Baxter**
*Australian National University*

"For his original and groundbreaking contributions to the field of exactly solved models in statistical mechanics, which continue to inspire profound developments in statistical physics and related fields."

## Oliver E. Buckley Prize

**Noel A. Clark**
*University of Colorado*

**Robert Meyer**
*Brandeis University*

"For groundbreaking experimental and theoretical contributions to the fundamental science and applications of liquid crystals, particularly their ferroelectric and chiral properties."

## George E. Pake Prize

**Charles B. Duke**
*Xerox Innovation Group*

"For groundbreaking theoretical contributions to the understanding of tunneling in solids, and inelastic scattering of low-energy electrons in solids, and for his outstanding contributions to Xerox Corporate Research both as an intellectual leader and research manager."

## Frank Isakson Prize

**Roberto Merlin**
*University of Michigan*

"For original contributions to spontaneous Raman and ultrafast spectroscopy of fundamental excitations in solids."

## Earle K. Plyler Prize

**Mark Johnson**
*Yale University*

"For the applications of spectroscopic methods towards the understanding of solvation on the microscopic scale, especially the solvation of protons and hydroxide anions by water."

## James C. McGroddy Prize

**Hongjie Dai**
*Stanford University*

**Alex Zettl**
*University of California, Berkeley*

"For developing novel synthesis pathways for preparing carbon and boron nitride nanotubes and for pioneering applications of these for sensing, electronics and nanomechanics."

## Polymer Prize

**Ludwik Leibler**
*Ecole Superieure de Physique et Chimie Industrielles, Paris*

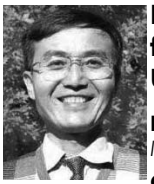
"For outstanding theoretical contributions to the fundamental understanding of self-assembly of diblock copolymers and gels, and wetting."

# 2006 PRIZES AND AWARDS

## Aneesur Rahman Prize

**David Vanderbilt**
*Rutgers University*

"For his conceptual breakthroughs in his development of the ultrasoft pseudopotential and the modern theory of polarization, and their impact on first-principles investigations of the properties of materials."



## Prize to a Faculty Member for Research in an Undergraduate Institution

**Rainer Grobe**
*Illinois State University*

**Q. Charles Su**
*Illinois State University*

"For their outstanding effort at creating a successful and renowned optical theory research program at Illinois State University, and for their exemplary involvement of undergraduates in this research."

## David Adler Lectureship Award

**James Chelikowsky**
*University of Texas*

"For his creative and outstanding research in computational materials physics and for his effectiveness in communicating research results through lectures and publications."

## LeRoy Apker Award

**Nathaniel Craig**
*Harvard University*

**Matthew Paoletti**
*Bucknell University*

"Tunable Nonlocal Spin Control in a Coupled Quantum Dot System."
"Experimental Studies of the Effects of Chaotic Mixing on an Advection-Reaction-Diffusion System."

## Edward A. Bouchet Award

**Angel Garcia**
*Rensselaer Polytechnic Institute*

"For his contributions to the understanding of the role of water in the dynamics and folding of proteins through computer simulations."

Photo not available

## John H. Dillon Medal

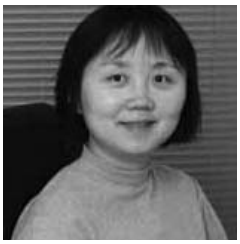
**Kenji Urayama**
*Kyoto University*

"For insightful experiments that probe the nature of polymer networks."

## Keithley Award

**Frances Hellman**
*University of California, Berkeley*

"In recognition of using emerging micromachining techniques to significantly extend the range of calorimetry into the realm of nano-scale science, by construction of Si based microcalorimeters capable of operating in extreme environments with unprecedented sensitivity and accuracy."



## Maria Goeppert-Mayer Award

**Hui Cao**
*Northwestern University*

"For her groundbreaking contributions to the experimental studies of coherent light generation and transport in disordered media, including her invention of microlasers based on disordered media."

Photo not available

## Nicholas Metropolis Award

**Joseph A. Barranco**
*University of California, Berkeley*

"For the development of computational techniques to handle 3D compact vortices in rotating shear flows, and for the application of these techniques to solve longstanding problems in the theory of planet and star formation."

**Additional Awards:**

**Marshak Lectureship Award: Zohra ben Lakhdar (Session D3)**

**Beller Lectureship Award: Pierre-Gilles de Gennes (Session Y29)**

Each year, the APS Committee on International Scientific Affairs (CISA) will award the APS Beller and Marshak Lectureships to bring distinguished foreign scientists to speak at the March and April meetings.

The Beller Lectureship was endowed by Esther Hoffman Beller for the purpose of bringing distinguished physicists from abroad as invited speakers at APS meetings. The Marshak Lectureship, endowed by Ruth Marshak, in honor of her late husband and former APS president, Robert Marshak, provides travel support for physicists from a developing country or Eastern Europe invited to speak at APS meetings.

# FOCUS SESSIONS

**DAMOP**
A43 - Focus Session: Strongly Interacting Fermi Gases and the BCS - BEC Crossover I
D43 - Focus Session: Vortices and Vortex Lattices in Fermi and Bose Superfluid Gases
H43 - Focus Session: Strongly Interacting Fermi Gases and the BCS - BEC Crossover II
U43 - Focus Session: Novel Phases in Low Dimensional Quantum Gases

**DAMOP/GQI**
W43 - Focus Session: Cold Atoms in Optical Lattices

**DBP**
G26 - Focus Session: Trapping of Nanoscale Biological Objects
G29 - Focus Session: Physical and Engineering Constraints on the Function of Biological Systems
H29 - Focus Session: Physical Aspects of Morphogenesis: Computational Approaches
N29 - Focus Session: Physical Models of Ion Channel Function
R26 - Focus Session: Counterion Dynamics in Charged Biopolymer Systems
R28 - Focus Session: Biological Networks: Structure, Dynamics and Function
W26 - Focus Session: Biological Photophysics
Y26 - Focus Session: Physics of Physiological Systems

**DBP/DCMP**
K26 - Focus Session: Single Molecule Biophysics I

**DBP/DCP**
P26 - Focus Session: Protein Dynamics in Folding and Function

**DBP/DFD**
N26 - Focus Session: DNA and Protein Analysis with Micro and Nano Fluidics

**DBP/DPOLY**
B26 - Focus Session: Single Molecule Biophysics: DNA & RNA
D26 - Focus Session: Dynamics of Nuclei Acid-Protein Interaction: Single Molecule
U29 - Focus Session: Nonequilibrium Fluctuation in Biomolecules and Artificial Nanodevices
Y29 - Focus Session: Noise and Fluctuation in Biological Systems

**DBP/GSNP**
B29 - Focus Session: Micro-Organism Motility
A39 - Focus Session: Magnesium Diboride and Related Compounds: Multi Gap Superconductivity
D15 - Atomic Tunneling, Films, Nanostructures
H39 - Focus Session: Josephson Junctions and Pairing State Symmetry

**DCMP/DCOMP**
*G39* - Focus Session: Superconductivity: Theory and Computation I

**DCMP/GSCCM**
R42 - Focus Session: Plasticity and Phase Transitions

**DCOMP**
D27 - Focus Session: Novel Computational Algorithms I
G27 - Focus Session: Novel Computational Algorithms II

**DCOMP/DFD**
V8 - Focus Session: Simulations Using Particles

**DCOMP/DCMP**
K39 - Focus Session: Superconductivity: Theory and Computation II
P39 - Focus Session: Superconductivity: Theory and Computation (Mainly First Principles)
V39 - Focus Session: Superconductivity: Theory and Computation III
Z39 - Focus Session: Superconductivity: Theory and Computations (Mostly Phonons)

**DCOMP/DMP**
B32 - Focus Session: Computational Nanoscience I
D32 - Focus Session: Computational Nanoscience II
G31 - Focus Session: Simulation of Complex Materials I
H31 - Focus Session: Simulation of Complex Materials II
H32 - Focus Session: Computational Nanoscience III
K31 - Focus Session: Simulation of Complex Materials III
K32 - Focus Session: Computational Nanoscience IV
R32 - Focus Session: Computational Nanoscience V

**DCOMP/GSCCM/DMP**
N42 - Focus Session: Simulations of Matter at Extreme Conditions I
U42 - Focus Session: Simulations of Matter at Extreme Conditions II
W42 - Focus Session: Simulations of Matter at Extreme Conditions III

**DCOMP/GQI**
P40 - Focus Session: Pathways to Practical Quantum Computing I
R40 - Focus Session: Pathways to Practical Quantum Computing II

**DCOMP/GQI/DAMOP**
U40 - Focus Session: Pathways to Practical Quantum Computing III

**DCP**
A10 - Focus Session: Physical Chemistry of Nanoscale Systems I
A11 - Focus Session: Promises and Challenges in Chemical Dynamics I
B10 - Focus Sessions: Physical Chemistry of Nanoscale System II
B11 - Focus Session: Promises and Challenges in Chemical Dynamics II
D10 - Focus Session: Physical Chemistry of Nanoscale System III
D11 - Focus Session: Promises and Challenges in Chemical Dynamics III
G10 - Focus Sessions: Physical Chemistry of Nanoscale System IV
G11 - Focus Session: Promises and Challenges in Chemical Dynamics IV
H10 - Focus Session: Frontiers in Computational Chemical Physics I
H11 - Focus Session: Chemical and Spectroscopic Applications of Nonlinear Optics I
K10 - Focus Session: Frontiers in Computational Chemical Physics II
K11 - Focus Session: Chemical and Spectroscopic Applications of Nonlinear Optics II

# FOCUS SESSIONS

N10 - Focus Session: Frontiers in Computational Chemical Physics III
N11 - Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects I
N13 - Focus Session: Ultrafast and Ultrahigh Field Chemistry I: Strong Field Phenomena
P10 - Focus Session: Frontiers in Computational Chemical Physics IV
P11 - Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects II
P13 - Focus Session: Ultrafast and Ultrahigh Field Chemistry II: Quantum Control
R10 - Focus Session: Surfaces and Interfaces in Electronic Materials I
R11 - Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects III
R13 - Focus Session: Ultrafast and Ultrahigh Field Chemistry III: Ultrafast Processes
U10 - Focus Session: Surfaces and Interfaces in Electronic Materials II
U11 - Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects IV
V10 - Focus Session: Surfaces and Interfaces in Electronic Materials III
V11 - Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects V
W10 - Focus Session: Surfaces and Interfaces in Electronic Materials IV
W11 - Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects VI

**DCP/DBP**

A13 - Focus Session: Spectroscopy of Biomolecules from Isolated Molecules to Cell Environoment I
B13 - Focus Session: Spectroscopy of Biomolecules from Isolated Molecules to Cell Environoment II
D13 - Focus Session: Spectroscopy of Biomolecules from Isolated Molecules to Cell Environoment III
G13 - Focus Session: Spectroscopy of Biomolecules from Isolated Molecules to Cell Environoment IV

**DFD**

H21 - Focus Session: Microfluidic Physics I

**DFD/DBP**

R21 - Focus Session: Biological Hydrodynamics I
U28 - Focus Session: Biological Hydrodynamics II

**DFD/GSNP**

P8 - Focus Session: Jets, Shocks & Splashes

**DMP**

A18 - Focus Session: Carbon Nanotubes: Synthesis and Growth I
A35 - Focus Session: Nanoscale Thermal, Thermoelectricity and Mass Transport: Measurement and Characterization
A46 - Focus Session: Wide Bandgap Semiconductors I
B18 - Focus Session: Carbon Nanotubes: Synthesis, Processing and Characterization
B35 - Focus Session: Nanoscale Thermal, Thermoelectricity and Mass Transport: Theory and Simulation
B46 - Focus Session: Wide Band Gap Semiconductors II
D18 - Focus Session: Carbon Nanotubes: Synthesis and Growth II
D35 - Focus Session: Thermal Transport and Thermoelectricity in Nanotubes and Graphene
D38 - Focus Session: Magnesium Diboride and Related Compounds: Properties of Doped and Irradiated MgB2
D46 - Focus Session: Wide Band Gap Semiconductors III
G18 - Focus Session: Carbon Nanotubes: Electronic and Optical Properties I
G37 - Focus Session: Nanoscale Materials Physics of Phase Transitions I

Z20 - Focus Session: Novel Ferromagnetic Semiconductors II

**GMAG/DMP/DCOMP**
D23 - Focus Session: MAG.THY I / Spin Structures and Dynamics
G23 - Focus Session: MAG.THY II / Transport & General
N23 - Focus Session: MAG.THY III: Oxides and Phase Transitions
W23 - Focus Session: MAG.THY IV / ab initio Studies

# FOCUS SESSIONS

*Focus Sessions (cont'd)*

**GMAG/FIAP**
R23 - Focus Session: Theory and Simulation for Information Storage Applications
Y22 - Focus Session: Coupled Thin-Film Structures for Magnetic Recording
Z22 - Focus Session: FePt Nanoparticles for Information Storage

**GMAG/FIAP/DMP**
A22 - Focus Session: Current Driven Magnetization Dynamics I
B22 - Focus Session: Current Driven Magnetization Dynamics II
K22 - Focus Session: Magnetization Dynamics
P22 - Focus Session: Spin Transport in Metals
U22 - Focus Session: Magnetic Tunneling I
V22 - Focus Session: Magnetic Tunneling II

**GSCCM/DCMP**
H42 - Focus Session: Dynamic Compression

**GSNP**
A33 - Focus Session: Econophysics
H8 - Focus Session: Jamming in Glasses, Grains, and Gels I
K8 - Focus Session: Jamming in Glasses, Grains and Gels II
N33 - Focus Session: Instabilities & Turbulence in Complex Fluids
N35 - Focus Session: Organization of Complex Networks
V33 - Focus Session: Social Networks

**GSNP/DBP**
P7 - Focus Session: Physics of Transcriptional Regulatory Networks
U26 - Focus Session: Cytoskeletal Dynamics

**GSNP/DFD**
B8 - Focus Session: Granular Materials Near Jamming
W8 - Focus Session: Nonlinear Electrokinetics

**GQI/DCMP**
D40 - Focus Session: Foundations of Quantum Theory
V40 - Focus Session: Linear Optics Quantum Computation

# POSTER SESSIONS

**Poster Sessions**
*Exhibit Hall*
Poster sessions will be held Monday, Tuesday and Wednesday. Posters will be on display from 10:00am to 5:00pm on Monday and Tuesday and from 10:00am to 4:00pm on Wednesday. Authors should be in attendance at the times listed below. APS is not responsible for poster materials that are left in the exhbiti hall after the session is over. No A/V is allowed in poster sessions.

**C1: Poster Session 1**
**Monday, March 13**
Authors in attendance from 2:00pm – 5:00pm
(DPOLY Session from 11:15am – 2:15pm)

Posters 1-99: DPOLY Posters I
Posters 100-152: Biological Physics
Posters 153-184: Chemical Physics
Posters 185-215: Statistical and Nonlinear Physics
Posters 216-256: Artificially Structured Materials
Posters 257-270: Instrumentation and Measurements

**J1: Poster Session II**
**Tuesday, March 14**
Authors in attendance from 2:00pm – 5:00pm

- Posters 1-19: Metals
- Posters 20-48: Semiconductors
- Posters 49-65: Insulators and Dielectrics
- Posters 66-88: Superconductivity
- Posters 89-147: Magnetism Poster
- Posters 148-195: Complex Structured Materials
- Posters 196-245: Fluids and Soft Matter Poster
- Posters 246-259: Phase Transitions and Strongly Correlated Systems
- Posters 260-292: Surfaces, Interfaces and Thin Films

**Q1: Poster Session III**
**Wednesday, March 15**
Authors in attendance from 1:00pm – 4:00pm
(DPOLY Session from 11:15am – 2:15pm)

- Posters 1-97: DPOLY Posters II
- Posters 98-122: Applications
- Posters 123-144: General Theory
- Posters 145-154: General Physics
- Posters 155-157: Quantum Fluids and Solids
- Posters 158-173: Atomic, Molecular & Optical (AMO) Physics
- Posters 174-186: Physics Education
- Posters 187-199: Quantum Information, Concepts, and Computation
- Posters 200-333: Post-Deadline Posters

# PROGRAM FORMAT

**Program Time-Blocks**

Normally contributed and invited sessions at APS general meetings are three hours in length - three sessions per day at 8:00am, 11:15am, and 2:30pm. The time blocks are designated in alpha order beginning with time-block "A" on Monday at 8:00am, and ending with "Z" designating the 11:15 time-block on Friday.

**Session Codes**

The number following the alpha that designates the time-block represents the sequential numbering of the sessions within the time-block. Session A1 is one of several sessions taking place in parallel in the first time-block on Monday. The number following the decimal in the session code represents the sequence of the papers to be presented in that session. For *example:* B3.004 = Time-block B (Monday at 11:15am); Session 3 (of several) within that time-block; and the 4th paper to be presented in that session.

**Poster Codes**

The poster sessions will take place on Monday, Tuesday, and Wednesday in the Exhibit Hall. A breakdown of the topics presented in each category is listed on page 19.

- Monday poster sessions = Sessions C1
- Tuesday poster session = Sessions J1
- Wednesday poster sessions = Sessions Q1

Each poster presentation (board) within each poster session is numbered sequentially.

## GUIDELINES FOR SPEAKERS

**Oral Presentations**

Please arrive at least 15 minutes prior to the scheduled time of your talk. Contributed papers are allocated 12 minutes each - 10 minutes for presentation and 2 minutes for questions from the audience, unless otherwise specified. Invited papers are allocated 36 minutes - 30 minutes for presentation and 6 minutes for questions from the audience.

Note: Occasionally (and unfortunately) the chair for a session may not appear, in which case we ask that the first presenter serve as chair of the session.

**Poster Presentations**

If you are presenting a poster, please be sure to have your poster up prior to 10:00am on the day of your poster presentation to which you have been assigned, and taken down immediately at the end of the day. You must be on hand at the beginning of the poster session (see epitome for times). APS will not be responsible for posters left up after the end of each poster session. No A-V is allowed in the poster sessions. Posters will be on display between the hours of 10:00am to 5:00pm Monday, Tuesday; 10:00am to 4:00pm, Wednesday. Consult the Poster Session Schedule for exact times and a breakdown of poster topics.

## GUIDELINES FOR SESSION CHAIRS

- Prior to the session, check the Corrigenda distributed with the Bulletin, as well as the Program-Changes Board in the registration area to see if any papers in the session you are chairing have been withdrawn.
- Arrive at the meeting room about 15 minutes prior to the start of the session and familiarize yourself with the controls for lights, microphones, A-V equipment and the timer. Technicians will be on hand to assist. If you encounter problems, you should immediately alert the Meetings Manager and/or the A-V specialist.
- Start the session on time. Briefly introduce yourself, announce the first paper and author, and start the timer.
- Please adhere to the time schedule listed in the Bulletin, so that simultaneous sessions are as closely synchronized as possible. Many attendees move from session to session in order to hear specific papers.

Note: any time used by the speaker and/or technicians to set up laptops for LCD (Powerpoint) presentations is deducted from the time allocated for the talk.

- The allotted time for contributed papers is 12 minutes; for invited papers - 36 minutes. If you are chairing a session that includes both contributed and invited papers please be aware of the different times allocated for each and set the timer as follows:

*Contributed papers* - set timer for 8 minutes to give initial warning, then set the final bell to go off 2 minutes later. When this time is up, allow 2 additional minutes for questions relating to the paper, thank the speaker and promptly introduce the next paper and speaker.

Invited papers - set timer for 25 minutes for initial warning, and the final bell to ring 5 minutes later. Then set the timer for 6 additional minutes for questions from the audience.

Explain the timing system to the audience prior to the start of the session, and as often during the session as you think necessary.

- The By-Laws of the Society request that speakers be asked to stop when their allotted time is up in a courteous but firm manner. Keep in mind that the session must end on time, and that the last speaker has just as much right to an audience as does the first speaker.
- Should a speaker fail to appear, you must wait 12 minutes before going on to the next speaker. At the end of the session, call again for the regularly scheduled paper, if time allows.
- When two or more papers are submitted by an author, only one of these will be assigned a scheduled presentation time within that session. It is assumed that the first author listed in the abstract is the person who will present the paper at the meeting. A second abstract submitted by the same author is automatically assigned to a poster.
- If any problems arise that you are unable to handle relative to successfully chairing the session, please inform the A-V tech in the room, or go immediately to the APS registration desk to alert the APS staff.

**General A-V Policy**

In keeping with our legally binding contract with our A-V vendor, speakers are not permitted to bring their own projection equipment for use at the meeting.

**Standard A-V in all Sessions**

The standard A-V package consists of an LCD projector, overhead projector, screen, laser pointer and 2 lapel microphones – one for the chair and one for the speakers. Any additional A-V equipment must be rented by the speaker directly through APS's designated A-V provider located in Rooms 331-332. The speaker is responsible for the cost of renting any additional equipment.

# PROGRAM FORMAT

**Policy and Guidelines on Use of LCD Projectors**

The responsibility for a smooth, technically trouble-free presentation ultimately rests with the presenter. Speakers who plan to use LCDs must do the following:

• Bring your own laptop computer, power cord, and any proprietary cords required for your computer. Do not bring your own projector to the meeting. NOTE: APS is not responsible for the security of personal laptop computers.

• Visit the Speaker-Ready room located in Room 330 to run through the presentation to ensure a smooth and technically trouble-free talk. Testing your presentation in the Speaker-Ready room prior to your presentation is strongly recommended to minimize equipment compatibility difficulties. Remember that time used to set up equipment reduces the time you have to make your presentation.

• Bring a back-up vu-graph presentation in case there are set-up difficulties with the LCD equipment.

# PROGRAM FORMAT & UNIT ACRONYMS

**Divisions**

DAMOP ..... Division of Atomic, Molecular and Optical Physics
DAP ..... Division of Astrophysics
DBP ..... Division of Biological Physics
DCP..... Division of Chemical Physics
DCMP ..... Division of Condensed Matter Physics
DCOMP ..... Division of Computational Physics
DFD..... Division of Fluid Dynamics
DLS..... Division of Laser Science
DMP ..... Division of Materials Physics
DNP..... Division of Nuclear Physics
DPB ..... Division of the Physics of Beams
DPF..... Division of Particles and Fields
DPP..... Division of Plasma Physics
DPOLY ..... Division of Polymer Physics

**Topical Groups**

GFBS ..... Few Body Systems Topical Group
GFC.....Precision Measurement and Fundamental Constants Topical Group
GGR ..... Gravitation
GHP.....Topical Group on Hadronic Physics
GIMS .....Instrumentation and Measurement
GMAG .....Magnetism and Its Applications Topical Group
GPAP .....Topical Group on Plasma Astrophysics
GQI.....Quantum Information, Concepts and Computation
GR.....Gravitation Topical Group
GSNP.....Statistical and Non-linear
GSCCM .....Shock Compression of Condensed Matter

**Forums**

FEd .....Forum on Education in Physics
FGSA .....Forum on Graduate Student Affairs
FHP.....Forum on History of Physics
FIAP .....Forum on Industrial and Applied Physics
FIP .....Forum on International Physics
FPS .....Forum on Physics and Society

**Committees**

COM ..... Committee on Minorities
CSWP ..... Committee on the Status of Women in Physics

# MARCH EXHIBIT SHOW GUIDE 2006

The following is a list of exhibitors participating in the March Meeting 2006. For complete information on exhibiting companies and their booth numbers, consult the Pocket Epitome/Exhibitor Guide distributed at registration. Please take time during the meeting to visit the exhibits. You must wear your badge to be admitted to the exhibits.

**APS Exhibit Hours:**
Monday, March 13 • 10:00am–5:00pm
Tuesday, March 14 • 10:00am–5:00pm
Wednesday, March 15 • 10:00am–4:00pm

# *Epitome of the March Meeting 2006*

**15:00 SUNDAY AFTERNOON**
**12 MARCH 2006**

1B GSCCM: **GSCCM Business Meeting**
Falkland, Marriott Waterfront Hotel

**19:30 SUNDAY EVENING**
**12 MARCH 2006**

1A **NAS Town Meeting**
Grand Ballroom Salon V, Marriott Waterfront Hotel

**8:00 MONDAY MORNING**
**13 MARCH 2006**

A1 DCMP: **Quantum Properties of Superconducting Nanowires**
*Sachdev, Tian, Rogachev, Khlebnikov, Arutyunov*
Ballroom IV, Baltimore Convention Center

A2 DCMP: **Magnetic-Ferroelectric Coupling in Multiferroics**
*Cheong, Vajk, Harris, Chu, Mostovoy*
Ballroom III, Baltimore Convention Center

A3 DCMP: **Bilayer 2D Systems: Interlayer Drag and Spontaneous Coherence**
*Pillarisetty, Das Sarma, Kivelson, Simon, Pellegrini*
Ballroom I, Baltimore Convention Center

A4 DPOLY: **Particle Self Assembly**
*Crocker, Starr, Hammond, Douglas, Walker*
308, Baltimore Convention Center

A5 DMP/ FIAP: **Advanced Materials for Energy Applications**
*Dresselhaus, Kanatzidis, Christensen, Mavrikakis, Schubert*
309, Baltimore Convention Center

A6 DCOMP: **Frontiers of Computational Materials**
*Asta, Johnson, Marzari, Hart, Kolmogorov*
310, Baltimore Convention Center

A7 DBP: **Bacterial Flagellar Dynamics, Polymorphism, and Conformational Spread**
*Powers, Stark, Darnton, Shaevitz*
307, Baltimore Convention Center

A8 DFD/ GSNP: **Pattern Formation and Nonlinear Dynamics**
314, Baltimore Convention Center

A9 DCMP: **Electronic Structure on Surfaces and in Reduced Dimensions**
301, Baltimore Convention Center

A10 DCP: **Focus Session: Physical Chemistry of Nanoscale Systems I**
*Nesbitt, Van Duyne*
302, Baltimore Convention Center

A11 DCP: **Focus Session: Promises and Challenges in Chemical Dynamics I**
*Shapiro, Lin*
303, Baltimore Convention Center

A12 DMP/ DCMP: **Focus Session: Steps, Growth, and Smoothing**
*Margetis*
304, Baltimore Convention Center

A13 DCP/ DBP: **Focus Session: Spectroscopy of Biomolecules from Isolated Molecules to Cell Environment I**
*Anfinrud, Spence*
305, Baltimore Convention Center

A15 DCMP: **Metals: 1D, 2D, 3D**
311, Baltimore Convention Center

A16 FIAP: **Focus Session: Hydrogen Storage I**
*Frederick Pinkerton*
312, Baltimore Convention Center

A17 FIAP: **Focus Session: Structure and Properties of Nanoscale Oxide Films**
*Pennycook, Freund*
313, Baltimore Convention Center

A18 DMP: **Focus Session: Carbon Nanotubes: Synthesis and Growth I**
*Hata*
315, Baltimore Convention Center

A19 GMAG/DMP: **Focus Session: Optical and Electrical Spin Generation in Semiconductors**
*Sipe*
316, Baltimore Convention Center

A20 DMP/GMAG: **Focus Session: Complex Oxide Thin Films Surfaces and Interfaces I: Superlattice Fabrication and Properties**
*Varela*
317, Baltimore Convention Center

A21 DFD: **Colloids I: Emulsions, Foams, and Suspensions**
318, Baltimore Convention Center

A22 GMAG/FIAP/DMP: **Focus Session: Current Driven Magnetization Dynamics I**
*Pufall*
319, Baltimore Convention Center

A23 GMAG: **Strongly Correlated Electrons I**
320, Baltimore Convention Center

A24 DPOLY: **Semi-Crystalline and Structured Polymers**
321, Baltimore Convention Center

A25 DPOLY/DMP: **Focus Session: Organic Field Effect Transistors**
*Marks*
322, Baltimore Convention Center

A26 DBP: **Biomolecular Computation**
323, Baltimore Convention Center

A28 DPOLY: **Polymer Blends**
325, Baltimore Convention Center

A29 DBP: **Experimental Techniques in Biophysics**
326, Baltimore Convention Center

A30 DPOLY: **Focus Session: Block Copolymer Dynamics**
*Morse*
327, Baltimore Convention Center

A31 DCMP: **Metallic Nanostructures**
328, Baltimore Convention Center

A32 DCMP: **Fullerenes**
329, Baltimore Convention Center

A33 GSNP: **Focus Session: Econophysics**
*Yakovenko*
336, Baltimore Convention Center

A35 DMP: **Focus Session: Nanoscale Thermal, Thermoelectric and Mass Transport: Measurement and Characterization**
*Fon*
338, Baltimore Convention Center

A36 DCMP: **Structural, Optical, and Electronic Properties of Nanostructures**
339, Baltimore Convention Center

A38 DCMP: **Superconductivity—Vortex Matter**
341, Baltimore Convention Center

A39 DMP: **Focus Session: Magnesium Diboride and Related Compounds: Multi Gap Superconductivity**
342, Baltimore Convention Center

A40 TGQI/DCMP: **Quantum Entanglement**
343, Baltimore Convention Center

A41 DCMP: **Quantum Fluids and Solids**
344, Baltimore Convention Center

A42 DMP/DCOMP: **Focus Session: Planetary Materials I**
*Gironcoli, Lin*
345, Baltimore Convention Center

A43 DAMOP: **Focus Session: Strongly Interacting Fermi Gases and the BCS-BEC Crossover I**
*Denschlag*
346, Baltimore Convention Center

A45 GMAG: **Cuprates and Nickelates**
348, Baltimore Convention Center

A46 DMP: **Focus Session: Wide Bandgap Semiconductors I**
*Wetzel*
349, Baltimore Convention Center

**11:15 MONDAY MORNING**
**13 MARCH 2006**

B1 DCMP: **DCMP/DCOMP Prize Session**
*Clark, Meyer, Merlin, Vanderbilt*
Ballroom IV, Baltimore Convention Center

B2 DCMP: **Solid Helium**
*Clark, Beamish, Dai, Reatto, Ceperley*
Ballroom III, Baltimore Convention Center

B3 GSNP: **Uncovering the Structure of Complex Networks**
*Newman, Guimera, Vicsek, Muñoz, Almaas*
Ballroom I, Baltimore Convention Center

B4 DMP/ FIAP: **Advances in ZnO Materials Physics and Applications**
*Van de Walle, Tsukazaki, Brillson, Hsu, Norton*
308, Baltimore Convention Center

B5 FPS: **Nuclear Proliferation & Nuclear Terrorism**
*Cirincione, Fetter, Park, Carter*
309, Baltimore Convention Center

B6 DCMP: **Spin-Based Quantum Computing**
*Hanson, Ghosh, Flatté, Finley, Burkard*
310, Baltimore Convention Center

B7 DBP/ DCMP: **Bionanotechnology: Application and Fundamental Aspects of Processes at Nano-scale**
*Eisenberg, Kosztin, Stein, Yu, Kohli*
307, Baltimore Convention Center

B8 GSNP/ DFD: **Focus Session: Granular Materials Near Jamming**
*Campbell, Daniels*
314, Baltimore Convention Center

B9 DCMP: **Phase Transitions, Dynamics, and Excitations**
301, Baltimore Convention Center

B10 DCP: **Focus Sessions: Physical Chemistry of Nanoscale System II**
*El-Sayed, Dexheimer*
302, Baltimore Convention Center

B11 DCP: **Focus Session: Promises and Challenges in Chemical Dynamics II**
*Jortner, Brus*
303, Baltimore Convention Center

B12 DCMP/ DMP: **Quantum Metal Films and Overlayer Structures**
304, Baltimore Convention Center

B13 DCP/ DBP: **Focus Session: Spectroscopy of Biomolecules from Isolated Molecules to Cell Environment II**
*de Vries, Jarrold, Jockusch*
305, Baltimore Convention Center

B15 DCMP: **Metals: Lattice, Low D, Phonons**
*Burin*
311, Baltimore Convention Center

B16 FIAP: **Focus Session: Molecular-Scale Electronics I**
*Champagne*
312, Baltimore Convention Center

B17 FIAP: **Focus Session: Phase Transitions and Domains in Ferroelectric Nanostructures I**
*Levanyuk*
313, Baltimore Convention Center

B18 DMP: **Focus Session: Carbon Nanotubes: Synthesis, Processing and Characterization**
*Arnold*
315, Baltimore Convention Center

B19 GMAG/ DMP: **Focus Session: Transition Metal Oxide Ferromagnetic Semiconductors**
*Ogale*
316, Baltimore Convention Center

B20 GMAG/ DMP: **Focus Session: Phase Competition and Separation in Pervoskite Oxides**
*Wu*
317, Baltimore Convention Center

B21 DFD: **Colloids II: Colloidal Crystals, Gels, and Glasses**
318, Baltimore Convention Center

B22 GMAG/ FIAP/ DMP: **Focus Session: Current Driven Magnetization Dynamics II**
*Beach*
319, Baltimore Convention Center

B23 GMAG: **Quantum Spin Chains I**
320, Baltimore Convention Center

B26 DBP/ DPOLY: **Focus Session: Single Molecule Biophysics: DNA & RNA**
*Nelson*
323, Baltimore Convention Center

B28 DBP: **Experimental Techniques in Biomaterials Science**
325, Baltimore Convention Center

B29 DBP/ GSNP: **Focus Session: Micro-Organism Motility**
*Bodenschatz*
326, Baltimore Convention Center

B31 DCMP: **Insulating Nanostructures**
328, Baltimore Convention Center

B32 DCOMP/ DMP: **Focus Session: Computational Nanoscience I**
*Roundy*
329, Baltimore Convention Center

B33 GSNP: **Financial Markets and Other Applications of Statistical Physics**
336, Baltimore Convention Center

B35 DMP: **Focus Session: Nanoscale Thermal, Thermoelectric and Mass Transport: Theory and Simulation**
*Heinze*
338, Baltimore Convention Center

B36 DCMP: **Electronic Properties of Nanowires**
339, Baltimore Convention Center

B37 DCMP: **High-Tc: STM and Pseudogap**
340, Baltimore Convention Center

B38 DCMP: **Superconducting Devices and Applications**
341, Baltimore Convention Center

B39 DCMP: **Superconductivity—Magnetic Properties**
342, Baltimore Convention Center

B40 TGQI/ DCMP: **Topics in Quantum Foundations**
343, Baltimore Convention Center

B42 **SPS Undergraduate Research I**
345, Baltimore Convention Center

B43 DAMOP: **BEC in Trapped Atomic Gases**
346, Baltimore Convention Center

B46 DMP: **Focus Session: Wide Band Gap Semiconductors II**
*Wright*
349, Baltimore Convention Center

**13:30 MONDAY AFTERNOON 13 MARCH 2006**

B34 **Session on Authoring**
337, Baltimore Convention Center

**14:00 MONDAY AFTERNOON 13 MARCH 2006**

C1 **Poster Session I**
Exhibit Hall 2:00pm–5:00pm (DPOLY session: 11:15am–2:15pm), Baltimore Convention Center

**14:30 MONDAY AFTERNOON 13 MARCH 2006**

D1 DCMP: **Fluctuation and Relaxation Near Jamming**
*Langer, Makse, Abate, Silbert, Losert*
Ballroom IV, Baltimore Convention Center

D2 DCMP: **Quantum Hall Effect in Graphene**
*Kim, Geim, Sharapov, De Heer*
Ballroom III, Baltimore Convention Center

D3 FIP: **Scientists from Developing Countries: Is There an Effective Way to Support Meaningful Research?**
*Kofane, Ben lakdar, de Brito Cruz, M'Passi-Mabiala*
Ballroom I, Baltimore Convention Center

D4 DPOLY/ DMP: **Organic Electronics**
*Friend, Martin, Loo, Chabinyc, Lin*
308, Baltimore Convention Center

D5 FIAP: **Catalysis and Complexity: Ken Hass Memorial**
*Schneider, Wolverton, Carlsson, Davis*
309, Baltimore Convention Center

D6 DCOMP: **Simulating Hydrogen Storage: From Current Challenges to Future Promises**
*Johnson, Tse, Zhao, Jena, Goddard*
310, Baltimore Convention Center

D7 GMAG: **New Results in Geometrically Frustrated Magnets**
*Mendels, Moessner, Gardner, Schiffer, Lunkenheimer*
307, Baltimore Convention Center

D8 DFD/ GSNP: **Patterns and Instabilities I**
314, Baltimore Convention Center

D9 DBP: **Methods in Nanobiotechnology**
*Roukes, Austin, Michl, Wiseman, Hla*
301, Baltimore Convention Center

D10 DCP: **Focus Session: Physical Chemistry of Nanoscale System III**
*Leone, Xie*
302, Baltimore Convention Center

D11 DCP: **Focus Session: Promises and Challenges in Chemical Dynamics III**
*Kawasaki*
303, Baltimore Convention Center

D12 DCMP/ DMP: **Morphological Evolution and Instabilities**
304, Baltimore Convention Center

D13 DCP/ DBP: **Focus Session: Spectroscopy of Biomolecules from Isolated Molecules to Cell Environment III**
*Baumgart, Ha*
305, Baltimore Convention Center

D15 DCMP: **Focus Session: Atomic Tunneling, Films, Nanostructures**
*Enss*
311, Baltimore Convention Center

D16 FIAP: **Focus Session: Negative Refractive Index I**
*Brueck*
312, Baltimore Convention Center

D17 FIAP: **Focus Session: Phase Transitions and Domains in Ferroelectric Nanostructures II**
*Gregg*
313, Baltimore Convention Center

D18 DMP: **Focus Session: Carbon Nanotubes: Synthesis and Growth II**
315, Baltimore Convention Center

D19 GMAG/ DMP: **Focus Session: Semiconductor Spin Injection and Detection**
*Crowell*
316, Baltimore Convention Center

D20 DMP/ GMAG: **Focus Session: Multiferroics I**
317, Baltimore Convention Center

D21 DFD: **Colloids III: Particles at Interfaces and in Confined Geometries**
318, Baltimore Convention Center

D22 GMAG/ DMP: **Focus Session: Magnetic Nanopatterns**
*Chien*
319, Baltimore Convention Center

D23 GMAG/ DMP/ DCOMP: **Focus Session: MAGTHY I/Spin Structures and Dynamics**
*Dobrovitski*
320, Baltimore Convention Center

D25 DPOLY: **Focus Session: Particle Dynamics and Organization; Polymer Tethers and Interfacial Segregation**
*Smith*
322, Baltimore Convention Center

D26 DBP/ DPOLY: **Focus Session: Dynamics of Nuclei Acid-Protein Interaction: Single Molecule**
*Wang, Wuite*
323, Baltimore Convention Center

D27 DCOMP: **Focus Session: Novel Computational Algorithms I**
*Hu, Aspuru-Guzik*
324, Baltimore Convention Center

D28 DPOLY: **Block Copolymer Thin Films**
325, Baltimore Convention Center

D29 DBP/ GSNP: **Molecular Machines and Motors**
*Flood, Goldman*
326, Baltimore Convention Center

D30 DPOLY: **Multiphase Polymer Materials**
327, Baltimore Convention Center

D31 DCMP: **Properties of Semiconducting Nanostructures**
328, Baltimore Convention Center

D32 DCOMP/DMP: **Focus Session: Computational Nanoscience II**
329, Baltimore Convention Center

D33 DMP/GSNP: **Focus Session: Friction, Fracture and Deformation I**
*Dickinson*
336, Baltimore Convention Center

D35 DMP: **Focus Session: Thermal Transport and Thermoelectricity in Nanotubes and Graphene**
*Shi*
338, Baltimore Convention Center

D38 DMP: **Focus Session: Superconductivity—Properties of Doped and Irradiated Magnesium Diboride and Related Compounds**
*Putti*
341, Baltimore Convention Center

D39 DCMP: **Spin Properties of Superconductors**
342, Baltimore Convention Center

D40 TGQI/DCMP: **Focus Session: Foundations of Quantum Theory**
*Hardy*
343, Baltimore Convention Center

D42 SPS: **SPS Undergraduate Research II**
345, Baltimore Convention Center

D43 DAMOP: **Focus Session: Vortices and Vortex Lattices in Fermi and Bose Superfluid Gases**
*Zwierlein*
346, Baltimore Convention Center

D45 GMAG: **Strongly Correlated Electrons on Triangular Lattices**
348, Baltimore Convention Center

D46 DMP: **Focus Session: Wide Band Gap Semiconductors III**
*Huang*
349, Baltimore Convention Center

## 17:45 MONDAY EVENING 13 MARCH 2006

E5 **APS Prizes and Awards Ceremony**
309, Baltimore Convention Center

## 18:45 MONDAY EVENING 13 MARCH 2006

E6 **Welcome Reception**
Ballroom II, Baltimore Convention Center

## 20:00 MONDAY EVENING 13 MARCH 2006

F50 DCMP: **Emerging Emergent Phenomena**
*Witten, Lolle, Barabási, Sadoulet*
Grand Salons V-VI, Marriott Waterfront Hotel

## 8:00 TUESDAY MORNING 14 MARCH 2006

G1 **Nobel Prize Symposium and Special Prize Session**
*Hänsch, Hall, Glauber, Su, Grobe*
Ballroom IV, Baltimore Convention Center

G2 DCMP: **Quantum Criticality in Cuprates**
*Chamon, Tallon, Shibauchi, Lake, Broun*
Ballroom III, Baltimore Convention Center

G3 DCMP: **Coupled Superconducting Qubits**
*Shnirman, Martinis, Schuster, Plantenberg, Morpurgo*
Ballroom I, Baltimore Convention Center

G4 DPOLY: **Polymer Physics Prize**
*Leibler, Möller, Fredrickson, Candau, Colby*
308, Baltimore Convention Center

G5 DMP/FIAP: **Advanced Materials for Solar Energy Utilization**
*Lewis, Kurtz, Yong, Moore, Carlson*
309, Baltimore Convention Center

G7 GSNP: **Shear-Induced Patterns in Complex Fluids and Granular Matter**
*van Saarloos, Reichmann, Register, Davidovitch, Jaeger*
307, Baltimore Convention Center

G8 DFD/ GSNP: **Patterns and Instabilities II**
314, Baltimore Convention Center

G10 DCP: **Focus Sessions: Physical Chemistry of Nanoscale System IV**
*Yang, Xia*
302, Baltimore Convention Center

G11 DCP: **Focus Session: Promises and Challenges in Chemical Dynamics IV**
*Shafer-Ray*
303, Baltimore Convention Center

G12 DCMP/ DMP: **Self-Assembled Nanostructures: Growth and Patterning**
304, Baltimore Convention Center

G13 DCP/ DBP: **Focus Session: Spectroscopy of Biomolecules from Isolated Molecules to Cell Environment IV**
*Zwier, Hochstrasser, Mons*
305, Baltimore Convention Center

G15 DCMP: **Mechanical Properties of Metals**
311, Baltimore Convention Center

G16 FIAP: **Focus Session: Negative Refractive Index II**
*Narimanov*
312, Baltimore Convention Center

G17 FIAP: **Focus Session: Emerging Research Devices and Materials for Microelectronics Industry I**
*Vogel*
313, Baltimore Convention Center

G18 DMP: **Focus Session: Carbon Nanotubes: Electronic and Optical Properties I**
*Spataru*
315, Baltimore Convention Center

G19 GMAG/ DMP: **Focus Session: III-V Magnetic Semiconductors I**
*Poggio*
316, Baltimore Convention Center

G20 DMP/ GMAG: **Focus Session: Complex Oxide Thin Films Surfaces and Interfaces II: Surfaces and Theory**
317, Baltimore Convention Center

G21 DFD: **Colloids IV: Polymeric and Colloid-Polymer Systems**
318, Baltimore Convention Center

G22 GMAG/ DMP: **Focus Session: Magnetic Nanoparticles I**
*Leslie-Pelecky*
319, Baltimore Convention Center

G23 GMAG/ DMP/ DCOMP: **Focus Session: MAGTHY II/ Transport & General**
*Yao*
320, Baltimore Convention Center

G24 DPOLY: **Polymer Nanomaterials I**
321, Baltimore Convention Center

G25 DPOLY: **Structure and Dynamics of Functional Macromolecules**
322, Baltimore Convention Center

G26 DBP: **Focus Session: Trapping of Nanoscale Biological Objects**
*Cohen, Gratton*
323, Baltimore Convention Center

G27 DCOMP: **Focus Session: Novel Computational Algorithms II**
*Bai, Baroni*
324, Baltimore Convention Center

G28 DPOLY: **Focus Session: Microphysical Properties of Block Copolymer Aggregates I**
*Discher*
325, Baltimore Convention Center

G29 DBP: **Focus Session: Physical and Engineering Constraints on the Function of Biological Systems**
*Lezon, Doyle*
326, Baltimore Convention Center

G30 DPOLY/ DMP: **Focus Session: Electronic Transport in Organic Films**
*De Feyter, Charra*
327, Baltimore Convention Center

G31 DCOMP/ DMP: **Focus Session: Simulation of Complex Materials I**
*Wagner*
328, Baltimore Convention Center

G32 DMP/ GMAG: **Focus Session: Orbital/Charge Order in Complex Oxides**
*Ye*
329, Baltimore Convention Center

G33 GSNP: **GSNP Student Award Session and Glasses**
336, Baltimore Convention Center

G34 DFD: **Glassy Dynamics and Jamming**
337, Baltimore Convention Center

G35 DCMP: **Nanoparticles, Nanotubes and Nanocrystals: Optical and Structural Properties**
338, Baltimore Convention Center

G37 DMP: **Focus Session: Nanoscale Materials Physics of Phase Transitions I**
*Dawber*
340, Baltimore Convention Center

G38 DMP: **Focus Session: Superconductivity—Carbon Alloying of Magnesium Diboride and Related Compounds**
*Wilke*
341, Baltimore Convention Center

G39 DCMP/ DCOMP: **Focus Session: Superconductivity: Theory and Computation I**
*Scalapino*
342, Baltimore Convention Center

G40 DMP: **Focus Session: Materials for Quantum Computing I**
343, Baltimore Convention Center

G41 DCMP: **Supersolid**
344, Baltimore Convention Center

G42 FEd: **Physics Education Research and Undergraduate Education**
345, Baltimore Convention Center

G44 DCMP: **Charge-Density Waves**
347, Baltimore Convention Center

G45 GMAG: **Phase Transitions in Ruthenates**
348, Baltimore Convention Center

G46 FIAP: **QHE, Including Graphene**
349, Baltimore Convention Center

## 11:15 TUESDAY MORNING 14 MARCH 2006

H1 GQI: **Quantum Information, Concepts and Computation**
*Blatt, Yamamoto, Raizen, Gisin, Whaley*
Ballroom IV, Baltimore Convention Center

H2 DCMP: **Spin Liquids in 2D Frustrated Quantum Magnets**
*Coldea, Alicea, Kanoda, Motrunich, Lee*
Ballroom III, Baltimore Convention Center

H3 DCMP: **Soft Interfaces**
*Quere, Zhang, Stebe, Hilgenfeldt, Gopal*
Ballroom I, Baltimore Convention Center

H4 DCMP: **Physics for Everyone and Depletion Forces In Vitro and Out of Equilibrium**
*Dahlberg, Falco, Schwartz, Snir, Lewis*
308, Baltimore Convention Center

H5 FEd/ FGSA/ FPS/ CSWP: **Forum: What Has Actually Changed in Physics Departments in the Situation for Women, Graduate Students and Other People?**
309, Baltimore Convention Center

H6 DCOMP: **The Response of Extended Systems to Electrical and Magnetic Fields: Novel, Theoretical, and Computational Methods**
*Thonhauser, MacDonald, Cai, Umari, Ghosez*
310, Baltimore Convention Center

H7 DBP: **Nanopore Biophysics**
*Kasianowicz, Dekker, Movileanu, Li, Aksimentiev*
307, Baltimore Convention Center

H8 GSNP: **Focus Session: Jamming in Glasses, Grains, and Gels I**
*Maloney*
314, Baltimore Convention Center

H10 DCP: **Focus Session: Frontiers in Computational Chemical Physics I**
*Lin, Angel*
302, Baltimore Convention Center

H11 DCP: **Focus Session: Chemical and Spectroscopic Applications of Nonlinear Optics I**
*Eisenthal, Shultz*
303, Baltimore Convention Center

H12 DCMP/ DMP: **Thin Film Growth and Interfaces**
304, Baltimore Convention Center

H13 DCP: **Colloid and Polymer Interfaces**
305, Baltimore Convention Center

H15 DCMP: **Metals: Electronic Structure, Fermiology, Transport**
311, Baltimore Convention Center

H16 FIAP: **Focus Session: Hydrogen Storage II**
*Ahn*
312, Baltimore Convention Center

H17 FIAP: **Focus Session: Emerging Research Devices and Materials for Microelectronics Industry II**
*Coufal*
313, Baltimore Convention Center

H18 DMP: **Focus Session: Carbon Nanotubes: Electronic and Optical Properties II**
*Lienau, Chang*
315, Baltimore Convention Center

H19 GMAG/ DMP: **Focus Session: III-V Magnetic Semiconductors II**
*Burch*
316, Baltimore Convention Center

H20 GMAG: **Frustration in 3D**
317, Baltimore Convention Center

H21 DFD: **Focus Session: Microfluidic Physics I**
*Paoletti*
318, Baltimore Convention Center

H22 GMAG/ DMP: **Focus Session: Nanoparticles and Nanocomposites**
*Wang*
319, Baltimore Convention Center

H23 GMAG/ DMP/ FIAP: **GMR and AMR**
320, Baltimore Convention Center

H24 DPOLY: **Polymers at Interfaces**
321, Baltimore Convention Center

H25 DPOLY: **Focus Session: Particle Dynamics and Organization**
322, Baltimore Convention Center

H27 DCOMP: **Computational Methods: Multiscale Modeling**
324, Baltimore Convention Center

H28 DPOLY/ DMP: **Focus Session: Energetics and Transport in Conjugated Organics**
*Silva*
325, Baltimore Convention Center

H29 DBP: **Focus Session: Physical Aspects of Morphogenesis: Computational Approaches**
*Brodland, Jiang*
326, Baltimore Convention Center

H30 DPOLY: **Padden Award Symposium**
327, Baltimore Convention Center

H31 DCOMP/ DMP: **Focus Session: Simulation of Complex Materials II**
*Ogitsu*
328, Baltimore Convention Center

H32 DCOMP/ DMP: **Focus Session: Computational Nanoscience III**
*Zhang*
329, Baltimore Convention Center

H33 DMP/ GSNP: **Focus Session: Friction, Fracture and Deformation II**
*Gnecco*
336, Baltimore Convention Center

H35 DCMP: **Electronic Properties of Quantum Wells and Superlattices**
338, Baltimore Convention Center

H36 DMP: **Focus Session: Single Molecule Conductance**
*Weber*
339, Baltimore Convention Center

H37 DMP: **Focus Session: Nanoscale Materials Physics of Phase Transitions II**
*Albrecht*
340, Baltimore Convention Center

H38 DCMP: **Superconductivity—Disordered Thin Films and Quantum Phenomena**
341, Baltimore Convention Center

H39 DCMP: **Focus Session: Superconductivity—Josephson Junctions and Pairing State Symmetry**
*Klemm*
342, Baltimore Convention Center

H40 DMP: **Focus Session: Materials for Quantum Computing II**
*Buhrman*
343, Baltimore Convention Center

H41 DMP: **Dielectric, Ferroelectric, and Piezoelectric Oxides I**
344, Baltimore Convention Center

H42 GSCCM/ DCMP: **Focus Session: Dynamic Compression**
*Hayes, Minich*
345, Baltimore Convention Center

H43 DAMOP: **Focus Session: Strongly Interacting Fermi Gases and the BCS-BEC Crossover II**
*Regal*
346, Baltimore Convention Center

H44 DCMP: **Quantum Phase Transitions**
347, Baltimore Convention Center

H45 DCMP: **Theoretical Methods in Strongly Correlated Electron Systems**
348, Baltimore Convention Center

H46 DMP: **Focus Session: Wide Band Gap Semiconductors IV**
*Qian*
349, Baltimore Convention Center

## 14:00 TUESDAY AFTERNOON 14 MARCH 2006

J1 **Poster Session II**
Exhibit Hall, 2:00pm–5:00pm, Baltimore Convention Center

## 14:30 TUESDAY AFTERNOON 14 MARCH 2006

K1 DAMOP: **Optical Frequency Clocks and Experimental Quantum Optics**
*Gill, Udem, Ye, Bergquist, Haroche*
Ballroom IV, Baltimore Convention Center

K2 DCMP: **Exotic Ordering in Spinels**
*Croft, Horibe, Khomskii, Sushkov, Radaelli*
Ballroom III, Baltimore Convention Center

K3 DCMP: **Electron Doped High Tc Superconductors**
*Dagan, Blumberg, Takahashi, Motoyama, Naito*
Ballroom I, Baltimore Convention Center

K4 DMP/ CSWP: **DMP/CSWP Prize Symposium**
*Chelikowsky, Cao, Dai, Zettl*
308, Baltimore Convention Center

K5 FIAP: **Microelectronics for Mid-Infrared through Terahertz**
*Gmachl, Prober, Shaner, Tredicucci, Schmidt*
309, Baltimore Convention Center

K6 COM: **Minorities in the Nanosciences**
*Mason, James, Noveron, Stokes*
310, Baltimore Convention Center

K7 DBP: **New Methods and Algorithms for Biomolecular Modeling**
*Darve, Sagui, Thorpe, Tuckerman, Yang*
307, Baltimore Convention Center

K8 GSNP: **Focus Session: Jamming in Glasses, Grains and Gels II**
*Blair*
314, Baltimore Convention Center

K10 DCP: **Focus Session: Frontiers in Computational Chemical Physics II**
*Reuter*
302, Baltimore Convention Center

K11 DCP: **Focus Session: Chemical and Spectroscopic Applications of Nonlinear Optics II**
*Shen, Simpson, Morita*
303, Baltimore Convention Center

K12 DMP/DCMP: **Focus Session: Magnetic Thin Films and Narrow Gap Semiconductors**
*Weitering*
304, Baltimore Convention Center

K13 DCP: **Atomic And Molecular Processes at Solid Surfaces**
305, Baltimore Convention Center

K16 FIAP: **Focus Session: Molecular-Scale Electronics II**
*Karna*
312, Baltimore Convention Center

K17 FIAP: **Focus Session: Si, Ge and SiGe Nanostructures**
*Ross, Kamins*
313, Baltimore Convention Center

K18 DPOLY: **Focus Session: Dillon Medal Symposium**
*Urayama*
315, Baltimore Convention Center

K19 GMAG/DMP: **Focus Session: III-V Magnetic Semiconductors III**
*van Schilfgaarde*
316, Baltimore Convention Center

K20 DMP/GMAG: **Focus Session: Multiferroics II—Hexagonal Systems**
*Fennie*
317, Baltimore Convention Center

K21 DFD: **Colloids V**
318, Baltimore Convention Center

K22 GMAG/FIAP/DMP: **Focus Session: Magnetization Dynamics**
*Rasing*
319, Baltimore Convention Center

K23 GMAG: **Quantum Magnets: BEC and 2D**
320, Baltimore Convention Center

K24 DPOLY: **Polymer Nanomaterials II**
321, Baltimore Convention Center

K25 DPOLY: **Polymer Electrolytes and Conduction**
322, Baltimore Convention Center

K26 DBP/DCMP: **Focus Session: Single Molecule Biophysics I**
*Chu*
323, Baltimore Convention Center

K27 DCOMP: **Density Functional Theory**
324, Baltimore Convention Center

K28 DPOLY: **Focus Session: Microphysical Properties of Block Copolymer Aggregates II**
*Santore*
325, Baltimore Convention Center

K29 DBP: **Proteins Structure and Function**
326, Baltimore Convention Center

K30 DMP: **Carbon Nanotubes: Applications and Novel Phenomena**
327, Baltimore Convention Center

K31 DCOMP/DMP: **Focus Session: Simulation of Complex Materials III**
*Blum*
328, Baltimore Convention Center

K32 DCOMP/DMP: **Focus Session: Computational Nanoscience IV**
329, Baltimore Convention Center

K33 GSNP: **Novel Moving Boundary Problems**
*Krug, Kessler, Ebert, Goldstein, Karma*
336, Baltimore Convention Center

K34 **Panel Discussion**
337, Baltimore Convention Center

K35 DCMP: **Electronic Properties and the Kondo Effect in Quantum Dots**
338, Baltimore Convention Center

K36 GMAG: **Magnetic Domains and Applied Magnetic Materials**
339, Baltimore Convention Center

K37 DCMP: **Superconductivity—Time Resolved Optical and Inelastic X-ray Scattering in Cuprates**
340, Baltimore Convention Center

K38 DCMP: **Superconductivity—Mesoscopics and Theory**
341, Baltimore Convention Center

K39 DCOMP/DCMP: **Focus Session: Superconductivity—Theory and Computation II**
*Fabrizio*
342, Baltimore Convention Center

K40 DMP: **Focus Session: Materials for Quantum Computing III**
*McDermott*
343, Baltimore Convention Center

K41 DMP: **Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides II**
*Venturini*
344, Baltimore Convention Center

K42 DMP/DCOMP: **Focus Session: Planetary Materials II**
345, Baltimore Convention Center

K43 DAMOP: **Trapped Fermi Gases**
346, Baltimore Convention Center

K44 DCMP: **Transport in Disordered Electronic Systems**
347, Baltimore Convention Center

K45 DCMP: **Heavy Fermions: Experiment**
348, Baltimore Convention Center

K46 FIAP: **Spectroscopy of Semiconductors**
349, Baltimore Convention Center

**17:30 TUESDAY EVENING**
**14 MARCH 2006**

L9 GIMS: **GIMS Business Meeting**
301, Baltimore Convention Center

L10 DCP: **DCP Business Meeting**
302, Baltimore Convention Center

L16 FIAP: **FIAP Business Meeting**
312, Baltimore Convention Center

L18 DPOLY: **DPOLY Business Meeting**
315, Baltimore Convention Center

L23 GMAG: **GMAG Business Meeting**
320, Baltimore Convention Center

L29 DBP: **DBP Business Meeting**
326, Baltimore Convention Center

L33 GSNP: **GSNP Business Meeting**
336, Baltimore Convention Center

L40 TGQI: **TGQI Business Meeting**
343, Baltimore Convention Center

L48 FIP: **FIP Business Meeting**
Galena, Marriott Waterfront Hotel

**17:45 TUESDAY EVENING**
**14 MARCH 2006**

L7 DBP: **Flexible Molecular Recognition: The New Paradigm**
*Matthews, Kern, Taylor, Jennings, Wang*
307, Baltimore Convention Center

**19:00 TUESDAY EVENING**
**14 MARCH 2006**

L49 DCMP: **DCMP Business Meeting**
Dover A, Marriott Waterfront Hotel

L50 DMP: **DMP Business Meeting**
Dover B, Marriott Waterfront Hotel

**19:30 TUESDAY EVENING**
**14 MARCH 2006**

M50 FPS: **Intelligent Design: Its Impact and Responses to It**
*Gunn, Berman, Slakey, Dean*
Grand Salon V, Marriott Waterfront Hotel

**8:00 WEDNESDAY MORNING**
**15 MARCH 2006**

N1 DCMP: **Topological Phases and Quantum Computing**
*Kitaev, Hermele, Freedman, Stern, Fendley*
Ballroom IV, Baltimore Convention Center

N2 DCMP: **Nanoscale Crystals**
*Craig, Alivisatos, Drndic, Krauss*
Ballroom III, Baltimore Convention Center

N3 DCMP: **Insulating Cobaltates: Mottness on a Triangular Lattice**
*Gasparovic, Hasan, Zandbergen, Balicas, Imai*
Ballroom I, Baltimore Convention Center

N4 DPOLY/DMP: **Polymer Crystallization**
*Cheng, Hsiao, Ungar, Muthukumar, Granasy*
308, Baltimore Convention Center

N5 FIAP: **Pake and AIP Industrial Physics Prizes**
*Duke, Semerjian, Palffy-Muhoray, Lubell, Edelstein*
309, Baltimore Convention Center

N6 DAMOP: **Fermi Superfluid Gases: Non-equal Spin Polarization (FFLO State) and p-Wave pairing**
*Son, Yip, Hulet, Diener, de Melo*
310, Baltimore Convention Center

N7 DCOMP: **Recent Advances in the Computation of Optical and Transport Properties of Nanostructures**
*Weissker, Bester, Gebauer, Sanvito, Pecchia*
307, Baltimore Convention Center

N8 DFD: **Granular Flows**
314, Baltimore Convention Center

N10 DCP: **Focus Session: Frontiers in Computational Chemical Physics III**
*Cui*
302, Baltimore Convention Center

N11 DCP: **Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects I: Helium Nanodroplets I**
*Drabbels, Tiggesbäumker*
303, Baltimore Convention Center

N12 DMP/ DCMP: **Focus Session: Alloy and Interface Composition**
*Hannon*
304, Baltimore Convention Center

N13 DCP: **Focus Session: Ultrafast and Ultrahigh Field Chemistry I: Strong Field Phenomena**
*Jones, Yamanouchi*
305, Baltimore Convention Center

N16 FIAP: **Focus Session: Hydrogen Storage III**
*Yildirim*
312, Baltimore Convention Center

N17 FIAP: **Focus Session: Semiconductors for THz and IR I**
*Perera*
313, Baltimore Convention Center

N18 DMP: **Focus Session: Carbon Nanotubes: Transport I**
*Strunk*
315, Baltimore Convention Center

N19 GMAG/ DMP: **Semiconductor Spin Transport**
316, Baltimore Convention Center

N20 DMP/ GMAG: **Focus Session: Complex Oxide Thin Films Surfaces and Interfacess III: New Materials, New Techniques, and Effects of Strain**
317, Baltimore Convention Center

N21 DFD: **Microfluidic Physics II**
318, Baltimore Convention Center

N22 GMAG/ DMP: **Focus Session: Magnetic Vortices and Exchange Biased Thin Films**
*Roshchin*
319, Baltimore Convention Center

N23 GMAG/ DMP/ DCOMP: **Focus Session: MAGTHY III: Oxides and Phase Transitions**
*Schulthess*
320, Baltimore Convention Center

N24 DPOLY: **Structure and Dynamics in Polymer Thin Films**
321, Baltimore Convention Center

N25 DPOLY/ DMP: **Focus Session: Organic Photovoltaics**
*Inganäs*
322, Baltimore Convention Center

N26 DBP/ DFD: **Focus Session: DNA and Protein Analysis with Micro and Nano Fluidics**
*Riehn, Hansen*
323, Baltimore Convention Center

N27 DCOMP: **Electronic Structure I**
324, Baltimore Convention Center

N28 DPOLY: **Polymer Adsorption and Surface Modification**
325, Baltimore Convention Center

N29 DBP: **Focus Session: Physical Models of Ion Channel Function**
*Gillespie, Coalson*
326, Baltimore Convention Center

N30 DPOLY: **Block Copolymer Phase Behavior**
*327, Baltimore Convention Center*

N31 DCMP: **Carbon Nanotubes: Theory**
*328, Baltimore Convention Center*

N32 DMP/ DPOLY: **Focus Session: Carbon Nanotubes: Composites and Applications**
*Baughman*
329, Baltimore Convention Center

N33 GSNP: **Focus Session: Instabilities & Turbulence in Complex Fluids**
*Sureshkumar*
336, Baltimore Convention Center

N35 GSNP: **Focus Session: Organization of Complex Networks**
*Mendes*
338, Baltimore Convention Center

N36 DMP: **Focus Session: Optical Properties of Nanostructures with S, Se, Te, and Ge**
339, Baltimore Convention Center

N37 DMP: **Focus Session: Nanoscale Fabrication, Assembly and Semiconductor Nanowires**
*Misra*
340, Baltimore Convention Center

N38 DCMP: **Transport Properties of High-Tc Superconductors**
341, Baltimore Convention Center

N39 DMP: **Focus Session: Superconductivity—Thin Films and Junctions Magnesium Diboride and Related Compounds**
*Xi*
342, Baltimore Convention Center

N41 DCMP: **Insulating and Dielectric Oxides**
344, Baltimore Convention Center

N42 DCOMP/ GSCCM/ DMP: **Focus Session: Simulations of Matter at Extreme Conditions I**
*Johansson*
345, Baltimore Convention Center

N43 DAMOP: **Quantum Optics and Strong Field Physics**
346, Baltimore Convention Center

N44 DCMP: **Quantum Criticality and Nematic Ordering**
347, Baltimore Convention Center

N45 DCMP: **Exotic Phases in Strongly Correlated Systems**
348, Baltimore Convention Center

N46 FIAP: **Semiconductor Devices/ Semiconductors General**
349, Baltimore Convention Center

## 9:30 WEDNESDAY MORNING 15 MARCH 2006

N34 **Session on Referreeing**
337, Baltimore Convention Center

## 11:15 WEDNESDAY MORNING 15 MARCH 2006

P1 DCMP: **Electron Transport in Single Molecules**
*Tao, Yao, Flensberg, Wolkow, Bar-Joseph*
Ballroom IV, Baltimore Convention Center

P2 DCMP: **The Electronic Properties of Overdoped Cuprates: The Clean Gateway to High-Tc Superconductivity**
*Hussey, Damascelli, Slezak, Taillefer, van der Marel*
Ballroom III, Baltimore Convention Center

P3 FEd: **Physics Teacher Preparation at a Crisis: Innovative Programs Addressing a National Need**
*Heron, Marder, Stewart, Finkelstein, Hein*
Ballroom I, Baltimore Convention Center

P4 GIMS: **Keithley Award Session**
*Hellman, Jach, Fortune, Migliori*
308, Baltimore Convention Center

P5 DFD: **Shedding Light on the Enigma of the Transition to Turbulence in Pipes and other Shear Flows**
*Mullin, Henningson, Waleffe, Kerswell, Tumin, Eckhardt*
309, Baltimore Convention Center

P6 GMAG: **Quantum Spin Dynamics in Molecular Nanomagnets**
*Waldmann, Chudnovsky, Sessoli, Harmon, Park*
310, Baltimore Convention Center

P7 GSNP/DBP: **Focus Session: Physics of Transcriptional Regulatory Networks**
*You, Buchler, Li, Huang, Vazquez*
307, Baltimore Convention Center

P8 DFD/GSNP: **Focus Session: Jets, Shocks & Splashes**
*Xu, Lohse*
314, Baltimore Convention Center

P10 DCP: **Focus Session: Frontiers in Computational Chemical Physics IV**
*Martinez*
302, Baltimore Convention Center

P11 DCP: **Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects II: Helium Nanodroplets II, Aerosols, and Miscellaneous**
*Signorell*
303, Baltimore Convention Center

P12 DCMP/DMP: **Metal Islands and Clusters**
304, Baltimore Convention Center

P13 DCP: **Focus Session: Ultrafast and Ultrahigh Field Chemistry II: Quantum Control**
*Silberberg, Girard*
305, Baltimore Convention Center

P16 FIAP: **Focus Session: Molecular-Scale Electronics III**
*Janes*
312, Baltimore Convention Center

P18 DMP: **Focus Session: Carbon Nanotubes: Opto-Electronics**
*Chen*
315, Baltimore Convention Center

P19 GMAG/DMP: **Focus Session: Spin Interference and Spin Hall Effect**
*Sih*
316, Baltimore Convention Center

P20 DMP/GMAG: **Focus Session: Cobaltites, Nickelates and Vanadates**
317, Baltimore Convention Center

P21 DFD: **Microfluidic Physics III**
318, Baltimore Convention Center

P22 GMAG/FIAP/DMP: **Focus Session: Spin Transport in Metals**
*Garzon*
319, Baltimore Convention Center

P23 GMAG: **Quantum Spin Chains II**
320, Baltimore Convention Center

P26 DBP/DCP: **Focus Session: Protein Dynamics in Folding and Function**
*Mildvan, de Alba, Miller, Summers, Campbell, Hall, Pastor, Redfield*
323, Baltimore Convention Center

P27 DCOMP: **Electronic Structure II**
324, Baltimore Convention Center

P29 DBP: **Biomolecular Structure and Functions**
326, Baltimore Convention Center

P30 DPOLY/DMP: **Focus Session: Organic Interfaces**
*Rosei*
327, Baltimore Convention Center

P31 DCMP: **Nanotubes: Theory and Experiment**
328, Baltimore Convention Center

P32 GMAG: **Spin Glasses**
329, Baltimore Convention Center

P33 DMP/GSNP: **Focus Session: Friction, Fracture and Deformation III**
*Falk*
336, Baltimore Convention Center

P35 DCMP: **Nanostructure Fabrication, Quantum Point Contacts, and Single Electron Transistors**
338, Baltimore Convention Center

P36 DMP: **Focus Session: Plasmon Resonances in Nanostructures**
339, Baltimore Convention Center

P38 DCMP: **Superconductivity—Optical Spectroscopy of Cuprates**
341, Baltimore Convention Center

P39 DCOMP/DCMP: **Focus Session: Superconductivity—Theory and Computation (Mainly First Principles)**
*Mazin*
342, Baltimore Convention Center

P40 DCOMP/TGQI: **Focus Session: Pathways to Practical Quantum Computing I**
*DiVincenzo*
343, Baltimore Convention Center

P41 DMP: **Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides III**
*Dierolf*
344, Baltimore Convention Center

P42 DMP/ DCOMP: **Focus Session: Planetary Materials III**
345, Baltimore Convention Center

P43 DAMOP: **Novel Phases in Quantum Gases**
346, Baltimore Convention Center

P44 DCMP: **Organic Conductors**
347, Baltimore Convention Center

P45 DCMP: **Structural and Ferroelectric Phase Transitions**
348, Baltimore Convention Center

P46 FIAP: **FQHE**
349, Baltimore Convention Center

## 13:00 WEDNESDAY AFTERNOON 15 MARCH 2006

Q1 **Poster Session III**
Exhibit Hall, 1:00pm–4:00pm (DPOLY session: 11:15am–2:15pm), Baltimore Convention Center

## 14:30 WEDNESDAY AFTERNOON 15 MARCH 2006

R1 DCMP DBP: **Cytoskeletal Dynamics and Mechanics**
*Svitkina, Julicher, Gopinathan, Gardel, Storm*
Ballroom IV, Baltimore Convention Center

R2 DCMP: **Fractional Quantum Hall Systems**
*Csathy, Gallais, Peterson, Kim, Schulze-Wischeler*
Ballroom III, Baltimore Convention Center

R3 DCMP: **Lateral Spin Transport**
*Ji, Bauer, Valenzuela, Otani*
Ballroom I, Baltimore Convention Center

R4 DPOLY: **Ionic, Dipolar and H-bonding Polymers**
*Breedveld, Dormidontova, Pochan, Cremer, Prabhu*
308, Baltimore Convention Center

R5 FGSA/ FIAP: **Paths from Academics to Employment**
*Czujko, Silbernagel, Seiler, Stanton, Garg*
309, Baltimore Convention Center

R6 CSWP: **U.S. Women in Physics: An International Perspective**
*Michelman-Ribeiro, Whitten, Horton, Ong, Hodari*
310, Baltimore Convention Center

R7 DBP/ FEd/ FPS: **The Experimental and Theoretical Foundations of Evolution**
*Keymer, Deem, Fisher, Lenski, Shapiro*
307, Baltimore Convention Center

R8 DFD: **Monolayers, Membranes & Microemulsions**
314, Baltimore Convention Center

R9 GIMS: **Imaging, Signal Detection and Processing**
301, Baltimore Convention Center

R10 DCP: **Focus Session: Surfaces and Interfaces in Electronic Materials I**
*Wieckowski, Switzer*
302, Baltimore Convention Center

R11 DCP: **Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects III: Molecular Clusters**
*Johnson*
303, Baltimore Convention Center

R12 DCMP/ DMP: **Dynamics at Silicon Surfaces**
304, Baltimore Convention Center

R13 DCP: **Focus Session: Ultrafast and Ultrahigh Field Chemistry III: Ultrafast Processes**
*Schafer, Villeneuve, Matsumoto*
305, Baltimore Convention Center

R16 FIAP: **Thermoelectrics**
312, Baltimore Convention Center

R17 FIAP: **Focus Session: Semiconductors for THz and IR II**
*Zhang*
313, Baltimore Convention Center

R18 DMP: **Focus Session: Carbon Nanotubes: Transport II**
*Roche*
315, Baltimore Convention Center

R19 GMAG/DMP: **Focus Session: Spin Hall Effect and Spin Transport**
*Engel*
316, Baltimore Convention Center

R20 DMP/GMAG: **Focus Session: Multiferroics III: Perovskites**
317, Baltimore Convention Center

R21 DFD/DBP: **Focus Session: Biological Hydrodynamics**
*Aranson*
318, Baltimore Convention Center

R22 GMAG/DMP: **Focus Session: Biomagnetism and Exchange Biased Thin Films**
*Hoffmann*
319, Baltimore Convention Center

R23 GMAG/FIAP: **Focus Session: Theory and Simulation for Information Storage Applications**
*Schrefl*
320, Baltimore Convention Center

R24 DPOLY: **Block Copolymer Applications**
321, Baltimore Convention Center

R25 DPOLY: **Adhesion and Viscoelasticity in Polymer Thin Films**
322, Baltimore Convention Center

R26 DBP/DPOLY: **Focus Session: Counterion Dynamics in Charged Biopolymer Systems**
*Wong, Netz*
323, Baltimore Convention Center

R27 DCOMP: **Many-Body/Strongly Correlated**
324, Baltimore Convention Center

R28 DBP: **Focus Session: Biological Networks: Structure, Dynamics and Function**
*El-Samad, Suel*
325, Baltimore Convention Center

R29 DBP: **Biomolecular Structure and Function**
326, Baltimore Convention Center

R30 DPOLY: **Polymer Nanocomposites**
327, Baltimore Convention Center

R31 DCMP: **Properties of Carbon Nanotubes**
328, Baltimore Convention Center

R32 DCOMP/DMP: **Focus Session: Computational Nanoscience V**
*Tangney*
329, Baltimore Convention Center

R33 DMP/GSNP: **Focus Session: Friction, Fracture and Deformation IV**
*Houston*
336, Baltimore Convention Center

R34 DFD: **Turbulence**
337, Baltimore Convention Center

R36 DMP: **Focus Session: Optical and X-ray Properties of Nanostructures**
*Vasiliev*
339, Baltimore Convention Center

R37 DMP: **Focus Session: Nanoscale Conductance Theory I**
*Baranger*
340, Baltimore Convention Center

R38 DCMP: **Superconductivity—Optical Spectroscopy of Cuprates: IR Hall Effect**
341, Baltimore Convention Center

R39 DCMP: **Superconductivity—Sodium Cobaltate**
342, Baltimore Convention Center

R40 DCOMP/TGQI: **Focus Session: Pathways to Practical Quantum Computing II**
*Laflamme*
343, Baltimore Convention Center

R41 DMP: **Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides IV**
*Streiffer*
344, Baltimore Convention Center

R42 DCMP/GSCCM: **Focus Session: Plasticity and Phase Transitions**
*Robinson, Lorenz*
345, Baltimore Convention Center

R43 DAMOP: **One Dimensional Bose Gases**
346, Baltimore Convention Center

R44 DCMP: **Experimental Studies of 115 Materials**
347, Baltimore Convention Center

R45 DCMP: **Strong Correlation in Metals: Mott Transition**
348, Baltimore Convention Center

R46 FIAP: **Electronic and Optical Properties of Semiconductors: First Principals**
349, Baltimore Convention Center

**17:30 WEDNESDAY EVENING 15 MARCH 2006**

S48 FED: **FED Business Meeting & Reception**
Grand Ballroom Salon III, Marriott Waterfront Hotel

**17:45 WEDNESDAY EVENING 15 MARCH 2006**

T7 DBP: **Physics, Chemistry and Biology of the Hydrophobic Effect**
*Li, Widom, Chandler, Truskett*
307, Baltimore Convention Center

**18:30 WEDNESDAY EVENING 15 MARCH 2006**

S49 DCOMP: **DCOMP Business Meeting**
Dover C, Marriott Waterfront Hotel

**19:30 WEDNESDAY EVENING 15 MARCH 2006**

T50 **Perspectives on our Energy Future**
*Koonin, Dehmer*
Grand Salon V, Marriott Waterfront Hotel

**8:00 THURSDAY MORNING 16 MARCH 2006**

U1 DCMP: **Spin Liquids and Superconductivity near the Mott Transition**
*Lee, Schmalian, Tremblay, Mook, Bourges*
Ballroom IV, Baltimore Convention Center

U2 DCMP: **Quantum Magnets in High Magnetic Fields**
*Broholm, Grenier, Zheludev, Hagiwara, Essler*
Ballroom III, Baltimore Convention Center

U3 DCMP: **Nanomechanical Architecture of Strained Thin Films**
*Prinz, Liu, Schmidt, Blick*
Ballroom I, Baltimore Convention Center

U4 DPOLY: **Lithography**
*Willson, Dammel, Nealey, Jones, Hinsberg*
308, Baltimore Convention Center

U5 FHP: **Low Temperature Physics, A Historical Perspective**
*Wheeler, Donnelly, Meyer, Lee*
309, Baltimore Convention Center

U6 DCOMP: **Strong Electronic Correlation in Solids: Applications of the LDA+U method**
*Louie, Janotti, Lichtenstein, Kunes, Cococcioni*
310, Baltimore Convention Center

U7 FIAP: **Nanoscale Pattern Generation and Lithography**
*Hector, Smith, Baglin, Kim, Russell*
307, Baltimore Convention Center

U8 DFD: **Granular Materials**
314, Baltimore Convention Center

U9 GIMS: **Scanning Probe Microscopy**
301, Baltimore Convention Center

U10 DCP: **Focus Session: Surfaces and Interfaces in Electronic Materials II**
*Buriak, Wang*
302, Baltimore Convention Center

U11 DCP: **Focus Session: Aerosols, Clusters, Droplets: Physics and Chemistry of Nanoobjects IV: Metal Clusters I**
*Duncan, Woeste*
303, Baltimore Convention Center

U12 DMP/ DCMP: **Focus Session: Electrochemical and Related Growth**
*Wang*
304, Baltimore Convention Center

U16 FIAP: **Nanotechnology: Applications and Measurements**
312, Baltimore Convention Center

U17 DBP: **Physics and Imaging in Medicine**
*Amols, Soares, Baird, Gueye*
313, Baltimore Convention Center

U18 DMP: **Focus Session: Carbon Nanotubes: Transport III**
*Ferrari*
315, Baltimore Convention Center

U19 GMAG/ DMP: **Focus Session: Semiconductor Spin Nanostructures for Quantum Computing**
*Mizel*
316, Baltimore Convention Center

U20 DMP/ GMAG: **Focus Session: Metal-Insulator Transition and Electron Phonon Coupling in Perovskites**
*Alvarez*
317, Baltimore Convention Center

U21 DFD: **Liquid Crystals I**
318, Baltimore Convention Center

# MAIN TEXT

**SESSION 1B: GSCCM BUSINESS MEETING**
**Sunday Afternoon, 12 March 2006; Falkland, Marriott Waterfront Hotel at 15:00**

**SESSION 1A: NRC/NAS TOWN MEETING**
**Sunday Evening, 12 March 2006; Grand Ballroom Salon V, Marriott Waterfront Hotel at 19:30**

**SESSION A1: QUANTUM PROPERTIES OF SUPERCONDUCTING NANOWIRES**
**Monday Morning, 13 March 2006; Ballroom IV, Baltimore Convention Center at 8:00**
**Nina Markovic, Johns Hopkins University, presiding**

**8:00**
**A1 1 Universal conductance of nanowires near the superconductor-metal quantum transition.**
SUBIR SACHDEV, *Harvard University*

We consider wires near a zero temperature transition between superconducting and metallic states. The critical theory obeys hyperscaling, which leads to a universal frequency, temperature, and length dependence of the conductance; quantum and thermal phase slips are contained within this critical theory. Normal (NN), superconducting (SS) and mixed (SN) leads on the wire determine distinct universality classes. For the SN case, wires near the critical point have a universal d.c. conductance which is independent of the length of the wire at low temperatures.

**8:36**
**A1 2 Suppression of superconductivity in zinc nanowires by bulk superconductors.**
MINGLIANG TIAN, *Center For Nanoscale Science and Department of Physics, Penn State University, University Park, PA 16802*

When a superconducting nanowire of a few micrometers in length is connected to two macroscopic normal metal electrodes, a substantial fraction of the wire will become resistive due to the proximity effect. When such a wire is sandwiched between two macroscopic superconducting electrodes, the superconductivity of a nanowire is intuitively expected to become more robust through the coupling with its strong superconducting environment. This expectation is not fulfilled in our recent observation in a system consisting of zinc nanowires (ZNWs) between two bulk superconductors (Sn, In and Pb). We found evidence that the superconductivity of the ZNWs of 40 nm in diameter and 2 or 6 it $\mu$m in length is suppressed completely or partially when bulk Sn or In electrodes are superconducting. When bulk Sn or In electrodes are driven into the normal state by applying a magnetic field, the ZNWs switch back to their superconducting state. This anti-proximity effect is significantly weakened when both Sn or In leads were replaced by Pb or one of the two superconducting electrodes is replaced by a normal metal. The phenomenon is not seen in wires with diameters equal to and thicker than 70 nm. itThis work is in collaboration with N. Kumar, S. Y. Xu, J. G. Wang, J. Kurtz and M.H.W.Chan and supported by the Center for Nanoscale Science (Penn State MRSEC) funded by NSF under grant DMR-0213623.

**9:12**
**A1 3 Effects of a strong magnetic field on superconducting nanowires.**
ANDREY ROGACHEV, *Department of Physics, University of Illinois at Urbana-Champaign*

Effects of strong magnetic fields on superconducting Nb and MoGe nanowires with diameters 5-15 nm have been studied. We have found that the Langer-Ambegaokar-McCumber-Halperin (LAMH) theory of thermally activated phase slips is applicable in a wide range of magnetic fields and describes well the temperature dependence of the wire resistance, over 11 orders of magnitude. We do not observe any resistance in excess of the LAMH theory, even in wires, which are close to the critical point of the superconductor-insulator transition. This fact can be considered as an evidence of the absence of quantum phase slippage. In thicker wires the field dependence of the critical temperature agrees well with the theory of pair-breaking perturbations that takes into account both spin and orbital contributions. In the insulating-phase wires, the magnetic field has a little effect on electron transport, indicating that the superconductivity in the insulating-phase wires is completely suppressed and the Coulomb blockade is the dominant factor, which causes suppression of the charge transport. [1] A. Rogachev, A.T. Bollinger, and A. Bezryadin, Phys. Rev. Lett. 94, 017004 (2005).

**9:48**
**A1 4 Quantum phase slips with and without disorder.**
SERGEI KHLEBNIKOV, *Purdue University*

The rate of quantum phase slips (QPS) in one-dimensional superfluids and superconductors can be computed from first principles in two limiting cases. One [1] is the uniform (no-disorder) limit, appropriate for suitably prepared atomic gases. The other [2] is the limit when the core resistance of a QPS is effectively infinite, appropriate for a sufficiently long disordered superconducting wire. In the latter case, the calculation applies on the superconducting side of the superconductor-insulator transition, where the dilute instanton gas approximation can be used. It is essential to first compute the instanton rate for a given disorder configuration and then average over disorder, as opposed to working with instantons of a disorder-averaged effective theory. Curiously, in neither of the above cases the system is in the XY universality class: in the uniform limit, the QPS rate is suppressed exponentially at low temperatures, as a consequence

of the momentum conservation, while the second case (a relatively long disordered wire) maps onto dissipative quantum mechanics, with the dissipative coefficient controlled by the plasmon impedance *Z*. The role of a finite core resistance can be understood within the picture of effective resistors, representing different dissipative effects, connected in parallel. [1] S. Khlebnikov, Phys. Rev. Lett. **93**, 090403 (2004); Phys. Rev. A **71**, 013602 (2005). [2] S. Khlebnikov and L. P. Pryadko, Phys. Rev. Lett. **95**, 107007 (2005).

**10:24**
**A1 5 Size Dependent Breakdown of Superconductivity in Ultra-Narrow Nanowires.**
KONSTANTIN ARUTYUNOV, *NanoScience Center, Department of Physics, University of Jyväskylä, PB 35, 40014, Jyväskylä, Finland*

Below a certain temperature $T_c$ (typically cryogenic) some materials lose their electric resistance R entering a superconducting state. Following the general trend towards a large scale integration of greater number of electronic components it is desirable to use superconducting elements in order to minimize heat dissipation. It is expected that the basic property of a superconductor, i.e. dissipationless electric current, will be preserved at reduced scales required by modern nanoelectronics. Unfortunately, there are indications that for a certain critical size limit of the order of $\sim$ 10 nm below which a 'superconducting' nanowire is no longer a superconductor in a sense that it acquires a finite resistance even at temperatures close to absolute zero. We developed a method of non-destructive reduction of a nanostructure dimension(s) by low-energy $Ar^+$ ion sputtering. The method enables study of a purely size phenomena between the sputtering sessions: itsame sample with progressively reduced characteristic dimension. We were able to trace the evolution of the shape of superconducting transition R(T) an aluminum nanowire with original effective diameter $\sim$ 70 nm down $\sim$ 8 nm. Below $\sim$ 15 nm the initially abrupt R(T) dependence suddenly broadens. With further reduction of the wire cross section finite resistance is observed down to temperatures much below the initial superconducting transition. We associate the observed phenomena with the quantum phase slippage process: destruction of superconductivity in quasi-1D channels due to quantum fluctuations of the order parameter. The effect should have a universal validity setting a fundamental size limit for utilization of superconducting elements as building blocks of nanoelectronics circuits.

## SESSION A2: MAGNETIC-FERROELECTRIC COUPLING IN MULTIFERROICS
**Monday Morning, 13 March 2006; Ballroom III, Baltimore Convention Center at 8:00**
**Jeffrey Lynn, National Institute of Standards and Technology, presiding**

**8:00**
**A2 1 Multifunctional Multiferroics.**
SANG-WOOK CHEONG, *Rutgers Center for Emergent Materials*

Discovery of intriguing phenomena due to significant cross-coupling in multiferroics where magnetic order and ferroelectric structural distortion coexist has drawn enormous attention in materials science and condensed mater physics community for the last about two years, partially due to the possible realization of new multifunctional devices. I will overview the recent progress and discuss the key issues in understanding and optimizing the cross-coupling effects.

**8:36**
**A2 2 Magnetic Order and Spin Dynamics in Ferroelectric $HoMnO_3$ and $TbMnO_3$.**
OWEN VAJK, *National Institute of Standards and Technology*

Although there are many ferroelectric and magnetic materials, very few have simultaneous magnetic and ferroelectric order. Only a select few of these materials, known as multiferroics, exhibit significant coupling between the magnetic and ferroelectric properties, and the nature of these interactions is not well understood. We have performed neutron scattering studies of two multiferroics which exhibit significant magnetic-ferroelectric coupling, hexagonal $HoMnO_3$ [1] and perovskite $TbMnO_3$ [2]. In $HoMnO_3$, inelastic neutron scattering measurements of the $Mn^{3+}$ spin-wave spectrum and $Ho^{3+}$ crystal field excitations reveal a significant coupling between magnons and the crystal field levels which may contribute to the complex phase diagram and strong magnetic-ferroelectric coupling. In $TbMnO_3$, extensive neutron diffraction studies show that the magnetic transition from a spin density wave to an incommensurate spiral order phase breaks the inversion symmetry of the lattice and induces the onset of ferroelectric distortion. Our results should help lead to a fuller understanding of the interaction between magnetism and ferroelectricity in multiferroics.

[1] O.P. Vajk et al., Phys. Rev. Lett. 94, 087601 (2005) [2] M. Kenzelmann et al., Phys. Rev. Lett. 95, 087206 (2005)

**9:12**
**A2 3 Ferroelectricity in Incommensurate Magnets.**
A. BROOKS HARRIS, *University of Pennsylvania*

In several systems (e. g. $Ni_3V_2O_8$ and $TbMnO_3$) there occurs a phase transition in which a new incommensurate magnetic order parameter appears simultaneously with the development of a uniform spontaneous electric polarization, $P$. Here I review the Landau theory which gives a phenomenological explanation (independent of the microscopic details) of this phenomenon. The key point is that although the quadratic term in $P$ in the free energy is always stable (positive), a nonzero value of $P$ is induced by a trilinear coupling of the $\Sigma_{kmn}a_{kmn}P_kM_m(q)M_n(-q)$, where subscripts label Cartesian components and $M(q)$ is the $q$-Fourier component of the magnetization. Using representation theory to identify the symmetry of the magnetically ordered phases, I identify the symmetry of this term which is consistent with crystal symmetry. This analysis shows that in the highest temperature magnetically incommensurate phase a nonzero value of $P$ is not allowed (as observed) and also that in the lower temperature magnetically incomensurate phase a nonzero $P$ can only appear in the direction which is observed by experiment. This theory indicates that a microscopic model must involve a trilinear interaction between a phonon displacement and two spin operators. A microscopic analysis of phonon distortions of the spin Hamiltonian reproduces these symmetries, as expected and indicates which gradients of the most general anisotropic exchange tensor can possibly come into play. Inelastic neutron scattering data on a $Ni_3V_2O_8$ powder sample and a symmetry analysis of the phonon spectrum enables us to speculate as to which phonon modes are crucial for this phenomenon. See PRL **95**, 087205 and cond-mats: 0508617, 0508730, 0510386, and 0510807 whose coauthors I hereby acknowledge.

**9:48**
**A2 4 (H,T,P) Phase Diagrams in Multiferroics: $RMnO_3$, $RMn_2O_5$ (R = Rare Earth) and $Ni_3V_2O_8$.**
PAUL C.W. CHU, *University of Houston*

Recently, great interest has been generated in the class of materials known as multiferroics (MF), which exhibit the simultaneous occurrence of two or more of the following properties, namely, ferro(anti) magnetic, ferro(anti) electric, ferroelastic, ferroacoustic, and ferroplastic. A subset of MF, known as magnetoelectrics (ME), in which the magnetic and ferroelectric orders coexist, can display the ME-effect where their magnetic and dielectric properties can be affected by an electric and a magnetic field, respectively. The attention first generated in the 60's waned due to the smallness of the effect. However, the situation has drastically changed in recent years due to the observation of a giant ME-effect [1]. Complex diagrams have been induced by magnetic field in the hexagonal single-crystalline rare-earth manganites $RMnO_3$ [2] and the Kagome-staircase compound $Ni_3V_2O_8$ [3], as evidenced by anomalies in their dielectric constant, specific heat, magnetic susceptibility, and thermal expansion coefficients at the phase boundaries. Some of these anomalies occur simultaneously. In this talk, our results of the dielectric, magnetic, calorimetric, and dilatometric properties of $RMnO_3$ (R = Ho, Y, Dy, Er, Tm, and Tb), $HoMn_2O_5$ and $Ni_3V_2O_8$ at ambient pressure in different magnetic fields up to 7 T and some under high pressures up to 2 GPa will be presented. Analysis of the anomalies and examination of the pressure effects on the phase boundaries demonstrate the critical role of strong spin-phonon coupling in the ME-effect and the richness of physics in the study of ME phase diagrams. Possible avenues to further enhance the ME-effect will be discussed. [1] see for example N. Hur et al., PRL 93, 107207 (2004). [2] B. Lorenz et al., PRL 92, 087204 (2004); B. **A2 5 Ferroelectricity in frustrated magnets.***
MAXIM MOSTOVOY

The coupling between ferroelectricity and magnetism in multiferroics is a complex many-body phenomenon resulting from the interplay between charge, spin, and lattice degrees of freedom, and interesting both for its fundamental physics and possible technological applications. An exceptionally strong sensitivity of ferroelectric ordering to an applied magnetic field was recently found in a number of frustrated magnets with periodic non-collinear spin structures. In this talk I will present a phenomenological approach to ferroelectric magnets, which explains the relation between electric polarization and magnetic ordering, anomalies in dielectric constant at magnetic transitions, and sudden flops of electric polarization in magnetic field, observed in these materials. I will also discuss microscopic mechanisms that can give rise to ferroelectricity in magnetically ordered states and possible roads to high- temperature multiferroics.

**A3 1 Coulomb drag experiments in dilute p-GaAs double layer systems.***
RAVI PILLARISETTY,† *Princeton University*

Low density (or dilute) two-dimensional systems, which have large ratios of Coulomb interaction energy to kinetic energy ($r_s$ is roughly greater than 10), are found to exhibit some bizarre transport properties. These include an anomalous metallic temperature dependence and an apparent metal-insulator transition. Furthermore, the application of an in-plane magnetic field, which spin polarizes the 2D system, produces some very unique effects, including a giant magnetoresistance. These unusual transport properties have raised serious doubts regarding the applicability of Fermi liquid theory to the large $r_s$ regime. Despite intense efforts, no conclusive understanding of these transport anomalies currently exists. To gain new insights into the role the strong carrier interactions play in this regime, we have measured the Coulomb drag in low density p-GaAs 2D bilayers. The drag resistivity is directly proportional to the interlayer carrier-carrier scattering rate, and allows us to directly study the carrier interactions in this regime. Our findings are that as the density is lowered into the large $r_s$ regime, the drag resistivity develops a two to three orders of magnitude enhancement over that expected from simple Fermi liquid calculations. We also observe significant deviations from the expected $T^2$ dependence, which correlate with the anomalous metallic temperature dependence observed in the single layer resistivity. Furthermore, we find that both the single layer resistivity and drag resistivity exhibit the exact same qualitative in-plane magnetic field dependence, with both exhibiting similar features associated with spin polarization. These observations suggest that the origin of these transport anomalies, affects both the single layer resistance and drag resistance in exactly the same way, and is surprising since these are two extremely different transport properties. We conclude by discussing these experimental results in light of recent theoretical interpretations of our data.

**A3 2 Many-body effects in low-density strongly-interacting 2D structures: Fermi liquids or not?**
SANKAR DAS SARMA, *Condensed Matter Theory Center, University of Maryland*

I will discuss our many-body theoretic studies of low-density semiconductor-based 2D carrier systems, emphasizing remarkable qualitative and semi-quantitative agreement with recent experimental measurements. In particular, our Fermi liquid many-body theory quantitatively explains the experimentally measured density, temperature, disorder, and magnetic field dependence of bilayer drag, thermodynamic parameters (e.g. spin susceptibility, quasiparticle effective mass), and transport properties in both electron and hole-based low-density 2D semiconductor structures. Our work convincingly demonstrates that the 2D electron liquid remains a Fermi liquid down to fairly low densities, and speculative non-Fermi liquid considerations are unnecessary in order to understand the phenomenology of low-density 2D systems. This work is done in collaboration with Euyheon Hwang, and supported by ONR, LPS, and NSF.

**9:12**
**A3 3 Drag resistance of 2D electronic microemulsions.***
STEVEN KIVELSON, *Stanford University*

In two dimensional electron systems with Coulomb or dipolar interactions, a direct transition, whether first or second order, from a liquid to a crystalline state is forbidden. As a result, between these phases there must be other (microemulsion) phases which can be viewed as a meso-scale mixture of the liquid and crystalline phases. We investigate the transport properties of these new electronic phases and present arguments that they are responsible for the various transport anomalies that have been seen in experiments on the strongly correlated 2DEG in high mobility semiconductor devices with low electron densities. In particular, motivated by recent experiments of Pillarisetty et al, PRL 90, 226801 (2003), we present a theory of drag in electronic double layers at low electron concentration. We show that the drag effect in such systems is anomalously large, it has unusual temperature and magnetic field dependences associated with the Pomeranchuk effect, and does not vanish at zero temperature.

**A3 4 Transition between Composite-Bosons and Composite-Fermions in $\nu = 1/2 + 1/2$ Quantum Hall Bilayers.***
STEVEN H. SIMON, *Lucent Technologies, Bell Labs*

There has been considerable recent interest in bilayer quantum Hall systems at filling fraction $\nu = 1/2 + 1/2$. At large spacing between the layers, the system is described as two independent $\nu = 1/2$ composite fermion fermi seas, with each electron being bound to two vortices of the wavefunction within the same layer. At small spacing between the two layers the system can be described as a composite boson condensate (also known as ''111 state'' or exciton condensate) where each electron is bound to one vortex of the wavefunction within the same layer and to one vortex of the wavefunction in the opposite layer. As the spacing between the layers is continuously decreased, intra-layer correlations must be replaced by inter-layer correlations, and the composite fermion sea must be replaced by the composite boson condensate. In this talk we will focus on the nature of this transition. For intermediate distances between the two layers, we propose a scenario where composite bosons and composite fermions coexist in two interpenetrating fluids[1]. In other words, we allow some electrons to bind to vortices within the same layer, and some to bind to vortices in the opposite layer. Trial wavefunctions describing these mixed composite-boson-composite-fermion states compare favorably with exact diagonalization results. A Chern-Simons transport theory is constructed that is compatible with experiment. More recent work[2] has shown that pairing interactions between the composite fermions occur. Once this pairing is treated properly we obtain almost perfect numerical agreement with exact diagonalizations. Possible implications for experiments are discussed. [1] S. H. Simon, E. H. Rezayi, and M. V. Milovanovic. Phys. Rev. Lett. 91, 046803 (2003) [2] G. Moller, E. H. Rezayi, and S. H. Simon, to be published.

**A3 5 Spectroscopy of Emergent Phases of Electron Bilayers in the Quantum Hall Regime.***
VITTORIO PELLEGRINI, *NEST INFM-CNR Scuola Normale Superiore, Pisa (Italy)*

Electron bilayers in semiconductor heterostructures in the quantum Hall regime are contemporary realizations of highly correlated systems where bizarre quantum phases may appear. A mean field configuration occurs when a tunneling gap splits the single-particle levels in their symmetric and anti-symmetric combinations and the Landau level filling factor is 1. This configuration has full spin and pseudospin ferromagnetic order, where pseudospin is a quantum operator describing layer occupation. The presentation considers optics experiments that offer evidence of the breakdown of the pseudospin order of the mean-field paradigm based on measurements of low-lying spin excitations [1]. The suppression of the pseudospin order manifests a new quantum phase that can be interpreted as a highly correlated fluid of electron-hole excitonic pairs across the tunneling gap. Evidence of a phase transition to a non-quantum-Hall phase is found in measurements of elastically-scattered light (Rayleigh scattering) and of spectral lineshapes of spin-excitations [2]. The transition occurs when the pseudospin order fully collapses by application of an in-plane magnetic field component. [1] S. Luin, et al. Phys. Rev. Lett. **94**, 146804 (2005). [2] S. Luin, et al., to be submitted.

## SESSION A4: PARTICLE SELF ASSEMBLY
**Monday Morning, 13 March 2006; 308, Baltimore Convention Center at 8:00**
**Maria Santore, University of Massachusetts, presiding**

**8:00**
**A4 1 DNA-Mediated Colloidal Crystallization, Interactions and Dynamics.**
JOHN CROCKER, *University of Pennsylvania*

DNA has emerged as a powerful and versatile tool for nanoscale self-assembly. Several researchers have assembled nanoparticles and colloids into a variety of structures using the sequence specific binding properties of DNA. Until recently, however, all of the reported structures were disordered, even in systems where ordered colloidal crystals might be expected. We detail the experimental approach and surface preparation that we used to form the first DNA-mediated colloidal crystals, using polystyrene microspheres. We also report the first direct measurements of such DNA-induced interactions between such micron-sized particles. The interactions measured with our optical tweezer method can be modeled in detail by well-known statistical physics and chemistry, boding well for their further application to directed self-assembly. The microspheres reversible adhesion dynamics have an unexpected power-law scaling, which we hypothesize is due to the non-exponential kinetics of DNA hybridization process itself.

**8:36**
**A4 2 Assembly and Gelation of Four-Armed DNA Dendrimers.***
FRANCIS STARR, *Wesleyan University*

The disordered-arrested state of matter is ubiquitous in existing materials like glasses, and is prevalent in many new materials, due to the uncommon mechanical, thermal and electrical properties. The ''bottom-up'' construction of new materials is one of the central aims of nanotechnology. DNA is potentially an optimal choice for the construction of three-dimensional supramolecular assemblies since it can self-assemble into long and fairly rigid helices, based simply on sequence complementarity. We numerically study a model designed to mimic the behavior of recently synthesized single-stranded DNA dendrimers. Complementarity of the base sequences of different strands results in the formation of strong cooperative intermolecular links with a valency controlled by the number of strands. We simulate the bulk behavior of a system containing many 4-armed DNA dendrimers and find that in an extremely narrow temperature range the system forms a large-scale, low-density network via a thermo-reversible gel transition. The sharpness of the crossover the gel state can be controlled by the length of the DNA strands, since longer strands will form cooperative bonds over a narrower temperature range. As a result, the percolation temperature of the network formed by the dendrimers can be made arbitrarily close to the gel transition by tuning the length of DNA strands. This is in contrast with recent model systems designed to understand thermo-reversible gelation. Given that gelation and percolation coincide in irreversible chemical gels, this system provides an excellent model material to bridge the understanding between reversible and chemical gels.

**A4 3 Directing Colloidal Particle Organization Using Soft Lithography and Polyelectrolyte Assembly.***
PAULA HAMMOND, *Massachusetts Institute of Technology*

The use of electrostatic interactions to guide colloidal assembly can be used to achieve an elegant level of control on the ordering of particles at surfaces. We have utilized a combination of self-assembled monolayers and electrostatic layer-by-layer assembled thin films as templates for the directed deposition of colloidal particles. In this work, it is also of interest to manipulate two or more colloid components on a surface using attractive and/or repulsive interactions. This work has since led to an investigation into other interactions that can be used to guide colloid assembly. By extending our understanding of interactions between polyelectrolytes and different forms of functional surfaces, we have been able to guide polyelectrolyte coated colloids to different surface regions based on hydrophobic or hydrogen bonding interactions as well as charge attraction. Recent success has been obtained in our group on the use of DNA acid/base pairs to direct the deposition of polyion functionalized colloids to specific regions of surfaces. In this work, the strong and highly specific hydrogen bonding interactions that take place between poly(phosphonic acids) is being pursued. New developments have included the formation of hydrogen bonded Janus particles – colloids that have been functionalized with a different polybase on either side of the particle. Finally, we have also begun to use a range of soft lithographic methods, combined with polyelectrolyte multilayer assembly on nanometer scale patterns to direct nanoparticles into patterned arrays. The interactions involved in this work, guiding principles, as well as the interplay between hard boundaries and surface chemistry in template surfaces, will be discussed, and potential applications and new collaborations will be addressed in display, microfluidic and biological applications.

**A4 4 Symmetry, Equivalence and Self-Assembly.**
JACK DOUGLAS, *Polymers Division, NIST*

Molecular self-assembly at equilibrium is central to the formation of many biological structures and the emulation of this process through the creation of synthetic counterparts offers great promise for nanofabrication. The central problems in this field are an understanding of how the symmetry of the interacting particles encodes the geometrical structure of the organized structure and the nature of the thermodynamic transitions involved. Our approach is inspired by the self-assembly of actin, tubulin and icosahedral structures of plant and animal viruses. We observe chain, membrane,'nanotube' and hollow icosahedron structures using 'equivalent' particles exhibiting an interplay between directional (dipolar and multi-polar) interactions and short-range (van der Waals) interactions. Specifically, a dipolar potential (continuous rotational symmetry) gives rise to chain formation, while potentials having discrete rotational symmetries (e.g., square quadrupole or triangular ring of dipoles) led to the self-organization of nanotube and icosahedral structures with some resemblance to tubulin and icosahedral viruses. The simulations are compared to theoretical models of molecular self-assembly, especially in the case of dipolar fluids where the corresponding analytic theory of equilibrium polymerization is well developed. These computations give insights into the design elements required for the development of synthetic systems exhibiting this type of organization.

**10:24**
**A4 5 Structured Nanocomposites: Organization of Particles Templated in Self-Assembled PEO-PPO-PEO Mesophases.**
LYNN WALKER, *Carnegie Mellon University*

The design of materials with tailored properties and function requires control over their structure in the nanometer scale. It is advantageous to many engineering applications that this is carried out using self-assembly processes that occur at reasonable concentrations ( $\sim 10^{20}$ particles/L) and short timescales (ns – $\mu$s). In this work, we have developed a novel approach using an ordered template to control the nanoscale structure of materials that would not otherwise order in solution. We use close-packed cubic and cylindrical mesophases of a thermoreversible block copolymer (PEO-PPO-PEO) to impart spatial order on dispersed nanoparticles. The thermoreversible nature of the template allows for the dispersion of particles synthesized outside the template. This feature extends the applicability of this templating method to many particle-polymer systems and also permits a systematic evaluation of the impact of design parameters on the structure and mechanical properties of the nanocomposites. The approach is extremely robust and we have successfully templated solutions of silica and gold inorganic nanoparticles as well as a series of proteins, which act as organic nanoparticles in our system. The influence of relative size (particle to template sites), relative concentration, temperature and shear are experimentally determined using small angle neutron scattering (SANS) and rheology. SANS with contrast variation is used to characterize the structure of the polymer mesophase and the templated particles in a nanocomposite independently. SANS experiments also demonstrate that shear can be used to align the nanocomposites into single-crystal macro-domains; the first demonstration of the formation of single-crystal nanoparticle superlattices. The outcome of this work serves as a basis for designing new soft nanocomposite materials.

## SESSION A5: ADVANCED MATERIALS FOR ENERGY APPLICATIONS
**Monday Morning, 13 March 2006; 309, Baltimore Convention Center at 8:00**
**George Crabtree, Argonne National Laboratory, presiding**

**8:00**
**A5 1 Overview of the Hydrogen Initiative.**
M. S. DRESSELHAUS, *Massachusetts Institute of Technology, Cambridge, MA*

One of the Grand Challenges of the 21st Century is to achieve a sustainable energy supply. The 20th Century has seen remarkable advances in Science and Technology, resulting in expectations for a higher standard of living. This has required large increases in global per capita energy consumption. Projections of per capita energy needs for the 21st Century indicate that new technologies for sustainable energy production, storage and use will need to be developed in the next 50 years. The so-called hydrogen economy is one such proposal that is presently being considered worldwide. In this talk the big picture of the Grand Energy Challenge will be presented. In this context requirements of a hydrogen economy will be broadly discussed in terms of hydrogen production, storage and utilization, with emphasis given to the large gap between present science and technology know-how and the requirements in efficiency and cost for a sustainable hydrogen economy. Opportunities for nanoscience and nanotechnology to narrow this gap will be discussed, and examples of recent progress will be presented.

**8:36**
**A5 2 Direct Energy Conversion: Chemistry, Physics, Materials Science and Thermoelectrics.***
MERCOURI KANATZIDIS, *Michigan State University*

Interest in all-solid-state thermal to electrical conversion has been steadily increasing in recent years and this has been coinciding with an increasing recognition of rising energy demands in the future. Thus there is now renewed awareness of the need to find new energy sources and make conservation efforts more efficient. In this context thermoelectric materials seem poised to have an impact. Research is needed to understand at the fundamental level the scientific issues that are crucial in designing and discovering new highly efficient thermoelectrics. The progress in the field of thermoelectrics has been significant both at the concept level and at the materials discovery level thanks to a convergence of chemistry, physics and materials science efforts. I will describe how each of these disciplines impact each other to produce synergies that propel advances in this area. I will present recent progress in novel nanostructured chalcogenide materials that stimulate new experimentation and hold considerable promise for higher efficiencies in heat to electricity conversion.

*Supported by ONR.

**9:12**
**A5 3 Novel Indirect Hydrogen Storage Materials.**
CLAUS HVIID CHRISTENSEN, *Technical University of Denmark*

Materialization of a hydrogen economy could provide a solution to significant global challenges. In particularly, the possibility of improving the efficiency and simultaneously minimizing the environmental impact of energy conversion processes, together with the opportunity to reduce the dependency of fossil fuels, are main drivers for the currently increasing research and development efforts. However, significant technological breakthroughs are necessary for making a hydrogen economy feasible. Particularly, it is necessary to develop appropriate hydrogen storage and transportation technologies. Recently, metal ammine salts were proposed as safe, reversible, high-density and low-cost hydrogen carriers. Here, we discuss how this development could provide a platform for using ammonia as a fuel for the hydrogen economy. We do that by comparing various possible hydrogen carriers with respect to energy and cost efficiency, infrastructure requirements, safety concerns and also environmental impact.

**9:48**
**A5 4 Near-surface alloys for improved catalysis.**
MANOS MAVRIKAKIS, *UW-Madison*

Periodic self-consistent Density Functional Theory (DFT-GGA) calculations have emerged as a valuable partner to experiment in explaining reactivity of transition metal surfaces. These methods provide detailed itatomic level mechanistic information on individual elementary reaction steps, in terms of reaction thermochemistry, reaction paths, and activation energy barriers. itTrends in reactivity derived from systematic investigations of specific steps on a number of different metal surfaces are reliable, when compared to experiment. In particular, we will attempt to demonstrate how first-principles methods can extend beyond the detailed mechanistic analysis of catalytic reactions to reach the ambitious goal of identifying promising catalysts for specific applications. Among others, we will discuss opportunities to design bimetallic catalysts for highly selective hydrogen transfer reactions, and for designing cheaper and more active oxygen reduction catalysts, the latter being most relevant to the cathode reaction of low temperature fuel cells.

**10:24**
**A5 5 Materials challenges for solid-state lighting.**
E. FRED SCHUBERT

The use of highly efficient semiconductor light-emitting diodes (LEDs) suitable for illumination applications will enable huge energy savings and have a very positive effect on the environment. This talk will discuss materials challenges in solid-state lighting, including a new class of materials, low-refractive-index materials, with refractive indices much lower than conventional materials. Arrays of $SiO_2$ nanorods are shown to have unprecedented low refractive indices ( $<$ 1.10) yet viable thin-film properties. Their use for omni-directional reflectors and the resulting improvement in LED light-extraction efficiency will be discussed. We will show that optimized phosphor distributions in white LED lamps, particularly remote-phosphor distributions, combined with diffuse reflectors, strongly enhance luminous efficiency. Finally, we will discuss materials issues that limit the efficiency of ultraviolet (UV) light emitters.

## SESSION A6: FRONTIERS OF COMPUTATIONAL MATERIALS

**A6 2 Reliable First-Principles Alloy Thermodynamics via Optimal, Truncated Cluster Expansions.***
DUANE JOHNSON, *Department of Materials Science and Engineering*

Cluster expansions (CE) are increasingly used to combine first- principles electronic-structure structural formation energies and Monte Carlo methods to predict phase stability in alloys, and search for new materials. As a basis-set expansion in terms of lattice geometrical clusters and effective cluster interactions, the CE is exact if infinite, but is

tractable only if truncated. We present an optimal truncation for CE basis sets that provides reliable thermodynamics and is easy to implement in mulitcomponent alloys, whereas former truncations were not well defined and sometimes led to unreliable results. We discuss predictive error estimation, error estimation of temperature prediction, Rayleigh- Ritz variation errors associated with basis set truncation for both concentration-dependent and independent version (similar to local compact support in finite-element methods), as well as a means for rapid assessment of transition temperatures without performing Monte Carlo. We exemplify all of the issues in various binary alloys. A Thermo Toolkit (TTK) that automates construction of the optimal, truncated CE, generation of linear-independent unit-cell structures, electronic-structure job submission for the required unit-cell, collection into database, and ultimately Monte Carlo construction of phase diagram is exemplified also.

*Acknowlegdments to Dr. Nikolai Zarkevich and Teck Tan Leong for developments of TTK and funding through the National Science Foundation ITR (DMR-03-25939), and DOE under grant DE-FG02-03ER46026, and the Metal-Hydride Center of Excellence at Sandia.

**9:12**
**A6 3 Realistic nanostructures from first-principles: fluxional handles to control the conductance of carbon nanotubes.***
NICOLA MARZARI, *Department of Materials Science and Engineering, Massachusetts Institute of Technology*

We have combined large-scale, $\Gamma$ − point electronic-structure calculations and the maximally-localized Wannier functions approach to calculate efficiently and with full first-principles accuracy the electronic structure and the quantum conductance of complex systems containing thousands of atoms. This approach is applied to study covalent functionalizations in metallic single-wall carbon nanotubes. We find that for most covalent ligands (from hydrogens to aryl moieties) the electronic structure around the Fermi energy is much less dependent on the chemical nature of the ligands than on the $sp^3$ functionalization pattern disrupting the conjugation network. These covalent functionalizations are more stable when paired with saturating hydrogens. Even when paired, they still act as strong scattering centers that degrade the conductance of the tubes already at low degrees of coverage. Instead, we find that cycloadditions of carbenes or nitrenes can preserve metallicity to an unusually high degree, whenever bond cleavage between two sidewall carbon atoms is induced. This process restores the original $sp^2$ hybridization for the sidewall carbons and preserves, even in the presence of significant distortions, the original ''transparency'' of the $\pi$ manifold. The chirality and curvature of the nanotube and the chemistry of the addends determine this bond cleavage and in turn the transport properties. Remarkably, a well-defined range of diameters can be found for which certain addends - such as dicyanocarbene - exhibit a bistable switchable state, where the opening or closing of the bond, and thus the opening and closing of the conduction channels, could be directed with chemical, electrochemical or optical means. This discovery opens the way to novel and promising routes to control and modulate nanotube conductance, with applications ranging from sensors to memories to opto- and nano-electronics.

*Support from NSF-NIRT DMR-0304019 and from MIT Institute for Soldier Nanotechnologies is gratefully acknowledged.

**A6 4 Evolutionary approach for determining first-principles model Hamiltonians.***
GUS L. W. HART, *Northern Arizona University*

The ability to perform accurate solid-state calculations based completely on first principles (for relatively small unit cells) has made it possible to develop model Hamiltonians that can be rapidly ''searched'' for optimal target properties—i.e., true materials-by-design. Recent applications include ferroelectric properties and band-gap engineering. The most difficult step in ''training'' such model Hamiltonians is making choices for the number and types of parameters in the model that insure the *predictive* power of the model. Based on an evolutionary approach, we have developed an algorithm[1] for selecting the types and number of terms in a Cluster Expansion model for a binary alloy. This approach removes much of the tedium of constructing the model and robustly finds the best possible set of parameters. The approach is general and can be applied to a wide variety of other models as well. I illustrate the success of the new approach first on systems where the best parameter set is known analytically, and second, as applied to several recent ''real-world'' examples, including (1) the role of long-period-superlattices in the Cu-Pd system, (2) predicting configuration-dependent bulk-moduli in transition- metal carbides and nitrides, (3) predicting optimal superlattice stacking/orientations to engineer desired band-gaps in MgO-ZnO wide gap alloys.

**A6 5 Prediction of new crystal structure phases in metal borides.**
ALEKSEY KOLMOGOROV, *Duke University*

Identification of novel crystal structures is an important step for predicting new stable compounds in alloys, since most theoretical search algorithms are restricted to a given prototype library or a lattice type. Performing *ab initio* data mining [1] of intermetallic compounds we have discovered that even in such a well-studied class of systems as metal borides there are previously unknown phases comparable in energy to the existing ones [2]. We demonstrate that even though the new structures are relatively simple, their identification is not straightforward. We systematically investigate the stability and electronic properties of the new metal boride phases. Our calculations show that some phases exhibit electronic features similar to those in the famous $MgB_2$ and could be good superconductors. The new phases are likely to have random stacking faults, so they might not be detected with standard x-ray methods. Our results could thus be used as an important guide in the search for new superconducting metal borides. [1] S. Curtarolo *et al.*, Phys. Rev. Lett. **91**, 135503 (2003). [2] A.N. Kolmogorov *et al.*, submitted (2005).

## SESSION A7: BACTERIAL FLAGELLAR DYNAMICS, POLYMORPHISM, AND CONFORMATIONAL SPREAD
**Monday Morning, 13 March 2006; 307, Baltimore Convention Center at 8:00**

**8:00**
**A7 1 Theory of polymorphic transformations of flagella.**
THOMAS POWERS, *Brown University*

Bacterial flagellar filaments can abruptly change shape in response to mechanical load or changes in solution pH or ionic strength. These polymorphic transformations are an instance of a ubiquitous phenomenon, the spread of conformational change in large macromolecular assemblies. We propose a new theory for polymorphism, whose essential elements are two molecular switches, an elastic mismatch strain between the inner and outer cores of the filament, and cooperative interactions between neighborhing subunits on the same protofilament. We calculate the phase diagram for helical and straight states, and the response of a helical filament to an external moment.

**8:36**
**A7 2 Synchronization of rotating flagella by hydrodynamic interactions.**
HOLGER STARK, *Universität Konstanz, Fachbereich Physik, D-78457 Konstanz, Germany*

Rotating bacterical flagella form bundles, which means that their rotations have to be synchronized. The aim of our study [1] is to show that hydrodynamic interactions, i.e., interactions mediated by the flow field the helical flagella create, can be at the origin of such a synchronization. We consider two stiff helices that are modeled by rigidly connected beads, neglecting any elastic deformations in a first approach [1]. The helices are driven by constant and equal torques. They are fixed in space by anchoring their terminal beads in harmonic traps so that they can jiggle around. We observe that, for finite trap strength, hydrodynamic interactions, treated in the low-Reynolds-number regime, do indeed synchronize the helix rotations to a phase difference zero. The speed of phase synchronization decreases with increasing trap stiffness and becomes zero in infinitely stiff traps. So strictly parallel helices do not synchronize. This limit is consistent with recent work based on slender-body theory [2]. We furhermore show that phase synchronization is stable against fluctuations in the torques driving the helices. Our results clearly indicate that some kind of flexibility is essential to allow for phase synchronization. In reality, this flexibility might have its origin in the proximal hook connecting the flagellum to the rotatory motor or in elastic deformations of the rotating flagella. Indeed, when we extend our model by implementing the elasticity of a helical worm-like chain, synchronization occurs much faster even for relatively stiff helices.

**A7 3 Bacterial Flagellar Transformations.**
NICHOLAS DARNTON, *Rowland Institute at Harvard*

In many of the bacteria that swim by rotating helical flagella, the flagellum itself is not a simple, passive propeller. Flagella can adopt several helical shapes of varying pitch, radius and handedness in response to changing conditions such as temperature, pH, and load. In itEscherichia coli, in particular, at least 5 (out of 12 predicted) helical forms are observed

during normal swimming. Polymorphic changes commonly occur during tumbling, appear to aid in the reorientation of swimming direction, and are induced by torque- changing variations in motor speed. Measurements on individual, isolated flagellar filaments are revealing the forces required to cause polymorphic transformations. These data will be necessary for a quantitative understanding of the connections between motor reversal, polymorphic change, and tumbling behavior. Since the filament is a uniform polymer of flagellin protein, whose structure is known, it provides a simple, macroscopically visible model of highly cooperative conformational changes in a biological polymer.

**9:48**
**A7 4 Spiroplasma swim by a processive change in body helicity.**
JOSHUA SHAEVITZ, *University of California, Berkeley*

Microscopic organisms must rely on very different strategies than their macroscopic counterparts to swim through liquid. To date, the best understood method for prokaryotic swimming employs the rotation of flagella. I will present data that Spiroplasma, tiny helical bacteria that infect plants and insects, use a very different approach. By measuring cell kinematics during free swimming, we find that propulsion is generated by the propagation of kink pairs down the length of the cell body. A processive change in the helicity of the body creates these waves and enables directional movement. Unlike the motion of other helical swimmers such as Spirochetes, Spiroplasma swimming velocity increases with increasing viscosity. In addition, cell morphological parameters such as helical pitch and cell length influence swimming velocity.

**A8 1 The effects of initial seed size and transients on dendritic crystal growth** ANDREW DOUGHERTY, THOMAS NUNNALLY, *Dept. of Physics, Lafayette College* The transient behavior of growing dendritic crystals can be quite complex, as a growing tip interacts with a sidebranch structure set up under an earlier set of conditions. In this work, we report on two observations of transient growth of $NH_4Cl$ dendrites in aqueous solution. First, we study growth from initial nearly-spherical seeds. We have developed a technique to initiate growth from a well-characterized initial seed. We find that the approach to steady state is similar for both large and small seeds, in contrast to the simulation findings of Steinbach, Diepers, and Beckermann[1]. Second, we study the growth of a dendrite subject to rapid changes in temperature. We vary the dimensionless supersaturation $\Delta$ and monitor the tip speed $v$ and curvature $\rho$. During the transient, the tip shape is noticeably distorted from the steady-state shape, and there is considerable uncertainty in the determination of the curvature of that distorted shape. Nevertheless, it appears that the ''selection parameter'' $\sigma^* = 2d_0D/v\rho^2$ remains approximately constant throughout the transient. [1] I. Steinbach, H.-J. Diepers, and C. Beckermann, itJ. Cryst. Growth, **275**, 624-638 (2005).

**8:12**
**A8 2 Control of eutectic solidification microstructures through laser spot perturbations** SILVERE AKAMATSU, *CNRS* KYUYONG LEE, *Ames Laboratory* WOLFGANG LOSERT, *UMD* We report on a new experimental technique for controlling lamellar eutectic microstructures and testing their stability in directional solidification (solidification at fixed rate V in a uniaxial temperature gradient) in thin sample of a model transparent alloy. A eutectic binary alloy solidifies into a mixture of two crystal phases. In stationary regimes, periodic front patterns made of an alternate stacking of lamellae of the two solid phases are observed. We observe the solidification front in real time by optical microscopy. We use micromanipulation with laser spot arrays for perturbing the solidification front on a scale ranging from one to ten times the average value of the lamellar spacing (spatial period), i.e., typically 10 to 100 microns. These perturbations arise from local heating due to the absorption of the laser light by the liquid slightly ahead of the front. We use the laser spot perturbation technique as a tool for mapping out the large range of accessible lamellar spacings at given V and for creating desired patterns (smooth spatial modulation, tilt domains).

**8:24**
**A8 3 Pattern Formation in a NaCl Crystal undergoing Strain-enhanced Dissolution** ZVI KARCZ, DENIZ ERTAS, RICHARD POLIZZOTTI, *ExxonMobil Research and Engineering* EINAT AHARONOV, *Weizmann Institute of Science* CHRIS SCHOLZ, *Lamont Doherty Earth Observatory* Observations of an initially circular contact ( $\sim 300\mu$m in diameter) between the [100] face of a single-crystal NaCl shaped as a truncated cone and a flat silicate plate immersed in saturated solution indicate that the crystal deforms in two sequential stages under constant normal load. The first is characterized by contact area reduction and slow convergence rates, and the second by fluctuations in contact area and fast and fluctuating convergence rates. Fluctuations are on a timescale of $\sim$ 14 hours. The transition between the stages occurs at the maximum contact stress, which shortly precedes the maximum convergence rate. Confocal images indicate that the crystal dissolves coaxially during the first stage, producing a decreasing static contact. During the second stage, the contact shape is highly irregular, with channels and ridges forming inside the contact. These observations reflect a system evolving towards a non-equilibrium steady state, controlled by the interaction between strain-energy driven undercutting dissolution and plastic flow. Undercutting dissolution reduces the area of the contact, and preferentially removes regions with high dislocation density, while plastic flow increases the contact area by mobilizing dislocations that strain harden the crystal. The feedback between these two mechanisms drives the system towards a dynamic steady state.

**8:36**
**A8 4 Controlled Irradiative Formation of Penitentes** VANCE BERGERON, *Ecole Normale Superieure, Lyon* CHARLES BERGER, *Ecole Normale Superieure, Paris* M. D. BETTERTON, *University of Colorado* Spike-shaped structures are produced by light-driven ablation in very different contexts. Penitentes 1-4 m high are common on Andean glaciers, where their formation

changes glacier dynamics and hydrology. Laser ablation can produce cones 10-100 $\mu$m high with a variety of proposed applications in materials science. We report the first laboratory generation of centimeter-scale snow and ice penitentes. Systematically varying conditions allows identification of the essential parameters controlling the formation of ablation structures. We demonstrate that penitente initiation and coarsening requires cold temperatures, so that ablation leads to sublimation rather than melting. Once penitentes have formed, further growth of height can occur by melting. The penitentes intially appear as small structures (3 mm high) and grow by coarsening to 1-5 cm high. Our results are an important step towards understanding and controlling ablation morphologies.

**8:48**

**A8 5 Transient growth and controlled side branching of xenon dendrites** MARCO FELL, J. H. BILGRAM, *ETH Zurich, Switzerland* In our experiments we study the influence of transient growth conditions on the growth of xenon dendrites from undercooled melt. Here we report on the response of crystal growth on heating the melt. We start heating at a given temperature and steady-state growth. The dendrite tip reacts on this change by slowing down growth rate $v$ and increasing tip radius $R$. We observe that side branches emerge from an unstable surface. As we continue heating up to slightly above melting temperature, the tip radius continuously decreases to a new value. The reverse temperature change unveils a hysteretic behavior: As soon as we cool down the melt from a temperature tight above melting temperature, $v$ and $R$ both increase. The curvature of the tip becomes too small to be stable at the given undercooling and an instability leads to a new, thin tip growing out of the oversized sphere-like tip. The value $R^2v$ shows a sharp peak and then settles to a constant value in only about 20 seconds. The same instability also gives rise to side branches whose formation can be controlled by a repetitive application of the described mechanisms. Highly symmetric xenon crystals can be grown by this technique.

**A8 6 Late time growth dynamics in the Cahn-Hilliard equation*** TMOTHY S. SULLIVAN, *Department of Physics, Kenyon College* P. PALFFY-MUHORAY, *Liquid Crystal Institute, Kent State University* Numerical simulations were carried out in 2D of the scaled Cahn-Hilliard equation $[\partial\psi/\partial t = (1/2)\nabla^2(-\psi + \psi^3 - \nabla^2\psi)]$ starting from Gaussian distributed, random initial conditions on a 540x540 square grid. Simulations were run for a dimensionless time of 200,000, a factor of ten beyond previously reported results. The simulations also covered a broad range of values of the mean composition, including several at values that had not previously been reported. For each composition and for time intervals of no longer than 5000 in dimensionless time, the structure factor was calculated for sixty separate runs and averaged. The pair correlation function was then calculated from the average structure factor and its first zero crossing,$R_G(t)$, taken as a measure of the average domain size, was determined. An equation of the form $R_G(t) = at^b + c$ was then fit to our data over the dimensionless time range from 5000 to 200,000. In contrast to previous work, we find that the scaling exponent $b$ varies with mean coomposition and does not appear to be consistent with the Lifshitz-Slyozov result $b = 1/3$. The largest deviation occurs at a mean composition of 0.2, where $b = 0.244 \pm 0.003$. We discuss the possible effects of morphology on both the scaling law and the time it takes to reach the scaling regime.

**A8 7 Domain Growth in 2D Hexagonal Patterns with Diffuse Interfaces** DANIEL A. VEGA, LEOPOLDO R. GÓMEZ, *Department of Physics - Universidad Nacional del Sur - CONICET. (8000) - Bahía Blanca - Argentina* RICARDO J. PIGNOL, *Department of Mathematics - Universidad Nacional del Sur. (8000) - Bahía Blanca - Argentina* The coarsening process in planar patterns has been extensively studied during the last two decades. Although progress has been made in this area, there are still many open questions concerning the basic mechanisms leading the system towards equilibrium. Some of these mechanisms (including curvature driven growth, grain rotation and defect annihilation) have mostly been addressed in systems displaying sharp interfaces. In this work we traced the dynamics of phase separation in hexagonal patterns with diffuse interfaces through the Cahn-Hilliard model. By studying orientational and translational order and densities of topological defects we were able to identify a mechanism of coarsening simultaneously involving curvature driven growth, front propagation and grain rotation. In this regime we found that different correlation lengths characterizing the hexagonal pattern increase logarithmically with time.

**9:24**

**A8 8 Oscillatory patterns near the instability threshold in extended systems with reflection symmetry** ALEXANDER NEPOMNYASHCHY, IRINA SMAGIN, *Technion, Haifa, Israel* VLADIMIR VOLPERT, ALEXANDER GOLOVIN, *Northwestern University* It is well known that the envelope function of a modulated traveling wave spontaneously generated by a short-wave instability is governed by a complex Ginzburg-Landau equation (CGLE). Various modulation phenomena, which include the nonlinear development of a modulational instability of periodic waves in the supercritical region, as well as the formation of stable modulated waves in the subcritical region, have been extensively studied in the framework of CGLE. The nonlinear interaction between two waves moving in the opposite directions is described by a system of two non-locally coupled CGLEs that has not been studied in detail yet. We use this system for studying several phenomena related to modulations of standing waves: (i) nonlinear development of a modulational instability; (ii) propagation of defects in standing-wave patterns; (iii) subcritical modulated waves. The results are applied to problems of transverse instabilities of fronts in combustion and explosive crystallization.

**9:36**

**A8 9 Effects of the Deep of Quench on the Mechanisms of Pattern Formation of Sphere Forming Block Copolymers** LEOPOLDO R. GÓMEZ, DANIEL A. VEGA, *Department of Physics - Universidad Nacional del Sur - CONICET. (8000) - Bahía Blanca - Argentina* ENRIQUE M. VALLÉS, *Plapiqui - Universidad Nacional del Sur - CONICET. (8000) - Bahía Blanca - Argentina* The disorder-order transition of a two dimensional sphere forming block copolymer is studied through the Cahn-Hilliard model at different deeps of quench. The process of microphase separation and kinetic of pattern formation are controlled by the spinodal and order-disorder temperatures. In the spinodal region the deep of quench strongly affect both, ordering times and

density of topological defects. As the spinodal temperature is approached, the density of disclination becomes very small and grains show a perfect orientational and translational order. In a narrow region of temperatures the system relax towards equilibrium via the nucleation and growth mechanism. In this region the critical grain size is approximately one lattice constant in the neighborhood of the spinodal line and diverges as the order-disorder temperature is approached.

**9:48**

**A8 10 Feedback Control of Pattern Formation** LIAM STANTON, ALEXANDER GOLOVIN, *Northwestern University* Global feedback control of spatially-regular patterns described by the Swift-Hohenberg (SH) equation is studied. Two cases are considered: (i) the effect of control on the competition between roll and hexagonal patterns; (ii) the suppression of sub-critical instability by feedback control. In case (i), it is shown that control can change the stability boundaries of hexagons and rolls. Particularly, for certain values of the control parameter, both hexagons and rolls are unstable, and one observes non-stationary patterns with defects. In case (ii), the feedback control suppresses the unbounded solutions of a sub-critical SH equation and leads to the formation of spatially-localized patterns.

**A8 11 Grain boundary stability in stripe configurations of non potential, pattern forming systems** JORGE VINALS, ZHIFENG HUANG, *McGill University* We describe numerical solutions of nonpotential models of pattern formation in non equilibrium systems to address the motion of grain boundaries separating large domains of stripe configurations. One of the models allows for mean flows. Wavenumber selection at the boundaries, boundary instability, and defect formation and motion at the boundary are described as a function of the distance to onset.

**10:12**

**A8 12 Mesoscale Theory of Grains and Cells: Crystal Plasticity and Coarsening*** SURACHATE LIMKUMNERD, JAMES SETHNA, *Laboratory of Atomic and Solid State Physics, Cornell University* Line-like topological defects inside metals are called dislocations. At high temperatures, polycrystalline grains form from the melt and coarsen with time: these dislocations can both climb and glide. At low temperatures under shear the dislocations (which allow only glide) form into cell structures. While both the microscopic laws of dislocation motion and the macroscopic laws of coarsening and plastic deformation are well studied, we have had no simple, continuum explanation for the evolution of dislocations into sharp walls. We present here a mesoscale theory of dislocation motion which provides a quantitative description of deformation and rotation, grounded in a microscopic order parameter field exhibiting the topologically conserved quantities. The topological current of the Nye dislocation density tensor is derived from a microscopic theory of glide driven by Peach-Koehler forces between dislocations using a simple closure approximation. The evolution law leads to singularity formation in finite time, both with and without dislocation climb. Implementation of finite difference simulations using the upwind scheme and the results in one and higher dimensions will be discussed.

**A8 13 Numerical Studies of annular electroconvection in the weakly nonlinear regime** PEICHUN TSAI, *Department of Physics, University of Toronto* ZAHIR A. DAYA, *Defence R&D Canada* STEPHEN W. MORRIS, *Department of Physics, University of Toronto* We study 2D electrically-driven convection in an annular geometry by direct numerical simulation. The simulation models a real experiment which consists of a weakly conducting, submicron thick liquid crystal film suspended between two concentric electrodes. The film is driven to convect by imposing a sufficiently large voltage $V$ across it. The flow is driven by a surface charge density inversion which is unstable to the electrical force. This instability is closely analogous to the mass density inversion which is unstable to the buoyancy force in conventional thermally-driven Rayleigh-Bénard convection. The important dimensionless parameters are a Rayleigh-like number $R$, proportional to $V^2$, a Prandtl-like number $P$, equal to the ratio of the charge and viscous relaxation times, and the radius ratio $\alpha$, characterizing the annular geometry. The simulation uses a pseudo-spectral method with Chebyshev polynomials in the radial direction and Fourier modes in the azimuthal direction. We deduce the coefficient $g$ of the leading cubic nonlinearity in the Landau amplitude equation from the computed amplitude of convection. We investigate the dependence of $g$ on $\alpha$ and $P$ and compare the results to experimental data and to linear and nonlinear theory.

**A8 14 Demodulation of Electroconvective patterns in Nematic Liquid Crystals*** GYANU ACHARYA, *Kent State University* JOSHUA LADD, *Colorado State University* J.T. GLEESON, *Kent State University* IULIANA OPREA, GERHARD DANGELMAYR, *Colorado State University* We present the results of pattern formation in electroconvection of liquid crystal 4-ethyl-2-fluoro-4'-[2-(trans-4-pentylclohexyl)-ethyl]biphenyl(I52) with planar alignment. The pattern was a function of three control parameters: applied ac voltage, driving frequency and electrical conductivity. Over certain range of conductivity, the initial transition (supercritical Hopf bifurcation) leads to right and left traveling zig and zag rolls.For the demodulation of images, Fourier transform (FT) of a time series of images were taken with the sampling rate greater than the Hopf frequency. To demodulate zig/zag rolls, the region around $\mathbf{k}_n$( the wave vector of a given mode) of interest at one quarter of the FT was taken setting all FTs zero. Taking the index of the maximum FT value at that region as the reference point, again this region was separated into four parts and redistributed at four corners. The absolute value of the inverse FT of the modified function gives the required envelope.

**A8 15 Pattern Formation and Dynamics in Electroconvection of Nematic Liquid Crystals: a Theoretical and Experimental Study of the Weak Electrolyte Model*** IULIANA OPREA, *Colorado State University* J.T. GLEESON, *Kent State University* GERHARD DANGELMAYR, *Colorado State University* Ginzburg Landau formalism is used in the study of electrohydrodynamic convection in a planar layer of nematic liquid crystal based on the weak electrolyte model. Stable wave patterns predicted by weak electrolyte model near a Hopf bifurcation of the basic state are analyzed and bounds for the Eckhaus stability are obtained. The weak electrolyte model, that treats the conductivity as a dynamical variable, is tested by quantitative comparison of experimentally measured and theoretically calculations of specific pa-

rameters, such as the recombination rate and charge transport, for the nematic I52. The experimentally observed spatiotemporal chaos evolving at the onset is qualitatively compared with the spatiotemporal chaos obtained in the numerical simulations of the four globally coupled Ginzburg Landau equations describing the dynamics of the amplitudes of the bifurcated patterns.

**A9 1 Single-electron tunneling force spectroscopy of electronic states in nonconducting surfaces*** EZRA BUSSMANN, NING ZHENG, CLAYTON C. WILLIAMS, *University of Utah* Typically, the scanning tunneling microscope (STM) cannot directly perform current-voltage spectroscopy on any electronic state with a lifetime greater than $\sim 10^{-6}$ seconds—the state cannot empty fast enough to supply the necessary $\sim 0.1$ pA ( $\sim 10^6$ e/s) imaging current. Recently, we reported a scanning probe technique that detects, by electrostatic force, single-electron tunneling events between a probe and states in a nonconducting surface. Here we determine the energy level of such a state by a single-electron tunneling spectroscopy, implemented by tuning the probe Fermi level with respect to the state by a dc voltage. A random telegraph signal (RTS), due to an electron tunneling back-and-forth between the probe and state, is observed when the Fermi level is near the state energy. We present spectroscopic data and extract the energy of a state in a thermal silicon dioxide film. The origin of the RTS is discussed. Additionally, we find evidence for energy relaxation and charge movement in these states. This new nanometer-scale approach provides the means to characterize electronic states in nonconducting surfaces, opening for exploration materials not accessible to the STM. [1] E. Bussmann, D. J. Kim & C.C. Williams, itAppl. Phys. Lett. **85**, 2538 (2004)

**8:12**
**A9 2 High Resolution Studies of the Electronic Properties of Graphite and Graphene** SHUYUN ZHOU, *Department of Physics, University of California, Berkeley, CA 94720; Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA* GEY-HONG GWEON, DANIEL GARCIA, ELIZABETH ROLLINGS, *Department of Physics, University of California, Berkeley, CA 94720* CATALIN SPATARU, STEVEN LOUIE, DUNG-HAI LEE, ALESSANDRA LANZARA, *Department of Physics, University of California, Berkeley, CA 94720; Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA* We report a high-resolution angle-resolved photoemission spectroscopy (ARPES) study on the electronic properties of bulk graphite and atomically-thin graphene layers. Data as a function of both in-plane and out-of-plane momenta, binding energy and photon energy will be presented. We have observed for the first time using ARPES some very interesting electronic properties near the Fermi energy $E_F$, whichshows that inter layer coupling is an important ingredient in understanding the electronic properties of graphite. In addition, the unique electronic properties in atomically–thin graphene layers will be discussed and compared with those from the bulk graphite sample.

**8:24**
**A9 3 Positron Trapping and Annihilation at Reconstructed Ge(100)-(2x1) and Ge(111)-(2x8) Surfaces** ARNAB K. PAL, NAIL G. FAZLEEV, *University of Texas at Arlington* The results of experimental studies of Ge(100) and Ge(111) surfaces using high-resolution positron-annihilation-induced Auger electron spectroscopy are analyzed by performing calculations of the ''image-potential'' surface states and annihilation characteristics for positrons trapped at the reconstructed Ge(100)-(2x1) and Ge(111)-(2x8) surfaces. Estimates of positron binding energy, work function, and annihilation characteristics reveal their sensitivity to surface reconstruction of the topmost layers of clean Ge. These results are compared to the ones obtained for the reconstructed Si(100)-(2x1), Si(100)-p(2x2), and Si(111)-(7x7) surfaces. Comparison of theoretical positron annihilation probabilities computed for different reconstructed surfaces of Ge with experimental ones estimated from the measured Auger peak intensities permits identification of the atomic structure of the topmost layers of the reconstructed surfaces. The effects of adsorbates on the localization of positron surface state at the semiconductor surface and positron annihilation characteristics are discussed.

**8:36**
**A9 4 Probing electron correlation effects of Ni(111) with STM** KEES FLIPSE, *Eindhoven University of Technology* K. BRAUN, *Ohio University, Athens, USA* A. GRECHNEV, M. KATSNELSON, *Radboud University of Nijmegen, The Netherlands* K. RIEDER, *Free University of Berlin, Germany* The role of electron correlation effects in the electronic structure of Ni-metal has been attracting interest for a long time. Here we present an extensive scanning tunneling microscopy and spectroscopy investigation on Ni(111) at low temperature which shows a parabolic surface state with a surprisingly low effective mass compared to the noble metals like Au, Ag and Cu and a d-surface resonance showing an electron-electron interaction signature which can be understood by a many-body calculation of the electronic structure (DMFT). For the first time, a small energy shift and a significant broadening of the electron state due to electron-electron correlation effects are obtained in a STM experiment. This opens the possibility to study electron many-body effects of surface states in detail with a very high energy resolution on a clean and defect free part of the surface.

**8:48**
**A9 5 Low temperature scanning tunneling microscopy study on electronic standing waves and step motion on Au(111) surface** HUI WANG, JONGHEE LEE, DAN SULLIVAN, *Lab for Physical Sciences, Dept. of Physics, University of Maryland* MICHAEL DREYER, *Lab for Physical Sciences, Dept. of Electrical And Computer Engineering, University of Maryland* BARRY BARKER, *Lab for Physical Sciences, National Security Agency* We present a Low Temperature Scanning Tunneling Microscope investigation of step motion and electronic standing waves of Au(111) surface epitaxially grown on Mica. By performing Fourier Transform Scanning Tunneling Spectroscopy, we measured the parabolic surface state dispersion with an effective

mass of $0.25m_e$. This agrees well with the theory and the photoemission data. We also report the step motion of Au(111) surface at 4K. The speed of the motion is around 5 to 20nm/hr. Potential causes for this motion include tip-sample interaction and surface contamination. These and other possible causes will be discussed.

**9:00**

**A9 6 On the inhomogeneous structure and charge transfer of $C_{60}$ monolayer on Ag(001)** XIEQIU ZHANG, AIDI ZHAO, XUDONG XIAO, *Department of Physics and Institute of Nano Science and Technology, Hong Kong University of Science & Technology, Hong Kong, China* WEI HE, JINLONG YANG, *Heifei National Laboratory for Physical at Microscales, University of Science and Technology of China, Heifei, Anhui 230026, China* We have studied the morphological and electronic structure of $C_{60}$ ML/Ag(001) by STM/STS and first principles calculation. The bright-dim contrast of adsorbed $C_{60}$ molecules is identified as originating from geometric effects. Among the dim $C_{60}$ molecules, there consist of dim monomers (DM) and dim dimers (DD), which display distinguished STS. The dI/dV spectra give the energy locations of HOMO, LUMO and LUMO+1-derivated energy bands and the different STS spectra for B, DM, and DD $C_{60}$ molecules indicate that the charge transfer from the substrate is strongly inhomogeneous. The charge transfer has been estimated as $\sim$ 0, $\sim$ 1, $\sim$ 2 electrons/molecule for B, DM and DD from the shift of their corresponding LUMO+1 energy bands, respectively. The DFT calculations give the consistent spectra for B, DM and DD $C_{60}$ molecules with experimental STS data, but with smaller charge transfer.

**9:12**

**A9 7 Electronic Effects in the Length Distribution of Si(553)-Au Chains*** JASON CRAIN, MARK STILES, JOSEPH STROSCIO, DANIEL PIERCE, *Electron Physics Group, NIST* The electronic structure of nanostructures directly impacts their energetics. For example, the confinement of electronic states determines preferred sizes for clusters and thin films. In the present study we investigate the effects of the electronic structure on the self-assembly of Si(553)-Au atomic chains, which are broken into finite-size segments by defects [1,2]. Chains are first fabricated by depositing gold on stepped silicon surfaces [3]. Scanning tunneling microscopy measures the distribution of chain lengths and the correlation between defects separating chains. The distribution of chain lengths reveals incommensurate oscillations that are linked to the electronic scattering vectors at the Fermi surface of the surface states. The pairwise correlation function between defects shows long-range correlations that extend beyond nearest-neighbor defects, indicating coupling between chains. [1] J. N. Crain, A. Kirakosian, K. N. Altmann, C. Bromberger, S. C. Erwin, J. L. McChesney, J. L. Lin, and F. J. Himpsel, Phys. Rev. Lett., 90, 176805 (2003). [2] J. N. Crain and D. T. Pierce, Science, 307, 703 (2005). [3] J. N. Crain, J. L. McChesney, F. Zheng, M. C. Gallagher, P. C. Snijders, M. Bissen, C. Gundelach, S. C. Erwin, and F. J. Himpsel, Phys. Rev. B, 69, 125401 (2004).

**A9 8 An Electronic View of the Step-edge Schwoebel Barrier Problems** YINA MO, *Harvard University* ZHENYU ZHANG, *Oak Ridge National Lab, University of Tennessee* EFTHIMIOS KAXIRAS, *Harvard University* Using First-principle calculations, we studied the energetics of adatoms Co, Fe, Cu, and Zn on the stepped Cu(111) surfaces and that of adatoms Rh, Pd, and Ag on the stepped Pd(111) surfaces. We found that the behavior of the adatoms at the step edge of these substrates is governed by the electronic interactions instead of stain strain effects. The different energetics and kinetics of the different adatoms on the same substrates result from the difference in which these adatoms *see* the charge distributions from the identical substrates. We further clarified that atomic level studies of these cases are required because the bond counting rules are not univeral.

**9:36**

**A9 9 Electronic Structure of NiO (100) and CoO (100) Ultrathin Films on $Fe_3O_4$(100)*** HUI-QIONG WANG, VICTOR HENRICH, *Department of Applied Physics, Yale University, PO Box 208284, New Haven, CT 06520* The electronic structure of ultrathin epitaxial films of two insulating antiferromagnets, NiO and CoO, grown on the metallic ferrimagnet $Fe_3O_4$ is being investigated. NiO (100) and CoO (100) are grown monolayer by monolayer on $Fe_3O_4$ (100) using molecular beam expitaxy; the thin-film electronic properties are characterized by measuring ultraviolet photoelectron spectra (UPS) as a function of overlayer thickness. The evolution of the density-of-states in the O 2p/Fe 3d and O 2p/Ni 3d bands exhibits a shift in the position of the NiO valence band for ultrathin films relative to bulk-like thick films; that band shift is also observed for ultrathin CoO (100) films grown on $Fe_3O_4$ (100). Several possibilities for the origin of that shift will be discussed: one is modification of metal 3d - O 2p hybridization in the thin film; another is change of the on-site Coulomb interaction, U, due to polarization energy and substrate image potentials.

**A9 10 Modification of Surface States in Ultrathin Films via Hybridization with the Substrate – a Study of Ag on Ge** SHU-JUNG TANG, TOM MILLER, TAI-CHANG CHIANG, *University of Illinois at Urbana-Champaign* The Shockley surface state of Ag(111) develops unusual band dispersion relations for Ag films of decreasing thicknesses on Ge(111), as observed by angle-resolved photoemission. Its parabolic dispersion in the thick-film limit shifts toward higher binding energies and splits into multiple bands with dispersions that reflect the valence band structure of Ge including the heavy-hole, light-hole, and split-off bands. The results are explained in terms of a hybridization interaction between the Ag surface state and the Ge substrate states.

**10:00**

**A9 11 Surface electronic structure of H/Li(110) – an application of the semi-infinite method.*** YONAS ABRAHAM, N.A.W. HOLZWARTH, *Wake Forest University* We report the application of our new semi-infinite method to study the Li (110) surface. This method calculates continuum and bound electronic states in the vicinity of a surface of a semi-infinite crystal. It is designed for solving the Kohn-Sham equations in a pseudopotential formulation, including both local and separable non-local contributions. It is based on the Numerov integration algorithm and uses singular value decomposition to control the exponentially growing contributions. For Li (110), we see that H changes the interference patterns of the continuum states. In addition, we are able to locate the energies of H-induced surface states relative to the bulk band edges. Comparison with supercell calculations of the same system, reveal interesting differences.

**A9 12 Possible superconductivity in hetero-polar interfaces of CuCl/Si superlattices: (001) and (111)*** S. H. RHIM, R. SANIZ, A.J. FREEMAN, *Northwestern U,* J.J. YU, *Seoul Natl. U.* To investigate possible interfacial superconductivity[1] in CuCl/Si superlattices, we carried out first-principles calculations using the highly precise FLAPW[2] method. Two possible growth directions, (001) and (111), are compared through their band structures, density of states (DOS), charge densities and Fermi surfaces. While the (111) superlattice is always metallic, the (001) superlattice is metallic or insulating depending on the number of Si and CuCl layers. Both directions exhibit two dimensional (2D) character at the interfaces which is a result of charge transfer between CuCl and Si layers. For metallic superlattices, the 2D conduction bands at the interfaces, resemble the 2D Cu-O $dp\sigma$ bands of cuprate superconductors. To obtain $T_C$ based on conventional electron-phonon (e-p) interactions, we calculated the e-p coupling constant, $\lambda$, within the rigid muffin-tin approximation.[3] The results indicate that while e-p coupling is present in both directions, it gives $T_C = 0.41 \sim 1.69$ K, i.e. one order of magnitude lower than the previously reported high transition temperature[2]- which, if confirmed, would indicate a possible role for excitonic effects.

**A9 13 Measurement of Valley Splitting in a Si/SiGe 2DEG Point Contact** L.M. MCGUIRE, K.A. SLINKER, S. GOSWAMI, *University of Wisconsin-Madison* J.O. CHU, *IBM Research Division, T. J. Watson Research Center* M.A. ERIKSSON, *University of Wisconsin-Madison* We measure the valley splitting as a function of magnetic field in a Si/SiGe two-dimensional electron gas (2DEG) point contact defined by metal top-gates. Using a pair of point contacts on a quantum dot, and a two-point measurement technique, we apply a small ac bias to the source-drain and measure the differential current as we pinch off the channel by applying a negative voltage to the top-gate. As the voltage on the top-gate is varied in zero magnetic field, we observe the conventional steps at conductance values of multiples of $4e^2/h$. By applying a perpendicular magnetic field, we lift both the spin and valley degeneracies, and we see corresponding steps in conductance at every $e^2/h$. By fitting the conductance as a function of magnetic field, we can extract both the subband spacing and the valley splitting energy. Temperature dependence and source-drain spectroscopy plots are shown. At high magnetic fields, step-like features appear at non-integer conductance values in addition to the integer steps. Research made possible by ARDA, the NSA, and NSF.

**A9 14 Quantum effects in the conductivity of high-mobility Si MOSFETs at ultra-low temperatures.** NIKOLAI N. KLIMOV, *Rutgers University* ALEXANDER KUNTSEVICH, VLADIMIR M. PUDALOV, *Lebedev Physics Institute* HARRY KOJIMA, MICHAEL E. GERSHENSON, *Rutgers University* By thorough suppression of electromagnetic noise in our experimental set-up, we were able to cool the electrons in high-mobility Si MOSFETs down to 17mK. We have studied how the conductivity depends on the temperature and the in-plane magnetic field over the density range $n = (2 - 10) \cdot 10^{11} cm^{-2}$, with the focus on the crossover from ballistic transport ($T\tau \gg 1$, where $\tau$ is the momentum relaxation time) to diffusive transport ($T\tau \ll 1$). For our samples, this crossover was observed $T \sim 0.3K$. The quasi-linear dependence $\sigma(T)$ observed in the ballistic regime [1] is in a quantitative agreement with the theory of interaction corrections to the conductivity [2]. At lower temperatures, the interaction corrections are strongly affected by the inter-valley scattering. We have determined the inter-valley scattering rate by analyzing the weak-localization corrections and the dephasing time in the studied Si inversion layers. We will discuss how the interaction corrections in the diffusive regime are modified by the inter-valley scattering. **A10 2 Magneto-optical spectroscopy of single CdSe nanocrystal quantum dots** H. HTOON, V. I. KLIMOV, *Chemistry Division, Los Alamos National Laboratory, New Mexico* M. FURIS, S. A. CROOKER, *National High Magnetic Field Laboratory, Los Alamos, New Mexico* Understanding the spin structure of excitons within nanocrystal quantum dots (NCs) is important on both fundamental grounds and also for technological spintronic applications. While single-NC photoluminescence (PL) studies have become routine, there are no reports of spin-resolved magneto-PL studies with single-NC sensitivity. To this end, we measure low temperature (4 K), polarization resolved, magneto-PL of individual CdSe NCs to 5 Tesla. We clearly observe an energy splitting between left- and right-circularly polarized PL peaks and a strong degree of circular polarization in a subset ( $< 10\%$) of the studied NCs. We attribute this effect to a Zeeman splitting of spin-up and spin-down excitons in those NCs having wurzite-c

axes aligned parallel to the applied magnetic field. Our data reveal that 5T Zeeman splittings vary widely from one NC to another, occasionally reaching values in excess of 2 meV. We compare the results from many single nanocrystals with magneto-PL measurements of NC ensembles.

**8:48**
**A10 3 Optical properties of current carrying molecular wires** MICHAEL GALPERIN, *Northwestern University* ABRAHAM NITZAN, *Tel Aviv University* We consider several fundamental optical phenomena involving single molecules in biased metal-molecule-metal junctions. The molecule is represented by its highest occupied and lowest unoccupied orbitals, and the analysis involves simultaneous consideration of three coupled fluxes: the electronic current through the molecule, energy flow between the molecule and electron-hole excitations in the leads, and the incident and/or emitted photon flux. Using a unified theoretical approach based on the non-equilibrium Green function method we derive expressions for an absorption lineshape (not an observable but a useful reference for considering yields of other optical processes) and for the current induced molecular emission in such junctions. We find that current driven molecular emission and resonant light induced electronic currents in single molecule junctions can be of observable magnitude under appropriate realizable conditions. In particular, light induced current should be observed in junctions involving molecular bridges that are characterized by strong charge transfer optical transitions. For observing current induced molecular emission we find that in addition to the familiar need to control the damping of molecular excitations into the metal substrate the phenomenon is also sensitive to the way in which the potential bias is distributed on the junction.

**A10 4 Observation of Synchronous Photoluminescence Intensity Fluctuations within Single CdSe Quantum Wires** JOHN GLENNON, RUI TANG, WILLIAM BUHRO, RICHARD LOOMIS, *Department of Chemistry and Center for Materials Innovation Washington Unviersity in St. Louis* The intensity of the photoluminescence (PL) within single colloidal CdSe quantum wires (QWs) is observed to synchronously fluctuate along the entire length of the wire in time. Statistical analysis of 'on' and 'off' events within the QWs indicates a power-law temporal dependence nearly identical to that seen in colloidal CdSe quantum dots (QDs). The low PL quantum yields (0.2-2%) of ensemble samples of CdSe QWs suspended in solution are placed in perspective by considering the large inhomogeneity observed in the PL intensities of different QWs. Estimates of the quantum yields for the 'on' events in CdSe QWs are similar to those of CdSe QDs. We also report on the observation of coordinated PL intensity fluctuations in multiple QWs that lie in contact with each other, a surprising entity dubbed a quantum network.

**9:12**
**A10 5 Plasmons in nearly touching metallic nanoparticles: singular response in the limit of touching dimers** ISABEL ROMERO, *Donostia Intl Physics Center, DIPC, Donostia, Spain* JAVIER AIZPURUA, *DIPC, Donostia, Spain* GARNETT W. BRYANT, *NIST, Gaithersburg, MD* F. JAVIER GARCIA DE ABAJO, *Unidad mixta CSIC-UPV/EHU and DIPC, Donostia, Spain* The response of gold nanoparticle dimers is studied near and beyond the limit where the particles are touching. As the particles approach each other, a dominant dipole feature is observed that is pushed into the infrared due interparticle coupling and that is associated with a large pileup of induced charge in the gap region. Lower-frequency, higher-order modes are observed in near touching dimers. After touching, singular behavior is observed through the emergence of infrared absorption peaks, accompanied by huge charge pileup at the nanoparticles junction region. These results explain recent experiments on metallic nanoparticle dimers and are relevant in the design of nanoparticle-based sensors and plasmon circuits.

**9:24**
**A10 6 Surface-Enhanced Raman Scattering Based on Novel Metal Nanostructures (Aggregates, Nanorods, and Nanoshells)** JIN ZHANG, ADAM SCHWARTZBERG, LEO SEBALLOS, TAMMY OSHIRO, *UC Santa Cruz* CHAD TALLEY, *Lawrence Livermore National Lab* REBECCA SUTPHEN, *University of South Florida* YIPING ZHAO, *University of Georgia Athens* Rational design and study of new surface enhanced Raman scattering (SERS) substrates is key to advancing chemical and biological sensing. The next generation of biological probes will ideally be single, small, SERS active nanostructures able to penetrate the inner workings of cells. To this end, we have developed various metal nanostructures based on aggregates, nanorods, and nanoshells with the goal to optimize their SERS activities. We have very recently demonstrated SERS from single, hollow nanostructures. Exceptional sample homogeneity leads to a nearly tenfold increase in signal consistency over standard silver substrates. At 30 nm in diameter, this is the smallest confirmed single SERS active particle ever reported, representing a major step in advancing sensing technology based on SERS. In the meantime, we have applied some of the substrates developed in detection of cancer biomarkers and have achieved high sensitivity and molecular selectivity. The results have shown that SERS is extremely promising for chemical and biological sensing and imaging applications. To control the structure of the nanomaterials and thereby their optical absorption as well as SERS properties is critical for these emerging technological applications.

**A10 7 Nanoparticle Optics: New Materials, Concepts, and Characterization Methods.**
RICHARD VAN DUYNE, *Northwestern University Department of Chemistry*

Nanoparticle Optics is a materials driven subject. The unifying theme in this lecture will be the fabrication of size and shape-tunable, metal nanoparticles using nanosphere lithography (NSL), electron beam lithography (EBL), and chemical synthetic methods. Size and shape tunability leads to an exquisite degree of control over the magnitude and spatial extent of the surface electromagnetic fields that surround optically excited nanoparticles. In turn, this has enabled fundamental

new insights into the electromagnetic (EM) field enhancement mechanism underlying both localized surface plasmon resonance (LSPR) spectroscopy and surface enhanced Raman spectroscopy (SERS). This lecture will focus on three topics: (1) LSPR spectroscopy and its application to the development of nanoscale optical biosensors for the study fundamental biological recognition events; (2) Dark-field Rayleigh scattering spectroscopy is used to show that diffractively narrowed plasmon bands can be produced in columnar arrays of Ag nanoparticles, fabricated by EBL, that are spaced by approximately the single particle plasmon wavelength; and (3) the relationship between the LSPR spectrum of Ag nanoparticles and the wavelength-scanned excitation spectra for both surface-enhanced Raman spectroscopy (WS SERES) and second harmonic generation (WS SHGES) is discussed.

**A10 8 Dielectric confinement effects on the emission lineshipe of single semiconductor nanocrystals** DANIEL GOMEZ, JOEL VAN EMBDEN, PAUL MULVANEY, *The University of Melbourne* We have explored the influence of different matrices on the photoluminescence line shape of individual CdSe core shell nanocrystals (NCs) at room temperature using confocal microscopy / spectroscopy. The results obtained corroborate previous observations of a correlation between blinking events and spectral diffusion but in addition, we have found that the extent of spectral diffusion is almost independent of the dielectric environment of the NC, thus suggesting that ionization and charge reorganization events in the matrix are not responsible for the observed continuous spectral shifts. We also observed that the emission line width is correlated with the emission peak position and that the correlation coefficient between these two variables is a function of the dielectric constant of the matrix surrounding the NC. These results are analyzed in terms of dynamic rearrangements of charges trapped at the surface of the nanocrystal.

**10:24**

**A10 9 Semi-empirical Study of a Multi-associated Rotaxane** KI-HO LEE, KARL SOHLBERG, *Drexel University* Rotaxanes are prototype molecular devices based on two components; one or more ring molecules threaded by a dumbbell-shaped, shaft molecule. In a switchable rotaxane, the shaft has two or more sites strongly attracting the ring with different binding intensity, and translation of the ring between the sites may be induced by switching the relative binding intensity. For amine binding sites, for example, this switching may be accomplished by the protonation of the amine to form a cationic ammonium site. In this study, semi-empirical (AM1) electronic structure calculations have been carried out for a multi-ring, multi-shaft rotaxane. Each of three rings is threaded by a shaft and the three shafts are chemically bonded to each other, limiting the number of degrees of freedom in co-conformations of the entire complex. Each of the three shafts contains one bipyridinium site and one amine site. The latter can be switched to an ammonium site by protonation to induce translation of the associated shaft. We investigate concerted versus stepwise protonation of the amine sites.

**A10 10 Unoccupied electronic structure of and CO Chemisorption on ultrathin Ni films** HUA YAO, A.G DANESE, R.A BARTYNSKI, *Rutgers University* The Ni/Cu(100) system has drawn considerable of attention in recent years because of its importance in both fundamental research and technological applications. Whereas many ultrathin metal systems are dominated by quantum size effects (QSEs), for epitaxial Ni films on Cu(100) there is an intermingling of QSEs, electronic hybridization, and surface/interface effects, making it complicated and challenging to obtain a microscopic picture of this bimetal system. We have performed a series of inverse photoemission (IPE) studies of the unoccupied electronic structure of the Ni/Cu(100) and CO/Ni/Cu(100) systems as a function of Ni thickness. IPE spectra from Ni films exhibit very rich structures. A Phase Accumulation Model calculation suggests only one of the three main features is consistent with metallic quantum well (MQW) State in Ni film. CO adsorption strongly modifies the spectrum by dramatically suppressing one of the main features indicating that this feature is a Ni surface resonance. Furthermore, by comparing spectra from Ni/Cu(100) with results from Cu/Ni/Cu(100), we suggest the third feature is a state confined to the Ni/Cu interface. Since the electronic structure of these films changes as a function of film thickness, it provides a very interesting opportunity to investigate how different electronic state can modify the chemisorption properties of Ni/Cu(100). We have used temperature programmed desorption (TPD) to investigate the bonding between CO and Ni in Ni/Cu(100) system.

**A10 11 Are mechanochemistry and thermal chemistry equal?: probing by nanonewton forces.** MARTIN KONOPKA, IVAN STICH, *Slovak University of Technology* DOMINIK MARX, *Ruhr Universitaet Bochum* Chemical reactions can be triggered by different energies, the most common being the thermal energy. Despite the fact that mechanochemistry, where mechanical energy is used instead of the thermal energy was long known, its practical use and impact was limited. Recently advances in experimental techniques, such as atomic force microscopy, fully opened the intriguing possibility to use mechanical energy as a tool for chemical reactions driven by mechanical energy. We use technologically important systems, short−chain (ethyl) thiolated copper clusters and surfaces to investigate the differences between mechano andthermal chemistry. This is an important and opened question as mechanochemistry and thermal chemistry are rarely applied to the same system. Quantum mechanics simulations based on density functional theory indicate that the two chemical reactions are vastly different. While thermal chemistry affects selectively the thiolate-carbon bond, mechanochemistry leaves that bond intact and leads to metal-metal bond breaking processes and creation of unusual high- energy structures nonexistent in the nature.

**A11 1 Symmetry breaking and coherent control: the importance of the envelope.**
MOSHE SHAPIRO, *University of British Columbia*

I shall review the progress of the field of ''coherent control,'' according to which control of dynamical processes is achieved by using lasers to induce (destructive or constructive) interferences between different quantum pathways leading to the same final outcome. I shall then discuss symmetry breaking stimulated by external laser fields and the role played by the relative and the ''envelope'' phase. Applications to chiral purification and the control of photo-current directionality in semiconductors will be given.

**A11 2 Coherent Phase Control of the Ionization and Dissociation of Vinyl Chloride*** ROBERT J. GORDON, VISHAL J. BARGE, ZHAN HU, JOYCE WILLIG, *Department of Chemistry, University of Illinois at Chicago* Two-pathway quantum interference was used to control the photochemical reactions of vinyl chloride ($C_2H_3Cl$, VCl). A molecular beam of VCl was irradiated simultaneously with 532 and 177 nm laser light, produced from the second and sixth harmonics of a Nd:YAG laser. The relative phase of the visible and UV lasers was adjusted by passing them through a cell containing a variable pressure of hydrogen gas, and the parent and fragment ($C_2H_3$ and HCl) ions of VCl were detected with a time-of-flight mass spectrometer. The phase lags between different pairs of modulated ion signals depended on the location of the laser focus. This variation of the phase lags was produced by the axial spatial phase of the focused laser beam. A non-zero phase lag between the parent and fragment ions produced when the laser was focused in the center of the spectrometer slit is indicative of coherent control of the branching between ionization and dissociation.

**A11 5 Energy transfer of highly vibrationally excited azulene: crossed-beam study of collisions between azulene and krypton** CHI-KUNG NI, *Institute of Atomic and Molecular Sciences, Academia Sinica* The energy transfer dynamics between highly vibrationally excited azulene molecules and Kr atoms in a series of collision energies was studied using a crossed-beam apparatus along with time-sliced velocity map ion imaging techniques. The shapes of the collisional energy-transfer probability distribution functions were measured directly from the scattering results of highly vibrationally excited or ''hot'' azulene. At low enough collision energies an azulene-Kr complex was observed, resulting from small amounts of translational to vibrational/rotational (T-V/R) energy transfer. T-V/R energy transfer was found to be quite efficient. On the other hand, only a small fraction of vibrational energy is converted to translational energy (V-T). We find that substantial amounts of energy are transferred in the backward scattering direction due to supercollisions at high collision energies.

**9:48**
**A11 6 Systematic degeneracies as a guide to the vibrational dynamics of methanol** DAVID PERRY, *The University of Akron* The vibrational dynamics of the CH stretch and torsional vibrations of methanol are explored using a 4-dimensional effective Hamiltonian. The model parameters are constrained by a combination of low-resolution and high-resolution spectral data. At low excitation energies, the torsion-vibration states are at most 2-fold

degenerate as expected for the combination of the E-type torsional tunneling species with the A' and A'' (in Cs) CH stretch vibrations. At high torsional energies, we find a series of approximate 4-fold degeneracies characteristic of a degenerate E-type asymmetric CH stretch in combination with the decoupled degenerate free internal rotation. When a single CH bond is excited to a high level, torsional tunneling is quenched causing all such levels to be 3-fold degenerate. When both a local CH stretch and internal rotation are highly excited, we find systematic 6-fold degeneracies characterized by free internal rotation decoupled from three equivalent local CH stretches. The transition regions between these simple limiting behaviors are explored.

**10:00**
**A11 7 Vibrationally Enhanced Reactions of Highly Excited Pyridine-$d_5$ ($E_{vib}$=38,000 $cm^{-1}$) with Cl Radicals** AMY MULLIN, ZIMAN LI, QINGNAN LIU, *University of Maryland* High resolution transient IR probing of DCl reaction products at 4.9 $\mu$m is used to study the influence of large amounts of internal energy on D-atom abstraction reactions of pyridine-$d_5$ ($E_{vib}$=38,100 $cm^{-1}$) with Cl radicals. Vibrationally hot pyridine-$d_5$ molecules are prepared using 266 nm pulsed excitation and Cl radicals are generated by photodissociation of $Cl_2$ at 355 nm. Cl radicals undergo collisions with pyridine-$d_5$ with $E_{rel}$=2990 $cm^{-1}$ which is near $\Delta H_{rxn}$=3050 $cm^{-1}$. The D-atom abstraction rates are enhanced by a factor of 200-300 when the pyridine reactant is vibrationally excited. Energy measurements of the products show that the pyridinyl radical has lost only one quantum of the C-D stretch. We find that the reaction mechanism is direct with a linear transition state. The lack of energy equilibration among the reaction products highlights the local nature of the transition state and shows that most of the pyridine vibrational energy is not available to the reaction. The experimental results are compared to phase space theory calculations that predict a vibrational enhancement of $\sim 10^6$-$10^8$.

**A12 1 Crystal Surface Morphological Evolution: From Step Motion to A Continuum Theory.**
DIONISIOS MARGETIS, *Massachusetts Institute of Technology*

Modern technological advances rely on the synthesis of nanoscale surface features on crystalline materials. Despite 50 years of progress, the related evolution laws have evaded a complete theoretical description. In this talk I describe analytically the recent derivation and applications of a continuum theory in 2+1 dimensions for crystal surfaces evolving below the roughening temperature. First, microscopic laws are formulated for the motion of atomic steps, which compose crystal surfaces, by incorporating: (i) diffusion of point defects (adatoms) on each terrace between steps; (ii) atom attachment-detachment at step edges; (iii) step curvature and elastic step interactions; and (iv) material deposition from above. Second, macroscopic laws are derived from step models: The surface height satisfies a fourth-order, nonlinear PDE for the anisotropic effect of fluxes of adatoms via an appropriate tensor mobility. The continuum solutions become questionable near macroscopic, flat surface regions (''facets'') and step bunches. Third, particular solutions are invoked to plausibly unify experimental observations of decaying bi-directional profiles via an interplay of step kinetics and surface topography. Fourth, free-boundary problems are solved for the facet evolution of axisymmetric crystal shapes: The appropriate boundary conditions are nonlocal with time. The continuum predictions compare favorably with numerical simulations for individual steps. The formation of step bunches is studied via suitable continuum coordinates of step motion.

**A12 2 Mass Transport in Nano-scale Step Fluctuations*** FERENC SZALMA, T.L. EINSTEIN, M. DEGAWA, E.D. WILLIAMS, *U. of Maryland* D.B. DOUGHERTY, *U. of Pittsburgh* Extending earlier work,[1] we investigate the linear response of a 2D nano-scale system to small perturbations and determine its transport properties. We use a 2-parameter-based energy landscape to simulate a supersaturated lattice gas by a BKL kinetic MC algorithm. The 2D gas atoms condense into a small island surrounded by a dilute gas. Island-edge fluctuations are due to both the diffusion of island atoms along its edge and atom exchange with the surrounding rare gas. Their relative importance depends on the ratio of the two energy parameters. We focus on adatom diffusion on Pb(111) surfaces below the roughening temperature, with energy parameters taken from EAM calculations. We find that edge fluctuations are mainly due to diffusion along the island edge, and determine the temperature dependence of the associated hopping rate. The Arrhenius behavior of the rates yields an effective energy barrier which fits well in the series of similar barriers for Pt, Au, and Ag. After comparing with experiments involving spirals as well as islands on Pb, we assess our simple model.

**A12 3 Persistence Properties of Interacting Steps: Qualitative Failure of Mean Field*** HAILU GEBREMARIAM, T. L. EINSTEIN, *U. of Maryland, College Park* CHANDAN DASGUPTA, *Indian Inst. of Science, Bangalore* In studying the persistence properties of fluctuating steps on a vicinal surface, we examine the effect of interactions between steps on the correlation function $C(t)$ of step excursions from their mean position. For times much

longer than the correlation time $\tau_c$, $C(t) \propto exp(-t/\tau_c)$. The standard way to include step repulsions ($\propto A/l^2$) simply is the mean field, Gruber-Mullins (GM) approximation, in which each step experiences a harmonic potential that narrows with increasing repulsion.[1] Monte Carlo simulations of a terrace-step-kink model show that $\tau_c$ then decreases with increasing $A$. Including the full repulsion between neighboring steps, we find the opposite trend: $\tau_c$ increases with $A$, due to in-phase meandering absent in GM.[2] However, the time constant $\tau_s$ associated with the exponential decay of the survival probability decreases with $A$. The ratio $\tau_s/\tau_c$ decreases slowly with $A$, from 0.38 at $A = 0$, thereby satisfying the theorem that this ratio be $< 1$.[2]. We also discuss the scaling properties of autocorrelation and survival, in particular the dependence on sampling time and on lateral system size.

**A12 4 Debye Model of Steps on Vicinal Crystal Surfaces*** HOWARD L. RICHARDS, CLINT A. GREENE, *Texas A & M University-Commerce* The steps on a vicinal crystal surface can be mapped onto the world lines of spinless fermions, with the average direction of the steps (the $y$-direction) being mapped to time. If the interaction energy per unit length between neighboring steps is given by $V(L) = A/L^2$ (as is common), this resulting quantum system is integrable for only three values of $\tilde{A} \equiv \tilde{\beta}A/(k_BT)^2$. For other values of $\tilde{A}$, the Pairwise Einstein Model gives an excellent approximation for the Terrace Width Distribution (TWD, the histogram of $x_{i+1}(y) - x_i(y)$) but is severely limited in describing $g_x(\Delta y) \equiv \langle [x_i(y + \Delta y) - x_i(y)]^2 \rangle$, particularly for $\Delta y > \xi$, the correlation length. Here we show how the one- dimensional Debye model correctly gives $g_x(\Delta y)$ even for large $\Delta y$. The Pairwise Einstein Model also suggests a relationship between the compressibility of the steps and the tails of the TWD, a relationship we clarify using the Debye model.

**A12 5 Step Evolution Toward Equilibrium: Fokker-Planck Approach*** AJMI BEN HAMOUDA, ALBERTO PIMPINELLI, *LASMEA, U. Blaise Pascal Clermont-2, France* HAILU GEBREMARIAM, T. L. EINSTEIN, *U. of Maryland, College Park* We have derived a Fokker-Planck equation (FPE) that describes the relaxation of steps on vicinal surfaces toward the generalized Wigner surmise $P_\varrho(s) = as^\varrho \exp(-bs^2)$, arguably the best (both conceptually and quantitatively) description of the equilibrium terrace-width distribution (TWD) of steps on a vicinal surface.[1] Focusing on the variance of the terrace-width distribution, we consider several physically-relevant initial states: perfect cleavage (straight, uniformly spaced), step bunch, and equilibrated distributions at different temperatures (prior to quenching), as well as other models. We compare analytic results with Monte Carlo studies, Metropolis and kinetic. We discuss the crucial question of how to make connections between the FPE time scale in analytic results and the actual time scale in simulations of models and in measurements of physical systems.

**A12 6 Ab-initio Evaluation of Extended Lattice Gas Interactions of Cu on Cu(111) and Cu(001)*** T. J. STASEVICH, T. L. EINSTEIN, *University of Maryland, College Park* S. STOLBOV, *Kansas State University* Lattice gas models connect macroscopic evolution to microscopic energies. The traditional empirical parameterization of these models can lead to incomplete descriptions that yield effective rather than actual energies. More recently, self-consistent computations from first principles of the relevant interaction energies can be used to diminish the risk of incompleteness. We have used such an approach to calculate a variety of lattice-gas interaction energies between Cu adatoms on Cu(001) and Cu(111). We find that pair interactions beyond first neighbors are negligible on Cu(111), whereas second neighbor interactions are significant on Cu(001). Besides pair-interactions, we find that trio-interactions can also be quite large. On Cu(111) these include two orientation dependent trios that account for the difference in the formation energies of A- and B-steps. When taken together, the calculated interaction energies are self-consistent and compare well with previous theory and experiment[1].

**A12 7 Surface Smoothening Mechanism of Plasma-Deposited Amorphous Silicon Thin Films** MAYUR VALIPA, *University of California, Santa Barbara* TAMAS BAKOS, *University of Massachusetts, Amherst* ERAY AYDIL, *University of Minnesota, Minneapolis* DIMITRIOS MAROUDAS, *University of Massachusetts, Amherst* An important concern in the plasma deposition of thin hydrogenated amorphous silicon (a-Si:H) films is to obtain smooth surfaces. Under conditions that lead to device-quality a-Si:H films, the dominant deposition precursor is the $SiH_3$ radical. In this presentation, we report results of molecular-dynamics simulations combined with first-principles density functional theory calculations to elucidate the smoothening mechanism of plasma deposited a-Si:H thin films. We show that $SiH_3$ may diffuse rapidly on the a-Si:H film surface via overcoordinated surface Si atoms and incorporate into the film preferentially in surface valleys, after H atom transfer and formation of two Si-Si backbonds, with activation barriers for incorporation dependent on the local surface morphology. Experimental data on smoothening and $SiH_3$ diffusion are accounted for.

**A12 8 On the Phase Shift of RHEED Intensity Oscillation during Homoepitaxy by MBE** B. SHIN, *DEAS, Harvard Univ.* J.P. LEONARD, *Dept. Mat. Sci. & Eng., Univ. of Pittsburgh* J.W. McCAMY, M.J. AZIZ, *DEAS, Harvard Univ.* Despite the widespread usage of RHEED over many years, there still remain fundamental questions unanswered with regard to the interpretation of RHEED measurements. One of these issues is the phase shift of the RHEED intensity oscillations upon changing the incidence angle of electron beams. Therefore, we have conducted a systematic investigation of the phase shift of the RHEED intensity oscillations during homoepitaxy of Ge(001) by MBE for a wide range of diffraction conditions. Our results show that for small incidence angles with a beam azimuth several degrees away from crystallo-

graphic symmetry directions, the phase stays the same; it starts to shift once the (004) Kikuchi line appears in the RHEED pattern. Moreover, under some conditions we observe the oscillations from only the Kikuchi feature and not from the specular spot, and the oscillatory behavior of the Kikuchi feature is almost out of phase with that of the specular spot. All these results convincingly demonstrate that the phase shift is caused by the interference of the specular spot by the Kikuchi features. The lesson that can be learned from our study is that in order to use the RHEED specular intensity oscillation to learn about surface morphology, one must be extremely careful that the RHEED measurements be conducted under conditions where the influence of the Kikuchi features is minimal.

**A12 9 Properties of steps at faceted crystal-melt interfaces from molecular dynamics simulations** DOREL BUTA, *Northwestern University* MARK ASTA, *University of California Davis* JEFFREY HOYT, *Sandia National Laboratories* The properties of steps at faceted solid-liquid interfaces are key elements to understanding the anisotropy of interfacial free energies and mobilities, which in turn control the morphology of crystals grown from the melt. We investigate the equilibrium and non-equilibrium dynamics of arrays of steps at vicinal interfaces of Si(111) with molecular dynamics simulations of the Stillinger-Weber model. Step mobilities determined from isothermal crystallization simulations are found to decrease as the density of steps increases. We relate the decrease in step mobility to an increase in the effective stiffness of the interacting steps, manifested by a reduction in the width of equilibrium step fluctuations as the average distance between steps decreases. The analysis of step fluctuations is also instrumental in determining the nature of step-step interactions.

**A12 10 Ensemble Approach to Vicinal Crystal Surfaces** RYAN P. JACOB, HOWARD L. RICHARDS, *Physics, Texas A & M University-Commerce* T.L. EINSTEIN, *Physics, University of Maryland* Recent studies of the Step Position Distribution (SPD) have made it clear that there exists a characteristic length $L_W$ (along the $y$-axis, parallel to the average step direction) at which the variance of the SPD is correctly predicted by the Pairwise Einstein Model. We extend this to the case when neighboring steps have different stiffnesses. A similar characteristic length along $y$ must be introduced to calculate average properties from an ensemble of Gruber-Mullins models, subject to the constraint that the variance of the Terrace Width Distribution (TWD) is as given by the Pairwise Einstein Model. We discuss the relationship between these length scales for a range of step interactions.

**A12 11 Growth and Atomic Structure of Periodically Striped Ag Films on a One-dimensional Surface Reconstruction** TAKASHI UCHIHASHI,* *Nanomaterial Laboratory, National Institute for Materials Science, 1-1, Namiki, Tsukuba, Ibaraki, 305-0044, Japan* CHIGUSA OHBUCHI, SHIGERU TSUKAMOTO, TOMONOBU NAKAYAMA, We report the growth behavior of Ag thin films formed on the Si (111)4x1-In reconstruction, which is composed of periodic indium atomic chain arrays on a silicon surface. We use a two- step growth method, i.e., low temperature ( 100K) deposition of a Ag film followed by annealing up to room temperature. Scanning tunneling microscope (STM) and low energy electron diffraction (LEED) measurements clarify that Ag films have stripe structures with a periodicity equal to that of the Si (111)4x1-In reconstruction (= 1.33 nm), thus demonstrating its viability of an atomic-scale geometrical template. The stripe structure persists up to the film thickness as large as 30 monolayers (ML), contrary to the expectation that strained films should relax rapidly. We attribute this stability to a coincidental matching of the transverse periodicity and the corrugation amplitude between the stripe structure and the substrate, which is realized by periodic insertion of stacking faults into the Ag fcc lattice.

**A12 12 Mound slope and shape selection during unstable multilayer growth: Exact continuum formulation from a step dynamics model** JIM EVANS, *Iowa State University* MAOZHI LI, *Iowa State University* Multilayer growth is unstable in the presence of a step-edge barrier which leads to the formation of mounds. Mound sides steepen at first, but then often attain a selected slope controlled by such processes as downward funneling. Atomistic modeling is very successful in describing such behavior [1], but continuum PDE formulations are often more efficient and instructive [2]. However, by analysis of a step-dynamics model for mound formation, we show that existing phenomenological PDEs fail to correctly predict mound slopes and shapes [3]. We coarse-grain the step-dynamics models to obtain a correct theory. [1] K.J. Caspersen et al. PRB 65 (2002) 194407; [2] M. Siegert, PRL 81 (1998) 5481; [3] M. Li and J.W. Evans, PRL in press.

**A13 1 Watching proteins function with picosecond X-ray crystallography and molecular dynamics simulations.*** PHILIP ANFINRUD, *NIH*

Time-resolved electron density maps of myoglobin, a ligand-binding heme protein, have been stitched together into movies that unveil with $<$ 2-Å spatial resolution and 150-ps time-resolution the correlated protein motions that accom-

pany and/or mediate ligand migration within the hydrophobic interior of a protein. A joint analysis of all-atom molecular dynamics (MD) calculations and picosecond time-resolved X-ray structures provides single-molecule insights into mechanisms of protein function. Ensemble-averaged MD simulations of the L29F mutant of myoglobin following ligand dissociation reproduce the direction, amplitude, and timescales of crystallographically-determined structural changes. This close agreement with experiments at comparable resolution in space and time validates the individual MD trajectories, which identify and structurally characterize a conformational switch that directs dissociated ligands to one of two nearby protein cavities. This unique combination of simulation and experiment unveils functional protein motions and illustrates at an atomic level relationships among protein structure, dynamics, and function. In collaboration with Friedrich Schotte and Gerhard Hummer, NIH.

**A13 2 Raman spectra of normal and cancerous mouse mammary gland tissue using near infrared excitation energy** VAMAN NAIK, *University of Michigan-Dearborn* G.K. SERHATKULU, H. DAI, N. SHUKLA, R. WEBER, J.S. THAKUR, D.C. FREEMAN, A.K. PANDYA, G.W. AUNER, R. NAIK, *Wayne State Univ.* R.F. MILLER, *Karmanos Cancer Research Inst., Detroit, MI* A. CAO, M.D. KLEIN, R. RABAH, *Children's Hospital of Michigan* Raman spectra of normal mammary gland tissues, malignant mammary gland tumors, and lymph nodes have been recorded using fresh tissue from mice. Tumors were induced in mice by subcutaneously injecting 4T1 BALB/c mammary tumor (a highly malignant) cell line. The Raman spectra were collected using the same tissues that were examined by histopathology for determining the cancerous/normal state of the tissue. Differences in various peak intensities, peak shifts and peak ratios were analyzed to determine the Raman spectral features that differentiate mammary gland tumors from non-tumorous tissue. Tissues that were confirmed by pathology as cancerous (tumors) show several distinctive features in the Raman spectra compared to the spectra of the normal tissues. For example, the cancerous tissues show Raman peaks at 621, 642, 1004, 1032, 1175 and 1208 $cm^{-1}$ that are assignable to amino acids containing aromatic side-chains such as phenylalanine, tryptophan and tyrosine. Further, the cancerous tissues show a greatly reduced level of phospholipids compared to the normal tissues. The Raman spectral regions that are sensitive to pathologic alteration in the tissue will be discussed.

**A13 3 Probing the $\beta$-hairpin local structure by FTIR, 2D IR and ab initio calculations*** JIANPING WANG, *Department of Chemistry, University of Pennsylvania, PA 19104* JIANXIN CHEN, ROBIN M. HOCHSTRASSER, Small peptides form vibrational exciton systems that can be examined by means of recently developed two-dimensional infrared (2D IR) correlation techniques. We used these methods to examine a 12-residue $\beta$-hairpin (trpzip2) and its two $^{13}C$-isotopomers in the 6-$\mu$m region. Different frequency shifts are seen when $^{13}C{=}^{16}O$ substitution is in the terminal or turn region of the hairpin. The difference is believed to be due to the localization of the amide-I modes, which is supported by molecular dynamics simulations. In addition, $^{13}C$-substitution perturbs the amide-I vibrational exciton band, providing a spectroscopic probe for peptide local conformation. Peptide global and local structural information were derived from the diagonal and the cross peaks of the 2D IR correlation spectra. The measured intermode vibration coupling constants were compared with those predicted by ab initio DFT computations and transition charge coupling calculations.

**A13 4 Spectral Signatures of $3_{10}$- and $\alpha$-Helices Revealed by Two-Dimensional Infrared Spectroscopy*** NIEN-HUI GE, HIROAKI MAEKAWA, *Department of Chemistry, University of California at Irvine* CLAUDIO TONIOLO, *Department of Chemistry, University of Padova, Italy* QUIRINUS BROXTERMAN, *DSM Research, Life Sciences, Advanced Synthesis and Catalysis, The Netherlands* Femtosecond two-dimensional infrared (2D IR) spectroscopy is applied to the amide I modes of the homo-octapeptide *Z*-[L-($\alpha$Me)Val]$_8$-O*t*Bu in $CDCl_3$, TFE and HFIP solutions to acquire 2D spectral signatures that distinguish between $3_{10}$- and $\alpha$-helix structures. Suppression of diagonal peaks by controlling polarizations of IR pulses clearly reveals cross-peak patterns that are crucial for structural determination. A doublet feature is observed when the peptide forms a $3_{10}$-helix in $CDCl_3$ and TFE, and when it is at the initial stage of $3_{10}$- to $\alpha$-helix transition in HFIP. In contrast, the 2D IR spectrum shows a multiple peak pattern after the peptide has become an $\alpha$-helix in HFIP. This is the first report on the experimental 2D IR signature of a $3_{10}$-helical peptide. These results for a model octapeptide demonstrate the powerful capability of 2D IR spectroscopy to discriminate between different helical structures.

**A13 5 Terahertz Absorption and Circular Dichroism Spectroscopy of Solvated Biopolymers*** JING XU, *Physics, UCSB* KEVIN PLAXCO, *Chemistry and BioChemistry, UCSB* S. JAMES ALLEN, *Physics, UCSB* Biopolymers are expected to exhibit broad spectral features in the terahertz frequency range, corresponding to their functionally relevant, global and sub-global collective vibrational modes with $\sim$ picosecond timescale. Recent advances in terahertz technology have stimulated researchers to employ terahertz absorption spectroscopy to directly probe these postulated collective modes. However, these pioneering studies have been limited to dry and, at best, moist samples. Successful isolation of low frequency vibrational activities of solvated biopolymers in their natural water environment has remained elusive, due to the overwhelming attenuation of the terahertz radiation by water. Here we have developed a terahertz absorption and circular dichroism spectrometer suitable for studying biopolymers

in biologically relevant water solutions. We have precisely isolated, for the first time, the terahertz absorption of solvated prototypical proteins, Bovine Serum Albumin and Lysozyme, and made important direct comparison to the existing molecular dynamic simulations and normal mode calculations. We have also successfully demonstrated the magnetic circular dichroism in semiconductors, and placed upper bounds on the terahertz circular dichroism signatures of prototypical proteins in water solution.

**A13 6 Intermediate couplings: NMR at the solids-liquids interface.**
MEGAN SPENCE, *University of Pittsburgh*

Anisotropic interactions like dipolar couplings and chemical shift anistropy have long offered solid-state NMR spectroscopists valuable structural information. Recently, solution-state NMR structural studies have begun to exploit residual dipolar couplings of biological molecules in weakly anistropic solutions. These residual couplings are about 0.1% of the coupling magnitudes observed in the solid state, allowing simple, high-resolution NMR spectra to be retained. Inthis work, we examine the membrane-associated opioid, leucine enkephalin (lenk), in which the ordering is ten times larger than that for residual dipolar coupling experiments, requiring a combination of solution-state and solid-state NMR techniques. We adapted conventional solid-state NMR techniques like adiabatic cross- polarization and REDOR for use with such a system, and measured small amide bond dipolar couplings in order to determine the orientation of the amide bonds (and therefore the peptide) with respect to the membrane surface. However, the couplings measured indicate large structural rearrangements on the surface and contradict the published structures obtained by NOESY constraints, a reminder that such methods are of limited use in the presence of large-scale dynamics.

**A13 7 Time correlation functions in Light Harvesting Complexes embedded in Glassy Hosts*** FELIPE CAYCEDO, FERNEY RODRIGUEZ, *Universidad de los Andes* Using a Monte Carlo Wave function approach we describe the dynamics and correlation functions of light harvesting complexes (LH2) embedded in glassy hosts interacting with a classical light field. Using a dipolar interaction, we investigate the general features of coherence and (anti) bunching on a multiple-molecular system subject to cw excitation light. Spectral difusion due to environmental perturbations, produces distinct features on the fluorescent intensity and statistical properties of light emitted by the chromophores. We demonstrate how it is possible to quantify the number of chromophores involved in emission through the second-order correlation function $g^{(2)}(\tau)$ at small $\tau$ values. By changing properly the incident field, it is possible modulate the bunching or antibunching features. Finally we compare $g^{(2)}(\tau)$ for different environment conditions.

**A13 8 Conformational Dynamics of the Receptor Protein Galactose/Glucose Binding Protein*** TROY MESSINA, DAVID TALAGA, *Rutgers, the State University of New Jersey, Department of Chemistry and Chemical Biology, Pistataway, NJ 08854* We have performed time-correlated single photon counting (TCSPC) anisotropy and Stokes Shift measurements on bulk solutions of galactose/glucose binding protein. Site-directed mutagenesis was used to provide a single cysteine amino acid near the sugar-binding center of the protein (glutamine 26 to cysteine – Q26C). The cysteine was covalently labeled with the environmentally-sensitive fluorophore acrylodan, and a long-lived ruthenium complex was covalently attached to the N-terminus to provide a fluorescent reference. The TCSPC data were analyzed using global convolute-and-compare fitting routines over the entire glucose titration and temperature range to provide minimal reduced chi-squared values and the highest time resolution possible. Using a standard ligand-binding model, the resulting distributions show that the closed (ligand-bound) conformation exists even at zero glucose concentration. At 20°C, the relative abundance of this conformation is as high as 40%. The temperature dependence of this conformational study will be discussed and related to the ligand-binding free energy surface.

**A13 9 Quantifying Energy, Entropy and Free-Energy in Protein Folding Funnels*** BERNARD GERSTMAN, PREM CHAPAGAIN, *Department of Physics, Florida International University* The folding of proteins is a self-organizing process in which a long chain heteropolymer in a disorganized configuration spontaneously changes its shape to a highly organized structure. Several different forces work together to organize the structure while random thermal motion tends to cause disorganization. In order for folding to occur in a biologically relevant time, the Levinthal Paradox shows that folding cannot occur by a process that samples all of configuration space by randomly jumping from one microstate to another. Instead, folding pathways allow the organizing forces to incrementally direct the chain to ever-shrinking regions of configuration space in a funneling process. In order to understand how these self-organizing forces direct folding, we have quantified the narrowing of the folding funnel for a model two helix bundle. We have calculated the dependence of entropy and free-energy as a function of average energy by determining the statistical mechanical canonical probability for the chain to occupy each possible configuration as a function of average energy.

**A13 10 Landscape model of protein-DNA search: coupling of folding and sliding.** MICHAEL SLUTSKY, MEHRAN KARDAR, LEONID MIRNY, *MIT* In search for its specific site on genomic DNA, a DNA-binding protein needs to sample $10^6$-$10^9$ other sites. Classical model of this process suggests that sliding along DNA provides an efficient mechanism for sampling sites. This model however disregards the sequence-specific energy of binding and flexibility of the protein. Recent NMR studies suggest that a protein searching for its site is partially unfolded, while folding on the cognate site. Can conformational flexibility of the protein-DNA complex help it to sample sites fast and then strongly bind its cognate site? Here we study how a protein finds its site on DNA by modeling protein sliding as diffusion in the sequence-specific free energy landscape. The landscape has two dimensions: one corresponds to motion along DNA, the other is a reaction coordinate of protein's conformational transition. Our simulations demonstrate that low-energy sites can trigger folding transition in the protein, making it fold preferentially on cognate-like sites. This mechanism provides kinetic pre-selection of sites, allowing a protein to search fast and strongly bind its cognate site. Importantly our study connects microscopic time of the conformational transition ($10^{-5}$-$10^{-3}$s) to the macroscopic time of promoter binding ($10^1$-$10^3$s). Comparison with recent experimental studies of LacI conformational dynamics suggests that coupling between protein flexibility and sequence-specific binding is necessary for rapid regulation of gene expression.

**A13 11 Modelling Ultra-fast folding proteins** KINGSHUK GHOSH, S. BANU OZKAN, KEN DILL, *Dept of Pharm. Chem, University of California, San Francisco* Ultrafast-folding proteins are interesting because of their complex temperature dependent rates (including negative activation barriers). We develop a simple mesoscopic model that represents protein folding as a funnel through multiple routes. We have compared the model to experiments on several ultra-fast folding proteins. The model predicts the observed temperature dependences of folding and unfolding relaxation. Our model allows us to calculate the number of routes a molecule takes as it folds. We show that number of folding routes correlates with the folding time and also with the relative contact order: faster folders have more folding routes. Our model suggests a hard speed limit of 50 ns, when every protein folds via its own private route, and this corresponds to the folding time of an alpha helix. The model also computes folding time distributions which will be of interest for single molecule experiments.

**A15 1 Ultrasmall metal clusters and their interaction with a molecular matrix – the fullerene-Au model system** PETRA REINKE, HUI LIU, *University of Virginia* HELGE KROEGER, *Universitaet Goettingen* Metal clusters with less than 50 atoms, are of great interest in the development of true nanoscale electronics. The electronic structure is strongly size dependent and future applications rely on a narrow size distribution. Our goal was to investigate the possibility to use fullerene surfaces as templates in the formation of cluster arrays, to analyze the cluster-fullerene interface and the electronic structure of the components. This study was performed by using photoelectron spectroscopy, and scanning tunneling microscopy and spectroscopy (UHV-conditions). The Au-cluster size is controlled by the coverage and the fullerene lattice limits the cluster surface mobility, making them accessible to STM analysis. The fullerene matrix enhances the cluster stability and ripening occurs above 500 K. A comprehensive description of the Au-cluster-fullerene system has been achieved and includes the interface characteristics, local and global electronic structure, and the spatial distribution of Au-clusters with respect to the fullerene matrix. Our understanding is currently most advanced for the Au-$C_{60}$ and Si- $C_{60}$system, where in the latter, a preferential nucleation at the interstitial lattice sites of the $C_{60}$ was confirmed.

**8:12**

**A15 2 Simulation of tunneling I-V curves from gold nanocrystals** JIANFEI SHAO, PHILLIP FIRST, *Georgia Institute of Technology* Tunneling current versus voltage (I-V) spectra were simulated for model double junction systems where the central electrode has a discrete energy spectrum, chosen to approximately model gold nanocrystals in the diameter range of 1-3 nm. The interplay between Coulomb charging and the discrete energy states introduces interesting features in the I-V curves. Electron-hole excited configurations of the nanocrystal, with up to two e-h excitations, have been included in the calculations. As compared with the orthodox theory, features in the dI/dV spectra can be modified substantially as a consequence of the nanocrystal excited states, depending on the energy spacing between states relative to both the HOMO-LUMO gap and the charging energy.

**A15 3 Modeling of UV laser-induced patterning of ultrathin Co films on bulk SiO2: verification of short- and long-range ordering mechanisms** JUSTIN TRICE, *Department of Physics, Washington University in St. Louis, MO 63130* CHRISTOPHER FAVAZZA, *Department of Physics, Washington University in St. Louis, MO 63130* RAMKI KALYANARAMAN, *Department of Physics, Washington University in St. Louis, MO 63130* R. SURESHKUMAR, *Department of Chemical Engineering, Washington University in St. Louis, MO 63130* DEPARTMENT OF PHYSICS, WASHINGTON UNIVERSITY IN ST. LOUIS, MO 63130 TEAM, DEPARTMENT OF CHEMICAL ENGINEERING, WASHINGTON UNIVERSITY IN ST. LOUIS, MO 63130 COLLABORATION, Irradiating ultrathin Co films (1 to 10 nm) by a short-pulsed UV laser leads to pattern formation with both short- and long-range order (SRO, LRO). Single beam irradiation produces SRO, while two-beam interference irradiation produces a quasi-2D arrangement of nanoparticles with LRO and SRO. The pattern formation primarily occurs in the molten phase. An estimate of the thermal behavior of the film/substrate composite following a laser pulse is presented. The thermal behavior includes the lifetime of the liquid phase and the thermal gradient during interference heating. Based on this evidence, the SRO is attributed to spinodal dewetting of the film while surface tension gradients induced by the laser interference pattern appear to influence LRO [1]. [1] C.Favazza, J.Trice, H.Krishna, R.Sureshkumar, and R.Kalyanaraman, unpublished.

**A15 4 X-Ray Study of the Epitaxial Growth of Magnetron Sputtered Ni-Al Thin Films** WOLFGANG DONNER, *University of Houston* NOUREDDINE ANIBOU, *University of Houston* Epitaxial growth of metals on semiconductors is of significant interest for both fundamental and technological reasons. Nickel-rich NiAl alloys are model materials for high-temperature shape-memory alloys. The sputter deposition growth of NiAl thin films and the X-ray study of the different phases grown on those films are the main purpose of this work. NiAl films were grown on different substrates. The Ni63Al37/Si(001) system is investigated and showed a fiber textured growth along the [111] direction of the low temperature phase L1o. On the other hand, the system NiAl/Cu(001)/Si(001) with different compositions ranging from 36% to 50% Aluminium showed epitaxial BCC films with 2 different domains. The two domains grow in the [110] direction and are rotated 90 degrees with respect to each other. The FCC phase L12 (Ni3Al) was seen to grow first in sample Ni63Al37/Cu(001)/Si(001).

**A15 5 Two-dimensional magic Ag nanopucks on Pb quantum islands*** Y.P. CHIU, L.W. HUANG, *Institute of Physics, Academia Sinica, Taipei, Taiwan, ROC* C.M. WEI, *Institute of Physics, Academia Sinica, Taipei, Taiwan, ROC and Institute of Atomic and Molecular Sciences, Academia Sinica, Taipei106, Taiwan, ROC* C.S. CHANG, TIEN T. TSONG, *Institute of Physics, Academia Sinica, Taipei, Taiwan, ROC* Periodic patterns of electronic origin found on Pb quantum islands can be employed as the templates to grow self-organized nanopucks of various materials. Owing to a strong interaction existing between Ag and the template, nearly perfect two-dimensional arrays of Ag nanopucks can be grown from 70 K to 150K. Not only is the notable site-selected feature of Ag nanopucks observed on Pb islands but their size distribution also registers a remarkable abundance variation. Those nanopucks with significantly enhanced intensity are denoted as two dimensional magic Ag nanoclusters. Detailed calculations based on itab initio density functional theory have been made to illuminate how the size and shape effects related to electronic confinement influence the formation of two-dimensional metal nanostructures. Furthermore, when the Ag nanopuck grows to a certain size, the geometrical effect takes hold from the electronic effect as the major attribute, which drive the Ag nanopucks towards well defined hexagonal crystalline structures.

**A15 6 Geometric and Electronic Structure of Self-Assembled Monolayers Grown on Noble Metal Substrates: Dodecanethiol on Au, Ag, Cu, and Pt** HEIKE GEISLER, LAUREN POWELL, *Dept. of Chemistry, Xavier Univ.* SHAWN HUSTON, TIM SWEENEY, DANIEL BORST, CARL VENTRICE, *Dept. of Physics, Univ. of New Orleans* The geometric and electronic structure of dodecanethiol ($C_{12}H_{25}SH$) SAMs on Au(111), Ag(111), Cu(111), and Pt(111)) substrates has been studied using angle-resolved ultra-violet photoelectron spectroscopy and low energy electron diffraction. The SAMs were grown both by vapor deposition in UHV and in solution. The electronic structure of the fully saturated SAM is similar on all of these substrates, with peaks observed at binding energies of 6.5, 10, 14, and 20 eV. The geometric structure of the molecular films at intermediate coverages is different for each substrate. Growth on Au proceeds through a well-ordered lying-down phase followed by a disordered phase and a well-ordered $\sqrt{3}$ standing-up phase at saturation. Initial growth on Pt(111) shows first a p(2x2)symmetry followed by a $\sqrt{3}$ symmetry, which indicates that the initial growth is via standing-up phases on Pt. This is followed by a disordered phase at saturation. Films on Ag show a great deal of disorder at all stages of growth.

**9:12**

**A15 7 Scanning tunneling microscopy study of the charge density wave in rare-earth tritellurides*** ALEKSANDRA TOMIC, CHRISTOS MALLIAKAS, HYUN-JEONG KIM, MERCOURI KANATZIDIS, SIMON BILLINGE, STUART TESSMER, *Michigan State University* A number of correlated electron oxides exhibit surprisingly intricate ordered density modulations which underlie their novel properties. These modulations arise from incommensurate charge density waves (IC-CDWs). We have applied scanning tunneling microscopy (STM) to study the nature of IC-CDWs in the rare- earth tritellurides – simple, cleavable, layered materials. In particular, for CeTe3 we have observed both the atomic lattice of surface Te atoms and the CDW modulations oriented at 45 degrees with respect to the Te net. Two-dimensional Fourier transforms of the STM images were obtained to search for discommensurations. These are essentially domain walls whose presence has been strongly suggested by atomic pair distribution function studies. We observe satellite peaks in addition to the principal CDW peaks. These represent strong evidence for the presence of discommensurations with a characteristic length scale of about 38 angstroms.

**A15 8 Electronic Structure of Ultra-thin Graphite** GEY-HONG GWEON, ELIZABETH ROLLINGS, SHUYUN ZHOU, *University of California, Berkeley* BONGJIN MUN, ALEXEI FEDOROV, *ALS, LBNL* P. N. FIRST, W.A. DE HEER, *School of Physics, Georgia Tech* ALESSANDRA LANZARA, *University of California, Berkeley* We report a high resolution angle resolved photoemission spectroscopy (ARPES) study on ultra-thin graphite samples, grown and characterized successfully in ultra-high-vacuum environment by a thermalization of SiC. We discuss similarities to and differences from the data obtained on bulk graphite. Notable differences include doping, electronic structure as a function of $k_z$ (momentum component perpendicular to graphene layer), line width, and substrate-induced features in ultra-thin graphite samples. We discuss the effects of grain boundaries, disorder, and symmetry breaking, as possible explanations of these differences.

**9:36**

**A15 9 Transverse Plasmon Wakes in the Electron Gas** ZACHARY LEVINE, *NIST* ERIC COCKAYNE, *NIST* Relativistic electrons have transverse electric fields comparable in magnitude to the longitudinal fields. We determine the relative effects of transverse and longitudinal fields of a moving point charge on the dielectric response of a uniform electron gas, using Lindhard's longitudinal and transverse dielectric functions and, separately, the Drude dielectric function. In the direction of motion, the transverse wake fields are approximately $-v^2/c^2$ times the longitudinal wake fields. The stopping power, as determined by applying

Poynting's theorem, is reduced. Perpendicular to the direction of motion, the transverse wake fields are small compared to the longitudinal fields. Electromagnetic fields of a moving point charge are given in Fourier space for the Lorentz, Hamiltonian, and Coulomb gauges.

**A15 10 Optical conductivity of MnN: a combined experimental and theoretical study.** WALTER R. L. LAMBRECHT, *Case Western Reserve University* S. GRANVILLE, B. J. RUCK, F. BUDDE, A. KOO, J. E. DOWNES, H. J. TRODAHL, *Victoria University of Wellington* A. BITTAR, N. STRICKLAND, G. V. M. WILLIAMS, *Industrial Research Limited, Lower Hutt, NZ* TIMOTHY LEARMONT, KEVIN E. SMITH, *Boston University* V. J. KENNEDY, A. MARKWITZ, *Inst. Geol. and Nuclear Sciences, Lower Hutt, NZ* A comparison between measured and calculated optical conductivity is presented for MnN films prepared by ion assisted deposition. X-ray diffraction and extended x-ray absorption fine structure show the films to be nanocrystalline but phase pure. X-ray emission spectroscopy of the N K-edge and X-ray absorption near edge spectroscopy of the N K- and Mn L-edges are used to probe the occupied and empty densities of states, which compare well with the N-2p and Mn-3d partial densities of states calculated using the linearized muffin-tin orbital method. The optical conductivity was measured by spectroscopic ellipsometry/reflectivity in the infared to UV range. The major differences between calculated and measured spectra can be understood on the basis of a limited electron mean-free-path in these nanocrystalline films, which relaxes the momentum conservation requirement. The calculated optical functions are analyzed in terms of their dominant band-to-band contributions including the polarization dependence. The temperature dependent conductivity shows a clear metallic behaviour and a weak Kondo-like low temperature anomaly.

**A15 11 Europium $L_{2,3}$ and iron $K$-edge x-ray magnetic circular dichroism investigation of ferromagnetic ordering in $EuFe_4Sb_{12}$*** VEMURU KRISHNAMURTHY, *Oak Ridge National Laboratory* JONATHAN LANG, DANIEL HASKEL, GEORGE SRAJER, *Advanced Photon Source, Argonne National Laboratory* LEE ROBERTSON, BRIAN SALES, DAVID MANDRUS, *Oak Ridge National Laboratory* The magnetic behavior of Eu and Fe in the filled skutterudite ferromagnet $EuFe_4Sb_{12}$ has been investigated using Eu $L_{2,3}$ edge and Fe $K$ edge x-ray magnetic circular dichroism (XMCD) spectroscopy. Eu $L_3$ edge x-ray absorption spectra (XAS) in $EuFe_4Sb_{12}$ clearly show that Eu is in a mixed valence state with about 15% non-magnetic $Eu^{3+}$ states at 5 K. By comparing the XMCD spectra measured at the Eu $L_{2,3}$ edges in the ferromagnetic state at 5 K in $EuFe_4Sb_{12}$ and in the clathrate $Eu_8Ga_{16}Ge_{30}$, in which the *4f* magnetic moment of Eu is known to be 7 $\mu_B$, and by accounting for the mixed valence of Eu in the XAS, we show that $Eu^{2+}$ has the free ion like magnetic moment of $\sim$ 7 $\mu_B$ in $EuFe_4Sb_{12}$. XMCD observed at the Fe $K$ edge in $EuFe_4Sb_{12}$ at 5 K indicates magnetic short range order and a small orbital magnetic moment for the *4p* states of Fe. The relative signs of XMCD at Eu $L_3$ edge and Fe $K$ edge indicate that the $5d$ spin moment of Eu and the $4p$ spin moment of Fe are ferromagnetically coupled in $EuFe_4Sb_{12}$.

**A15 12 Modeling of LMM-MVV Auger-Auger Coincidence Spectra From Solids** R. SUNDARAMOORTHY, A.H. WEISS, *University of Texas at Arlington* S.L. HULBERT, *Brookhaven National Laboratory* R.A. BARTYNSKI, *Rutgers University* Atoms that are highly excited due to the presence of a hole in an inner shell often relax via an Auger transition. This auto-ionizing process results in a final state with two or more holes from an Auger cascade. We present results of the direct measurements of the second and third Auger decays in this sequence. We have measured the Mn MVV Auger spectra from a single-crystal sample of MnO in time coincidence with Auger electrons emitted from prior Mn LMM Auger decays and find these to be much wider than the MVV spectrum measured in time coincidence with M core photoelectron emission. We present a model which attributes the increased energy width of the MVV transitions that follow LMM decays to the rearrangement of ''not so innocent'' bystander hole(s) in the valence band. The energetics of the Auger cascade process are modeled mathematically in terms of correlation integral(s) and convolution integral(s) over the valence band density of states. Comparisons with recent Auger-Auger coincidence studies of Ag and Pd will be made. Acknowledgements: Welch Foundation, NSF DMR98-12628, NSF DMR98-01681, and DOE DE-AC02-98CH10886.

**A15 13 $EuB_6$ and the Low-Density Double Exchange Model*** VITOR M. PEREIRA, J.M.B. LOPES DOS SANTOS, *CFP and Departamento de Física, Faculdade de Ciências Universidade do Porto, 4169-007 Porto, Portugal* ANTONIO H. CASTO NETO, *Department of Physics, Boston University, 590 Commonwealth Avenue, Boston, Massachusetts 02215, USA* The low electronic density regime of the double exchange model is explored in the presence of electron-electron interactions. The single particle problem and its extension to low densities, when a Wigner crystal of magnetic polarons is generated due to unscreened Coulomb interactions, is studied. It is argued that the Wigner crystal is the natural alternative to phase separation when the Coulomb interaction is taken into account. We address the thermal and quantum stability of the crystalline phase towards a polaronic Fermi liquid and a homogeneous, metallic, ferromagnetic phase. These results are relevant in the context of the polaronic physics recentely observed in $EuB_6$, and provide an important consistency-check for the double-exchange description of these magnetic hexaborides. **References:** V. **A15 14 Magneto-optical evidence of double exchange in a percolating lattice** G. CAIMI, A. PERUCCHI, H.R. OTT, *ETH Zurich* V.M. PEREIRA, A.H. CASTRO NETO, *Dept. of Physics, Boston University* A.D. BIANCHI, *Hochfeldlabor Dresden* Z. FISK, *Dept. of Physics, UC Davis* L. DEGIORGI, *ETH Zurich* Substituting $Eu$ by $Ca$ in ferromagnetic $EuB_6$ leads to a percolation limited magnetic ordering. We present and discuss magneto-optical data of the $Eu_{1-x}Ca_xB_6$ series, based on measurements of the reflectivity $R(\omega)$ from the far infrared up to the ultraviolet, as a function of temperature and magnetic field. Via the Kramers-Kronig transformation of $R(\omega)$ we extract the complete absorption spectra of samples with different values of $x$. The change of

the spectral weight in the Drude component by increasing the magnetic field agrees with a scenario based on the double exchange model, and suggests a crossover from a ferromagnetic metal to a ferromagnetic Anderson insulator upon increasing *Ca*-content at low temperatures.

**A15 15 Constructing the effective spin model of $Mn_6R_6$ from ab initio calculations** SHUN TONOOKA, KOICHI KUSAKABE, *Osaka University* HIROKI NAKANO, *University of Hyogo* NAOSHI SUZUKI, *Osaka University* Determination of the effective spin model is an important issue for molecular magnetism. Generally, the effective spin model is determined so that the model reproduces the structure of the excitation spectrum. Only this strategy sometimes could not determine which model is the most suitable among several candidates. An example showing this difficulty is seen in $[Mn(hfac)_2NITPh]_6$ abbreviated as $Mn_6R_6$. Two different models are proposed for $Mn_6R_6$ by reproducing the magnetization process. One is the Heisenberg model with three-spin interactions. The other is the Heisenberg model with frustration. In this work, in order to examine the validity of each model, we calculate the spin density by the itab- initio calculation based on the unrestricted Hartree-Fock method and the density functional theory. We also calculate the spin density of the ground state in each model by numerical diagonalization. Each model shows the different spin density. The spin density of the ground state should give essential knowledge so as to constructing the effective spin model. We discuss the method to connect the effective spin model with the first principle calculation by calculating the spin density.

**8:00**
**A16 1 Quaternary Li-B-N-H Hydrides: New Hydrogen-Rich Storage Materials.**
FREDERICK PINKERTON, *General Motors Research and Development Center*

We have synthesized light metal Li-B-N-H quaternary hydrides by ball milling mixtures of $LiNH_2$ and $LiBH_4$ for a series of compositions $(LiNH_2)_x(LiBH_4)_{1-x}$ (x = 0.33 to 0.8). We discovered a new quaternary hydride phase, referred to here as $\alpha$ Li-B-N-H, as the primary constituent for amide-rich (x > 0.6) compositions. Although previously tentatively identified as $Li_3BN_2H_8$, its true equilibrium composition is $Li_4BN_3H_{10}$ as determined by single crystal x-ray diffraction (XRD). $Li_4BN_3H_{10}$ has a body-centered cubic crystal structure, space group $I2_13$ (# 199) with a = 10.68 Å. In situ XRD data demonstrate that the $\alpha$-phase also forms without ball milling by reacting mixed $LiNH_2$ and $LiBH_4$ powders at temperatures above about 95$^o$C. The $\alpha$ phase melts at about 190[r]C and releases hydrogen from the liquid above 250[r]C, forming solid $Li_3BN_2$. Using mass spectrometry residual gas analysis (RGA) we observe that $NH_3$ is released concurrently, and the quantity of $NH_3$ released is strongly dependent on the composition x. Maximum hydrogen release, exceeding 10 wt%, with minimum $NH_3$ release (1-3 mole % of the evolved gas) occurs for compositions near $LiNH_2$:$LiBH_4$ = 2:1 (x = 0.667). Small additions of Ni, Pt, or Pd as powder or metal chloride reduce the dehydrogenation temperature by as much as 112[r]C, and also reduce the quantity of $NH_3$ released by about an order of magnitude. Differential scanning calorimetry shows an endothermic melting peak above 190[r]C, followed by substantial exothermic heat flow above 250[r]C associated with hydrogen release and solidification of $Li_3BN_2$. The exothermic hydrogen release suggests that the reverse reaction is not thermodynamically favored. This new quaternary compound and its derivatives nonetheless represent promising research candidates in the search for practical on-board hydrogen storage materials.

**A16 2 Composition dependence of hydrogen and ammonia release in the lithium-boron-nitrogen-hydrogen quaternary system** GREGORY P. MEISNER, MATTHEW L. SCULLIN, FREDERICK E. PINKERTON, MARTIN S. MEYER, MICHAEL P. BALOGH, *Materials and Processes Lab and Chemical and Environmental Sciences Lab, General Motors Research and Development Center* The new quaternary hydride in the lithium-boron-nitrogen-hydrogen (Li-B-N-H) quaternary phase diagram forms by the reaction of lithium amide ($LiNH_2$) and lithium borohydride ($LiBH_4$) near the approximate composition $LiB_{0.33}N_{0.67}H_{2.67}$. When heated, the quaternary hydride first melts and then releases greater than 10 wt% hydrogen and a small amount of ammonia (2-3 mole% of the generated gas). We studied hydrogen and ammonia release from the series of reactant mixtures $(LiNH_2)_x(LiBH_4)_{1-x}$ as a function of composition using volumetric, gravimetric, mass spectrometer, and itin situ x-ray diffraction measurements. We found that maximum hydrogen and minimum ammonia release do occur for x = 0.67. We observe that this composition corresponds to the ternary decomposition end product $Li_3BN_2$ rather than to the true single phase composition of the quaternary hydride as determined from our single crystal x-ray diffraction measurements.

**8:48**
**A16 3 First-principles Study on Li-N-H System for Hydrogen Storage** TAKAO TSUMURAYA, TATSUYA SHISHIDOU, TAMIO OGUCHI, *ADSM, Hiroshima University* Lithium amide ($LiNH_2$) and lithium imide ($Li_2NH$) have been noticed as one of the most promising candidates for hydrogen storage due to their high gravimetric densities of hydrogen. As regards the hydrogenating and dehydrogenating processes that involve these lithium

hydrides, there is an argument about whether ammonia gas is relevant and it still remains as a matter to be studied. Furthermore, the crystal structure of $Li_2NH$ is not fully determined yet because of the difficulty in identifying hydrogen positions. Recently, various transition-metal compounds have been examined with ball milling technique for exploring catalysis to promote reaction processes, and they found that some of the Ti compounds show good performance. Measurements of x-ray absorption spectroscopy (XAS) at Ti K edge are currently under way to have a clue for understanding the catalysis mechanism. To address these issues and to get fundamental insights from microscopic level, we performed first-principles calculations by using all-electron full-potential linear augmented plane wave (FLAPW) method. We will discuss structural stability, electronic structure of lithium hydrides $LiNH_2$ and $Li_2NH$ and the heat of formation in reaction processes. Structural optimization is carried out to evaluate total energies involved in reaction processes. XAS spectra and electronic structure of Ti compounds are also discussed.

**9:00**

**A16 4 First-principles study of structural properties of $Li_2NH$** AMRA PELES, *Georgia Institute of Technology, Atlanta, Georgia, USA* SUCHISMITA SANYAL, MAHESH CHANDRAN, *GE Global Research, John F Welch Technology Centre, Bangalore, 560066 INDIA* JOB RIJSSENBEEK, *GE Global Research, 1 Research Circle, Niskayuna, New York, 12309 USA* MEI-YIN CHOU, *Georgia Institute of Technology, Atlanta, Georgia, USA* Nitrogen containing hydrides have attracted much attention recently as viable candidates for hydrogen storage materials. One example is the amide and imide involved in the reversible chemical reaction

$$LiNH_2 + LiH \rightarrow Li_2NH + H_2 .$$

In an effort to understand the reaction mechanism, one needs to have the informations on the structural properties of these compounds. There is a disagreement in the existing literature regarding the crystal symmetry of $Li_2NH$. We present a summary of first-principles investigations of the structural properties of $Li_2NH$ in an attempt to identify the lowest energy structure. Calculations were performed within density functional theory framework employing plane waves and projector-augmented-wave potentials. Various crystal structures were obtained by minimazing the total energy and the forces. The stability and energetics of these structures will be discussed.

**9:12**

**A16 5 Theoretical Investigation of the Li amide/Li imide Hydrogen Storage Reaction** JAN HERBST, LOUIS HECTOR, JR., *GM R&D Center* Considerable recent interest has centered on the reaction $LiNH_2 + LiH \leftrightarrow Li_2NH + H_2$ as a mechanism for hydrogen storage. We have conducted density functional calculations of the electronic structure, vibrational properties, and enthalpy of formation for each component. The long established crystal structures for LiH and $LiNH_2$ (Li amide) were employed, while a newly determined orthorhombic structure for $Li_2NH$ (Li imide) was used. Our 298K results within the generalized gradient approximation for $\Delta H(LiNH_2)$ and $\Delta H(LiH)$, as well as for the overall heat of reaction, are in excellent accord with experiment, suggesting that the measured $\Delta H(Li_2NH)$ is inaccurate. Phonon densities of states calculated for the amide and imide compare very favorably with observed infrared and Raman spectra.

**9:24**

**A16 6 More insights into $LiNH_2$-(LiH, $MgH_2$) system from DFT studies** C. MOYSÉS ARAÚJO, RALPH H. SCHEICHER, *Condensed Matter Theory Group, Dept of Physics, Uppsala University, Sweden* PURU JENA, *Physics Dept, Virginia Commonwealth University, Richmond VA* RAJEEV AHUJA, *CMT Group, Uppsala; Applied Materials Physics, Dept of Materials Science and Engineering, Royal Institute of Technology, Stockholm, Sweden* First-principles calculations based on density functional theory have been carried out by us to understand the hydrogen desorption reactions for systems involving $LiNH_2$ mixed with either LiH or $MgH_2$. We first determined the crystalline structures and total energies of the reactants and possible products, which have been proposed from experiment. Our results for $LiNH_2$ and $Li_2NH$ show good agreement with experimental data. For the mixed compound $Li_2Mg(NH)_2$, we have performed geometry optimization by force minimization and in addition also using molecular dynamics and simulated annealing. The circumstance that the crystalline structure of this system has not yet been resolved-prevented us from comparing our results with experimental data. However, the calculated reaction enthalpy agrees very well with recent measurements [1]. Furthermore, we have also investigated all involved reactions in the gas phase by carrying out molecular calculations. This approach has allowed us to achieve a better understanding of the reaction mechanisms. We found that reaction energies for the molecular systems follow the same trend as for the bulk systems. [1] Weifang Luo, J. Alloys Comp. 381, 284 (2004).

**A16 7 In-situ Neutron Diffraction Studies of the Hydrogen storage material $Li_3N$*** ASHFIA HUQ, *IPNS, Argonne National Laboratory* JAMES W. RICHARDSON, *IPNS, Argonne National Laboratory* EVAN R. MAXEY, *IPNS, Argonne National Laboratory* DHANESH CHANDRA, *Metallurgical and Materials Engineering, University of Nevada, Reno* WEN-MING CHIEN, *Metallurgical and Materials Engineering, University of Nevada, Reno* The search for alternative fuel has spurred interest in complexes with high hydrogen absorption-desorption capacities. Among these compounds complex metal hydrides have received much attention. More recently it was proposed that simple metal nitrides such as Lithium Nitride ($Li_3N$), with its 9 wt % recyclable hydrogen uptake, could be good candidates for reversible hydrogen storage. In this presentation we present the results of detailed structural study of $Li_3N$ through the temperature range 20K to 673K using Neutron Powder Diffraction. Commercially purchased compound showed a coexistence of alpha and beta phases of $Li_3N$. We observed a steady decline of the beta phase above 473K and a very small fraction ( $\sim$ 3 wt %) was frozen in at 673K. This transformation ($\beta$ to $\alpha$) was not reversible on cooling. We will also present the findings of in-situ neutron diffraction measurements of hydrogen absorption and desorption of the title material.

*Research carried out at the Intense Pulsed Neutron Source at Argonne National Laboratory is funded by the U.S. Department of Energy under Contract W-31-109-ENG-38.

**9:48**

**A16 8 Characterization of Lithium Borohydride using Neutron Scattering Techniques** MICHAEL HARTMAN, JACK RUSH, TERRY UDOVIC, *National Institute of Standards and Technology* Lithium borohydride, $LiBH_4$, is a complex metal hydride that shows great promise as a hydrogen storage medium with a volumetric hydrogen density of 122 kg H/$m^3$ and a gravimetric hydrogen density of 18.5 wt. %. While numerous NMR, Raman,

and infrared investigations have been reported in the literature, neutron scattering investigations of $LiBH_4$ have been limited due to the large neutron absorption cross-section of naturally occurring lithium and boron. We have recently synthesized an isotopically-enriched lithium borohydride, containing $^7Li$ and $^{11}B$, which eliminates the large neutron absorption cross-section that arises from the presence of $^6Li$ and $^{10}B$. The results of powder neutron diffraction, inelastic neutron scattering, and quasi-elastic neutron scattering investigations on the $^7Li^{11}BH_4$ material are presented. These measurements provide a fundamental understanding of the behavior of hydrogen within lithium borohydride, and they provide a basis to understand changes concomitant with the introduction of catalytic or destabilizing compounds.

**10:00**
**A16 9 Structural transitions in NaBH4 under pressure*** RAVHI KUMAR, ANDREW CORNELIUS, *University of Nevada, Las Vegas* The structure of the technologically important hydrogen storage compound $NaBH_4$ has been investigated under pressures up to 30 GPa by itin situ angle dispersive high pressure x-ray diffraction using synchrotron x-rays and a diamond anvil cell. Our experimental results show pressure-induced structural transitions of $\alpha$-$NaBH_4$ (cubic – itFm3m) to $\beta$ – $NaBH_4$ (tetragonal – $P42_1c$) at 6.3 GPa and further to orthorhombic phase (itPnma) at 8.9 GPa. The high pressure orthorhombic phase is found to be stable up to 30 GPa. The cubic phase is completely recovered on releasing the pressure to the ambient.

**A17 1 Crystallization and defect formation in $HfO_2$ films on silicon.** JACOB GAVARTIN, ALEXANDER SHLUGER, MARSHALL STONEHAM, *University College London* GENNADI BERSUKER, *SEMATECH* Hafnium dioxide currently is considered a dielectric of choice for novel MOSFET devices but it has an important drawback (as most high-k films on silicon) of low crystallization temperature. We use large scale plane wave density functional simulations of the $HfO_2/SiO_x/Si$ system to determine the properties of the amorphous hafnia films and the mechanisms of their crystallization and defects formation associated with it. We propose that the kinetics of interface formation stipulates some oxygen sub-stoichiometry in hafnia. The resulting 'amorphous' films are characterized by the sub-coordinated (by less than 7 oxygen) Hf ions and some shortened Hf-Hf distance ( $\sim$ 3 Å compared to $\sim$ 3.5 Å in the monoclinic $HfO_2$). Such structures may not have defect states (understood as localized states with energies in the band gap). However, they are characterized by the long band tails, whose origin will be discussed. Crystallization of such amorphous structures during thermal annealing results in the oxygen vacancy formation. We discuss the role of these vacancies in the trapping and de-trapping of carriers from the channel and the possibilities of control of their concentration.

**8:12**
**A17 2 Observation of Oxygen Bridging at the Si-$SiO_2$ Interface** PHILIP BATSON, *IBM Thomas J. Watson Research Center* Annular Dark Field (ADF) images of the Si-$SiO_2$ interface have been obtained using a 0.08 nm probe in an aberration corrected Scanning Transmission Electron Microscope (STEM). The 2 nm thick $SiO_2$ layer lies under an $HfO_2$ high dielectric constant structure, and contains isolated Hf atoms which are highly mobile under the beam. Assuming that Hf atoms occupy low energy sites within the oxide, they can substitute for Si atoms in tetrahedral coordination, or occupy incomplete octahedral pockets. In either case, they should provide a probe of the structure of the amorphous oxide. 0.3-0.6 nm from the crystalline Si, Hf atoms move mostly parallel to the interface, suggesting that quasi-planar structures may occur near the Si interface. Within 0.3 nm of the Si, tunnels run parallel to the [110] direction. Inside the tunnels, a single column of atoms is observed between two adjacent interface Si columns. ADF image simulations show that the observed scattering intensity for this column is consistent with oxygen, supporting the oxygen bridging model proposed by Tu and Tersoff (Phys Rev. Lett. **84** 4393 (2000)).

**8:24**
**A17 3 Atomic-level imaging and properties of stray Hf atoms in Si-$SiO_2$-$HfO_2$ nanoscale structures.*** STEPHEN PENNYCOOK, *Oak Ridge National laboratory*

The aberration-corrected scanning transmission electron microscope (STEM) provides a new level of sensitivity for analyzing nanoscale oxide films. The sub-Ångstrom probe provides much improved resolution, but equally important, greatly increased sensitivity to individual atoms. Single Hf atoms are visible within the nanometer thick $SiO_2$ interlayer between a $HfO_2$ dielectric and the Si substrate. Furthermore, the depth of focus of the aberration-corrected STEM is greatly reduced, and Hf atoms can be located in depth to better than 1 nm precision. Strikingly, no Hf atoms are seen to be in contact with the Si substrate, and exhibit preferred distances from the interface. First-principles density-functional calculations find that the energy of single Hf atoms rises sharply if they approach closer than $\sim$ 0.3 nm, in agreement with

observations. The Hf atoms introduce localized states within the Si band gap, which are detected by electron energy loss spectroscopy. These states may mediate leakage currents. The effect of the stray Hf atoms on the electron mobility in the Si channel has been calculated using a novel first-principles approach and found to be consistent with measured mobility values. Work performed in collaboration with K. van Benthem, S. N. Rashkeev, M. H. Evans, and S. T. Pantelides.

**A17 4 Characterization of local electronic structure and dielectric properties at a HfO2/SiO2/Si gate dielectric interface.*** KLAUS VAN BENTHEM, *ORNL* SERGEY RASHKEEV, *ORNL* GENNADI BERSUKER, *International Sematech* SOKRATES PANTELIDES, *Vanderbilt University* STEPHEN PENNYCOOK, *ORNL* Electron Energy-Loss Spectroscopy (EELS) measurements were performed using an aberration-corrected Scanning Transmission Electron Microscope (STEM) to investigate local electronic structure across a HfO2/SiO2/Si gate dielectric interface with a lateral resolution of approximately 0.1 nm. The low energy-loss regime in EELS is dominated by intra-and interband transitions and plasmon excitations. Hence, by a Kramers-Kronig analysis of the low energy-loss regime the determination of the complex dielectric function becomes possible on a sub-nanometer length scale. As a consequence, local optical properties and the local interband transition strength can be discussed as a function of position across the gate dielectric. Single Hf atoms present within the SiO2 interlayer introduce localized states in the Si band gap and gradients in the local dielectric function. Microscopic measurements will be correlated with macroscopic device characteristics.

**9:12**

**A17 5 Oxygen transport and interfacial layer engineering in high-k metal oxide gate stacks** LYUDMILA GONCHAROVA, MATEUS DALPONTE, ERIC GARFUNKEL, TORGNY GUSTAFSSON, *Rutgers University* GENNADI BERSUKER, BRENDAN FORAN, PAT LYSAGHT, *Sematech* Much recent work has been devoted to integrating metal oxide dielectrics into silicon based CMOS. High-$\kappa$ metal oxide stacks processing may lead to diffusion and reactions with negative impact on the electrical properties. We report here results from Medium Energy Ion Scattering (MEIS) on (i) the mechanism of oxygen transport and interfacial layer behavior in multilayer high-$\kappa$ gate stacks and (ii) the influence of crystallinity and grain boundaries on thin Hf oxide and silicate films using isotope tracing. Changes in oxide and silicate interface composition and thickness, phase mixing and crystallization within the film, and film decomposition will be discussed in terms of bulk and grain boundary diffusion. A functional device must include not just a dielectric, but a conducting gate as well. Our results show that the interfacial $SiO_2$ layer thickness is reduced by using a Ti overlayer with high solubility for oxygen. We also find that Si atoms initially present in the interfacial $SiO_2$ layer incorporate in the high-$\kappa$ layer. Oxygen is also being removed from the Hf oxide, leaving an oxygen depleted $HfO_x$ layer. The presence of grain boundaries in crystalline $HfO_2$ films suggests an additional path for Si diffusion through the high-$\kappa$ film in the presence of Ti gate.

**A17 6 Defects on Magnesium Oxide Surfaces: An STM and ESR Study.** HANS-JOACHIM FREUND, *Fritz Haber Institute*

Thin MgO(100) films have been prepared on Ag(100) und Mo(100) substrates. Color centers are not present on these MgO surfaces but can be induced by electron bombardment. $F^+$ and $F^0$ centers may be identified with scanning tunnelling spectroscopy and found to be located not on terrace but rather on edge sites primarily. This is corroborated by electron spin resonance experiments. Methods are described to engineer surfaces with particular defects and thus its interaction with both, molecules and metal atoms, can be studied. Additional techniques such as Fourier-Transform Infrared Spectroscopy allow us to get closer insight into the influence of defects on the properties of adsorbed atoms and molecules.

**A17 7 Zintl Concepts for Interface Engineering** ALEX DEMKOV, *The University of Texas at Austin* Crystalline epitaxial oxides on semiconductors (COS) could very well extend the Complimentary Metal Oxide Semiconductor (CMOS) technology from Si to other semiconductors and thus give new lease on life to the paradigm responsible for the outstanding success of the semiconductor electronics. Another tantalizing possibility is the growth of functional oxide structures utilizing ferroelectricity, superconductivity, magnetism, and other such properties not normally accessible in conventional semiconductors in monolithic integration with Si. There also may be applications of COS at the end of the Si Roadmap. Two dimensional (2D) crystal growth of ionic oxides on covalent semiconductors and visa versa is essential for these approach to work. In this talk I will discuss how concepts developed by Edward Zintl more than seventy years ago can be used for interface engineering. I will use itab-initio density functional theory to demonstrate how the bonding character at the oxide/semiconductor interface is manipulated through charge transfer in the engineered intermetallic contact layer. This transition layer lowers the energy of the interface and results in 2D growth, and high quality epitaxial films.

**A17 8 One-dimensional $PtO_2$ oxide at Pt steps: formation and reaction with CO** J.G. WANG, W.X. LI, T.M. PEDERSEN, B. HAMMER, *University of Aarhus, Denmark* J. KLIKOVITS, M. SCHMID, *Technische Universität Wien, Austria* M. BORG, J. GUSTAFSON, A. MIKKELSEN, J. WEISSENRIEDER, E. LUNDGREN, J.N. ANDERSEN, *Lund University, Sweden* The structure and catalytic activity of a one-dimensional $PtO_2$ oxide, which forms along the steps on the Pt(332) surface, is studied using HRCLS and DFT [1]. Our investigations reveal a much higher CO-oxidation activity of the one-dimensional oxide as compared to the chemisorbed oxygen phase of Pt(111). The reason could be explained by DFT by the detection of a significantly lower barrier for the $CO_2$ formation using O from the oxide stripe, as compared to the O chemisorbed on the terrace. Finally, the one-dimensional oxide is predicted to be stable at conditions between chemisorbed oxygen and the bulk oxide, which at 500 K includes ambient oxygen pressures. This range is expected to be similar on other step structures of Pt. Hence the one-dimensional oxide could be of major importance for the catalytic activity of Pt nano particles, as used in industrial catalytic devices. [1] J. G. Wang et al., Phys. Rev. Lett. **A17 9 Ultrathin $TiO_x$ films on Pt(111)** GAETANO GRANOZZI, FRANCESCO SEDONA, *Dept. of Chemical Sciences, University of Padova* KLAUS SCHIERBAUM, *Heinrich-Heine-Universität Düsseldorf* Ultrathin ordered titanium oxide films on Pt(111) surface were prepared by reactive evaporation of Ti in oxygen. By varying the Ti dose and the annealing conditions, several long-range ordered phases were obtained and characterized by means of LEED, XPS, UPS, photoelectron diffraction, STM and XAS. XPS and photoelectron diffraction data indicate that all the phases, except two, are one-monolayer thick and composed of a Ti-O bilayer with interfacial Ti. Atomically resolved STM images of all the prepared phases have been obtained. At a low Ti dose (0.4 MLE), an incommensurate itkagomé-like low density phase is observed where hexagons are sharing their vertices. At a higher Ti dose (0.8 MLE) two denser phases are found, both characterized by a zigzag motif, but with distinct rectangular unit cells. When the post-annealing of the 0.8 MLE deposit is carried out at high temperatures and oxygen partial pressures, an incommensurate non-wetting fully oxidized phase is found, whose symmetry and lattice dimensions are almost identical with those observed in the system $VO_x$/Pd(111). At higher coverage, two commensurate hexagonal phases are formed, which show wagon-wheel-like structures and have slightly different lattice dimensions. Competitively to the formation of ultrathin films, nanosized $TiO_2$ crystallites can grow on top of the surface. They predominate the entire morphology only for large initial Ti deposits.

**A17 10 Surface structure of alumina ultrathin film grown on Ni3Al (111) studied by nc-AFM** CLAUDE R. HENRY, CLEMENS BARTH, GUIDO HAMM, *CRMCN-CNRS, Campus Luminy, 13288 Marseille* CLUSTER GROUP TEAM, Alumina ultrathin films grown by high temperature oxidation of a Ni3Al (111) surface have the peculiarity to be nanostructured. Indeed, as shown previously by the group of C. Becker [1], they present two hexagonal structures with lattice parameters of 2.4 and 4.16 nm. However, no atomic resolved structure was evidenced by this STM study. In the present study we used the same preparation technique to grow the alumina film. The surface structure of the film was studied, in situ under UHV, by nc-AFM. By this technique we confirm the presence of the two structures and we clearly show that the larger one is the basic structure of the topmost layer of the film. The 2.4 nm structure is a sub-lattice of the 4.1 structure. These two structures provide two different local environments that could explain why metals condensed on this film form hexagonal lattice with a parameter of 2.4 or 4.1 nm. Atomic resolution has been obtained showing that the topmost surface is terminated by a distorded hexagonal lattice of atoms (most probably oxygen). The relationships betwen the atomic lattice and the two superstructures have been derived from the nc-AFM measurements. We will discuss on the possible origin of the complex structure of this films. **A17 11 Oxygen storage and release by Ceria: New insights into the mechanism based on STM** FRIEDRICH ESCH, *CNR-INFM Laboratorio TASC* STEFANO FABRIS, *SISSA and CNR-INFM DEMOCRITOS, Trieste* CRISTINA AFRICH, CECILIA BLASETTI, *University of Trieste and CNR-INFM Laboratorio TASC* PAOLO FORNASIERO, *University of Trieste and INSTM* RENZO ROSEI, GIOVANNI COMELLI, *University of Trieste and CNR-INFM Laboratorio TASC* In the attempt to understand the structure-dependent characteristics of ceria ($CeO_2$) surfaces with various morphologies (films, nanoparticles, single crystals), we focus on high-resolution scanning tunneling microscopy of a (111) single crystal surface. A new preparation procedure is described that generates one trilayer deep pits on the surface, exposing (001) and (110) steps that can systematically be studied. Pit shapes reflect the surface mobility of ceria and relative stability of the steps. Atomic oxygen exposure leads to the formation of ceria nanoparticles at step edges. Upon reduction, various oxygen vacancies can be distinguished on the (111) terraces and are assigned to single 1st layer vacancies, single 2nd layer vacancies, linear and other vacancy clusters (VCs) by comparison to density functional calculations [1]. It is shown that electron localization determines which VCs can be formed and which can not: VCs expose exclusively reduced $Ce^{3+}$ ions. In linear VCs, that dominate the strongly reduced surface, this occurs by including one single subsurface vacancy per VC. [1] F. Esch et al., Science 309 (2005) 752.

**A18 1 Super Growth Carbon Nanotubes.**
KENJI HATA, *AIST*

Water assisted CVD (denoted as Super Growth) results in a significant enhanced catalyst activity and enlonged lifetime of the catalysts to synthesize carbon nanotubes. The high efficient growth results in massive growth of vertically-aligned single-walled nanotubes forests with heights up to 2.5 millimeters and carbon purity over 99.98%. Super Growth simultaneously addresses many critical problems such as scalability, purity, and cost, and opens up innumerable opportunities ranging from fundamental research to real applications. This presentation will provide an overview of our recent development of the ''Super Growth'' CVD. First, the synthesis of highly efficient impurity free SNWT forest will be described. Second, the growth dynamics will be explored with our recent advance in CNT synthesis, as well as characterizing the physical and chemical properties of SWNT forests. Third, various new forms of carbon nanotube material such as DWNT forests, SWNT solids made by utilizing the super-growth technique will be demonstrated with emphasis on their applications such as super-capacitors. Lastly, challenges and future projects that are planed will be summarized.

**A18 2 Density functional study of cyclacene-based carbon nanotubular compounds.*** SHINYA OKANO, *Michigan State University* GLEN P. MILLER, *University of New Hampshire* DAVID TOMANEK, *Michigan State University* We use *ab initio* Density Functional calculations to investigate the interplay between structural and electronic properties of a new class of one-dimensional nanowires, related to carbon nanotubes. The cyclacene building blocks consist of phenyl rings, and can be viewed as the shortest segments of (n,0) zigzag nanotubes. In our study, we focus on cyclacenes with n=6-12 phenyl rings, and compare our results to infinitely large cyclacenes, corresponding to narrow graphene ribbons. The nanowires are formed by inter-connecting cyclacenes to a chain using biphenyl, tetrazine, or acetylene linkers. Depending on the nature and the orientation of the linkers, we find it possible to change the systems from narrow- to wide-gap semiconductors, and to modulate the band dispersion, suggesting the possibility of band gap engineering. We will also discuss the relevance of our results for a diameter- and chirality-selective synthesis of carbon nanotubes.

**A18 3 The mechanism for low temperature growth of vertically aligned boron nitride nanotubes*** JIESHENG WANG, *Michigan Tech University* MING XIE, *Michigan Tech University* YOKE KHIN YAP, *Michigan Tech University* Boron nitride nanotubes (BNNTs) are well recognized as the candidate that will complement the uses of carbon nanotubes (CNTs) in nanotechnology. However, high growth temperatures ( $>$ 1100 $^{o}$C), low production yield, and impurities have prevented effective synthesis and applications of boron nitride nanotubes (BNNTs) in the past ten years. For the first time, we have succeeded on the growth of pure BNNTs on substrates [1, 2]. This has been realized based on our experiences of growing CNTs and boron nitride (BN) phases (cubic phase BN, hexagonal phase BN). According to our hypothetical model, energetic growth species play an important role on controlling the phases of BN solids. We have experimentally verified that BNNTs can be grown by energetic growth species by a plasma-enhanced pulsed laser deposition (PEPLD) technique. These BNNTs can be grown vertically aligned into arrays of regular patterns at 600 $^{o}$C, and can be used for applications without purification. The growth mechanism of thee BNNTs will be discussed. [1]. Yap et al., Bull APS Vol 50, 1346-1347 (March 2005). [2]. Wang itet al., nano Letters (2005) ASAP, DOI: 10.1021/nl051859n.

**A18 4 Selective Growth of Single Wall Carbon Nanotubes from Superparamagnetic Maghemite** RAMA BALASUBRAMANIAN, RICHARD GRANT, *Roanoke College* PAOLA BARBARA, *Georgetown University* The growth of carbon nanotubes in specific configurations and geometry is crucial to developing useful applications in nanoelectronics and smart coatings. We have shown that single wall carbon nanotubes (SWNT) of diameters less than 2 nanometers can be grown directly from catalyst particles comprising of maghemite ( $\gamma - Fe_2O_3$) on a Silicon substrate using the conventional chemical vapor deposition process. The sizes of SWNT were measured using Atomic Force Microscopy. The average tube diameter was measured to be 1.5$\pm$ 0.2 nm. Scanning Electron Microscopy measurements revealed that the catalyst oxide particles formed in clusters of 100 nm diameters. Transmission Mössbauer measurements at room temperature showed the presence of a magnetic sextet corresponding to maghemite with a particle size $>$ 100 nm and a superparamagnetic phase with particle size less than 20 nm. Our results also indicate that the superparamagnetic phase of maghemite with average particle size of about 5 nm plays a critical role in the formation of SWNT with specific tube dimensions. Experiments are currently underway to characterize the relaxation rates of the superparamagnetic phase of maghemite. The fundamental role of arrays of metal nano-catalysts and superparamagnetic nanoclusters

of maghemite in the selective growth of single wall carbon nanotubes will be presented.

**A18 5 Controlling the height of CVD-grown multi-wall nanotube arrays** MICHAEL STADERMANN, SARAH SHERLOCK, BRIAN DICK, HYUNG-GYU PARK, ALEXANDER ARTYUKHIN, WILLIAM PITZ, ALEXANDER NOY, OLGICA BAKAJIN, *Lawrence Livermore National Laboratory* Due to various difficulties, carbon nanotube arrays have seen only limited use in industrial applications to date. One of the difficulties is the reproducible growth of these arrays, let alone a good measure of control over the obtained height. In this work, we have preformed a parametric study of multi-wall carbon nanotube (MWNT) growth. The investigated parameters were gas flow rate, process pressure, and water content of the feed gas. We were able to identify a region in the parameter space that yields stable and highly reproducible growth of tall nanotubes arrays. As a result, we can controllably grow MWNT forests to any height between 1 $\mu$m and 1 mm by choosing the right combination of pressure, humidity, flow rate, and growth time. Additionally, we were able to perform kinetic studies of the carbon nanotube growth, and our results suggest that the precursor for nanotube growth is formed in the gas phase.

**A18 6 Real-Time Study of the Kinetics of Vertically Aligned Single Wall Carbon Nanotube Array Nucleation and Growth** GYULA ERES, *Oak Ridge National Laboratory* H. CUI, C. M. ROULEAU, A. A. PURETZKY, D. B. GEOHEGAN, A molecular beam of carbon containing molecules in conjunction with time resolved reflectivity was used to study the kinetics of nucleation and growth of vertically aligned single wall carbon nanotube arrays. The molecular beam environment decouples the source gas and the substrate temperature dependent variables and eliminates secondary gas phase reactions, to allow carbon nanotube growth by surface reactions only [1]. The incidence rate of the carbon containing species is the key variable that through the nucleation density determines all the important properties of the arrays including the type, the diameter, and the packing density of the nanotubes. The addition of trace amounts of impurities such as water and oxygen enhances the nucleation density but does not affect growth. This highly controlled reaction environment reveals that carbon nanotube growth is a complex multicomponent reaction in which not just C but also H and O play a critical role. The picture that emerges form this study is at odds with the conventionally accepted dissolution/precipitation model for carbon nanotube growth. Instead, we explain the observed results by a new mechanism that is based on carbon network formation and stabilization by stepwise addition of acetylene type species. [1] G. Eres itet al. J. Phys. Chem. B **109**, 16684 (2005).

**A18 7 Defect induced modification in thermal property of Regioreguler Poly(3-hexylthiophene) nanotube composites** ANANTA ADHIKARI, *College of Nanoscale Science and Engineering, State University of New York, Albany, NY-12203* CHANG RYU, *Department of Chemistry and Chemical Biology, Rensselaer Polytechnic Institute Troy, NY-12180* PULLICKEL AJAYAN, *Department of Material Science and Engineering, Rensselaer Polytechnic Institute Troy, NY-12180* HASSARAM BAKHRU, The interaction particularly, interfacial bonding between polymer and filler has remained a crucial phenomenon to be understood to optimize their uses in many practical applications. Up to now, most of the work is on the chemical fuctionalization for improving nanotube/matrix interaction. In this paper, we studied the effects of ion irradiation induced defects on thermal behaviors of Poly(3-hexylthiophene) nanotube composites using Thermogravimetry Analysis (TGA) and Differential Scanning Calorimetry (DSC). Where, the irradiation is used to introduce the defects in a control way on pristine nanotube before composite formation. Several interesting effects were observed; including thermal stability enhancement and defects induced enhanced interaction between nanotube and polymer, and substantial changes in spectroscopic behaviors of the composites due to irradiation.

**9:48**

**A18 8 Effect of graphitic order on the electron field emission of carbon nanotube films*** BENJAMIN ULMEN, *Michigan Tech University* VIJAYA KAYSTHA, *Michigan Tech University* YOKE KHIN YAP, *Michigan Tech University* Carbon Nanotubes (CNTs) are known to be excellent electron field emitters. However, the fundamental factors that contribute to the emission stability have not been well studied. Here, we found that stability of emission current from CNTs is related to their graphitic orders. We have tested various types of CNTs grown by thermal chemical vapor deposition (CVD) and plasma enhanced CVD (PECVD). Our samples were grown in a circular area of 0.385cm$^2$ on low resistance Si substrates. Field emission measurements were conducted in a planar diode configuration, with a pair of electrodes separated with a gap of 1000 $\pm$ 10 $\mu$m. The vacuum level during the measurement is $\sim$ 2.0 X $10^{-7}$ mbar. We found that the emission currents from PECVD grown CNTs degraded by as much as 70% within a period of 20 hours. In contrast, random CNTs grown by thermal CVD exhibit stable emission current for at least 20 hours. These CNTs also have relatively lower threshold electric field of field emission. Since all samples are tested in a same condition, the detected results are thus related to the structural order of the CNTs. Transmission electron microscopy and Raman spectroscopy confirmed that field emission stability is depends on the graphitic structures of these CNTs.

**A18 9 Structure and Applications of Nanoporous Carbon*** MIKAEL WOOD, JACOB BURRESS, ROBERT SCHOTT, DEMETRIUS TAYLOR, PETER PFEIFER, *Physics Dept., University of Missouri, Columbia, MO 65211* Recently fractal networks of nanopores in activated carbon have been discovered (Pfeifer et al., Phys. Rev. Lett. 88, 115502 (2002)). We study the formation and properties of these networks with the goal of using them to store methane at low pressures (Alliance for Collaborative Research in Alternative Fuel Technology, http://allcraft.missouri.edu). Van der Waals forces in the nanopores force methane into a dense fluid (supercritical adsorption). We investigate the pore structure by nitrogen and methane adsorption isotherms, small-angle x-ray scattering (SAXS), and electron microscopy, and use the data to model the formation of the pore network using probabilistic cellular automata on a lattice. The calculated scattering from our simulated networks is in close agreement with experimental SAXS data. The models are designed to give us a deeper understanding of the growth of these networks and allow us to optimize their properties. Currently our best sample stores 0.11

g methane per $cm^3$ monolithic carbon at 25 $^oC$ and 34 atm (90% of industry target).

**A18 10 Boron-doped SWNTs for Electromagnetic Interference Shielding** P. EKLUND, D. NAREHOOD, *Dept. of Physics, The Pennsylvania State University* N. DITROLIO, N. ANDREWS, *CarboLex, Inc., 500 Parkway Ave, Broomall, PA 19008* U.J. KIM, X.M. LIU, H.R. GUTIERREZ, *Dept. of Physics, The Pennsylvania State University* SWNTs have been proposed for electromagnetic interference shielding as an additive in polymers. However, 2/3 of the SWNTs are expected to be semiconducting and only 1/3 are metallic. B-doping of graphite is known to lead to strongly p-doped material. In SWNTs, doping is therefore expected to lead to degenerately-doped semiconducting tubes and then a shielding benefit can be derived from all tubes in the sample. We find that 1-2 at% B-doping is possible at 25-50 gr/hr production. The quality of the HCl-purified product has been investigated by Raman scattering (RS), optical adsorption, transmission electron microscopy and temperature programmed oxidation. RS spectra were found to exhibit sharp G,R bands and a very weak D-band component is also observed. We note that after B-doping the $2^{nd}$ order RS cross section is enhanced, as reported previously for pulsed laser produced B-doped SWNTs by Rao et al. All band positions are very close to that observed for undoped SWNTs, indicating a reasonably good molecular structure of the B-SWNTs and consistent with the small size of atomic boron (i.e., substitutional dopant). OA show that the interband absorption peaks associated with semiconducting and metallic tubes upshift by 20-50 meV, indicating p-doping.

**10:24**

**A18 11 Detachment and re-attachment of vertically aligned single-walled carbon nanotube films** YOICHI MURAKAMI, SHIGEO MARUYAMA, *The University of Tokyo* A hot-water assisted detachment method of CVD-grown vertically aligned single-walled carbon nanotube (VA-SWNT) films from substrates has been developed. In particular, we found that the VA-SWNT films is efficiently peeled off by submersing the substrate into heated ( $\geq$ 60 [r]C) distilled water, and the detached film floats on the water surface. Furthermore, the detached film is readily re-attached to arbitrary surfaces. SEM observation confirms that the aligned morphology is perfectly preserved even after the re-attachment to other substrates. Mechanism of the proposed hot-water assisted film detachment method is investigated and suggested.

**A18 12 Fabrication and characterization of nanopatterned ultrathin epitaxial graphite films.*** ZHIMIN SONG, XUEBIN LI, TIANBO LI, CLAIRE BERGER, PHILLIP FIRST, WALTER A. DE HEER, *Georgia Institute of Technology* High quality ultrathin graphite films, composed of less than 10 graphene layers, have been epitaxially grown on single crystal SiC substrate by thermal decomposition. Hall bar structures, top gate and side gated field transistor structures have been fabricated using electron beam lithography methods. Scanning Electron Microscopy (SEM), Atomic Force Microscopy (AFM) and Electrostatic Force Microscopy (EFM) have been used to characterize the structures. These results demonstrate that nanopattened epitaxial graphite (NPEG) is a promising quasi-two-dimensional electronic material.

**A18 13 Structural modification of boron nitride nanotubes by plasma irradiation** TAKASHI IKUNO, GAVI BEGTRUP, SHAUL ALONI, ANDRAS KIS, DAVID OKAWA, ALEX ZETTL, *UC Berkeley, Lawrence Berkeley National Laboratory* Boron nitride (BN) and boron-carbon-nitride (B-C-N) nanotubes (NTs) are candidates for potential nanosized electronic and optical devices due to extraordinary physical and chemical properties. In terms of electronic property, in contrast to the insulating BNNTs with about 5.5 eV band gap, ternary B-C-N NTs has semiconducting property, the band gap of which is primarily determined by their chemical compositions. Although one of the methods to make B-C-N NTs is C doping to BNNTs, it is difficult to modify the structure and composition of BNNTs due to its chemical inertness and strong sp2 bond. In this study, we performed to modify the structure and composition of BNNTs by plasma irradiation for synthesizing B-C-N NTs. Hydrocarbon plasma was utilized for structural modification of BNNTs. The structural properties and the composition were characterized by high-resolution transmission electron microscopy and electron energy loss spectroscopy. After the plasma irradiation, outer several BN layers were modified to wavy structure from straight shape, and the defects were observed in almost BN layers, indicating destruction of crystal structure by collision of energetic particles in plasma and BNNTs. There are 5 – 30 at% of C in BNNTs and C atoms were inhomogeneously distributed in B-C-N NTs. The electron transport property of the modified B-C-N NTs will be reported in our presentation.

## SESSION A19: FOCUS SESSION: OPTICAL AND ELECTRICAL SPIN GENERATION IN SEMICONDUCTORS

**A19 1 Spatial Imaging and Mechanical Control of Spin Coherence in Strained GaAs Epilayers*** HADRIAN KNOTZ, VANESSA SIH, JASON STEPHENS, DAVID AWSCHALOM, *Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106* Recent work has shown that electron spins in GaAs and related compounds respond to strain dramatically. In particular, the manipulation of the spin-orbit coupling in GaAs via strain may be used for the development of all-electrical spintronic devices. Here we have developed a mechanical vise to controllably and reproducibly tune the tensile strain in-situ over a typical range for strain engineered heterostructures, from 0.0 - 0.2%[1]. The effect of uniaxial tensile strain on spin

coherence and transport phenomena in n-type GaAs epilayers is probed using time-resolved Kerr rotation, photoluminescence, and optically-detected nuclear magnetic resonance spectroscopies. The bandgap, electron spin lifetime, electron g-factor, and nuclear quadrupole splitting are imaged over millimeter scale areas of the epilayers for continuously varying values of strain. Simple non-destructive techniques for characterizing strain dependent phenomena in semiconductor heterostructures will facilitate the development of strain engineered spintronic devices.

**A19 2 Generating spin currents mechanically in a semiconductor*** PRASHANT SHARMA, *Argonne National Laboratory* It is theoretically predicted that a traveling shear wave will create a spin current in certain direct-gap (for example III-V compound) semiconductors with contributions from both the valence bands and the conduction band (for *n*-doped semiconductors). We show that this spin-current is a property of the Fermi-Dirac sea, and is controlled by a geometric phase accumulated by the strain-induced Rashba parameters in a cycle.

**A19 3 Adiabatic quantum pumping of a desired ratio of spin current to charge current** SUNGJUN KIM, *Department of Physics, The Pennsylvania State University, University Park, PA* KUNAL DAS, *Department of Physics, Fordham University, Bronx, NY* ARI MIZEL, *Department of Physics, The Pennsylvania State University, University Park, PA* We present a prescription for generating pure spin current or spin selective current, based on adiabatic quantum pumping in a tight-binding model of a one dimensional conductor. A formula for the instantaneous pumped current is derived without introducing the scattering matrix. Our calculations indicate that some pumping cycles produce the maximum value 2 of pumped spin while others reverse the direction of current as a result of small alterations of the pumping cycle. We find pumping cycles which produce essentially any ratio of spin current to charge current.

**A19 4 Theory of coherent optical generation of ballistic spin currents.**
JOHN SIPE, *Department of Physics and Institute for Optical Sciences, University of Toronto*

Ballistic spin polarized currents, and ballistic pure spin currents, can be directly injected in semiconductors by a variety of all-optical processes. No bias voltage is required. Carrier and spin distributions far from equilibrium can thus be produced in both doped and undoped semiconductors, and their evolution and the resulting transport studied. We review the calculations we have made of these processes, and highlight some of the experimental results of our colleagues.

**A19 5 Ballistic-diffusive crossover in spin propagation and precession** CHRIS WEBER, JOE ORENSTEIN, JASON STEPHENS, DAVID AWSCHALOM, *University of California, Berkeley* In the transient spin grating (TSG) technique, electron spins are optically oriented in a standing wave (''grating'') of spin polarization with wavevector $q$. TSG measures spin propagation through the time-dependence of the grating amplitude. We have shown[1] that for GaAs 2DEGs diffusive spin motion at low mobility $\mu$ crosses over at high $\mu$ to motion that is ballistic on length-scale of the grating—the mean free path exceeds $q^{-1}$. The ballistic regime is characterized by oscillations in the spin-grating amplitude with frequency $\omega \approx v_F q$. In this talk we present data from TSG and time-resolved Kerr rotation measurements on *n*-doped GaAs quantum wells. We explore the crossover between ballistic and diffusive behavior as a function of temperature and of disorder. We also explore a second, distinct crossover in the spin dynamics that occurs as $v_F q$ is tuned through the spin-orbit precession frequency, $\Omega_{SO} \approx 0.2$ THz. [1] C. P. Weber itet al. Nature **437** p. 1330 (2005).

**A19 6 Dissipation through spin Coulomb drag in electronic spin transport and optical excitations*** IRENE D'AMICO, *Department of Physics, University of York* CARSTEN A. ULLRICH, *Department of Physics and Astronomy, University of Missouri-Columbia* Spin Coulomb drag (SCD) constitutes an intrinsic source of dissipation for spin currents in metals and semiconductors. We discuss the power loss due to SCD in potential spintronics devices and analyze in detail the associated damping of collective spin-density excitations. It is found that SCD contributes substantially to the linewidth of intersubband spin plasmons in semiconductor quantum wells, which suggests the possibility of a purely optical quantitative measurement of the SCD effect in a parabolic well through inelastic light scattering.

**A19 7 Inhomogeneously-doped semiconductor junctions as a source of spontaneous spin polarization*** YUNONG QI, MICHAEL FLATTÉ, *University of Iowa* The dynamics of electric-field-driven packets of spin polarized carriers passing through an n+/n semiconductor junction have been studied. We find that spin packets that are initially very weakly spin polarized can have their polarization significantly amplified within the junction. The nonlinear spin transport and amplification is due to a spin-polarization dependent mobility originating from the Pauli exclusion principle that also gives rise to the spin Gunn effect. The spin polarization amplification we describe here is driven by the inhomogeneous doping density, and thus does not require the large applied electric field of the spin Gunn effect. Hence it may apply

to situations at low electric fields and low temperatures in which spontaneous spin polarization has been seen experimentally. We further believe that these studies provide a direct way to study the spin-polarization dependent mobility in semiconductors.

*Work supported by DARPA/ARO DAAD19-01-1-0490.

**9:48**

**A19 8 Enhancement and suppression of spin density polarization due to inhomogeneous electric fields*** DAN CSONTOS, SERGIO ULLOA, *Dept. of Physics and Astronomy, Ohio University, Athens, OH 45701* We report on a theoretical and computational study of the spin polarization propagation in charge and spin inhomogeneous semiconductor structures. We use a self-consistent, semiclassical approach based on the Boltzmann transport equation to calculate the spin density imbalance, $\delta n_s$, defined as $\delta n_s = n_\uparrow - n_\downarrow$, and the spin density polarization, $P_s$, defined as the ratio $P_s = \delta n_s / n$, where $n$ is the total charge density, in the presence of inhomogeneous electric fields. We find that the spin-polarized transport can be drastically enhanced or suppressed by inhomogeneous electric fields, such as those arising at semiconductor interfaces. Furthermore, we find that the spin density imbalance, $\delta n_s$, and spin density polarization, $P_s$, have diametrally opposite dependence on doping concentrations and charge inhomogeneous distributions. This is in contrast to the common assumption in the literature that these two quantities essentially have the same spin relaxation lengths.

*This work was supported by the Indiana 21st Century Research and Technology Fund.

**10:00**

**A19 9 Spin polarization amplification within nonmagnetic semiconductors at room temperature** SOON-WOOK JUNG, HYUN-WOO LEE, *Department of Physics, Pohang University of Science and Technology* We show theoretically that the spin polarization of current can be electrically controlled within nonmagnetic semiconductors by exploiting the fact the spin current, compared to the charge current, is weakly perturbed by electric driving forces. In particular, in a T-shaped current branching geometry made entirely of a nonmagnetic semiconductor, the spin polarization can be amplified to 100% by tuning current branching ratios properly. The proposed amplification scheme does not use ferromagnets or magnetic field, and does not require low temperature operation, providing an efficient way to generate a highly spin polarized current in nonmagnetic semiconductors at room temperature.

**10:12**

**A19 10 Spin currents in the presence of non-uniform fields.** ADNAN REBEI, *Seagate Technology* A two dimensional electron gas with spin-orbit coupling and in the presence of an in-plane electric field give rise to a spin Hall current independent of the Rashba coupling. We show that this universality of the strength of the spin current survives even in the presence of non-uniform electric and magnetic fields. Gradients in magnetic fields are shown to couple charge and spin transport and hence provide a better way to detect spin currents. Our calculation parallels that of the derivation of the Chern-Simons effective action in a relativistic electron gas and hence avoids the use of the Kubo formula. The spin conductivity is also discussed in terms of spin accumulation in a non-uniformly magnetized square loop.

**10:24**

**A19 11 Magneto-Oscillations of Current-Induced Spin Polarization in 2DEG** MAXIM VAVILOV, *Yale University* We consider a disordered two-dimensional electron gas with spin-orbit coupling placed in a perpendicular magnetic field and calculate the magnitude and direction of the current-induced spin polarization. We find that in strong magnetic fields the polarization becomes an oscillatory function of the magnetic field and that the amplitude of these oscillations is parametrically larger than the polarization at zero magnetic field. We show that the enhanced amplitude of the polarization is a consequence of strong electron-hole asymmetry in a quantizing magnetic field.

**A19 12 Spontaneous Spin Polarization in Quantum Wires*** A. D. KLIRONOMOS, J. S. MEYER,† K. A. MATVEEV,‡ *Materials Science Division, Argonne National Laboratory, Argonne IL, 60439, USA* A number of recent experiments report spin polarization in quantum wires in the absence of magnetic fields. These observations are in apparent contradiction with the Lieb-Mattis theorem, which forbids spontaneous spin polarization in one dimension. We show that sufficiently strong interactions between electrons induce deviations from the strictly one-dimensional geometry and indeed give rise to a ferromagnetic ground state in a certain range of electron densities. At higher densities, more complicated spin interactions lead to a possibly novel ground state.

**A19 13 Spin-polarized current created by quantum point contacts with spin-orbit interaction** MIKIO ETO, *Faculty of Science and Technology, Keio University, Japan* We propose a new idea to create spin-polarized currents using quantum point contact (QPC) with spin-orbit interaction.[1] Neither magnetic fields nor magnetic materials are required. By numerical studies using Green function recursion method,[2] we show that (i) the conductance is quantized in units of $2e^2/h$ even in the presence of spin-orbit (SO) interaction, (ii) the current is spin-polarized in the transverse direction, and (iii) a spin polarization of more than 50% can be realized with SO interaction strength in InGaAs heterostructures. The spin polarization stems from the transition between subbands of different spins during the transport through QPC. The spin-polarization ratio is determined by the adiabaticity of the transition, which is evaluated by the Landau-Zener theory. Since the two-terminal devices with QPC are easy to fabricate on semiconductors, they may be utilized for the spin injection in the spintronics.

**A20 1 An atomic-scale view of the structure and electronic properties of manganite thin films and superlattices.***
MARIA VARELA, *Oak Ridge National Laboratory*

Epitaxial manganite ultrathin films and heterostructures constitute an ideal system to study the nature and effects of inhomogeneity and phase competition in these materials. The presence of interfaces and epitaxial strain may cause new phenomena to arise, and a comprehensive study of the relations between structural, chemical and electronic properties at the atomic scale is needed. The combination of scanning transmission electron microscopy and energy loss spectroscopy represents a very powerful tool to analyze locally such relations. Unlike diffraction techniques, STEM-EELS allows clear separation of electronic valence from structural relaxations. Several examples will be presented, including the study of charge ordering in $Bi_{0.37}Ca_{0.63}MnO_3$. We find atomically-resolved striping of the Mn $L_{2,3}$ spectra that correlate with two distinct formal charge states (+3/+4). Theoretical results obtained by first-principles density-functional calculations reproduce the structural relaxation that leads to the striping with minimal charge transfer. In contrast, charge transfer may occur across $YBa_2Cu_3O_{7-x}/La_{0.67}Ca_{0.33}MnO_3$interfaces, where extensive charge transfer processes drastically affect the ferromagnetic/superconducting properties. Epitaxial strain can also play a determining role in ultrathin LCMO films, inducing a nanoscale modulation in the Mn+3/Mn+4 ratio which evidences the existence of nanoclusters with different electronic densities.

**A20 2 Doping without Disorder: Digital Synthesis of Manganite Superlattices*** ANAND BHATTACHARYA, *Argonne National Laboratory* XIAOFANG ZHAI, MAITRI WARUSAWITHANA, *University of Illinois at Urbana Champaign* JERALD KAVICH, *University of Illinois, Chicago and Argonne National Laboratory* JOHN FREELAND, *Argonne National Laboratory* JIM ECKSTEIN, *University of illinois at Urbana Champaign* SAM BADER, *Argonne National Laboratory* We have synthesized digital superlattices of $(LaMnO_3)_m(SrMnO_3)_n$ using ozone-assisted oxide MBE. This technique of itdigital synthesis allows the realization of superlattices with the same overall stoichiometry as random alloys of composition $La_{m/m+n}Sr_{n/m+n}MnO_3$, without introducing the random *A*-site disorder associated with bulk synthesis. In these digital superlattices, the 'doping' or charge transfer occurs at well ordered coherent interfaces, whose electronic and magnetic properties may be studied by local probes, scattering techniques, and transport and magnetization studies. We shall present our results on a series of samples synthesized for various values of *m* and *n*, exploring both metallic and insulating phases of the nominal phase diagram for the bulk counterpart. The results will be discussed in the context of the interfacial states that arise in structures obtained with digital synthesis.

**A20 3 Electronic Interfacial Effects in Epitaxial Heterostructures based on $LaMnO_3$.** HANS M. CHRISTEN, M. VARELA, H.N. LEE, D.H. KIM, M.F. CHISHOLM, C. CANTONI, L. PETIT, T.C. SCHULTHESS, D.H. LOWNDES, *Oak Ridge National Laboratory, Oak Ridge, TN, USA* Studies of chemically abrupt interfaces provide an ideal platform to study the effects of discontinuities and asymmetries of the electronic configuration on the transport and magnetic properties of complex oxides. In addition, the behavior of complex materials near interfaces plays the most crucial role not only in devices and nanostructures but also in complex structures in the form of composites and superlattices, including artificial multiferroics. Interfaces in the $ABO_3$ perovskite system are particularly attractive because structurally similar oxides with fundamentally different physical properties can be integrated epitaxially. To explore the electronic effects at interfaces and to probe the physical properties that result from local electronic changes, we have synthesized structures containing $LaMnO_3$ and insulating perovskites using pulsed laser deposition. The local electron energy loss spectroscopy (EELS) capability of a scanning transmission electron microscope (STEM) is used to probe the electronic configuration in the $LaMnO_3$ films as a function of the distance from the interfaces. The results are compared to macroscopic measurements and theoretical predictions. Research sponsored by the U.S. Department of Energy under contract DE-AC05-00OR22725 with the Oak Ridge National Laboratory, managed by UT-Battelle, LLC.

**A20 4 Phase Separation in Ferromagnetic/Charge-ordered Superlattices** T. ZAC WARD, *University of Tennessee* JIANXING MA, *University of Tennessee* DANE GILLASPIE, *Unversity of Tennessee* HONG-YING ZHAI, *ORNL* E. WARD PLUMMER, *University of Tennessee* JIAN SHEN, *ORNL* The coexistence of ferromagnetic metal (FFM) and charge-ordered insulator (COI) observed in manganites, such as $La_{5/8-y}Pr_yCa_{3/8}MnO_3$, has been an intensive focus in the study of transition metal oxides (TMO).

Theories related to structural nanoscale disorder of charge carrier dopants and self-organization caused by an intrinsic elastic energy landscape have been proposed. To understand the subtle balance and competition between the different electronic phases, we have grown $La_{5/8}Ca_{3/8}MnO_3/Pr_{5/8}Ca_{3/8}MnO_3$ superlattices with different stacking periods in order to control the chemical ordering of La/Pr ions and thus the elastic energy landscape. The magnetic and transport properties of FM/CO superlattices as well as La/Pr disordered $La_{5/16}Pr_{5/16}Ca_{3/8}MnO_3$ will be presented and the driving mechanism of FM/CO phase separation will be discussed. Research sponsored by the U. S. Department of Energy under contract DE-AC05-00OR22725 with the Oak Ridge National Laboratory, managed by UT-Battelle, LLC

**A20 5 New metallic interface state in oxide artificial superlattices investigated by optical spectroscopy** SUNG SEOK A. SEO, WOO SEOK CHOI, KYUNGWAN KIM, *School of Physics and Research Center for Oxide Electronics, Seoul National University, Seoul 151-747, Korea* HO NYUNG LEE, *Condensed Matter Sciences Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831* LI YU, CHRISTIAN BERNHARD, *Department of Physics, University of Fribourg, Fribourg, CH-1700, Switzerland* TAE WON NOH, *School of Physics and Research Center for Oxide Electronics, Seoul National University, Seoul 151-747, Korea* Interfaces between the artificial structures of oxides have been attracting a lot of attention because of their novel physical properties, which are usually not obtained in single-phase bulk materials. As a model system to understand the interfaces between the Mott insulators and the band insulators, high quality artificial superlattices of $SrTiO_3$ / $LaTiO_3$ were epitaxially grown by pulsed laser deposition equipped with reflection high energy electron diffraction. Mid infrared-visible optical transmittance and reflectance spectra were measured to show highly conducting interface, providing clear evidences for electronic reconstruction at the interface. Moreover, temperature-dependent infrared ellipsometry results showed that the interface state was different from conventional metal, indicating a new two dimensional metallic state.

**9:24**

**A20 6 Understanding the atomic structure of epitaxial $SrTiO_3$-GaAs (001) hetero-interfaces.** ROBERT KLIE, YIMEI ZHU, *Center for Functional Nanomaterials, Brookhaven National Laboratory, Upton NY 11021* YONG LIANG, *Motorola Labs, Tempe, AZ 85284* ERIC ALTMAN, *Department of Chemical Engineering, Yale University, New Haven, CT 06520* WERONIKA WALKOSZ, JUAN-CARLOS IDROBO, SERDAR OGUT, *Department of Physics, University of Illinois at Chicago, Chicago IL 60607* The combination of high-resolution Z-contrast imaging, electron energy-loss spectroscopy (EELS), and density functional theory (DFT) calculations was used to study the interfacial structure of ultra-thin $SrTiO_3$ films on GaAs(001). Z-contrast imaging suggests an atomically sharp hetero-interface with $SrTiO_3$ [110] in registry with As-terminated GaAs [100] with no visible reconstruction of either surface. Our initial DFT-calculations reveal that such a stoichiometric interface would have states in the band gap, while X-ray photoelectron spectroscopy (XPS) shows a clean band gap and a valence band offset more than twice of the calculated offset. Therefore, we will use atomic-column resolved EELS and further DFT-calculations to explore the role of oxygen vacancies at the interface in compensating for the As dangling bonds and search for the low-energy semi-conducting $SrTiO_3$/GaAs-system.

**A20 7 Magnetic properties of $La_{2/3}Sr_{1/3}MnO_3/Pr_{2/3}Ca_{1/3}MnO_3$ superlattices** DARIO NIEBIESKIKWIAT, *Department of Physics, University of Illinois at Urbana-Champaign, Urbana, IL 61801* LUIS HUESO, *Department of Materials Science, University of Cambridge, Cambridge CB2 3QZ, UK* MYRON SALAMON, *Department of Physics, University of Illinois at Urbana-Champaign, Urbana, IL 61801* NEIL MATHUR, *Department of Materials Science, University of Cambridge, Cambridge CB2 3QZ, UK* We present a magnetization study of ferromagnetic/antiferromagnetic (FM/AFM) manganite superlattices, grown by pulsed laser deposition on $SrTiO_3$ substrates. The FM layers are 15-nm-thick $La_{2/3}Sr_{1/3}MnO_3$ (LSMO) sheets and the AFM layers were made of $Pr_{2/3}Ca_{1/3}MnO_3$ (PCMO), with variable thickness $t_A$ between 0 and 7.6 nm. Although all our multilayers exhibit a PM-FM transition of the LSMO layers at $T_C \sim 340$K, only for $t_A = 0$ do we observe a FM moment $M_0$ close to the expected saturation for the 1/3 doping. As soon as the AFM layers are added ($t_A = 0.8$nm) $M_0$ decreases, related to the introduction of the FM/AFM interfaces. The lack of exchange bias would indicate that the reduction of the FM moment is due to the appearance of a magnetically dead layer in the LSMO close to the interface with the AFM volume. Upon a further increase of $t_A$, the FM moment increases again and develops a peak at $t_A \sim 3.5$ nm. We explain this behavior in terms of the accommodation of nanometric FM droplets in the PCMO layers.

**9:48**

**A20 8 Strong interaction of ultra thin cuprate superconductor and ferromagnetic manganites** XIAOFANG ZHAI, JAMES ECKSTEIN, *University of Illinois, Urbana* We have made bi-layer films with thick manganite layers on top of thin layers of the cuprate superconductor $Bi_2Sr_2CaCu_2O_{7+\delta}$ (BSCCO). The samples were grown using ozone assisted atomic layer by layer molecular beam epitaxy. For samples in which the manganite is the ferromagnet $La_{2/3}Sr_{1/3}MnO_3$(LSMO), the normal and superconducting properties of the BSCCO can be strongly affected by the LSMO when the BSCCO layer is sufficiently thin. In particular, samples with ten molecular layers of BSCCO were largely unaffected by the LSMO. On the other hand, when the number of BSCCO molecular layers was reduced to 5 and then to 4, the normal state above 80K became much more resistive and the superconducting Tc was reduced. However, a sample with four molecular layers of BSCCO capped with insulating and presumably antiferromagnetic SrMnO3 showed no effect of the manganite of BSCCO transport. This indicates that the reduced conductivity of the 4-layer sample capped with LSMO is due to the interaction of mobile carriers from the two systems at the interface. This interaction extends about 4 unit cells into the BSCCO.

**A20 9 Oscillatory behavior of the magnetoresistance of F/S/F trilayers** NORBERT M. NEMES, *Instituto de Ciencia de Materiales de Madrid (ICMM-CSIC). 28049 Cantoblanco. Madrid* M. GARCIA-HERNANDEZ, *ICMM* V. PEÑA, Z. SEFRIOUI, J. GARCIA-BARRIOCANAL, C. VISANI, D. ARIAS, C. LEON, *UCM* J. SANTAMARIA, *GFMC, Departamento de Física Aplicada III, Universidad Complutense de Madrid, 28040 Madrid, Spain* S.G.E. TE VELTHUIS, *ANL* A. HOFFMANN, *Materials Science Division, Argonne National Laboratory, Argonne, Illinois 60439* We have measured magnetoresistance of trilayers made of highly spin polarized $La_{0.7}Ca_{0.3}MnO_3$ ferromagnets and high-$T_c$ superconducting $YBa_2Cu_3O_{7-\delta}$ with the current in plane

(CIP) geometry. Large magnetoresistance peaks occur for antiferromagnetic (AF) alignment of the manganite layers, much resembling the GMR in metallic superlattices, and probably resulting of enhanced interface scattering in the AF configuration. We show RKKY-type oscillations in the intensity of the giant magnetoresistance (GMR) peak as a function of the thickness of the superconductor, perhaps originating in oscillatory magnetic coupling. The magnetoresistance vanishes for thickness of the superconductor in excess of 30 nm suggesting that this length could be an upper limit for the spin diffusion length.

**A21 1 Bubble size distribution in a steady-state column of aqueous foam.** KLEBERT FEITOSA, DOUGLAS J. DURIAN, *University of Pennsylvania* We report on measurements of the distribution of bubble sizes in a vertical column of aqueous foam. The sample is generated and maintained in steady-state by continuous bubbling of gas ([**mathtt**]$CO_2$) in a surfactant solution ([**mathtt**]$H_2$[**mathtt**]$O$ + AOS + NaCl) at the bottom of a tall Lucite cylinder. The constant flow of gas produces nearly identical bubbles that accumulate at the liquid/foam interface and subsequently move up with constant velocity. The distribution of bubble sizes depends on height, being monodisperse near the bottom, turning bidisperse at some intermediate height, and then becoming polydisperse further up in the column. This behavior is exclusively due to coarsening and drainage, since film-rupture and convection are not observed. The development of a bidisperse distribution cannot be explained by mean-field theories of coarsening, in which bubbles of a given size grow or shrink at a rate that depends only on their size in comparison with a mean size.

**8:12**
**A21 2 Rheology of Foams Bubble by Bubble** STEPHAN KOEHLER, *Physics, Emory University* We present rheological measurements of single bubbles, and collections of bubbles to investigate cooperative effects between the bubbles that comprise a foam. For small numbers of monodisperse bubbles we measure the elastic behavior and yield stresses, and make comparisons with polydisperse foams composed of many bubbles. We also present a technique for measuring an ageless foam, where the bubble size and liquid volume fraction remain constant, outside of a microgravity environment.

**8:24**
**A21 3 Pattern formation in flowing foams.** SOMA SANYAL, JAMES GLAZIER, *Indiana University* We report on a new fingering morphology which an expanding air bubble generates in a foam flowing due to an applied pressure across a Hele-Shaw cell. Previous studies have only looked at patterning when the background is stationary. Our simulations using the Glazier & Grainer's Cellular Potts model show that the transition between the different morphologies depend on the rate of bubble flow into the foam. Since the rate of bubble in-flow is related to the shear strain rate, this agrees with previous experiments which have shown fingering morphologies in foams depend on the shear strain rate. The new mushroom morphology occurs for a high rate of bubble inflow corresponding to a very low shear strain rate. It is associated with a highly non-uniform velocity profile of the bubbles in the foam. These new morphologies should be easy to observe experimentally.

**8:36**
**A21 4 Rigidity percolation in foamy sands** SYLVIE COHEN-ADDAD, REINHARD HOHLER, MARCEL KRZAN, MARIJO MARINIC, *Universite de Marne-la-Vallee* BENJAMIN HERZHAFT, *Institut Francais du Petrole* When subjected to a small shear stress, an aqueous foam behaves as a linear viscoelastic materials, whereas large applied shear stress triggers bubble rearrangement which causes the foam to flow as a viscous liquid. The elastic behavior arises from the surface tension of the gas-liquid interfaces. We study experimentally how the shear modulus and the yield stress of foam are modified if non colloidal solid particles of controlled size are dispersed in the sample. We show that even small amounts of non colloidal particles added to a foam can enhance the viscoelastic shear modulus by more than an order of magnitude. The yield stress is also increased, but to a smaller extent. The scaling of the elasticity enhancement with solid fraction qualitatively agrees with that predicted by an effective medium rigidity percolation model in the superelastic limit. To gain insight about the interactions between solid particles that are involved in the rigidity percolation, we study the dependence of the percolation threshold with particle to bubble size ratio.

**8:48**
**A21 5 Diffusive liquid transport in poroelastic materials : the case of foams in microgravity** ARNAUD SAINT-JALMES, SEBASTIEN MARZE, HERNAN RITACCO, DOMINIQUE LANGEVIN, *Laboratoire de Physique des Solides, Universite Paris-Sud, Orsay* On Earth, the liquid inside an aqueous foam irreversibly flows due to coupled gravitational and capillary effects. In microgravity, one can study liquid transport with only capillarity as a driving force. Here, we report results of capillary imbibition experiments performed in parabolic flights in which we follow how and where some liquid locally injected into a foam spreads with time. Different setup geometries, imbibition modes and bubble surface mobilities are studied. New behaviors, not observed on ground, with high liquid fractions are found. Comparisons with theoretical models are presented, allowing us to find their limits of validity as the liquid fraction is increased. These experiments also give us some insights on the convective instability occurring on ground, and allow us to discuss the analogy with diffusive liquid transport and swelling in other poroelastic materials, like plants and tissues.

**9:00**
**A21 6 Structure and dynamics of foam-like emulsions** VINOTHAN MANOHARAN, *Dept of Physics and Division of Engineering and Applied Sciences, Harvard University* JOHN C. CROCKER, *Chemical and Biomolecular Engineering, University of Pennsylvania* We report the results of real-space, microscopic experiments on model concentrated emulsions ($\phi > 0.65$) in which the continuous and dispersed phases are both index- and density-matched. Like foams, these systems coarsen and age due to diffusion of fluid from small to large droplets, but unlike foams,

they are transparent and do not drain during the course of an experiment. Thus we are able to probe their internal structure and dynamics at volume fractions ranging from 0.65 to 0.90. Measurements of the mean-squared displacement of small tracer particles embedded in the emulsion reveal that the system exhibits non-thermal stress fluctuations with Lorentzian power spectral density. We relate these fluctuations to intermittent droplet rearrangements, presumably driven by coarsening, that we observe directly through confocal microscopy.

**9:12**

**A21 7 Mean Field Theory of Foam Aging** OLIVIA HALT, *University of Pennsylvania* RANDALL KAMIEN, *University of Pennsylvania* We describe our work on the geometrical properties of a random foam as a function of the number of faces, based on Isotropic Plateau Polyhedra [1,2]. Analytic values of specific area, the stretching moment, and curvature can be obtained for these geometrical constructs. The expression for curvature is a ratio of the volume to the area of the foam cell. Focusing on this quantity will allow a better description of the coarsening of a foam. Conclusions from this mean field study will be discussed. [1] Glicksman M., itPhil. Mag., **85** (2005) 3. [2] Hilgenfeldt S., Kraynik A., Reinelt D., and Sullivan J. itEurophys. Lett. **67** (2004) 484.

**9:24**

**A21 8 Emulsions Plugging Agent for Sealing Leaky Gas Wells** KHALIL ZEIDANI, MARCEL POLIKAR, *University of Alberta* This study was undertaken to investigate the physics of emulsion flow in porous media. The objective of experiments were to study the applicability of oil-in-water emulsion as a plugging agent in the vicinity of the well bore for thousands of Canadian gas wells that are continuously leaking gas to surface. The motion of oil droplets and the capture mechanisms were investigated through visualized experiments. Well-characterized emulsions were injected into a micro model resembling a two parallel plate model packed with glass beads. Effects of emulsion properties and wettability of the medium were studied on a plugging mechanism. The results demonstrate the reduction in permeability mainly due to droplets size exclusion compared to the pore constrictions. Also, smaller droplets may lodge and coalesce in pores crevices thereby accelerating the blockage process. Moreover, more viscous emulsions are more effective compared with the less viscous ones due to combined effects of capillary and viscous forces. The deposition of droplets was adjusted through utilizing different preflush solutions. Criteria were set for enhancing emulsion penetration depth thereby defining the extent of the blocked region. In conclusion, this work characterizes the physics of emulsion flow in porous media and demonstrates its application as a novel sealant in near well bore region. The novelty, which constitutes a step-change in technology, is a method that emplaces an emulsion at a desired location in underground media.

**9:36**

**A21 9 Wigner Crystals from Charge Stabilized Water in Oil Emulsions** MIRJAM E. LEUNISSEN, ALFONS VAN BLAADEREN, *University of Utrecht* ANDREW D. HOLLINGSWORTH, MATT SULLIVAN, *Princeton Unviersity* PAUL CHAIKIN, *New York University* SOFT CONDENSED MATTER GROUP COLLABORATION, PRINCETON INSTITUTE FOR THE SCIENCE AND TECHNOLOGY OF MATERIALS COLLABORATION, A drop of water shaken or sonicated in a CHB-Decalin oil mixture produces a stable emulsion of 1-100 micron scale water droplets. The interdroplet correlations indicate strong electrostatic repulsion. When the preparation is by sonication the particle size is smaller and more uniform and the water droplets arrange in a BCC structure characteristic of a Wigner Crystal. The lattice constants are up to 20 microns. We suggest that the water droplets deionize the organic solvent due to water's high dielectric constant and hydration energy. This decreases the electrostatic screening. A slight preference of the water hydration energy for different ionic species will lead to slightly larger droplet uptake of one charge over the other and will result in the droplets being charged. The amount of charging can be controlled by changing pH. Experiments with oil-water and colloids will also be discussed.

**9:48**

**A21 10 Microrheological Study of the Time Dependent Gelation of Single Wall Carbon Nanotube Suspensions** D.T.N. CHEN, L.A. HOUGH, M.F. ISLAM, A.G. YODH, *Dept. of Physics & Astronomy, University of Pennsylvania* Single wall carbon nanotubes (SWNTs) dispersed in water using an anionic surfactant, sodium dodecylbenzene sulfonate (NaDDBS) form reversible gels because of the bonding between the individual nanotubes (L.A. Hough, M.F. Islam, P.A. Janmey and A. G. Yodh Phys. Rev. Lett. **93**, 168102 (2004)). We study the time dependence of this reversible gelation using particle tracking microrheology. We empirically collapse the mean square displacement onto a single master curve that extends over several decades in time using a time-cure superposition. The frequency scaling exhibited by the viscoelastic moduli obtained from the master curve is remarkably similar to that of semiflexible polymer networks. By comparing the results from a range of initial SWNT concentrations below and above the rigidity percolation threshold, we gain insight into the evolution of structure during gelation. This work has been partially supported by the NSF through Grants DMR 05-20020 (MRSEC) and DMR-0505048, and by NASA grant NAG8-2172.

**A21 11 Yielding and flow of soft particle dispersions: the role of elasto-hydrodynamic interactions.** MICHEL CLOITRE, *Matiere Molle et Chimie (UMR ESPCI-CNRS 7167), ESPCI, 10 rue Vauquelin, Paris, France* JYOTI SETH, ROGER BONNECAZE, *Department of Chemical Engineering and Texas Materials Institute, The University of Texas at Austin, Austin, Texas 78172, USA* Concentrated dispersions of soft particles such as emulsions, colloidal pastes and granular suspensions exhibit many fascinating phenomena such as yielding, shear thinning, aging and memory, slip and fracture. Elucidating the physical parameters controlling these properties and the mechanisms at work is a formidable challenge. Recently we have found that various soft particle pastes share in common universal flow properties that can be characterized with very simple constitutive equations involving the solvent viscosity, the bulk elasticity and geometrical factors. We shall describe a generic flow model based on internal slip and non-contact elasto-hydrodynamic forces between squeezed particles[1] that quantitatively accounts for the measured properties. This approach offers new routes to predict the bulk non-linear rheology of pastes. [1]S.P. Meeker, R.T. Bonnecaze, M. Cloitre, itPhys. Rev. Lett. **92**, n[r] 198302 (2004).

**10:12**

**A21 12 Mixture Stress in a Non-Uniform Suspension*** QUAN ZHANG, ANDREA PROSPERETTI,[†] *Johns Hopkins University* In nature, most suspensions are non-uniform and the particles are subjected to external forces, such as gravity. The external force induces relative motions between the particles and the fluid, which

introduce a new degree of freedom. We investigate the ensemble averaged stress system in a non-uniform suspension of equal spheres with external forces. It is found that, as a consequence of the spatial non-uniformity of the particle distribution and the relative motion between the two phases, new terms arise in the symmetric part of the bulk stress. In addition, an anti-symmetric contribution is found even in the absence of external torques. All the new terms in the stress tensor depend on the particle volume fraction and the gradient of the relative velocity but, for a given volume fraction, are independent of the particle size. To determine the new transport coefficients for small volume fractions, the renormalization method is extended to the non-uniform situation. For finite volume fractions, numerical simulations of several prototypical physical problems are carried out, from which the new transport coefficients are calculated. The numerical results agree well with the dilute limit calculations.

**A21 13 Brownian Motion of an ellipsoid*** YILONG HAN, *Department of Physics and Astronomy; University of Pennsylvania* AHMED ALSAYED, MAURIZIO NOBILI, *CNRS-University Montpellier II, France* JIAN ZHANG, TOM LUBENSKY, ARJUN YODH, We report direct digital-video-microscopy measurements of the Brownian motion of isolated anisotropic (ellipsoidal) particles in water under quasi-2D confinement. The probability density function (PDF) of displacements in the lab-frame is found to be nonGaussian. This effect originates from the anisotropy of the hydrodynamic drag coefficient. The transition from anisotropic to isotropic diffusion and the correlations between translational and rotational motions are also measured. The observations are confirmed numerically and understood theoretically via a Langevin formalism. We also observed the ratio of diffusion coefficients, $D_a/D_b$, along long and short axes, respectively, could be larger than 2, the theoretical upper limit in three dimension.

**10:36**

**A21 14 Sound propagation in nanofluids** X. XIE, R. ANNAMALAI, R. SOORYAKUMAR, D. STROUD, V. SUBRAMANIAM, J. HEREMANS, *The Ohio State University* The thermal properties of nanofluids, i.e. liquids containing nanoparticles of sizes in the 3 to 100 nm range, have recently been shown to exhibit an unexpectedly large enhancement in thermal conductivity. While this enhancement has been observed for metallic nanoparticles and carbon nanotubes, the physical origin of the enhancement remains to be understood. The propagation of acoustic waves through a nanoparticle-laden colloidal fluid system offers many advantages towards understanding its thermal properties. We report on results of Brillouin scattering which probes the frequency range of $\sim$ 1 – 100 GHz to study sound propagation in such complex fluids which possess structures on length scales larger than the molecules that comprise the host fluid. Thus compared to simple liquids, nanofluids possess additional relaxation mechanisms that can be observed in the frequency dispersion of the sound propagation. We present light scattering results from nanofluids comprised of a suspension of relatively long (1 - 2 $\mu$m) 20 nm diameter single-walled carbon nanotube bundles dispersed in N,N dimethylformamide.

The colloids consist of urea coated $Ba_{0.8}Rb_{0.4}TiO(C_2O_4)_2$ particles suspended in silicon oil. In the experiment, a cell with cross-aligned top and bottom stripe-electrodes is used. The electric potential, the field and the field gradient, therefore, possess different space distribution. Significant difference of colloids motions and equilibrium particle distributions are observed under ac, dc and ac+dc fields. The result suggests dipole may not be the only factor for colloid aggregation (meso-structure), and hence, its electrorheological effect. *also at Hong Kong University of Science and Technology and Lawrence Berkeley National Laboratory

## SESSION A22: FOCUS SESSION: CURRENT DRIVEN MAGNETIZATION DYNAMICS I

**A22 1 Spin-Transfer Effect in Nanopillar Spin Valves With A Thick Polarizing Layer** VLAD PRIBIAG, G.D. FUCHS, P.M. BRAGANCA, N.C. EMLEY, O. OZATAY, J. SANKEY, D.C. RALPH, R.A. BUHRMAN, *Cornell University* I. KRIVOROTOV, *U.C. Irvine* Current-induced magnetization switching has been the object of intensive study, motivated in part by possible applications for non-volatile magnetic storage. To date, the majority of studies have focused on structures where the moments of the magnetic layers lie in plane. Recently, however, it has been predicted that significantly faster switching times, as well as lower switching currents could be achieved in a device where the magnetization of the polarizing layer is perpendicular to the plane of the free layer [1, 2]. To study this effect we have fabricated Py 60nm / Cu 40nm / Py 5nm nanopillar spin valves patterned as 80 nm by 150 nm ellipses. The magnetization of the thick polarizing layer can be readily coerced to high out-of-plane angles by applying a weak field perpendicular to plane, while the much thinner free layer is only weakly affected. Here we present a phase diagram for our devices, obtained through DC and microwave-

frequency measurements as function of current and applied out-of-plane field. We will discuss the results in the context of switching with an out-of-plane polarizer. [1] A. D. Kent et al., Appl. Phys. Lett. 84, 3897 (2004). [2] K. J. Lee et al., Appl. Phys. Lett. 86, 022505 (2005).

**8:12**
**A22 2 Spin-transfer-induced magnetization reversal in bilayer magnetic nanopillars at high fields: dependence on free layer thickness*** WENYU CHEN, ANDREW D. KENT, *Department of Physics, New York University* M.J. ROOKS, N. RUIZ, JONATHAN Z. SUN, *IBM T. J. Watson Research Center* Spin transfer in asymmetric Co/Cu/Co bilayer magnetic nanopillar junctions has been studied as a function of free (thin) Co layer thickness from 1.8 to 5.3 nm. In particular, the critical current for magnetization reversal in large magnetic fields applied perpendicular to junction surface has been measured. Junctions with submicron lateral size were fabricated using a nano-stencil process. Junctions resistances scale with lateral area and their in-plane magnetoresistance was found to be independent of free layer thickness. The critical current decreases linearly with decreasing free layer thickness and extrapolates to a finite critical current in the limit of zero thickness. This can be understood as either a decrease in efficiency of the spin-transfer torque and/or an interfacial contribution to the damping of the free magnetic layer.

*The research is supported by NSF-DMR-0405620.

**8:24**
**A22 3 Linewidths for spin-transfer-driven precession in magnetic nanopillars as a function of the direction of applied magnetic field** KIRAN V. THADANI, J.C. SANKEY, I.N. KRIVOROTOV, O. OZATAY, P.M. BRAGANCA, R.A. BUHRMAN, D.C. RALPH, *Cornell University* In a magnetic multilayer spin valve, the spin-transfer torque from a spin-polarized DC current can drive the free-layer magnetic moment into steady-state precessional modes [1, 2]. We report measurements of how the linewidths of these modes depend on the angle and magnitude of an applied magnetic field, for devices in the nanopillar configuration with elliptical cross sections. We find that the field direction studied most commonly, in-plane along the magnetic easy axis of the ellipse, generally gives the largest linewidths, corresponding to the least coherent precession. As the field is rotated either in plane or out of plane, the linewidths can change dramatically, decreasing by a factor of 50 or more in some devices. We will discuss the temperature dependence of the linewidths for the field directions that give the minimum linewidths, and we will compare both the field-angle dependence and the temperature dependence to theoretical models. **A22 4 Phase Locking of Spin-Transfer Oscillators.**
MATTHEW PUFALL, *NIST, Boulder, CO*

DC current flowing through a nanometer-scale lithographic contact made to a continuous spin-valve multilayer induces stable magnetic precession of the free layer at GHz frequencies. The resonance frequency of the spin-transfer oscillator (STO) is a function of both the applied current and external magnetic field, and the resonance has linewidths on the order of MHz. To study the properties of this resonance, and to determine the suitability of STOs for communications applications, we measured the response of these oscillators to variations in the magnetic field, electric current, and spin-wave environments. We studied phase locking effects induced by injecting ac currents, and by applying ac magnetic fields near the precession frequency of the device. In addition, we have fabricated two nanocontact devices in close proximity on the same magnetic film, and looked at the interactions between the two devices. In each case, when the impressed ac signal is sufficiently close to the STO frequency, the device will phase lock. For ac currents and fields, the device locks to the external signal via injection locking, a general property of nonlinear oscillators, taking on the frequency and phase characteristics of the source. For interacting nanocontacts, the devices modify each other's resonances, and lock together at frequency slightly different from the individual resonances. I will review these phase locking results, and discuss the variations of the locking with the excited mode of the oscillator. I will also present results on mutual locking of STOs, discuss the relative roles of dipolar fields and spin-wave interactions in the locking mechanism, and comment on the possible uses of phase controlled, coherent STOs.

**A22 5 Probing wavenumbers of current-induced excitations in point-contact experiements** MAXIM TSOI, *The University of Texas at Austin* ZHEN WEI, *The University of Texas at Austin* The magnetic state of a ferromagnet can be altered by an electrical current. For instance, the current was shown to induce spin waves, precession, and reversal of magnetization in magnetic nanostructures. Today a variety of experimental techniques provide a vast amount of data on such current-induced excitations. A typical experiment usually exploits dc resistance measurements to detect the excitations. In addition, high-frequency techniques can provide valuable information on frequencies of the current-induced spin waves. Probing wavenumbers of the excitations, however, represents an experimental challenge. Point contacts were instrumental both for our original observation of current-induced excitations and in providing the first data on frequencies of the current-induced spin waves. In the present work we demonstrate that point-contact technique can also provide valuable information on the wavenumber of spin waves induced by the current. By varying the size of point contacts we have been able to control the size of the excitation volume and therefore the wavelength of current-induced spin waves. This leads to a technique with in situ sensitivity to wavenumbers of current-induced excitations. The detailed size-dependent measurements of the current-induced excitations display an interesting relation between current and voltage thresholds for such excitations.

**A22 6 Influence of Electrode Structure on Switching Characteristics in Nanopillar Spin Valves** P. M. BRAGANCA, O. OZATAY, A. G. F. GARCIA, J. C. SANKEY, N. C. EMLEY, D. C. RALPH, R. A. BUHRMAN, *Cornell University* We examine the effect spin scattering within the electrodes of a spin-valve nanopillar has on spin torque and damping within the structure. Devices were fabricated with the free layer adjacent to either the top or bottom electrode and with Au or Pt top electrodes. Macrospin simulations, when compared to pulsed current switching experiments, indicate that gold electrode samples of either free layer orientation have similar switching parameters, while devices with the free layer adjacent to a top platinum electrode exhibit lower spin torque and larger damping than Au capped devices, in agreement with spin accumulation [1, 2] and spin pumping [3] models. However, by placing the free layer opposite a platinum cap, the largest values for spin torque and damping were achieved, which was an unexpected result. In addition, we will discuss how placement of the free layer close to the bottom electrode induces effects such as fixed layer switching and microwave excitations in zero effective field, which are not seen in the opposite configuration. **A22 7 X-Ray Imaging of Spin Transfer Induced Magnetization Reversal** YVES ACREMANN, *Stanford Synchrotron Radiation Laboratory* J.P. STRACHAN, V. CHEMBROLU, *Department of Applied Physics, Stanford University* S.D. ANDREWS, *Department of Materials Science and Engineering, Stanford University* T. TYLISZCZAK, *Advanced Light Source* J.A. KATINE, M.J. CAREY, *Hitachi Global Storage Technologies San Jose Research Center* B.M. CLEMENS, *Department of Materials Science and Engineering, Stanford University* H.C. SIEGMANN, J. STÖHR, *Stanford Synchrotron Radiation Laboratory* Magnetization switching by spin injection has been observed in giant magnetoresistance measurements, giving an insight into the temporal evolution of the magnetization. So far, however, the nanoscale magnetization distribution during the switching process has remained hidden. Here we report, for the first time, imaging the magnetic switching process using advanced pump-probe x-ray microscopy. We observe that the switching process is initiated and determined by the lateral motion of a magnetic vortex driven by the spin current. Motion pictures with 200 picosecond time resolution show that the switching process is based on the motion of a magnetic vortex, leading to C-like patterns which may decay later into a uniform magnetic state. Our measurements show the fundamental role played by the curled Oersted field which necessarily accompanies the spin injection current.

**9:48**

**A22 8 Effects of current on the magnetization states of Permalloy nanodisks** SERGEI URAZHDIN, *West Virginia University* CHIA-LING CHIEN, *Johns Hopkins University* KONSTANTIN GUSLIENKO, *Argonne National Laboratory* We will describe expreimental evidence and theoretical model demonstrating that both the vortex and the single domain magnetic configurations of Ni80Fe20 circular nanodiscs can be achieved by the application of magnetic field or current flowing perpendicular to the disc plane. The magnetic configurations of Ni80Fe20/Cu/Ni80Fe20 trilayers have been determined by the response to a small current via the giant magnetoresistance. In addition, we report detection of the vortex state in a single magnetic layer, by exploiting a magnetoresitance arising from the suppression of spin-accumulation in the vortex state. Our analysis shows that this magnetoresistance effect becomes increasingly significant in small nanostructures.

**10:00**

**A22 9 Spin-mixing effects on magnetic switching, probed by thermoelectric measurements*** JEAN-PHILIPE ANSERMET, LAURENT GRAVIER, MOHAMED ABID, SANTIAGO SERRANO-GUISAN, *IPN, EFPL, Station 3, CH-1015 Lausanne, Switzerland* Current-Induced Magnetization switching has been observed in single nanowires of Co, Ni, Co-Cu and Ni-Cu multilayers. A novel thermoelectric measurement under high DC current is presented. It features a field dependence stronger than GMR. Its dependence on field orientation shows that it provides information complementary to GMR or magneto-thermoelectric power measurements. It is argued with a simple model that this measurement depends strongly on the difference of spin mixing rates of spin conversions going from ''up'' to ''down'' and conversely. Thus, this novel transport measurement provides information on electron-magnon collisions in magnetic nanostructures. The field dependence of this signal is about 10 times larger than the magnetoresistance of the same sample, be it AMR or GMR. In multilayers, the field dependence is shown to decay away when the thickness of the layers is larger than the spin-diffusion length.

**A22 10 Universal spin pumping with rf magnetic fields** S. M. WATTS, C. H. VAN DER WAL, B. J. VAN WEES, MATERIALS SCIENCE CENTER, UNIVERSITY OF GRONINGEN, PHYSICS OF NANODEVICES TEAM, A new method for generating spin accumulation in metals or semiconductors is by application of an rf magnetic field [1], similar to the spin battery effect induced by a ferromagnet in resonance [2]. A dc spin accumulation is produced that is in general a small fraction of $\hbar\omega$, where $\omega$ is the rotation frequency of the rf field. When a resonant dc magnetic field is also applied the spin accumulation can be enhanced towards the universal value $\hbar\omega$. In addition, spin diffusion into an adjacent region without fields can dramatically enhance spin accumulation at the interface. We discuss the application of this method to produce spin accumulation in semiconductor or metal spin electronic devices without the necessity of either ferromagnetic electrodes or charge currents. [1] S. M. Watts *et al.*, submitted to PRL [2] A. Brataas *et al.*, Phys. Rev. **B** 66 (2002).

**A22 11 Spin Transfer in Magnetic Nano Devices with Perpendicular Anisotropy** JIAN-PING WANG, HAO MENG, *Electrical Engineering, University of Minnesota* Spin transfer predicted by Slonczewski and Berger has attracted a great deal of attention in recent years. Experimental findings have proved spin transfer in current-perpendicular-to-plane (CPP) spin-valves (SV) and magnetic tunnel junctions (MTJs) with in-plane magnetization configuration. MRAM cells with perpendicular magnetic anisotropy may support high recording density than that using shape anisotropy with in plane magnetization configuration. However, there is no report on spin transfer in any magnetic nano device with perpendicular anisotropy. In this work, perpendicular magnetized

spin transfer nano-devices with sub-200 nm dimensions: Si/$SiO_2$/bottom electrode/$[CoFe2.5Å/Pt15 Å]_m$/CoFe5 Å /Cu30 Å /$[CoFe4.5 Å /Pt23 Å]_n$/Top electrode, has been fabricated and tested. Two $[CoFe/Pt]_n$ multilayers with different coercivities are used as the free layer and fixed layer in nano-devices. CPP magnetoresistive (MR) loop tested under perpendicular magnetic field shows the GMR is around 0.47%. The switching field for the free layer is around 200 Oe. Current induced magnetization switching was realized with a positive switching current 48 mA and a negative switching current -62 mA, respectively. Furthermore, field dependence of the switching current will also be demonstrated.

**A23 1 High magnetic field thermal-expansion and magnetostriction of $URu_2Si_2$** VICTOR CORREA, TIMOTHY MURPHY, ERIC PALM, STANLEY TOZER, *National High Magnetic Field Laboratory, Florida State University* PETER SHARMA, NEIL HARRISON, MARCELO JAIME, *National High Magnetic Field Laboratory, Los Alamos National Laboratory* GEORGE SCHMIEDESHOFF, *Occidental College* JOHN MYDOSH, *II Physikalisches Institut, Universität zu Köln* We present high magnetic field (up to 45 T) thermal-expansion and magnetostriction results on $URu_2Si_2$ single crystals. The volume change associated with the transition to the ''hidden'' order phase becomes increasingly discontinous as the magnetic field is raised above 30 T. This confirms recent thermal conductivity and specific heat experiments indicating a strong coupling between the ''hidden'' order parameter and the lattice which suggest some sort of charge ordered state. Several other transitions are observed at higher fields, many of them showing hysteresis, while a change in the sign of the magnetostriction coefficient is observed at the metamagnetic transition ($B_M \sim$ 38 T).

**8:12**
**A23 2 Phonon Thermal Transport of $URu_2Si_2$: Broken Translational Symmetry and Strong-Coupling of the ''Hidden Order'' to the Lattice** PETER SHARMA, *National High Magnetic Field Laboratory-LANL* N. HARRISON, M. JAIME, *NHMFL-LANL* Y.S. OH, K.H. KIM, *Seoul Nat'l University* C.D. BATISTA, *LANL* H. AMITSUKA, *Hokkaido University* J.A. MYDOSH, *Max Planck Institute, Dresden* A dramatic increase in the total thermal conductivity ($k$) is observed in the Hidden Order (HO) state of single crystal $URu_2Si_2$. Through measurements of the thermal Hall conductivity, we explicitly show that the electronic contribution to $k$ is extremely small, so that this large increase in $k$ is dominated by phonon conduction. An itinerant BCS/mean-field model describes this behavior well: the increase in $k$ is associated with the opening of a large energy gap at the Fermi Surface, thereby decreasing electron-phonon scattering. Our analysis implies that the ''Hidden Order'' parameter is strongly coupled to the lattice, suggestive of a broken symmetry involving charge degrees of freedom.

**8:24**
**A23 3 On Heavy Fermion Superconductivity and Quantum Criticality in the 115 series** KENNETH BURCH, *University of California, San Diego* We have performed a detailed analysis of the optical properties of the 1-1-5 series (CeTIn5 where T=Co,Ir,Rh), revealing the hybridization gap ($\Delta$) as key to understanding their rich phase diagram. Surprisingly we find that $\Delta$ for only one of the four bands crossing the Fermi surface determines the properties of the system. Furthermore, these carriers are the lightest and produce the smallest $\Delta$. Additionally we discuss connections between this $\Delta$, the superconducting transition temperature and the symmetry of the superconducting gap. This study demonstrates an experimental link between superconductivity and the parameter governing the magnetic Quantum Critical Point.

**8:36**
**A23 4 Quantum Criticality in $CeMIn_{5-x}Sn_x$ (M = Rh, Co)** FILIP RONNING, ED BAUER, *Los Alamos National Laboratory* C. CAPAN, *Louisiana State University* Y. TOKIWA, J.D. THOMPSON, J.L. SARRAO, R. MOVSHOVICH, *Los Alamos National Laboratory* Non-Fermi liquid behavior, as characterized by a T-linear resistivity and a T log(T) behavior in specific heat, is observed in zero field in the heavy fermion system $CeCoIn_5$. The application of magnetic field has revealed a field tuned quantum critical point surprisingly coincident with the superconducting $H_{c2}$. We present data that shows the application of pressure reduces the critical field $H_{QCP}$ more rapidly than $H_{c2}$ is suppressed. We also investigate doping studies which show an anisotropically field tuned QCP in $CeRhIn_{5-x}Sn_x$ at x=1.0, the critical doping where antiferromagnetism is suppressed, while results on $CeCoIn_{5-x}Sn_x$ maintains that the quantum critical field and the superconducting upper critical field are intimately connected. We attempt to reconcile whether all the critical behavior in the $CeMIn_5$ family can have a common origin.

**8:48**
**A23 5 Superconducting properties of $Ce_2CoIn_8$** N. HUR, T. PARK, E. D. BAUER, J. D. THOMPSON, J. L. SARRAO, *Los Alamos National Laboratory, Material Science Technology Division, MST-10, Los Alamos, NM 87545* The new family of Ce-based heavy-fermion compounds with the general formula $Ce_nTIn_{3n+2}$ (T=transition metal) have attracted sparked interest in recent years owing to their various interesting phenomena, such as pressure induced superconductivity, quantum criticality, and non-Fermi liquid behaviors. However, among n=2 compounds, $Ce_2CoIn_8$ has not been studied sufficiently mainly because of the difficulty in the synthesis of crystals of decent size. Herein, we report the successful reproduction of $Ce_2CoIn_8$ single crystals and present their magnetic, thermal and transport properties. Observed anomalies in resistivity and their magnetic field dependence will be explained within the context of a filamentary superconductivity. The nature and possible origin of the resistivity transition is discussed in comparison with that in $CeIrIn_5$.

**9:00**
**A23 6 Point Contact Spectroscopy Study of the Heavy Fermion Superconductor $Pr(Os_{1-x}Ru_x)_4Sb_{12}$*** C. S. TUREL, J. Y. T. WEI, *University of Toronto* N. A. FREDERICK, W. M. YUHASZ, S. K. KIM, J. PAGLIONE, M. B. MAPLE, *University of California at San Diego* The recent discovery of superconductivity in the heavy fermion material $Pr(Os_{1-x}Ru_x)_4Sb_{12}$ has generated widespread interest. In particular, there is evidence for the existence of two competing superconducting order parameters, at least

one of which is believed to have nodes. We have performed point-contact spectroscopy measurements on single crystals of $Pr(Os_{1-x}Ru_x)_4Sb_{12}$, using Pt-Ir tips in a dilution refrigerator with a pulsed technique to minimize Joule heating. We present differential conductance spectra down to 100 mK, along with the magnetic field evolution. We discuss the implications of our data in relation to recently proposed pairing symmetries.

**A23 7 de Haas van Alphen perspective on the origin of heavy fermions in $UPt_3$** PATRICK ROURKE, *University of Toronto* ALIX McCOLLAM, *University of Toronto* GREG McMULLAN, *MRC-LMB, Cambridge* MIKE NORMAN, *Argonne National Laboratory* STEPHEN JULIAN, *University of Toronto* ANDREW HUXLEY, *DRFMC-CEA, Grenoble* Precise de Haas van Alphen (dHvA) oscillation measurements on the heavy fermion superconductor $UPt_3$ are available as a function of magnetic field angle. It was recently proposed that the heavy quasiparticles in this material arise from the localization of two of the three 5f electrons of the U ions [Zwicknagl et al., PRB 65, 081103R (2002)]. The predicted Fermi surface topology however differs from traditional band-structure calculations. We will focus on the experimentally observed angle dependence of the hole-like $\delta$-orbit, as this appears difficult to reconcile with the Fermi surface of Zwicknagl et al.

**9:24**

**A23 8 NMR measurement of spin-spin relaxation ($T_2$) of $URu_2Si_2$** TOD CALDWELL, *Los Alamos National Laboratory* NICHOLAS CURRO, *Los Alamos National Laboratory* We report detailed temperature dependences of the 29Si spin-spin relaxation rate T2 in the heavy fermion superconductor $URu_2Si_2$ as a function of field and temperature. All experimental work was carried out on an aligned powder sample. Both Carr-Purcell-Meiboom-Gill (CPMG) and Hahn-Echo pulse sequence techniques were employed to examine differences in spin-spin relaxation. We find unusual enhancements of the relaxation rate near the hidden order transition, and will discuss our results in the context of various theoretical scenarios.

**9:36**

**A23 9 Indications of a Field Dependent Vortex Core Size in $CeCoIn_5$** L. DEBEER-SCHMITT, M. R. ESKILDSEN, *Department of Physics, University of Notre Dame, Notre Dame, IN 46556 USA* C. D. DEWHURST, *Institut Laue-Langevin, 6 Rue Jules Horowitz, F-38042 Grenoble, France* B. W. HOOGENBOOM, *University of Basel, Klingelbergstasse 70, CH-4056 Basel, Switzerland* C. PETROVIC, *Department of Physics, Brookhaven National Laboratory, Upton, NY 11973 USA* Using Small-Angle Neutron Scattering, we have imaged the flux- line lattice (FLL) in the *d*-wave, heavy fermion superconductor $CeCoIn_5$. At low fields, a hexagonal FLL is observed which undergoes a first order transition to a rhombic (distorted square) symmetry as the field is increased above 0.55 T. As the field is increased futher, the FLL approaches a square symmetry. Measurements of the FLL reflectivity yields a constant form factor independent of the applied magnetic field, in stark contrast to the exponential decrease usually observed. The field-independent form factor may indicate a field dependent vortex core size, $\xi \propto H^{-1/2}$, in qualitative agreement with recent theoretical predictions for ultra-clean, high-$\kappa$ superconductors [V.G. Kogan and N.V. Zhelezina, PRB **71**, 134505 (2005)].

**9:48**

**A23 10 Quantum Criticality in Itinerant Antiferromagnet $Cr_{0.965}V_{0.035}$** D.A. SOKOLOV, G. STRYCKER, M.C. ARONSON, M.C. BENNETT, *The University of Michigan* S.E. NAGLER, M. LUMSDEN, *HFIR, ORNL* We report results of triple-axis neutron scattering experiments, in which we studied the development of the magnetic fluctuations in the quantum critical itinerant antiferromagnet $Cr_{0.965}V_{0.035}$. Unexpectedly, we found temperature dependent elastic scattering at the incommensurate wavevector q $*=(001\pm\ \delta)2\ \pi$/a, which corresponds to the spin density wavevector in pure Cr and no elastic scattering at the commensurate wavevector $q=(001)2\ \pi$/a. We propose an electronic phase separation scenario to account for the observed elastic scattering. Temperature independent inelastic scattering was observed at the commensurate wavevector q. This scattering showed a linear increase with energy transfer $E_t$, saturating at $E_t=18$ meV, which we interpret as a characteristic energy scale expected for the Fermi liquid. The wave vector dependence of the scattering at q* is Lorentzian, with an intensity which decreases with increasing energy transfer, and is temperature independent below 100 K. The Lorentzian linewidth approaches the spectrometer resolution at the lowest temperatures and energy transfers. These observations suggest that the susceptibility underlying the incommensurate scattering is maximized, and is perhaps critical, for $q=q^*$, $E\rightarrow 0$, and $T \rightarrow 0$, as has been observed near other antiferromagnetic quantum critical points. Work at the University of Michigan supported by the National Science Foundation.

**10:00**

**A23 11 Attractive electron-electron interaction induced by the Bloch band topological field** JUNREN SHI, *Institute of Physics, Chinese Academy of Sciences* QIAN NIU, *University of Texas at Austin* We demonstrate a new possibility for the occurrence of the attractive electron-electron interaction in ferromagnetic metals. Unlike that of the conventional origin via the boson-exchange (spin fluctuation), this attractive interaction is induced by the Bloch band topological field, which transforms the Coulomb repulsion to a direct attractive interaction between electrons, resulting in unconventional superconductivity with the isotropic $p-$wave pairing. Our study highlights the fundamental effects of the Bloch band topological field, which presents in a large class of crystalline materials. It also provides a plausible alternative theory for the recently discovered ferromagnetic superconductors $UGe_2$ and $ZrZn_2$.

**10:12**

**A23 12 Theory of the helical spin crystal. A candidate for the partially ordered state of MnSi** BENEDIKT BINZ, ASHVIN VISHWANATH, *UC Berkeley* VIVEK AJI, *UC Riverside* MnSi is an itinerant magnet which at low temperatures develops a helical spin density wave. Under pressure it undergoes a transition into an unusual partially ordered state whose nature is debated. Here we propose that the helical spin crystal (the magnetic analog of a solid) is a useful starting point to understand partial order in MnSi. We consider helical spin crystals with BCC structure (composed of superpositions of six different helical spin-density waves) and determine conditions under which they may be energetically fa-

vored. We introduce a Landau theory to study the properties of these states, in particular the effect of crystal anisotropy, magnetic field and disorder. These results compare favorably with existing data on MnSi from neutron scattering and magnetic susceptibility measurements. Future experiments to test this scenario are also proposed.

**10:24**

**A23 13 Anomalous quasiparticle transport in the superconducting state of $CeCoIn_5$** YUICHI KASAHARA, *Department of Physics, Kyoto Univ.* YASUYUKI NAKAJIMA, *ISSP Univ. of Tokyo* KOICHI IZAWA, *CEA-Grenoble, ISSP Univ. of Tokyo* KAMRAN BEHNIA, *Laboratoire de Physique Quantique (CNRS) ESPCI, ISSP Univ. of Tokyo* YUJI MATSUDA, *Kyoto Univ., ISSP Univ. of Tokyo* HIROAKI SHISHIDO, RIKIO SETTAI, YOSHICHIKA ONUKI, *Osaka Univ.* To investigate the quasiparticle dynamics in the superconducting state of quasi-two dimensional heavy fermion superconductor $CeCoIn_5$, the thermal Hall conductivity $\kappa_{xy}$ is measured. In zero magnetic field, thermal Hall angle shows up a steep increase below $T_c$, indicating that the quasiparticle mean free path is strongly enhanced. In spite of the presence of a periodic vortex lattice, this enhancement is easily suppressed by a very weak magnetic field. We found that the density states of the delocalized quasiparticles $N_{\mathrm{del}}$, which is obtained from $\kappa_{xx}$ and $\kappa_{xy}$, exhibits a $\sqrt{H}$- dependence, indicating a Volovik effect. Moreover, $\kappa_{xy}$ reveals the scaling relation with respect to $T/\sqrt{H}$, which is expected for *d*-wave symmetry. These results provide a further support for *d*-wave superconducting symmetry in $CeCoIn_5$. We also argue that a small Fermi energy, a short coherence length, and a long quasiparticle mean free path all indicate $CeCoIn_5$ is in the superclean regime. These results highlight that $CeCoIn_5$ is unique among superconductors.

## SESSION A24: SEMI-CRYSTALLINE AND STRUCTURED POLYMERS

**Monday Morning, 13 March 2006**

**8:00**

**A24 1 Crystalline Structure, Morphology and Gas Transport in Semicrystalline Syndiotactic Polystyrene** BRIAN OLSON, JUSTIN BRANDT, SERGEI NAZARENKO, *School of Polymers and High Performance Materials, University of Southern Mississippi* Crystalline syndiotactic polystyrene (s-PS) continues to amuse the researchers by showing very unusual properties. This work mainly explored the remarkable free volume properties of the crystalline structure of this polymer, and also very unusual gas transport behavior. It was possible by varying the temperature of the melt and crystallization conditions to prepare a series of semicrystalline samples with different crystallinities (0-50%) containing either pure $\alpha$-form, pure $\beta$-form and pure $\gamma$-form. Solid-state structure and the morphology of all prepared systems were examined by an assortment of techniques: DSC, density, WAXS, SAXS, and AFM. The structure was also probed by passing through small gas molecules, and by means of positron lifetime spectroscopy (PALS).

**A24 2 Large Strain Requirements for Shear Induced Crystallization of Isotactic Polypropylene*** H. HENNING WINTER, AADIL ELMOUMNI, DEEPAK ARORA, *University of Massachusetts Amherst* Strain effects on the crystallization of a series of isotactic polypropylenes (*i*PP), with various molecular weights, were studied using rheology, light transmission, birefringence, differential scanning calorimetry, and wide-angle X-ray diffraction. Transmitted light intensity measurements demonstrate that the effect of pre-shear on crystallization rate keeps increasing up to very larger strain levels, much beyond strains that are required to reach steady shear flow (at given itWe). Crystal orientation sets in at a total strain of about it$\gamma_0 = 600$ or higher. WAXD and DSC analyses corroborated the light transmission results. The samples were pre-sheared and then crystallized at constant temperature. Total shear strains it$\gamma_0$=200 to 1000 were applied to the *i*PP samples at the beginning of a crystallization experiment, after the samples had reached the crystallization temperature of 145$^o$C (undercooled state). A constant Weissenberg number itWe=1 (itWe, defined as the product of shear rate and a relaxation time) was maintained throughout the study. itWe=1 corresponds to the onset of shear thinning in steady shear. Deborah number values were low, itDe$< <$1, indicating that steady shear flow had been reached in all pre-shearing runs.

**A24 3 Real-time, Depth-Resolved Structure Development of Flow-Induced ''Skin-Core'' Morphologies in Polypropylene.** LUCIA FERNANDEZ-BALLESTER, DEREK THURMAN, *California Institute of Technology* IGORS SICS, LIXIA RONG, *Brookhaven National Lab* JULIE KORNFIELD, *California Institute of Technology* We present a new method to isolate the signal arising from a given depth at each time point during flow-induced crystallization of isotactic polypropylene using real time rheo-optical and rheo-WAXD measurement based on the linear stress-depth relationship in a pressure-driven flow through a rectangular slit. Using thoughtfully selected sets of shearing conditions (constant ts with varied $\sigma$w), data analysis of the suite of experiments allows us to examine the incremental contribution to the real-time data from one shear stress to another (with all other conditions fixed) and to attribute the difference to a small spatial region of the sample. This ''depth sectioning'' technique has enabled us to confirm several existing results and uncovers several new keys to understanding how anisotropic crystalline is induced by flow. Threads first form near the channel wall where stress is highest and grow in length with prolonged flow. After sufficient time, thread length per unit volume saturates. The propagation of threads varies in a nonlinear manner with stress. Prior to saturation, thread propagation is linear with shearing time, providing promising conditions for measuring the thread propagation velocity.

**A24 4 Crystallization in Precision Polyolefins** RUFINA ALAMO, ANINDYA GHOSAL, *FAMU-FSU College of Engineering, Tallahassee Fl* EMINE BOZ, KENNETH WAGENER, *University of Florida, Chemistry Department, Gainesville, Fl* RIQIANG FU, *NHMFL, Tallahassee, Fl* ALAMO, GHOSAL, FU COLLABORATION, WAGENER, BOZ COLLABORATION, Understanding the crystallization behavior of highly branched polyolefins can be accomplished with model polymers with well defined microstructures. Models for branched polyethylenes with

precisely placed O, F, Cl or Br on each and every 19 carbons have been synthesized via acyclic diene metathesis (ADMET) polymerization followed by hydrogenation. Compared to broad WAXS and DSC melting peaks of systems with a random distribution of the substituent, similar properties of precisely substituted polyolefins are very sharp, typical of the behavior of homopolymers. A uniform partitioning of the substituent between crystalline and non-crystalline regions, observed by NMR, relatively thick lamellar crystallites (240 A) and WAXS angular shifts, parallel the homopolymer-like crystallization behavior. In this series, orthorhombic isomorphic structures are maintained in O and F substituted polymers or up to a van der Waals radius of about 1.6 A, while accommodation of bulkier atoms in the lattice promotes the formation of a new triclinic form. A linear correlation between melting points and vdw radius in the halogen series is indicative to the degree to which each substitution perturbs the symmetry of the neighboring carbons in the lattice.

**A24 5 Transitions of Polymers with Precise Oligomethylene Sequences.*** BERNHARD WUNDERLICH, WULIN QIU, *University of Tennessee, Knoxville, and ORNL, Oak Ridge* Polyethylene, PE, with precise branches has been analyzed by TMDSC and X-ray diffraction. The branches were methyl, dimethyl, and ethyl groups. Furthermore, atactic poly(octadecyl acrylate) and poly(4,4'-phthaloimidobenzoyl-doeicosyleneoxycarbonyl) were studied. All are compared to LLDPE, of similar branch concentration and linear PE. Compared to LLDPE the precisely structured polymers show much sharper melting. Compared to HDPE lower melting temperatures and heats of fusion were observed, and all have non-orthorhombic structures. In contrast to paraffins of equal length which melt fully reversibly at a similar temperature, the precisely designed polymers melt largely irreversibly with only small amounts of reversing melting which is least for the best-grown crystals. These results have important implications for the description of melting of copolymers. Initial literature: W. Qiu, J. Sworen, M. Pyda, E. Nowak-Pyda, A. Habenschuss, K. B. Wagener, B. Wunderlich, itMacromolecules, **39** (2006).

**A24 6 Ellipsometry as a Probe of Crystallisation Kinetics in Thin Diblock Copolymer Films** JESSICA L. CARVALHO, MICHAEL V. MASSA, KARI DALNOKI-VERESS, *Physics and Astronomy, McMaster University* We present our recent results on the use of ellipsometry to probe the crystallisation kinetics of thin films of a diblock-copolymer. Ellipsometry uses the ellipticity induced upon reflection of light from a film covered substrate to allow calculation of the refractive index and thickness of the film. By studying the temperature dependence of these quantities one can measure phase transitions including the crystallisation kinetics. The samples used are thin films of a polybutadiene-b-poly(ethylene oxide) diblock. The PB-b-PEO diblock has block molecular weight of 26,000 and 6,800 respectively and micro phase-separates into PEO minority spheres in a PB matrix. The study presented is very similar to what is typically performed by DSC, except that the ellipsometer also provides the expansion and contraction of the film (i.e. expansion coefficients, contraction upon crystallisation). We will discuss the results which can be obtained with this approach.

**A24 7 Growth mechanism changes in pseudo-dewetted monolayer poly(ethylene oxide) crystallization** DUN-SHEN ZHU, ER-QIANG CHEN, AN-CHANG SHI, STEPHEN CHENG, PEKING UNIVERSITY, CHINA COLLABORATION, MCMASTER UNIVERSITY, CANADA COLLABORATION, UNIVERSITY OF AKRON, USA COLLABORATION, Crystal growth mechanism changes have been observed in pseudo-dewetted monolayers of low molecular weight (LMW) (PEO) on freshly cleaved hydrophilic mica surfaces [HPEO(4250) which have -OH groups at both ends and MHPEO(4700) which has one -OH and one -$OCH_3$ as end groups]. X-ray scattering reflectivity measurements show a wetted monolayer of molten PEO with a thickness of $\sim$ 4.5 nm on the mica surface. Non-adsorbed PEO droplets sit on top of the wetted monolayer. A two-step process for PEO single crystal growth under isothermal conditions was identified utilizing in-situ atomic force microscopy at different crystallization temperatures ($T_x$). In the first step, the crystal grows within the droplet which supplies the molten PEO that participates in the crystal formation. In this second-step, the wetted monolayer at the growth front is depleted by about 1.5 - 2.5 nm. The growing crystal lateral sizes obey a power law of $t^{\alpha}$ ($t$: time). At a high $T_x$ of 63 [r]C for MHPEO(4700), the growth behavior obeys itr $\propto$ t ($\alpha = 1$). While in the case of HPEO(4250), its growth behavior follows itr $\propto$ $t^{0.5}$ ($\alpha = 0.5$) in the whole $T_x$ range. With decreasing $T_x$, the growth of MHPEO(4700) falls into a scaling law of itr $\propto$ $t^{\alpha}$ ($0.5 < \alpha < 1$).

**A24 8 Guiding the orientation of polymer crystals by nanoimprint lithography** ZHIJUN HU, JEAN-FRANÇOIS GOHY, VINCENT BAYOT, ALAIN JONAS, *Universite catholique de Louvain* CERMIN TEAM, Polymer crystallization is notoriously difficult to control at a local scale. Here, we report on a fast and easy method to guide the orientation of crystals of semicrystalline polymers at the nanometer scale by using nanoimprint lithography (1). Whenever a silicon mold bearing topographical nano-features (typical lateral size 50-250 nm; typical height 100 nm) is pressed against a molten film of a crystallizable polymer (poly(vinylidene fluoride was used here), the molten polymer is forced to flow into the cavities of the mold. The isolation of polymer in separate nano-cavities, which strongly decreases the importance of nucleation by impurities, the confinement of the polymer in nano-sized cavities, the probable partial orientation of chains near the vertical walls of the mold due to polymer flow, and interfacial effects, lead to a fine control over crystallographic orientation, crystal size and shape. This is shown for a series of geometries, from simple straight lines to more complex shapes such as concentric circles and small squares. References (1) Zhijun Hu et al., Nano Letters 2005, 5, 1738.

**A24 9 An Atomic Force Microscopy study of the thin film crystallization behavior of blends of poly-(L-lactide) and poly-(D-lactide).** YURY YURYEV, PAULA WOOD-ADAMS, *Concordia University* JOSEE BRISSON, *Universite Laval* MARIE-CLAUDE HEUZEY, CHARLES DUBOIS, *Ecole Politechnique* POLYLACTIDE RESEARCH COLLABORATION, Blends of poly-(L-lactide) and poly-(D-lactide) form a triclinic stereocomplex during racemic crystallization while the pure optical isomers crystallize in a pseudo-orthorhombic crystalline form. The triclinic stereocomplex has a high melting point of 503 K compared to 453 K for the other crystalline form. Atomic Force Microscopy (AFM)

allows one to image a polymer surface with nanoscale resolution and is best suited for the studies of crystalline morphology in thin polymer films. Individual spherulitic morphology, its growth rate and its dependence on temperature and blend composition were studied using tapping mode AFM. 500-600 nm thick polylactide films were produced by solution casting. Excess nucleation sites were eliminated by melting for a short time. It is found that spherulites protrude from the surface of the film after annealing. The crystallization rate is slower when both optical isomers are present.

**A24 10 Spectroscopic Analysis of Unusual Poly (lactic acid) Structures.** KAORU AOU, GUOLIN WU, SHUHUI KANG, SHAW LING HSU, *Polymer Sci. and Engn., Univ. of Massachusetts Amherst* Poly (lactic acid) (PLA) is a biomass-derived polymer with a broad range of applications. We previously unambiguously determined the chain conformation of PLA to be a 10/3 helix based on a combination of experimental and normal coordinate analyses, in the process assigning band splittings to the intrahelical interactions. Here, we investigate the nature of intermolecular interactions within the PLA crystals as well as their molecular orientation. In PLA, specific intermolecular interactions such as dipolar coupling strongly influence the spectral features. Crystal field splitting bands in the PLA crystal vibrational spectra were identified. They indicated the strength and proximity of interacting carbonyls and C-H groups and are thus relevant to PLA crystal packing. Results of the studies were used to understand the origins of unusual thermal stability of the PLA stereocomplex with a melting point higher than the $\alpha$-crystal by at least 50 $^{o}$C. The knowledge was also applied to characterization of orientation development in PLA tubes during different stages of sequential biaxial deformation.

**A24 11 Poly(L-lactic acid) Crystals: From 2D to 3D** SUOLONG NI, ROBERT E. MAJOR, ALAN R. ESKER, *Department of Chemistry (0212), Virginia Tech, Blacksburg, VA 24061* The crystallization behavior of poly(L-lactic acid) (PLLA) is studied in Langmuir and Langmuir-Blodgett (LB) films. PLLA Langmuir films exhibit a first-order liquid expanded to condensed (LE/LC) phase transition. Temperature dependent isotherm studies reveal an experimentally accessible critical temperature (Tc) for the LE/LC phase transition. Below Tc, the LE/LC phase transition induces the ordering of PLLA single chain helices, giving rise to two dimensional (2D) smectic liquid crystalline-like lamella in the condensed phase. The nucleation and growth of three dimensional (3D) crystals from 2D helices can be achieved through isobaric experiments. Above Tc, PLLA Lamgmuir monolayers collapse directly from the isotropic LE phase to form 3D single crystals. Annealing studies of the LB-films with 2D lamellar patterns via in-situ atomic force microscopy track the time and temperature dependence growth of 3D crystals. Our system provides a model system for studying crystallization kinetics in ultra-thin films.

**A24 12 Amylose Crystallization From Concentrated Aqueous Solution: Role of Degree of Polymerization** JOHN CREEK, JAMES RUNT, GREGORY ZIEGLER, *The Pennsylvania State University* In earlier research, we demonstrated that amylose forms a spherulitic morphology when crystallized from concentrated amylose - water solutions, over a wide degree of crystallization conditions. The process has been described as depending on a competition between crystallization and liquid-liquid phase separation processes. In the present study acid degradation and enzymatic debranching are utilized to create a number of amylose fractions differing in degree of polymerization, ranging from DPs of 20 to 920. It was determined (using DSC and x-ray diffraction) that the shorter the chain length, the higher the final degree of crystallinity. Atomic force microscopy is used to investigate the microstructure of amylose lamella within the spherulites.

**10:24**

**A24 13 Diffusion-limited growth of poly (caprolactone) in poly (tert-butyl acrylate) matrices at the air/water interface** BING-BING LI, ALAN R. ESKER, *Department of Chemistry (0212), Virginia Tech, Blacksburg, VA 24061* Surface pressure induced crystallization of poly (caprolactone) (PCL) in poly (tert-butyl acrylate) (PtBA) matrices at the air/water interface has been monitored in real time by Brewster angle microscopy (BAM). Diffusion-limited morphologies of PCL crystals grown in PCL/PtBA mixed monolayers were observed during the compression process. The lateral forces applied on the mixed monolayer during compression assist the diffusion of PCL molecules from the surrounding monolayer to the crystal growth fronts, where the amorphous PtBA components are excluded. Surface pressure-area per monomer isotherm studies suggest that the nucleation and growth of PCL occurs at about 11 mN/m. The lamellar thickness of PCL dendrites determined by atomic force microscopy is about 7-8 nm. With decreasing surface concentration during expansion of the mixed films, PCL chains slowly detach from the crystalline domains and diffuse into the monolayer. These findings provide an interesting model system for future studies of crystallization in confined geometries.

**A24 14 Crystallization and orientation studies in SWNTs based nanocomposites** TIRTHA CHATTERJEE, *University of Houston* RAMANAN KRISHNAMOORTI, *University of Houston* VIKTOR HADJIEV, *University of Houston* Single walled carbon nanotubes (SWNTs) based polymer nanocomposites are attractive for their improved mechanical, electrical and thermal properties. We have obtained well-dispersed SWNTs samples in two semi-crystalline polymers poly($\varepsilon$-caprolactone) and poly(ethylene oxide) respectively. Initial crystallization studies show tubes acts as a nucleating agent for PCL where as it hinders nucleation of PEO crystals. Both polymer composites are studied for aligned SWNTs samples. Raman spectroscopy studies show SWNTs are aligned along the draw direction. The crystallization studies of the aligned nanocomposites are performed using synchrotron small angle x-ray scattering (SAXS). Our studies reveal that for an aligned tube direction polymer crystals arrange themselves in a particular orientation. For PCL the lamellar normal is parallel to the tube axis where as for PEO it is perpendicular to the draw direction. As SWNTs act as a nucleating agent for PCL, chains grow parallel to the draw direction. For PEO, SWNTs act as barriers and polymer lamellae grow parallel to the SWNTs axis. This observation is interesting because oriented tubes can be used as a template to orient polymer crystals.

**A25 1 Organic Semiconductors and Nanodielectrics for Flexible, Low Voltage Thin-Film Transistors.**
TOBIN MARKS, *Northwestern University*

Molecular materials scientists are skilled at designing and constructing individual molecules with the goal of imbuing them with predetermined chemical and physical properties. However, the subsequent task of rationally assembling them into organized, functional supramolecular architectures with precise, nanometer-level control of bulk opt-electronic properties presents another level of challenge. In this lecture, synthetic and computational approaches to addressing such problems are described in which the ultimate goal is the fabrication of flexible electronic circuits employing unconventional materials classes and unconventional fabrication techniques. The issues here concern not only the rational design, realization, and understanding of high-mobility p- and n-type organic semiconductors, but also robust enabling nanoscopic gate dielectrics having ultra-high capacitance, low leakage, and high breakdown fields. In the former area, routes to and properties of, new high-mobility heterocyclic materials are described. These materials are then used to fabricate high-performance organic thin film transistors and CMOS circuits. In the latter topic, the design, synthesis, and characterization of new high-k nanoscopic gate dielectrics are described. It is then shown how these dielectrics can be employed to significantly enhance the performance of thin-film transistors and other devices fabricated from a wide variety of both organic as well as inorganic semiconductors.

**A25 2 Complex Organic Semiconductor Devices Utilizing Threshold Voltage Shifting and Carrier Sign Reversal** HOWARD KATZ, CHENG HUANG, JAMES WEST, *Johns Hopkins University* We consider a range of materials and mechanisms that lead to nonvolatile switching in field-effect transistors made from organic semiconductors (OFETs). Charging of gate dielectrics, secondary dielectrics, and/or the semiconductor/dielectric interface can greatly shift the threshold voltage in these OFETs. The dielectrics can consist of nonpolar electrets or ferroelectric polymers. In the particular case of $SiO_2$ electret coated with a hydrophobic surface layer, the shift is permanent on the timescale of years and is in quantitative agreement with measured surface charge. The semiconductor perfluoro copper phthalocyanine is shifted from electron- to hole-carrying by application of sufficient field from a corona apparatus. Inverter circuits were built from pairs of OFETs based on a single semiconductor, differing only in the quantity of stored gate charge.

**A25 3 Improving the electrical characteristics of a solution-processable, anthradithiophene organic semiconductor by solvent vapor annealing** KIMBERLY DICKEY, *University of Texas at Austin* JOHN ANTHONY, *University of Kentucky* YUEH LIN LOO, *University of Texas at Austin* The development of organic semiconductors is driven by the promise of low-cost device applications. To fully realize cost-effective organic electronics, solution-processable materials need to be developed. While several solution-processable materials have been demonstrated, these materials often suffer from significantly reduced carrier mobilities due to defects and grain boundaries introduced during the deposition process. We have been studying triethylsilyl anthradithiophene (TES ADT), a solution-processable, p-type organic semiconductor. Transistors fabricated with spun-cast TES ADT exhibit low carrier mobilities ($0.002 cm^2$/V-s). Subjecting the fabricated transistors to dichloroethane solvent vapor annealing, however, yields average carrier mobilities of $0.2 cm^2$/V-s. Additionally, the current hysteresis observed during device operation is eliminated with this annealing. This dramatic improvement in transistor performance is solvent choice dependent, and can be directly correlated with morphological transformations in the thin film.

**9:00**
**A25 4 Dielectric relaxation in semiconducting regioregular poly(3-hexylthiophene)*** TATIANA PSUREK, JAN OBRZUT, *Polymers Division, National Institute of Standards and Technology* Regioregular effect transistor applications. While, the electrical mobility properties of P3HT have been examined the dielectricpoly (3−hexylthiophene) (P3HT) is a material typically used as an organic semiconductor in thin film field−relaxation processes have not been systematically studied. We investigated the dielectric response of P3HT films in the temperature range of 240 K to 315 K and at frequencies up to 12 GHz. In the low frequency range P3HT shows a semi−conducting character and the overall dielectric response is dominated by dc−conductivity with $E_a$=17 kJ/mol. The apparent semi−conducting character cease at certain frequency above which, the material becomes a dielectric. At room temperature the semi−conducting to dielectric transition takes place at about 5 kHz. In the range of 10 kHz to 12 GHz the dielectric dispersion is insignificant and the dielectric constant is about 4. The dielectric relaxation process, with $\tau = 3*10^{-5}$s and $E_a$ = 24 kJ/mol, can be attributed to local molecular motion of thiophene rings.

**9:12**

**A25 5 All Electronic Time of Flight Mobility Measurements in Pentacene Organic Field Effect Transistors** LAWRENCE DUNN, *University of Texas at Austin and Institute of Materials Research and Engineering, Singapore* DEBARSHI BASU, LIANG WANG, ANANTH DODABALAPUR, *University of Texas at Austin* One of the most important figures of merit for an organic semiconductor is its mobility, which is the proportionality constant relating the velocity of charge carriers to the electric field in the material. We present an all-electronic time of flight method for measuring the in-plane mobility of charge carriers using a voltage pulse (rise time $<$ 60 ns) applied to the source of an OFET at temperatures between 300 K and 77 K. The transit time mobilities extracted at all temperatures are compared with the DC mobilities extracted from the OFET transfer characteristics. We observe significantly higher transit time mobilities at higher temperatures that merge with the DC mobilities at lower temperatures. This is noteworthy because the transit time technique measures the mobility of the fastest carriers, which at higher temperatures seems to be uninfluenced by the interaction of charge carriers with deep traps, and also before the bias stress effect influences transport. By comparing the DC and transit time mobilities at varying temperatures we may gain an understanding of the time scale of the charge carriers' interaction with traps in the semiconducting material.

**A25 6 Infrared Imaging of Charge Injection Landscape in Organic Field-Effect Transistors** ZHIQIANG LI, *UCSD* GUANGMING WANG, *UCSB* NA SAI, *UCSD* DANIEL MOSES, *UCSB* MICHAEL MARTIN, *Lawrence Berkeley National Laboratory* MASSIMILIANO DI VENTRA, *UCSD* ALAN HEEGER, *UCSB* DIMITRI BASOV, *UCSD* UCSD COLLABORATION, UCSB COLLABORATION, LAWRENCE BERKELEY NATIONAL LABORATORY COLLABORATION, We report on infrared (IR) spectro-microscopy study of charge injection phenomena in organic field-effect transistors (OFET) based on regioregular poly(3-hexylthiophene) (P3HT). An analysis of the oscillator strength of the spectroscopic signatures of charge injection allowed us to quantify the density of the injected carriers and examine its evolution with applied voltages. Using IR microscopy, the uniformity of the field- induced charge layer in OFETs with high dielectric constant insulator $TiO_2$ as well as $SiO_2$ as gate dielectrics was explored. These data uncover the critical role of the gate insulator in defining the relevant charge injection length scales. This work demonstrates the unique potential of IR spectroscopy for the investigation of the electronic excitations in nanometer-thick accumulation layers in OFET devices.

**A25 7 Oligothiphene nanostructure evolution in transition from monolayer to multilayers.** GEETHA DHOLAKIA, M. MEYYAPPAN, *NASA Ames Research Center, Moffett Field, CA 94035* ANTONIO FACCHETTI, TOBIN MARKS, *Department of Chemistry, Northwestern University, Evanston, IL 60208.* Organic electronics offers tremendous potential in applications requiring structural flexibility and large area coverage, with the added advantage of low fabrication cost. While the mobilities of organic field effect transistors (OFETs) have recently increased to the level needed for practical applications, differences in the orientation of interchain stacking, as well as defects in the film interfaces and the presence of grain boundaries act as scattering centers and charge traps, hence degrade their performance. Here we present tunneling spectroscopic results and STM studies at the nanoscale analyzing the evolution in morphology and grain connectivity of fluoroalkyl-functionalized DFH-4T (a, w-diperfluorohexyl-4T) oligothiophene films on Au(111) substrates, as the thickness is varied from one monolayer to many multilayers. Monolayer thick DFH-4T films exhibit a featureless morphology except for a number of pits similar to those in self-assembled thiol monolayers, while multilayer films have a drastically different terraced morphology consisting of overlapping platelets. This study provides important information on the nature of the interface between organic semiconductors and the source\drain electrodes in OFET devices.

**9:48**

**A25 8 Charge injection and band alignment in organic field effect transistors.** BEHRANG HAMADANI, *Department of Physics and Astronomy, Rice University* HUANJUN DING, *Department of Physics and Astronomy, University of Rochester* JACOB CISZEK, *Department of Chemistry, Rice University* YONGLI GAO, *Department of Physics and Astronomy, University of Rochester* JAMES TOUR, *Department of Chemistry, Rice University* DOUGLAS NATELSON, *Department of Physics and Astronomy, Rice University* GAO LABORATORY COLLABORATION, TOUR LABORATORY COLLABORATION, We have studied metal/organic semiconductor charge injection in poly(3-hexylthiophene) (P3HT) field effect transistors with Pt and Au electrodes as well as Au electrodes modified by self-assembled monolayers (SAMs) as a function of annealing in vacuum. At low impurity dopant densities, Au/P3HT contact resistances show nonohmic behavior, whereas Pt/P3HT contacts remain ohmic. Ultraviolet photoemission spectroscopy (UPS) reveals that metal/P3HT band alignment shifts dramatically as samples are dedoped, leading to an increased injection barrier for holes. We also present the results of a preliminary study in which we modified the Au surface with electron poor (rich) SAMs, resulting in an effective increase (reduction) of the workfunction of Au and drastically changing the nature of charge injection at the contacts. Our results indicate that understanding the band alignment at the metal/polymer interface is an important step towards understanding the nature of charge injection in these devices.

**A25 9 Structural Determination of Interfaces in Organic Semiconductors using Coherent Bragg Rod Analysis** BRANDON CHAPMAN, RONALD PINDAK, *Brookhaven National Lab* YIZHAK YACOBY, *Hebrew University* JULIE CROSS, *Argonne National Lab* EDWARD STERN, *University of Washington* CHRISTIAN KLOC, *Bell Labs* The low charge carrier mobilities long associated with organic semiconductors have increased by several orders of magnitude in recent years. Charge mobilities in field-effect transistors (FETs) using single-crystals of rubrene (5,6,11,12-tetra-phenyl-tetracene) have been reported with values in the range from 5 to 30 cm2/Vs. However, little information is known about the integrity of interfaces formed by electrical contacts in organic FETs, which can play a significant role in determining device performance. We are using a novel approach called Coherent Bragg Rod Analysis (COBRA) to determine the atomic structure of interfaces in organic FETs. COBRA uses the measured x-ray diffraction intensities along the substrate defined Bragg (crystal truncation) rods to investigate the electron density near the surface, interface and throughout the thin-film. The COBRA method is uniquely suited for probing buried interfaces formed by electrical contact materials on molecular crystals. Here,

we present preliminary measurements of Bragg rods from the free surface of rubrene single-crystals and we discuss progress toward measuring a complete set of inequivalent Bragg rods from rubrene that will provide a model-independent determination of the surface structure.

**10:12**

**A25 10 Transfer Printing of Pentacene Thin-Film Transistors onto Flexible Substrates** DANIEL HINES, *University of Maryland* VINCE BALLAROTTO, *Laboratory for Physical Sciences* ELLEN WILLIAMS, *University of Maryland* Transfer printing methods were optimized to fabricate high quality organic thin-film transistors (TFT) on flexible substrates. Flexible TFT devices fabricated from a 50 nm thick pentacene (Pn) semiconductor layer, a 600 nm thick polymer dielectric layer and Au electrodes on a polyethylene terephthalate (PET) substrate constitute a model system. A set of TFT devices with length L = 1 $\mu$m to 45 $\mu$m and width W = 100 $\mu$m were fabricated with both poly(methyl methacrylate) (PMMA) and poly(4-vinylphenol) (PVP) as the dielectric material. Output and transfer IV characteristics of these devices were measured as a function of L. The data sets were analyzed to determine both contact resistance and mobility. The Pn/PMMA/PET device set exhibited a contact resistance of 2 M$\Omega$ and a mobility of 0.237 $cm^2$/Vs while the Pn/PVP/PET device set exhibited a contact resistance of 0.5 M$\Omega$ and a mobility of 0.2 $cm^2$/Vs. A detailed comparison of these transfer printed device sets will be presented. *Work supported by the Laboratory for Physical Sciences, College Park, MD and ARDA.

**A25 13 ESR Study of Electric-Field Controlled Conductance of Fully-doped Polymers in a Transistor Structure*** FANG-CHI HSU, ARTHUR J. EPSTEIN, *Department of Physics, The Ohio State University* It was recently reported that use of doped ''metallic'' polymer as the active channel in a field effect transistor structure results in unexpected ''normally on'' transistor-like behavior. Epstein itet al. proposed [1] that ion motion is involved in the conductance modulation of the ''metallic'' polymer. We study here the role of ion migration in the ''metallic'' polymer (poly(3,4-ethylenedioxythiophene) doped with poly(styrenesulfonic acid) (PEDOT:PSS)) based transistors by employing ESR spectroscopy. We found that approximately 18% reduction of localized polaron concentration in PEDOT:PSS caused by ions insertion results in $10^3$ times decrease in the polymer conductance. The $N(E_F)$ determined from the Pauli susceptibility remains essentially unchanged after ions are inserted into the active channel. This indicates that the major conductance suppression in PEDOT:PSS occurs in the disordered regions. We proposed that the inserted ions modulate the charge carrier hopping distance in the disordered regions of the PEDOT:PSS resulting in a conductor-nonconductor transition. [1]A. J. Epstein itet al., Curr. Appl. Phys. **2**, 339 (2002).

## SESSION A26: BIOMOLECULAR COMPUTATION

**Monday Morning, 13 March 2006**
**323, Baltimore Convention Center at 8:00**
**Thomas Darden, National Institute of Health, presiding**

**8:00**

**A26 1 Quantum Mechanical Study of C-Terminal Cleavage Reaction in Inteins*** PHILIP SHEMELLA, SAROJ NAYAK, BRIAN PEREIRA, SHEKHAR GARDE, GEORGES BELFORT, *Rensselaer Polytechnic Institute - Troy, NY* PATRICK VAN ROEY, VICKY DERBYSHIRE, MARLENE BELFORT, *Wadsworth Center - Albany, NY* Although inteins undergo autocatalytic cleaving and splicing reactions via a relatively well accepted reaction scheme, the mechanism that induces these reactions is not well understood. The reactions can be prevented or speeded up through mutations of various critical amino acids proximal to the active site or through changes in the solution pH and/or temperature. We are interested in obtaining an atomic level understanding of the C-terminal cleavage reaction using quantum mechanical reaction simulation techniques. The reaction is based on the highly conserved catalytic module of histidine-asparagine-cysteine. Ex-

perimentally, intein C-terminal cleavage occurs more readily at low pH and high temperature. Working closely with experimentalists, we use a combination of gas phase and implicit solvent techniques with density functional theory to compare energy barriers for various proposed mechanisms. The mechanism with the lowest energy barrier is consistent with experimental results and is based on the protonation of the peptide amide by a hydronium ion and the subsequent cyclization of the asparagine amino acid, resulting in cleavage of the peptide bond.

*Supported by NSF CTS03-04055-NIRT

**8:12**

**A26 2 Evolutionary Strategies for Protein Folding** SRINIVASA MURTHY GOPAL, WOLFGANG WENZEL, *INT, Forschungszentrum Karlsruhe* The free energy approach for predicting the protein tertiary structure describes the native state of a protein as the global minimum of an appropriate free-energy forcefield. The low-energy region of the free-energy landscape of a protein is extremely rugged. Efficient optimization methods must therefore speed up the search for the global optimum by avoiding high energy transition states, adapt large scale moves or accept unphysical intermediates. Here we investigate an evolutionary strategies(ES) for optimizing a protein conformation in our all-atom free-energy force field([1],[2]). A set of random conformations is evolved using an ES to get a diverse population containing low energy structure. The ES is shown to balance energy improvement and yet maintain diversity in structures. The ES is implemented as a master-client model for distributed computing. Starting from random structures and by using this optimization technique, we were able to fold a 20 amino-acid helical protein and 16 amino-acid beta hairpin[3]. We compare ES to basin hopping method. [1]T. Herges and W. Wenzel,Biophys.J. **87**,3100(2004) [2] A. Verma and W. **8:24**

**A26 3 Towards predictive molecular dynamics simulations of DNA: electrostatics and solution/crystal environments** VOLODYMR BABIN, JASON BAUCOM, *North Carolina State University* THOMAS DARDEN, *National Institute of Environmental Health Sciences* CELESTE SAGUI, *North Carolina State University* We have investigated to what extend molecular dynamics (MD) simulatons can reproduce DNA sequence-specific features, given different electrostatic descriptions and different cell environments. For this purpose, we have carried out multiple unrestrained MD simulations of the duplex d(CCAACGTTGG)2. With respect to the electrostatic descriptions, two different force fields were studied: a traditional description based on atomic point charges and a polarizable force field. With respect to the cell environment, the difference between crystal and solution environments is emphasized, as well as the structural importance of divalent ions. By imposing the correct experimental unit cell environment, an initial configuration with two ideal B-DNA duplexes in the unit cell is shown to converge to the crystallographic structure. To the best of our knowledge, this provides the first example of a multiple nanosecond MD trajectory that shows and ideal structure converging to an experimental one, with a significant decay of the RMSD.

**8:36**

**A26 4 Coarse-grained model of chaperonin-mediated protein folding** GEORGE STAN, *National Institutes of Health* D. THIRUMALAI, GEORGE LORIMER, *University of Maryland* BERNARD BROOKS, *National Institutes of Health* Chaperonins are biological nanomachines that employ a spectacular mechanism for simulated annealing. During the chaperonin cycle, concerted, large scale, rigid body conformational changes, ultimately driven by ATP hydrolysis, result in a dramatically expanded chaperonin cavity serving as folding chamber. Chaperonins repeatedly bind misfolded proteins, randomly disrupt their structure, and release them in less folded states, allowing these substrate proteins multiple opportunities to find pathways leading to the native state. What is the fate of the non-native protein during the chaperonin cycle? We addressed this question using coarse-grained molecular dynamics simulations. We find that the fundamental annealing function of the GroEL chaperonin consists of forced unfolding and refolding of the substrate protein. The annealing action is related to the change in the nature of the interaction between the substrate protein and the GroEL particle from predominantly hydrophobic to largely hydrophilic. To identify the proteins most likely to be natural substrates for GroEL we use a bioinformatic approach. Our hypothesis is that natural substrates contain patterns of residues similar to the co-chaperonin GroES.

**8:48**

**A26 5 Using Molecular Dynamics simulations in the analysis of Electron Spin Resonance spectra** DENIZ SEZER, *Physics Dept., Cornell Univ.* BENOIT ROUX, *IMPS, IBD, CIS, Univ. of Chicago* ESR spectra from spin labeled sites in proteins are sensitive both to the conformations of the spin label at the labeled site and to its flexibility and rate of transition between multiple conformations. Even though measures of spin label mobility can be extracted directly from the spectrum, deducing the wealth of factors that affect the spectral line shape is impossible in most of the cases. Often, one has to model the motion of the spin label and calculate spectra for different values of the parameters of the model. From the work where this approach has been followed it appears that anisotropic Brownian diffusion in a restricting potential constitutes a good description of the spin label motion. This hydrodynamic depiction correlates poorly with the molecular structure of the spin label and its linker. To address this limitation, we combine MD simulations with stochastic models in the simulation of ESR spectra. This allows us to treat the structure and the fast dynamics of the spin label and its environment in atomistic detail, while handling the slower motional modes to which the spectrum is susceptible phenomenologically. We analyse the MD trajectories with the Redfield formalism, appropriate in the fast motional regime. The exchange between the populated rotamers of the spin label and the overall tumbling of the macromolecule, occurring on a longer time scale, are accounted for using stochastic dynamics.

**9:00**

**A26 6 Locating structural energy minimum of biological molecules in explicit solvent** ERIC DYKEMAN, OTTO SANKEY, *Arizona State University* Biological molecules in waters often adopt several structural conformers. These structures correspond to the various local energy minima on the solute-solvent potential energy hyper-surface. Methods capable of predicting the various conformations that a molecule can adopt in solution have involved, (naming a few), annealing and replica exchange molecular dynamics simulations. However, implementation of these methods

with systems containing explicit solvent still requires large amounts of computation time due to the requirement of a small time step. The recent development of the activation relaxation technique (ART) of Mousseau et al. provides an alternative that may reduce computational costs. Instead of following a Newtonian trajectory, ART locates local energy minima through a series of activations to energy saddles followed by relaxation to a local energy minimum. Here we discuss extensions of the method to explicit solvent models. This development and extension of the technique offers insight into how water affects the potential energy surface of molecules in solution.

**9:12**

**A26 7 Predicting 3D structures of transient protein-protein complexes** PETRAS KUNDROTAS, EMIL ALEXOV, *Dept. of Physics & Astronomy, Clemson University, Clemson, South Carolina* Predicting transient protein-protein complexes is a major task of the post genomic era since the ultimate goal is to understand how proteins interact in the living cell. Apparently experimental methods as X-ray and NMR cannot be used at such large scale and therefore numerical methods for predicting protein-protein complexes should be applied. In this presentation we propose homology based approach to predict 3D structure of protein complexes. The underlying presumption is that if two proteins are homologous to other two proteins that form a complex then they will form a complex, 3D structure of which should be similar to the 3D structure of the existing complex. In order to test our method we have created a database of template complexes. The methodology of database creation will be presented and discussed. Due to very limited number of protein-protein complexes in the Protein Data Bank we expanded our database by including proteins containing loosely connected domains. A jack-knife test was performed and the quality of the models was evaluated against existing protein-protein complexes. It is shown that including interfacial information and residue pairing restrains in the sequence alignment improves the results.

**9:24**

**A26 8 Charge transfers from Na atom in (H2O)n clusters and in water solution** TAKESHI NOZUE, JUNICHI HOSHINO, KAZUO TSUMURAYA, *Meiji University* The charge state of sodium ions in water is an essential issue in both biophysical and physicochemical areas. Although the nominal charge state of sodium is +1 in water solution, the true charge is less than unity and will depend on the environments. We clarify the true charges states with ab initio density functional methods. There have been several methods to evaluate the charges that belong to each atom in molecules: Bader analysis divides up into regions where the dividing surfaces are at a minimum in the density. [1] The Bader charge analysis [2] has difficulty of finding all the critical points around the atom. Henkelman et al. have proposed a modified partition scheme. [3] We use a modified version of the Henkelman's scheme to integrate the core charge densities separately. The method gives the charge transfer from Na to H2O to be 0.167e and that to (H2O)2 to be 0.522e. The original Bader charge scheme gives 0.156e and 0.596e respectively. We present the transfers surrounded by a large number of water molecules and those in water solution in periodic system. [1]R.F.W.Bader, Atoms in Molecules: A Quantum Theory, Clarendon:Oxford. 1990. [2]C.F-.Guerra, et al., J.Comp.Chem. 25, 189(2003). [3]G.Henkelman, et al., Comp. Mat. Sci. in press.

**9:36**

**A26 9 Coarse-graining protein energetics in sequence variables** FEI ZHOU, GEVORG GRIGORYAN, AMY KEATING, *Departments of Biology, MIT* GERBRAND CEDER, *Departments of Materials Science and Engineering, MIT* DANE MORGAN, *Department of Materials Science and Engineering, University of Wisconsin - Madison* We show that cluster expansions (CE), previously used to model solid-state materials with binary or ternary configurational disorder can be extended to the protein design problem. We present a generalized CE framework, in which properties such as energy can be unambiguously expanded in the amino-acid sequence space. The CE coarse grains over non-sequence degrees of freedom (e.g., side-chain conformations) and thereby simplifies the problem of designing proteins, or predicting the compatibility of a sequence with a given structure, by many orders of magnitude. The CE is physically transparent, and can be evaluated through linear regression on the energies of training sequences. [PRL 95, 148103 (2005)]. We show, as example, that good prediction accuracy is obtained with up to pairwise interactions for a coiled-coil backbone, and that triplet and/or quadruplet interactions are important in the energetics of the more globular zinc-finger and WW domain backbones. In the coiled-coil system, where experimental data is available, the calculated pair interaction parameters compare favorably with measured coupling energies. The clear advantage of a CE driven optimization over a direct one is demonstrated by searching for low-energy sequences on the zinc-finger backbone. Other possible applications of our approach are also discussed.

**9:48**

**A26 10 MAME Water Model: hydrogen bonding, electrostatic, polarization and van der Waals interactions in water.** EUGENE TSIPER, Hydrogen bonding is key to many unusual properties of water and its role in biological systems. I will describe an elegant water model derived using the minimal atomic multipole expansion (MAME). The minimal set for water consists of three multipoles that are chosen to satisfy experimental molecular dipole and both components of the molecular quadrupole. Two atomic polarizabilities, $\alpha_O = 1.4146\ \mathrm{A}^3$ and $\alpha_\mathrm{H} = 0.0836\ \mathrm{A}^3$, reproduce all three components of the polarizability tensor due to a relation between the latter, which follows from the model and is indeed satisfied experimentally. The model thus based on the known monomer properties reproduces hydrogen bonding in the dimer and compares favorably to the best available water-water interaction potentials. I will also discuss the meaning of distributed polarizabilities for computing dispersion (van der Waals) interactions. The atomic polarizabilities in water yield reasonable dispersion energy of 1.4 kcal/mol, which is otherwise underestimated when water molecules are treated as polarizable points. [E.V. Tsiper, Phys. Rev. Lett. 94, 013204, 2005]

**10:00**

**A26 11 Accurate computation and interpretation of spin-dependent properties in metalloproteins*** JORGE RODRIGUEZ, *Department of Physics, Purdue University* Nature uses the properties of open-shell transition metal ions to carry out a variety of functions associated with vital life processes. Mononuclear and binuclear iron centers, in particular, are intriguing structural motifs present in many heme and non-heme proteins. Hemerythrin and methane monooxigenase, for example, are members of the latter class whose diiron active sites display magnetic ordering. We have developed a computational protocol based on spin density functional theory (SDFT) to accurately predict

physico-chemical parameters of metal sites in proteins and bioinorganic complexes which traditionally had only been determined from experiment. We have used this new methodology to perform a comprehensive study of the electronic structure and magnetic properties of heme and non-heme iron proteins and related model compounds. We have been able to predict with a high degree of accuracy spectroscopic (Mössbauer, EPR, UV-vis, Raman) and magnetization parameters of iron proteins and, at the same time, gained unprecedented microscopic understanding of their physicochemical properties. Our results have allowed us to establish important correlations between the electronic structure, geometry, spectroscopic data, and biochemical function of heme and nonheme iron proteins.

*Supported by NSF grant CHE-0349189 (JHR)

**10:12**

**A26 12 Computational studies of a redox-driven proton pump: Cytochrome c oxidase and biological energy transduction*** ALEXEI A. STUCHEBRUKHOV, *UC Davis* Cytochrome c oxidase (CcO) is a redox-driven proton pump, an energy converting molecular machine, which reduces atmospheric oxygen to water and couples the oxygen reduction reaction to the creation of a membrane proton gradient. The proton gradient subsequently drives the synthesis of ATP. The structure of the enzyme has been solved; however, the molecular mechanism of proton pumping is still poorly understood. The correlated electron and proton transport plays a crucial role in the function of the enzyme. Our computer simulations – combined ab initio and classical, MD and MC-indicate a possible mechanism of CcO. We find that one of the His ligands of the catalytic site, and certain chains of water molecules inside of the enzyme play a crucial role. In this presentation, computational and experimental studies directed toward understandingthe mechanism of cytochrome c oxidase will be discussed. D.M. Popovic and A.A. Stuchebrukhov, Proton pumping mechanism and catalytic cycle of cytochrome c oxidase: Coulomb pump model with kinetic gating, FEBS Lett. 2004.

**10:24**

**A26 13 Ab Initio QM/MM Study of the Ester-hydrolysis Reaction Mechanism in Haloalkane Dehalogenase** YIMING ZHANG, *Departent of Physics and Astronomy, Rensselaer Polytechnic Institute* YU ZHOU, *Departent of Physics and Astronomy, Rensselaer Polytechnic Institute* SAROJ NAYAK, *Departent of Physics and Astronomy, Rensselaer Polytechnic Institute* ANGEL GARCIA, *Departent of Physics and Astronomy, Rensselaer Polytechnic Institute* CENTER FOR BIOTECHNOLOGY AND INTERDISCIPLINARY STUDIES COLLABORATION, DEPARTMENT OF PHYSICS COLLABORATION, Ab Initio QM/MM calculations are used to investigate the ester-hydrolysis step of dichloroethane hydrolysis catalyzed by haloalkane dehalogenase. Amino acids around the active site (which includes ASP124, HIS289, ASP260, TRP125, TRP175), dichoroethane and water are treated by QM at a level of HF/6-31G(d,p). The remainder of the protein and solvent are treated classically. Two scenarios of hydrolysis mechanism for the alkyl-enzyme intermediate have been considered. In one, the HIS289-catalyzed water oxygen could be incorporated in the carboxylate group of ASP124, leading the cleavage of one of the original carbonyl bonds on ASP124. In the other, the ASP124 and HIS289 as general base, activate water as the nucleophilic agent, which attacks the alkyl carbon in substrate. The reaction paths and potential energy profiles are compared for both mechanisms.

**10:36**

**A26 14 Combining biophysical and bioinformatical approaches for predicting residue's contacts.** EMIL ALEXOV, AMBER ALLARDICE, PETRAS KUNDROTAS, *Clemson University* One of the most important task of the post genomics era is to utilize the enormous sequence information delivered from the genomes and to predict 3D structure of proteins. The quality of the predicted structure depends on many factors including the improvement made in ab initio, threading and homology modeling methods. Here we combine the method of correlated mutations with biophysical restrains in order to predict residue's contacts from amino acids sequence alone. The parameters of the protocol were optimized against a set of 21 proteins with known high resolution 3D structures. The effects of the degree of residue conservation, sequence similarity among the sequences within the multiple sequence alignment and conservation coefficient of two amino acids positions were studied. It was shown that the prediction accuracy of the method of correlated mutations alone is pure, on average only 10% of the contacts are predicted correctly. However, adding biophysical filters greatly improves the accuracy of the predictions. Thus, implying pairing rules for charged, polar and hydrophobic residues significantly reduces the total number of the predictions, e.g. reduces the coverage, however, most of the rejected predictions are false positives. As result, the relative rate of the correct predictions increases.

## SESSION A28: POLYMER BLENDS
**Monday Morning, 13 March 2006**
**325, Baltimore Convention Center at 8:00**
**Kalman Migler, National Institute of Standards and Technology, presiding**

**8:00**

**A28 1 Component Terminal Dynamics in PEO / PMMA Blends** TIMOTHY LODGE, ILAN ZERONI, SAHBAN OZAIR, *University of Minnesota* FRED COLLABORATION, As our understanding of the linear viscoelasticity of linear homopolymers improves, miscible blends of linear homopolymers constitute model systems at the next level of complexity. PEO / PMMA miscible blends are remarkable in that the disparity between the component glass transitions and monomeric friction factors is immense. We are exploring this system further by obtaining component terminal dynamics for linear PEO/PMMA miscible blends of various compositions using two different methods: forced Rayleigh scattering, providing tracer diffusivity of a labeled component, and tracer rheology, examining the relaxation of a few long chains in lower molecular weight blend matrices of varying composition. Results obtained by the two methods agree well. Furthermore, results show that the mobility of PMMA is strongly affected by the presence of PEO, its monomeric friction factor dropping precipitously upon addition of small amounts of PEO. The mobil-

ity of PEO, on the other hand, is not as greatly affected by the presence of PMMA, although still much more than indicated by published measurements on PEO segmental dynamics. These results will be discussed in the context of current models.

**8:12**

**A28 2 A molecular dynamics simulation study of the segmental relaxations in model polymer blends** DMITRY BEDROV, *University of Utah* Molecular dynamics simulations of model miscible polymer blends consisting of chemically realistic 1,4-polybutadiene (CR-PBD) (slow component) and PBD chains with reduced dihedral barriers (LB-PBD) (fast component) have been performed in order to study the influence of blending on segmental relaxation processes. We find that blending with a slow (high glass transition temperature, or $T_g$) component significantly increases the separation between the $\alpha$- and $\beta$-relaxations of the fast (low $T_g$) component, which may be unresolvable or nearly unresolvable in the pure melt. Detailed analysis of the dielectric response of the blend allows us to conclude that the high-frequency loss observed in numerous dielectric spectroscopy studies of miscible polymer blends that is apparently uninfluenced by blending can be due to the intrinsic $\beta$-relaxation of the fast component and not due to concentration fluctuations and/or structural heterogeneities within the blend. In other words, instead of assuming that some fraction of the fast component is not affected upon blending due to presence of the pure melt-like local environments. We further investigate the segmental relaxations by examining torsional autocorrelation functions, dipole moment autocorrelation function, and dielectric response for each component and for the blend as a function of temperature and concentration.

**8:24**

**A28 3 Dielectric Spectroscopy of Miscible Polymer Blends** WENJUAN LIU, RALPH H. COLBY, *Materials Science and Engineering Department, Penn State University* JANE E. G. LIPSON, *Department of Chemistry, Dartmouth College* Segmental dynamics are studied in two miscible polymer blends; both involve polystyrene, which has sufficiently small polarizability to be ignored in dielectric spectroscopy. One blend is with poly (vinyl methyl ether) where the low-$T_g$ component is seen in dielectric response and the other blend is with tetra-methyl BPA- polycarbonate where the high-$T_g$ component dominates the dielectric response. Both blends have reasonably disparate glass transitions, and both are weakly interacting. The glass transition temperature ($T_g$), linear viscoelasticity and dielectric spectroscopy of the pure components and blends, respectively, are measured by differential scanning calorimetry, Rheometric Scientific ARES$^{TM}$ Rheometer and Novocontrol Broadband Dielectric Spectrometer in the frequency range of $10^{-2} \sim 10^{6}$ Hz. We compare the experimental results with a prediction for the relaxation spectrum obtained using a simple lattice model, wherein we generate a distribution of environments around a given segment in the blend which leads to a prediction for that component's dielectric relaxation spectrum. We show that it is possible to model the dielectric relaxation spectrum by considering concentration fluctuations at the scale of the Kuhn length (the shortest Rouse mode), which we take to be both composition and temperature independent.

**8:36**

**A28 4 Assessment of the Flory diluent theory to evaluate its applicability in the determination of the amorphous-amorphous interaction energy*** RUSHIKESH MATKAR, THEIN KYU, *University of Akron* In the derivation of the Flory diluent theory, Flory has removed two of three assumptions inherent in Prigogine's model to determine the solubility of solids using regular solution theory, but the third assumption that solvent is completely immiscible in the crystal. An analytical expression for the calculation of the liquidus line is a consequence of the third assumption. Various researchers have also applied this theory to determine $\chi_{FH}$ representing the amorphous-amorphous interaction energy. We contest this methodology in light of the reported discrepancies in the determination of $\chi_{FH}$ in comparison with other test methods. We have removed the third assumption and established the thermodynamics of binary crystalline mixtures by the incorporation of crystal-solvent interaction effects. We identify the source of the discrepancies in this framework and recommend that all literature regarding the present topic should be treated with circumspect.

*NSF-DMR 05-14942

**8:48**

**A28 5 Designing Balanced Surfactants for Organizing Immiscible Polymers** MEGAN RUEGG, BENEDICT REYNOLDS, NITASH BALSARA, *University of California, Berkeley* MIN LIN, DAVID LOHSE, *ExxonMobil Research and Engineering* The phase behavior of A/B/A-C polymer blends with attractive and repulsive interactions was analyzed with scattering experiments and mean field theories. Transitions between lamellar phases, microemulsions, homogeneous phases and macrophase separated states are easily accessed in A/B/A-C blends simply by adjusting the temperature. The domain spacing was predicted utilizing the Random Phase Approximation (RPA) and Self-Consistent Field Theory (SCFT) in the homogeneous and organized states, respectively, with no adjustable parameters. The only inputs into the calculations were the binary Flory-Huggins interaction parameters (chi) and statistical segment lengths. The domain spacing determined from theory was often within 5 percent of the experimental values. Furthermore, in this particular A/B/A-C system, in which the chi parameter between the immiscble A and B homopolymers is 2.0-2.6 in our accessible temperature range, a blend was found to form an organized phase with only 3 percent of the diblock copolymer in the blend. This is the lowest amount of polymeric surfactant to form an organized phase to our knowledge. The transition temperature from single-phase systems to a macrophase separated state determined from theory was in good agreement with experimental values.

**9:00**

**A28 6 The Effect of Copolymer Composition on the Dynamics of Random Copolymers in a Homopolymer Matrix.** SUDESH KAMATH, MARK DADMUN, *University of Tennessee* Copolymers can be used as interfacial modifiers in phase separated polymer blends and selective surface segregation. Important parameters in both processes include the amount of copolymer that migrates to the surface and the rate of this segregation, both of which are altered by changing the copolymer composition. The dynamics of random copolymers in a homopolymer matrix are studied using Neutron Reflectivity (NR), Quasi-Elastic Neutron Scattering (QENS) and Lattice Monte Carlo simulations. We have carried out NR and QENS measurements on blends containing 10% Poly(S-ran-MMA) random copolymers with 3 different copolymer compositions dispersed in a PMMA matrix. We have also carried out lattice Monte-Carlo simulations on blends of A-B random copolymers containing 33%, 50% and 66% A in a matrix of

a homopolymer melt containing only A monomers using the bond-fluctuation model for polymer melts. Our results indicate that the copolymer composition has a significant impact on the dynamics of the copolymer. Our simulation results also indicate that copolymer composition has a significant impact on the conformation of the copolymer in the homopolymer melt, which in turn has an impact on the system dynamics.

**9:12**

**A28 7 Dynamics of Ternary Mixtures with Photosensitive Chemical Reactions: Designing Three Dimensional Hierarchically Ordered Composites** OLGA KUKSENOK, RUI D.M. TRAVASSO, ANNA C. BALAZS, *University of Pittsburgh* Using coarse-grained computer modeling, we show that photo-induced chemical reactions can be exploited to create long-range order in binary and ternary mixtures. In the binary case, a photosensitive AB blend is illuminated by a spatially uniform light and therefore undergoes both a reversible chemical reaction and phase separation. The late-time morphology resembles the lamellar morphology of diblock copolymers, with lamellae oriented isotropically within the sample. Rastering a secondary, higher intensity light over the sample locally increases the reaction rate and introduces long-range ordering along the rastering direction (i.e., effectively ''combing'' the lamellar domains). We also illustrate an application of our combing technique as a replicative process, which transfers an image on the substrate through the sample. In the ternary case, we add a non-reactive component C, which is immiscible with both A and B. We show that C migrates to regions that are illuminated by the secondary, higher intensity light. Using a stationary secondary light source allows us to effectively write a three-dimensional pattern of C onto the AB sample. Rastering over the ternary system with an additional light source leads to hierarchically ordered patterns of A, B and C.

**9:24**

**A28 8 Shear-Induced Crystallization and Rheology Behavior of Isotactic Polypropylene and Poly (ethylene-co-octene) Blend** XIA DONG, KUN MENG, CHARLES C. HAN, *PPCL, Joint Lab. of Polymer Science and Materials, Institute of Chemistry, Chinese Academy of Sciences, Beijing 100080, China* YONGYAN PANG, DUJIN WANG, *KLEP, Joint Lab. of Polymer Science and Materials, Institute of Chemistry, Chinese Academy of Sciences, Beijing 100080, China* Shear-induced crystallization of isotactic polypropylene (iPP) and poly (ethylene-co-octene) (PEOc) blend was studied by means of in-situ optical microscopy with a shear hot stage. Shear promoted the orientation of the polymer chains in shear direction, which results in cylindrite crystals. The cylindrites were observed when the shear rate is necessarily higher than $10s^{-1}$after liquid-liquid phase separation (LLPS) at 170° for 420min. The cylindrites appear and grow across the phase regions and have some defects after decomposition. The cylindrites growth rates remain unchanged with shear at any given temperature, while the nucleation density increases dramatically after LLPS when shear rate is more than $10s^{-1}$. The Blends viscosity and modulus depending on shear frequency was increased with the PEOc contents.

**9:36**

**A28 9 Eutectic Modeling of Blend Crystallization from the Homogeneous Melt** SUDHAKAR BALIJEPALLI, *Dow Chemical Company* JEROLD SCHULTZ, *University of Delaware* The morphology and kinetics of binary polymer blends crystallizing from the homogeneous melt is similar to that of eutectic crystallization in small-molecule or metal systems. While analyses of the small molecule case exist, extension to the polymer blend case requires accounting for (a) large deviation from equilibrium and (b) growth velocity dependence on temperature and composition. Such analytical modeling has been performed, assuming low Peclet numbers. The model and results are presented here and compared with the crystallization of a blend of high and low molecular weight fractions of poly(ethylene oxide). The analysis shows a sharply peaked relationship between growth arm periodicity and velocity of growth. An assumption that the operating condition is the maximum growth velocity appears to hold. A satisfactory correlation between analysis and experiment is found.

**9:48**

**A28 10 Interplay Between Two Phase Transitions: Crystallization and Liquid-Liquid Phase Separation in a Polyolefin Blend** CHARLES C. HAN, XIAOHUA ZHANG, *PPCL, Joint Lab. of Polymer Science and Materials, Institute of Chemistry, Chinese Academy of Sciences, Beijing 100080, China* The correlation between liquid-liquid phase separation (LLPS) and crystallization at several compositions in statistical copolymer blends of poly (ethylene-co-hexene) (PEH) and poly (ethylene-co-butene) (PEB) has been examined by optical microscopy (OM), atomic force microscopy (AFM) and differential scanning calorimetry (DSC). The overwhelming change in the crystallization kinetics due to the density fluctuation caused by the spontaneous spinodal LLPS is observed. This coupling mechanism suggests a new mechanism in the nucleation-crystallization process. All evidences are pointing to a cross-over mechanism from the spinodal fluctuations (of liquid-liquid phase separation) to the nucleation and than crystallization. The detailed experimental evidences and a suggested physical model will be presented.

**10:00**

**A28 11 Rheological modeling relating mesoscopic morphology for polymer blends** YUANZE XU, *Dept. Macromol.Sci., Fudan University, Shanghai 200433, China* WEI YU, *Department of Polymer Science and Engineering, Shanghai Jiao Tong University, Shanghai 200240, P.R. China* CHARLES C. HAN, *PPCL, Joint Lab. of Polymer Science and Materials, Institute of Chemistry, Chinese Academy of Science, Beijing 100080, China* The key issue to model polyblends rheologically is to solve the problem of dynamic coupling between interfacial morphology and viscoelastic flow. This work will outline our approaches. The framework of irreversible thermodynamics was employed and the conformation of both polymer chains are introduced. By comparing with the ellipsoidal model, the constitutive equation of dilute immiscible viscoelastic blends is established. To construct the model of concentrated blends, the hydrodynamic interaction of drops was treated. The theoretical predictions were proved by measured rheological material functions and the drop dynamics in a four-roll mill rheometer. Even greater challenge exists in the formulation of multi-scale rheological model of immiscible blends with complex morphology evolution, including drop break-up and collapse. Experiments show how the interfacial processes are interfered by non-linear viscoelasticity of polymers.

**10:12**

**A28 12 Design of Co-Continuous Nanostructured Polymer Blends by Solid-State Shear Pulverization.** YING TAO, JUNGKI KIM, JOHN M. TORKELSON, *Northwestern University, Evanston, IL 60208* Achievement of co-continuous nanostructured polymer blends is of interest as such materials may have enhanced properties (e.g., toughness, stress at break, and creep

resistance) in comparison to conventional blends with a micron-scale dispersed phase in a matrix phase. Leibler and co-workers (Nature Materials 1, 54 (2002)) recently produced co-continuous nanostructured blends via reactive melt blending in which irregular graft copolymers were made in situ. Here we demonstrate that achievement of such blends is possible in the solid state by use of solid-state shear pulverization (SSSP). During SSSP, polymers are mixed by exposure to high shear and compressive forces in the absence of melt processing. The morphology of the blended SSSP output is obtained by forming a consolidated sample using a cold platen press and then analyzing by scanning electron microscopy. In the case of polystyrene (PS)/poly(methyl methacrylate) (PMMA) blends, the PMMA phase can be etched with acetic acid, revealing the presence of a 3-D, nanostructured ( $\sim$ 100 nm length-scale), irregular morphology. Studies are underway to determine whether such a blend nanostructure can be maintained during subsequent, limited melt processing into a final product via addition of block copolymers or gradient copolymers to the blend during SSSP. Studies are also underway with other blend systems.

**10:24**

**A28 13 Polymer blends containing Linear Telechelic Supramolecular Polymers** MITCHELL ANTHAMATTEN, *University of Rochester, Dept. of Chemical Engineering* MICHELLE WRUE, *University of Rochester, Dept. of Chemical Engineering* We are studying a new class of polymer blends: linear polymers blended with end-to-end associating supramolecular polymers (unimers). Since the degree of unimer association depends on concentration and temperature, we expect unusual phase behavior that differs greatly from traditional blends of two linear polymers. Low molecular weight polybutadiene unimers that bear strong hydrogen-bonding, ureidopyrimidinone end groups were synthesized. These polymers were systematically blended with monodisperse polystyrene polymers, and the resulting blends were studied using a combination of optical microscopy and light scattering techniques. Results are compared to predictions made using a simple lattice association model. Inputs include the lengths of the unimers and polymers, the free energy of forming supramolecular bonds, and a Flory-Huggins interaction parameter.

**10:36**

**A28 14 Rheology of blends of dense star-like polystyrene soft nanospheres** AJAY KULKARNI, R.M. KANNAN, *Wayne State University* Highly branched polymeric materials exhibit significantly different rheological behavior compared to linear polymers, suggesting that controlled branch density can have technological benefits. We have synthesized a dense star polystyrene molecule, ($PS_{nano}$) with 50 arms, $M_a$= 5,000 g/mol. Using rheo-optics and triple-detection GPC, we have shown that these materials act as soft nanospheres, with a size of $\sim$ 8 nm. We are studying the effect of the nanospheres on the blending behavior of miscible polystyrene/ poly (vinyl methyl ether) (PS/PVME) blends with the help of dynamic stress-optical measurements. In $PS_{nano}$/PVME blends, at higher $PS_{nano}$wt. fractions, the interparticle distance between $PS_{nano}$ is smaller than radius of gyration of PVME. Therefore we expect to see the conformational changes in PVME chains induced by $PS_{nano}$ and compare it with linear PS (L−PS)/ PVME blends. However the rheo−optics data suggests that the relaxation dynamics of PVME is not significantly altered by $PS_{nano}$ whereas for L−PS/PVME blends the relaxation dynamics of PVME is slowed down by L−PS. DSC results show a single transition suggesting miscibility. Our results suggest that, the segments of PS near the periphery of $PS_{nano}$ may be miscible, but the segments at the core would be immiscible, resulting in a molecularly dispersed blend, rather than a segmentaly miscible L−PS/ PVME blend.

**10:48**

**A28 15 Reactive extrusion: A computational approach.** MANORANJAN PRUSTY, PATRICK ANDERSON, HAN GOOSSENS, HAN MEIJER, *Technical Univeristy Eindhoven* Reactive extrusion is attractive for various reasons. One of them is the flexibility of extruders for processing of polymers, but also the choice of the scale of the operation that can be adjusted to the needs for research and development or commercial production. We model reactive extrusion using a diffuse interface modeling (DIM) approach. The problem is studied by dividing it into four small/sub problems. First, the structure growth in case of homopolymer blends was studied with the effect of hydrodynamics. The logarithmic structure factor was found to scale as 1/3 with time for higher capillary numbers and 2/3 for lower capillary numbers. Second, the growth of structure for the block copolymer was studied for the symmetric blocks, for which only micro phase separation was observed. Then, the structure growth for the mixture of block copolymers and homo-polymers was studied and both micro and macro phase separation can be observed. The final step including the reaction kinetics of the formation of block copolymers from the homo-polymer is studied. Results are mainly presented showing morphology development and growth rates as a function of time.

## SESSION A29: EXPERIMENTAL TECHNIQUES IN BIOPHYSICS

**Monday Morning, 13 March 2006**
**326, Baltimore Convention Center at 8:00**
**J. P. Landry, University of California, Davis, presiding**

**8:00**

**A29 1 The healing mechanism for excited molecules near metallic surfaces** B. BARBIELLINI, *Northeastern U.* P.M. PLATZMAN, *Bell Labs* Radiation damage prevents the ability to obtain images from individual molecules. We suggest that this problem can be avoided for organic molecules by placing them in close proximity with a metallic surface. The molecules will then quickly dissipate any electronic excitation via their coupling to the metal surface. They may therefore be observed for a number of elastic scattering events that is sufficient to determine their structure.[1] B. Barbiellni and P. M. Platzman, cond-mat/0506403

**8:12**

**A29 2 Pulse-shaping and Fourier Transform Techniques in Multiphoton Microscopy** JENNIFER OGILVIE,*DELPHINE DÉBARRE, EMMANUEL BEAUREPAIRE, ANTIGONI ALEXANDROU, MANUEL JOFFRE, *Laboratoire d'Optique et Biosciences, Ecole Polytechnique* Multiphoton microscopy is an important tool that is increasingly used in biological research. The ease with which broadband femtosecond pulses can be created and manipulated has opened up new directions for enhancing multiphoton microscopy. In particular, pulse-shaping techniques can

tailor broadband light to selectively excite fluorescent species.[1] Here we demonstrate the use of pulse-shaped excitation to enhance multiphoton fluorescence imaging of live drosophila embryos. Other promising multiphoton techniques include coherent anti-Stokes Raman scattering (CARS) microscopy, which offers endogenous contrast based on the inherent vibrations of different chemical species.[2] Most implementations of CARS microscopy image single vibrational modes, providing limited ability to simultaneously follow multiple chemical species. An alternate time-domain Fourier transform-based method can produce spectrally resolved CARS images over the considerable bandwidth of a broadband laser source, This approach provides straightforward removal of the nonresonant background from CARS images while offering a compact, single-laser approach. [1] V. V. Lozovoy et al. J. Chem. Phys, (2003) 118, 3187. [2] A. Zumbusch et al. Phys. Rev. Lett. (1999) 82 4142.

**A29 3 Templated biomineralization on self assembled protein fibers** S. PALMACCIO, *Sachem High School NY* K. SUBBURAMAN, N. PERNODET, *Stony Brook Univ Stony Brook NY* S.-Y. KWAK, E. DIMASI, *BNL, Upton, NY* S. GE, *Stony Brook Univ Stony Brook NY* N.L. YANG, *CUNY, Staten Island, NY* M. RAFAILOVICH, *Stony Brook Univ Stony Brook NY* We have previously shown that fibrillogenesis of extracellular matrix (ECM) proteins like Fibronectin and Elastin can be induced when adsorbed on charged polymer surfaces. These self assembled fiber networks reach sizes of dimensions similar to natural ECM. Here we present a study of biomineralization on these protein fibers, achieved using $CaCO_3$ through Kitano & Flow cell methods. The mechanical properties were measured usingShear Modulation Force Microscopy (SMFM) as part of early stage mineralization studies. Results indicated increase in modulus with exposure time on fibers, with no increase off the fibers. Control studies with other Ca salts showed no change in fiber modulus, differentiating mineralization from salt adsorption. Late Stage Mineralization studied using ToF SIMS showed preferential Ca adsorption on the fibers. Optical Microscopy also showed preferential crystal formation on fibers. TEM was used to identity the crystal structure and orientation. Effect of proteins on crystal orientation and mineralization of natural ECM from osteoblasts are under study. Supported by USDOE Contract No. DE−AC02−98CH10886, NSF−MRSEC & BNL−SBU Seed Grant.

**8:36**

**A29 4 Advances in energy filtered electron tomography for quantitative 3-D phosphorus imaging of cell nuclei** MARIA A. ARONOVA, GUOFENG ZHANG, RICHARD D. LEAPMAN, *NIH* Electron tomography (ET) is an established and valuable tool for determining three-dimensional subcellular structure at a macromolecular scale. Contrast in conventional tomograms is generated through high-angle elastic scattering of the incident electrons by heavy atoms in stained plastic sections or through phase differences of elastic scattering in frozen hydrated specimens. Energy filtered transmission electron microscopy (EFTEM) has undergone recent developments to provide an improved capability for quantitative mapping of elemental distributions. We have developed a new approach where specific chemical elements in biological systems can be imaged in three dimensions. This method of collecting electron tomograms with inelastically scattered electrons combines ET and EFTEM. We have applied this technique to analyze unstained sections of rapidly frozen, freeze-substituted and embedded cells. Using intrinsic phosphorus as a label for nucleic acid, we have investigated the distribution of DNA in nuclei of itDrosophila larvae. We show that quantitative analysis of the three-dimensional phosphorus distribution has the potential to provide new information about the DNA packing density of chromatin.

**8:48**

**A29 5 Adaptive wave-front correction for multi-photon microscopy using coherence-gated wave-front sensing** MARKUS RUECKEL, WINFRIED DENK, *Max-Planck Institute for Medical Research, Germany* The contrast and the resolution of a multiphoton microscope highly depend on the shape of the focus which can be distorted by refractive index inhomogeneities within the specimen. Coherence-gated wave-front sensing (CGWS) allows reliable adaptive wave-front correction of these distortions (M. Feierabend, M. Ruckel, and W. Denk, Optics Letters, 2004, 29(19)). We developed a model for CGWS for which we evaluated in detail, using Monte-Carlo simulations, how the measured wave-fronts depend on the density of scatterers, the position and length of the coherence gate, and on the polarization of the light used. Predictions from this model were confirmed experimentally. Further we report on early results from an exploration of how much the two-photon excitation efficiency improves when applying corrections as predicted by CGWS. Experiments and numerical simulations show for a wave-front with a RMS distortion of $\lambda/5$ that the excitation efficiency was about 60% of that for a diffraction-limited focus. This was done for both astigmatism and coma.

**9:00**

**A29 6 Label-free optical detection of protein binding on small-molecule ligand microarrays*** Y. S. SUN, J. P. LANDRY, X. D. ZHU, *Dept. of Physics, Univ. of California at Davis* T. BAO, K. S. LAM, *Dept. of Internal Medicine, Univ. of California at Davis Medical Center* Biomolecular microarrays are becoming indispensable tools in proteomic research and biomarker discovery processes. The need for label-free microarray detection methods that are complementary to fluorescence-based methods is also increasing. We have developed oblique-incidence reflectivity difference (OI-RD) microscopes for detecting protein-protein and protein-small molecule reactions in microarray format through changes in density, thickness, and conformation of surface-bound proteins on solid supports. This can be done without extrinsic labeling molecules (e.g. organic fluorophores or quantum dots), which are costly and potentially intrusive. Of particular interest to one of our current investigations are microarrays of small molecules that may be used for high-throughput screening for protein ligands. With OI-RD microscopes, we have detected antibody-antigen capture and streptavidin-biotin binding reactions in microarray format using mixtures of proteins as well as pure proteins in prescribed sequences. In the streptavidin-biotin binding reaction, we used BSA molecules as the scaffold to anchor biotin molecules on the solid support. We will report these recent experimental results and the analysis.

**A29 7 Dynamic Dimensional Analysis of itIn-Vivo Microorganisms Using Polarized Light Scattering** WILLEM VAN DE MERWE, *Indiana Wesleyan University* JOZSEF CZEGE, *USUHS* We have successfully determined average lengths and diameters of randomly-oriented rod-shaped bacteria in-vivo by evaluating the Mueller matrix ratio $< S_{34} > / < S_{11} >$ together with Coulter counter measurements of cell volumes (references 1 and 2.) We showed that our technique allows one to follow real-time dimensional changes taking place at a rate of about 14 nm/min. We expect to extend this method to synchronized cultures and will attempt to measure changes in the ratio for partially aligned bacterial cells. We will give a rationale for our expectation that this will provide additional information for example about growth characteristics of the bacteria. We used the coupled dipole model to compare theoretical predictions and experimental observations. Specifically, by refining our dimensional analysis we expect soon to be able to study the dynamic of bacterial cell division real-time as well as obtain additional identifying signatures of importance to medicine, biotechnology and detection. 1) Applied Optics 43 (2004) 5295-5302 2) Biophysical J. 69 (1995) 1170-1177

**A29 8 Fast Cooling and Vitrification of Aqueous Solutions for Cryopreservation*** MATT WARKENTIN, *Laboratory of Applied and Solid State Physics, Physics Department, Cornell University* NAJI HUSSEINI, VIATCHESLAV BEREJNOV, *Laboratory of Applied and Solid State Physics, Physics Department, Cornell University* ROBERT THORNE, *Laboratory of Applied and Solid State Physics, Physics Department, Cornell University* In many applications, a small volume of aqueous solution must be cooled at a rate sufficient to produce amorphous solid water. Two prominent examples include flash-freezing of protein crystals for X-ray data collection and freezing of cells (i.e. spermatozoa) for cryopreservation. The cooling rate required to vitrify pure water ( $\sim 10^6$ K/s) is unattainable for volumes that might contain cells or protein crystals, but the required rate can be reduced by adding cryoprotectants. We report the first measurements of the critical concentration required to produce a vitrified sample as a function of the sample's volume, the cryogen into which the sample is plunged, and the temperature of the cryogen, for a wide range of cryoprotectants. These experiments have broad practical consequences for cryopreservation, and provide insight into the physics of glass formation in aqueous systems.

**A29 9 Active and Passive Microscopic Viscoelastic Response in Poly(Ethylene) Oxide Solutions** OLGA LATINOVIC, H. DANIEL OU-YANG, It has been proposed that one can determine the viscoelastic response function from the thermal fluctuations of colloidal tracer particles. Despite attempts to validate the approach, there has not been a direct comparison between the viscoelastic response obtained by thermally driven particles, and independent microscopic measurements which do not depend on thermal fluctuations. This paper reports a study that compares the two approaches. In the passive measurements, the Brownian motion of a probe particle was used to obtain the viscoelastic modulus of poly (ethylene) oxide solutions using the fluctuation-dissipation theorem and the generalized Stokes-Einstein relation. In the active measurements, the same probe particle is set into forced oscillations by oscillating optical tweezers and the viscoelastic moduli of the solution are obtained from the in-phase and out-of-phase components of the particle's motion.

**A29 10 Specifically Detect Vascular Endothelia Growth Factor (VEGF) with Micro Cantilever Resonator*** JIANHUA GU, DEBIN LI, DAVID LEDERMAN, *Dept of Physics, West Virginia University* JAROD KABULSKI, PETER GANNETT, *Basic Pharmaceutical Sciences, West Virginia University* DANIEL FLYNN, *Mary Babb Randolph Cancer Center, West Virginia University* VEGF is an important protein marker for lung cancer. Current state of the art detection strategies use enzyme linked immunosorbent assays (ELISA), where only nanogram levels can be detected in serum. We have developed a sensing method to rapidly detect VEGF based on the micro cantilever resonator technique, which has advantages over the standard ELISA method. We have covalently linked a polyclonal anti-VEGF antibody to a silicon cantilever surface. The shift of cantilever resonant frequency due to specific VEGF binding with this antibody allows us to detect the presence of VEGF in solution at detection levels of approximately one picogram or even smaller. Efforts were made to reduce non-specific adsorption on cantilever either by covering non-specific sites on the cantilever with proteins (such as bovine serum albumin (BSA)), or by self-assembly of a protein resistant monolayer on the cantilever surface. We also used different protein samples (like VEGF-C or MMP-9) to confirm the specific detection of VEGF.

**A29 11 Serial Crystallography: imaging single proteins at a synchrotron*** DAVID SHAPIRO, *Center for Biophotonics Science and Tech.* JOHN SPENCE, R. BRUCE DOAK, DMITRI STARODUB, UWE WEIERSTAL, *Arizona State University* HENRY CHAPMAN, STEFANO MARCHESINI, *Lawrence Livermore Nat. Lab.* MALCOLM HOWELLS, *Lawrence Berkeley Nat. Lab.* A new method is proposed for the imaging of uncrystallized proteins at third generation x-ray sources. The method, serial crystallography, uses the diffraction pattern produced by a beam of hydrated proteins as they sequentially traverse a continuous x-ray beam after having been aligned by an intense laser field. Each particle is exposed to the x-ray beam so briefly that radiation damage is not a concern. The diffraction pattern is integrated as many identically aligned particles cross the beam and then the laser polarization is rotated to allow collection of other particle orientations. The diffraction pattern can then be phased by an iterative algorithm and the protein structure recovered with a Fourier transform. We are currently constructing a serial crystallography apparatus to be installed on beamline 9.0.1 of the Advanced Light Source at Lawrence Berkeley National Lab that will be operational by May, 2006. Preliminary experiments will use a 5 Watt CW IR laser to align particles of Tobacco Mosaic Virus and their soft x-ray diffraction patterns will be collected. We present the design of the serial crystallography apparatus and the current status of this project.

**10:12**
**A29 12 Structural investigations of human hairs by spectrally resolved ellipsometry** BENJAMIN SCHULZ, D. CHAN, M. RUEBHAUSEN, *Institute of Applied Physics, Jungiusstrasse 11, D-20355 Hamburg, Germany* S. WESSEL, R. WEPF, *Beierdorf AG, Hamburg, Germany* Human hair is a biological layered system composed of two major layers, the cortex and the cuticle. We show spectrally resolved ellipsometry measurements of the ellipsometric parameters $\Psi$ and $\Delta$ of single human hairs. The spectra reflect the layered nature of hair and the optical anisotropy of the hairs structure. In addition, measurements on strands of human hair show a high reproducibility of the ellipsometric parameters for different hair fiber bundles from the same person. Based on the measurements, we develop a model of the dielectric function of hair that explains the spectra. This model includes the dielectric properties of the cuticle and cortex as well as their associated layer thicknesses. In addition, surface roughness effects modelled by a roughness layer with an complex refractive index given by an effective medium approach can have a significant effect on the measurements. We derive values for the parameters of the cuticle surface roughness layer of the thickness $d_{ACu} = 273 - 360$nm and the air inclusion $f_A = 0.6 - 5.7\%$. [1] accepted for publication in J. Biomed Opt., 2005

**10:24**
**A29 13 Evanescent Wave Excitation and Raman Spectroscopy of Bacteriorhodopsin on Gallium Nitride Waveguide Structures** ALFONS SCHULTE, SONYA ORTIZ, ALFRED KELLER, APRIL POPE, YU GUO, HEIDI HOCKEL, ERIC JOHNSON, *University of Central Florida* Composite structures of protein-semiconductor layers have potential for molecular electronics and sensor applications. We investigate gallium nitride waveguide structures created by UV lithographic techniques as substrates for photoactive bacteriorhodopsin films. The waveguides were characterized through electron and optical interference microscopy. The top biomolecular layer is optically accessible through the evanescent field of a mode propagating in the gallium nitride waveguide. A 488 nm or 514 nm beam from an Argon ion laser was coupled into the waveguide and the evanescent field was employed to initiate the photocycle and excite Raman scattering in the bacteriorhodopsin film. Under stationary conditions the Raman spectrum in the fingerprint region shows the presence of the light-adapted state and the M intermediate. This suggests that the protein is in its native state and that optical switching of bacteriorhodopsin can be achieved and probed by evanescent wave excitation.

**10:36**
**A29 14 Probing Protein Structural Dynamics Using Microfluidic Diffusional Mixer Based FT-MIR Micro-Spectroscopy** PETER GALAJDA, ROBERT AUSTIN, *Princeton University* JARMILA GURJARRO, JESUS VEGA, CYRUS ARIAN, AIHUA XIE, *Oklahoma State University* AUSTIN TEAM, XIE TEAM, Time-resolved Fourier transform Infrared (FTIR) spectroscopy is a powerful technique to ''see'' proteins in action. Such a technique has been mostly applied to study photoreceptor proteins since their biological functions can be conveniently triggered in synchronization using short laser pulses. However, only a few proteins in nature are photo-active. In order to study a broad range of chemically activated proteins, we have developed a microfluidic diffusional mixing device, based on computational modeling of microfluidic flow and advection diffusion, microlithographic fabrication, and time-resolved FTIR micro-spectroscopy. This technique can be applied to probe functionally important structural dynamics of proteins that are chemically activated, thus opening up a broader application of time-resolved FTIR spectroscopic techniques. We will report such applications including experimental studies on GTPase system in biological signal transduction.

**10:48**
**A29 15 Modeling Electric Fields of Peripheral Nerve Block Needles.*** JAMES CH. DAVIS, NORMAN E. ANDERSON, MARK W. MEISEL, *Dept. of Physics, Univ. of Florida* JASON G. RAMIREZ, F. KAYSER ENNEKING, *Dept. Anesthesiology, Univ. of Florida* Peripheral nerve blocks present an alternative to general anesthesia in certain surgical procedures and a means of acute pain relief through continuous blockades. They have been shown to decrease the incidence of postoperative nausea and vomiting, reduce oral narcotic side effects, and improve sleep quality. Injecting needles, which carry small stimulating currents, are often used to aid in locating the target nerve bundle. With this technique, muscle responses indicate needle proximity to the corresponding nerve bundle. Failure rates in first injection attempts prompted our study of electric field distributions. Finite difference methods were used to solve for the electric fields generated by two widely used needles. Geometric differences in the needles effect variations in their electric field and current distributions. Further investigations may suggest needle modifications that result in a reduction of initial probing failures.

**A30 1 A Renormalized Theory of Composition Fluctuations in Polymer Mixtures.**
DAVID MORSE, *University of Minnesota*

Attempts to calculate corrections to Flory-Huggins theory using field theoretic methods have been plagued by an unwanted sensititivity to very short wavelength fluctuations, or to the value of an arbitrary cutoff length. This reflects the fact that the total free energy of a polymer mixture is dominated by effects of local fluid structure. Z.-G. Wang [1] has shown how the cutoff-dependence of a one-loop approximation for the free energy of a binary blend can be absorbed into

an expression for the experimentally observed $\chi$ parameter, yielding a cutoff-independent renormalized theory of the contributions of mesoscopic fluctuations. We apply an analogous renormalization procedure to one-loop calculations of intramolecular and collective correlation functions at arbitrary wavenumbers in both homopolymer blends and copolymer melts, in which the dependence on local fluid structure is absorbed into the values of $\chi$ and of statistical segment lengths. We discuss predictions for homopolymer blends and diblock copolymer melts, and relationships to earlier work. [1] Z.-G. Wang, J. Chem. Phys. 117, 481 (2002).

**A30 2 An efficient pseudo-spectral algorithm for the RPA response of ordered phases of block copolymer melts** AMIT RANJAN, DAVID MORSE, *Department of Chemical Engineering and Materials Science, University of Minnesota* We present a pseudo-spectral algorithm for calculating the linear response of monomer concentration field in ordered phases of block copolymer melts to small perturbations of the monomer chemical potential fields. The method is both considerably simpler and more efficient than the fully spectral perturbation theory presented by Laradji, Shi and coworkers.[1] The method will be used to re-examine the stability of the gyroid phase in diblock copolymer melts. [1] Laradji *et al.*, *Macromolecules*, **30**, 3242 (1997).

**8:48**

**A30 3 Random isotropic structures and possible glass transitions in diblock copolymer melts** CHENGZHONG ZHANG, ZHEN-GANG WANG, *Chemical Engineering, Caltech* We study the microstructural glass transition in diblock-copolymer melts using a thermodynamic replica approach. Our approach performs an expansion in terms of the natural smallness parameter – the inverse of the scaled degree of polymerization $\bar{N}$, which allows us to systematically study the approach to mean-field behavior as the degree of polymerization increases. We find that in the limit of infinite chain length, both the onset of glassiness and the vitrification transition (Kauzmann temperature) collapse to the mean-field spinodal, suggesting that the spinodal can be regarded as the mean-field signature for glass transitions in this class of microphase-separating system. We also study the order-disorder transitions (ODT) within the same theoretical framework; in particular, we include the leading-order fluctuation corrections due to the cubic interaction in the coarse-grained Hamiltonian, which has been ignored in previous studies on the ODT in block copolymers. We find that the cubic term stabilizes both the ordered (body-centered-cubic) phase and the glassy state relative to the disordered phase. In melts of symmetric copolymers the glass transition always occurs after the order-disorder transition (below the ODT temperature), but for asymmetric copolymers, it is possible for the glass transition to precede the ordering transition.

**9:00**

**A30 4 Dynamics of PEO-PMMA diblock copolymers.** JAVIER SACRISTAN, CHUNXIA CHEN, JANNA MARANAS, *Department of Chemical Engineering, The Pennsylvania State University, University Park, Pennsylvania 16802* The structure and dynamics of a poly(ethylene oxide)–poly(methyl methacrylate) diblock copolymer (PEO-PMMA) are studied by molecular dynamics simulation using a united atom model, with emphasis on the junction point effect. These results are compared to those from a homopolymer blend. The intermolecular pair distribution function reveals that the internal packing of unlike segments is enhanced in the copolymer with respect to the blend. Thus the effective concentration of both PEO and PMMA decay towards the bulk faster as a function of local volume size in the copolymer than in the blend. The mean square displacement (MSD) illustrates differing mobilities of PEO and PMMA in both systems. In the copolymer, their mobilities are separated by less than in the blend. The junction point accelerates motion of PMMA up to a distance of 5A. In contrast, on both systems PEO mobility reach the average value close to the junction point. In spite of the different PMMA effective concentration on both systems copolymer and blend its dynamics are not affected by changes in local packing. In contrast PEO dynamics are strongly influenced by the differences on its effective concentration.

**9:12**

**A30 5 Kinetics of Transition between HEX and Lamellar Phases in a triblock copolymer solution in a selective solvent.** YONGSHENG LIU, RAMA BANSIL, *Boston University* MILOS STEINHART, *Institute of Macromoleculear Chemistry, Academy of Sciences of the Czech Republic* Synchrotron based time-resolved small angle x-ray scattering (SAXS), was used to study the kinetics of ordering transition (OOT) between cylindrical micelles in HEX phase and lamellar (LAM) phase in a 0.4 (w/v) solution of a triblock of polystyrene (PS) and poly(ethylene-itco-butylene) (PEB), SEBS (PS-PEB-PS) copolymer in Dibutyl Phthalate (DBP), a selective solvent for the PS block. From a temperature ramp experiment the OOT was identified at about 137C and an ODT above 160 C. Several temperature jump experiments from HEX to LAM and the reverse were performed over the temperature range of 110-155C. Detailed analysis of the time evolution of the intensities of the Bragg peaks to follow the kinetics of the transition between HEX and LAM phases will be presented. A model to explain the transition mechanism will be discussed. This research was supported by NSF-DMR.

**9:24**

**A30 6 Kinetics of HEX-BCC Transition of Cylinders to Spheres: Comparison of Time-resolved SAXS data with a Model of Coupled Anisotropic Fluctuations*** RAMA BANSIL, MINGHAI LI, *Boston University* MILOS STEINHART, *Institute of Macromolecular Chemistry, Czech Academy of Sciences* The kinetics of the transition of HEX cylinders to BCC spheres was studied by coupling anisotropic fluctuations on cylinders, similar to the pearling instability, according to which the amplitude of a transverse wave along the length of the cylinder grows causing the cylinder to break up into spheroidal droplets. We find that the sphere BCC phase arises with phase shifts of 0, **it4$\pi$/3** and **it8$\pi$/3** for the sinusoidal waves on 3 neighboring cylinders on the HEX lattice, which correspond to the minimum of overlap volume of rippled cylinders and wavelength it$\lambda$ related to the nearest neighbor distance of the rippled cylinders by $d = 2\sqrt{2}\lambda/3$. The azimuthally averaged scattering function from an un-oriented system of cylinders, as well as the 2-dimensional scattering from an oriented system was calculated with varying amplitude of the fluc-

tuation. The results are in excellent agreement with time-resolved SAXS measurements of the kinetics of this transition in a Styrene (S)-ethylene-co-butylene (EB)-Styrene (S)) triblock copolymer in mineral oil, a selective solvent for the EB block.

**9:36**

**A30 7 Modeling of twist grain boundaries in block copolymers: structure, stability, and motion** XUSHENG ZHANG, ZHI-FENG HUANG, JORGE VINALS, *McGill University* Twist grain boundaries, which are widely observed in block copolymer samples of lamellar phase, have been investigated through both direct numerical solution and multiscale analysis of a coarse-grained mesoscopic model equation. We show that the twist boundary profile can be well described by two sets of appropriate amplitude equations characterizing the slow evolution of lamellae. Stability of the grain boundary configuration has been examined, and our results show that the boundary width, albeit varying with twist angle, is of order $\epsilon^{-1/4}$, with $\epsilon$ the measure of the distance from the order-disorder threshold. We also study the motion of twist grain boundaries subjected to slow transversal modulations of lamellae, and obtain both analytically and numerically the traveling velocity of the boundary as well as its dependence on modulation wave number.

**9:48**

**A30 8 Removal of non-equilibrium microdomain defects in block copolymer thin film simulations** AUGUST BOSSE, *University of California, Santa Barbara* SCOTT SIDES, *Tech-X Corporation* KIRILL KATSOV, CARLOS GARCIA-CERVERA, GLENN FREDRICKSON, *University of California, Santa Barbara* In recent years, there has been increased interest in using microphase-separated block copolymer thin films as sub-optical lithographic masks in next generation semiconductor and magnetic media fabrication. However, if such techniques are to evolve into a useful and commercially feasible lithographic tool, one must have control over, or at least an understanding of the in-plane ordering of the block copolymer microdomains. In the context of self-consistent field theory (SCFT), we introduce new simulation techniques intended to efficiently remove non-equilibrium microdomain defects in 2D block copolymer simulations, and thus allow further study of equilibrium defect populations associated with 2D systems (cf., KTHNY theory) and/or defects induced by confinement. The first technique, which we call *spectral amplitude filtering*, is used in parallel with a saddle point relaxation algorithm. Spectral amplitude filtering zeros out all Fourier components with amplitude below some fraction of the maximum amplitude. This encourages symmetries associated with the dominant Fourier modes to rapidly set in. The other technique is a variation on a force-biased, Fourier-accelerated Monte Carlo algorithm, which is shown to be efficient in controlled removal of non-equilibrium microdomain defects.

**A30 9 Mixed Lamellae in Symmetric Diblock Copolymer Thin Films** DONG MENG, QIANG WANG, *Colorado State University* For symmetric diblock copolymers confined between two flat and homogeneous surfaces, three morphologies (parallel, perpendicular, and mixed lamellae) have been obtained in experiments. While the effects of surface preference (for one of the two blocks) and film thickness on the thin-film morphology are well understood, less studied is the influence of a hard (impenetrable) surface on the copolymer chain conformations, referred to as the ''hard-surface effect.'' It is this effect that favors the perpendicular lamellae between two neutral surfaces over parallel lamellae, at all film thicknesses. It also leads to the formation of mixed lamellae between asymmetric surfaces. Here we use the self-consistent field (SCF) theory in continuum to study the morphology of mixed lamellae. The SCF equations are solved in real space with high accuracy. Results under different boundary conditions (zero-density vs. non-flux) are compared to examine their effects on the copolymer chain conformations near the surface. We also study in detail the chain conformations at the T-junction in the mixed lamellae. Conditions under which the mixed lamellae are a stable phase (over parallel and perpendicular lamellae) are determined, and compared with experiments and Monte Carlo simulations.

**A30 10 Correlated defect dynamics in block copolymer melts*** ROBERT MAGERLE, *Technische Universitaet Chemnitz* LARISA TSARKOVA, ARMIN KNOLL, *Universitaet Bayreuth* With in-situ scanning force microscopy we image the ordering of cylindrical microdomains in a thin film of a diblock copolymer melt. Tracking the evolution of individual defects reveals their annihilation pathways via interfacial undulations and formation of transient phases, such as spheres and lamella. Repetitive transitions between distinct defect configurations suggest a cooperative movement of chain clusters. The microdomain dynamics is correlated on a length scale of several domain spacings. Characteristic times of structural relaxations range from $\sim$ 1 to $\sim$ 100 min.

**10:24**

**A30 11 Dislocation Density and Orientational Order of Spherical Microdomains in Shear-Aligned Block Copolymer Thin Films** ANDREW MARENCIC, MINGSHAW WU, RICHARD REGISTER, *Princeton University* PAUL CHAIKIN, *New York University* Studies of annealed monolayers of cylindrical diblock copolymers (striped patterns) showed that the disclination density dictated the orientational correlation length. Here we test the role of dislocations in the orientational order of shear aligned hexagonal patterns. Shearing block copolymer thin films using a viscous fluid overlayer creates long-range orientational order of the microdomains, extending over a centimeter or more, by eliminating grain boundaries. However, some isolated dislocations remain that perturb the both translational and local orientational order of the hexagonal lattice formed by the spherical microdomains in these thin films. Atomic force microscopy was used to image the lattice, and image analysis software was written to determine dislocation density and alignment quality using an orientational order parameter. In such shear- aligned films, a linear relationship between the density of isolated dislocations and the orientational order parameter was found.

**A31 1 Gold Nanorod/Single-Wall Carbon Nanotube Heterojunctions Formed Directly on Surfaces** ROMANEH JALILIAN, *University of Louisville, Department of Physics* ANETA MIESZAWSKA, FRANCIS ZAMBORINI., *University of Louisville, Department of Chemistry* GAMINI SUMANASEKERA, *University of Louisville, Department of Physics* In this presentation we describe work on the formation of heterojunctions between single-wall carbon nanotubes (SWNTs) and one-dimensional (1D) gold nanorods (AuNRs) assembled directly on surfaces. The chemical procedure is a simple benchtop method using commercially available reagents. Au NRs are grown directly and selectively on surface-attached SWCNTs by depositing hexanethiolate-terminated Au monolayer protected clusters (MPCs) on the SWCNTs and growing Au MPCs into NRs by seed-mediated growth, involving reduction of $AuCL_4^-$ onto Au MPCs in the presence of cetyltrimethylammonium bromide (CTAB). UV-vis, AFM, and SEM show highly selective growth of Au on SWCNTs only. Different combinations of junctions are possible, including AuNRs connecting two CNTs or two AuNRs attached to one CNT. We also show that Au nanostructures enhance Raman scattering of SWNTs. Several NRs and CNTs integrated into a connected assembly were studied. Electrical measurements with contacts on the AuNRs of these heterostructures will be presented. Finally carbon-supported metal structures with unique size and shape may be useful in electrocatalysis or electrochemical sensing applications.

**8:12**

**A31 2 Formation of Silver Nanostructures (nanowires, nanoshells, and nanorods) on MgZnO hexagonal and Cubic Alloys** SHIVA HULLAVARAD, TA KUN CHEN, R. VISPUTE, T. VENKATESAN, *University of Maryland* With potential applications in many fields from fundamental science to engineering technology, multi-dimensional (MD) metal nanostructures such as nanowires, nanoshells, and nanotubes have been very popular topics of research. They have been used to experimentally probe the effects of quantum confinement on electronic, magnetic, and other related properties, and they could be used as active components or interconnects in fabricating electronic, photonic, and sensing devices. Silver nanowires are particularly interesting to explore because bulk silver exhibits the highest electrical and thermal conductivities among all metals. Other modern applications of silver nanowires have also been discovered in many fields including catalysis, electronics, photonics, and photography. In this study, we present the formation of silver nanowires, shells and rods by the thermal reduction of an aqueous silver nitrate solution on the surface of Magnesium Zinc Oxide ($Mg_xZn_{1-x}O$) multiphase alloy thin films. In this context, the formation of silver nanostructures on MgZnO alloy films is technologically important as it would lead in to the potential area of nano metallic contacts to emerging oxide electronic materials.

**8:24**

**A31 3 Oxygen clamps in gold nanowires.** ANTÔNIO J. R. DA SILVA, FREDERICO D. NOVAES, EDWIN HOBI JR., A. FAZZIO, *Instituto de Física, Universidade de São Paulo* EDISON Z. DA SILVA, *Instituto de Física ''Gleb Wataghin,'' UNICAMP* We investigate how the insertion of an oxygen atom in an atomically thin gold nanowire can affect its rupture. We find, using itab initio total energy density functional theory calculations, that O atoms when inserted in gold nanowires form not only stable but also very strong bonds, in such a way that they can extract atoms from a stable tip, serving in this way as a clamp that could be used to pull a string of gold atoms (see Novaes et al., Phys. Rev. Lett. 2006). In all calculations we have used a GGA-PBE approximation and norm-conserving pseudopotentials. All calculations were performed using the SIESTA code, and we employ a DZP basis function. We observe that the presence of O atoms increases the stability of a local configuration composed of the O atom and its two nearest neighbors at each side (an Au-Au-O-Au-Au structure). This indicates that in an oxygen reach atmosphere it may be possible to pull a longer string of gold atoms (an effect as predicted here has been observed by W. H. A. Thijssen et al., cond-mat/0509376). Finally, local vibrational modes will be investigated.

**A31 4 Phase transitions in escape processes of metal nanowires*** JÉRÔME BÜRKI, *University of Arizona* CHARLES STAFFORD, *University of Arizona* DANIEL STEIN, *New York University* Thermally induced conductance jumps of metal nanowires are modeled using stochastic Ginzburg-Landau field theories. The activation rate displays nontrivial dependence on nanowire length, and undergoes first- or second-order-like transitions, with a critical length proportional to the wire radius. Several experimental manifestations of the predicted phase transition are identified, including the temperature- and radius-dependence of peak heights in conductance histograms, and the length dependence of I-V characteristics of gold nanowires.

*This work was supported by NSF Grant Nos. 0312028 and 0351964.

**8:48**

**A31 5 Stability of metal nanowires with multipolar cross sections** CHARLES STAFFORD, *University of Arizona* HAKAN TÜRECI, *Yale University* JÉRÔME BÜRKI, *University of Arizona* DANIEL URBAN, *Albert-Ludwigs University, Freiburg, Germany* HERMANN GRABERT, *Albert-Ludwigs University, Freiburg, Germany* DOUGLAS STONE, *Yale University* A linear stability analysis of metal nanowires with arbitrary cross sections is performed within the nanoscale free-electron model, focusing on quadrupolar, hexapolar, and octopolar deformations. Families of stable wires with similar cross sections and various dimensions are found, which are stabilized semiclassically in the vicinity of bifurcations of important classical periodic electron orbits. For large deformations, quadrupolar cross sections are found to be most favorable. The predicted highly-deformed stable structures are compared to experimental data for Aluminum nanowires.

**9:00**

**A31 6 Mechanical testing of slanted and isolated copper nanorods using Atomic Force Microscope*** C. GAIRE, D.-X. YE, T.-M. LU, G.-C. WANG, *Dept. of Physics, Rensselaer Polytechnic Inst, Troy, NY 12180* C. R. PICU, *Dept. of Mechanical, Aerospace and Nuclear Engg, Rensselaer Polytechnic Inst, Troy, NY,*

*12180* Recently, the study of mechanical properties of sub-micron and nano-scale specimen has drawn a renewed attention. With the atomic force microscope (AFM) it is possible to probe the mechanics of these structures. Here we report one such test to find the force constant, Young's modulus and yield stress of a new type of nanostructures - polycrystalline Cu slanted nanorods of approximately rectangular cross section, fixed at one end to the substrate. These were grown by oblique angle physical vapor deposition. An AFM was used to image, locate the rod and apply force to get deflection at its free end as a function of applied force. Samples with different dimensions and rise angles were tested in bending using this technique. The method employed by our group for fabrication as well as the mechanical testing will be discussed and a comparison of the mechanical properties of the bulk and nanoscale specimen will be made based on our results. *Supported by NSF grant No. CMS-0324490.

**A31 7 Electron Transport through curved and rolled Two Dimensional Electron Gas** NAKUL SHAJI, *Univeristy of Wisconsin-Madison* HUA QIN, LEVENTE KLIEN, MARK ERIKSSON, ROBERT BLICK, CHRISTOPHER DENEKE, *Max-Plank-Institut für Festkörperforschung* OLIVER SCHMIDT, We report on topology dependent electron transport in tubular shaped two-dimensional electron gases. These micron-sized tubes are realized in a strained InGaAs quantum well. This is the first step towards investigating geometric potentials in low dimensional quantum systems. We investigate magneto-resistance of the tubular systems in a perpendicularly applied magnetic field. At low magnetic field, an increased zero field magneto resistance followed by a negative magneto resistance is observed. We ascribe this effect to an increase in electron scattering along the curved regions due to newly formed dangling bonds. At high magnetic fields we observe a linear increase in resistance of the curved region as compared to planar regions.

**9:24**

**A31 8 Intensity-Intensity correlations of waves propagating in disordered quasi-one-dimensional geometries** GABRIEL CWILICH, *Department of Physics, Yeshiva University* LUIS S. FROUFE-PEREZ, JUAN JOSE SAENZ, *Departamento de Fisica de la Materia Condensada, Universidad Autonoma de Madrid* Spatial intensity correlations between waves transmitted through random media are analyzed within the framework of the random matrix theory of transport. Assuming that the statistical distribution of transfer matrices is isotropic, we found that the spatial correlation function of the normalized intensity can be expressed as the sum of three terms, with distinctive spatial dependences. This result coincides with the one obtained in the diffusive regime from perturbative calculations, (Patrick Sebbah et al in Phys. Rev. Lett. 88, 123901,(2002)) but holds all the way from quasi-ballistic transport to localization. Only the specific value of the prefactors depends on the transport regime. Their values obtained from the Monte Carlo solution of the Dorokhov, Mello, Pereyra, and Kumar (DMPK) scaling equation are in full agreement with microscopic numerical calculations of bulk disordered wires. The experimental and numerical results are recovered in the large-N (number of propagating channels)limit in Random Matrix theory. While correlations are positive in the diffusive regime, we predict a transition to negative correlations as the length of the system decreases.

**9:36**

**A31 9 Manipulation of nanowires in suspension by ac electric fields** D.L. FAN, F.Q. ZHU, R.C. CAMMARATA, C.L. CHIEN, *Johns Hopkins University* While highly desirable for nanoscale devices, manipulation of nanoentities in suspension has been a formidable problem because of the extremely low Reynolds number at the level of $10^{-5}$. In this work, we show that nanowires a few m in length can be efficiently manipulated by ac electric fields applied to strategically designed microelectrodes. The nanowires, both magnetic and non-magnetic, can be driven to align, to chain, to accelerate in directions parallel or perpendicular to the nanowires orientation. The nanowires can also be patterned into desired structures with high efficiency. This versatile method of manipulation has also been applied to other small elongated entities such as carbon nanotubes.

**9:48**

**A31 10 On the Formation of Monatomic Metal Wires** A. HASMY,* *NIST Center for Theoretical and Computational Nanosciences, Gaithersburg,MD* R. HERNANDEZ, *Escuela de Quimica, UCV, Caracas, Venezuela* L.C. RINCON, *Dpto. de Quimica, ULA, Merida, Venezuela* V. MUJICA, *Escuela de Quimica, UCV, Caracas, Venezuela* R.J. MAGYAR, C. GONZALEZ, *NIST Center for Theoretical and Computational Nanosciences, Gaithersburg,MD* The formation of monatomic metal wires under stress has been observed with HRTEM. It has been revealed that gold chains can be obtained if the stress is applied on the (111) and (100) orientations, while not on the (110) orientation. Other experiments have evidenced that some metals are unable to exhibit this monatomic wire formation. Theoretical efforts addressed to determine what are the geometrical and chemical conditions for such monatomic chain formations is still lacking in the literature. We have implemented Tight-Binding Molecular Dynamics simulations for the formation of metallic wires under stress, making special attention to the dynamics at the end of the contact breakage. Different geometrical orientations and chemical elements were considered. In order to determine the evolution of the electronic structure the simulations were complemented with ab initio calculations of the atomic configurations. The study allows us to give some insights about the required conditions for the formation of such monatomic metal wires.

**A31 11 Quantum confinement between self-organized Pt nanowires on Ge(001)** NURI ONCEL, ARIE VAN HOUSELT, JEROEN HUIJBEN, WOUTER J. VAN BEEK, ANN SOFIE HALLBÄCK, HAROLD J.W. ZANDVLIET, BENE POELSEMA, *University of Twente, MESA + Institute for Nanotechnology, Solid State Physics Group* Annealing of Pt covered Ge(001) surface leads to formation of one atom thick, hundreds of nanometers long, literally defect free chains of Pt atoms, hereafter named as Pt nanowires. By using scanning tunneling spectroscopy (STS) we have discovered one dimensional (1D) electronic states, confined between these Pt nanowires. The nanowires are separated by either 1.6 or 2.4 nm. The Pt atoms create a potential barrier for the surface state electrons on modified Ge-terraces located just below the Fermi level. The peak positions obtained from I-V spectroscopy experiments are in good agreement with the eigenvalues of a quantum mechanical particle in box problem. The spatial mapping of the differential conductivity of the 1D states reveals that the states are confined in the troughs between the nanowires.

As an additional proof, we performed careful analysis of the regions, where either the nanowires or the underlying substrate have defects. This analysis clearly shows that the confined states around the defect sites fade away, i.e. the electron states ''leak'' out of the trough via the defects.

**10:12**

**A31 12 Hall of Mirrors Scattering from Impurities in Quantum Waveguides** J. Y. VAISHNAV, *Harvard University Department of Physics* A. ITSARA, *Harvard College* E. J. HELLER, *Harvard University Department of Physics and Harvard University Department of Chemistry and Chemical Biology* We develop a scattering theory to examine how a point impurity affects transport through multimode quantum wires. While some of our new results apply specifically to hard-walled wires, others are more general; for example, an effective optical theorem which we derive for two- dimensional waveguides. Using the method of images, we examine the hard-walled guide, explicitly showing the effect of each reflection from the impurity on the wire's conductance. We express the effective cross section of a confined s-wave scatterer entirely in terms of the empty waveguide's Green's function, suggesting a way in which to use semiclassical methods to understand transport properties of smooth wires. In addition to predicting some new phenomena, our approach provides a simple physical picture for previously observed effects such as conductance dips and confinement-induced resonances. We discuss generalizations of this work to include higher partial waves, as well as the case of two interacting particles confined in other geometries, such as nanotubes and tori.

**10:24**

**A31 13 A fine-scale nanostructure in $\gamma$-alumina*** GIANLUCA PAGLIA, EMIL BOZIN, SIMON BILLINGE, *Department of Physics and Astronomy, Michigan State University, Biomedical Physical Sciences, East Lansing, MI, 48824-2320* Despite the preeminent industrial importance of $\gamma$-alumina in catalysis, details of the structure remain unresolved due to its 15-30$\sim$ nm domain nanocrystalline nature. Diffraction patterns are broad and single crystals are not available making accurate structural solution difficult using conventional crystallographic methods. We have applied a local structural technique, the atomic pair distribution function (PDF) analysis of powder diffraction, to obtain a quantitative structure. This is a total scattering technique that incorporates both Bragg and diffuse scattering information in the PDF, allowing all diffracted intensities from the XRD pattern to be equally considered. Surprisingly, we find a previously unknown fine-scale nanostructure with a domain size $\sim$ 1 nm. Within these nanodomains the oxygen sublattice is modified from the average structure and retains aspects of the boehmite precursor. This results in a novel and unexpected view of the $\gamma$-alumina structure since earlier controversies about it centered on the arrangement of Al ions among different cation sites, whereas the oxygen sublattice arrangement was not usually questioned.

*The work at MSU was funded under National Science Foundation (NSF) grant no. CHE-0211029. X-ray data were collected at beamline 6IDD of the Advanced Photon Source at Argonne National Laboratry.

**A31 14 Conversion of CDW $TaS_3$ to superconducting $TaS_2$ nanowires** YEW SAN HOR, TAO WU, JOHN F. MITCHELL, *Materials Science Division, Argonne National Laboratory, Argonne, Illinois 60439* PETER L. LEE, *Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 60439* The synthesis of nanowires has attracted considerable interest for their potential applications in many areas of advanced nanotechnologies. Recently we have developed a simple method to fabricate nanowires of a transition metal dichalcogenide through a nondestructive reduction from one-dimensional (1D) trichalcogenide nanostructures.[1] In this report, we present results on synthesis and characterization of $TaS_2$ nanowires. Our approach includes the synthesis of 1D charge-density-wave (CDW) $TaS_3$ nanostructure precursors followed by the nondestructive and controlled adjustment of the S composition. The nanowires, as identified with scanning electron microscopy, have a rectanglelike cross section with widths of 20 to 700 nm and lengths of up to a few millimeters. $TaS_3$ nanowires show the canonical CDW behaviors. However, the converted $TaS_2$ nanowires show superconducting behavior with Tc $\sim$ 4 K, which is different from the bulk property. [1] Appl. Phys. Lett. 87, 142506 (2005).

**A32 1 The measuring the conductance of carbon fullerene and onion.** MAKOTO YOSHIDA, YOSHIHIKO KURUI, YOSHIFUMI OSHIMA, KUNIO TAKAYANAGI, *Tokyo Institute of Technology Department of Physics* TOKYO INSTITUTE OF TECHNOLOGY DEPARTMENT OF PHYSICS TEAM, In this study, we simultaneously observed the conductance and the structure of carbon nano-materials (C60 and carbon onion) using transmission electron microscopy(TEM). This TEM is combined with scanning tunneling microscope (STM) system. C60 and carbon onion was fabricated and sandwiched between two gold electrodes of STM. As a results, the C60 and carbon onion show a metallic conductance (the same order magnitude of $2e^2/h$) at the low bias. These values are near to results of previous theoretical reports. Further more, we obtained the conductance variation which is strongly affected by the connection between the C60 and metal electrodes.

**8:12**

**A32 2 On the zero-bias anomaly in K-doped $C_{60}$ on Ag(100)** NOAH BRAY-ALI, AMY KHOO, *Department of Physics, UC Berkeley* JEFFREY NEATON, STEVEN LOUIE, *Department of Physics, UC Berkeley and the Molecular Foundry, Lawrence Berkeley National Laboratory* RYAN YAMACHIKA, ANDRE WACHOWIAK, MICHAEL CROMMIE, JOEL MOORE, *Department of Physics, UC Berkeley and the Materials Science Division, Lawrence Berkeley National Laboratory* The fullerene molecule $C_{60}$ is known to undergo a strong Jahn-Teller distortion when electrons are added. Recent STM/STS experiments indicate that a single $C_{60}$ molecule on a Ag(100) surface can be control-

lably doped with charge-donating potassium atoms; [1] moreover, the experiments suggest that the molecular electronic structure can be tuned so that a single electronic orbital lies near the Fermi level. Starting from a Hamiltonian with parameters inferred from companion density functional theory (DFT) calculations of $K_xC_{60}$ on Ag(100), we use Wilson's numerical renormalization group to compute the spectrum near the Fermi level of a doped $C_{60}$ molecule coupled to a metallic continuum. The result compares favorably with spectroscopic measurements of the zero-bias anomaly and, together with the DFT calculations, explains the electronic structure of this system over a range of dopings. [1] R. Yamachika, M. Grobis, A. Wachowiak, and M.F. Crommie, *Science* **304**, 281-284 (2004).

**8:24**

**A32 3 Ab initio modeling of STM elastic and inelastic tunneling spectra of tetramantane on Au(111) surface.** EMMANOUIL KIOUPAKIS,*R. YAMACHIKA, Y. WANG, X.H. LU, *Department of Physics, University of California at Berkeley* M.F. CROMMIE, STEVEN G. LOUIE, *Department of Physics, University of California at Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory* The recent discovery of the higher diamondoids in crude oil has stimulated interest in their study and several potential technological applications of these molecules have already been proposed. In studying the electronic properties of molecular or nanoscale structures on surfaces, the scanning tunneling microscope is usually the probe of choice. Currently, scanning tunneling microscopy experiments of isolated tetramantane molecules on a (111) gold surface are being carried out. We have performed ab initio pseudopotential density functional theory calculations of the electronic properties of tetramantane and provide a comparison of the elastic and inelastic tunneling spectra between our simulation and the ongoing experiment. This work was supported by the NSF Grant Nos. DMR04-39768 and EEC-0425914 and U.S. DOE Contract No. DE-AC03-76SF00098.

**8:36**

**A32 4 Anomalous electric conductivity in C60-Ag co-deposited films at low temperature** GENKI YOSHIKAWA, *IMR, Tohoku University; The University of Tokyo* YUKI TSURUMA, SUSUMU IKEDA, KOICHIRO SAIKI, *The University of Tokyo* The C60-Ag interface has attracted interest recently. In addition to charge transfer from Ag to C60 or metallization of C60, temperature dependent gap was observed at the Fermi level of the C60 monolayer on Ag, suggesting the possibility of interfacial superconductivity. In order to clarify the effect of this interfacial electronic state on the transport properties, we measured the electric conductivity of the C60-Ag complex films. To increase the interface area, Ag and C60 were co-deposited on the insulating substrate, such as mica, maintained at 23 K, suppressing the aggregation of Ag atoms. The electric conductivity of the C60-Ag co-deposited films was measured in-situ in a temperature range of 23-300 K. Two peaks were observed in the conductivity curve around 50 K and 85 K. They disappeared once the film was annealed up to room temperature. This phenomenon was observed when the Ag/C60 ratio is approximately 1 to 6 while we studied in the range of 0.5-20. We confirmed that these peaks were not caused by the influence of Joule heating or residual gases. The observed anomalous electric conductivity strongly suggests the formation of peculiar structure and electronic states in the films at low temperature.

**8:48**

**A32 5 Novel orientational ordering in a K-doped $C_{60}$ monolayer** RYAN YAMACHIKA, YAYU WANG, ANDRE WACHOWIAK, MICHAEL GROBIS, DUNG-HAI LEE, AMY KHOO, STEVEN LOUIE, MICHAEL CROMMIE, *Department of Physics, University of California, Berkeley, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA* Orientational ordering, which originates from broken rotational symmetry, is a central feature of a broad range of materials including liquid crystals, quantum magnets, and some biological systems. By doping $C_{60}$ monolayers with alkali impurities, the symmetry of $C_{60}$ molecules can be broken, opening up the possibility for unique two-dimensional molecular orientational ordering. Here we present a scanning tunneling microscopy/spectroscopy study of $K_xC_{60}$ monolayers on Au(111), $x \geqslant 4$. We find novel orientational orderings in the $C_{60}$ monolayers at different doping levels, which coincide with strong variations in the monolayer local density of states. This demonstrates the importance of the interplay between Coulomb repulsion, electron-phonon coupling, electronic quadrupolar interactions, and direct orbital overlap in determining the behavior of fullerene nanostructures.

**A32 7 Novel Silicon-Carbon Nanostructures: A DFT Study on the Stability of $Si_{60}C_{2n}$ (n= 3, 10, 12) Clusters.*** A. SRINIVASAN, *University of Texas at Arlington* M.N. HUDA, *University of Texas at Austin* A.K. RAY, *University of Texas at Arlington* In this work, we extend our previous work on $Si_{60}C_{2n}$ (n=1, 2) clusters by the addition of six, twenty and twenty-four carbon atoms on the surfaces of the $Si_{60}$ cages by substitution and inside the cage at various symmetry orientations [1]. The theoretical formalism used is the generalized gradient approximation to density functional theory and full geometry and spin optimizations have been performed using the Gaussian 03 software. For the silicon atom, the Hay-Wadt pseudo-potential with the associated basis set is used for the core and the valence electrons, respectively. For the carbon atom, the Dunning/Huzinaga double zeta basis set is employed. Different electronic properties of these nanostructures will be discussed in detail. The binding energy per atom for these nanostructures increases with the number of carbon atoms, with

the structures having carbon atoms on the surface being more stable. The stability of the nanostructures depends on the orientation of the carbon atoms, as well as on the natures of Si-C and C-C bondings. [1] A. Srinivasan, M. N. Huda and A. K. Ray, Phys. Rev. A, in press; A. Srinivasan and A. K. Ray, J. Nanosci. and Nanotech., in press.

**A32 8 What is the Goundstate Structure of Intermediate-sized Carbon Clusters?** M. YU, I. CHAUDHURI, C.S. JAYANTHI, S.Y. WU, *Univ. of Louisville* Recent study on the equilibrium structures of quantum dots of tetravalent semiconductors such as Si clusters revealed that the ground state structures of these clusters with diameters d$<$ 5 nm are icosahedrons comprising of tetrahedral building blocks rather than corresponding bulk-truncated clusters[1]. Among tetravalent semiconductors, carbon is the only element whose atoms could form sp, or $sp^2$ or $sp^3$ bonding configurations, leading to compact, fullerene, and bucky-diamond clusters[2]. It is then natural to raise the question as to what is the ground-state structure for the carbon cluster $C_n$ for a given $n \geqslant 20$? We have recently initiated a preliminary study on the relative stability of carbon clusters $C_n$ with $n$up to 700, using a molecular dynamics scheme based on a self-consistent and environment-dependent Hamiltonian developed at the U. of Louisville in the framework of the linear combination of atomic orbitals[3]. Our preliminary result indicates that in the range of $n$ studied, the carbon fullerene clusters are still the most stable clusters, in contrast to the icosahedral cluster being the ground state structure for a series of discrete $n$ values for the other tetravalent clusters. We will also discuss the other electronic properties of intermediate-sized carbon clusters. This work was supported by the U.S. DOE (DE-FG02-00ER4582). [1] Y. Zhao, itet al**it.,** Phys. Rev. Lett. **93**, 015502 (2004). [2] J. Y. Raty, itet al.**it,** Phys. Rev. Lett. **90**, 037401 (2003). [3] S.Y. Wu, itet. al., itHandbook of Materials Modeling Vo.**l,** p.2935 (2005).

**A32 9 Electronic structure and electron-phonon coupling in carbon diamondoids studied by scanning tunneling microscopy** YAYU WANG, X.H. LU, R. YAMACHIKA, A. WACHOWIAK, E.S. KIOUPAKIS, S.G. LOUIE, M.F. CROMMIE, *Department of Physics, University of California at Berkeley, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA* J.E. DAHL, S.G. LIU, R.M.K. CARLSON, *MolecularDiamond Technologies, ChevronTexaco Technology Ventures, CA* Diamondoids are hydrocarbon molecules with diamond-like cage structures. Their structural complexity and chemical bond tunability make them ideal building blocks for creating novel nanostructures. We have used cryogenic scanning tunneling spectroscopy to examine the electronic structure of individual diamondoid molecules on the Au(111) surface. We observed variations in the filled and empty state local density of states for individual 121-tetramer diamondoid molecule. Despite a large HOMO-LUMO gap ($\Delta >$ 5eV) around the Fermi energy, there exists a strong interaction between the tunneling electrons and the diamondoid C-H stretch mode, as revealed by inelastic tunneling spectroscopy (IETS). We further show that the strength of the electron-phonon coupling has a distinct spatial distribution with the dominant inelastic channel localized to a specific region of the diamondoid molecule.

**A32 10 NMR Probes of the Molecular Orientational Dynamics of the Endohedral Fullerene $Sc_3N@C_{80}$.** JOE MARTINDALE, KRZYSZTOF GORNY, CHARLES PENNINGTON, *Department of Physics, The Ohio State University* PAGE PHILLIPS, STEVEN STEVENSON, *Department of Chemistry and Biochemistry, University of Southern Mississippi* We report NMR lineshapes and spin-lattice relaxation times for both $^{13}C$ and $^{45}Sc$ in the endohedral fullerene $Sc_3N@C_{80}$. The data show rapid reorientation of the molecule with an activated temperature dependence for the motion over the observed temperature range (50 – 350 K). The ratchet to rotator transition found in $C_{60}$ is not observed in $Sc_3N@C_{80}$. The measurements strongly suggest the motion of the encapsulated $Sc_3N$ derives from the reorientational dynamics of the $C_{80}$ cage, however without the $Sc_3N$ being fixed to the cage in the motional narrowing regime.

**A32 11 Towards Implementation of a Solid State Quantum Computer Based on Endohedral Fullerenes** D.V. PELEKHOV, *The Ohio State University* P. BANERJEE, *The Ohio State University* I.H. LEE, *The Ohio State University* K.C. FONG, *The Ohio State University* YU. OBUKHOV, *The Ohio State University* J. MARTINDALE, *The Ohio State University* P. C. HAMMEL, *The Ohio State University* J.P. PHILLIPS, *University of Southern Mississippi* S. STEVENSON, *University of Southern Mississippi* We report on progress investigating the feasibility of fabricating a Solid State Quantum Computer based on endohedral fullerenes (fullerenes containing species with unpaired electron spins). The results of experiments on endohedral fullerene systems using Magnetic Resonance Force Microscopy, conventional Electron Spin Resonance and Scanning Tunneling Microscopy will be presented.

**10:12**

**A32 12 Quasi Small-World Nanomaterials: Quantum Studies*** M.A. NOVOTNY, JEREMY YANCEY, STEVEN GWALTNEY, SERKAN CALISKAN, *Mississippi State U.* We present results for two studies of quasi-small-world nanomaterials [1,2]. These are materials that would have the connectivity governed by small-world (SW) networks. Hence these materials should have both their critical behavior and transport properties governed by mean-field fixed points, not finite-dimensional fixed points. One study utilizes density-functional-theory to obtain reasonable carbon-based molecules that should have the SW property. In particular, several candidates for quasi- SW nanomaterials (or molecules) based solely on carbon will be presented. Trends in the energy per atom of various types of SW nanomaterials and numbers of carbon atoms will be presented. The transmission coefficient and conductivity for related quantum models of SW nanomaterials connected to metal leads will also be presented. [1] M.A. Novotny, et al, J. Appl. Phys, vol. 97, p.10E510 (2005). [2] M.A. Novotny and S.W. Wheeler, Brazilian J. Phys., vol. 34, p. 395 (2004).

**A32 13 Dynamics of Bulk vs. Nanoscale $WS_2$: Local Strain and Charging Effects*** J. L. MUSFELDT, S. BROWN, R. D. LUTTRELL, J. CAO, *University of Tennessee, Knoxville* R. ROSENTSVEIG, R. TENNE, *Weizmann Institute of Science, Israel* We measured the infrared vibrational properties of bulk and nanoparticle $WS_2$ in order to investigate the structure- property relations in these novel materials. In addition to the symmetry-

breaking effects of local strain, nanoparticle curvature modifies the local charging environment of the bulk material. Performing a charge analysis on the *xy*-polarized $E_{1u}$ vibrational mode, we find an approximate 1.5:1 intralayer charge difference between the layered 2H material and inorganic fullerene-like (IF) nanoparticles. This effective charge difference may impact the solid-state lubrication properties of nanoscale metal dichalcogenides.

**A32 14 Collective excitations in concentric metallic nanoshells** SHYAMALENDU BOSE, EDWARD ZALE, *Drexel University* Invention of nanoshells made of a silica core coated with an ultrathin metallic layer [1] has opened a floodgate of many applications in medical and other fields. Most of these applications are triggered by the fact that the nanoshells have unusual electronic and optical properties which can be controlled by controlling the inner and outer radii of the nanoshell. Employing a classical hydrodynamic model, we have obtained a general expression for the resonant frequencies (plasmons) of the electrons for N concentric nanoshells. Results obtained using this theory will be compared with previous calculations for two concentric nanoshells [2] and possible applications of the new results will be discussed. 1. S.J. Oldenburg, et al., Chem. Phys. Letts. **288**, 243 (1998). 2. E. Prodan, et al., Science **302**, 419 (2003).

**A32 15 A $^{13}$C NMR Spectroscopic Investigation of Carbon Nanohorns** HIDETO IMAI, PANAKKATTU BABU, ERIC OLDFIELD, ANDRZEJ WIECKOWSKI, DAISUKE KASUYA, TAKESHI AZAMI, YUICHI SHIMAKAWA, MASAKO YUDASAKA, YOSHIMI KUBO, SUMIO IIJIMA, UNIVERSITY OF ILLINOIS AT URBANA-CHAMPAIGN TEAM, FUNDAMENTAL AND ENVIRONMENTAL RESEARCH LABORATORIES, NEC CORPORATION, JAPAN TEAM, SORST, JAPAN SCIENCE AND TECHNOLOGY AGENCY, C/O NEC TEAM, MEIJO UNIVERSITY, NAGOYA, JAPAN TEAM, $^{13}$C NMR spectroscopic investigation of carbon nanohorn aggregates (CNH) shows that they consist of two components, characterized by different chemical shifts and spin-lattice relaxation ($T_1$) behavior. The first component with a chemical shift of 124 ppm and faster $T_1$ is assigned to the nanotube-like horns on the particles' surface. The second component with a chemical shift of 116 ppm and much slower $T_1$ is assigned to the graphite-like part of the CNH. Integrated peak area measurements indicate a 1:2 ratio of nanohorns to the graphite-like substrate. The lack of a Knight shift and the absence of a clear Korringa relaxation for either component of $T_1$ ruled out any metallic behavior and indicate a relaxation behavior characteristic of semiconducting materials with paramagnetic centers arising from structural defects. We also observed an anomalous change in $T_1$ in the nanohorn domains near 17 K, suggesting the development of an antiferromagnetic correlation between localized electron spins.

**A33 1 Statistical Mechanics of Money, Income, and Wealth.**
VICTOR YAKOVENKO, *Department of Physics, University of Maryland*

In Ref. [1], we proposed an analogy between the exponential Boltzmann-Gibbs distribution of energy in physics and the equilibrium probability distribution of money in a closed economic system. Analogously to energy, money is locally conserved in interactions between economic agents, so the thermal Boltzmann-Gibbs distribution function is expected for money. Since then, many researchers followed and expanded this idea [2]. Much work was done on the analysis of empirical data, mostly on income, for which a lot of tax and census data is available. We demonstrated [3] that income distribution in the USA has a well-defined two-class structure. The majority of population (97-99%) belongs to the lower class characterized by the exponential Boltzmann-Gibbs (''thermal'') distribution. The upper class (1-3% of population) has a Pareto power-law (''superthermal'') distribution, whose parameters change in time with the rise and fall of stock market. We proposed a concept of equilibrium inequality in a society, based on the principle of maximal entropy, and quantitatively demonstrated that it applies to the majority of population. Income distribution in other countries shows similar patterns. For more references, see http://www2.physics.umd.edu/~ yakovenk/econophysics.html. References: [1] A. A. Dragulescu and V. M. **A33 2 A study of personal income distributions in Australia and Italy** ANAND BANERJEE, VICTOR YAKOVENKO, *Department of Physics, University of Maryland* The study of income distribution has a long history. A century ago, the Italian physicist and economist Pareto proposed that income distribution obeys a universal power law, valid for all time and countries. Subsequent studies proved that only the top 1-3% of the population follow a power law. For USA, the rest 97-99% of the population follow the exponential distribution [1]. We present the results of a similar study for Australia and Italy. [1] A. C. Silva and V. M. Yakovenko, Europhys. Lett.**69**, 304 (2005).

**A33 3 An out-of-equilibrium price model for Gamma-Pareto distributions of wealth and income** NICOLA SCAFETTA, *Duke University* SERGIO PICOZZI, BRUCE J. WEST, The distribution of wealth/income among the members of a society is herein assumed to result from two fundamental mechanisms, trade and investment. An empirical distribution of wealth/income shows an abrupt change between the low-medium range, that may be fitted by a non-monotonic function with an exponential-like tail such as a Gamma distribution, and the high wealth range, that is well fitted by a Pareto or inverse power-law function. We demonstrate that an appropriate trade-investment model, depending on three adjustable parameters associated with the total wealth of a society, a social differentiation among agents, which causes the prices to be out-of-equilibrium, and economic volatility referred to as investment can successfully reproduce the distribution of empirical wealth/income data in the low, medium and high ranges.

**9:00**
**A33 4 Boltzmann–Gibbs distribution of fortune and broken time reversible symmetry in econodynamics** PING AO, *University of Washington* Within the framework of stochastic differential equations it is demonstrated that the existence of Boltzmann–Gibbs type distribution in economy is independent of the time reversal symmetry in econodynamics. Both power law and exponential distributions can be accommodated naturally. The demonstration is based on a mathematical structure discovered during a study in gene regulatory network dynamics. Further possible analogy between equilibrium economy and thermodynamics is explored, suggesting that statistical physics methods can indeed play an important role in the study of complex systems. **9:12**
**A33 5 The Inequality Process as a Wealth Maximizing Process** JOHN ANGLE, *Inequality Process Inst., P.O. Box 429, Cabin John, MD 20818-0429* The Inequality Process (IP) is a particle system scattering a positive quantity, wealth. The IP is abstracted from social theory which sets tests for it. It is a jump process in which wealth exchange is driven by a discrete 0,1 uniform random variable. The losing particle, $i$, gives up a fixed proportion of its wealth, $\omega_i$. IP win/loss asymmetry is clearer than in more recent generalizations of the ideal gas model, some isomorphic to the IP up to its stochastic driver. The IP's asymmetry acts like Maxwell's Demon transferring wealth from particles with larger $\omega_i$ to smaller $\omega_i$, those more productive of wealth. While the stationary distribution of the IP is not a gamma pdf, a gamma pdf approximation to it is found from the IP's solution. This gamma pdf model is tightly constrained, expressed in terms of IP parameters, and fits both the IP's stationary distribution and empirical distributions. Annualizing the IP's wealth allows it to model the distribution of wage income conditioned on education in the U.S. 1961-2001. Smaller $\omega_i$ fit the distribution of the more educated, as hypothesized. The IP is also confirmed by the dynamics of individual wage incomes and wealth distributions over techno-cultural evolution. The smaller the harmonic mean of the $\omega_i$'s, the more active the IP's Demon, the less noise and the more $\omega_i$ signal there is in wealth, the ''cooler'' the process. The process models the emergence of skill as a society's primary form of wealth and the reduction in competition that accompanies it. To appear in Physica A.

**9:24**
**A33 6 Econo-Thermodynamics: The Nature of Economic Interactions** JUERGEN MIMKES, *Physics Department, Paderborn University, Germany* Physicists often model economic interactions like collisions of atoms in gases: by interaction one agent gains, the other loses. This leads to a Boltzmann distribution of capital, which has been observed in wealth distributions of different countries. However, economists object: no economic agent will attend a market in which he gets robbed! This conflict may be resolved by writing basic laws of economics into terms of calculus. In these terms the daily struggle for survival of all economic systems turns out to be a Carnot cycle that is driven by energy: heat pumps and economic production depend on oil, GNP and oil consumption run parallel for all countries. Motors and markets are based on the same laws of calculus (macro-economics) and statistics (micro-economics). Economic interactions mean exploiting a third party (nature) and are indeed close to robbing! A baker sells bread to his customers, but the flour comes from nature. Banks sells loans to investors, but the money comes from savers. Econo-thermodynamics is a thrilling new interdisciplinary field.

**9:36**
**A33 7 Correlation between the Gini index and the observed prosperity** IGOR MAZIN, *Georgetown University* It has been well established by computer simulations that a free, unregulated market economy (in the simplest model of a yard sale economy) is unstable and collapses to a singular wealth distribution. It is now a common procedure in computer simulations to stabilize a model by favoring the poorer partner in each transaction, or by redistributing the wealth in the society in favor of the poorer part of the population. Such measures stabilize the economy and create a stationary state with a Gini index $G < 1$. This suggests that there is some optimal range of the Gini index which is indicative of a healthy and dynamic economy. To verify this assumption, I plotted the PPP (parity purchasing power) for all countries in the world against their Gini indices, and found that they all (with only 2 outliers) fall into one of two groups: ''wealthy'' countries with PPP$>$ \$10,000/year, and the rest. The former are characterized by $G = 0.29 \pm 0.07$, and the latter by a uniform distribution of all

possible $G$s. This means that an enforced wealth redistribution is not a moral act of social consciousness, but a necessary precondition for a sustainable economy. The existence of an optimal $G$ is illustrated through a simple model of a yard sale economy with taxation.

**A33 9 Proposal of a New SI Base Unit for Value. An Hedonic Estimation of the Physical Purchasing Power (PhPP) of Money.** STEIVAN DEFILLA, *Technology, Environment and Energy Policy Division, SECO, Berne* Hitherto, the purchasing power of money, i.e. its transaction value, has been measured in terms of inflation index numbers and consumer baskets. Consumer baskets are variable phenomena and their use as measurement units for value confuses the measuring with the measurand. We propose an invariant numeraire, or value unit, based on the market value of a Planck energy (1956 MJ). Planck units form a natural system of units independent of any civilization. The hedonic estimation of the PhPP of a currency differentiates energy by product as well as by thermodynamic quality (exergy). Following SI rules, we propose to name the value unit walras (Wal) in honour of the economist Leon Walras (1834 - 1910). One Wal can also be interpreted as the minimum cost of physiological life of a reference person during one year. The study uses official disaggregated Swiss Producer and Consumer Price Index data and estimates the PhPP of the Swiss franc in 2003.

**10:12**

**A33 10 Wealth per capita in inhomogeneous wealth distributions model of self-organized hierarchies** MARCELO CASTILLO-MUSSOT, GERARDO NAUMIS, LUIS PEREZ, GERARDO VAZQUEZ-FONSECA, *Instituto de Fisica, UNAM, Mexico* A simple model explained the emergence of social hierarchies through fighting and randomness, and a phase transition between an egalitarian and an hierarchical society was found when the past fights are not forgotten fast enough [1]. Here we include in the model inhomogeneous wealth (water, food, oil, etc.) in the 2D lattice. Agents move randomly except when a preferred rich rich site is nearby. A strong dependence of the global inequality on the distribution of wealth is found, specially in the case when the density of the agents is small. Therefore, the overall phase diagram for the first-order transition between egalitarian and hierarchical societies does change much by inclusion of preferred sites. For low densities of agents with a poor distribution of wealth, it is found that the wealth per capita does not reach its maximum value due to lack of global information of the agents. [1] A. O. Sousa and D. Stauffer, Int. J. Mod. Phys. C, **11**, 1063 (2000).

**10:24**

**A33 11 A Statistical Approach to Project Cost Estimation: Modeling the Stochastic Component of the Projected Cost** DORU VELEA, ANATOLEY ZHELEZNYAK, *Planning Systems Inc., VA* Based on the assumption that there is always a stochastic component in project cost data, we developed a statistical methodology for the analysis of the project cost fluctuations. We considered as examples two different AF projects: a relatively short term project in the framework of the Earned Value Model, and a long-term project in the framework of the traditional accounting. For both data sets we extracted the stochastic component of the project cost fluctuations and found the appropriate statistical description. We calculated the variance on different time scales and established the presence of two statistical regimes: uncorrelated with linear time dependence of variance, and correlated where variance saturates as a function of time. We applied the Ornstein-Uhlenbeck stochastic model and calculated the time scaled parameter of the so-called return force, which characterizes the time period it typically takes for the project cost to return to the estimated value. We predicted the project cost for the near term future and defined the respective cost margins. We formulated criteria for the identification of the potential cost overruns.

**10:36**

**A33 12 Statistical Anomalies of the Project Cost and Stock Market Fluctuations** ANATOLEY ZHELEZNYAK, DORU VELEA, *Planning Systems Inc., VA* Based on the analysis of fluctuations of both project cost and stock market data, we identified some conditions when the statistics significantly depart from conventional distributions such as Heston and Ornstein-Uhlenbeck. Considering the Probability Distribution Functions (PDF) for subsets of fluctuations with the initial conditions corresponding to the extreme fluctuations, we found that the bell-shaped PDFs are gradually distorted and approach the form that is better approximated by the uniform distribution, once the magnitude of initial fluctuations is increased. Similar statistical anomalies were found from analysis of the stock market time series intra-day data. Considering the PDFs for different volumes, we found the similar distortion of the statistical regimes when the large volume transactions occur on the short time intervals, which potentially could be used as a viable tool for identifications of the extreme fluctuations. We believe that the fluctuations could be divided into two classes: the first class covering the majority of fluctuations that obeys the conventional statistical models, and the second class of the fluctuations having the entirely different statistical behavior and possibly belonging to non-Markov processes.

**SESSION A35: FOCUS SESSION: NANOSCALE THERMAL, THERMOELECTRIC AND MASS TRANSPORT: MEASUREMENT AND CHARACTERIZATION**

**A35 1 Nanoscale, phonon-coupled calorimetry with sub-attojoule/kelvin resolution.**
WARREN FON, *Caltech*

We have developed a nanofabricated calorimeter for ultrasensitive heat capacity measurements upon externally-affixed (phonon-coupled) samples at low temperatures. For a 5s measurement at 2K, we demonstrate unprecedented resolution of C of 0.5 aJ/K (approximately 36,000 kB). This sensitivity enables, for example, possible applications such as heat capacity measurements upon zeptomole-scale samples and upon adsorbates at extremely minute coverage. We describe the configuration and operation of these devices, and demonstrate their operation by measuring an adsorbed He4 film with maximum resolution of approximately 3 x 10e-5 monolayers upon the minute device surface area, A approximately 1.2 x 10e-9 m2.

**A35 2 Thermal relaxation below 1 K by phonons and photons in metallic nanostructures** ILARI MAASILTA, JENNI KARVONEN, PANU KOPPINEN, LASSE TASKINEN, *University of Jyvaskyla, Finland* We present experimental results on thermal energy flow (dissipation) from different metallic nanostructures below 1K, concentrating on the two possible channels: relaxation by phonon or by photon emission. We show how phonon emission can be suppressed either by lowering the dimensionality of the phonon gas (2D membranes), or by introducing impurities into the metal. As an example, we discuss Aluminum doped with Manganese, a material with significant technological importance for ultrasensitive detectors and solid-state coolers. We also discuss relaxation by photon emission in the near field, which becomes siginificant for distances in the sub-micron lengthscale at the sub-Kelvin temperature range. Theoretical understanding for most of the results obtained is still lacking.

**8:48**
**A35 3 Profiling the Seebeck Coefficient of III-V Superlattice Structures with nanometer resolution using Scanning Thermoelectric Microscopy (SThEM)** JIANLONG LI, ALEXANDER KHAJETOORIANS, HO-KI LYEO,*COLIN FOLTA, *The Univ. of Texas at Austin, Dept. of Mech. Engr.* ALI SHAKOURI, *Univ. of California Santa Cruz, Dept. of Elect. Engr., Quantum Electronics Group* LI SHI, *The Univ. of Texas at Austin, Dept. of Mech. Engr.* CHIH-KANG SHIH, *The Univ. of Texas at Austin, Dept. of Physics* Recent theoretical efforts demonstrate that quantum well structures such as superlattices, nanowires, and quantum dots are good candidates for high itZT materials. The ability to probe the thermoelectric properties of these materials on the nanometer scale requires the ability to resolve thermoelectric parameters with high spatial resolution. Recently, Scanning Thermoelectric Microscopy (SThEM) has demonstrated the ability to resolve the Seebeck coefficient and the carrier profile of GaAs $p-n$ junctions with unprecedented spatial resolution (H.K. Lyeo et al itScience v.303 p816 (2004)). By applying this new technique, this work focuses on direct measurement of local thermoelectric power of GaAs/AlAs and GaAs/InGaAs superlattice structures using ultra high vacuum SThEM. We observed that the thermoelectric power in the superlattice region is greatly enhanced. Moreover, oscillations of Seebeck coefficient within the superlattice regions, with a periodicity commensurating with the superlattice structure, are also observed.

**A35 4 A modified high-resolution TEM for thermoelectric properties measurements of nanowires and nanotubes** C. DAMES, C. T. HARRIS, *Mechanical Engineering, MIT* S. CHEN, J. Y. HUANG, Z. F. REN, *Physics, Boston College* M. S. DRESSELHAUS, *Physics and EECS, MIT* G. CHEN, *Mechanical Engineering, MIT* Nanowires are interesting candidates for thermoelectric applications because of their potentially low thermal conductivity and high Seebeck coefficient. However, measurements at the single-wire level are challenging and tend to lack detailed information about the atomic-level structure of the sample and contacts. We are modifying a high-resolution transmission electron microscope (HRTEM) with integrated scanning tunneling microscope (STM) for in-situ measurements of thermoelectric properties. A slender Wollaston wire is used to make electrical and thermal contact to the free end of a single nanowire or nanotube. The electrical conductance of the sample can be measured with the usual STM mode of operation. The Seebeck coefficient of the sample can be extracted from the transient voltage response to a step change in the joule heating of the Wollaston wire. These measurements are combined with detailed HRTEM observations.

**9:12**
**A35 5 Bi nanobelts, nanocubes and their thermoelectric properties** WENZHONG WANG, SHUO CHEN, JIANYU HUANG, ZHIFENG REN, *Boston College* T. HARRIS, GANG CHEN, M. DRESSELHAUS, *Massachusetts Institute of Technology* Highly crystallized Bi nanobelts and monodispersed nanocubes have been synthesized via a low-temperature organic solution approach, in which sodium bismuthate was reduced by ethylene glycol in the presence of poly(vinylpyrrolidone) (PVP). By changing some experimental conditions, Bi nanobelts and nanocubes have been prepared successfully. The as-prepared Bi nanobelts are single crystal with high crystallinity. The width of the nanobelts is in the range

of 50-500 nanometers and the length is up to of several tens of micrometers. The as-synthesized Bi nanocubes are highly crystallized and monodispersed with edge length of 50-60 nm. The electrical, thermal, and Seebeck properties of the as-grown nanobelts were studied by a TEM-STM probe inside a high resolution TEM. The same studies were also carried out on bulk samples made by hot-press using the nanocubes.

**9:24**

**A35 6 Bismuth Nanobelts for Enhanced Thermoelectric Performance*** XU ZHAO, MING TANG, GANG CHEN, M. S. DRESSELHAUS, *Massachusetts Institute of Technology, Cambridge, MA* ZHIFENG REN, *Boston College, Chestnut Hill, MA* Bismuth is a semimetal with high promise for thermoelectric applications if it could be made into a semiconductor by a combination of size reduction (based on quantum confinement considerations) and antimony addition. The recent experimental preparation of bismuth Nanobelts has motivated calculation of the phase diagram for the bismuth-antimony system in the regime of nanobelt cross sectional area and antimony concentration where semiconducting behavior is expected. Both direct and indirect bandgap regions are considered and regimes where the highest valence band is at the T-point, the L-point and the H-point are identified. The dependence of the semiconductor-semimetal transition on sample geometry, crystal orientation and temperature will be considered to guide in the preparation of a sample set for use in exploration of this materials system for thermoelectric applications.

**A35 7 Facet-edge fluctuations on finite volume crystallites*** MASASHI DEGAWA, WILLIAM CULLEN, ELLEN WILLIAMS, *Univ. of MD phys dept. MRSEC* Technological demands of the fabrication of nano-structures provide renewed motivation for understanding the atomistic properties that control the morphology changes of nano-structures and nano-crystallites. Using the continuum step model of the thermodynamic correlation function of step fluctuation has proven to be very powerful in such studies. For straight isolated steps on fcc(111) metal surfaces, the principal mass transport mechanism is often found to be periphery diffusion, with time correlations $\sim t^{1/4}$. However with decreasing structure size, issues of finite size and shape effects become non-negligible. When considering facet-edge fluctuations, the normal assumptions of ''straight'' and ''isolated'' do not apply. ''Straight'' is changed to ''curved'' due to finite size, which results in a KPZ term in the equation of motion. ''Isolated'' is changed to ''restricted'' where the amplitude of fluctuation is restricted due to mass conservation, which alters the scaling property of the noise term. Such considerations result in a different universality class of dynamic scaling giving $\alpha=1/3$, $\beta=1/11$ and $z=11/3$. Here we present results of facet-edge fluctuation measurements on Pb crystallites using scanning tunneling microscopy. Results of the temporal correlation function show an exponent different from 1/4, of $0.15\pm 0.02$ at early times, closer to 2/11 predicted for facet-edge fluctuations. *Supported by the UMD NSF-MRSEC, with originating support from DOE-NNI.

**A35 8 Pb-based Nanomaterials for Thermoelectric Application** BED POUDEL, DEZHI WANG, LILI CHEN, WENZHONG WANG, YI MA, ZHIFENG REN, *Boston College* QING HAO, HOHYUN LEE, GANG CHEN, *Department of Mechanical Engineering, MIT* MILDRED S. DRESSELHAUS, *Department of Physics and Department of Electrical Engineering, MIT* PbTe, PbSe, PbSeTe, and PbSnTe nanocrystals having sizes in the range of $\sim$ 5-50 nm have been synthesized using a simple hydrothermal method. As-prepared nanopowder was processed using $P^2C$ device, and samples with almost 100 percent density and small grain sizes were achieved. The thermoelectric properties of such samples have been investigated. Lower values of thermal conductivity were obtained from the samples prepared from nanomaterials. For further enhancement of the thermoelectric properties, the nanocrystals were doped with different elements, for example Ag, Cu, Eu, Bi, Sb, etc., and their thermoelectric properties have been studied.

**10:00**

**A35 9 Nanoscale clusters in the thermoelectric $AgPb_mSbTe_{m+2}$ and $Ag_nSn_mSb_nTe_{m+2n}$ materials*** HE LIN, EMIL BOZIN, KHANG HOANG, S.D. MAHANTI, SIMON BILLINGE, *Department of Physics and Astronomy, Michigan State University* ERIC QUAREZ, JOHN ANDROULA, MERCOURI KANATZIDIS, *Department of Chemistry, Michigan State University* The local structure of the $AgPb_mSbTe_{m+2}$ series of high performance thermoelectric materials has been studied using the atomic pair distribution function (PDF) method. The dimensionless thermoelectric figure of merit, $ZT$, of the $m \sim 18$ composition material was found to reach 1.7 at 700 kelvin, compared to the highest observed $ZT$ of only 0.84 for PbTe at 648 kelvin in n-doped material. This is asurprisingly large enhancement in $ZT$ for the addition of just 10%per formula-unit of silver and antimony ions. It is clearly of the greatest importance to trace the origin of the $ZT$ enhancement. Three candidate-models were attempted for thestructure of this class of materials using either a one-phase or a two-phase modeling procedure. Combining modeling the PDF with HRTEM data we show that $AgPb_mSbTe_{m+2}$ contains nanoscale inclusions with composition close to $AgPb_3SbTe_5$ randomly embedded in a PbTe matrix. We extended the local structural PDF study to $Ag_nSn_mSb_nTe_{m+2n}$, preliminary results of which suggest the presence of nanoscale inclusions in this system as well.

**10:12**

**A35 10 Thermal conductivity of nanoparticle suspensions** DAVID CAHILL, SHAWN PUTNAM, *University of Illinois* We present our experimental study on the thermal conductivity of nanofluids loaded with small volume fractions of $C_{60}$-$C_{70}$ fullerenes and alkanethiolate-protected Au nanoparticles. We use an optical beam deflection technique that measures the thermal diffusivity of fluid mixtures and suspensions of nanoparticles with a precision of better than 1%. Our approach is tested using the thermal conductivity of ethanol-water mixtures; in nearly pure ethanol, the increase in thermal conductivity with water concentration is a factor of two larger than predicted by effective medium theory. The solutions of the $C_{60}$-$C_{70}$ fullerenes and the alkanethiolate-protected Au nanoparticles were measured to maximum volume fractions of 0.6% and 0.35 vol%, respectively. We do not observe anomalous enhancements of the thermal conductivity that have been reported in previous studies of nanofluids; the largest increase in thermal conductivity we have observed is 1.3

± 0.8% for 4 nm diameter Au particles suspended in ethanol. However, within the context of effective medium theory, these findings are expected: effective medium theory predicts that the largest possible increase in the thermal conductivity of a fluid loaded by a volume fraction $\phi \ll 1$ of spherical particles will be $3\phi\Lambda_0$, where $\Lambda_0$ is the thermal conductivity of the carrier fluid.

**10:24**
**A35 11 Thermal Conductance of metal-metal interfaces** BRYAN GUNDRUM, DAVID CAHILL, ROBERT AVERBACK, *University of Illinois* The first quantitative measurement of a metal-metal interface thermal conductance has been carried out using time-domain transient reflectivity in the temperature rage 78 $<$ T $<$ 278 K. The thermal conductance, at room temperature, for the as deposited Al-Cu interface was measured to be 4 GW $m^{-2}$ $K^{-1}$. This is an order of magnitude larger than the largest phonon-mediated interface transport measured to date. It is shown that an extension of the diffusive mismatch model to electrons reproduces the magnitude and temperature dependence accurately. The chemical abruptness of the Al-Cu interface is systematically varied by ion-beam mixing using 1 MeV Kr ions. These results combined with the interface form of the Wiedemann-Franz law could provide a powerful tool for investigating the thermal and electrical transport across metal interfaces.

**10:36**
**A35 12 Thermal conductance of hydrophilic and hydrophobic interfaces** ZHENBIN GE, PAUL BRAUN, DAVID CAHILL, *University of Illinois at Urbana-Champaign* Interfaces between water and hydrophilic or hydrophobic surfaces are of great importance for many biological and engineering systems. Using time-domain thermoreflectance, we have measured the transport of thermally-excited vibrational energy across planar interfaces between water and solids that have been chemically functionalized using self-assembled monolayer. The thermal conductance per unit area of the interface G for hydrophobic Al or Au surface in water is determined to be 37 to 55 MW $m^{-2}$ $K^{-1}$. G for hydrophilic Al or Au surface in water is 150 to 300 MW $m^{-2}$ $K^{-1}$. Our new work on thermal transport complements the extensive research literature on momentum transport at aqueous interfaces: the Kapitza length—i.e., the thermal conductivity of water divided by the thermal conductance per unit area of the interface—is analogous to the ''slip-length'' for water flowing tangentially past a solid surface. We find that the Kapitza length at hydrophobic interfaces (11-16 nm) is a factor of 3-8 larger than the Kapitza length at hydrophilic interfaces (2-4 nm); a change of terminal group from methyl to hydroxyl increases the Kapitza length by approximately 10 nm.

**10:48**
**A35 13 Interfacial thermal transport at Liquid-Liquid and Biomolecular Interfaces** PAWEL KEBLINSKI, NATALIA SHENOGINA, HARSHIT PATEL, SHEKHAR GARDE, *Rensselaer Polytechnic Institute* Systems with nanoscopic features contain a high density of interfaces. Thermal transport in such systems can be governed by the resistance to heat transfer of the interface. Although soft interfaces, such as those between immiscible liquids or between a biomolecule and solvent, are ubiquitous, few studies of thermal transport at such interfaces have been reported. Here we characterize the interfacial conductance, i.e., the inverse of the interfacial resistance, of soft interfaces as a function of molecular architecture, chemistry, and the strength of cross-interfacial intermolecular interactions through detailed molecular dynamics simulations. The conductance of various interfaces studied here, for example, water-organic liquid, water-surfactant, surfactant-organic liquid, is relatively high (in the range of 65-370 MW/m2/ K) compared to that for solid-liquid interfaces ( 10 MW/m2/ K). Interestingly, the dependence of interfacial conductance on the chemistry and molecular architecture cannot be explained solely in terms of either bulk property mismatch or the strength of intermolecular attraction between the two phases. We will also discuss vibrational mode dependent thermal coupling at biomolecule-water interfaces.

**SESSION A36: STRUCTURAL, OPTICAL, AND ELECTRONIC PROPERTIES OF NANOSTRUCTURES**
**Monday Morning, 13 March 2006**
**339, Baltimore Convention Center at 8:00**
**Stefan Badescu, Naval Research Laboratory, presiding**

**8:00**
**A36 1 3-D Structure of Semiconductor Nanomaterials** ILKE ARSLAN, *University of Cambridge* NIGEL BROWNING, *University of California-Davis* TIMOTHY YATES, JENNA TONG, PAUL MIDGLEY, *University of Cambridge* In recent years, nanotechnology has become a key component in the field of materials physics, placing a more rigorous demand on characterization of nanomaterials, ultimately in three dimensions. This has led to the development of electron tomography for inorganic materials using Z-contrast imaging in the scanning transmission electron microscope (STEM). Here we present high resolution 3-D reconstructions of quantum dots and tetrapods. The results from Sn quantum dots in a Si matrix illustrate the ability to identify the size, shape and distribution of embedded dots in a layer in three dimensions, as well as identifying their formation mechanism. Dual axis tomography is demonstrated for the first time for inorganic materials on semiconducting nanorods in the shape of tetrpaods made of CdTe. These results indicate approximately 1nm resolution in all three dimensions using single axis tomography.

**8:12**
**A36 2 Propagation of coherence in X-ray Optics for Nanocrystallography** MENGNING LIANG, IAN ROBINSON, *University of Illinois at Urbana-Champaign* Coherent X-ray Diffraction is a powerful tool for studying the internal structure of nanostructures to angstrom precision in three dimensions. A coherent diffraction pattern is a single 2D slice through the 3D Fourier Transform of an object. These diffraction images can be inverted with iterative phasing algorithms to obtain an image of a projection of the physical object. The success and accuracy of the inversion depends strongly on the quality of the initial diffraction pattern and thus on the coherence properties of the incoming X-ray beam. Coherence of synchrotron radiation depends on machine parameters but also on the optics in the beam path. Focusing optics, which are necessary to provide sufficient flux onto the sample, distort the wavefront and can especially alter the coherence of the beam. For a finite object, fringes will result from the interference

of opposite sides or facets and the visibility of these fringes is a quantitative measure of the coherence quality. We present a study of the effect of optical elements in altering the coherence of an x-ray beam by using the coherent diffraction images from gold nanoparticles.

**A36 3 X-ray Studies of Ultrathin Wires and Tubes in Nanoscale Confinement** JONATHAN M. LOGAN, OLEG G. SHPYRKO, ERIC D. ISAACS, *Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL and JFI/Physics Department, University of Chicago, Chicago, IL* RAFAEL JARAMILLO, YEJUN FENG, *JFI/Physics Department, University of Chicago, Chicago, IL* JEFFREY W. ELAM, *Energy Systems Division, Argonne National Laboratory, Argonne, IL* DAVID J. COOKSON, *Australian Synchrotron Research Program, Argonne, IL* MICHAEL J. PELLIN, *Materials Science Division, Argonne National Laboratory, Argonne, IL* Nanoporous Anodized Aluminum Oxide (AAO) membranes are composed of self-assembled, densely packed, co-aligned cylindrical pores. The pore diameter of these membranes can be controllably reduced to as little as $\approx$ 1 nm through Atomic Layer Deposition (ALD) process. AAO pores have been used as templates for formation of metallic nanotubes and nanowires through ALD or thermal vapor deposition. These embedded structures have been characterized by small- and wide-angle x-ray scattering (SAXS, WAXS). The penetrating ability of x rays provides a non- destructive structural characterization technique for materials confined within AAO matrix, on both atomic (WAXS) and nanometer (SAXS) length scales.

**8:36**

**A36 4 Three-dimensional Structure of Nanoparticles from High-energy X-ray Diffraction and Atomic Pair Distribution Function Analysis** VALERI PETKOV, *Dept. Physics, Central Michigan University* Knowledge of the atomic-scale structure is an important prerequisite to understand and predict the properties of materials. In the case of crystals it is obtained from the positions and intensities of the Bragg peaks in the diffraction patterns. However, materials constructed at the nanoscale lack the translational symmetry and long-range order of perfect crystals. The diffraction patterns of such materials show only a few Bragg peaks, if any, and a pronounced diffuse component. This poses a real challenge to the usual techniques for structure characterization. The challenge can be met by employing the so-called atomic Pair Distribution Function (PDF) technique and high energy x-ray diffraction. This non-traditional experimental approach takes into account both Bragg and diffuse scattering and yields the atomic structure in terms of a small set of parameters such as a unit cell and atomic coordinates. The basics of the technique will be introduced and its potential demonstrated with results from recent structural studies gold, $ZrO_2$ and GaN nanoparticles.

**A36 5 Anomalous scattering and PDF analysis of HgSe nanoclusters in zeolites using synchrotron X-ray radiation*** M. CASTRO-COLIN, M. ABEYKOON, S.C. MOSS, W. DONNER, E. ANOKHINA, A.J. JACOBSON, *U. of Houston* HgSe, has been grown inside LTL and Nd-Y zeolites (tubular and spherical nanosized pores, respectively). A first sharp diffraction peak appears in an X-ray diffraction profile, that we associate with the clustering of HgSe constrained to the zeolite pore diameter. Charge imbalance within the zeolite pores, combined with the guest material properties, affects the cluster-cluster correlation (clusters in separate pores), either in a filled-unfilled-like fashion or through a relative local orientational order. Such correlations are expressed through a broad diffuse modulation, absent in the pure host, upon which the more obvious, Bragg peaks are imposed. This effect might be seen via pair-distribution function (PDF) analysis. Anomalous scattering experiments carried out both below the Se K-edge and the Hg L-edge, as well as off-edge for each zeolite, aided in calculating average crystallographic parameters of HgSe. These results and the PDF analyses promise to reveal an understanding of the structural configuration and cluster allocation mechanisms. A potential technological application of this system should arise, due to the transparency of these zeolites and ease of interaction of visible light with species contained within the pores.* M.C-C. now at U.T. **A36 6 Amorphous-Ge Nanocluster Formation During Ion Implantation** I.D. SHARP, *Materials Science and Engineering, University of California, Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory, CA 94720* D.O. YI, *Applied Science and Technology, University of California, Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory, CA 94720* C.W. YUAN, Q. XU, C.Y. LIAO, *Materials Science and Engineering, University of California, Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory, CA 94720* J.W. AGER III, *Materials Sciences Division, Lawrence Berkeley National Laboratory, CA 94720* DARYL CHRZAN, E.E. HALLER, *Materials Science and Engineering, University of California, Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory, CA 94720* Ge nanocrystals formed by ion implantation followed by thermal annealing have an average diameter of 5.1 nm with a distribution full width at half maximum (FWHM) of 3.4 nm. This contrasts with Kinetic Monte Carlo (KMC) and rate equation predictions which give a much narrower distribution. Here, we show that the difference between theory and experiment is the result of amorphous nanocluster formation during room temperature implantation. Therefore, thermal annealing to form nanocrystals is predominantly a crystallization process rather than a conventional nucleation, growth, and coarsening process during thermal annealing. This work is supported in part by U.S. Department of Energy under contract No. DE-AC02-05CH11231 and in part by U.S. NSF Grant No. DMR-0109844.

**A36 7 A Computational Investigation of the Structure and Optical Properties of Nanoconfined Semiconducting Polymers** M.L. DRUMMOND, B.G. SUMPTER, *Oak Ridge National Laboratory* M.D. BARNES, *University of Massachusetts, Amherst* W.A. SHELTON, JR., R.J. HARRISON, *Oak Ridge National Laboratory* The promise of semiconducting organic polymers lies in their incredible flexibility, both through varied structure types and via chemical modifications of the polymer backbone. One type of structure we have recently explored, both experimentally and theoretically, arises from the use of ink-jet printing methods to produce nanoconfined particles with arbitrary size and composition. We have found substantial evidence indicating the production of highly ordered, rod-shaped, pi-stacked folded chain structures for single molecule PPV-based systems. Results show that chain organization, which is greatly influenced by the solvent, is crucial in determining the photophysical properties. Recent multiscale calculations, including molecular dynamics, molecular mechanics,

and both ground-state and excited-state ab initio calculations, have been used to elucidate the role of the substituents in controlling the structure of the nanoconfined polymer, as well as the resultant effect on the optical properties. Through this work, a structure-property relationship is developed that will prove to be of great utility to experimentalists and polymer theorists alike.

**A36 8 Single-particle energy levels and interparticle Coulomb interactions in CdSe quantum dots measured by Scanning Tunneling Spectroscopy** LUCIAN JDIRA, *Institute for Molecules and Materials, Radboud University Nijmegen, The Netherlands* PETER LILJEROTH, *Debye Institute, Utrecht University, The Netherlans* ERIC STOFFELS, *Institute for Molecules and Materials, Radboud University Nijmegen, The Netherlands* DANIEL VANMAEKELBERGH, *Debye Institute, Utrecht University, The Netherlans* SYLVIA SPELLER, *Institute for Molecules and Materials, Radboud University Nijmegen, The Netherlands* Semiconductor quantum dots (QDs) provide the opportunity to study the evolution of electronic properties in a size range intermediate between molecular and solid state regime. We report a detailed size evolution analysis of the electronic structure of colloidal CdSe QDs of different sizes, by employing Scanning Tunneling Spectroscopy to individual dots. Tuning the tunnelling-in versus tunnelling-out rates allows one to show the electron occupation in the dot. The energy level structure and electron-hole Coulomb attraction in the dot are obtained by a combination of shell-tunneling spectroscopy and optical spectroscopy. The results are in agreement with tight-binding calculations. The electron-electron interactions are investigated by shell-filling spectroscopy. The tunneling spectra in this regime are analyzed by solving the master equation for electron and hole occupancy of the QD.

**A36 9 Optical Phonons and Multiphonon Raman Scattering in Spherical PbSe Quantum Dots*** SERGEI KLIMIN, VLADIMIR FOMIN, JOZEF DEVREESE, *TFVS, Departement Fysica, Universiteit Antwerpen, B-2610 Antwerpen, Belgium* YUL HYUN, FRANK WISE, *Department of Applied Physics, Cornell University, Ithaca, New York 14853, USA* The experimentally observed multi-phonon resonant Raman scattering spectra in spherical PbSe quantum dots are interpreted using our non-adiabatic approach [1]. The optical phonons in quantum dots are treated within the multimode dielectric continuum model, taking into account both the electrostatic and mechanical boundary conditions for the relative ionic displacement. Our multimode dielectric continuum model, which includes, as a substantial ingredient, the realistic dispersion of optical phonons, adequately describes the optical-phonon spectra of spherical PbSe quantum dots. The non-adiabaticity leads to a substantial enhancement of the relative intensities of multiphonon peaks with respect to the intensity of the one-phonon peak. The peak positions and intensities of the calculated Raman scattering spectra for spherical PbSe quantum dots are in good agreement with recent experimental results on the Raman scattering in oleic-acid-capped colloidal PbSe nanocrystals. **A36 11 Experimental and numerical confirmation of composite diffracted evasnescent-wave (CDEW) model for enhanced transmission of subwavelength apertures** HENRI J. LEZEC, *Caltech, Pasadena CA, and CNRS, Paris, France* TINEKE THIO, *Arinna LLC* When a subwavelength aperture in an opaque film is surrounded by periodic surface corrugations, its optical transmission can be enhanced or suppressed with respect to that of an identical aperture without surface corrugations. We have proposed a model in which the subwavelength surface structure scatters the incident light into evanescent waves: The total, or composite, diffracted evanescent waves (CDEWs) travel along the surface and their interference with the light directly falling on the aperture leads to the transmission modulation. The CDEW model is valid for metallic as well as non-metallic surfaces, and thus differs qualitatively from the surface plasmon model, which requires a metallic surface. We show that the optical transmission of an embedded periodic array of dots, where the surface is absent altogether, is related to the transmission of hole arrays by Babinets principle, underscoring the importance of diffraction. Furthermore, numerical calculations on small- area corrugations verify the functional form of the CDEWs.

**A36 12 Transport Properties of Gold Nanoparticle Arrays at Low Temperatures** T. TRAN, *University of Chicago* I. BELOBORODOV, X.M. LIN, V. VINOKUR, *Argonne National Laboratory* P. JIANG, W. KANG, H. JAEGER, *University of Chicago* We investigated the effects of elastic and inelastic cotunneling on the electronic transport properties of Au monolayers and multilayers. Highly-ordered monolayers of dodecanethiol-ligated Au particles (6nm in diameter)[1] were assembled onto $Si_3N_4$ substrates with prefabricated electrodes. Multilayers were created by adding layers to the original monolayers[2]. Current-voltage (IV) measurements were performed with 50fA resolution down to 30mK. TEM images were taken posterior to all measurements. We found that transition from inelastic to elastic cotunneling occurred at T$\sim$ 5K. In the inelastic cotunneling regime, the IV curves were found to be nonlinear for $k_BT < eV/N < E_C$ and linear when $k_BT > eV/N$ where N is the number of grains across the electrode gap. In the elastic regime below 5K, the IV curves were found to be linear for $eV/N < (E_C\ \delta)^{1/2}$where $\delta$ is the level spacing and $E_C$ is the charging energy. As a consequence of cotunneling, Efros-

Shklovskii variable-range-hopping-like conduction (VRH) was observed near zero bias. Above T~ 80-100K, transition from VRH to nearest-neighbor hopping took place. X.M. Lin, itet.al., J. Nanoparticle Res. **2** 157 (2000). T.B. Tran, itet.al., Phys. Rev. Lett. **95** 076806 (2005),

**10:24**

**A36 13 Observation of Optical Signature of the Aharonov-Bohm Phase in Type-II Quantum Dots** IGOR KUSKOVSKY, W. MACDONALD, *Queens College, NY* M.C. TAMARGO, *City College, NY* A.O. GOVOROV, *Ohio U., Athens* X. WEI, *NHMFL* M. TADIC, F.M. PEETERS, *University of Antwerp* Recent theoretical studies[1,2] on the optical response of type-II excitons in the magnetic field have shown that the excitons will acquire the Aharonov-Bohm (AB) phase as the electrical dipole, formed due to carrier separation, interacts with the field, resulting in the field dependent exciton energy and the emission intensity. Experimentally, the former has been reported[3]; however, the behavior of the intensity is still not fully understood. We present results of magneto-photoluminescence studies on type-II ZnTe/ZnSe quantum dots (QDs) formed in Zn-Se-Te multilayer systems[4]; this ensures that electron move within the $x - y$ plane. The observed strong oscillations in the intensity is explained in terms of the AB effect[1,2,5] due to the electron motion around a stack of QDs, when the hole is strongly localized in one them. This is in qualitative agreement with the theoretical predictions[2]. 1. Kalameitsev, itet al., JETP Lett. **68**, 669 (1998); Govorov, itet al., PRB **R66**, 081309 (2002); Janssens, itet al., PRB **67**, 235325 (2003). 2. **10:36**

**A36 14 Observation of the Aharonov-Bohm Effect in Self-Assembled InGaAs/GaAs Nano-Volcanoes*** N.A.J.M. KLEEMANS, P. OFFERMANS, J.H. WOLTER, P.M. KOENRAAD, *Department of Semiconductor Physics, TU Eindhoven, The Netherlands* I.M.A. BOMINAAR-SILKENS, U. ZEITLER, P.C.M. CHRISTIANEN, J.C. MAAN, *High Field Magnet Laboratory, IMM, Radboud University Nijmegen, The Netherlands* D. GRANADOS, J.M. GARCÍA, *Instituto de Microelectrónica de Madrid, CSIC, Spain* V.M. FOMIN, V.N. GLADILIN, J.T. DEVREESE, *TFVS, Universiteit Antwerpen, Belgium* According to our X-STM data, self-assembled InGaAs/GaAs nano-volcanoes are characterized by an asymmetric rim and a depression rather than an opening at the center. We show that these asymmetric singly connected structures still can effectively manifest the electronic properties, like the Aharonov-Bohm (AB) oscillations, peculiar to the doubly connected geometry of ideal rings. AB oscillations in the persistent current are observed in low temperature magnetization measurements using torsion magnetometry in magnetic fields up to 15 T. The experimental results are in excellent agreement with theoretical predictions for strained nano-volcanoes.

*The work has been supported by the GOA BOF UA 2000, IUAP, FWO-V project G.0435.03, the WOG WO.035.04N (Belgium), MEC NANOSELF project (Spain) and the EC SANDiE Network of Excellence.

**A36 15 Mesoscopic conductance fluctuations in a coupled quantum dot system** KAZUTAKA TAKAHASHI, *RIKEN, Japan* TOMOSUKE AONO, *Ben-Gurion University of the Negev, Israel* We study electron transport properties of an Aharonov-Bohm ring containing two quantum dots. One of the dots has well-separated resonant levels and the other dot is chaotic and is treated by random matrix theory. We develop a statistical theory of the conductance through the dot using the supersymmetry method and the numerical calculation, and find that the conductance is significantly affected by mesoscopic fluctuations. The Breit-Wigner resonant peak of the conductance is changed to an antiresonance by increasing the ratio of the level broadening to mean level spacing of the random dot. The asymmetric Fano form turns into a symmetric one and the resonance peak can be controlled by magnetic flux. We also find that the conductance distribution shows rich behavior depending on the fluctuations of the chaotic dot and the position of the resonance peaks.

**8:00**

**A38 1 Josephson-vortex states in $Bi_2Sr_2CaCu_2O_{8+y}$** KAZUTO HIRATA, *National Institute for Materials Science* SHUUICHI OOI, TAKASHI MOCHIKU, Josephson-vortex (JV) states have been studied by measuring the flow resistance in $Bi_2Sr_2CaCu_2O_{8+y}$ (Bi-2212) as a function of the parallel magnetic field with the current along the *c*-axis. From the periodic oscillations, we can assign the three-dimensionally long-range-ordered state (3DLOS) of JVs (PRL**89**, 247002(2002), Physica **C412-414**, 454(2004)). The lower and upper boundaries of 3DLOS were determined from the magnetic field of beginning and stopping in the oscillations, respectively. From the flow resistance and the $I - V$ characteristics measurements crossing the upper boundary, we suggest that the JVs are in ordered state in itin-plane, but have less ordering along the *c*-axis. This JV state may correspond to the 2D-quasi-long-range ordered state, proposed by Hu&Tachiki (PRB**70**, 064506(2004)).

**8:12**

**A38 2 Vortex phase diagram of nearly stoichiometric $Bi_2Sr_2CaCu_2O_{8+\delta}$ single crystal*** NORIKO CHIKUMOTO, *Superconductivity Research Laboratory, ISTEC* There have been a large number of reports on the vortex phase diagram of Bi2212. However, the Bi2212 crystals used for these studies mostly have Bi-rich composition, with typically Bi : Sr = 2.1 : 1.9. Recently, Eisaki *et al.* [1] reported that $T_c$ in Bi2212 single crystal is largely depressed by the cation disorder at the Sr-site, typically the substitution of Sr-site by $Bi^{3+}$. In the present study, we found that the Bi-Sr substitution also depress the vortex pinning. We have successfully grown Bi2212 single crystals with Bi : Sr ratio very close to 2:2. It showed very high critical current density, $2 times 10^6$

A/cm$^2$, at 20K, and reduced reversible region ($J_c = 0$ region) in the magnetic phase diagram. We also show the dependence of the irreversibility field on the cation nonstoichiometry. The author thanks K. Furusawa, H. Eisaki and Y. Nakayama for growing Bi2212 single crystals.

*This work was partially supported by the New Energy and Industrial Technology Department Organization (NEDO).

**8:24**

**A38 3 Melting of vortex solid phase in irradiated $Bi_2Sr_2CaCu_2O_{8+\delta}$ single crystals in tilted magnetic fields** JOVAN MIRKOVIC, *Inst of Materials Science, Univ of Tsukuba, 305-8573 Tsukuba, Japan, and Faculty of Sciences, Univ. of Montenegro, Podgorica, Serbia and Montenegro* SERGEY SAVEL'EV, *Frontier Research System, The Institute of Physical and Chemical Research (RIKEN), Wako-shi, Saitama, 351-0198, Japan* HIROKAZU SATO, TAKASHI YAMAMOTO, ITSUHIRO KAKEYA, *Institute of Materials Science, University of Tsukuba, 305-8573 Tsukuba, Japan* FRANCO NORI, *Frontier Research System, The Institute of Physical and Chemical Research (RIKEN), Wako-shi, Saitama, 351-0198, Japan* KAZUO KADOWAKI, *Institute of Materials Science, University of Tsukuba, 305-8573 Tsukuba, Japan* The boundary between the vortex-solid and the vortex-liquid in $H_c - H_{ab}$ phase plane for irradiated $Bi_2Sr_2CaCu_2O_{8+\delta}$single crystals is studied by measuring the local ac-magnetic permeability by using the miniature coils in tilted magnetic fields. It was found that the *c*-axis magnetic field component at the phase transition decreases linearly when increasing the in-plane magnetic field at high temperatures even in a wider angular range than in pristine samples. At lower temperatures, this linear decrease transforms to a concave (hyperbolic-like) curve that differs even stronger from the usual elliptical phase boundary derived from Ginzburg-Landau theory. A theoretical approach to this challenging problem is discussed.

**8:36**

**A38 4 Field dependence of the lock-in transition of Josephson vortex in $Bi_2Sr_2CaCu_2O_{8+\delta}$ mesoscopic crystals** ITSUHIRO KAKEYA, YUIMARU KUBO, MASASHI KOHRI, TAKASHI YAMAMOTO, KAZUO KADOWAKI, *University of Tsukuba, Tsukuba, Ibaraki 305-8573 Japan* We have investigated vortex states in magnetic fields close to the *ab*-plane of $Bi_2Sr_2CaCu_2O_{8+\delta}$ (Bi2212) by means of the *c*-axis resistivity $\rho_c$ in Bi2212 mesoscopic crystals fabricated by the FIB technique. When magnetic field $H \leqslant$ 1T was tilted from the *ab*-plane at $T$ = 60 K, a sharp drop in $\rho_c$ was observed at an angle $\theta_{th}$ ($\theta$ = 0 for $\mathbf{H} \| ab$-plane) depending on the field (typically $\theta_{th}$=0.5 deg. for $H$ = 1T). $\rho_c$ below $\theta_{th}$ does not depend on angle and is almost proportional to $H$, suggesting $\rho_c$ being Josephson vortex (JV) flow resistivity. Above $\theta_{th}$, it is considered that the JV flow is strongly impeded by pancake vortices (PVs), which attract with JVs and do not flow by the *c*-axis current, resulting in $\rho_c \approx 0$. Moreover, the penetration field of PVs $H\sin\theta_{th}$ decreases with increasing $H$. This is considered to be yielded by decrease of the line energy of pancake stacks due to the formation of the crossing lattice (CL). Therefore, the drop in $\rho_c$ corresponds to the transition from the lock-in (LI) state to the CL state. At high magnetic fields, the decrease in $\rho_c$ is broadened and has a shoulder structure. These results suggest that other vortex states between the LI and CL states emerge with increasing magnetic field and have intermediate JV viscosity. The expected vortex structures will be argued.

**8:48**

**A38 5 Vortex phase diagram from $^{17}$O NMR study in single crystal BSCCO*** BO CHEN, WILLIAM HALPERIN, *Northwestern University* One of the most fascinating aspects of high temperature superconductors is the extreme anisotropy and the effect this has on the properties of vortices. At sufficiently high magnetic field it is expected that vortices are two dimensional and the melting transition temperature tends to a constant value, independent of field. For the most anisotropic materials such as $Bi_2Sr_2Ca_1Cu_2O_{8+\delta}$ such fields are attainable allowing almost complete decoupling of the two dimensional vortex pancakes from each other along the direction of the anisotropy axis. In our work the vortex melting phase diagram for single crystals of $Bi_2Sr_2Ca_1Cu_2O_{8+\delta}$ have been determined from $^{17}$O NMR up to 22 Tesla and can be related to results at low field for the more strongly coupled three dimensional case that has been extensively studied by transport and magnetization methods. Additionally, an abrupt change in vortex structure, seemingly an order−disorder transition, was found between 5 and 8 Tesla, below 10 K.

**A38 6 Anomalous angular dependence of the *c*-axis resistivity in $Bi_2Sr_2CaCu_2O_{8+x}$ mesas*** TAKASHI TACHIKI, *MSD, Argonne Nat. Lab. and Dept. of E & E Eng., Nat. Defense Academy, Japan* L. OZYUZER, *MSD, Argonne Nat. Lab. and Dept. of Phys., Izmir Inst. of Technol., Turkey* C. KURTER, *MSD, Argonne Nat. Lab. and Illinois Inst. of Technol.* U. WELP, A. KOSHELEV, D. HINKS, K. GRAY, W. KWOK, *MSD, Argonne Nat. Lab.* K. KADOWAKI, *Institute of Mat. Sci., Univ. of Tsukuba, Japan* We study flux-flow properties of Josephson vortices in highly anisotropic high-$T_c$ superconductors. The flux-flow resistance in pristine and $HgBr_2$-intercalated $Bi_2Sr_2CaCu_2O_{8+x}$ (BSCCO) single crystals was measured as a function of the angle between the itab-plane and an applied magnetic field. These samples have a mesa structure with the in-plane area of 200 $\mu$m x 20 $\mu$m and consist of 50 – 70 intrinsic junctions. For both pristine and intercalated BSCCO, a sharp resistance peak was observed within a threshold angle of a few degrees. However, while the angle decreases with increasing field for the pristine BSCCO, the intercalated BSCCO shows the opposite field dependence. We interpret this peak and its field dependence as an interplay between two effects: initial penetration of pancake vortices and extra damping of Josephson-vortex lattice induced by pancake vortices.

**A38 7 Thermal depinning and transverse-field tilting transitions in a planar vortex array pinned by a columnar defect*** LEO RADZIHOVSKY, *University of Colorado at Boulder* I will discuss results on a thermal and a transverse magnetic field response of a vortex line array confined to a plane with a dilute concentration of columnar pins. As a function of temperature, for a magnetic field aligned with defects this system exhibits a one-dimensional analog of a roughening transition, with a low-temperature ''smooth'' phase corresponding to a vortex array pinned by the defects, and a high-temperature ''rough'' phase in

which at long scales thermal fluctuations effectively average away pinning by the defects. In the low-T pinned phase, the vortex lattice tilt response to a transverse magnetic field proceeds via a soliton proliferation ''transition,'' governed by an integrable sine-Hilbert equation. Combining the aforementioned roughenning transitition with this commensurate-incommensurate transition, I map out the transverse-field—temperature phase diagram for this system.

**A38 8 RF-induced flux lattice annealing (RIFLA) in the electron-doped superconductor $Pr_{1.85}Ce_{0.15}CuO_{4-y}$.*** W.G. CLARK, GUOQING WU, S.E. BROWN, *UCLA Physics and Astronomy* R.L. GREENE, *U. of Maryland Physics* H. BALCI, *UIUC Physics* A strained flux lattice (FL) in a superconductor (SC) can be annealed to a lower free energy by the RF-field used to generate an NMR spin-echo signal [W.G. Clark et al., J. Phys. IV Proceedings **9**, Pr10-49-52 (1999)]. Here, this effect is reported for the SC phase of $Pr_{1.85}Ce_{0.15}CuO_{4-y}$. The distorted FL is prepared by rotating the sample through a small angle in a magnetic field well below the transition temperature, which leaves the FL pinned in a non-equilibrium configuration. Then, the first spin echo has almost no amplitude. Subsequent echoes have a progressively larger amplitude until a final, steady value is reached. The interpretation is that shaking of the distorted vortex lattice by the RF pulses progressively anneals it to a lower free energy configuration. The corresponding change in the local field between the de-phasing and re-phasing pulse for each echo then reduces the height of the echo.

**A38 9 Ground state of interlayer Josephson vortex systems: General description based on energy landscape** YOSHIHIKO NONOMURA, XIAO HU, *Computational Materials Science Center, National Institute for Materials Science, Tsukuba, Ibaraki 305-0047, Japan* Although Josephson vortex systems have been intensively studied, their phase diagrams have not been established yet even in the ground state. In the present study, we draw the full energy landscape with respect to magnetic field and the displacement from aligned vortex lattices by neglecting the spatial variation in the amplitude of superconductivity order parameter and in the gauge field in the Lawrence-Doniach model. We find that the ground state changes continuously from the aligned lattice to sheared lattices, and then to rotated lattices as the magnetic field decreases, and that rotated lattices are characterized by multi-valley structures of the energy landscape. Owing to effects of the underlying layer structures, the rotated vortex lattices realized at the valleys of the energy landscape are distorted from the rigid ones expected from the picture based on the London model, and this distortion becomes weak as the magnetic field decreases. We would like to thank Dr. A. E. Koshelev for sending his article prior to publication.

**A38 10 Vortex dynamics investigated using low temperature scanning tunneling microscope: collective motion and collective pinning of vortices in $NbSe_2$** JONGHEE LEE, WANG HUI, DAN SULLIVAN, *Department of Physics, University of Maryland, College Park, MD 20740* MICHAEL DREYER, *Department of Electrical & Computer Engineering, University of Maryland, College Park, MD 20740* BARRY I. BARKER, *Laboratory for Physical Sciences, National Security Agency, College Park, MD 20740* PAVEL SHUK, MARK HIGGINS, EVA Y. ANDREI, *Department of Physics, Rutgers University, Piscataway, NJ 08854* We report the observation of the collective motion and the collective pinning of vortices of $NbSe_2$ under various magnetic fields and from $\sim$ 6 K to $\sim$ 2 K using scanning tunneling microscopy (STM). Scanning Tunneling Spectroscopic maps were taken continuously, providing ''movies'' of the vortex motion. Based on the analysis of this data, the speed of the collective motion of vortices was $\sim$ 1 pm/s. The vortices showed clear signs of weak collective flux pinning. We will quantify the collective transport behavior of vortices based on our STM measurements and compare with the pertinent theories as well as related measurements done by other groups.

**A38 11 Observation of the Signatures of Glassy Vortex Dynamics in $2H$-$NbSe_2$*** XU DU, GUOHONG LI, EVA Y. ANDREI, MARK J. HIGGINS, *Department of Physics and Astronomy, Rutgers University* PAVEL SHUK, MARTHA GREENBLATT, *Department of Chemistry, Rutgers University* Using time resolved transport measurements, we observed clear evidence of glassy dynamics in the current driven vortex system in clean, weak pinning $2H$-$NbSe_2$single crystals prepared by field cooling through the superconducting transition. Simple aging was observed by means of scaling over the waiting times between two consecutive current pulses. A memory function was defined to describe how the previous pulse is ''memorized'' when the system is probed by a second pulse. The complex behavior of the driven vortex system in the glassy state is well characterized by a simple picture of the time evolution of the glassy states in configuration space. Preliminary results on direct imaging of the current driven vortices using Hall probe microscopy will be discussed.

**A38 12 Thermodynamic Measurements at the Bragg Glass Transition in Nb*** N. D. DANIILIDIS, I. K. DIMITROV, V. MITROVIC, C. ELBAUM, X. S. LING, *Brown University* We report measurements of mixed-state entropy changes and specific-heat on a Nb single crystal, in which previous neutron scattering studies showed that an order-disorder transition of the vortex lattice occurs at the peak effect (PE). Preliminary measurements of (dS/dH) as a function of field applied in the [111] direction reveal a sharp peak at the PE. This corresponds to a discontinuity in the entropy of the vortex system of order $\Delta s = 2.7\ k_B$ per vortex per (111) Nb plane at 5.16 K. The entropy discontinuity is found to decrease and finally disappear as the multicritical[1] point is approached on increasing temperature. The behavior of S(H,T) in the vicinity of the PE shows hysteresis on increasing and decreasing field due to nonequilibrium magnetization effects. In specific heat measurements there is no sign of latent heat at the PE, indicating that the latent heat is very small in this system. [1] S. R. Park itet al. PRL **91** 167003 (2003).

**A38 13 Vortex chains decoration in anisotropic spin-triplet superconductor $Sr_2RuO_4$*** KLAUS HASSELBACH, *CRTBT-CNRS* VOICU DOLOCAN, *CRTBT-CNRS* YING LIU, *Pennsylvania State University* PASCAL LEJAY, *CRTBT-CNRS* DOMINIQUE MAILLY, *LPN-CNRS* CRTBT-CNRS TEAM, PENNSYLVANIA STATE UNIVERSITY TEAM, LPN-CNRS TEAM, We study flux structures in single crystals of the anisotropic spin triplet superconductor $Sr_2RuO_4$ by scanning microSQUID microscopy[1]. The appearance of vortex chains is noted as the applied field is tilted towards the inplane direction of the 3D superconductor. The vortex chains are easily turned in the ab plane by rotation of the inplane component of the applied magnetic field. The decoration of vortex chains by crossing vortices is observed: two vortices orientations appear, one along the layers and the other closely perpendicular to the layers. The findings are discussed in view of the Lawrence-Doniach and Ginzburg Landau models of anisotropic superconductors. Ref. 1 V.O. Dolocan PRL Vol 95 (2005) 97004

**A39 1 Current-induced phase textures and pairbreaking in multilayered structures and two-gap superconductors.** ALEX GUREVICH, *University of Wisconsin, Madison, WI* VALERII VINOKUR, *Argonne National Laboratory, Argonne, IL* We predict an inhomogeneous state in current-carrying multilayers or superconductors with multicomponent order parameters. Using the GL theory, we show that the current I flowing along a weakly coupled bilayer (with two different superconducting layers) can result in a two-stage pairbreaking process: 1. Current-induced interlayer decoupling due to a transition from the phase-locked state at $I < I_b$ to a periodic chain of interlayer $2\pi$ phase slips for $I > I_b$. This phase texture re-distributes currents between the layers, the period of the texture L(I) decreases as I increases similar to the period of the vortex lattice L(H) in a long Josephson junction. 2. The global pairbreaking at the depairing current $I_d >> I_b$. The same current-induced band decoupling and interband phase textures occur in two-gap superconductors with two weakly coupled s-wave order parameters, such as $MgB_2$.Using the Usadel equations we derive an equation for the interband phase difference valid for all temperatures. This equation shows that at small currents $I < I_b$, the $\pi$ and $\sigma$ bands are phase-locked, while for $I > I_b$, the band decoupling transition occurs as an equilibrium interband phase slip structure forms along the direction of current flow. These interband phase textures can manifest themselves in dc transport, vortex properties and nonlinear rf impedance.

**A39 2 Theory of superconducting fluctuations in magnesium diboride** ANDREI VARLAMOV, *Coherentia-INFM-CNR, via del Politecnico, 1, 00133 Rome, Italy* ALEXEI KOSHELEV, VALERII VINOKUR, *Argonne National Laboratory* A theory of fluctuations in two-band superconductor $MgB_2$ is developed. Since the standard Ginzburg-Landau (GL) approach fails in description of its properties, we generalize it basing on the microscopic theory of a two-band superconductor. Calculating the microscopic fluctuation propagator, we build up the nonlocal two-band GL functional and the corresponding time-dependent GL equations. This allows us to calculate the main fluctuation observables. Temperature dependencies of the fluctuation specific heat, magnetic susceptibility, and in-plane conductivity are determined by the same function which interpolates between two regimes: the standard GL regime very close to $T_c$, where superconductivity is described by the unique order parameter for both bands, and the regime of dominating $\sigma$-band which is settled at temperatures slightly further away from $T_c$. This work was supported by the U.S. DOE, Office of Science, under contract # W-31-109-ENG-38. A.A.V. acknowledges the support of the FIRB project of the Italian Ministry of Science and Education.

**A39 3 Multi-Gap Superconductivity in $MgB_2$: Magneto-Raman Spectroscopy** A. MIALITSIN, B.S. DENNIS, G. BLUMBERG, *Bell Labs, Lucent Technologies* N. D. ZHIGADLO, J. KARPINSKI, *ETH, Zurich* We report polarization-resolved Raman scattering measurements on $MgB_2$ single crystals as a function of excitation, temperature and magnetic field with special attention paid to the superconductivity induced electronic collective modes and phonon renormalization. In addition to the two previously reported SC features: a fundamental gap below 32 and a SC coherence peak at 109 $cm^{-1}$ - we observe a continuum onset shoulder at 48 and a collective mode at 78 $cm^{-1}$ in the $A_{1g}$ channel. Because $MgB_2$ optical conductivity exhibits inter-band excitation in the visible range resonant Raman coupling allows us to turn on and off SC features induced by different coupling mechanisms as we scan the Raman excitation energy. Since the absorption at 2.6 eV originates from distinctive inter-band transitions we are able to selectively determine inter-band coupling constant. Finally we demonstrate how the frequency and the line width of the Raman active $E_{2g}$ phonon evolve with temperature and magnetic field. Tracking this evolution across the SC phase transition illustrates the self energy effect as the electronic spectra renormalize along with the blue-shift of the $E_{2g}$ phonon.

**A39 4 Feshbach shape resonance in a superlattice of superconducting layers: the case of aluminum doped magnesium diboride*** A. BIANCONI, M. FILIPPI, M. FRATINI, V. PALMISANO, L. SIMONELLI, N. L. SAINI, *Dept. of Physics, University of Rome ''La Sapienza'' P.le. A. Moro 2, 00185 Roma, Italy* E. LIAROKAPIS, *Department of Applied Mathematics and Physics, National Technical University of Athens, GR-157 80 Athens, Greece* We have synthesized highly pure cristalline magnesium diboride samples where Mg is substituted by Al. We show that by electron doping magnesium diboride it is possible to tune the chemical potential to the Feshbach shape resonance in a superlattice of metallic layers. In this multiband superconductor in the clean limit, showing two gap superconductivity, the interband exchange like pairing term shows a Feshbach shape resonance in the proximity of the 2D to 3D Lifshitz electronic topological transition

(2D/3D ETT). This is shown that the Feshbach resonance is the key term controlling the increase of the critical temperature in the low temperature range to 40K. The variation of the electron phonon interaction is probed by micro-Raman. The 2D/3D ETT is shown by micro Raman and a lattice anomaly. The control of the nanoscale phase separation tuning the chemical potential in the proximity of the ETT is discussed. The Feshbach resonance inthe interband pairing is indicated by the suppression of the isotope coefficient in the critical temperature as a function of aluminum substitution.

**A39 5 Ground electronic state of $MgB_2$: Intrinsic nonadiabatic state at broken translation symmetry.** PAVOL BANACKY, *Comenius University* Study of the band structure of $MgB_2$has shown that electron coupling to $E_{2g}$ phonon mode induces not only $\sigma$-bands splitting at $\Gamma$ point but also fluctuation of the top of one of $\sigma$ band at the Fermi level, resulting in dramatic decrease of the Fermi energy. As a consequence, the original adiabatic state ($\omega/E_F < 1$) corresponding to the equilibrium nuclear geometry has been changed to the intrinsic nonadiabatic state ($\omega/E_F > > 1$) at distorted geometry, already at the displacement which is smaller than the rms. displacement of B-B atoms corresponding to zero-point energy of the $E_{2g}$ phonon mode. At these circumstances, not only Migdal theorem but also Born-Oppenheimer approximation has been broken, and standard treatment of EP interactions, including calculation of nonadiabatic corrections to adiabatic ground state by means of perturbation theory, can not be applied. Study of the electron-nuclear Hamiltonian by means of the quasiparticle unitary transformation (Q,P–dependent) which treats electrons and nuclei on the same footing, has revealed that EP interactions in the intrinsic nonadiabatic state stabilize the fermionic ground state of $MgB_2$ at broken translation symmetry and corresponding wave function is dependent not only on nuclear coordinates, but it is strongly modulated mainly by nuclear momenta. From the results follow that in this case, instead of Cooper pairs formation, condensation process is represented rather by real-space, T-dependent formation of mobile bipolarons.

**A39 6 Elucidating strong coupling between $E_{2g}$ phonon mode and electrons in $MgB_2$*** RICHARD PEREZ, YONG-JIHN KIM, OSWALD UWAKEH, *University of Puerto Rico - Mayaguez* ERIC HELLSTROM, *University of Wisconsin - Madison* Although the isotope effect and the Testardi correlation provide definite proof of the phonon mechanism in $MgB_2$, the detailed electron-phonon coupling is not clear yet. For instance, point contact and tunneling spectroscopy experiments show only qualitative information on the (strong) coupling between the $E_{2g}$ phonon mode and the electrons that was predicted by theory. Raman scattering and inelastic x-ray scattering demonstrate the anomalously damped and broad $E_{2g}$ phonon mode due to strong electron-phonon coupling. We follow the change of the anomalously broadened linewidth of the$E_{2g}$mode as the system becomes disordered by impurity substitution and/or ball milling. We expect that the broadening due to the electron-phonon coupling will decrease significantly when $T_c$ is reduced to zero due to weak localization. We combine Raman scattering and resistance ratio data to clarify the importance of the coupling between the $E_{2g}$ phonon mode and the electrons in $MgB_2$.

**A39 7 Electron phonon coupling and phonon renormalization in covalent metals** PEIHONG ZHANG, *SUNY - Buffalo* STEVEN G. LOUIE, MARVIN L. COHEN, *UC Berkeley* Electron-phonon (el-ph) coupling contributes to the finite lifetime of both electrons and phonons, renormalizes their energy, and is responsible for conventional superconductivity. Therefore, phonon renormalization relates directly to the el-ph coupling in metals and is a convenient indication of the coupling strength. In this talk, we will discuss phonon renormalization effects in materials with strong el-ph coupling using a recently developed formalism [1]. We will focus on covalent metals such as $MgB_2$ and related systems and heavily doped covalent semiconductors. [1] P. Zhang, S. G. Louie, and M. L. Cohen, PRL **94**, 225502 (2005).

**A39 8 Hole-doped diamond: a 3D version of MgB2?** JENS KORTUS, *Leipziger Str. 23, D-09596 Freiberg (Germany)* LILIA BOERI, OLE KROGH ANDERSEN, *Max-Planck Institut fuer FestKoerperForschung, Heisenbergstrasse 1, D-70569 Stuttgart, Germany* The discovery of superconductivity in heavily-boron doped diamond in 2004 has caused great excitement both in the fields of superconductors and of semiconductors. In this contribution we show, via first-principles and analytical calculations, that the observed superconductivity can be explained with an electron-phonon mechanism very similar to the one which is causing superconductivity in MgB2: holes at the top of the zone-centered, degenerate $\sigma$ bands couple strongly to the optical bond-stretching modes. We discuss similarities and differences between the two materials, the doping dependence of the critical temperature and the possibility to observe superconductivity in the other group-IV semiconductors.

**9:36**

**A39 9 Studying the electronic structure in pure and electron doped $MgB_2$*** Y. ZHU, R.F. KLIE, L. WU, J.C. ZHENG, *Center for Functional Nanomaterials* L.D. COOLEY, *Dept. Cond. Matt. Phys. & Mat.Sci., Brookhaven National Lab* We use high-energy electrons to reveal electronic structure information to understand the effects of electron doping in $MgB_2$ superconductors. Angle-resolved electron energy-loss spectroscopy was used to investigate the difference in the excited states, while image-coupled quantitative electron diffraction was used to map the valence electron distribution, in pure and Al-doped $MgB_2$. The results were compared with density functional theory calculations. We found significant changes in the B K-edge fine structure as a function of electron doping concentration, suggesting the corresponding $\sigma$ and $\pi$ bands are being filled simultaneously. The filling of the $\sigma$-band states near the Fermi level reduces the critical temperature $T_c$ of highly doped $MgB_2$ to a level comparable to that of other $\pi$-band superconductors such as intercalated graphite. Valence electron maps reveal that electron doping causes considerable charge transfer and accumulation in charge density between both Al-B and B-B bonds. This results in a shortened c-axis of the unit cell and higher phonon frequency, which eventually quenches su-

perconductivity altogether. The relationship between charge transfer and inter-band scattering are also examined.

**A39 10 $MgB_2$; Al and C doping, $\sigma$-band filling and anisotropy reduction** SABINA RUIZ-CHAVARRIA, PABLO DE LA MORA, *Depto. de Fis., Fac. de Ciencias, UNAM, Mexico* GUSTAVO TAVIZON, *Depto. de Fis. y Quim. Teorica, Fac. de Quimica, UNAM, Mexico* Al and C-$MgB_2$ doping adds an electron to the system for each atom. This extra electron fills up the $\sigma$-bands thus diminishing the number of $\sigma$-carriers; this has been the usual explanation for the $T_c$ reduction. Nevertheless in this work we show that there is also a large reduction of anisotropy in the electrical conductivity due to the $\sigma$-carriers which should also have an effect on the $T_c$ reduction. Al and C doping produce a different $T_c$ pattern; this difference can be largely explained by the relative shift between the $\sigma$-bands and $\pi$-bands. After adjusting to this shift there is a small but visible difference, at low doping $T_c$ in the Al compounds drops faster than in the C compounds, this can be directly related to the faster loss of conductivity anisotropy in the Al compounds.

**A39 11 Electrons and phonons in the hexagonal layered superconducting alloy $CaAl_{2-x}Si_x$** GIOVANNI B. BACHELET, *INFM and Dipartimento di Fisica, Università ''La Sapienza,'' I-00185 Roma, Italy* LILIA BOERI, *Max-Planck-Institut für Festkörperforschung, D-70569 Stuttgart, Germany* MATTEO GIANTOMASSI, *UPCPM, Université Catholique de Louvain, B-1348 Louvain-la-Neuve, Belgium* We report a first-principles study of structural, electronic and vibrational properties of the superconducting $C_{32}$ phase of the ternary alloy $CaAl_{2-x}Si_x$, both in the experimental range of stability, $0.6 \leqslant x \leqslant 1.2$, and outside, in the limits of high Al and high Si concentration. We find that the dependence of the electronic bands on composition is well described by a rigid-band model, which breaks down outside the experimental range of stability. This breakdown, in the limit of high Al concentration, is connected to vibrational instabilities, and results in important differences between $CaAl_2$ and $MgB_2$. Unlike $MgB_2$, the interlayer band and the out-of-plane phonons play a major role on the stability and superconductivity of CaAlSi and related $C_{32}$ intermetallics.

**10:12**

**A39 12 Direct observation of superconducting gap anisotropy in $YNi_2B_2C$ : Angle-resolved photoemission spectroscopy** TERUHISA BABA, *Institute for Solid State Physics., Univ. of Tokyo* TAKAYOSHI YOKOYA, *Okayama University* SHUNSHUKE TSUDA, SHIK SHIN, TADATAKA WATANABE, *Institute for Solid State Physics., Univ. of Tokyo* MINORU NOHARA, HIDEAKI TAKAGI, *Dept. of Advanced Materials Science., Univ. of Tokyo* TAMIO OGUCHI, *Dept, of Quantum Matter., Hiroshima University* In a borocarbide superconductor $YNi_2B_2C$($T_c$=15K), various experimental results have shown the existence of a gap anisotropy with node. More recently even the direction and type of node have been reported. However, the type of the nodal structure (point or line) seems to be controversial. Also, the position of the node on Fermi surfaces, which is essential for determining the origin of the large anisotropy, has not been clarified, yet. Therefore, we have performed low-temperature ultrahigh-resolution angle-resolved photoemission spectroscopy (ARPES) to clarify the origin of the large anisotropy. We successfully observed experimental valence band dispersions, Fermi surfaces, and momentum-dependent superconducting gap of $YNi_2B_2C$ (001). Superconducting gaps have shown large anisotropy. From these results, we discuss possible orgins of the large anisotropy in $YNi_2B_2C$.

**A40 3 Dynamics and scaling of multi-partite entanglement** FLORIAN MINTERT, *Harvard University* We derive reliable estimates which allow for an efficient evaluation of a specific entanglement measure, concurrence, for further implementation in the monitoring of the time evolution of multipartite entanglement under incoherent environment coupling. This allows us to define a life time of entanglement for different realistic experimental scenarios, and investigate its scaling behaviour with increasing system size.

**8:36**

**A40 4 The entanglement entropy and the Berry phase in solid states*** SHINSEI RYU, *KITP, UCSB* YASUHIRO HATSUGAI, *Dept. of Appl. Phys., Univ. of Tokyo* The entanglement entropy (von-Neumann entropy) has been used to characterize the quantum entanglement of many-body ground states in strongly correlated systems. In this talk, we try to establish a connection between the lower bound of the von-Neumann entropy and the Berry phase defined for quantum ground states. As an example, a family of 1D Hamiltonians with two bands separated by a finite gap is investigated. We argue that when the Berry phase (Zak's phase) of the occupied band is equal to $\pm\ \pi \times$ (odd integer) and when the ground state respects a discrete unitary particle-hole symmetry (chiral symmetry), the entanglement entropy in the thermodynamic limit is at least larger than ln2 (per boundary), i.e., the entanglement entropy that corresponds to a maximally entangled pair of two spins. We also discuss it is related to vanishing of the expectation value of a certain non-local operator which creates a kink in 1D systems.

**A40 7 Entanglement of overlapping systems and the breakdown of the tensor product** MATTHEW LEIFER, *Perimeter Institute for Theoretical Physics* Recent work on entanglement in the presence of superselection rules has shown that entanglement ought to be defined operationally, i.e. with respect to sets of local operations actually available to Alice and Bob rather than with respect to an arbitrary tensor product factorization of the state space. Usually Alice and Bob's local operations are assumed to commute, which is an appropriate assumption when their systems are well separated. In this talk I address the question of how far the usual formalism can be maintained if the local operations do not commute. This might be an appropriate description of the spin entanglement between two particles with overlapping spatial wavefunctions, since local operations might then have an effect on both spins. In this situation, the appropriate notion of entanglement is no longer associated to a tensor product factorization of the state space, but it can be approximated by one provided the overlap of the two systems is small and/or the preparable states are sufficiently mixed. In this talk I will present a simple model of the breakdown of the tensor product for two qubits, characterize the states that need to be prepared to observe the effect and discuss how the observed entanglement is related to the entanglement with respect to the usual tensor product factorization.

**A40 8 Modelling Pauli measurements on arbitrary stabilizer states via local hidden variables assisted by classical communication** MATTHEW ELLIOTT, BRYAN EASTIN, CARLTON CAVES, *University of New Mexico* JONATHAN BARRETT, *Perimeter Institute* STEFANO PIRONIO, *California Institute of Technology* In this talk I present communication-assisted local-hidden-variable models for measurements of products of Pauli matrices on stabilizer states. Models are analyzed with respect to restrictions imposed and their efficacy in predicting overall measurement outcomes as well as outcomes of correlated subsets of measurements. In particular, I present a model in which the quantum mechanical results of Pauli product measurements can be predicted by a local-hidden-variable table supplemented by an efficient amount of classical communication and computation.

**A40 9 Quantum Chaos, Localization, and Entanglement in Disordered Heisenberg Models** WINTON BROWN, *Dartmouth College* DAVID STARLING, *SUNY Fredonia* LEA SANTOS, LORENZA VIOLA, *Dartmouth College* We explore the relation between quantum chaos, localization, and entanglement in a two-dimensional disordered Heisenberg spin-1/2 system. Apart from the recent interest in such systems as models for proposed quantum computing architectures, they exhibit interesting transition regions from integrability to chaos and from higher to lower degree of symmetry. Complementing the standard eigenvalue-based analysis for identifying the cross-over into chaos, we suggest looking at the relative delocalization of eigenvectors related to different disorder realizations as a basis-independent indicator of chaoticity. We investigate the behavior of several measures of bipartite and multipartite entanglement – including concurrence; von Neumann entropy; and, using the framework of generalized entanglement, a family of local purities. Our results indicate that bipartite entanglement decreases in the chaotic region, whereas the opposite holds for multipartite entanglement. Connections are established with predictions from random matrix theory.

**A40 10 Entanglement Scaling at Quantum Phase Transitions in Correlated Electron Systems** DANIEL LARSSON, *Philipps-Universität Marburg, Germany* HENRIK JOHANNESSON, *Göteborg University, Sweden* We have carried out an analytic study of the entanglement scaling properties in the one-dimensional Hubbard model. We present exact scaling formulas for the local (''single-site'') entanglement $\mathcal{E}$ at a quantum phase

transition driven by a magnetic field or a chemical potential. The leading divergences of $d\mathcal{E}/dh$ and $d\mathcal{E}/d\mu$ are shown to be directly related to those of the zero-temperature spin and charge susceptibilities. Logarithmic corrections signal a change in the number of local states accessible to the system as it undergoes the transition. We show that the results for the leading divergences are generic, and follow from the scaling hypothesis that any local observable exhibits a singularity at a quantum phase transition. Illustrations from other strongly correlated electron systems are given, including the long-range Hubbard model in one dimension.

**10:00**

**A40 11 Coherent Interaction of Spins Induced by Thermal Bosonic Environment.** DENIS TOLKUNOV, DMITRY SOLENOV, VLADIMIR PRIVMAN, *Clarkson University* We obtain the indirect exchange interaction between two two-state systems, e.g., spins, in a formulation that also incorporates the quantum noise that they experience, due to an environment of bosonic modes, for instance, phonons. We predict that for low enough temperatures the interaction is coherent over time scales sufficient to create entanglement, dominated by the zero-point quantum fluctuations of the environment. We utilize a perturbative approach to obtain a quantum evolution equation for the two-spin dynamics. The induced interaction is calculated exactly. We identify the time scales for which the spins develop and sustain entanglement for various spatial separations.

**10:12**

**A40 12 Entanglement entropy of random quantum critical points with general spin** JOEL MOORE, *UC Berkeley* GIL REFAEL, *California Institute of Technology* The bipartite entanglement at 1D critical points of a subsystem of $N$ sites with the remainder is known to diverge as log$N$, with a coefficient that is related to the central charge for conformally invariant critical points. It was recently shown that for a class of spin-half random critical points, there is also a logarithmic divergence with a coefficient that is universal and corresponds to an irrational ''effective central charge.'' This talk discusses generalizations of this result to higher-spin chains, including the permutation-symmetric critical points found by Damle and Huse, using a combination of analytic and numerical real-space renormalization group methods. Higher-spin chains show numerous complications relative to the spin-half case, such as the introduction of ferromagnetic bonds; their study provides a stringent test of the conjectured $c$-theorem for central charges defined via entanglement entropy.

**A40 13 Local Entanglement and Quantum Phase Transition in Spin Models*** SHI-JIAN GU, *Department of Physics and Institute of Theoretical Physics, The Chinese University of Hong Kong, Hong Kong, China* GUANG-SHAN TIAN, *School of Physics, Peking University, Beijing 100871, China* HAI-QING LIN, *Department of Physics and Institute of Theoretical Physics, The Chinese University of Hong Kong, Hong Kong, China* In this work, we study quantum phase transitions in both the one- and two-dimensional XXZ models with either spin $S=1/2$ or $S=1$ by a local entanglement We show that the behavior of $E_v$ is dictated by the low-lying spin excitation spectra of these systems. Therefore, the anomalies of $E_v$ determine their critical points. It reminds us the well-known fact in optics: The three-dimensional image of one subject can be recovered from a small piece of holograph, which records interference pattern of the reflected light beams from it. Similarly, we find that the local entanglement, which is rooted in the quantum superposition principle, provides us with a deep insight into the long-range spin correlations in these quantum spin systems. **References:** [1] S. **A40 14 Quantum Entanglement in a Spin Ladder with Ring Exchange*** JUN-LIANG SONG, SHI-JIAN GU, HAI-QING LIN, *Institute of Theoretical Physics and Physics Department, The Chinese University of Hong Kong, Hong Kong, China* In this paper we've studied entanglement properties of a spin ladder with ring exchange. Several entanglement properties, e.g. pair concurrence and block-block entanglement were obtained by exact diagonalization method. The relationship between the global phase diagram and ground-state quantum entanglement was investigated. It was shown that block-block entanglement of different block size and configurations manifests richer information of the system. It was also found that the block-block entanglement reaches its maximum or minimum at some QPT points which is also the high symmetry point. The temperature dependence of the entanglement properties is also investigated and it is shown that entanglement is suppressed by the temperature fluctuations and vanishes at some threshold temperatures.

*This work is supported by RGC Projects CUHK 401703 and 401504.

**A40 15 Entanglement and dissipation in a quantum-dot array.** LESVIA DEBORA CONTRERAS-PULIDO, *Centro de Investigacion Cientifica y de Educacion Superior de Ensenada (CICESE)* FERNANDO ROJAS, *Centro de Ciencias de la Materia Condensada-UNAM* RAMON AGUADO, *Condensed Matter Theory, ICMM, CSIC* Primarily motivated by quantum information theory, charge in quantum dots (QD) seems to be a promising candidate for implementation of qubits and entangled states [1]. We explore theoretically the dynamical formation of entangled states, including dissipative effects, of two parallel double QD uncoupled between them but strongly coupled to the same phonon thermal bath. The QD array is modeled with an extended Hubbard type Hamiltonian and dissipation is taken into account by using a polaron transformation to obtain the reduced density matrix of the system [2]. We find that it is possible to obtain entangled electronic states through a strong electron-phonon interaction, characterized by: Wootters' concurrence, charge distribution and probabilities for each Bell state as a function of relevant parameters (hopping, temperature, electron-phonon amplitude). The work is supported by DGAPA project IN114403 and CONACyT project 43673-F [1] Hichri et al., Phys.E 24,234 (2004) [2] Aguado and Brandes, Phys.Rev.Lett.92, 206601 (2004).

**A41 1 Specific heat of liquid He-4 near the superfluid transition and confined in cylindrical channels*** TAHAR AOUAROUN, GUENTER AHLERS, *UCSB* We present new measurements of the specific heat near the lambda transition of liquid He-4 at saturated vapor pressure and confined in microchannel plates containing cylindrical holes. We investigated two channels diameters: 1$\mu$m and 2$\mu$m. Our results for the scaling function near the specific-heat maximum are in reasonably good agreement with previous measurements on channels with a 1 $\mu$m $\times$ 1 $\mu$m square cross section[1] and on cylindrical channels with a 0.26$\mu$m diameter[2]. They also are consistent with the scaling function derived from Monte Carlo calculations.[3] However, they suggest a size- dependent systematic departure from a unique scaling function that is consistent with earlier measurements[3] on cylindrical channels of 8$\mu$m diameter.

**A41 2 Deformation and damage in silica aerogels during fluid filling*** TOBIAS HERMAN, JOHN BEAMISH, *University of Alberta* Interfaces are present throughout any porous medium during fluid adsorption below the liquid-vapor critical point. Surface tension in these curved liquid-vapor interfaces produces the pressure difference between the two phases which is responsible for capillary condensation. The surface tension also exerts a force on the solid, although it is usually much smaller than the elastic moduli of the porous medium. Aerogels, however, have extremely small elastic moduli so surface tension induced deformation can be significant and even destructive. We present measurements of the dilation and compression of two silica aerogels (densities 110 and 51 kg/m$^3$) during adsorption and desorption of low surface tension fluids (helium and neon). The denser aerogel changed its length by up to 2% during adsorption of helium, still within its elastic regime; the lighter aerogel shrank by even larger amounts and appeared to sustain permanent damage.

**A41 3 Cryogenic Pulsed Laser Deposition of Lithium for $^4$He Absorption Experiments** E. VAN CLEVE, P. TABOREK, J.E. RUTLEDGE, *University of California, Irvine* We are developing techniques to prepare films of alkali metals on cryogenic surfaces by laser ablation. The alkali metals are known to provide weak adsorption potentials for $^4$He which results in nontrivial wetting and superfluid onset phenomena. Film preparation technique strongly affects some $^4$He wetting properties as has been seen in contact angle measurements of $^4$He on Cs surfaces. Of particular interest are Li surfaces which at low temperatures are predicted (1) to be superfluid with less than monolayer total $^4$He coverage. We have grown Li films on using 532 nm light from an Nd-YAG laser on to room temperature quartz crystal microbalances (QCM). We will present measurements of film growth rate as a function of the laser fluence. Preliminary $^4$He isotherm measurements on Li films laser ablated onto 4K QCMs will be compared with adsorption isotherms on the heavier alkali metal surfaces. (1) Massimo Boninsegni and Milton W. Cole, J. Low Temp. Phys. 113, 393 (1998).

**A41 4 Acoustic crystallization*** SEBASTIEN BALIBAR, RYOSUKE ISHIGURO, FREDERIC CAUPIN,[†] *ENS-Paris* By focusing high intensity acoustic waves in the middle of a liquid, it is possible to pressurize it far beyond its solid-liquid equilibrium pressure. This is because, in the absence of walls or defects, the nucleation of crystals needs to be ''homogeneous,'' and that the threshold pressure for this phenomenon is usually very high. In a classical liquid, the viscosity increases with pressure so that the dynamics blocks as the pressure is increased and a transition to a glassy state occurs. However, we did not expect this to occur in a superfluid, and we looked for acoustic crystallization in liquid helium. We have found evidence that an acoustic wave travelling in superfluid helium can indeed crystallize this liquid on its path. We relate this phenomenon to the existence of an instability where Landau's ''rotons'' become soft modes. We discuss further developments of this experiment in relation with the existence of superfluidity in a very dense liquid.

**A41 5 Bose-Einstein Condensation and atomic kinetic energies in liquid $^3$He-$^4$He mixtures*** SOULEYMANE DIALLO, *University of Delaware* JONATHAN PEARCE, *Institut Laue Langevin* RICHARD AZUAH, *NIST Center for Neutron Research* HENRY GLYDE, *University of Delaware* We present neutron scattering measurements of the momentum distribution of liquid $^3$He-$^4$He mixtures. The experiments were performed at wavevectors $Q$, 26 $\leqslant$ $Q \leqslant$ 29 Å$^{-1}$, on the MARI time-of-flight spectrometer at the ISIS pulsed spallation neutron source. Mixtures with $^3$He concentrations $x$ between 0 and 20% were investigated both in the superfluid and normal phases. From the data, we extract, to new accuracy, the Bose-Einstein condensate fraction $n_0$ and the momentum distributions of $^3$He and $^4$He atoms. We find an increase in $n_0$ above the pure $^4$He value; from 7.25$\pm$ 0.75% ($x$ = 0%) to 11.2 $\pm$ 1.85% at $x$ = 15%, in agreement with theoretical calculations but in disagreement with the only other measurement. The $^4$He kinetic energy, \kef, is found to be largely independent of $x$. The $^3$He momentum distribution $n(\mathbf{k})$ is not well fitted with a Fermi step function alone. A high momentum tail in $n(\mathbf{k})$ is needed to get a good fit - a tail that is consistent with calculated tails in $n(\mathbf{k})$. The $^3$He atomic kinetic energy, $K_3$, is determined almost entirely by this tail. It is therefore not a well determined single property for comparing theory and experiment. This finding resolves a long-standing discrepancy on $K_3$ between theory and experiment.

**A41 7 Bilayer Thermometers for Third Sound Detection*** J.D. CUMMINGS, R.B. HALLOCK, *Univ. of Mass. Amherst* We present results from an experiment to develop bilayer metallic films of aluminum and gold as superconducting transition edge thermometers for the detection of third sound waves. Generally, traditional transition edge thermometers operate in a temperature range that is dictated by the choice of superconductor, e.g. $\sim$ 1.5K for aluminum and $\sim$ 0.8K for zinc, which is tunable over a modest range by application of a magnetic field or bias current. Bilayers offer the option of selecting the optimal transition temperature for an experiment to be done by adjusting the ratio of normal metal (Au) thickness to the superconductor (Al) thickness. This allows a detector to be designed to operate at any temperature below the transition temperature for the pure superconducting film. We will present transition edge data for such thermometers and document their utility for third sound detection.

**A41 9 SQUID NMR Studies of Two-Dimensional $^3$He Films on HOPG ZYX Graphite** JINSHAN ZHANG, LEI GUO, YULIANG DU, C.M. GOULD, H.M. BOZLER, *Dept. of Physics & Astronomy, Univ. of Southern California, Los Angeles, CA 90089* SQUID NMR experiments on the second layer of $^3$He films on Grafoil substrates in the low field limit found ferromagnetic ordering for coverages over 20 atoms/nm$^2$. The appearance of ordering in a two-dimensional magnetic film can be caused by weak anisotropy and/or dipolar interactions, or could be a manifestation of finite size effects. By replacing Grafoil with Highly Oriented Pyrolytic Graphite (HOPG) ZYX grade, we increased the substrate structural coherence length by a factor of 10 in order to study the importance of finite size effects through a magnetization measurement on 2-D $^3$He films. Our recent experiments found the ferromagnetic ordering temperature to be the same or higher on ZYX than on Grafoil at coverages over 20 atoms/nm$^2$, showing no evidence for an increased suppression of the ordering due to the increasing coherence length. We also saw evidence for bound spin waves in the ordered layer. Studies in the coverage range 20-24 atoms/nm$^2$ are complicated by the possibility of coexistence of two phases. Recently we extended our measurements to higher coverages where the situation is less complicated and a single incommensurate solid phase is formed unambiguously. We report on these studies which continue to support the picture of a 2-D magnetically ordered solid. *Supported by NSF through grant DMR-0307382

**A41 10 Ultrasonic Spectroscopy in Liquid $^3$He in 98% Porosity Aerogel by Direct Propagation*** H.C. CHOI, N. MASUHARA, J.-H. PARK, M.W. MEISEL, Y. LEE, *Dept. of Physics, University of Florida, P.O. Box 118440, Gainesville, FL 32611, USA* N. MULDERS, *Department of Physics and Astronomy, University of Delaware, Newark, DE 19716, USA* Systematic investigations on the effect of static disorder on itp-wave superfluid $^3$He have been made possible by utilizing its unique structure of high porosity silica aerogel. For the past 10 years, a burst of experimental effort revealed that three distinct superfluid phases exist in the P-H-T phase diagram of the $^3$He/98% aerogel system. These three phases are conveniently named the A-, B-, and $A_1$-phases as in the bulk, although only spin structures of the superfluid phases have been identified. In particular, the verdict on the so called A-phase is by no means conclusive. As has been the case in the bulk, for a clear identification of the order parameter structure, both spin and orbital components need to be examined. We report our preliminary results of sound propagation in an attempt to directly investigate the orbital structure of the superfluid phases in 98% aerogel using a pulsed ultrasound spectroscopic technique. Preliminary data for the transmission and the surface impedance will be presented.

**A41 12 Spin Relaxation Phenomenon in Superfluid $^3$He $A_1$*** H. KOJIMA, *Rutgers University* S. KOBAYASHI, A. YAMAGUCHI, H. ISHIMOTO, *Institute for Solid State Physics* The spin relaxation phenomenon in superfluid $^3$He $A_1$ phase is studied using a newly constructed magnetic fountain pressure cell in which two reservoirs are connected via a superleak channels of height 20 $\mu$m. Experiments are carried out to explore the relaxation mechanism of the induced fountain pressure under externally applied magnetic field gradient along the superleak. The relaxation of fountain pressure reflects that of spin density. The observed relaxation time $\tau$ varies from less than 1 s near $T_{c2}$ to about 80 s near $T_{c1}$. The maximum relaxation time may be limited by the normal fluid flow in the channels. Near $T_{c2}$, the observed relaxation rate may be described by a power law dependence on reduced temperature as $1/\tau \propto [(T - T_{c2})/(T_{c1} - T_{c2})]^{-\beta}$, where $\beta \approx 1.5$ and has little dependence on the static magnetic field(up to 8 tesla) and liquid pressure(10 - 29 bars). To our knowledge, there is no theory which predicts such increase in relaxation rate over a relatively large temperature range near $T_{c2}$. A preliminary interpretation is given in terms of intrinsic spin relaxation arising from small but increasing presence of minority spin pair condensate in $A_1$ phase as $T_{c2}$ is approached.

**A41 13 Measurements of Longitudinal and Transverse NMR Frequencies in Superfluid $^3$He using dc SQUID Detectors*** YULIANG DU, H.M. BOZLER, C.M. GOULD, *University of Southern California* The most important tools in the initial identification of the order parameters of the superfluid phases of $^3$He in bulk were longitudinal and transverse NMR because the detailed comparison of these frequencies and their magnetic field dependences strongly differentiated between alternative models. In contrast, for superfluid $^3$He confined within aerogel, longitudinal resonance has not been measured to date, having only been inferred from transverse measurements and the simple sum of squares relation known to hold for the axial state in bulk. This relationship has not been confirmed for the aerogel-confined phase, and there are theoretical suggestions that it may not be valid. We have begun an experiment to directly compare longitudinal and transverse resonance frequencies in aerogel-confined superfluid $^3$He using some of the same dc SQUID NMR techniques we have developed over the last 20 years in our lab. In initial experiments to prove the technique, we are making optimal use of the broadband nature of the dc SQUID detector and have measured the superfluid's longitudinal response to a sudden field step.

**A42 1 Electronic structure and phase transition in iron bearing minerals.**
STEFANO DE GIRONCOLI, *SISSA and DEMOCRITOS – Trieste*

First-principles calculations are playing an important role in the development of our understanding of Earth interior. A proper treatment of iron bearing minerals is fundamental in this respect. Unfortunately standard DFT approaches such as the local density (LDA) or generalized gradient (GGA) approximations fail in describing even qualitative features of even simple iron minerals, such as the insulating nature and magnetic structure of many oxides. DFT+U approximation has demonstrated to improve significantly the physical description of transition metal and rare earth compounds. In order to make DFT+U a really ''ab-initio'' approach, an internally consistent determination of the involved U parameter is however needed. In alternative computationally more demanding, but supposedly more accurate, approaches such as PBE0 or B3LYP Hartree-Fock-DFT hybrid functionals can be explored. I'll report on my recent research on these subjects, focussing on iron oxide, magnisium-wustite high-spin-low-spin phase transition, and ematite.

**A42 4 Ab Initio Study of Thermodynamics of Fe and Spin Transitions in the Lower Mantle** DANE MORGAN, AMELIA BERTA, *University of Wisconsin - Madison* KRISTIN PERSSON, GERBRAND CEDER, *Massachusetts Institute of Technology* Recent experiments have demonstrated spin transitions in Fe in both the rocksalt ferropericlase (Mg,Fe)O and perovskite (Mg,Fe)$SiO_3$ phases at lower mantle pressures. The spin transitions have potentially profound implications for the materials properties of the lower mantle. However, the coupling of thermodynamic temperature effects and the spin transition is still poorly understood. In this talk we present an ab initio based thermodynamic model for Fe spin transitions in lower mantle phases. We build a free energy model which includes configurational, vibrational, magnetic, and electronic contributions. The resulting free energy expressions are used to construct a phase diagram for the lower mantle ferropericlase which includes the impact of Fe spin transitions.

**A42 5 Effects of the Spin Transition of Iron in Magnesiowüstite-(Mg,Fe)O: Applications to the Earth's Lower Mantle.***

JUNG-FU LIN, *Lawrence Livermore National Laboratory*

Magnesiowüstite [(Mg,Fe)O] is the second most abundant mineral in the Earth's lower mantle. Here I will discuss the spin states of iron in magnesiowüstite and the isolated effects of the electronic transitions on the elastic, thermodynamic, magnetic, and vibrational properties of magnesiowüstite under high pressures and high temperatures. Pressure-induced electronic spin transitions of iron from high-spin to low-spin states have been recently observed to occur in magnesiowüstite under high pressures using high-pressure X-ray emission spectroscopy and synchrotron Mössbauer spectroscopy. Based on the synchrotron Mössbauer studies of $(Mg_{0.75},Fe_{0.25})O$, the simultaneous disappearance of the quadrupole splitting and the drop of the isomer shift at above 62 GPa are consistent with a high-spin to low-spin electronic transition of iron in the sample between 62 and 70 GPa. Addition of FeO in MgO stabilizes the high-spin state to higher pressures and the high-spin to low-spin transition of iron in magnesiowüstite results in an abnormal compressional behaviour between the high-spin and the low-spin states[1]. Moreover, there are also significant changes in particular physical properties of magnesiowüstite such as force constant across the electronic spin transition. Here I have combined results from a variety of high-pressure techniques to understand the effects of the electronic transition on the physical properties of magnesiowüstite and to explore possible geophysical consequences of the transition in the Earth's lower mantle. [1]J. F. Lin, V. V. Struzhkin, S. D. Jacobsen, M. Hu, P. Chow, J. Kung, H. Liu, H. K. Mao, and R. J. Hemley, Spin transition of iron in magnesiowüstite in Earth's lower mantle, itNature, 436, 377-380, 2005.

**A42 6 Electronic Spin State and Elasticity of (Mg, Fe)(Si, Al)O3-perovskite at high pressure** LI LI, DONALD WEIDNER, *Stony Brook University* JOHN BRODHOLT, STEPHEN STACKHOUSE, MARIA ALFREDSSON, DAVID PRICE, *Universtiy College London* We investigate the effect of pressure on the electronic spin state of ferric iron in Al-bearing $MgSiO_3$-perovskite using first-principle computations (Density Functional Theory with the Generalized Gradient Approximation). We also calculate the single crystal elastic moduli ($c_{ij}$) for (Mg, $Fe^{3+}$)(Si, Al)$O_3$ perovskite to understand the effect of chemical variations and spin state transitions of the $Fe^{3+}$ ions on these properties. Ferric iron (6.25 mol%) and Al (6.25 mol%) substitute for Mg and Si respectively. Our results show that spin state transition from high spin (HS) to low spin (LS) occurs on the $Fe^{3+}$ ions at high pressure, while there is no stability field for the intermediate spin state. Fe $^{3+}$ alone can be responsible for the spin state transition. The models witness a transition pressure ranging from 97-126 GPa. Differential stress can change the pressure for the spin collapse. These results are one explanation to the reported experimental observations that the spin transition occurs over a wide pressure range. We find that ferric iron lowers the elastic moduli relative to the Al charge-coupled substitution. The spin state of the iron for this composition has a relatively small effect ( $<$ 0.5% variation) on both bulk modulus and shear modulus. Replace this text with your abstract body.

**A42 7 Theory of magnesium silicates with bearing Fe and Al in the lower mantle and the Earth's D'' layer*** FEIWU ZHANG,[†] ARTEM OGANOV,[‡] *ETH Zurich* Although iron and aluminum incorporation into Earth's mantle minerals are expected to have important effects, little is known about Fe valence and spin state in such major phases as $MgSiO_3$ perovskite (itPv, main mineral of the lower mantle) and post-perovskite (itPPv, main mineral of the Earth's D'' layer). Here, we perform itab initio simulations, indicating that $Fe^{2+} \rightarrow Fe(metal) + Fe^{3+}$ in itPv& itPPv. A new detailed microscopic picture of $MgSiO_3$ itPv& itPPv is presented, including the complexity of Fe-Al incorporation, the spin transitions in $Fe^{3+}$ and lack of such in $Fe^{2+}$, and the effects of $Fe^{2+}$,

$Fe^{3+}$, $Al^{3+}$ on the stability of itPPv. These theory results explain and reconcile the recent diverse experimental results on the iron-spin transition in $MgSiO_3$ and provide basis for future geodynamical and petrological studies of the mantle and the D'' layer.

**A42 8 High Pressure studies on nanoparticles of gamma $Fe_2O_3$** ARUN BOMMANNAVAR, MADDURY SOMAYAZULU, *HPCAT, Advanced Photon Source, Chicago* VAMAN NAIK, *University of Michigan-Dearborn* RATNA NAIK, *Wayne State University* Compressibility of the gamma phase of $Fe_2O_3$ (Maghemite) nano-particles was studied using angle dispersive x-ray diffraction on the micro-diffraction beamline at HPCAT of the Advanced Photon Source. Nano-particles of three different sizes (3 and10 and 20 nm) were studied up to 31 GPa using a diamond anvil cell equipped with c-BN seats. Two samples were synthesized by treating sulfonated divinyl benzene polystyrene resin matrix with aqueous solutions of (1) FeCl2,(2) $FeCl_3$. The particle size of $\gamma$-$Fe_2O_3$ prepared using FeCl3 was $\sim$ 3 nm and with FeCl2 was $\sim$ 10 nm. The 20 nm particle size sample was bought commercially. The bulk modulii for 10 nm and 20 nm samples were 212 (5) and 207 (5) GPa which are close to the bulk value of 203 (10) GPa, whereas 3.4 nm sample shows a higher value of 240 (5) GPa. Transition pressure ($P_{tr}$) at which maghemite transforms to hematite varies with particle size and was estimated to be 10 (2) GPa, 17 (2) GPa and 27 (2) GPa for 3 nm, 10 nm and 20 nm particle size samples, respectively.

**10:24**

**A42 9 Composition Dependence of Pressure-Induced Spin Transitions in the (Mg,Fe)SiO3 Perovskite and (Mg,Fe)O Rocksalt System** AMELIA BERTA, *University of Wisconsin-Madison* KRISTIN PERSSON, *Massachusetts Institute of Technology* GERBRAND CEDER, *Massachusetts Institute of Technology* DANE MORGAN, *University of Wisconsin-Madison* Recent experimental results suggest that Fe undergoes a high-spin to low-spin transition in both the rocksalt and perovskite phases at lower mantle pressures. These spin transitions may have a profound impact on the properties of lower mantle phases. In this work the critical spin-transition pressures for Fe in perovskite $(Mg,Fe)SiO_3$ and rocksalt (Mg,Fe)O are calculated using itab initio methods. We focus in particular on the alloy nature of the material, studying the spin-transition pressure for varying concentrations of Fe. The results show that as the concentration of Fe increases, the transition pressure decreases in the perovskite. This is directly opposite the trend observed for spin transition pressures found in rocksalt (Mg,Fe)O. The difference in trends in spin-transition pressure is explained by the difference in physics between the two structures.

**A43 1 A Two-Channel R-Matrix Analysis of Magnetic Field Induced Feshbach Resonances** PAUL JULIENNE, *National Institute of Standards and Technoloy* NICOLAI NYGAARD, *Aarhus University* BARRY SCHNEIDER, *National Science Foundation* A two channel model of magnetic field induced Feshbach resonances in ultra-low atom-atom collisions is presented. The model uses realistic potentials and is parametrized using available theoretical and experimental data to reproduce the known low-energy scattering properties of the colliding atoms. The coupled equations are solved using the R-Matrix method, expanding the wavefunction in a Finite Element Discrete Variable basis. This basis enables us to capture both the short-range behavior of the molecular vibrational states as well as the long-range scattering states. Results will be presented showing the behavior of the wavefunctions and T- matrices as a function of the external magnetic field for selected alkali atom pairs.

**8:12**

**A43 2 Many-body Feshbach Hamiltonians in the two-body limit.** NICOLAI NYGAARD, *University of Aarhus* JAMES E. WILLIAMS, PAUL S. JULIENNE, *NIST* We discuss how the many-body theory of a gas with interactions controlled by a Feshbach resonance can be constructed in a manner, which incorporates the correct two-body physics. This entails the introduction of an energy dependent renormalized coupling constant for atom-molecule conversion that embodies the low energy scattering properties of the entrance channel potential. We demonstrate that with this model the binding energies of the dressed Feshbach molecules may be faithfully reproduced.

**8:24**

**A43 3 Properties of the BCS-BEC condensate in the BEC regime** JESPER LEVINSEN, VICTOR GURARIE, *University of Colorado at Boulder* We study a gas of fermions undergoing a wide resonance s-wave BCS-BEC crossover, in the BEC regime at zero temperature. We calculate the chemical potential and the speed of sound of this Bose-condensed gas, as well as the condensate depletion, in the low density approximation. We discuss how higher order terms in the low density expansion can be constructed. We demonstrate that the standard BCS-BEC gap equation is invalid in the BEC regime and is inconsistent with the results obtained here. The low density approximation we employ breaks down in the intermediate BCS-BEC crossover region. Hence our theory is unable to predict how the chemical potential and the speed of sound evolve once the interactions are tuned towards the BCS regime. As a part of our theory, we derive the well known result for the bosonic scattering length diagrammatically and check that there are no bound states of two bosons.

**A43 5 Radio frequency spectroscopy and the pairing gap in trapped Fermi gases*** YAN HE, QIJIN CHEN, KATHRYN LEVIN, *University of Chicago* We present a theoretical interpretation of radio-frequency (RF) pairing gap experiments in trapped atomic Fermi gases, over the entire range of the BCS-BEC crossover, for temperatures above and below $T_c$. Our calculated RF excitation spectra, as well as the density profiles on which they are based, are in semi-quantitative agreement with experiment. We provide a detailed analysis of the physical origin of the two different peak features seen in RF spectra, one associated with nearly free atoms at the edge of the trap, and the other with (quasi-)bound fermion pairs. **A43 6 Dynamical projection of atoms to Feshbach molecules at strong coupling.** ROMAN BARANKOV, *UIUC* LEONID LEVITOV, *MIT* An interesting method of atomic state projection to the Feshbach molecules using the magnetic field sweep through the resonance was employed in the recent experiments [1]. The sweep could be made very fast compared to typical fermion time scales, such as the collision frequency or inverse Fermi bandwidth, making the process a ''snapshot probe'' with regard to the collective fermion processes. On a single particle level, broad Feshbach resonances studied in Ref.[1], exhibit strong atom-molecule coupling in a relatively wide detuning range. In this sense, the sweep speed [1] corresponds to essentially adiabatic atom/molecule conversion, slow on the scale of the resonance width. We develop a theory [2] that describes molecules at a sweep fast compared to the elastic collisions, when only the quantum-mechanical processes involving two atoms transition into a molecule are relevant. Our approach accounts for resonance dissociation/association in the presence of time-dependent detuning as well as for fermion pairing correlations in the initial state. An exact solution is found, predicting a 1/3 power law dependence on the inverse sweep rate for molecule production efficiency at fast sweep. The predicted production efficiency agrees with experimental observations for both condensed and incoherent molecules away from saturation. [1] C. A. Regal, *et al.*, Phys. Rev. Lett. **92**, 040403 (2004); M. W. Zwierlein, *et al.*, Phys. Rev. Lett. **92**, 120403 (2004) [2] R. A. Barankov and L. S. Levitov, cond-mat/0506323

**A43 7 Dressed Feshbach molecules in the BEC-BCS crossover** MATHIJS ROMANS, HENK STOOF, *Utrecht University* There has been a lot of interest in Feshbach resonances and the BEC-BCS crossover that is associated with it. We present work that describes the crossover in terms of dressed molecules, and gives a theory to calculate the internal structure of the paired state. We integrate out the fermions exactly, and take into account the fluctuations of the molecular field to determine the probability $Z$ for dressed molecules to be in the closed channel state. Our approach includes the relevant two-body physics completely. Also the density of condensed and noncondensed dressed molecules can be determined for the entire BEC-BCS crossover. We compare our results to experiment.

**9:48**
**A43 8 Two-fluid hydrodynamic modes in a trapped Fermi superfluid gas*** EDWARD TAYLOR, ALLAN GRIFFIN, *University of Toronto* In the collisional region at finite temperatures, the collective modes of superfluids are described by the Landau two-fluid hydrodynamic equations. This region can now be probed over the entire BCS-BEC crossover in trapped Fermi superfluids with a Feshbach resonance. We have recently developed a variational formulation of the two-fluid hydrodynamic equations that greatly simplifies calculations of the collective modes in trapped superfluid gases. The frequencies are given in terms of effective spring constants involving spatial integrals over position-dependent equilibrium thermodynamic functions. We present results based on this theory using the LDA and thermodyanmic functions for a uniform gas in the BCS-BEC crossover region, with pair fluctuations included using the Nozières and Schmitt-Rink approximation. The temperature dependent out-of-phase hydrodynamic modes (the analogue of second sound) are of particular interest.

**A43 9 Sound in a strongly-interacting Fermi gas*** BASON CLANCY, LE LUO, J. KINAST, J. JOSEPH, A. TURLAPOV, J.E. THOMAS, *Duke* Sound propagation in an optically-trapped gas of strongly interacting fermionic $^6$Li atoms is studied. The atoms are prepared as a 50/50 mixture of the two lowest-energy internal states. Strong interactions are achieved by applying a magnetic field in the vicinity of a broad (834 G) s-wave Feshbach resonance. A sound wave is excited by locally applying a pulse of a repulsive blue-light potential. We measure the propagation of the excitation along the axial direction of the cigar-shaped cloud.

**A43 10 Potential-energy (BCS) to kinetic-energy (BEC)-driven pairing in the attractive Hubbard model*** BUMSOO KYUNG, *University of Sherbrooke* ANTOINE GEORGES, *Centre de Physique Théorique, École Polytechnique* ANDRE-MARIE TREMBLAY, *University of Sherbrooke* UNIVERSITY OF SHERBROOKE COLLABORATION, CENTRE DE PHYSIQUE THÉORIQUE, ÉCOLE POLYTECHNIQUE COLLABORATION, The BCS-BEC crossover within the two-dimensional attractive Hubbard model is studied by using the Cellular Dynamical Mean-Field Theory both in the normal and superconducting

ground states. Short-range spatial correlations incorporated in this theory remove the normal-state quasiparticle peak and the first-order transition found in the Dynamical Mean-Field Theory, rendering the normal state crossover smooth. For $U$ smaller than the bandwidth, pairing is driven by the potential energy, while in the opposite case it is driven by the kinetic energy, resembling a recent optical conductivity experiment in cuprates. Phase coherence leads to the appearance of a collective Bogoliubov mode in the density-density correlation function and to the sharpening of the spectral function.

**A43 11 Many-body Effects near s- and p-wave Feshbach resonance in BEC-BCS Problem: A Tractable Crossing-symmetric Approach*** KHANDKER QUADER, RENYUAN LIAO, *Department of Physics, Kent State University* In the fermion BEC-BCS crossover problem. many-body effects may influence properties, such as scattering parameters, nature of pairing, etc. close to a Feshbach resonance. We study effects such as these using a tractable diagrammatic crossing-symmetric approach. Our method allows us to include quantum fluctuations, such as, density, current, spin, spin-current, and higher-order fluctuations in a self-consistent fashion. The underlying fermionic interaction is reflected in the ''driving'' term. Taking the ''driving'' term to be finite-range, and of arbitrary strength, we perform calculations on the BEC and BCS sides. These are related to the 2-body singlet and triplet scattering parameters, and can be connected with experimental s and p-wave Feshbach resonances. We include the l=0 density and spin fluctuations, as well as the l=1 current and spin-current fluctuatiuons. We obtain renormalized scattering amplitudes, pairing amplitudes and nature of pairing, etc. on the BEC and BCS side. We compare our results with experiment, and with other theory calculations.

**A43 12 Critical Rotating Frequency for Superfluid Fermionic Gases across Feshbach Resonance** HUI ZHAI, *Department of Physics, the Ohio State University* TIN-LUN HO, *Department of Physics, the Ohio State University* Vortex lattices have been observed recently in the rotating Fermionic quantum gases near Feshbach resonance. However, a much faster rotation may destroy the superfluid pairing amplitude and reveal the normal state. In this talk, we present the phase diagram for different interaction strength and rotating frequency. We discover that at resonance, pairing is so robust that it can not be destroyed by rotation. In the BCS side close to resonance, we find that the critical frequency as a function of interaction strength shows a series of plateaus as a consequence of quantized Landau levels. In a fast rotating harmonic trap, the superfluid core with vortices is surrounded by a normal cloud, and the area of the superfluid regime gradually shrinks as the increase of the rotating frequency.

**A45 1 Optical evidence for a magnetically driven structural transition in the spin web $Cu_3TeO_6$** L. DEGIORGI, G. CAIMI, *ETH Zurich* H. BERGER, L. FORRO', *EPF Lausanne* $Cu_3TeO_6$ is a modest frustrated $S = 1/2$ spin system, which undergoes an anti-ferromagnetic transition at $T_N \sim 61$ $K$. The anti-ferromagnetic spin alignment in $Cu_3TeO_6$ below $T_N$ is supposed to induce a magneto-elastic strain of the lattice. The complete absorption spectrum of $Cu_3TeO_6$ is obtained through Kramers-Kronig transformation of the optical reflectivity, measured from the far-infrared up to the ultraviolet spectral range as a function of temperature ($T$). Below $T^* \sim 50$ $K$, we find a new mode at 208 $cm^{-1}$. The spectral weight associated to this additional mode increases as $\propto (T^* - T)^{1/2}$ with decreasing $T$ below $T^*$. The implication of the optical findings will be discussed in relation to the magnetic phase transition at $T_N$.

**8:12**

**A45 2 Transport Anisotropy due to Spiral Spin Order in Underdoped Cuprates** VALERI KOTOV, *Boston University* OLEG SUSHKOV, *University of New South Wales* I will discuss the in-plane transport anisotropy in the spin-glass phase of $La_{2-x}Sr_xCuO_4$ within a theoretical scenario where the physics is purely spin driven (no charge order is present), and a spiral spin density wave is formed in the ground state. Such an approach is well justified for the extended t–J model at low doping. In the low-temperature, variable-range hopping regime, the calculated anisotropy of 50–80 percent (depending on temperature) is in excellent agreement with experiment [1], demonstrating that charge ordering tendencies are not necessary to explain the observed transport anisotropy. This work is part of a series in which we show that the spiral approach provides a consistent description of the low-doping region. [1] V.N. Kotov and O.P. Sushkov, Phys. Rev. B 72, 184519 (2005).

**8:24**

**A45 3 High Energy Spin Dynamics in the electron-doped high-$T_c$ cuprate $Pr_{.88}LaCe_{.12}CuO_4$ ($T_c$=21K)*** STEPHEN WILSON, SHILIANG LI, *University of Tennessee* PENGCHENG DAI, *University of Tennessee/Oak Ridge National Laboratory* HYUNGJE WOO, *University of Tennessee* CHRIS FROST, *ISIS Rutherford Appleton Laboratory* HERB MOOK, *Oak Ridge National Laboratory* YOICHI ANDO, SEIKI KOMIYA, *CRIEPI, Japan* We use high-resolution inelastic neutron scattering to study the low-temperature magnetic excitations of electron-doped superconducting $Pr_{0.88}LaCe_{0.12}CuO_{4-\delta}$ ($T_c$=21 K) over a wide energy range (4 meV$<$ hbar $\omega <$ 260 meV). The effect of electron-doping and superconductivity is to cause a wave vector broadening in the low-energy ( $<$ 50 meV) commensurate spin fluctuations at ($\pi$, $\pi$) and to suppress the intensity of spin-wave-like excitations at high energies ( $>$ 80 meV). This leads to a substantial redistribution in the spectrum of the local dynamical spin susceptibility $\chi''(\omega)$, and reveals a new energy scale considerably

smaller than that of the hole-doped materials [1]. [1] Stephen D. Wilson et. al., PRL submitted (2005).

**8:36**

**A45 4 Magnetic and transport properties of lightly doped $La_{2-x}Sr_xCuO_4$** V. JURICIC, M.B. SILVA NETO, C. MORAIS SMITH, *Inst. for Theoretical Physics, Univ. of Utrecht, The Netherlands* L. BENFATTO, *Dept. of Physics, Univ. of Rome ''La Sapienza,'' Italy* A.O. CALDEIRA, *Inst. of Physics, Univ. of Campinas, Brazil* We address the problem of the static magnetic correlations in $La_2CuO_4$ [1] and lightly doped $La_{2-x}Sr_xCuO_4$ within the framework of a dipolar frustration model for a canted antiferromagnet [2]. We show that the Dzyaloshinskii-Moriya and XY anisotropies are responsible for robustness of the Neel state for $x < 2\%$ while, for higher doping, the antiferromagnetic ground state is unstable towards a helicoidal magnetic phase. The helicoidal spin structure gives rise to incommensurate peaks in elastic neutron scattering, and is consistent with recent Raman and magnetic susceptibility experiments in $La_{2-x}Sr_xCuO_4$. We propose that the dissipative dynamics of topological defects in a spiral state is responsible for the transport properties in the spin-glass phase of cuprates [3]. The calculated damping matrix is related to the in-plane resistivity, which exhibits an anisotropy and linear temperature dependence in agreement with experimental data. References: [1] M. B. Silva Neto, L. Benfatto, V. Juricic, and C. Morais Smith, cond-mat/0502588. [2] V. Juricic, M. B. Silva Neto, and C. Morais Smith, cond-mat/0510312. [3] V. Juricic, L. Benfatto, A. O. **A45 5 High binding energy band structure of Bi-2212 as measured by ARPES** K. MCELROY, J. GRAF, *MSD, Lawrence Berkeley National Laboratory, California* G.-H. GWEON, S.Y. ZHOU, *Department of Physics, UC Berkeley, California* S. SAHRAKORPI, M. LINDROOS, R.S. MARKIEWICZ, A. BANSIL, *Physics Department, Northeastern University, Boston MA* H. EISAKI, *AIST, Tsukuba, Japan* T. SASAGAWA, H. TAKAGI, *Department of Advanced Materials Science, U of Tokyo, Japan* S. UCHIDA, *Department of Physics, U of Tokyo, Tokyo, Japan* A. LANZARA, *Department of Physics, UC Berkeley, California* The study of the electronic structure of high temperature superconductors by angle resolved photoemission spectroscopy (ARPES) has so far focused on the states near the Fermi level, believed to be fundamental for most of the properties of cuprates. However, it is well known that in doped Mott insulators the low and high energy physics are strongly coupled one to the other. Therefore, to gain insight on the real physics of cuprates a full characterization of the electronic band structure up to energies of the order of the lower Hubbard band and beyond is needed. Here we report a detailed, doping dependent study of the band structure of Bi2212 superconductors at energies of the order of 1-2 eV. The experimental results are interpreted in terms of local density approximation (LDA) based computations, where the presence of the ''spaghetti'' of Cu-O and O-bands is predicted. Comparison between computed and measured bands provides insight into many-body renormalization effects.

**A45 6 Unidirectional Order and 3D Stacking of Stripes in Orthorhombic $Pr_{1.67}Sr_{0.33}NiO_4$ and $Nd_{1.67}Sr_{0.33}NiO_4$.** MARKUS HÜCKER, JOHN M. TRANQUADA, GEN D. GU, *Brookhaven National Laboratory* MARTIN V. ZIMMERMANN, *HASYLAB at DESY, Hamburg, Germany* BERND K. BÜCHNER, *IFW Leibniz-Institute, Dresden, Germany* The crystal structure and charge stripe order in $Pr_{1.67}Sr_{0.33}NiO_4$ and $Nd_{1.67}Sr_{0.33}NiO_4$ was studied by means of single crystal x-ray diffraction in zero and high electric fields. In contrast to tetragonal $La_{1.67}Sr_{0.33}NiO_4$, these crystals are orthorhombic at room temperature. We find that the distortion of the $NiO_2$ planes associated with the orthorhombic strain dictates the direction of the charge stripes. The critical temperature for charge stripe order is the same as in $La_{1.67}Sr_{0.33}NiO_4$ ($T_{CO} \sim 245$ K), i.e., it does not depend on the crystal symmetry. A second structural transition observed only in $Nd_{1.67}Sr_{0.33}NiO_4$ at temperatures $T \sim 100$ K has no noticeable influence on the stripe order. In crystals with a hole content very close to 1/3 we observe a tripling of the charge stripe unit cell along the c-axis for temperatures $T < 225$ K, which indicates a strong tendency towards a well defined three dimensional order. A high electric field applied to $Nd_{1.67}Sr_{0.33}NiO_4$ had no noticeable impact on the charge stripe order, i.e., a sliding of stripes was not observed. *The work at Brookhaven was supported by the Office of Science, U.S. Department of Energy under Contract No. DE-AC02-98CH10886.*

**9:12**

**A45 7 The ground state of the quasi-one-dimensional cuprate $PrBa_2Cu_4O_8$: field-induced dimensional crossovers and disorder-induced one-dimensionality** ALESSANDRO NARDUZZO, ARAZ ENAYATI-RAD, *University of Bristol* SHIGERU HORII, *University of Tokyo* FEDOR BALAKIREV, *Los Alamos National Laboratory* NIGEL HUSSEY, *University of Bristol* $PrBa_2Cu_4O_8$, the non-superconducting analogue of the high-$T_c$ cuprate $YBa_2Cu_4O_8$, is an extremely anisotropic quasi-one-dimensional (Q1D) metal ($t_b^2 : t_a^2 : t_c^2 \sim$ 4000: 2: 1). The in-chain ($b$-axis) charge dynamics were investigated as a function of temperature and applied magnetic field for several samples of different disorder content. Measurements in magnetic fields up to 65 T confirm the correspondence between dimensional crossovers due to magnetic field carrier confinement and temperature-induced decoherence, opening the possibility of accessing the Tomonaga-Luttinger liquid state in this material. A metal-insulator transition is observed with increasing disorder concentration for samples with nominal mean free path of $\sim 100b$. The onset of this remarkable localisation phenomenon reveals a striking correlation between the scattering rate and the interchain hopping rate(s), suggesting a disorder-induced crossover to a one-dimensional (1D) ground state. $b$-axis magnetoresistance measurements were performed in order to identify the nature and properties of the Q1D metallic and disorder-induced 1D insulating states.

**9:24**

**A45 8 Lattice fermion models with spontaneous orbital currents in strong-interaction limit*** CHRISTOPHER L. HENLEY, *Cornell University* A suggestion that the cuprate pseudogap state has a hidden order, in the form of staggered currents [1], led to toy spinfull fermion models on ladders and bilayers which exhibit such a symmetry breaking [2]. This invites the question, which features of the model are conducive to such phases? Taking (for maximal simplicity) spinless fermions, with large or infinite repulsion, I find a ground state with spontaneous-current order in two models: each consists of rings of sites, coupled by weak hopping to form a ladder or a $d = 2$ lattice. So far, all my examples require lattices modulated with alternately strong and weak hopping. I also argue that spontaneous currents depend on the presence of Berry-

like phases as one takes the system around loops in the abstract graph of all configurations coupled by hops: it would follow that spontaneous currents are impossible in lattice boson models. [1] S. Chakravarty et al, Phys. Rev. B 63, 094503 (2001). [2] M. Tsuchiizu and A. Furusaki, %%% spontaneous currents Phys. Rev. B 66, 245106 (2002); U. Schollwöck et al, Phys. Rev. **A45 9 A proposal for giant spin-orbital resonance in AFM/SDW conductors.** REVAZ RAMAZASHVILI, *LPTMS, Bât. 100, Université Paris-Sud, 91405 Orsay cedex, France* SERGUEI BRAZOVSKII, *LPTMS, Bât. 100, Université Paris-Sud, 91405 Orsay cedex, France* Essential dependence of the electron *g*-factor on the quasiparticle momentum is a fundamental property of antiferromagnetic conductors (AFM), which so far has been largely overlooked. It leads to an anomalously strong spin-orbit interaction, of which a giant combined spin-orbital resonance may be a striking manifestation. We advance a theory of this combined resonance (excitation of electron spin transitions by AC *electric* field) in a weakly doped antiferromagnetic insulator. The combined resonance intensity exceeds that of the electron spin resonance (ESR) by orders of magnitude. We study transitions in the continuous spectrum, as well as in a quantizing magnetic field, and calculate the resonance lineshape, and the angular dependence of the resonance intensity. Our predictions may be relevant for various magnetically ordered conductors, including electron- and hole-doped cuprates, and organic metals with a spin density wave (SDW).

**9:48**

**A45 10 Dual vortex theory of doped antiferromagnets** SUBIR SACHDEV, *Harvard University* LEON BALENTS, *University of California, Santa Barbara* We present a general framework for describing the quantum phases obtained by doping paramagnetic Mott insulators on the square lattice. The undoped insulators are efficiently characterized by the projective transformations of various fields under the square lattice space group (the PSG). We show that the PSG also imposes powerful constraints on the doped system, and enables derivation of an effective action for the vortex and Bogoliubov quasiparticle excitations of superconducting states. This action also describes transitions to supersolid or insulating states at nonzero doping. For the case of a valence bond solid (VBS) insulator, we show that the doped system has the same PSG as that of elementary bosons with density equal to the density of electron pairs. We also obtain the action for a d-wave superconductor obtained by doping a ''staggered-flux'' spin liquid state.

**A45 11 Strong coupling theory of phonons in the Hubbard Model** SHILADITYA CHAKRABORTY, *Univ. of Illinois, Urbana-Champaign* TUDOR STANESCU, *Univ. of Illinois, Urbana-Champaign* PHILIP PHILLIPS, *Univ. of Illinois, Urbana-Champaign* The role of phonons in strongly correlated electronic systems including the high Tc cuprates has not been completely well understood. Recent experimental results, notably those of Lanzara et. al reveal the existence of a kink in the quasiparticle dispersion data for various classes of cuprate superconductors including BiSCO, LSCO and NCCO at an energy scale of around 50 meV to 70 meV using ARPES techniques. Direct comparison of ARPES and neutron scattering data has also been done for LSCO. One of the possible explanations for this kink is believed to be coupling of electrons with phonon modes of the above energy scale. We obtain the electron spectral function as a function of electron- phonon coupling strength using Cluster Dynamic Mean Field Theory (CDMFT on the 2-D Hubbard Model with phonons and compare it with the experimental data.

**10:12**

**A45 12 Spin Correlations and Magnetic Susceptibilities of Lightly Doped Antiferromagnets** I.R. PIMENTEL, F. CARVALHO DIAS, *University of Lisbon, Portugal* We calculate the spin correlation function and the magnetic longitudinal and transverse susceptibilities of a two-dimensional antiferromagnet doped with a small concentration of holes, in the t-J model. We find that the motion of holes generates spin fluctuations which add to the quantum fluctuations, the spin correlations decaying with the inverse of the spin distance, while increasing with doping as the critical hole concentration, where the long-range order disappears, is approached. Moreover, the longitudinal susceptibility becomes finite in the presence of doping, due to the strong damping effects induced by the hole motion, while the transverse susceptibility is renormalized by softening effects. Both the longitudinal and the transverse susceptibilities increase with doping, the former more significantly than the latter. Our results imply that doping destroys the long-range order while local antiferromagnetic spin correlations persist. This is consistent with experiments on the doped copper oxide superconductors.

**10:24**

**A45 13 Unconventional antiferromagnetism in the presence of Dzyaloshinskii-Moriya interactions: the case of $La_2CuO_4$** LARA BENFATTO, *CNR-INFM and University of Rome ''La Sapienza,'' Italy* MARCELLO SILVA NETO, *University of Utrecht, The Netherlands* Between the several anomalous properties of cuprates superconductors, the attention has been put recently on the magnetic properties of the undoped compounds, which display antiferromagnetism. In particular, $La_2CuO_4$ has been extensively investigated, and several unusal magnetic properties have been observed, as for example the temperature dependence of the uniform magnetic susceptibility and the magnetic-field dependence of the magnon gaps. Using a long-wavelength non-linear sigma model approach, we study effect of Dzyaloshinskii-Moriya interactions in the quantum Heisenberg antiferromagnet. With this technique one can easily recognize that the Dzyaloshinskii-Moriya interaction mediates an anomalous coupling between the uniform magnetic field and the antiferromagnetic order parameter. We can then provide a simple and clear explanation for all the recently reported anomalies, and we demonstrate explicitly why $La_2CuO_4$ can not be classified as an ordinary easy-axis antiferromagnet.

**A45 14 $^{63,65}$Cu NMR Spectrum and Spin Lattice Relaxation in the Two-dimensional Antiferromagnet $Pr_2CuO_{4-y}$*** G. GAIDOS, W.G. CLARK, *UCLA Physics and Astronomy* R.L. GREENE, B. LIANG, *U. of Maryland Physics* The $^{63,65}$Cu NMR spectra and spin lattice relaxation rate ($1/T_1$) are reported for a single crystal of the two-dimensional antiferromagnet $Pr_2CuO_{4-y}$ as a function of the applied magnetic field ($\mathbf{itB}_0$) over the temperature ($T$) range 3 - 20 K. When $\mathbf{itB}_0 = 0$, the NMR spectrum has six lines, which correspond to the quadrupolar spectrum (central transition and two satellites) of both Cu isotopes in an antiferromagnetic (AF) internal field of 9.626 T. This value is 0.75 T

less than that of the related compound $Nd_2CuO_{4-y}$ [1]. The spectra as a function of $\mathbf{itB}_0$ are consistent with the noncollinear structure of the AF ordered $Cu^{2+}$ spins seen in neutron diffraction studies [2]. The values of $1/T_1$ over the range $5\ K \leqslant T \leqslant 20\ K$ follow the power law $1/T_1 \propto T^2$, which may indicate $1/T_1$ is dominated by two-dimensional AF spin waves [3]. [1] Y. Yosinari itet al., J. Phys. Soc. Jpn. **59**, 36 (1990). [2] I. Sumarlin itet al., Phys Rev B, **51**, 5824 (1995). [3] S. Chakravarty itet al., Phys Rev B **43**, 2796 (1991).

**A45 15 Spectroscopy of stripe order in $La_{1.8}Sr_{0.2}NiO_4$ using resonant soft x-ray diffraction** J. SCHLAPPA, C. SCHUESSLER-LANGEHEINE, Z. HU, C. F. CHANG, M. BENOMAR, H. OTT, O. FRIEDT, M. BRADEN, L.H. TJENG, *II. Physikalisches Institut, Universitaet zu Koeln, Germany* A. TANAKA, *ADSM, Hiroshima University, Japan* E. SCHIERLE, E. WESCHKE, G. KAINDL, *Institut fuer Experimentalphysik, Freie Universitaet Berlin, Germany* G.A. SAWATZKY, *Department of Physics and Astronomy, UBC, Canada* H.-J. LIN, C.T. CHEN, *NSRRC, Hsinchu, Taiwan* We studied the electronic structure and temperature dependence of the stripe phase in Sr-doped $La_2NiO_4$ using resonant diffraction at the Ni $L_{2,3}$ and La $M_{4,5}$ edge in combination with a realistic microscopic theory. Making use of the very high sensitivity of the method to ordered modulations of the electronic state, we found the doped holes to be mainly located on the oxygen ligands in the $NiO_2$ planes, each centered around one Ni ion. The Ni ions in the hole-rich stripes are essentially in a high-spin $d^8$ state and the hole spin is coupled antiparallel to the Ni spin in close analogy to the Zhang-Rice singlet state in cuprates. Such an understanding of the charge-ordered phase could not be obtained before, neither by conventional x-ray or neutron diffraction techniques, nor by x-ray absorption spectroscopy.

**A46 1 Efficiency in Piezoelectric GaInN/GaN Green Light Emitting Diodes.**
CHRISTIAN WETZEL, *Rensselaer Polytechnic Institute*

The color of green is most closely related to human's perception of light, while red and blue have more of a signal character. Wide bandgap GaInN/GaN heterostruture devices successfully expanded the wavelength range of light emitting diodes (LEDs) from the red to blue and the UV. Performance in the green (500 – 570 nm), however, substantially lags behind requirements for energy efficient solid state white lighting. In particular, it is a significant challenge to extent the wavelength range from the blue back to the lower emission energies of green. Problems to incorporate high fractions of In and large biaxial strain are compounded by strong polarization properties of the material system. From detailed bandstructure spectroscopy we reveal that and how the piezoelectric properties play the pivotal role in the light emission properties. On these premises, polarization optimized green LED dies have been developed with superior performance at 525 nm and the deep green to 560 nm. In an ongoing process, device performance and efficiencies are analyzed and compared to a large set of sample data and provide relevant optimization feedback.

**A46 2 Growth and Characterization of III-Nitride LEDs on Vicinal Sapphire Substrates** N. KHAN, J. LI, J. Y. LIN, AND H. X. JIANG, *Department of Physics, Kansas State University, Manhattan, KS 66506-2601* GaN and related III-N alloys have great potential applications in optoelectronic devices such as light emitting diodes (LEDs), laser diodes (LDs) and high power electronic devices such as transistors. For improved performance and greater versatility of these devices, it is essential to improve the quality of materials and devices. It has been reported that growth on vicinal or misaligned substrates compared to flat ones, lead to smoother and higher crystalline quality thin films. Improved brightness and quantum efficiency, and a reduction of the forward current at which maximum quantum efficiency occurs are among the improved optical properties resulting from the use of misaligned substrates and a thick base layer. We report on the characteristics of InGaN based blue/green LEDs grown by metal organic chemical vapor deposition (MOCVD) on specially fabricated dome shaped sapphire substrates. These dome shaped substrates provide varying degrees of off-cut within a single wafer. Surface morphologies, crystalline qualities and emission properties across the entire wafer surface have been mapped by various techniques, including optical and atomic force microscopy (AFM), x-ray diffraction and electroluminescence and photoluminescence spectroscopy. The results are compared with those of blue/green LEDs grown on conventional on-axis substrates.

**A46 3 Improvement of AlGaN-based deep-ultraviolet light emitting diodes performance with a nano-textured/roughened sapphire substrate** MUHAMMAD KHIZAR, YASIN RAJA, *Department of Physics & Optical Sciences, University of North Carolina at Charlotte, NC 28223* Performance improvement of the fabricated AlGaN-based deep-ultraviolet light emitting diode (DUV LEDs) on sapphire with nano-textured/roughned substrate is reported. The output optical powers as well as the current-voltage characteristics of the processed devices with and without textured/roughened substrate are compared. Lapping/polishing

and dry-etching techniques were employed for nano-texturing/ roughening of the substrate. Magnetron dry etching was performed using a mixed $CF_2Cl_2$/Ar feed gases followed by an inductively coupled plasma (ICP) etching in $BCl_3/Cl_2$ plasma chemistry. An etching rate of $\sim$ 145 nm/min for the sapphire was easily obtained. The result show that the optical emission power of the fabricated devices with textured/roughened sapphire substrate is higher as compared to similar un-textured/roughened devices. Based on the analysis, it is concluded that a textured/roughened substrate surface with an RMS $\sim$ 15 – 25 nm shows improved light extraction efficiency, which is the result of the reduced internal reflection of the light caused by the nano-textured/roughened surface profile thereby causing deviation for critical angle.

**A46 4 Growth and Optical Properties of Al rich AlN/AlGaN Quantum Wells** T.M. AL TAHTAMOUNI, N. NEPAL, M.L. NAKARMI, J.Y. LIN, AND H.X. JIANG, *Department of Physics, Kansas State University, Manhattan, Kansas 66506-2601* Al rich AlGaN alloys are promising materials for the applications in the optoelectronic devices such as deep ultraviolet (UV) emitters and detectors in the spectral range down to 200 nm. AlGaN based UV emitters ($\lambda < 340$nm) has applications in bio-chemical agent detection and medical research/ health care. To realize deep UV emission ($\lambda <$ 280 nm) Al rich AlGaN based quantum wells (QWs) are required. We report here the growth of $AlN/Al_xGa_{1-x}N$QWs ($x>0.65$) on AlN/sapphire templates by metalorganic chemical vapor deposition (MOCVD). Deep UV photoluminescence (PL) was employed to study the optical properties of the QWs. Well width (Al composition) dependence was studied by varying the QW thickness (Al composition) with fixed $x\sim 0.65$ (well width at 3 nm). Optical properties of these QWs such as the effects of alloy fluctuation, temperature, strain and piezoelectric field, carrier and exciton localizations on the quantum efficiency have been studied. Carrier and exciton dynamics were probed. Implications of our findings on the applications of Al rich AlN/AlGaN QWs for UV emitters and detectors will also be discussed.

**9:12**

**A46 5 Optical properties of Er doped III-nitride epilayers and quantum wells synthesized by MOCVD** C. UGOLINI, M.L. NAKARMI, N. NEPAL, J.Y. LIN, AND H.X. JIANG, *Department of Physics, Kansas State University, Manhattan, KS 66506* The wide bandgap semiconductor, GaN, is an excellent host for Er since the thermal quenching of radiative intra-4f it$Er^{3+}$ transitions is very low in Er implanted or Er doped GaN, and the solubility of Er in GaN is high. Due to these properties and the characteristic transition of 1.54 $\mu$m of $Er^{3+}$, Er doped GaN structures are promising for Er related emitters operating in the infrared region. In recent studies, Er doped III-Nitride epilayers were obtained by ion implantation or molecular beam epitaxy (MBE). But, in-situ Er doping of III-Nitride epilayers has not been achieved by metalorganic chemical vapor deposition (MOCVD), mostly due to the low vapor pressure and lack of suitable, metalorganic Er sources. However, due to the large output and high-crystalline quality of MOCVD grown III-nitride epilayers, use of this process to grow Er doped III-nitride epilayers would be very useful for commercial applications. We report on the synthesis of Er doped III-nitride epilayers and quantum wells (QW) grown by MOCVD, and their optical properties. Optical properties in the visible and infrared region for epilayers and QW's of different Er concentrations and growth conditions are discussed. The mechanisms of optical transitions involving different intra-4f $Er^{3+}$ energy levels are also discussed. Lastly, potential applications of Er doped III-nitride structures in the communication wavelength will be presented.

**A46 6 Structural and optical properties of GaN films grown on GaAs substrates by molecular beam epitaxy** O. MAKSIMOV, V. HEYDEMANN, *Electro-Optics Center, Pennsylvania State University* P. FISHER, H. DU, M. SKOWRONSKI, *Dept. of Mat. Sci. and Eng., Carnegie Mellon University* Y. GONG, I. KUSKOVSKY, *Dept. of Physics, Queens College of NY* ELECTRO-OPTICS CENTER TEAM, CARNEGIE MELLON UNIVERSITY TEAM, QUEENS COLLEGE OF NY TEAM, GaN emerged during the past decade as a wide band gap semiconductor with promising material properties for the development of short-wavelength optoelectronic, high frequency and high power electronic devices. Most GaN research has been focused on the growth of high quality GaN epitaxial layer on A12O3 and SiC substrates. The MBE growth of GaN on GaAs substrates is much less studied, although it provides several advantages, such as a closer thermal expansion coefficient matching and a possibility to stabilize cubic $\beta$-GaN. In this work we report on MBE growth of GaN films on the (100) GaAs substrates. Contrary to previous literature accounts, we do not employ an As beam, neither during oxide desorption nor during GaN nucleation and growth. We determine that direct growth on thermally desorbed GaAs results in a polycrystalline film that contains inclusions of both $\alpha$ and $\beta$ GaN. Low-temperature nitridation followed by annealing improves structural properties resulting in the growth of $\alpha$-GaN with 0002 orientation.

**A46 7 Characterization of stress in thin-film wurtzite GaN grown on c-plane sapphire by molecular beam epitaxy.** FRANCISCO PARADA, MICHAEL MARCINIAK, *Air Force Institute of Technology* LAVERN STARMAN, JASON FOLEY, *Air Force Research Laboratory* YUNG KEE YEO, *Air Force Institute of Technology* The stress distribution in wurtzite gallium nitride (GaN) grown on c-plane sapphire substrates by molecular beam epitaxy is characterized. Micro ($\mu$)-Raman spectroscopy is particularly useful for stress characterization because of its ability to measure the spectral shifts in Raman peaks in a material, and correlate those shifts with stress and strain. The phonon deformation potential is determined by applying pressure to the material using a four-point strain fixture while simultaneously monitoring the applied pressure using a strain gauge and recording the Raman spectrum. The deformation potentials are then used to determine stress distribution; the spectral positions of the $E_2$ Raman mode ($\nu$ = 569 cm-1) in GaN and $A_{1g}$ Raman mode ($\nu = 418$ cm$^{-1}$) in sapphire are recorded at each spatial position in a raster map. The $\mu$-Raman spectroscopy is performed using a Renishaw InVia Raman spectrometer with argon ion ($\lambda = 514.5$ nm, $h\nu = 2.41$ eV) and helium-neon ($\lambda = 633$ nm, $h\nu = 1.96$ eV) excitation sources, and the data is collected across the samples with 5- to 10-$\mu$m spatial resolution. Inherent stress and evidence of significant damage in the GaN layer due to MEMS processing will be discussed.

**9:48**

**A46 8 The Influence of Phonons and Phonon Decay on the Optical Properties of GaN** D. Y. SONG, M. BASAVARAJ, S. A. NIKISHIN, M. HOLTZ, *Texas Tech University, Lubbock, Texas 79409* V. SOUKHOVEEV, A. USIKOV, V. DMITRIEV, *TDI, Inc., 12214 Plum Orchard Dr., Silver Spring, MD 20904* The temperature dependences of vibrational and optical properties of high-quality GaN are studied using Raman and photoluminescence (PL) spectroscopies in the range 20 to 325 K. The Raman-active $A_1$(LO) phonon has temperature dependence described well by combined two- and three-phonon decay. The temperature dependences of $E_2^2$phonon are almost entirely dominated by the thermal expansion, and the contribution of three-phonon decay process is very small throughout interested temperature range. The shallow neutral donor-bound exciton ($D^0$,X) and two free excitons ($X_A$ and $X_B$) are observed at low temperatrue PL spectra. Also seen are two $A_1$(LO) phonon sidebands (PSBs), originating from the $X_B$ free exciton, with the characteristic asymmetry attributed to interactions between discrete and continuum states. Analysis of the band-edge excitons reveals that energy gap shrinkage and exciton linewidths are completely described based on electron-phonon interactions with phonon properties consistent with the Raman analysis. First and second PSBs have temperature dependence associated with the $A_1$(LO) phonon. The shift, broadening, and asymmetry of the PSBs are explained by Segall-Mahan theory adding the decay mechanism of $A_1$(LO) phonon and the exciton broadening from electron-phonon interactions. Work at Texas Tech University supported by National Science Foundation grant ECS-0323640.

**A46 9 Bandedge transitions in GaN and AlN at elevated temperatures** N. NEPAL, M. L. NAKARMI, J. LI, J. Y. LIN, AND H. X. JIANG, *Department of Physics, Kansas State University, Manhattan, KS 66506* GaN and AlN are recognized as promising materials for high power high temperature optoelectronic and electronic devices. For device realization, understanding fundamental properties of these materials at elevated temperature is very important. Probing the optical properties such as the temperature dependence of the bandedge transitions reveals important information pertaining to the fundamental band structures, exciton and carrier recombination and activation processes. Deep-ultraviolet photoluminescence (PL) spectroscopy has been employed to study the bandedge transitions in metalorganic chemical vapor deposition grown GaN and AlN epilayers up to 800 K. The temperature dependence of the PL emission intensity revealed two different activation processes in both GaN and AlN epilayers. The first process occurring below $T_t$ = 325 K ($T_t$ = 500 K) for GaN (AlN) is due to the activation of free excitons to free carriers. Whereas the second activation process occurring above $T_t$ with an activation energy of 0.29 eV (0.3 eV) for GaN (AlN) is believed to be associated with the existence of a satellite valley ($\Gamma_3$) at about 0.3 eV above the conduction band minimum, $\Gamma_1$. Consequence of this satellite valley in the conduction band on the high temperature and high power device applications of GaN and AlN will be discussed.

**10:12**

**A46 10 Hot carrier dynamics in bulk GaN under short laser pulse excitation** S. RUDIN, *U.S. Army Research Laboratory* E. BELLOTTI, *Boston University* G. A. GARRETT, M. WRABACK, *U.S. Army Research Laboratory* In this work, we apply the semiconductor Bloch equation formalism to the study of the electron-hole dynamics in bulk GaN under short laser pulses excitation. Both coherent and non-coherent processes contribute to the dynamics on short time scales. The numerical solution of the equations of motion for the electron-hole plasma and the polarization is obtained by using a generalized Monte Carlo algorithm. This includes a direct solution of the coherent process and a stochastic description of the dephasing mechanisms. Screened carrier-carrier interaction and carrier-phonon interaction are considered in the dephasing processes. The model also includes the description of the interaction of the ultra-short laser pulse with the semiconductor media. The non-parabolic two-band analytical approximation was used in this work. The interaction of LO-phonons with electrons in GaN is much stronger than in GaAs, and the LO-phonon-electron scattering rate in GaN is almost one order higher than that in GaAs. The computed time dependent carrier densities were used to obtain time dependent luminescence at different probe wave-lengths for different excitation powers. The results were compared with the experimental results obtained by the subpicosecond time-resolved spectroscopy of UV luminescence.

**10:24**

**A46 11 Nonequilibrium carrier dynamics in AlGaN/GaN surface quantum wells monitored by time-resolved photoluminescence spectroscopy** Y. D. GLINKA,*J. V. FOREMAN,†W. DAVENPORT, H. O. EVERITT,‡ *U.S. Army Aviation and Missile RDEC, Redstone Arsenal, AL* X. ZHANG, I. P. WELLNIUS, J. F. MUTH, *Electrical and Computer Engineering, North Carolina State Univ., Raleigh, NC* J. ROBERTS, P. RAJAGOPAL, J. COOK, E. PINER, K. LINTHICUM, *Nitronex Corporation, Raleigh, NC* The photoluminescence (PL) from a GaN surface quantum well of an AlGaN/GaN heterostructure has been studied by using a wide range of ultrafast ( $\sim$ 200 fs) laser excitations and temperatures (4.2 – 300 K) for quantum wells of varying widths. We observe a broad ( $\sim$ 100 meV) PL band whose peak shifts linearly from 3.5 to 3.8 eV with decreasing GaN quantum well thickness from 2.9 to 1.5 nm. The spectral shift of the band is accompanied by the corresponding temporal shift in the range $<$ 30 ps. The dynamics of nonequilibrium electrons in the GaN layer confined by the AlGaN barrier and the vacuum level is discussed, with particular emphasis on carrier interactions with both acoustic and optical phonons.

**A46 12 Time Resolved Photoluminescence Measurements in hexagonal $Mg_xZn_{1-x}O$ (x=0.13) alloys** SHIVA HULLAVARAD, R. VISPUTE, S. DHAR, *University of Maryland* HENRY EVERITT, JOHN FOREMAN, *Duke University* I. TAKEUCHI, *University of Maryland* In this work we present results on the optical characterization of Pulsed Laser Deposited epitaxially grown thin films of $Mg_xZn_{1-x}O$ on sapphire. The crystalline quality and composition of the alloys are characterized by X-Ray Diffraction and Rutherford Back Scattering (RBS) – ion channeling techniques respectively. The composition of the films is found to have strong dependence on the growth parameters. The

photo generated carrier decay times are analyzed by time-resolved photoluminescence (TRPL) measurements. Since most optical and electrical devices are operated at room temperature, understanding the fundamental excess carrier recombination dynamics at 300 K is required to evaluate the relevant radiative and non-radiative recombination mechanisms and thus to improve the performance of devices. We have observed from initial PL measurements evidence of varying amounts of non-radiative relaxation processes competing with radiative PL in the MgZnO samples. More importantly, we have observed a decay time of 125 ps for films from TR-PL measurements. The efficiency of the radiative recombination, and therefore the material quality, is strongly related to the decay time of the particular transition. The correlation of the results obtained from RBS and PL-TRPL measurements will be presented.

**10:48**
**A46 13 Optical and magnetic properties of $Zn_{1-x}Co_xO$ and $ZnCo_2O_4$ thin films.** K. SAMANTA, P. BHATTACHARYA, R.S. KATIYAR, *University of Puerto Rico, PR* W. IWAMOTO, R.R. URBANO, C.P. PAGLIUSO, C. RETTORI, *Instituto de Fisica Unicamp, Campinos, Brazil* UPR TEAM, CAMPINO BRAZIL TEAM, The transition metal doped wide bandgap ZnO are considered possible candidates for room temperature ferromagnetic semiconductor for spintronic devices. Thin films of Co substituted ZnO and $ZnCo_2O_4$ were deposited using pulsed laser deposition on c-axis (0001) oriented $Al_2O_3$ substrates. The XRD results showed all the films were highly (002) oriented with a less intense peak of (311) for $ZnCo_2O_4$ thin film. Micro-Raman spectra of ceramic targets showed the modes related to wurtzite ZnO and spinel $ZnCo_2O_4$ structure. In thin films of $Zn_{1-x}Co_xO$ no such modes related to $ZnCo_2O_4$ were detected. The intensity of $E_1(LO)$ and multiphonon peaks at 540 and 584 $cm^{-1}$, respectively, increased with increase in the Co substitution. The optical absorption of the films showed that the band gap decreased with the increase of Co concentrations at room temperature along with the sub-bandgap absorption due to $d - d$ transitions of $Co^{2+}$. Similar sub-bandgap $d - d$ transition was also observed in absorption spectra $ZnCo_2O_4$ thin film.

**B1 1 Liquid Crystal Phases of Molecular Bananas: Polarity and Chirality as Broken Symmetries.***
NOEL CLARK, *University of Colorado*

The study of the interplay of chirality and polarity has been a particularly rich theme of soft matter science since Meyer's seminal discovery that tilted smectics of chiral molecules are macroscopically polar. This event, and the subsequent realization of polar domains and high-speed electro-optic switching in chiral smectics, engaged the liquid crystal community in a worldwide pursuit of novel smectics for applications, featured by the synthesis of more than 50,000 new liquid crystal compounds, and by a consequent broad diversification of the palette of liquid crystal phases and possibilities for supermolecular ordering. A current important activity in this scenario is the study of polar order in synthetically achiral molecules, for example, in molecular bananas, which, as their shape suggests, might be expected to organize in a polar way. Indeed they do, but beyond this, almost everything learned about them has been surprising, including their persistent tendency to exhibit chirality as a spontaneously broken symmetry. I will discuss some of these new phases and phenomena, including the discovery of fluid conglomerates (Pasteur's experiment in a fluid), triclinic fluid order, chiral twist grain boundary phases of achiral molecules, chirality flipping and field-induced deracemization, ferroelectric and antiferroelectric phases with supermolecular- scale polarization modulation, and chiral thermotropic sponge phases.

*Work in collaboration with the Boulder Liquid Crystal Group, supported by NSF MRSEC Grant DMR 0213918.

**11:51**
**B1 2 Curvature, chirality, and polar symmetry in liquid crystals.**
ROBERT MEYER, *Brandeis University*

Charles Frank taught us the relationship between curvature and polarity in liquid crystals. He showed that polar ordering of dipolar molecules, with the polar axis parallel to the nematic director, would lead to spontaneous splay deformation of the otherwise uniaxial nematic state. Likewise, he showed that molecular chirality leads to spontaneous twisting of the director field, resulting in the helicoidal textures of chiral nematics. Augmenting Frank's insight on polarity induced splay with the realization that bend induces polarization perpendicular to the director, led to the concept of curvature induced polarization of liquid crystals, or flexoelectricity. The concepts of chirality induced twist and bend induced polarization became intimately combined in the case of chiral smectic C liquid crystals. The chirality induced twisting of the molecular tilt direction from layer to layer in the smectic produces a helical state incorporating both spontaneous twist and bend, and therefore inducing polarization in the smectic layers, normal to the molecular tilt direction. Thus, Frank's original insights led eventually to the discovery of ferroelectric liquid crystals. In fact, spontaneous polarization and helical order are independent consequences of molecular chirality in tilted smectics. The fundamental combination of

monoclinic local symmetry in the smectic C phase with molecular chirality leads directly to spontaneous polarization, with no requirement of helical twisting. This realization leads to generalizations of ferroelectricity to include anti-ferroelectric and ferri-electric smectics, among the fascinating array of polar liquid crystal phases. The consequences of these concepts in fundamental science, materials development, and applications will be reviewed.

**12:27**
**B1 3 Generating Coherent Phonons and Spin Excitations with Ultrafast Light Pulses.***
ROBERTO MERLIN, *FOCUS Center and Department of Physics, University of Michigan, Ann Arbor, MI 48109-1040*

Recent work on the generation of coherent low-lying excitations by ultrafast laser pulses will be reviewed, emphasizing the microscopic mechanisms of light-matter interaction. The topics covered include long-lived phonons in ZnO [C. Aku-Leh, J. Zhao, R. Merlin, J. Menéndez and M. Cardona, itPhys. Rev.B **71**, 205211 (2005)], squeezed magnons [J. Zhao, A. V. Bragas, D. J. Lockwood and R. Merlin, itPhys. Rev. Lett. **93**, 107203 (2004)], spin- and charge-density fluctuations [J. M. Bao et al., itPhys. Rev. Lett. **92**, 236601 (2004)] and cyclotron resonance [J. K. Wahlstrand, D. M. Wang, P. Jacobs, J. M. Bao, R. Merlin, K. W. West and L. N. Pfeiffer, AIP Conference Proceedings **772** (2005), p. 1313] in GaAs quantum wells. In addition, unpublished results on surface -avoiding phonons in GaAs-AlAs superlattices [M. Trigo et al., itunpublished] and magnons in ferromagnetic $Ga_{1-x}Mn_xAs$ [D. M. Wang et al., itunpublished] will be discussed. It will also be shown that frequencies can be measured using pump-probe techniques with a precision comparable to that of Brillouin scattering. It is now widely accepted that stimulated Raman scattering (SRS) is (often but not always) the mechanism responsible for the coherent coupling. Results will be presented showing that SRS is described by two separate tensors, one of which accounts for the excitation-induced modulation of the susceptibility, and the other one for the dependence of the amplitude of the oscillation on the light intensity [T. E. Stevens, J. Kuhl and R. Merlin, itPhys. Rev. B **65**, 144304 (2002)]. These tensors have the same real component, associated with itimpulsive coherent generation, but different imaginary parts. If the imaginary term dominates, that is, for strongly absorbing substances, the mechanism for two-band processes becomes itdisplacive in nature, as in the DECP (displacive excitation of coherent phonons) model. It will be argued that DECP is not a separate mechanism, but a particular case of SRS. In the final part of the talk, an attempt will be made to identify emerging areas of research on coherent excitations and coherent control, relevant to condensed matter systems, that could benefit from ultrafast electron and x-ray diffraction studies.

**B1 4 Berry Phases and Curvatures in Electronic-Structure Theory.**
DAVID VANDERBILT, *Rutgers University*

In the last fifteen years, Berry phases have been found to play an increasingly important role in electronic-structure theory. I will briefly review some of the important developments in which Berry phases have been involved, starting with the modern theory of polarization[1] and the closely related theory of Wannier functions and their Wannier centers.[2] Next, I will discuss the theory of insulators in finite electric fields,[3] in which the field is taken to couple linearly to the Berry-phase polarization. I will then conclude by discussing the role of Berry phases and Berry curvatures in systems in which time-reversal symmetry has been broken, and in particular, the theory of orbital magnetization[4] and the anomalous Hall effect in ferromagnets.

**B2 1 Observation of superfluidity in solid helium and solid hydrogen.**
ANTHONY CLARK, *Penn State University*

A torsional oscillator technique is used to search for non-classical rotational inertia of solid helium[1] and solid hydrogen. Several important experimental details already observed will be reviewed for both systems. Some of these include the

transition temperature, supersolid fraction, and dependencies on oscillation speed and impurities. Comparisons will be made in order to demonstrate the similarities and/or differences between helium and hydrogen. With further work currently underway, we will also report on recent experimental progress. This work is done in collaboration with Eunseong Kim, Xi Lin and Moses Chan and is supported by the NSF under grant 0207071. [1] E. Kim and M. H. W. Chan, Nature **427**, 225 (2004); Science **305**, 1941(2004); J. Low Temp. Phys. **138**, 859 (2005).

**11:51**
**B2 2 Pressure-driven Flow of Solid Helium.***
JOHN BEAMISH, *University of Alberta*

Recent torsional oscillator measurements by Moses Chan's Penn State group showed evidence of ''non-classical rotational inertia'' for solid helium at temperatures below 200 mK. This discovery followed decades of theoretical speculation and experimental searches for ''supersolidity'' in helium. The experiments generated a great deal of interest but the origin and properties of such a state are still unclear. It would be very interesting to know whether supersolids share any of the other unusual properties of superfluids: persistent currents, second sound and quantized vortices. We have studied the response of solid helium to pressure changes in order to look for unusual flow properties that might be associated with supersolidity. The measurements involved both helium confined in the nanometer pores of Vycor glass and bulk solid helium, at temperatures as low as 30 mK. Pressure changes were generated with piezoelectrically driven diaphragm and flow was monitored with sensitive capacitive techniques. Near melting, solid helium flows very easily but we did not see any evidence of superflow at low temperatures. If helium does become a supersolid at low temperatures then its response to pressure gradients must be very different from that of liquid helium.

**12:27**
**B2 3 Theory for supersolid 4He: Vacancy condensation facilitated by a low-energy bound state.**
XI DAI, *Department of Physics, University of Hong Kong*

Although both vacancies and interstitials have relatively high activation energies in the normal solid, we propose that a lower energy bound state of a vacancy and an interstitial may facilitate vacancy condensation to give supersolidity in 4He. We use a phenomenological two-band boson lattice model to demonstrate this new mechanism and discuss the possible relevance to the recently observed superfluidlike, nonclassical rotational inertial experiments of Kim and Chan in solid 4He. Some of our results may also be applicable to trapped bosons in optical lattices.

**13:03**
**B2 4 Off diagonal long range order in solid 4He.**
LUCIANO REATTO, *Dipartimento di Fisica, Universita' di Milano*

The presence both of long range order (LRO) and of off diagonal long range order (ODLRO) in solid 4He is discussed on the basis of an accurate variational theory (shadow wave function, SWF) and of an exact projection method (shadow path integral ground state, SPIGS). If the solid is incommensurate (e.g. solid with a vacancy: number of atoms different from number of equilibrium sites) both SWF and SPIGS give ODLRO and close to melting density there is a BEC of about 0.3 He atoms per vacancy. For a commensurate solid (number of atoms equal to number of sites) SWF gives ODLRO with a condensate of about one part per thousand. Preliminary evidence indicates that also SPIGS gives a finite BEC. The key process is the spontaneous formation of unbound vacancy-interstitial pairs. These results support the presence of supersolidity in bulk solid 4He. As a final point we address the question if the exact ground state of bulk solid 4He is commensurate or incommensurate and conclude that there is not yet a definite answer to this question from microscopic theory.

**13:39**
**B2 5 Path Integral Simulations of Solid $^4$He.***
DAVID CEPERLEY, *University of Illinois Urbana-Champaign*

Kim and Chan have found indications that solid $^4$He is a supersolid by measuring the period of a torsional oscillator. To understand the state of solid $^4$He at low temperature, we [1] have calculated tunnelling frequencies for ring exchanges in bulk solid helium with Path Integral Monte Carlo by finding the free energy of a path that begins with the atoms in one configuration and ends with a permutation of those positions. The exchange frequencies are found to be described by a lattice model which does not show superfluid behavior. However, simulations [2] of $^4$He absorbed in Vycor find that $^4$He forms a layered structure with the first layer solid-like and highly localized, the second layer disordered with some atoms delocalized and possibly superfluid. This persistent liquid layer mechanism can only be relevant for bulk $^4$He in a very disordered crystal. New calculations [3] of the single particle density matrix, (the fourier transform of the momentum distribution) to measure ODLRA will also be discussed. [1] D. M. Ceperley and B. Bernu, Phys. Rev. Letts. 93, 155303(2004). [2] S. A. Khairallah and D. M. Ceperley, Phys. Rev. Letts. 95, 185301 (2005). [3] B. Clark and D. M. Ceperley, unpublished.

**B3 1 Modularity and community structure in networks.**
MARK NEWMAN, *University of Michigan*

Many systems of scientific interest can be represented as networks—sets of nodes joined in pairs by lines or edges. Examples include metabolic and other biochemical networks, neural networks, food webs, the Internet and the worldwide web, and social networks. The physics community has made substantial contributions to the study of networked systems in the last decade, drawing particularly on ideas from statistical physics, field theory, and data analysis. One issue that has received considerable attention is the detection and characterization of ''modules'' or ''communities'' within networks—densely connected groups of nodes, with only sparser connections between groups. The ability to find and quantify such communities has proved to be of significant practical worth in the study of biochemical, technological, and social networks, among others, and there has been a lot of activity directed at the development of community-finding methods and algorithms to make these kinds of studies possible. This talk will describe some of the work in this area, focusing in particular on several powerful methods developed recently that appear to outperform previous ones by a substantial margin. A number of example applications will be shown demonstrating the utility of community structure detection in the analysis of real-world network data.

**B3 3 Uncovering the overlapping modules of complex networks.***
TAMAS VICSEK, *Eotvos University*

Many complex systems in nature and society can be described in terms of networks capturing the intricate web of connections among the units they are made of. A fundamental question of great current interest is how to interpret the global organisation of such networks as the coexistence of their structural sub-units (called modules, communities, clusters, etc) associated with more highly interconnected parts. Identifying these unknown building blocks (e.g., functionally related proteins, industrial sectors, groups of people) is crucial to the understanding of the structural and functional properties of networks. The existing deterministic methods used for large data sets find separated modules, while most of the actual networks are made of highly overlapping cohesive groups of nodes. Here we introduce an approach to analyse the main statistical features of the interwoven sets of overlapping communities making a much needed step towards the uncovering of the modular structure of complex systems. After defining a set of new characteristic quantities for their statistics, we apply an efficient technique to explore overlapping communities on a large scale. We find that overlaps are indeed very significant, and the distributions we introduce reveal novel universal features of networks. Our studies of collaboration, word association, and protein interaction graphs demonstrate that the web of modules has highly non-trivial correlations and specific scaling properties.

**B3 4 Spectral methods and Network Communities.***
MIGUEL A. MUÑOZ, *Universidad de Granada (Spain)*

Spectral methods provide us with a powerful tool-box to explore the topology of networks. In this presentation we will review an application of spectral techniques to the analysis of communities in complex networks. Communities are network sub-groups formed by highly interconnected nodes, which are sparsely connected to the rest of the network. They appear ubiquitously in natural and artificial nets, and are believed to play a key role as functional units, and detecting them has become a crucial problem in complex-system analyses.The efficient and relatively fast algorithm we will present here exploits spectral properties of some matrices encoding the network topology (as the Laplacian matrix), combined with standard hierarchical-clustering techniques, and the use of the ''modularity parameter'' allowing to quantify the goodness of any possible community subdivision. The algorithm performance, will be compared with that of other existing methods, as applied to different well-known examples of artificial and real networks. Our results are in all the

tested cases, at least as good as the best ones obtained with any other methods, and faster in most of the cases than methods providing similar-quality results. This converts the algorithm in a valuable computational tool for detecting and analyzing communities and modular structures in complex networks.The connection of these results with the problem of determining the optimal network topology to achieve synchronization within the net and to optimize other dynamical processes will also be put forward.

**13:39**
**B3 5 Changes in metabolic modules under environmental variations.**
EIVIND ALMAAS, *Lawrence Livermore National Laboratory*

During the last few years, network approaches have shown great promise as a tool to both analyze and provide understanding of complex systems as disparate as the world-wide web and cellular metabolism. Much effort has been focused on characterizing topological properties of such systems. However, in order to develop detailed descriptions of complex networks, we need to look beyond their topology and incorporate dynamical aspects. The cellular metabolism, where nodes correspond to metabolites and links indicate chemical reactions, is an excellent model system where theoretical predictions can be compared with experimental results. I will present recent insights into the principles governing the modular utilization of the cellular metabolism [1,2,3]. We find that, while most metabolic reactions have small fluxes, the metabolism's activity is dominated by an interconnected sub-network of reactions with very high fluxes [1]. For the bacteria *H. pylori* and *E. coli* and the yeast *S. cerevisiae*, the metabolism responds to changes in growth conditions by reorganizing the rates of select reactions predominantly within this high-flux backbone. Furthermore, these networks are organized around the metabolic core – a set of reactions that are always in use [2]. Strikingly, the activity of the metabolic core reactions is highly synchronized, and the core reactions are significantly more essential and evolutionary conserved than the non-core ones. [1] E. **11:15**
**B4 1 Theory of defects and doping in ZnO.***
CHRIS G. VAN DE WALLE, *University of California, Santa Barbara*

In spite of rapid progress in materials quality, zinc oxide still suffers from serious problems in controlling its conductivity. We are addressing these issues by performing first-principles calculations based on density-functional theory (DFT) in the local density approximation (LDA). In addition, we have developed an approach (based on LDA+U) for overcoming the DFT band-gap problem, allowing us to more accurately compare and predict defect levels. Native point defects are still frequently invoked as sources of n-type conductivity, but our results do not support this hypothesis. Oxygen vacancies are deep donors; our configuration coordinate diagrams for this defect provide a detailed interpretation of the recent ODEPR results of Vlasenko and Watkins [1]. Zinc interstitials are shallow donors, but their formation energy is high and they diffuse very rapidly, with a migration barrier as low as 0.6 eV, making it very unlikely that they would be stable. For the zinc antisite, we find an unexpected low-symmetry configuration. While still high in energy, this defect may play a role under non-equilibrium conditions such as irradiation. We suggest that unintentional incorporation of impurities (such as hydrogen) is a more likely explanation for n-type background doping. However, native defects play a crucial role as compensating centers in p-type material, and we will discuss ways of overcoming this problem. Among the native defects that act as acceptors, zinc vacancies have the lowest formation energy; they introduce deep levels likely responsible for green luminescence. Our calculated migration barriers for the point defects are in good agreement with experimental data where available, and provide insight in the processes that take place during growth, irradiation, or annealing.

**B4 2 Key Materials Aspects for Valence Control of ZnO.**
ATSUSHI TSUKAZAKI, *Institute for Materials Research, Tohoku University*

ZnO has significant advantages for light emitting diodes (LEDs) and lasers from the following reasons; 1) exciton binding energy in ZnO is 60 meV and can be enhanced over 100 meV in superlattices, 2) it is possible to tune the bandgap from 3 eV to 4.5 eV in $Zn_{1-x}Cd_xO$ and $Mg_xZn_{1-x}O$ alloy films having quite small lattice mismatch, and 3) large and high-quality single-crystal wafers are commercially available. In order to harvest these advantages in real devices, reliable technique for fabricating p-type ZnO has to be properly established. Recently we have reported on the improvements of undoped ZnO film quality with inserting a ZnO self-buffer layer onto lattice matched $ScAlMgO_4$ substrate [1]. In view of point defect formation during the epitaxy, we have carefully optimized the growth conditions. We selected nitrogen as an acceptor, because the ionic radius is close to that of oxygen. Here we propose a repeated temperature modulation (RTM) technique for efficient nitrogen doping into ZnO with keeping high crystallinity [2]. By carefully optimizing the conditions, p-type ZnO with a hole concentration of $10^{16}$ - $10^{17}$ $cm^{-3}$ can be reproducibly fabricated. We also demonstrated blue electroluminescence from p-i-n homojunction LED [3]. The details of thin film growth, characteristics of p-type ZnO and device performance will be presented. [1] A. Tsukazaki et al. itNature Mater. **4**, 42 (2005). [2] A. Tsukazaki et al. itAppl. Phys. Lett.**83**, 2784 (2003). [3]A. Tsukazaki et al. itJpn. J. Appl. Phys.Lett.44, L643 (2005).

**12:27**
**B4 3 Localized States and Charge Transfer at ZnO Surfaces and Interfaces.***
LEONARD BRILLSON, *The Ohio State University*

With the advent of techniques to probe semiconductor electronic properties in the near-interface region on a nanometer scale, it is now possible to understand and control the mechanisms playing a role in localized state formation and charge transfer at ZnO interfaces. While world-wide research activity into this major new semiconductor has increased dramatically, the ability to control ZnO interfaces has been a major challenge to their opto- and microelectronic applications. Nanoscale depth-resolved cathodoluminescence and x-ray photoemission spectroscopies reveal the segregation of point defects and the donor character of hydrogen in the near-surface region. A conversion from ohmic to rectifying behavior is observed for gold contacts on atomically ordered polar ZnO surfaces following remote oxygen plasma treatment. This transition is accompanied by reduction of the well-known ''green'' deep level emission, suppression of the hydrogen donor-bound exciton photoluminescence and a large increase in n-type band bending. These results demonstrate that the contact type conversion involves more than one mechanism, specifically, removal of the adsorbate-induced accumulation layer plus lowered tunneling due to reduction of near-surface donor density and defect-assisted hopping transport. Schottky barriers for a wide array of metals on ZnO reveal that the strength of interface reaction plays a dominant role in forming near-interface defects and the resultant Schottky barriers. Similar correlations for other compound semiconductors indicate that the impact of near-interface native defects on Schottky barriers is more general in nature. [1] H.L. Mosbacker, Y.M. Strzhemechny, B.D. White, P.E. Smith, D.C. Look, D.C. Reynolds, C.W. Litton, and L.J. Brillson, ''Role of Near-Surface States in Ohmic-Schottky Conversion of Au Contacts to ZnO,'' Appl. Phys. Lett. 87, 012102 (2005). [2] Y.M. Strzhemechny, H.L. Mosbacker, D.C. Look, D.C. Reynolds, C.W. Litton, N.Y.Garces, NC. Giles, L.E. Halliburton, S. Niki, and L.J. **13:03**
**B4 4 Growth, Assembly, and Characterization of ZnO Nanostructures on Ag Films.***
JULIA W. P. HSU, *Sandia National Laboratories*

In the past decade, significant advances have been made in the synthesis of ZnO nanostructures. The next step in making these nanomaterials useful is to assemble them on surfaces in a controlled and desired fashion. In this talk, I will discuss the growth of complex ZnO nanostructures via a solution method in which organic templates are used to control assembly of these nanostructures on substrate surfaces. The low temperature aqueous growth method used in this work is an environmentally benign process, which is compatible with organic templates and modifiers, can be used to grow large areas uniformly, and has potential for inexpensive manufacturing. To control the assembly of these solution grown nanostructures, we modify the substrate surfaces with patterned self-assembled monolayers, which in turn determines the final spatial organization of the ZnO nanorods. This is a bottom-up approach in which materials are deposited only where they are needed. Using this approach, we have achieved excellent control in spatial placement, selectivity, crystal orientation, and nucleation density. In addition, complex, hierarchical structures have been synthesized by controlling solution chemistry and growth conditions. Due to lack of inversion symmetry in hexagonal crystal, ZnO is a piezoelectric material with Zn (0001) polar and O $(000\bar{1})$ polar surfaces exhibiting drastically different physical and chemical properties. Hence, it is important to determine the orientation of the ZnO nanorods on surfaces. Using piezoelectric force microscopy (PFM) and a well-characterized ZnO single crystal reference, we have measured the amplitude and phase of

piezoelectric responses of over 100 individual ZnO rods. The phase of the PFM signal is 180[r] from the applied electric field, indicating that the nanorods are [0001] oriented. This result contradicts what would have been expected based on an examination of rod morphology. Also, the PFM amplitude of the nanorods was found to be significantly larger than that of the ZnO single crystal. The origin behind this observation and the variation among different nanorods will be discussed.

**13:39**
**B4 5 Charge- and Spin-Based Devices in ZnO Thin Films and Nanostructures.**
DAVID NORTON, *Univeristy of Florida*

ZnO is a wide bandgap semiconductor of potential for device concepts based on charge and/or electron spin. As a direct bandgap material with emission in the ultraviolet, ZnO is being actively pursued in the areas of ultraviolet light emitting diodes and laser diodes. The critical issue in developing such optoelectronic devices is p-type doping. As a dilute magnetic semiconductor, numerous experimental reports indicate ferromagnetism in transition metal doped ZnO. However, the mechanism for this magnetic behavior continues to be a topic of debate. In addition, numerous techniques have been utilized to synthesize ZnO nanoscale structures, many of which appear to be useful for sensors and nanoelectronics. In this talk, pertinent issues for spin and charge-based ZnO devices will be discussed. The focus will be on p-type doping, pn junction formation, magnetic doping, and nanowire-based sensor development. This work is supported by the National Science Foundation (DMR-029086), the Department of Energy (DE-FC26-04NT42271), and the Air Force Office of Scientific Research (030967).

## SESSION B5: NUCLEAR PROLIFERATION & NUCLEAR TERRORISM

**12:27**
**B5 3 Advances in Nuclear Monitoring Technologies.**
BRENT PARK, *Los Alamos National Laboratory*

Homeland security requires low-cost, large-area detectors for locating and identifying weapons-usable nuclear materials and monitors for radiological isotopes that are more robust than current systems. Recent advances in electronics materials and nanotechnology, specifically organic semiconductors and inorganic quantum dots, offer potential improvements. We provide an overview of the physical processes involved in radiation detection using these new materials in the design of new device structures. Examples include recent efforts on quantum dots, as well as more traditional radiation-detecting materials such as CdZnTe and high-pressure xenon. Detector improvements demand not only new materials but also enhanced data-analysis tools that reduce false alarms and thus increase the quality of decisions. Additional computing power on hand-held platforms should enable the application of advanced algorithms to radiation-detection problems in the field, reducing the need to transmit data and thus delay analysis.

**B6 1 Spin Readout and Hyperfine Interaction in Few-Electron Quantum Dots.**
RONALD HANSON, *Kavli Institute of Nanoscience Delft*

This talk presents recent experimental progress toward using few-electron quantum dots as spin qubits. First, we have developed a new spin readout technique that is based on the difference in tunnel rate between different spin states[1]. Unlike earlier techniques, it is robust against background charge fluctuations and high-frequency noise, and presently achieves single-shot fidelities up to 90%. Using this readout technique, we have measured the two-electron spin relaxation time as a function of magnetic field strength and orientation, and studied the back-action of the charge detector. Second, we have investigated the effect of nuclear spins on the electron spin state[2]. Transport measurements on a double quantum dot in the spin blockade regime reveal that the delocalized two-electron singlet and triplet states are mixed by an inhomogeneous hyperfine field of about 1 mT. We demonstrate that this mixing can be controlled by changing either the external magnetic field or the interdot tunnel coupling. The transitions between triplet and singlet states in turn lead to current-induced dynamical nuclear polarization. In certain regimes, marked current bistabilities appear as a function of both field and time.

**B6 2 Enhancement of Spin Coherence Using Q-factor Engineering in Semiconductor Microdisk Lasers.***
SAYANTANI GHOSH,† *Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106, USA*

Semiconductor microcavities offer unique means of controlling light-matter interactions in confined geometries, resulting in a wide range of applications in optical communications and inspiring proposals for quantum information processing and computational schemes. Studies of spin dynamics in microcavities have revealed novel effects such as polarization beats, stimulated spin scattering, and giant Faraday rotation. Here, we study the electron spin dynamics in optically-pumped GaAs microdisk lasers with quantum wells (QWs) and interface-fluctuation quantum dots (QDs) in the active region. Using all-optical time-resolved measurement techniques, we examine how the electron spin dynamics are modified by the stimulated emission in the disks, and observe a surprising enhancement of the spin coherence time when the optical excitation is in resonance with a high quality ($Q \sim 5000$) lasing mode[1]. This resonant enhancement, contrary to expectations from the observed trend in the carrier recombination time, is then manipulated by altering the cavity design and dimensions. In analogy to devices based on excitonic coherence, this ability to engineer coherent interactions between electron spins and photons may provide novel pathways towards spin dependent quantum optoelectronics.

**B6 3 Teleportation of electronic many-qubit states via single photons.**
MICHAEL FLATTÉ, *The University of Iowa*

I will describe a proposed a teleportation scheme[1] that relies only on single-photon measurements and Faraday rotation, for teleportation of many-qubit entangled states stored in the electron spins of a quantum dot system. The interaction between a photon and the two electron spins, via Faraday rotation in microcavities, establishes Greenberger-Horne-Zeilinger entanglement in the spin-photon-spin system. The appropriate single-qubit measurements, and the communication of two classical bits, produce teleportation. This scheme provides the essential link between spintronic and photonic quantum information devices by permitting quantum information to be exchanged between them. Work supported by DARPA/ARO DAAD19-01-1- 0490. [1] M. N. Leuenberger, M. E. Flatté, and D. D. Awschalom, Phys. Rev. Lett. 94, 107401 (2005).

**13:03**
**B6 4 Optically probing charge and spin states in quantum dots and molecules.**
JONATHAN FINLEY, *Walter Schottky Institut*

In this talk I will discuss recent experiments in which we electrically manipulate coupled excitonic states (neutral and negatively charged single excitons) in individual QD-molecules using static electric fields. The samples investigated consist of a single pair of vertically stacked, self assembled InGaAs QD-molecules embedded in an n-type GaAs Schottky photodiode. This device geometry enables us to control the coherent coupling between excitonic states in the upper and lower dots by tuning the electric field oriented along the axis of the QD-molecule by applying a bias voltage between the n-contact and the Schottky-gate. New information is obtained on the spin structure of negatively charged trions in coupled quantum dot nanostructures. At low excitation power densities, field dependent luminescence reveals a clear anticrossing of spatially direct (e,h in the same dot) and indirect (e,h in different dots) neutral excitons, with coupling energies in the range $2E_{ee}$=1.2-3.2meV. Our experimental findings are shown to be in very good accord with realistic calculations of the single exciton spectrum, confirming that the tunnel coupling is mediated by hybridization of the electron component of the exciton wavefunction over the two dots. In contrast, the spectrum and controlled hybridization of itnegatively charged excitons is shown to be much richer due to the complex spectrum of three particle states ($X^-$=2e+1h) that can exist in a QD-molecule. For example, the spin structure of the spatially localized and dissociated $X^-$ states is found to play a major role in the spectrum of controlled hybridization with distinct triplet and single states evolving very differently as the coupling is tuned. The demonstration of tunable coupling and manipulation of spin and exchange couplings in negatively charged systems may constitute an important step towards the development of optically gateable QD-molecules for applications in quantum information science.

**13:39**
**B6 5 Production and Detection of Spin-Entangled Electrons in Mesoscopic Conductors.**
GUIDO BURKARD, *University of Basel, Switzerland*

Electron spins are an extremely versatile form of quantum bits. When localized in quantum dots, they can form a register for quantum computation. Moreover, being attached to a charge in a mesoscopic conductor allows the electron spin to play the role of a mobile carrier of quantum information similarly to photons in optical quantum communication. Since entanglement is a basic resource in quantum communication, the production and detection of spin-entangled Einstein-Podolsky-Rosen (EPR) pairs of electrons are of great interest. Besides the practical importance, it is of fundamental interest to test quantum non-locality for electrons. I review the theoretical schemes for the entanglement production in superconductor-normal junctions [1] and other systems. The electron spin entanglement can be detected and quantified from measurements of the fluctuations (shot noise) of the charge current after the electrons have passed through an electronic beam splitter [2,3]. This two-particle interference effect is related to the Hanbury-Brown and Twiss experiment and leads to a doubling of the shot noise $S_I = \langle \delta I \, \delta I \rangle_{\omega=0}$ for spin-entangled states, allowing their differentiation from unentangled pairs. I report on the role of spin-orbit coupling (Rashba and Dresselhaus) in a complete characterization of the spin entanglement [4]. Finally, I address the effects of a discrete level spectrum in the mesoscopic leads and of backscattering and decoherence. [1] P. Recher, E. V. Sukhorukov, D. Loss, Phys. Rev. ## SESSION B7: BIONANOTECHNOLOGY: APPLICATION AND FUNDAMENTAL ASPECTS OF PROCESSES AT NANO-SCALE

**Monday Morning, 13 March 2006; 307, Baltimore Convention Center at 11:15**
**Zuzanna S. Siwy, University of California, Irvine, presiding**

**11:15**
**B7 1 Ion Channels as Nanodevices.**
ROBERT EISENBERG,* *Molecular Biophysics: Rush University*

Ion channels are proteins surrounding a hole that allow substances to cross biological membranes. The concentration or current of these substances controls an enormous range of biological function: ion channels are nearly as important in biology as transistors in computers. Ion channels have a stable structure (on biological time scales $> 0.1\mu$sec) once open and so current through them can be analyzed by 'physics as usual'. The permanent charge on the wall of the channel is large and the volume is tiny, so the number density of ions in the channel is very large, $>$ 10 M. Physical properties of channels can be understood from the balance between electrical and van der Waals forces of charge crowded into a tiny space. Many biological properties of channels can be understood in the engineering tradition of devices: channels follow reasonably robust 'device equations' determined by their specific structural design and general physical environment. Channel research seeks to understand these device equations in **itjust** enough detail to control them. Channels—like most

engineering devices—function away from equilibrium, so spatially non-uniform boundary conditions and non-equilibrium statistical mechanics must be used in their description. Atomic scale simulations pose certain problems since trace concentrations of ions ( $< \mu$M) often control biological function and ions flow on time scales very much slower than the time steps of simulations. Atomic scale simulations of microM activities requires enormous numbers of water molecules ( $> 10^{11}$); direct simulation of ionic current involves many billions ( $> 10^{11}$) of time steps, suggesting that analysis must be multiscale if it is to be useful. This should come as no surprise, since the function of ion channels is inherently multiscale: ion channels act as nanovalves, nanodevices that allow details of atomic structure to control macroscopic flows and biological function.

**B7 2 Fluctuation driven active molecular transport in passive channel proteins.**
IOAN KOSZTIN, *University of Missouri - Columbia*

Living cells interact with their extracellular environment through the cell membrane, which acts as a protective permeability barrier for preserving the internal integrity of the cell. However, cell metabolism requires controlled molecular transport across the cell membrane, a function that is fulfilled by a wide variety of transmembrane proteins, acting as either passive or active transporters. In this talk it is argued that, contrary to the general belief, in active cell membranes passive and spatially asymmetric channel proteins can act as active transporters by consuming energy from nonequilibrium fluctuations fueled by cell metabolism. This assertion is demonstrated in the case of the E. coli aquaglyceroporin GlpF channel protein, whose high resolution crystal structure is manifestly asymmetric. By calculating the glycerol flux through GlpF within the framework of a stochastic model, it is found that, as a result of channel asymmetry, glycerol uptake driven by a concentration gradient is enhanced significantly in the presence of non-equilibrium fluctuations. Furthermore, the enhancement caused by a ratchet-like mechanism is larger for the outward, i.e., from the cytoplasm to the periplasm, flux than for the inward one, suggesting that the same non-equilibrium fluctuations also play an important role in protecting the interior of the cell against poisoning by excess uptake of glycerol. Preliminary data on water and sugar transport through aquaporin and maltoporin channels, respectively, are indicative of the universality of the proposed nonequilibrium-fluctuation-driven active transport mechanism. This work was supported by grants from the Univ. of Missouri Research Board, the Institute for Theoretical Sciences and the Department of Energy (DOE Contract W-7405-ENG-36), and the National Science Foundation (FIBR-0526854).

**12:27**
**B7 3 Pressure-driven DNA polymer transport in microfluidic and nanofluidic channels.**
DEREK STEIN, *Delft University of Technology*

The transport of DNA and proteins within micro- and nanofluidic channels is of central importance to ''lab-on-a-chip'' bioanalysis technology. As fluidic devices shrink, a new regime is encountered where critical device dimensions approach the molecular scale, and the behavior of polymers often departs significantly from the bulk. Here, we present a study of the pressure-driven transport of individual DNA molecules in 175 nm – 3.8 $\mu$m high silica channels. Two distinct transport regimes were observed: The pressure-driven mobility of DNA increased with molecular length in channels higher than a few times the molecular radius of gyration, whereas DNA mobility was practically independent of molecular length in thin channels. In addition, both the Taylor dispersion and the self-diffusion of DNA molecules were observed to decrease significantly in confined channels, each obeying a power-law scaling relationship. These unusual transport properties are shown to be rooted in the statistical nature of DNA polymer coils. Our results show that simple fluidic channels can be engineered to achieve either hydrodynamic DNA length separation or uniform transport with minimal dispersion using pressure-driven flows.

**13:03**
**B7 4 The Transportation System Inside a Living Cell.***
CLARE YU,† *University of California, Irvine*

A living cell has an infrastructure much like that of a city. We will describe the transportation system that consists of roads (filaments) and molecular motors (proteins) that haul cargo along these roads. This transportation system is essential for such diverse processes as neuronal function and mitochondrial transport. While there have been studies of how motors function at the single molecule level, and studies of the structure of filamentary networks, studies of how the motors effectively use the networks for transportation have been lacking. We will give an example showing that pigment cells regulate transport by controlling how often pigment granules switch from one filament to another, rather than by altering individual motor activity at the single molecule level, or by relying on structural changes in the network.

**13:39**
**B7 5 Bio-functionalized Nanotube Membranes For DNA Separation.**
PUNIT KOHLI, *Southern Illinois University*

The studies of translocation and transport of ions, biopolymers, and other genetics materials is very important in medical and scientific communities. The transport of biopolymers such as RNA, DNA, and polypeptides across membrane occurs in many biological systems. Examples include the transport of RNA molecules and transcription factors through nuclear pores, injection of DNA from a virus head into the host cell, and the uptake of oligonucleotides by specific membrane proteins. Another example is the transport of ions through protein ion channels across cell membranes, which converts the concentration of transported analytes through a channel into change in channel conductance. Nature's highly selective biosensor are based on molecular-recognition of one species of interest in the presence of others. In this presentation, I will discuss the fabrication of a new DNA biosensor. I will also talk about the transport behavior of DNA molecules through nanotubes. These sensors based on monodisperse ensemble of gold nanotubes. Single stranded oligonucleotides were immobilized onto the inner walls of nanotubes. These bio/nano-membranes selectively transport complementary DNA across the membrane with selectivity greater than 5 was observed. With these membranes, single nucleotide polymorphism detection is also demonstrated.

## SESSION B8: FOCUS SESSION: GRANULAR MATERIALS NEAR JAMMING

**11:15**
**B8 1 Elastic Granular Flows.**
CHARLES CAMPBELL, *University of Southern California*

There is no fundamental understanding of the mechanics of granular solids. Partially this is because granular flows have historically been divided into two very distinct flow regimes, (1) the slow, quasistatic regime, in which the bulk friction coefficient is taken to be a material constant, and (2) the fast, rapid-flow regime, where the particles interact collisionally. But slow hopper flow simulations indicate that the bulk friction coefficient is not a constant. Rapidly moving large scale landslide simulations never entered the collisional regime and operate in a separate intermediate flow regime. In other words, most realistic granular flows are not described by either the quasistatic or rapid flow models and it is high time that the field look beyond those early models. This talk will discuss computer simulation studies that draw out the entire flowmap of shearing granular materials, spanning the quasistatic, rapid and the intermediate regimes. The key was to include the elastic properties of the solid material in the set of rheological parameters; in effect, this puts solid properties back into the rheology of granular solids. The solid properties were previously unnecessary in the plasticity and kinetic theory formalisms that respectively form the foundations of the quasistatic and rapid-flow theories. Granular flows can now be divided into two broad categories, the Elastic Regimes, in which the particles are locked in force chains and interact elastically over long duration contact with their neighbors and the Inertial regimes, where the particles have broken free of the force chains. The Elastic regimes can be further subdivided into the Elastic-Quasistatic regime (the old quasistatic regime) and the Elastic-Inertial regime. The Elastic-Inertial regime is the ''new'' regime observed in the landslide simulations, in which the inertially induced stresses are significant compared to the elastically induced stresses. The Inertial regime can also be sub-divided into an Inertial-Non-Collisional where the stresses scale inertially, but the particles interact in clusters through long duration contacts, and the Inertial-Collisional (or the old rapid-flow) regime. Finally, the simulations show that Stress-Controlled flows are rheologically different from Controlled-Volume flows. Physically, there is a range of dense concentrations ($0.5 < \nu < 0.6$) in which it is possible, but not necessary to form force chains and demonstrate elastic behavior. (In other words it is possible for the material to exhibit two different states at the same concentration.) By forcing the material to support an applied loads across force chains, Stress-Controlled flows may behave elastically through this range of concentrations while, at the same shear rates rate Controlled-Volume flows, fixed at the average concentration of the Stress-Controlled flow, behave inertially.

**B8 2 Force distributions and stress fluctuations in a triangular lattice of rigid bars*** BRIAN TIGHE, JOSHUA SOCOLAR, *Physics Dept., Duke University, Durham, NC* We study the uniformly weighted ensemble of force balanced configurations on a triangular network of nontensile contact forces as a model of force distribution on a hyperstatic granular material. For periodic boundary conditions corresponding to isotropic compressive stress, the probability distribution for single-contact forces, $P(f)$, decays faster than exponentially, and a field closely related to the lattice version of the Airy stress function is found to have fluctuations characterized by a structure factor $S(q) \sim 1/q^4$. The super-exponential decay of $P(f)$ persists in lattices diluted to the rigidity percolation threshold. On the other hand, for anisotropic imposed

stresses, a broader tail emerges, becoming a pure exponential in the limit of infinite lattice size and infinitely strong anisotropy.

**B8 3 Measurement of Forces inside Three-Dimensional, Frictionless, Disordered Matter** JING ZHOU, ANTHONY DINSMORE, *University of Massachusetts at Amherst* We directly measured individual forces inside the concentrated piles of frictionless droplets. We report on the distribution of contact forces normalized by the droplet mean, in addition to the distribution of forces normalized by sample mean, as well as the distribution of contact angles. We compare these results to existing models and to a new, numerical calculation that treats the droplets as independent particles and derive the contact-force probability distribution that arises self-consistently from balancing forces. The force chain architecture was visualized, and quantified with a new definition based on long-range correlations. The obtained chain persistence length helps to establish a connection between microscopic force network and the modulus of meso- or macroscopic piles. This work is supported by NSF (DMR-0305395).

**12:15**

**B8 4 Effects of Particle Size Dispersity on the Response to Compressive Strains*** MEENAKSHI DUTT, *University of Cambridge* BRUNO HANCOCK, *Pfizer Inc., Groton, Connecticut, USA* CRAIG BENTHAM, *Pfizer Ltd., Sandwich, Kent, USA* JAMES ELLIOTT, *University of Cambridge* Particle packings found in nature and industry are rarely comprised of single components, in terms of particle size. These packings are generated under a variety of circumstances which influence its response to an external load or strain. We explore both the effect of packing history prior to application of compressive strain, and the variation in the response with the size distribution of the component particles. We generate the packings by allowing the particles to settle under gravity for a fixed interval of time, or until a cut-off packing fraction is attained, followed by application of a compressive strain for a fixed interval of time. We repeat these studies using numerical experiments for samples of discrete size (200 microns, 195-225 microns, 170-260 microns, 150-295 microns) and random (100-300 microns, 100-400 microns, 100-500 microns) size distributions. We find the number of particles with fewer than 4 contacts to increase with size dispersity of the sample after the particles settle under gravity. In addition, the fraction of plastic contacts decreases with increasing variation in particle size during the compression. We also present correlations between the populations of low and high force bearing contacts, particle size and the yield state of the contacts.

**12:27**

**B8 5 Measurements of the Yield Stress in Repulsive Athermal Systems** NING XU, COREY O'HERN, *Yale University* We performed molecular dynamics of dry frictionless granular media to gain a deeper understanding of the yield shear stress in these materials. The measurements were obtained by shearing the systems in both the constant shear force and constant shear velocity ensembles. At fixed shear force, we identified the yield shear stress as the shear stress $\Sigma_{yf}$ required to maintain steady flow in an initially unsheared static state. At fixed shear velocity, we identified the yield shear stress as the average shear stress $\Sigma_{yv}$ in the limit of zero shear velocity. At finite system size, $\Sigma_{yf} > \Sigma_{yv}$, which implies that there is a shear rate discontinuity when the system begins flowing in the constant shear force ensemble. However, the difference between the two measures of the yield shear stress decreases with increasing system size; $\Sigma_{yf}$ and $\Sigma_{yv}$ become identical in the infinite system size limit. Thus, the jump discontinuity in the shear rate at the unjamming threshold is a finite-size effect in frictionless granular systems.

**12:39**

**B8 6 Experiment test of a Janssen formula in a dense granular column*** KEVIN FACTO, *University of Massachusetts-Amherst* TOM SCHICKER, *University of Massachusetts-Amherst* NARAYANAN MENON, *University of Massachusetts-Amherst* The stresses inside a tall column of either static or flowing granular material saturate with depth, because the weight of the material is borne by friction with the walls. In the static case, the height dependence of the stress is traditionally described by the Janssen formulation, in which the shear stress at the wall is assumed to be proportional to the normal stress. We report measurements of all three components of force at the wall of a dense, gravity-driven flow of glass beads. We find that the depth dependence of the stress in this slow flow is well-described by a Janssen-like formula. We are also able for the first time to directly test the Janssen assumption, and find that the fluctuations in the shear and normal forces at the wall are highly correlated. The measured friction angle is independent of flow rates for the slow flows we have examined, and is surprisingly close to the ensemble average of the friction angle measured when the flow is stopped.

**12:51**

**B8 7 Impact of Particle Elasticity on Granular Force Networks** JOHN WAMBAUGH, *Duke University* ANNIE THEBPRASITH, *Mount Holyoke College* ROBERT HARTLEY, *Duke University* ROBERT BEHRINGER, *Duke University* We investigate the distribution of force within vertically-confined granular assemblies using photoelastic techniques that allow determination of both geometric configuration and force upon each particle. By binning multiple realizations with depth, we are able to compare our results with the simple, continuum model of Janssen. Recent experimental studies of the force at the boundaries of such assemblies have largely confirmed Janssen's prediction that mean force saturates exponentially with depth due to frictional contacts at the boundaries. [Ovarlez, Fond and Clement, PRE 67, 060302 (2003)] We have observed deviations from these predictions in our system, which we quantify in terms of the structure of the network that distributes forces. We examine the role of internal elasticity of the particles in causing these deviations. This research is supported by NSF grants DMR-0137119 and DMS-204677 and NASA grant NNC04GB08G.

**B8 8 Freezing and Melting in Granular Materials.**
KAREN DANIELS, *Dept. of Physics, North Carolina State University*

From bowls of nuts to eroding soil, granular materials are all around us. In spite of the fact that granular materials are dissipative and athermal, statistical mechanics allows considerable insight into their behavior. I will present experiments on particles which are vibrated from below and sheared from above within an annular channel. The vibrations have the remarkable effect of crystallizing the material, rather than melting it as temperature would an ordinary material. This freezing/melting transition is hysteretic, with the critical line corresponding to equal kinetic energies for vibration and shear. We characterize the transition between these two states, and observe features reminiscent of both a jamming transition and critical phenomena. Another remarkable property is the increase of pressure with volume over a continuum of partially and/or intermittently melted states, in contrast to standard thermodynamic behavior.

**13:39**
**B8 9 Plastic Failure Events in 2D Sheared Granular Systems*** TRUSH MAJMUDAR, ROBERT BEHRINGER, *Physics Department, Duke University* We present experimental measurements of plastic failure events in a two dimensional granular system consisting of polymer photoelastic disks, placed horizontally, and confined within a rectangular biaxial cell. The bi-refringence of these disks allows us to determine the normal and tangential components of contact forces. We image the system at various deformation states and measure the stress changes and displacements of the disks during one complete shear cycle. The stress changes are found by computing the stress tensor of each disk and the displacements are measured by particle tracking. We obtain bulk stress-strain curves by spatial averaging and find that the system exhibits regions of reversible deformation interrupted by irreversible plastic failure events. We also obtain the behavior of shear modulus of the system. The spatial distribution of reversible and plastic deformations found by studying the displacements of the disks show that in two corners, the disks move uniformly but in a central band aligned along a principal strain direction, we observe multiple vortices. Reversing the direction of shear causes maximum plastic deformation which results in disruption of the vortex structure. We compare our results to the shear transformation zone (STZ) theory.

**B8 10 Statistical Properties of Granular Solid to Liquid Transition in Small Systems under Shear** MARTIN MELHUS, IGOR ARANSON, *Argonne National Laboratory* DMITRY VOLFSON, LEV TSIMRING, *University of California, San Diego* The fluidization transition of a dense granular assembly under shear is studied numerically using soft particle molecular dynamics simulations in two dimensions using a previously verified predictor-corrector algorithm. We focus on small systems in a thin Couette cell, examining the bistable region while increasing shear, with varied amounts of random noise, and determine the statistics of shear required for fluidization. We find an approximately linearbetween noise and fluidization shear threshold over the transition regime, and that the variance in the threshold decreases as the system size increases.

**14:03**
**B8 11 Granular shear flow with imposed vibrations** BRIAN UTTER, *James Madison University* ERIC HOPPMANN, *James Madison University* We present results on a 2D photoelastic shearing experiment in which we impose force fluctuations by vibrating the shearing surface. The experiment consists of a dense assembly of 2D photoelastic grains between two belts moving in opposite directions, such that the central region approximates planar shear. The granular medium lies horizontally between the belts such that gravity does not compact the grains. One of the shearing surfaces is vibrated at a known frequency and amplitude during shear. We measure properties of the particle flow and characterize the force network by placing the photoelastic grains between crossed polarizers. We find that as vibration amplitude is increased, the number and magnitude of these force chains decreases drastically. The vibration also leads to increased slip at the shearing surface and decreased particle flow at both shearing surfaces.

**SESSION B9: PHASE TRANSITIONS, DYNAMICS, AND EXCITATIONS**

**B9 1 Competing periodicities in fractionally filled quasi-1D bands** P.C. SNIJDERS, *Kavli Institute of Nanoscience* S. ROGGE, *Kavli Institute of Nanoscience, Delft, The Netherlands* H.H. WEITERING, *University of Tennessee, Knoxville, and Oak Ridge National Laboratory, USA* We present a variable temperature Scanning Tunneling Microscopy and Spectroscopy (STM and STS) study of the Si(553)-Au atomic chain reconstruction. This quasi one-dimensional (1D) system undergoes at least two charge density wave (CDW) transitions at low temperature, which can be attributed to electronic instabilities in the fractionally-filled 1D bands of the high-symmetry phase. Upon cooling, Si(553)-Au first undergoes a single-band Peierls distortion, resulting in period doubling along the imaged chains. This Peierls state is ultimately overcome by a competing tripleperiod CDW, which in turn is accompanied by a $\times$ 2 periodicity in between the chains. These locked-in periodicities indicate small charge transfer between the nearly half-filled and quarter-filled 1D bands. The mobility of atomic scale dislocations in the $\times$ 3 CDW state indicates the pos-

sibility of manipulating phase solitons carrying a (spin,charge) of (1/2,± e/3) or (0,± 2e/3).

**B9 2 Order-disorder phase transitions: a DFT - (Wang-Landau) MC study** MIRA TODOROVA, *School of Physics, The University of Sydney, Australia* MIKAEL BORG, *University of Toronto, Toronto, Canada* CATHERINE STAMPFL, *School of Physics, The University of Sydney, Australia* MATTHIAS SCHEFFLER, *Fritz-Haber-Insitut der Max-Planck Gesellschaft, Berlin, Germany* Using a hybrid statistical mechanics method comprising the use of a Lattice-gas Hamiltonian (LGH) determined from ensity-functional theory and subsequent Monte Carlo (MC) calculations, we obtain a phase diagram for Na-Al surface alloys from first-principles and compare it to experimental results [1]. A safe approach towards parametrizing a LGH from the self-consistent evaluation of the electronic structure starts with an analytic form for the long-range pair-interactions. This expression is corrected in the short and medium range using DFT derived data, also including nearsighted many-body terms. An ensuing cross-validation is of utmost importance to ensure that the corrections (to the long-range part) are assessed with an optimum accuracy. The thus extracted LGH is used to perform MC calculations, also using the new Wang-Landau MC algorithm [2], which allows us to reliably determine the transition temperature. [1] M. Borg *et al.*, Chem. Phys.Chem. **6**, 1923 (2005). [2] F. Wang and D.P. Landau, Phys. Rev. Lett. **86**, 2050 (2001).

**B9 3 Bose Einstein condensation of magnons in mesoscopic ferromagnets.** L.H. BENNETT, E. DELLA TORRE, *George Washington University* R.E. WATSON, *Brookhaven National Laboratory* Bulk magnetic materials are comprised of magnetic domains. As the size of the sample is reduced, it forms a single domain state. Further reduction of particle size yields a superparamagnetic state. There is an apparent phase transition[1] between the single domain state and the superparamagnetic state at some critical size in the single-domain mesoscopic region. We had found[2,3] a Bose-Einstein condensation in a number of mesoscopic ferromagnets (30 - 60 nm diam). We hypothesize that the superparamagnetic-to-single domain ferromagnetic transition involves the same type of Bose-Einstein condensation.

**B9 4 Bose-Einstein Condensation of Ni spin degrees of freedom observed from susceptibility measurements at high magnetic field in $NiCl_2$-4SC$(NH_2)_2$** CATALIN MARTIN, KENNETH PURCELL, TIMOTHY MURPHY, ERIC PALM, STAN TOZER, *National High Magnetic Field Laboratory, FSU, Tallahassee, FL* VIVIEN ZAPF, ALEX LACERDA, *National High Magnetic Field, Los Alamos, NM* ARMANDO PADUAN-FILHO, *Instituto de Fisica, Universidade de Sao Paulo, Sao Paulo, Brazil* NHMFL, FSU, TALLAHASSEE, FL TEAM, LANL, LOS ALAMOS, NM TEAM, INSTITUTO DE FISICA, UNIVERSIDADE DE SAO PAULO, SAO PAULO, BRAZIL TEAM, The organic compound $NiCl_2$-4SC$(NH_2)_2$ is a new candidate for Bose-Einstein condensation (BEC) of spins system. Involving a technique based on a self-resonant LC-oscillator, we measured the change in magnetic susceptibility of $NiCl_2$- 4SC$(NH_2)_2$ in magnetic field up to 18 Tesla, and temperatures down to 60 mK. We have found the existence of two phase boundaries. One appears at $H_{c1} \sim 2$ T, where the gap between the $S_z = 0$ ground state and the $S_z = -1$ excited state is overcome by the Zeeman effect and the spin condensation starts. The other boundary is at $H_{c2} \sim 12$ T, where the system saturates. Our results on temperature and angular dependence of critical fields will be discussed in connection with previous experimental reports and theoretical predictions for BEC.

**12:03**

**B9 5 Spin Density Wave Suppression in Thin Films of Cr.** DANIEL QUEEN, ZOE BOEKELHEIDE, DAVID COOKE, FRANCES HELLMAN, *University of California, Berkeley* The magnetic and electronic properties of thin films of Cr are critical to their use in GMR multilayers and are not the same as bulk Cr. For example, itinerant spin density waves have been shown to be suppressed in thin films of Cr. This suppression has been attributed to disorder in the microstructure of the films. For bulk Cr the electronic contribution to the heat capacity $\gamma = 3.5$ J/mol $\cdot$ $K^2$ for nonmagnetic Cr and $\gamma = 1.4$ J/mol $\cdot$ $K^2$ for magnetic Cr. Recent heat capacity measurements on Cr thin films have found $\gamma = 3.2$ J/mol $\cdot$ $K^2$ in agreement with the nonmagnetic bulk value. These Cr films also have a reduced $\theta_D$ with respect to the bulk and indicate a softening of phonon modes as seen in nanocrystalline materials. We present magnetization and heat capacity results for Cr thin films.

**12:15**

**B9 6 Phase transitions in metal-oxide particulate-surface interactions: insights through ab initio study** DANIEL FREEDMAN, TOMAS ARIAS, *Cornell University* We present results for *ab initio* molecular dynamics calculations of collisions between metal-oxide particulates and metal-oxide surfaces. Detailed examinations of the resulting trajectories suggest particulate internal kinetic energy as a key parameter in obtaining smooth laminar deposition of thin films. Based on *ab initio* calculations and more extensive supporting classical molecular dynamics modelling, we propose a phase-diagram which maps both translational and internal kinetic energy to modes of crystal growth.

**12:27**

**B9 7 Optical Measurements of Grain Boundary Melting** ERIK THOMSON, *Yale University* JOHN WETTLAUFER, *Yale University* LARRY WILEN, *Ohio University* Bulk properties of polycrystalline solids are strongly influenced by effects of grain boundary melting. While numerical simulations and theory support the idea of disorder along grain boundaries, direct experimental access to the interface of two crystals in thermodynamic equilibrium remains difficult. Polycrystalline ice, however, possesses unique properties which lend it to experimental probing. In addition to its transparency and birefringency the melting temperature of ice, which is relatively close to ambient temperatures, make it an ideal solid within which to experimentally explore grain boundary melting. Here using light scattering by a 4mW Helium-Neon laser we

directly explore the boundary in an ice bicrystal, prepared within a thin ice growth cell. Reflected light intensity is measured as a function of the thermodynamic variables, temperature and impurity concentration. C-axis orientation of individual crystals can be determined by systematically measuring the difference between incident and transmitted polarized beams. Assuming the index of refraction for bulk water, for any melted layer, we anticipate a greater than 10% change in reflected signal strength for a 15 angstrom melt layer. Experimental results are compared with a recent theoretical study of impurity driven grain boundary melting.

**12:39**

**B9 8 Photoelectron Emission Microscopy at the Manganese L-edge of Thin $La_{1-x}$ $Sr_x$ Mn $O_3$ Films through the Phase Transition** M.A. DELEON, T. TYSON, *New Jersey Institute of Technology, Applied Physics* C. DUBOURDIEU, *Laboratoire des Máteriaux et du Génie Physique UMR CNRS 5628, INPG, 38402 St.Martin d'Héres, France* A. SCHOLL, A. DORAN, *ALS* Surface magnetization of $La_{1-x}$ $Sr_x$ Mn $O_3$ films has been observed directly by x-ray photoelectron emission microscopy (XPEEM) at the manganese L-edge. Two sets of films of similar thickness range have been grown via metal-organic chemical vapor deposition (MOCVD) on $LaAlO_3$ and $SrTiO_3$ substrates. The data provides direct observation of magnetic domain melting and growth through the transition temperature. A comparison of domain geometry between the two sets of films will be presented. The effect of the coupling of the strain (tensile vs. compressive) with the magnetization will be discussed. This research is supported by NSF DMR-0209243 and DMR-0512196.

**B9 9 Thermodynamic Investigation of n-Hexane and Cyclohexane on MgO (100) Surfaces*** PETER N. YARON, JOHN Z. LARESE, *Univ. of Tennessee, Knoxville* Thermodynamic properties of thin films of n-hexane and cyclohexane adsorbed on MgO (100) surfaces were investigated and compared using high-resolution volumetric isotherm techniques. A series of high-resolution adsorption isotherm measurements were recorded for n-hexane and cyclohexane between 197K to 255K and 230K to 280K respectively using an automated volumetric isotherm apparatus. Adsorption data was used to determine thermodynamic quantities e.g. the two-dimensional isothermal compressibility and isosteric heats of adsorption and to identify regions where phase transitions might occur. Evidence is found for the presence of two layering transitions in both systems.

**B9 10 Complex Conductance Measurements of Ultra-thin MoGe films near the Superconductor-Insulator Transition** LUKAS URBAN, MICHAEL CALLAHAN, *University of Illinois at Urbana-Champaign* ALI YAZDANI, *Princeton University* The application of a magnetic field drives a two-dimensional superconductor through an unexpected conducting state into an insulating state. While this transition has been studied using electrical transport techniques, we present a different way to study the magnetic field-tuned transition. Using a two coil mutual inductance probe inside a top-loading dilution refrigerator, we measure the complex conductance of $Mo_{43}Ge_{57}$ thin films as we vary the temperature or apply a magnetic field. From the complex conductance we determine the superconducting electron density around this field-tuned transition. This work was supported by NSF grants DMR-98-75565 and DMR-03-1529632, U.S. Department of Energy grant DEFG-02-91ER4539 through the Frederick Seitz Materials Research Laboratory and Office of Naval Research grant N000140110071.

**B9 11 Crystallization behaviors of *n*-nonadecane in confined space: observation of metastable phase induced by surface freezing** DUJIN WANG, BAOQUAN XIE, *KLEP, Joint Lab. of Polymer Science and Materials, Institute of Chemistry, CAS, Beijing 100080, China* HAIFENG SHI, XIA DONG, YING ZHAO, CHARLES C. HAN, DUANFU XU, *PPCL, Joint Lab. of Polymer Science and Materials, Institute of Chemistry, Chinese Academy of Sciences, Beijing 100080, China.* Crystallization and phase transition behaviors of *n*-nonadecane in microcapsules was studied with the combination of differential scanning calorimetry (DSC) and synchrotron radiation X-ray diffraction (XRD). As evident from the DSC measurement, a surface freezing monolayer, which is formed in the microcapsules before the bulk crystallization, induces a novel metastable rotator phase ($R_{II}$), which has not been reported anywhere else. We argue that the existence of the surface freezing monolayer decreases the nucleating potential barrier of $R_{II}$ phase and turns the transient $R_{II}$ phase to a 'long-lived' metastable phase.

**B9 12 Ordering and Dynamics of $CN^-$/Cu(001) Surfaces*** ERKAN CIFTLIKLI, IAN SHUTTLEWORTH, ALEXEI ERMAKOV, JANE HINCH, *Department of Chemistry and Chemical Biology, Rutgers University, NJ 08854.* $C_2N_2$ adsorption on Cu(001) is largely dissociative, yielding adsorbed $CN^-$ species. Exposure dependent angular-resolved Helium Atom Scattering (HAS) measurements show the initial development of a diffuse backscattered intensity, followed by the onset of c(10x6) superstructure domain growth only in a limited exposure temperature range. Diffraction from an ordered phase is not observed for exposures above 323K, nor below 223K. Yet, even at optimal deposition temperatures, a diffuse scattering contribution remains at saturation and persists beyond 473K. Energy and angular resolved measurements show that the diffuse He intensity is strongly inelastic, and multiphonon-like; i.e. not showing features with resolvable discrete energies. The surface temperature and momentum exchange dependencies of this intensity will elaborate the nature of the dynamics of $CN^-$ on Cu(001) surfaces. The $CN^-$ coverage dependence of the inelastic intensity also illustrates the influence of intermolecular interactions in $CN^-$ motion.

**B9 13 Theoretical treatment of non-vibrationally-relaxed electron transfer in organic solar cells** KUO KAN LIANG, *Division of Mechanics, Research Center for Applied Sciences, Academia Sinica, Taiwan* CHIH-KAI LIN, *Institute of Atomic and Molecular Sciences, Academia Sinica, Taiwan* HUAN-CHENG CHANG, *Institute of Atomic and Molecular Sciences, Academia Sinica, Taiwan* MICHITOSHI HAYASHI, *Center for Condensed Matter Sciences, National Taiwan University, Taiwan* SHENG HSIEN LIN, *Institute of Atomic and Molecular Sciences, Academia Sinica, Taiwan* In this work we shall show how to calculate the single vibronic- level electron transfer rate constant, which will be compared with the thermal averaged one. To apply the theoretical

results to the dye- sensitized nano-crystalline semiconductor (Grätzel type) solar cells, we use a simple model to describe how we model the final state of the eletron- transfer process (oxidized dye and reduced semiconductor). Numerical calculations of the single-level electron transfer rate constants and the simulation of the quantum beat in the photo-excited state and the product state will be performed to demonstrate the theoretical results.

**13:51**
**B9 14 Investigating chemicurrent production from hyperthermal-energy ion impacts** S.A. MOODY, M.P. RAY, C.E. SOSOLIK, *Department of Physics and Astronomy, Clemson University* The production of chemicurrents by thermal-energy molecular beam scattering from thin-film Schottky diode surfaces has generated considerable interest in the field of gas-surface physics. These experiments promise to give insight into energy transfer processes at surfaces. However, few experiments have investigated chemicurrent production at higher impact energies. We propose experiments to study beam impact events on Schottky diode/thin film surfaces using hyperthermal ion beams, with the added capability of studying the mechanism of charge transfer. These experiments will utilize our lab's highly versatile beamline. The beamline is ideal for exploring chemicurrent phenomena at higher energies because of the capability it gives us to producewell-characterized ion beams at hyperthermal- and low-energies with a wide variety of gas and solid-state sources. This talk will focus on optimization of our beamline for this experiment. Specific attention will be given to the addition of a new load lock/sample transfer system and the electronic interfacing required for simultaneous scattering/chemicurrent data acquisition. Preliminary results from hyperthermal impact events on thin film Schottky diodes are also presented.

**B10 1 Potential Application of the Enhanced Absorption and the Enhanced Scattering Processes of Plasmonic (Gold and Silver) Nanoparticles of Different Shapes.**
MOSTAFA EL-SAYED, *Georgia Institute of Technology*

The crossections of absorption and scattering of plasmonic nanoparticles are orders of magnitude larger than those of molecular dyes. Their strong scattering properties make them much better contrast agents in biological and medical applications than fluorescent dyes. Their strong absorption makes them useful in photothermal therapy and in changing their shape or their location in assembled arrays. These applications will be illustrated.

**B10 2 Studying Photoluminescence Dynamics of Single Quantum Dots Photon by Photon*** HAW YANG, KAI ZHANG, AIHUA FU, PAUL ALIVISATOS, *UC Berkeley* CARL HAYDEN, *Sandia National Laboratory* Colloidal semiconductor nanocrystals, or quantum dots (QDs), have been the focus of much research effort in the past decade. The development of these colloidal dots has allowed the concepts of quantum confinement and dimensional control of electronic and optical properties to find entirely new areas of application, for instance in fluorescent labeling of biological specimens. At the single-particle level, however, colloidal QDs exhibit surprisingly complicated time-dependent behavior in their photoluminescence (PL) characteristics. The PL dynamics of the biologically compatible CdSe/ZnS/streptavidin quantum dots were studied using time-resolved single-molecule spectroscopy. Statistical tests of the photon-counting data suggested that the simple ''on/off'' discrete state model is inconsistent with experimental results. Instead, a continuous emission state distribution model was found to be more appropriate. Autocorrelation analysis of lifetime and intensity fluctuations showed a nonlinear correlation between them. These results were consistent with the model that charged quantum dots were also emissive, and that time-dependent charge migration gave rise to the observed photo-luminescence dynamics.

**B10 3 Photothermal properties of gold nanocages studied by time-resolved spectroscopy** MIN HU, JINGYI CHEN, YOUNAN XIA, XINGDE LI, *University of Washington, Seattle* HRISTINA PETROVA, GREGORY HARTLAND, *University of Notre Dame* MANUEL MARQUEZ, *INEST Group, Research Center, Philip Morris USA Inc.* Gold nanocages of different sizes synthesized via galvanic replacement reaction have been studied by ultrafast time-resolved spectroscopy. The vibrational phonon modes were excited and the periods of these modes increase with the size of the gold nanocages. For a specific size of nanocage, experiments with different excitation powers of the pump laser were performed (from 2 $\mu$J to 20 $\mu$J), we found that the period of the vibrational mode increased with the laser intensity. This was compared to experiments on spherical gold nanoparticles, which allow us to roughly estimate the temperature of the nanocages when the electrons and the phonons reach the equilibrium. The temperature of the nanocages can increase up to 1000 K, near the melting point of the bulk metal, while the particles maintain their integrity. This makes the nanocages potentially useful for photothermal therapy applications. The heat dissipation rate for the nanocages was also studied in these experiments, and was found to have the similar trend as spherical nanoparticles, i.e., larger particles stay hot for longer times than smaller particles.

**12:15**
**B10 4 Photoluminescence and Dynamics Measurements of Individual CdSe Quantum Wires** JOHN GLENNON, RUI TANG, WILLIAM BUHRO, RICHARD LOOMIS, *Department of Chemistry and Center for Materials Innovation Washington University*

*in St. Louis* The photoluminescence (PL) spectroscopy of highly monodispersed colloidal CdSe quantum wires (QWs) are investigated in the single nanocrystal environment using confocal fluorescence microscopy and are compared to similar studies preformed on three dimensionally confined CdSe quantum dots (QDs). The PL intensity of the QWs is observed to increase and then to decrease at room temperature ambient conditions with continued irradiation at moderate to high laser powers ( $>$ 10 kW*cm$^{-2}$) at much slower rates than similar processes in QDs. The energy of the peak intensity of the PL is monitored throughout the experiments and does not shift for the QWs. This is in contrast to the blue-shift observed for QDs as the PL intensity decays. For the QWs, it is shown that the change in PL intensity is localized to the diffraction limit irradiation spot and is not delocalized along the length of the QW. Differences in exposed crystalline facets and surface coverage between QWs and QDs are explored in context of the experimental observations. These phenomena are studied under different atmospheres and surface environments in order to elucidate the optical properties of these quantum-confined semiconductors.

**12:27**
**B10 5 Photo-Induced Single Molecule Electron Transfer at the Molecule-Nanoparticle Interface*** TIANQUAN LIAN, WANHEE GOH, JIANCHANG GUO, XI LIU, *Dept. of Chemistry, Emory Univ.* MICHAEL AHRENS, EMILIE SCHIERLOH, MICHAEL WASIELEWSKI, *Dept. of Chemistry, Northwestern Univ.* Single molecule fluorescence spectroscopy was used to study photoinduced electron transfer (ET) dynamics across single donor-bridge-acceptor junctions consisting of perylene-3,4:9,10-bis(dicarboximide) (PDI), n-phenylene bridge with COOH anchoring group, and antimony doped Tin Oxide(ATO) nanoparticles. Photo-excitation of PDI initiates electron transfer from its excited state into ATO nanoparticles. Electron transfer was confirmed and ensemble average rate was measured by transient infrared absorption spectroscopy, in which injected electrons in ATO were directly monitored. Single molecule fluorescence from donor molecule was confirmed by the observed blinking behavior, fluorescence spectrum, and excitation polarization dependence. Single molecule fluorescence lifetime was measured by time-correlated single photon counting, from which forward electron transfer rate from adsorbate excited state to nanoparticle was determined. The dependence of these single molecule ET rates and their fluctuation on the length of phenylene bridge and the nature of semiconductors are being investigated.

**B10 6 Dynamics of photoexcitations in quasi-one-dimensional systems.***
SUSAN DEXHEIMER, *Washington State University*

Low dimensional materials, and in particular, quasi-one-dimensional systems have attracted considerable interest owing to their unusual electronic properties. In many of these systems, strong electron-phonon couplings can lead to the formation of nonlinear excitations such as self-trapped excitons and polarons, in which electronic excitations become localized as a result of their interaction with the lattice. I will present the results of femtosecond time-resolved experiments in which we have studied the dynamics of the formation and evolution of localized excitations in quasi-one-dimensional molecular solids. This work has been carried out on mixed-valence halide-bridged transition metal linear chain (or MX) complexes, a class of materials that serve as model systems for the physics of low-dimensional materials. In these complexes, the relative strengths of the electron-electron and electron-phonon interactions, the fundamental physical parameters that determine the properties of the excitations, can be systematically tuned by chemical substitutions in the chain structure. Using femtosecond vibrationally impulsive excitation techniques, we have studied the coupled electronic and vibrational dynamics associated with excitonic self-trapping in a series of quasi-one-dimensional structures, and using time-resolved THz techniques, we have studied the dynamics of the formation and subsequent evolution of polarons.

**B10 7 Dynamics of the heat transfer at the interface of diamond {111} nanosurfaces.** OLEG A. MAZYAR, *Texas Tech University* Energy transfer across the interface between a small, hot model diamond {111} nanosurface and a much larger identical, cold nanosurface was studied by a classical molecular dynamics method. Kinetics of this energy transfer was found to be exponential with a rate constant increasing linearly with the increase of the normal load applied to the hot nanosurface. The rate constant of the heat transfer depends on the thickness of the small, hot nanosurface, both chemical and isotopic composition of the interface, but does not demonstrate significant changes with the increase of the nanosurfaces' contact area or the increase of the initial temperature difference between the nanosurfaces.

**13:27**
**B10 8 The Static and Dynamic Wetting of Si Nanorod Arrays*** JIANGUO FAN, YIPING ZHAO, The wettability of a solid state surface is affected by both the surface roughness and the surface chemical composition. Here, we report a systematic investigation on the static and dynamic wetting of vertically aligned Si nanorod arrays with different heights (aspect ratio) fabricated by the glancing angle deposition technique. For as-deposited hydrophilic films, there was a contact angle transition from a rough surface to a hemi-wicking porous surface at normal film thickness $d$ = 500

nm; while for the HF treated hydrophobic films, a transition from partial composite to composite surface was observed at the same film thickness. The observed results can be reasonably interpreted within framework of the classic Young's theory. We have also observed that for the hydrophilic nanorod arrays, the spreading of the water droplet causes the bundling of Si nanorods, and generates intriguing percolation patterns that change with the spreading diameter. The dynamic spreading process of a water droplet on the same surface has been recorded by a fast CCD camera, and scaling laws of the contact line, the precursor rim, and the spreading speed have been observed. Models based on capillary force, mechanical bending, as well as flow in a groove, have been proposed to qualitatively explain all the phenomena observed.

**13:39**
**B10 9 Inorganic Nanotubes, Nanofluidic Transistors and DNA Translocation** PEIDONG YANG, *University of California* Inorganic nanotubes, representing a new class of nanostructures, have been attracting considerable attention during the past few years. Single crystalline semiconductor GaN nanotubes can be synthesized by nanowire templated epitaxial casting method. Partial conversion of existing nanowires leads to the synthesis of silica nanotubes after etching off remaining cores. Silica nanotubes can be integrated into metal-oxide-solution field effect transistors (MOSitolFETs) which exhibit rapid field effect modulation of ionic conductance. Surface functionalization can change inherent carrier concentration as well channel polarity to fabricate p-type, n-type and ambipolar transistors. These nanofluidic devices were further demonstrated to be useful in single molecule sensing. Single DNA molecules can be electrically detected either by charge effect or geometry effect. These nanofluidic FETs have potential implications in sub-femtoliter analytical technology and large-scale nanofluidic integration.

**B10 10 Monitoring Gold Nanorod Synthesis based on their Localized Surface Plasmon Resonance*** AMNEET GULATI, *Department of Physics and Astronomy, Rice University* HONG-WEI LIAO, *Department of Chemistry, Rice University* JASON HAFNER, *Department of Physics and Astronomy, and Chemistry, Rice University* The extinction spectra of structurally anisotropic gold nanoparticles exhibit surface plasmon resonances that may be tuned through the visible and near-infrared portions of the electromagnetic spectrum by controlling their geometry. Gold nanorods, whose longitudinal extinction peak is proportional to their aspect ratio, are synthesized by reduction of gold chloride onto gold seed nanoparticles. While growth anisotropy is known to be induced by a surfactant (cetyltrimethylammonium bromide), the detailed growth mechanism is poorly understood. Here, we study the growth kinetics of nanorods by continually monitoring their extinction spectra during synthesis. The spectra are analyzed by Rayleigh-Gans theory to determine the instantaneous length and diameter of the growing nanorods. This data yields microscopic growth rates which provide insight into the mechanism of nanorod synthesis.

**B11 1 Adventures in Cluster Dynamics.**
JOSHUA JORTNER

We report on the exploration of new scientific territories of energetics, response, dynamics and function of large, finite atomic and molecular systems. Studies of ultrafast (attosecond to femtosecond) electron and nuclear dynamics of clusters in ultraintense laser fields (peak intensity $10^{15}$–$10^{20}$Wcm$^{-2}$) led to the advent of table-top nuclear fusion driven by cluster Coulomb explosion. The eighty years' quest for nuclear fusion driven by chemical reactions was achieved by ''hot–cold'' fusion in the chemical physics laboratory. Moving from femtosecond nuclear dynamics in the energy domain of nuclear physics (1keV–1MeV) towards ultralow energies and ultraslow millisecond dynamics in ultracold (T = 100 $\mu$K–1nK) finite systems, we address the bridging between the nuclear dynamics of clusters and of finite, ultracold atomic clouds. **B11 2 Isomer morphology and vibrational mode dependence of the coupling between an excess electron and small water networks.** MARK JOHNSON, *Yale University* Negatively charged water clusters are presently the subject of intense study because of their promise to unravel the surprisingly complex dynamics of the hydrated electron. We focus on the use of vibrational spectroscopy to establish the morphologies and local binding motifs of the water networks that bind an electron. Here we will discuss the rearrangement pathways of the H-bond network in the elementary act of free electron accommodation, where we use argon-mediated population modulation to isolate the geometries of the neutral cluster precursors. We then obtain isomer-selective vibrational spectra of the anions that produced, where we correlate the local binding motifs with the overall electron binding energies. Finally, in the small cluster limit, we reveal how different intramolecular vibrational motions interact with the diffuse electron cloud by analysis of the resulting ''Fano'' lineshapes when vibrations are embedded in the electron continuum. These interactions vary by over an order of magnitude for various ''free OH'' bands. The implications of these observations on the extrapolation to bulk behavior will be considered in light of the trends displayed by the cluster properties up n=30 or so.

**12:03**
**B11 3 Vibrational energy at interfaces** DANA DLOTT, *University of Illinois* New advances in ultrafast vibrational spectroscopy now permit the real-time observation of vibrational energy at interfaces. Using a liquid suspension of reverse micelles, consisting of a nanodroplet of water separated from an organic solvent by a monolayer of surfactant, we pumped vibrational energy into either the water or surfactant layer using an ultrashort IR laser pulse. Incoherent anti-Stokes Raman probe techniques were used to watch the vibrational energy move across this surfactant monolayer. The results were quite different that what would be expected if we were watching heat flow. The specific pathways of vibrational energy are invoked to explain these results.

**12:15**
**B11 4 Atomic Beam Scattering as a Probe of the Glass Transition of Polymer Thin Films** MIRIAM FREEDMAN, AARON ROSENBAUM, STEVEN SIBENER, *The James Franck Institute and Department of Chemistry, University of Chicago* We have investigated the thin film dynamics of poly(methyl methacrylate) (PMMA) using inelastic helium atom scattering. The glass transition in the surface region of a polymer film is thought to be at a lower temperature than the bulk, but it is unclear whether this reduction is due to the film surface or the near-surface layer. Because helium atom scattering is a surface sensitive, nonperturbative technique with which we can directly probe the surface dynamics, we hope to be able to clarify this debate. We obtain broad time of flight spectra, which are well fit by a semi-classical scattering model. From these fits, we note deviations near the bulk glass transition that could be due to changes in surface presentation or dynamics. At low beam energies and sample temperatures, we observe elastic scattering from which we calculate Debye-Waller factors that are similar to other organic thin films. This study has shown that helium atom scattering provides a unique means of exploring the glass transition of polymer thin films.

**B11 5 Optical Spectroscopy and Photophysics of Single Wall Carbon Nanotubes.**
LOUIS BRUS, *Columbia University*

We explore the fundamental nature and dynamics of excited electronic states in SWNT. Psec luminescence and photobleaching dynamics of SWNTs in micellar solution show that non-radiative Auger recombination is extremely fast. At low pH, nanotube surface endoperoxides protonate and introduce holes that quench the luminescence. At higher concentration these holes also bleach the band gap optical absorption. Near infrared two photon luminescence excitation spectra quantitatively reveal the importance of excitons. In order to characterize excited states in both metallic and semiconducting SWNTs at the single-tube level, we detect white-light Rayleigh scattering from individual tubes suspended over an open slit in a substrate. Diagnostic spectra with high signal to noise are obtained in just a few minutes.

**B11 6 First hyperpolarizability ($\beta$) of bare and polymer protected copper nanoparticles** PUSPENDU DAS, MANABENDRA CHANDRA, *Indian Institute of Science* We have prepared bare as well as polyvinyl pyrrollidone (PVP) capped Cu nanoparticles (NPs) of $<$ 10 nm size by laser ablation and measured their first hyperpolarizabilities ($\beta$ values) using the hyper-Rayleigh scattering technique in solution. The $\beta$ values for the bare and capped NPs are 414 ( $\pm$ 19) x $10^{-30}$ and 808 ( $\pm$ 12) x $10^{-30}$ esu/atom$^{1/2}$, respectively. The bare NPs are stable in isopropanol for weeks but are short-lived compared to the capped particles. Our results of capped NPs having a $\beta$ value twice as high compared to the bare NPs of the same size show that surface capping is necessary for enhancing $\beta$ in noble metal NPs. In addition to the bulk and surface quadrupolar contributions which exist in bare NPs, dipolar contribution to $\beta$ becomes important for the capped NPs due to the destruction of centro-symmetry at the surface, leading to a significant increment in $\beta$. Experiments with smaller size NPs show that $\beta$ goes down with size. The bulkquadrupolar polarization which decreases with particle size, perhaps, rationalizes the size dependence of $\beta$.

**13:15**
**B11 7 RRKM Theory at the Gas-Surface Interface: Hydrogen Dissociation Dynamics on Cu(111)** HEATHER ABBOTT, IAN HARRISON, *Chemistry Department, University of Virginia* A simple picture of the hydrogen dissociation/associative desorption dynamics on Cu(111) emerges from a two-parameter, full dimen-

sionality microcanonical unimolecular rate theory (MURT) model of the gas-surface reactivity. Vibrational frequencies for the reactive transition state were taken from 6D density functional theory calculations [Hammer, itet al. Phys. Rev. Lett. **73**, 1400 (1994)]. The MURT's parameters were fixed by simulation of experiment as: a $H_2$ dissociation threshold energy of $E_0 = 79$ kJ/mol and $s = 1$ surface atoms that actively exchange energy within the reactive transition state. Remarkably, MURT quantitatively predicts much of the dynamical behavior observed. The divergence of the statistical theoretical predictions from the experimental results at low rotational quantum numbers, $J \leqslant 5$, points towards the importance of dynamical steering at low J. The surface degrees of freedom are calculated to provide $\sim$ 30% of the energy required to surmount $E_0$ under thermal equilibrium conditions. Explicit treatment of the surface (i.e., $T_s > 0\ K$) is a novel aspect of the MURT theoretical approach.

**B11 8 An STM and Theoretical Study of the Interaction of hexabenzocorone on a Ru(0001) Surface** KWANG TAEG RIM, LI LIU, *Department of Chemistry and Columbia Center for Integrated Science and Engineering, Columbia University* CHAOCHIN SU, *Department of Molecular Science and Engineering, National Taipei University of Technology* SHENGXIONG XIAO, MICHAEL STEIGERWALD, *Department of Chemistry and Columbia Center for Integrated Science and Engineering, Columbia University* MARK HYBERTSEN, *Department of Applied Physics and Applied Mathematics and Columbia Center for Integrated Science and Engineering, Columbia University* COLIN NUCKOLLS, GEORGE FLYNN, *Department of Chemistry and Columbia Center for Integrated Science and Engineering, Columbia University* The interaction of hexabenzocorone (hbc) with a metal surface has been investigated using Scanning Tunneling Microscopy (STM) and Scanning Tunneling Spectroscopy (STS) in ultrahigh vacuum. The images obtained at room temperature, after hbc molecules were vacuum deposited at 325$^o$C onto a pristine ruthenium (0001) surface, exhibit surface bound molecules with off-centered bonding sites. I(V) curves over hbc molecules show high tunneling current at positive bias voltages. After annealing of the hbc-bonded Ru sample surface at 600$^o$C for 15min, hbc molecules appear to aggregate laterally and to bond symmetrically to the surface. The possibility of growing carbon nanotubes on the hbc-Ru precursor surface upon dosing with $C_2H_2$ will also be discussed along with a theoretical model for bonding and growth of nanotubes.

**13:39**

**B11 9 Single-molecule vibrational spectroscopy of water molecules using an LT-STM** CHIKAKO MATSUMOTO, *Gakushuin Univ., RIKEN* YOUSOO KIM, *RIKEN* KENTA MOTOBAYASHI, *Univ. of Tokyo* MAKI KAWAI, *Univ. of Tokyo, RIKEN* Single-molecule vibrational spectroscopy has attracted considerable attention as a powerful tool for nanoscale chemistry. The adsorption of water molecules on metal surfaces plays an important role in understanding many phenomena in nature, such as heterogeneous catalysis and corrosion, etc. The structure of water at low coverage has been investigated on a variety of transition-metal surfaces with various techniques. But the microscopic understanding of the adsorption feature of single water molecules is still unclear. We report molecular scale study of adsorption behaviors of water molecules on Pt (111) surface at 4.7 K by use of single-molecule vibrational spectroscopy with the scanning tunneling microscopy (STM). The Pt (111) surface was dosed with a small amount of water molecules ( $<$ 0.01 ML) at the temperature less than 20 K. A water monomer appears as a single protrusion in the STM images. A dimer was formed by manipulating monomers with an STM tip. The shape of a water dimer looks like 'cherry blossom', which can be explained by one of the water molecules rotating around the other**.** Inelastic electron tunneling spectroscopy using the STM was utilized to determine vibrational modes of individual water dimers.

**13:51**

**B11 10 A Novel Vibrational Spectroscopic Study of a Single Molecule using an STM – Measurement and Selection rules of Action spectroscopy** YOUSOO KIM, *RIKEN* YASUYUKI SAINO, *Tohoku Univ.* TOSHIRO OKAWA, *Gakushuin Univ.* TADAHIRO KOMEDA, *Tohoku Univ.* HIDEMI SHIGEKAWA, *Univ. of Tsukuba* MAKI KAWAI, *Univ. of Tokyo, RIKEN* The excitation of molecular vibration by means of the inelastically tunneled electrons from the tip of a scanning tunneling microscope (STM) can lead to various dynamical processes at surfaces. In addition, inelastic electron tunneling spectroscopy with the STM (STM-IETS) is now applicable to the vibrational spectroscopy of the individual molecules. The vibrational spectrum of a single molecule provides useful information not only for the chemical identification of the molecule but also for investigating how molecular vibration can couple with the relevant dynamical processes. Inelastically tunneled electrons from the STM were used to induce vibrationally mediated motions of a single itcis-2-butene molecule among four equivalent orientations on Pd(110) at 4.7 K. Action spectrum obtained from the motions clearly detects more vibrational modes than STM-IETS. We demonstrate the usefulness of the action spectroscopy as a novel single molecule vibrational spectroscopic method. We also discuss its selection rules in terms of the resonance tunneling.

**B12 1 Growth of Pb nanowires on the Si(111)-In (4x1) a combined STM and SPALEED study*** MYRON HUPALO, MICHAEL YAKES, MICHAEL TRINGIDES, *Ames Laboratory-Iowa State University* Due to the combined effect of QSE and the anisotropic strain potential of the substrate, Pb deposited on Si(111)–In (4x1) at 180K grows in nanowires of uniform 4-layer height and controllable uniform width of $5w_0$ (where $w_0 = 1.33$nm is the width of the reconstruction unit cell along [1_1_2] direction). SPA-LEED studies confirm this selected 4-layer height (from Intensity vs $K_z$ variation) which is unusually stable because it is unchanged even after annealing to room temperature. The same selected 4-layer height is observed on a different interface Si(111)-In $\sqrt{31}$x$\sqrt{31}$ which independently confirms the unusual 4-layer stability. Differences in the observed corrugation on the tops of the nanowires due to the Moiré pattern at the metal/

semiconductor interface confirm the strain anisotropy on the reconstructed substrate. Further Pb deposition on top of the nanowires results in the completion of the Pb layer with unusually atomically flat film interfaces over mesoscopic distances.

*Ames Laboratory is operated by the U.S. Department of Energy by Iowa State University under Contract No. W-7405-Eng-82.

**B12 2 Novel Phase Separation for Pb/Ge(111)** SHIRLEY CHIANG, YU SATO, *University of California Davis* NORMAN BARTELT, *Sandia National Laboratories Livermore* Using low energy electron microscopy (LEEM), we have elucidated the phase diagram for the growth of Pb on Ge(111). As Pb is deposited on Ge, the Pb atoms substitute into the top layer, causing released Ge atoms to form into c(2x8) adatom islands, with the size and density of these Ge islands controllable by the substrate temperature. During the reversible $\beta$ (dense ($\sqrt{3}$x$\sqrt{3}$)R30[r]) to (1x1) phase transition, we discovered a novel phase separation mechanism. Above the 1.33ML saturation coverage of the $\beta$ phase, a sharp first order phase transition is observed near 295C. For Pb coverage just $<$ 1.33ML, the phase transition is no longer sharp, with $\beta$ and (1x1) phases coexisting and the transformation occurring from 232C to 181C. Reducing coverage by $\sim$ 0.01ML causes a dramatic change, with small domains of the new phase appearing and disappearing, due to fluctuations between the two phases. Additional domains appear and fluctuate until the whole surface is completely transformed. We attribute the fluctuating domains to thermal fluctuations of the density of Pb atoms within a domain. By comparing LEEM images of the $\beta$ and (1x1) phases during the phase transition between [$\alpha$+(1x1)] and ($\alpha$ + $\beta$), the Pb coverage of the (1x1) phase at the eutectic point was determined to be $\sim$ 1.29 ML.

**B12 3 Hard superconductivity of a soft metal in the quantum regime*** M.M. OZER, J.R. THOMPSON, H.H. WEITERING, *Physics, Univ. Tennessee, Knoxville, TN, 37996 & ORNL, Oak Ridge, TN, 37831* Superconductivity is a collective quantum phenomenon that is inevitably suppressed in reduced dimensionality. Questions of how thin superconducting wires or films can be before losing their superconducting properties have important technological ramifications and go to the heart of understanding formation, coherence, and robustness of the superconducting state in quantum confined geometries. Here, we exploit quantum confinement of itinerant electrons in a soft metal (Pb), to stabilize atomically-flat superconductors with lateral dimensions of mm and vertical dimensions of only a few atomic layers. They show no indication of defect- or fluctuation- driven suppression of superconductivity and support macroscopic super-currents of up to $\sim$ 10% of the depairing current density. The hardness of the critical state can be attributed to the presence of intrinsic vortex traps that are stabilized by quantum confinement. The study presents a conceptually appealing picture of a model nano-scale superconductor with calculable critical state properties, suggesting the possibility of achieving and exploiting superconductivity in the ultimate low-dimensional limit.

*This work is funded by NSF grant DMR-0244570. ORNL is managed by UT-Battelle, LLC, for US DOE under Contract DEAC05-00OR22725.

**B12 4 Modification of the Quantum Electronic Stability of Thin Films by Interfactants** T. MILLER, D. A. RICCI, M. H. UPTON, T.-C. CHIANG, *Univ. of Illinois at Urbana-Champaign* Electronic states are quantized in thin films, resulting in a modulation of physical properties with film thickness. The thermal stabilities of films differing in thickness by even a single monolayer can be dramatically different due to this quantization. The spectrum of allowed energy states depends on the film thickness, but it is also dependent on the phase shift of the wavefunctions reflected from the film-substrate interface. This phase shift in turn can be adjusted by changing the interface using interfactant atoms. This implies that the physical properties of thin films, including the thermal stability, could be controlled by interfacial engineering. We have grown atomically-uniform thin films of Pb on Si(111). Their thermal stabilities show bilayer oscillations with thickness due to the quantization of electronic states. The stabilities are strongly modified by the introduction of Au, In, or Pb at the film/substrate interface. For example, with In as an interfactant, films an odd number of monolayers thick are more stable than ones with an even number of layers, whereas for the other materials this pattern is reversed.

**B12 5 Novel Coarsening Behavior of Pb nanocrystals on Si(111)*** P. F. MICELI, C. A. JEFFREY, *Dept. of Physics and Astronomy, University of Missouri-Columbia* R. FENG, E. H. CONRAD, *School of Physics, Georgia Institute of Technology* M. HUPALO, M. C. TRINGIDES, *Ames Lab, Iowa State University* C. KIM, *Dept. of Physics and Research Inst. of Basic Sciences, Kyunghee University, Korea* P. J. RYAN, *MUCAT, Advanced Photon Source, Argonne National Lab* We show that Pb nanocrystals grown on Si(111)7x7 exhibit novel coarsening behavior that cannot be described by the classical Gibbs-Thomson effect. This system is known for quantum size effects (QSE) that lead to preferred island heights which depend on the coverage and temperature. Using complementary surface x-ray diffuse scattering and STM, we find an unexpected and unusual flux rate dependence, a lack of scaling of the island densities, and island decay times that are orders of magnitude faster than expected from the classical analysis. For example, a highly mono-disperse island height distribution is observed if the islands are grown at high rather than low flux rates. These results have important implications for understanding the controlled growth and self-organization of nanostructures.

*The MUCAT beamline is supported through the Ames Lab by the US-DOE. Research funding is supported by NSF, PRF (PFM, CAJ), Ames Lab (MCT, MH), Canim Scientific (EHC), NSERC-Canada (CAJ), Ministry of Science & Tech.-Korea (CK).

**B12 6 The formation of a sharp metal-semiconductor interface for the growth of Quantum Size Effect islands*** C.A. JEFFREY, P.F. MICELI, *Dept. of Physics and Astronomy, University of Missouri-Columbia* E.H. CONRAD, R. FENG, *School of Physics, Georgia Institute of Technology* C. KIM, *Dept. of Physics and Research Inst. of Basic Sciences, Kyunghee University, Korea* P.J. RYAN, *MUCAT, Advanced Photon Source, Argonne National Lab* In order to form Quantum Size Effect (QSE) metal islands on semiconductors, a smooth island-substrate interface is necessary to set up the electron standing waves that lead to the new quantum confined states. How this occurs for the Pb-Si(111)7x7 system is a mystery because of the large lattice mismatch and the highly cor-

rugated 7x7 reconstruction. To understand how QSE islands develop in this system we have performed structural Surface X-ray scattering measurements on the initial formation of Pb islands grown on Si(111). We show how a smooth Pb-semiconductor interface develops through a series of structural arrangements. Once a vertically disordered Pb monolayer is completed, second layer atoms nucleate fcc clusters. These clusters undergo a displacive transition lifting them above the Si adatoms. This allow the Pb islands to ''float'' above the Si substrate so that the first island layer is smooth, thus setting up the proper boundary condition for QSE.

*$\mu$CAT is supported through Ames Lab by the US-DOE. Research is supported by NSF, PRF (PM, CJ), DOE (MT, MH), Canim Scientific (EC), NSERC-Canada (CJ), Ministry of Sci. & Tech.-Korea (CK).

**B12 7 The Pb corrugation on Si(111) Pb $\alpha - \sqrt{3}x\sqrt{3}$ as a probe of the island crystallography*** MICHAEL YAKES, MYRON HUPALO, JIZHOU CHEN, MICHAEL TRINGIDES, *Ames Laboratory-Iowa State University* Although the corrugation on top of the uniform height Pb islands has been studied by STS, quantitative information about the island morphology is still missing. With this complementary study based on SPA-LEED and STM we use the dependence of the corrugation on coverage to deduce the detailed island crystallographic structure. The two types of bilayer islands which have been identified from their opposing contrasts in STM are analyzed with diffraction and extended STM images to deduce their relative population. Islands with one type of FCC faulted stacking (i.e. ACB) are replaced with coverage by the islands with opposite stacking (i.e. ABC). Since the island shapes are triangular (due to inequivalent type of A- and B- steps) the population reversal is also confirmed from changes in the island orientation with coverage. In addition, a change in the rotation of the Pb overlayer relative to the Si substrate (measured from the location of the Pb(10)) is used to explain the changing intensity ''hexagon-like'' to ''star-like'' distribution of the SPA-LEED pattern near the (00) spot. This rotation explains quantitatively the changing corrugation period. As the coverage increases the preferred Pb orientation changes from $0^o$ to $5.6^o$ rotated with respect to the [110] substrate direction.

**B12 8 Restructuring Due to Quantum Size Effects During Annealing in Ultrathin Films of Ag/Si(111)*** K.R. KIMBERLIN, D.C. LUDOIS, S.M. BINZ, K.R. ROOS, J. LOZANO, P.W. WANG, J.H. CRAIG, JR., *Bradley University* Ultrathin films of silver have been epitaxially grown itin situ at low temperature and studied with scanning tunneling microscopy (STM) and reflection high energy electron diffraction (RHEED). Restructuring occurs during annealing to 300 K producing flat-topped islands two atomic layers in height in accordance with previous work.[1] Further annealing produces a diverse distribution of heights and sizes of flat topped, vertical-sided islands. At higher coverage, a smooth films anneal to dentritic structures of a single height. A RHEED transmission pattern is formed after annealing the films and crystal orientation is determined. Finally, annealing above 550K produces typical 3D island ''wedding cake'' structures atop the $\sqrt{3} \times \sqrt{3}$ wetting layer on Si(111). These results will be discussed in an ''electronic growth'' model where Quantum Size Effects are thought to stabilize particular island heights, producing this unusual flat island growth.

**B12 10 Fluctuations of Pb/Si(111) Domain Boundaries*** WILLIAM CULLEN, *Department of Physics and MRSEC, University of Maryland* DANIEL DOUGHERTY,[†] *Department of Chemistry, University of Pittsburgh* MASA ISHIGAMI, *Department of Physics and MRSEC, University of Maryland* ELLEN WILLIAMS, *Department of Physics and MRSEC, University of Maryland* We have used variable-temperature scanning tunneling microscopy to study fluctuations of a 1D interface — the boundary between two coexisting surface phases. We have prepared Pb/Si(111) surfaces that consist of high-density $(1 \times 1)$-Pb domains coexisting with a lower-density $\sqrt{3} \times \sqrt{3} - R30°$-Pb phase. The domain boundaries between these phases fluctuate at moderate temperatures, allowing direct observation with STM. Measurement of the temporal correlation function for the fluctuating boundary between 525 K and 625 K allows determination of the mass transport mechanisms below and above the onset of thermal desorption of the $(1 \times 1)$ phase. In the desorption regime, our measured dynamical exponent of 1/2 provides microscopic confirmation that fluctuations of the $(1 \times 1)$ boundaries occur via exchange of mass with a 2D adatom gas on the $\sqrt{3} \times \sqrt{3}$ phase, consistent with the zeroth-order desorption kinetics inferred from macroscopic measurements.

**B12 11 Influence of Band Structure and Pb/Si Interfacial Property on Transmission Resonance of Thin Pb Films by Scanning Tunneling Spectroscopy** S.M. LU, M.C. YANG, C.L. JIANG, H.T. SHIH, W.B. SU, C.S. CHANG, TIEN T. TSONG, *Institute of Physics, Academia Sinica, Taipei, Taiwan, Republic of China* The transmission spectrum of a metal film for free electrons at low energy may reveal resonance, which is the quantum size effect above the vacuum level. We use scanning tunneling spectroscopy to observe the transmission resonance for Pb films grown on incommensurate Pb/Si(111) and Si(111)7x7 surfaces. Our observations demonstrate that Pb band structure and Pb/Si interfaces

significantly affect the signal of the transmission in the tunneling spectra. First, the transmission resonance is not detectable in the range of 5~ 6 eV above Fermi level, which can be attributed to that Pb band structure along the (111) direction in this energy range is flat. Secondly, the signal of the transmission resonance acquired on Pb films/incommensurate Pb/Si(111) is more obvious than that acquired on Pb films/Si(111)7x7. This difference can be attributed to that the Pb/Si interface for the former is adiabatic but is non-adiabatic for the latter.

**B12 12 Thin Film Fractal Morphology and the Enhancement of Superconducting Critical Parameters** J. KRIM, M. HIGHLAND, *North Carolina State University* In superconducting films, it is known that the use of artificial defects can enhance a films' superconducting critical parameters. In particular, it has recently been reported that regular arrays of sub-micron sized holes produced by means of lithographic techniques can substantially increase the critical temperature for all fields. [1] We report here our observations that careful control of Pb film deposition conditions can result in film texture that has naturally occurring ''holes'' and enhanced critical parameters reminiscent of the artificially structured films. We characterize the texture of these films via their fractal dimension, and find that it is a useful approach for characterizing a films superconducting critical parameters. This work was funded by NSF and AFOSR. [1] A.V. Silhanek et al., PRB **72**, 014507 (2005)

**B12 13 Binding site H3 to T4 occupation switching and the Pb/Si(111) ''Devil's Staircase'' phase diagram*** V. YEH, M. YAKES, M. HUPALO, M.C. TRINGIDES, *Ames Laboratory-Iowa State University* Z. CHVOJ, *Czech Academy of Science* With SPA-LEED and STM it has been observed that there is a switching occupation from only H3 sites to H3 and T4 sites within the unit cell of the DS (''Devil's Staircase'') (n,m) linear phases at the (1,1) phase or theta=1.25ML. This is observed from the doubling of the linear phase period and the ''flipping'' of the triangle diffraction pattern. The transition temperature from linear to HIC shows a minimum at ~ 120K for the (1,1) phase and follows a U-shaped curved in the whole DS range 6/5ML< theta< 4/3. This unusual dependence (instead of the monotonic decrease of the transition temperature expected for repulsive interactions) indicates the presence of other interactions in the system which can originate from the binding site switching. A statistical mechanical model that includes these two interactions is analyzed and accounts semi-quantitatively for the U-shaped curve and the phase diagram topology. However, a complete treatment should also include the comparison with the free energy of the HIC phases since the linear phases transform to these phases at higher temperatures. The binding site H3 to T4 switching is also relevant to theoretical predictions for the ordered phases in Ba(3x2) grown on stepped Si(111) due to the presence of similar long range interactions.

**B12 14 Quantum Size Effects in $\delta$ – Pu (111) and (110) Films*** HAORAN GONG, ASOK KUMAR RAY, *Department of Physics, the University of Texas at Arlington, Arlington, TX 76019* First-principles full-potential linearized-augmented-plane-wave (FP-LAPW) calculations have been carried out for $\delta$-Pu (111) and (110) films up to seven layers. The layers have been studied at the non-spin-polarized-no-spin-orbit coupling (NSP-NSO), non-spin-polarized-spin-orbit coupling (NSP-SO), spin-polarized-no-spin-orbit coupling (SP-NSO), spin-polarized-spin-orbit coupling (SP-SO), anti-ferromagnetic-no-spin-orbit coupling (AFM-NSO), and anti-ferromagnetic-spin-orbit-coupling (AFM-SO) levels of theory. The ground state of both $\delta$-Pu (111) and (110) films is found to be at the AFM-SO level of theory and the surface energy is found to rapidly converge. The semi-infinite surface energy for $\delta$-Pu (111) and (110) films is predicted to be 1.18 and 1.42 J/m$^2$, while the magnetic moments show an oscillating behavior, gradually approaching the bulk value of zero with increase in the number of layers. Work functions indicate a strong quantum size effect up to and including five layers for the (111) surface and seven layers for the (110) surface, respectively. The work functions of $\delta$-Pu (111) and (110) films at the ground state are predicted be 3.41 and 2.99eV, respectively. *This work is supported by the Chemical Sciences, Geosciences, and Biosciences Division, Office of Basic Energy Sciences, Office of Science, Department of Energy (Grant DE-FG02-03ER15409) and the Welch Foundation, Houston, Texas (Grant Y-1525).

**B12 15 Novel Atomic Rearrangement in the Pb Monolayer on Si(111) surfaces Induced by Atomic Hydrogen Adsorption.** CHUNG-KAI FANG, *Institute of Physics, Academia Sinica, Taiwan, R.O.C. and Department of Materials Science and Engineering, National Tsing Hua University,Taiwan, R.O.C* ING-SHOUH HWANG, SHIH-HSIN CHANG, *Institute of Physics, Academia Sinica, Taiwan, R.O.C.* LIH-JUANN CHEN, *Department of Materials Science and Engineering, National Tsing Hua University, Taiwan, R.O.C.* TIEN-TZOU TSONG, *Institute of Physics, Academia Sinica, Taiwan, R.O.C.* Using a scanning tunneling microscopy, we have observed interesting hydrogen-adsorption induced atomic rearrangements on Pb/Si(111) system at room temperature. A hexagonal ring-like pattern with decaying intensity is formed around the hydrogen-induced point defect. Moreover, interference-like patterns can be seen in the region among the H-induced point defects. The detailed pattern depends on the relative position of defects. With certain relative positions, a new superstructure of hexagonal cells can be seen. The phase boundaries are found to either enhance or suppress the formation of the hexagonal ring-like pattern. We believe that the intricate interplay between atomic displacement and electronic structure causes the formation of the patterns. [Ref] : I. S. Hwang, S. H. Chang, C. K. Fang, L. J. Chen, and T. T. Tsong, Phys. Rev. Lett. 94, 045505 (2005)

**B13 1 Structure and Interactions of Isolated Biomolecular Building Blocks.**
MATTANJAH DE VRIES, *UCSB*

We investigate biomolecular building blocks and their clusters with each other and with water on a single molecular level. The motivation is the need to distinguish between intrinsic molecular properties and those that result from the biological environment. This is achieved by a combination of laser desorption and jet cooling, applied to aromatic amino acids, small peptides containing those, nucleobases and nucleosides. This approach is coupled with a number of laser spectroscopic techniques, including resonant multi-photon ionization, spectral hole burning and infra-red ion-dip spectroscopy. We will discuss examples illustrating how information can be obtained on spatial structure of individual biomolecules, including peptide conformations and details of DNA base-pairing.

**B13 3 Folding an infinitely long polypeptide into a helical conformation** JOEL IRETA, MATTHIAS SCHEFFLER, *Fritz-Haber Institut der Max-Planck-Gesellschaft, Berlin, Germany* The potential-energy surface and harmonic vibrational analysis of an infinitely long polypeptide are studied using density- functional theory in the Perdew, Burke, and Ernzerhof approximation to the exchange-correlation functional. We find that the $\pi$-helix, $\alpha$-helix, and $3_{10}$-helix are stable respect to the fully extended structure (FES) at 0 K, both in right- and left-handed conformations. Accounting for the temperature effects it is found that the left-handed helices are energetically degenerated respect to FES and the right-handed helices slightly more stable than FES, at room temperature. The minimum-energy pathway along the potential- energy surface shows that the barrier to fold a FES into a left- handed helix is at least three times larger than the barrier to fold it into a right-handed helix. This suggests that the very low occurrence of left-handed helices in protein structures is due to both thermodynamic and kinetic effects.

**B13 4 The Effect of Terminal Truncation on the Folding Dynamics of Coiled-coil GCN4-p1** MICHELLE BUNAGAN, LIDIA CRISTIAN, WILLIAM DEGRADO, FENG GAI, *University of Pennsylvania* Structural perturbation by terminal truncation has been used extensively in protein folding studies because it yields valuable information that could be used to dissect the folding mechanism of the protein of interest. Herein, we studied the folding dynamics of a truncated variant of a cross-linked GCN4-p1 coiled-coil using the technique of laser-induced temperature-jump (T-jump) in conjunction with infrared spectroscopy. While the full-length GCN4-p1 exhibits first-order kinetics in stopped-flow CD and fluorescence folding experiments, a recent T-jump study has shown that one or two folding intermediates may exist at the native side of the major folding barrier. However, the current truncated variant of GCN4-p1 not only shows first order folding kinetics, but also exhibits ultrafast folding behaviors, suggesting that there are no detectable intermediates populated on its folding pathway. Therefore, these results have interesting implications for the understanding of the folding mechanism of coiled-coil structures.

**B13 5 Fast Events in Protein Folding following Ultrarapid Mixing** LISA LAPIDUS, KIMBERLY COOPER, EMILY TUBMANN, *Michigan State U.* DAVID HERTZOG, *Stanford U. & LLNL* JUAN SANTIAGO, *Stanford U.* OLGICA BAKAJIN, *LLNL* A continuous flow microfluidic mixer fabricated out of fused silica was used to study microsecond time scales of protein folding by monitoring natural tryptophan fluorescence. This mixer uses hydrodynamic focusing and diffusion to lower the concentration of the initial denaturant, inducing the protein to fold. The mixing time can be as fast as 8 $\mu$s and allows access to times that are inaccessible in conventional mixers. Using a confocal microscope we observe the UV fluorescence spectrum from naturally occurring tryptophans in 3 well-studied proteins, cytochrome c, apomyoglobin and lysozyme, as a function of time after rapid mixing. Single value decomposition of the time dependent spectra reveal two separate processes: 1) a spectral shift which occurs within the mixing time and 2) a fluorescence decay occurring between 100 and 300 microseconds. We attribute the first process to hydrophobic collapse and the second process the formation of the first tertiary contacts. While the slower rate obviously depends on the details of the folding trajectory of each protein, we note that all three measured rates anti-correlate well with the fraction of secondary structure formed. This work demonstrates that hydrophobic collapse is much faster than had been estimated with slower mixing methods and is in good agreement with measured rates of intramolecular diffusion in unstructured peptides.

**B13 6 Fast diffusive folding dynamics of Tryptophan Zipper peptides*** STEPHEN HAGEN, *Physics Dept., University of Florida, Gainesville FL 32611* Simple synthetic peptides that fold into elemental structures like $\alpha$-helices and $\beta$-hairpins serve as useful model systems for experimental and computational studies of protein folding dynamics. The folding of the Tryptophan Zippers, for example, represents an interesting case of nearly barrierless folding. These short (12-16 residue) peptides designed by Cochran et al. (2001) fold into stable, well-defined $\beta$-hairpins on time scales of just a few microseconds. Our laser temperature-jump fluorescence spectroscopy shows that the ''TrpZip'' molecules encounter little internal friction and almost no enthalpic barrier as they proceed from the unfolded to the folded state: Favorable solvent conditions reduce the entropic barrier as well, until the folding dynamics become complex and diffusive, and different experimental probes see the system as folding on rather different time scales. We will present experimental signatures of these complex dynamics, discuss the role of internal polymer friction in TrpZip folding, and briefly consider suitable approaches for modeling the free energy surface that controls such a folding reaction.

**B13 7 Sugars in the gas phase.**

REBECCA JOCKUSCH, *University of Toronto*

The functional importance of carbohydrates in biological processes, particularly those involving specific molecular recognition is immense. Characterizing the three-dimensional structures of carbohydrates and glycoconjugates and their interactions with other molecules, particularly the ubiquitous solvent, water, are key starting points on the road towards the understanding of these processes. A new strategy, combining electronic and vibrational spectroscopy of mass-selected carbohydrate molecules and their hydrated complexes, conducted under molecular beam conditions, with ab initio computation is being exploited to characterize carbohydrate conformations and hydrated structures, the hydrogen-bonded networks they support (or which support them) and the specificity of their interactions with other molecules. The spectral features of monosaccharide residues can be used to refine the assignment of larger, oligosaccharide structures - a supplementary 'building-block' approach to the study of complex structures based upon an 'alphabet' of established IR spectral signatures of different conformations of the monosaccharide units - when their spectroscopic patterns are retained. When their patterns are altered the changes may be understood by analyzing the modification of the hydrogen-bonded networks, eg., the retention (or disruption) of the secondary structural motifs generated by intra-residue hydrogen-bonding. Feedback from the increasing body of experimental data will also help to inform and guide future theoretical conformational searches.

**B13 8 2D IR measurements of the coupling in transmembrane helix dimers*** CHONG FANG, *Department of Chemistry, University of Pennsylvania* LIDIA CRISTIAN, ALESSANDRO SENES, WILLIAM DEGRADO, *Department of Biochemistry & Biophysics, University of Pennsylvania* ROBIN HOCHSTRASSER, *Department of Chemistry, University of Pennsylvania* Ultrafast 2D IR photon echo spectroscopy has been adapted to the study of transmembrane helix dimers. Residues Gly-79 on each of the two helical strands of Glycophorin A (GpA) dimers in sodium dodecyl sulfate (SDS) micelles were isotopically selected. The 2D IR spectra reveal the tertiary interaction between the helices. The waiting time dependence of the echo informs on the conformational dynamics of different regions of the GpA dimer. Both the $^{13}C$ and $^{13}C{=}^{18}O$ labeled homodimers showed elongated diagonal peaks in the 2D IR correlation spectra. The cross peaks in the heterodimer spectrum indicated an off-diagonal anharmonicity of $\sim$ 3.8 $cm^{-1}$. This anharmonicity is caused by through-space interactions between amide units on different strands. The angle between the two Gly-79 amide-I transition dipoles was estimated to be $\sim$ 35[r] from the polarization of the 2D IR signal in the cross-peak region. The method also identifies residues that are exposed to water.

**B13 9 Solvent and Peptide Conformational Fluctuations Revealed with Two-Dimensional Infrared Spectroscopy** ZIAD GANIM, ANDREI TOKMAKOFF, *Department of Chemistry, Massachusetts Institute of Technology* Two-dimensional nonlinear infrared spectroscopy (2D-IR) is emerging as a new biophysical tool that offers the sensitivity to protein secondary structure and fast time resolution of linear Fourier transform infrared spectroscopy (FT-IR), but with the added ability to separate overlapping contributions and reveal vibrational couplings. Amide I nonlinear spectroscopy has been used to probe the thermal stability of proteins and peptides and reveal a detailed picture of how the beta-sheet of ubiquitin unfolds from nanoseconds to milliseconds. We show that the standard techniques that are sufficient in calculating FT-IR spectra from a static structure fail to reproduce observed 2D-IR lineshapes. By combining DFT parameterized semi-empirical models and structure trajectories from molecular dynamics simulations, we obtain good agreement with experimental FT-IR and 2D-IR spectra of trpzip2, a model beta-hairpin. We then demonstrate how hydrogen bonding, conformational variation, and their fluctuations are each manifested in 2D-IR spectra.

This methodology provides a means of calculating FT-IR and 2D-IR spectra directly from any atomistic molecular dynamics simulation - allowing richer data analysis and a means of validating mechanistic predictions from simulations.

**B15 1 Anomalous equilibrium volume change of magnetic Fe-Al crystals** MARTIN FRIÁK, JÖRG NEUGEBAUER, *Max-Planck Institute for Iron Research, Max-Planck-Strasse 1, 40237 Düsseldorf, Germany* Iron aluminides represent a very promising class of intermetallic materials with great potential for substituting stainless steels at elevated and high temperatures. Experiments observed an anomalous equilibrium volume behaviour as a function of concentration in Fe-rich compounds [1]. This effect has been tentatively assigned to be due to an order-disorder transition. We have studied the role of magnetism in Fe-Al crystals employing density functional theory (DFT) within the generalized gradient approximation (GGA). The excess energies, equilibrium lattice parameters and magnetic states have been determined for a dense set of different iron concentrations and a large variety of atomic configurations. Both external and internal relaxations were allowed. The spin-polarized calculations for *ordered* ferromagnetic Fe-rich compounds nicely reproduce the anomalous volume behaviour, i.e. the effect is *not* related to an order-disorder transition. Analyzing different magnetic states we identified the change in magnetism to be the driving force. In fact, performing the same calculations but switching off magnetism removed the anomalous volume dependence and showed a clear linear dependence. Based on these results the importance of order-disorder transition in Fe-Al systems is revisited. [1] R. A. Buckley and S. Kaviani, Mat. Sci. Eng. A258, 173 (1998).

**B15 2 Internal stress generation during electrochemically deposited Volmer-Weber thin films.** TIANZHI LUO, ROBERT CAMMARATA, *Johns Hopkins University* The real-time itin situ stress generation during electrochemical deposition of metallic thin films deposited by an island (Volmer-Weber) growth process will be presented. The stresses were measured using a sensitive substrate curvature system optimized for use in an electrochemical cell. Films were deposited on crystalline and amorphous substrates. In many cases, the films displayed an early stage compressive stress, followed by a large tensile jump, and finally ending with a compressive stress at large thickness. Also, interruption of growth led to significant relaxation of the stress. These behaviors were qualitatively similar to those found for evaporated films, and suggest that similar stress generation mechanisms operate for both types of depositions. In other systems, the stress generation behavior was much different, generally displaying a small compressive stress throughout. Correlation of the stress behaviors with microstructural evolution will be presented, and possible mechanisms for the generation of the stresses will be discussed.

**B15 3 Anomalous Magnetic Particle Distribution in Annealed Granular CuCo Thin Films** JIAN-QING WANG, NAM H. KIM, JARDON PECK, A SQUID magnetometer was used to measure ZFC and FC c-T data to study the microstructure of annealed granular Cu80Co20 thin films. The films of thicknesses ranging from 40 nm to 1 mm with 20% vol. Co were magnetron sputtered at base pressure $<$ 1.5 10- 7 torr. The annealing was done at various temperatures up to 400°C in a tube furnace with a reducing gas flow. As-deposits showed the standard single-peak c-T curve with an average size of 3.0 nm in dia. for the Co nanoparticles as calculated by Curie-Weiss analysis. Langevin fitting to magnetization at elevated temperature of 300 K also provided the same particle size. As annealing temperature increased, the first peak occurring around 40K decreased in height while the second, occurring around 300 K, grew. These anomalous features, observed over a wide range of thickness (40-200 nm), appeared to result from microstructural evolution, namely an increase in large particle population at the expense of smaller particles. It is likely that the film contains a mixture of small particles and larger particles that are induced by annealing, which gives rise to the double peak structure.

**11:51**
**B15 4 Metal Diffusion in Granular Bismuth Thin Films** JOHN SADLEIR, *NASA GSFC & UIUC Physics Dept* Bismuth's exotic electro-thermal properties makes it attractive for many device applications. Despite such incentives, fabrication of high quality bismuth films has proven difficult, and measured properties of such films are highly variable in the literature. Implementing a bismuth deposition process in device fabrication presents additional challengesparticularly at interfaces due to the inherent granularity and surface roughness of its films, its low melting point, and its tendency to diffuse and form undesired intermetallic phases. We report on the properties of the granular bismuth films grown at NASA Goddard and studies of solid state diffusion of Au and Cu in these films.

**12:03**
**B15 5 Temperature effect on structure of copper phthalocyanine thin films** KEDAR MANANDHAR, KENNETH PARK, *Baylor University* ZHEN SONG, TANHONG CAI, JAN HRBEK, *Brookhaven National Laboratory* In situ deposited heteroepitaxial thin films of copper phthalocyanine (CuPc) on Ag(111) surfaces have been investigated by scanning tunneling microscopy. The molecules lay flat on the substrate forming a well ordered closed pack square lattice. A lattice vector of ordered film makes $4^0 \pm 0.5^0$with [0-11] direction of Ag (111) lattice. The lattice vectors of the overlayer have been measured 14Åx14Å corresponding to the surface molecular density of 5.10 x $10^{13}$molecules/cm$^2$. The close packed square lattice remains highly ordered when annealed up to $500^0$K. However further annealing of film to $\sim$ $700^0$K desorbs 75 % of molecules leaving submonolayers coverage of molecules. The remaining molecules aggregate to form dendrite like form, which appears to result from dimerization and polymerization. Molecular orientation in well ordered film, structural change of molecules in dendrite like form, and further discussion of temperature effects on CuPc thin films will be presented.

**12:15**

**B15 6 Lattice defects and electronic properties of graphene** FRANCISCO GUINEA, *Instituto de Ciencia de Materiales de Madrid. CSIC* NUNO M.R. PERES, *Universidade do Minho. Portugal* ANTONIO H. CASTRO NETO, We analyze the electronic properties of graphene. Extended lattice defects, and deviations from electron-hole symmetry, lead to self doping, and to a finite Fermi surface. Point lattice defects give rise to a finite inverse elastic lifetime at low energies, and to a universal value of the dc conductivity at low frequencies or temperatures. Transport properties at optical frequencies are also investigated.

**12:27**

**B15 7 Electron-phonon coupling at the Be(0001) Surface*** TIMUR KIM, *University of Aarhus, Denmark* PHILIP HOFMANN, *University of Aarhus, Denmark* TEYU CHIEN, *University of Tennessee, Knoxville TN 37996* HONG LIU, *University of Tennessee, Knoxville TN 37996* WARD PLUMMER, *University of Tennessee, Knoxville TN 37996* The temperature dependent angle-resolved photoemission spectrum (ARPES) of the surface state centered at $\Gamma$ point of Be(0001) surface along the $\Gamma$-K and the $\Gamma$-M directions have been measured as a function of binding energy and momentum. The surface state centered at $\Gamma$ point is highly symmetric in reciprocal space. The temperature dependent ARPES data along these two directions were analyzed by means of energy distribution curves (EDCs) and momentum distribution curves (MDCs) with the help of the spectral function. From the analysis, the information yields the magnitude of the imaginary part of the self energy as a function of E and **k**. Attempts to extract the electron-phonon coupling constant from this data are so dependent upon the model for the phonons and the bare band structure that it is impossible to extract any useful information. But the E and **k** dependence of the imaginary part of the self-energy can be compared directly to first-principles calculations.

**B15 8 Wannier-Stark Ladders in Torsional Waves** GUILLERMO MONSIVAIS, *Instituto de fisica, UNAM* RAFAEL MÉNDEZ-SÁNCHEZ, ALFREDO DIAZ-DE-ANDA, JORGE FLORES,* *Centro de Ciencias Físicas, UNAM* LUIS GUTIÉRREZ, ALEJANDRO MORALES, *Centro de Ciencias Físicas UNAM* We study the normal modes of torsional waves in an elastic rod consisting of a set of *n*circular cylinders of varying length determined by a parameter $\gamma$. We present experimental, theoretical, and numerical results. It is shown that some analogies to the Wannier-Stark ladders, originally introduced by Wannier (1960), are exhibited by this classical system. The ladders consist of a series of equidistant energy levels for the electrons in a crystal in the presence of a static external electric field, the nearest-neighbor spacing being proportional to the intensity of the external field. For the case of torsional waves in the rod, we have observed a similar behavior: the vibrations of the rod show resonances of equidistant frequencies, the nearest neighbor spacing being proportional to $\gamma$, associated with the geometry of the rod. One should point out, however, that the analogy is not perfect. References: Wannier G. H. (1960) Wave Functions and Effective Hamiltonian for Bloch Electrons in an Electric Field, Phys. Rev. **117**, 432-439; Wannier G. H.

**B15 9 Resonant frequency shifts of Al micro-resonator by electric currents and nonlinear oscillation** SEONG SOO KIM, JUNG HO KIM, KOOKRIN CHAR, *School of Physics, Seoul National University, Seoul, Republic of Korea* Mechanical microbridge resonators are fabricated from polycrystallin aluminum thin film using micromachining processes. A movement of the microbridge smaller than a nm can be measured by optical method. The microstructures are self-oscillating or can be actuated by an external electrostatic field, and oscillations with quality factors up to 2400 in vacuum were measured. The observed resonant frequencies reveal the important role of the internal stress in thin metal film. A substantial resonance frequency shift induced by electric current was observed, which we attribute to thermal expansion caused by Joule heating. Nonlinear oscillation was observed readily due to the large length to thickness aspect ratio ( $\sim$ 1000). Amplitude-dependent resonant frequency shifts show qualitative changes of the resonator response. We will try to correlate the motions of grain boundaries and/or dislocations with the resonator response.

**B15 12 Effect of nuclear quadrupole interactions on the dynamics of two-level systems in glasses.**
ALEXANDER BURIN, *Tulane University*

We consider the effect of the internal nuclear quadrupole interaction on quantum tunneling of complex multi-atomic two-level systems. Two distinct regimes of strong and weak interactions are found. They depend on the relationship between the characteristic energy of the internal interaction $\lambda_*$, which is directly proportional to the number of tunneling atoms per tunneling system, and a bare tunneling coupling strength $\Delta_0$. When $\Delta_0 > \lambda_*$, the internal interaction is negligible and tunneling remains coherent, being defined by the strength of $\Delta_0$. When $\Delta_0 < \lambda_*$, coherent tunneling breaks down and the effective tunneling amplitude decreases by an exponentially small overlap factor $\eta^* \ll 1$ between the internal ground states of the left and right well, affecting thermal and kinetic properties of tunneling systems.The theory is applied to interpret the anomalous behavior of the resonant dielectric susceptibility in amorphous solids for $T \leqslant 5mK$ in terms of the nuclear quadrupole interaction. This interaction breaks coherent tunneling for $T \leqslant 5mK$, where the characteristic tunneling amplitude becomes comparable with the interaction strength. We suggest clarifying experiments using external magnetic fields to test the theories predictions and to shed some light on the internal structure of tunneling systems in amorphous solids.

**B16 1 Mechanically-Adjustable and Electrically-Gated Single-Molecule Transistors.***
ALEXANDRE CHAMPAGNE,[†] *Cornell University*

We describe the fabrication and characterization of single-molecule transistors whose properties can be tuned in two independent ways to achieve systematic measurements of electron transport. The spacing between the source and drain electrodes can be adjusted with better than 1 pm stability using the mechanical breakjunction technique – the electrodes are freely suspended above a flexible substrate, and their spacing can be varied by bending the substrate. In the same devices, we are also able to apply a gate voltage to the molecule. This is done by employing lithographic techniques to suspend the breakjunction only 40 nm above the substrate surface and using the substrate as an electrostatic back gate. With the independent in-situ variations provided by these two experimental ''knobs,'' we are able to achieve a more detailed characterization of electron transport through the molecule than is possible with either technique separately. To demonstrate the device capabilities, we have studied transport through single $C_{60}$ molecules at low temperature. We observe Coulomb blockaded transport and can resolve discrete energy levels of the molecule. We are able to mechanically tune the spacing between the electrodes (over a range of 5 Å) to modulate the lead-molecule coupling, and we can electrostatically tune the energy levels on the molecule by up to 160 meV using the gate electrode. We will also present data of Kondo transport in single $[Co(tpy\text{-}SH)_2]^{2+}$ molecules. We are able to vary the strength of the Kondo resonance in these devices by changing the spacing between the source and drain electrodes.

**B16 2 Spontaneous oscillation of current in fullerene molecular junctions** CHAO-CHENG KAUN, RYAN JORN, TAMAR SEIDEMAN, *Department of Chemistry, Northwestern University* We study the correlated phenomena of resonant conduction and current-driven dynamics in Au–$C_{60}$–Au molecular junctions from first principles. A significant resonant component of the transmission gives rise to vibrations of the $C_{60}$ center of mass between the electrodes [C.-C. Kaun and T. Seideman, PRL 94, 226801 (2005)]. An interesting interplay between conductance channels of different symmetries and different degrees of spatial localization results in strong dependence of the transmission on the location of the fullerene within the junction. The distance-dependence, in turn, leads to oscillating current in the THz regime. Rotation of the $C_{60}$ about its axis likewise markedly modifies the transmission characteristics.

**12:03**
**B16 3 Nano-electromechanical structures for single molecule transport studies and position sensing** SHAWN TANNER, CHARLES ROGERS, *Department of Physics, University of Colorado, Boulder, CO 80309* We have developed a process for making sub-micron cantilevers, clamped beams, and more complicated electro-mechanical structures that carry integrated electrical leads.

Such objects are useful as test structures for measuring the electrical properties of molecular sized objects, as high frequency electromechanical components for radio frequency and microwave applications, and as sensor components for studying fluctuations in small systems. Our process uses two realigned electron beam lithography steps, a thin-film angled deposition system, and differential removal of sacrificial aluminum layers to produce freely suspended sub-micron electro-mechanical components. We have produced cantilevers and beams on a variety of substrates (silica, silicon, and polyimide) and have produced insulating, conductive, and multilayer electro-mechanical structures. The process allows the use of essentially any material that can be deposited from a thermal or electron-beam deposition source. We have constructed mechanically adjustable gold-vacuum-gold contacts and have demonstrated vacuum tunneling. The behavior of these contacts indicates a gold work function in excess of 4 eV, consistent with clean gold surfaces.

**B16 4 Gold Nanogap Junctions Fabricated by Temperature-Controlled Electromigration** G. ESEN, M.S. FUHRER, *Department of Physics and Center for Superconductivity Research, University of Maryland, College Park,MD* Electromigration of gold nanowires of different cross-sectional areas are studied using a feedback-controlled electromigration algorithm. We have observed a linear correlation between the cross sectional area of the gold nanowire and the power dissipated in the junction during electromigration, indicating that the feedback mechanism primarily controls the junction temperature. We also show that the role of external feedback circuit is to prevent thermal runaway; minimization of series resistance allows control of electromigration with a simple voltage ramp. We also discuss the I-V characteristics of the junctions after they are formed.

**12:27**

**B16 5 Electron transport through OPE-based molecules in junctions formed by electromigration** XUEQING LIU, WEI CHEN, ZHONGKUI TAN, KONSTANTIN K. LIKHAREV, JAMES LUKENS, *Department of Physics and Astronomy, Stony Brook University* ANDREAS MAYR, *Department of Chemistry, Stony Brook University* We have studied the self-assembly and electron transport properties of (i) simple oligo(phenylene ethynylene) (OPE) chains (2.2 nm) and (ii) OPE based molecules with a naphthalene diimide acceptor group (4.5 nm). Both are capped with terminal isocyanide groups. The molecules are self-assembled on gold wires with a cross-section $\sim 20\times 100$ nm$^2$. The junctions are formed by electromigration and the transport measurements are carried out at 4.2 K. For simple OPE chains, more than 40% of the junctions have shown non-linear I-V curves with resistance R in the range from M$\Omega$ to G$\Omega$, due to trapping of single or multiple molecules. In $\sim$ 10% of the junctions (R $\sim$ a few G$\Omega$), we observe I-V curves with discrete current steps due to electron transport through one or a few molecules. The histogram of the step voltages shows grouping at certain levels. These levels are in a semi-quantitative agreement with our calculations based on the general theory of single-electron transport. For long OPE molecules with acceptor groups, the yield is low ( $<$ 15%), and the data show Coulomb blockade with threshold voltages from 30 to 200meV. Currently we are working on different support nanostructures that will promise higher yield. This work is supported by AFOSR and NSF.

**B16 6 Electronic Quantum Interference in Molecular Devices** FENG MIAO, *Physics Department, University of California, Riverside, CA 92507* DOUGLAS OHLBERG, R. STANLEY WILLIAMS, *HP Labs, 1501 Page Mill Rd., Palo Alto, CA 94304* C.N. LAU, *Physics Department, University of California, Riverside, CA 92507* Understanding the mechanisms for electrical transport and conductance switching in molecular devices is necessary for developing molecular electronics. Here we use pressure-modulated conductance microscopy to characterize Pt/stearic acid monolayer/metal molecular heterostructures. We use either titanium or chromium as the top electrodes. By using atomic force microscope (AFM) to apply a localized force to the junction while monitoring device conductance, we observe nanoscale conductance peaks in response to applied pressure, indicating nanoscale conductance channels through the devices. Additionally, for devices with conductance of $\sim$ 1 to 2 conductance quantum, we also observe conductance dips and oscillations under localized pressure. The results are consistent with quantum interference of electrons between partially transmitting electrodes.

**B16 7 Molecular conductance measurements through printed Au nano-dots.** WEIRONG JIANG, *Rutgers University* NIKOLAI ZHITENEV, *Bell Laboratories, Lucent Technologies* ZHENAN BAO, *Standford University* DAVID ABUSCH-MAGDER, *Bell Laboratories, Lucent Technologies* DON TENNANT, *Bell Laboratories, Lucent Technologies* ERIC GARFUNKEL, *Rutgers University* Gold pads with $\sim$ 100 nm diameter are imprinted on self-assembled monolayers of alkane dithiols of different lengths using nano-transfer technique. The fabrication technique ensures formation of chemical bonds at both ends of molecules while minimizes defect creations compared to other metallization methods. The pads are contacted by conductive atomic force microscope (CAFM) to study electron transport through the SAM as a function of contact force. We found that atomic scale topography at the metal-molecules interface is essential to describe the conductance-stress relationship. In as-fabricated devices, only small percentage of molecules (below 1%) is wired to both contacts. A finite force (1-10 nN) deforms devices resulting in two competing effects: (a) contacting larger number of molecules leading; (b) deforming interfacial bonds and/or tilting the molecules. The estimated conductance of molecules is significantly smaller than in previous CAFM experiments and calculations.

**B16 8 Single-Molecule STM Studies on Atomically-Flat Nanoparticles*** D.H. DAHAYANAKA, D.W. KELLE, D.J. WASIELEWSKI, E.S. DAY, D.R. WHITE, L.A. BUMM, *Center for Semiconductor Physics in Nanostructures, Homer L. Dodge Department of Physics and Astronomy, University of Oklahoma, Norman, OK 73019, USA* C.M. WAITE, J.L. MOORE, R.L. HALTERMAN, *Department of Chemistry and Biochemistry, University of Oklahoma, Norman, OK 73019, USA* The scanning tunneling microscope (STM) has been broadly applied to measure electronic characteristics of individual molecules supported in an inert monolayer matrix, which is typically grown on gold thin films on mica or bulk single crystal substrates. Although these substrates are excellent for electronic measurements, they have serious disadvantages for optical measurements because they are not optically transparent and the metal surface can quench the molecular excited state. We demonstrate that single molecule electronic measurements can also be performed using atomically-flat

gold nanoparticles (FGNPs) supported on indium tin oxide coated glass as a replacement for the typical gold substrate. These substrates are optically transparent and each of the FGNP ''nanosubstrates'' is an optically resonant photonic antenna, thus they have the added advantage that optical measurements can be performed.

**B16 9 Theory of Molecular Conformational Switching** SHASHI KARNA, *US Army Research Laboratory* We have investigated stability and current switching as a function of conformational change in tolane molecule by ab initio Hartree-Fock and density functional theory approaches. The planar conformation of the molecule in which the two benzene rings are coplanar is calculated to be more stable than a twisted conformation. The current ($I$) with respect to the applied external potential ($V$) increases from minimum to maximum as the two $\pi$-rings become planar, suggesting the ''ON'' and ''OFF'' mechanism of the molecular switch at planar and perpendicular conformations, respectively.

**13:27**

**B16 10 Comparison of Transport and Switching Characteristics of Ti/Molecule/Pt and Cr/Molecule/Pt Devices** MICHAEL TABER, FENG MIAO, *Department of Physics, University of California at Riverside, Riverside, CA 92521* DOUGLAS OHLBERG, R. STANLEY WILLIAMS, *Hewlett-Packard Labs, 1501 Page Mill Rd, Palo Alto, California 94304* C.N. LAU, *Department of Physics, University of California at Riverside, Riverside,CA 92521* Molecular devices that consist of a monolayer of stearic acid molecules sandwiched between Pt and Ti electrodes can be switched ''on'' and ''off'' reversibly. To gain insight into the switching and mechanism, we fabricated and measured similar molecular junctions by replacing Ti with chromium as the top electrode. These devices can be switched ''off'' controllably, but not ''on.'' The conductances of both types of devices display similar dependence on temperature. Latest data will be discussed in terms of various theoretical models.

**13:39**

**B16 11 Controlling Negative Differential Resistance in Molecular Electronic Devices by Means of Designer Transition Metal Interfaces*** HUGH DALGLEISH, GEORGE KIRCZENOW, *Department of Physics, Simon Fraser University, Burnaby, BC, Canada, V5A 1S6* Observations of negative differential resistance (NDR) have been reported for a number of molecular junctions with potential for device applications and have helped fuel the promise of viable molecular nano-electronic technologies. Here we present predictions of non-linear transport phenomena in molecular junctions where single organic molecules bridge transition metal nanocontacts. We predict the transmission to be mediated by interface states that appear within the HOMO-LUMO gap due to hybridization between thiol-terminated ends of the molecules and the d-orbitals of the transition metal. Our calculations reveal resonant enhancement and reduction in the interface state transmission under the application of moderate bias that result in NDR in molecular junctions with Pd nanocontacts. We show that this NDR can be tailored by suitably choosing the nanocontact materials: If a Rh electrode is substituted for one Pd contact we predict the NDR of the molecular junction to be strongly enhanced.

**B17 1 Ferroelectric phase transitions in $BaTiO_3/SrTiO_3$ superlattices studied by ultraviolet Raman spectroscopy** DMITRI A. TENNE, X.X. XI, *Dept. of Phys., Pennsylvania State Univ.* A. SOUKIASSIAN, W. TIAN, Y.L. LI, L.Q. CHEN, D.G. SCHLOM, *Dept. of Mater. Sci. & Engin., Pennsylvania State Univ.* A. BRUCHHAUSEN, A. FAINSTEIN, *Centro Atomico Bariloche, Argentina* X.Q. PAN, *Dept. of Mater. Sci. & Engin., Univ. of Michigan* A. CANTARERO, *Univ. of Valencia, Spain* R.S. KATIYAR, *Dept. of Phys., Univ. of Puerto Rico, San Juan, PR* Ferroelectric $(BaTiO_3)_m/(SrTiO_3)_n$ superlattices (SLs) grown by molecular beam epitaxy on $SrTiO_3$ substrates have been investigated by ultraviolet (UV) Raman spectroscopy. Using the UV excitation allowed us to overcome the problem of overwhelming substrate contributions in Raman spectra and made possible the observation of phonons in SLs having the ferroelectric $BaTiO_3$ layers as thin as 2 unit cells. The ferroelectric-paraelectric phase transitions have been observed. Depending on the thickness of the $BaTiO_3$ layers and strain, the phase transition temperature varies by hundreds of degrees from $\sim$ 140 K to 630 K, which is over 200 degrees higher than in bulk $BaTiO_3$. Below $T_c$, the SLs likely remain in the single (tetragonal) ferroelectric phase down to 7 K, i.e. the low-temperature phases characteristic for bulk $BaTiO_3$, are suppressed by strain. The experimental data are in good agreement with the results of the thermodynamic calculations of polarization in SLs as a function of temperature. This work was supported by DOE, NSF, and ONR.

**11:27**

**B17 2 Interlayer Coupling and Dielectric Anomaly in Ferroelectric Bilayers and Multilayer Heterostructures** S. PAMIR ALPAY, SHAN ZHONG, *University of Connecticut* ALEXANDER L. ROYTBURD, *University of Maryland* JOSEPH V. MANTESE, *Delphi Research Laboratories* Ferroelectric multilayers and superlattices have gained interest for dynamic random access memory (DRAM) applications and as active elements in tunable microwave devices in the telecommunications industry. There have been a number of experimental studies that show that these materials have many peculiar properties that cannot be described by a simple series connection of the individual layers that make up the heterostructures. A thermodynamic analysis is presented to demonstrate that ferroelectric multilayers interact through internal elastic, electrical, and electromechanical fields and the ''strength'' of the coupling can be quantitatively described using Landau theory of phase transformations, theory of elasticity, and principles of electrostatics. The thermodynamic modeling indicates that the electrostatic coupling between the layers leads to the suppression of ferroelectricity at a critical paraelectric layer thickness for ferroelectric-paraelectric bilayers. This bilayer is expected to have a gigantic dielectric response similar to the dielectric anomaly near Curie-Weiss temperature in homogeneous ferroelectrics at this critical thickness.

**B17 3 Phase Transitions and Domain Structures in Nanoferroelectrics.**
ARKADI LEVANYUK

A review of the Landau-type theory of size effects in ferroelectric phase transitions will be presented. An aspect of this theory, a question about the ''critical thickness'' of ferroelectric thin films will be the main emphasis. This question can be reduced to that of the size dependence of temperature of ferroelectric phase transition by taking into account two possibilities for such a transition: formation of (i) single- or (ii) multi-domain ferroelectric state. In a defect-free sample, two factors would define which of these possibilities is realized: the depolarizing field and the specific features of the sample surface reflected in the boundary conditions for the Landau-type equations in addition to the conventional electrodynamics boundary conditions. The possibility of the transition into the single domain state strongly depends on a character of electrodes and the additional boundary conditions, while it is much less important for the multi-domain case. In realistic conditions, the transition would proceed into the multi-domain state, especially in near cubic ferroelectrics, e.g. films of cubic perovskites with an elastic mismatch between the film and a substrate. Importantly, the shift of a transition temperature with respect to a bulk is relatively small in this case. The message is that, while studying the question about the ''critical thickness,'' multi-domain states rather than single domain ones should be considered first of all, contrary to the approach in some recent papers where only monodomain state was studied. In particular, there is no definite indication of ultimate ''critical thickness'' for a multi domain ferroelectric state in nearly cubic samples. Along with ultra thin films the ferroelectric nanopowders are also intensively studied now. Here the size effects are more complicated because of long-range interaction between the particles. The problems which the theory faces here are briefly commented upon. It is worth mentioning that several important results in the theory of the size effects have been obtained long ago but, unfortunately, seem not to be well known by the ferroelectrics community. They will be exposed together with more recent results obtained in collaboration with A.Bratkovsky at Hewlett-Packard Laboratories, Palo Alto.

**B17 4 Ferrolectric nanodots and nanowires under different electrical and mechanical boundary conditions*** INNA PONOMAREVA, IVAN NAUMOV, LAURENT BELLAICHE, *University of Arkansas* Intense effort has been recently made in synthesizing, characterizing and/or simulating ferroelectric nanostructures (FENs), because of their technological and fundamental promise. Among the different possible classes of FENs, thin films are, by far, the ones that have been the most investigated. However what is crucially missing nowadays is to gain a deep knowledge of 0D-like and 1D-like FEN and understand how their properties depend on mechanical and electrical boundary conditions. We report results on ferroelectric nanodots and infinite wires of $Pb(Zr_{0.4}Ti_{0.6})O_3$ alloy under different boundary conditions investigated via Monte-Carlo simulations using an atomistic first-principle-based effective Hamiltonian[1]. It was found that these nanosystems all exhibit a spontaneous polarization that points along a non-periodic direction, for situations close to short circuit electrical boundary conditions and independently of the epitaxial strain. On the other hand, unusual dipole patterns arise in these systems when they experience a large-enough depolarizing field. The dependency of these patterns on the nanostructure's dimensionality is revealed and explained. [1] L. Bellaiche *et al*, Phys. Rev. Lett. **8**, 5427 (2000).

*This work is supported by NSF grants DMR-0404335 and DMR-9983678, by ONR grants N 00014-01-1-0365, N 00014-04-1-0413, N 00014-01-1-0600 and DOE grant DE-FG02-05ER46188.

**B17 5 Self-assembled Nanoscale Domain Structures in Ferroelectrics: Formation and Evolution*** VLADIMIR SHUR, *Ural State University, Ekaterinburg* FERROELECTRIC LABORATORY TEAM, The formation and propagation of self-assembled nanodomain structures have been experimentally studied in lithium niobate single crystals. It has been shown that the ''discrete switching'' through appearance of the quasi-regular patterns consisting of individual nanodomains is a result of decay of highly non-equilibrium domain state. We have demonstrated that the necessary and sufficient condition for such abnormal domain behavior is ineffective screening of depolarization fields, which is characterized by the ratio between bulk screening and switching rates. We have systematically studied this effect in three different experimental situations: (1) ''super-fast'' switching in external electric field, (2) spontaneous backswitching, (3) intensive pulse irradiation by UV laser. The obtained nanoscale structures were classified and explained within unified approach. The main laws of formation of oriented short arrays and growth of strictly oriented ''super-long'' nanoscale domain ''rays'' accompanied by discrete turning and branching have been revealed. The geometry of the domain patterns obtained by computer simulation demonstrates one to one coincidence with experimental images.

*The research was made possible in part by Grants 03-51-6562 of INTAS and 04-02-16770 of RFBR.

**12:39**
**B17 6 Potential distribution and domain structure of metal-ferroelectric-semiconductor-metal heterostructures** RENE MEYER, *Stanford University* PAUL McINTYRE, *Stanford University* Recently, we proposed a novel resistive non-volatile memory concept based on the ferroelectric effect. The resistance switching originates from the unscreened polarization charge at the ferroelectric/semiconductor interface, which affects the distribution of the inner electric potential. A depletion or enrichment of mobile charge carriers leads to a reduced or increased conductivity of the near-interface region. The depolarizing field, however, which is inherently present in the ferroelectric in the case of imperfect screening, causes the formation of 180 deg. domains. The resulting alternation of positive and negative polarization charges at the ferroelectric/semiconductor interface could deteriorate the

performance of the proposed resistance switch. In this contribution, the domain pattern is studied numerically for a metal-ferroelectric-semiconductor-metal structure. A 2-dimensional finite differences method is used to calculate the inner electric field, the potential distribution and the electrostatic energy under short circuit conditions and for external electric fields. Based on empirical data, the domain size is estimated as a function of the screening efficiency of the electrodes and the applied field. Results of the 2-dimensional model are compared to a 1-dimensional approach, where a voltage dependence of the macroscopic polarization is approximated by an effective polarization.

**B17 7 Fabrication and Electrical Measurements of $CoFe_2O_4$ Nanopillars in a $BiFeO_3$ matrix*** SCOTT RUTHERFORD,[†] *University of Wisconsin - Madison* RASMI DAS,[‡] *University of Wisconsin - Madison* XIANGLIN KE,[§] *University of Wisconsin - Madison* DMITRY RUZMETOV, *Northwestern University* DONG-MIN KIM,[‖] *University of Wisconsin - Madison* SEUNG HYUB BAEK, *University of Wisconsin - Madison* MARK RZCHOWSKI, *University of Wisconsin - Madison* CHANG-BEOM EOM, *University of Wisconsin - Madison* CHANG-BEOM EOM COLLABORATION, MARK RZCHOWSKI COLLABORATION, NORTHWESTERN UNIVERSITY COLLABORATION, Coupling between ferromagnetic and ferroelectric ordering has recently stimulated many scientific and technological interests. This ''coupling,'' would provide an additional degree of freedom in the design of micro and nano-electronic devices such as actuators, transducers, or memories. Unfortunately, the clamping effect of the substrate negates any such magnetoelectric coupling through elastic interactions which evident in a multilayer structures. Therefore our focus is directed towads the design of a novel vertically aligned oxide nano-structures, which will allow us to switch the magnetic domains by applying the electric field and vice versa. These nano-structures will also be used as model system to understand the physics of order parameter coupling in ferroelctric and ferromagnetic systems. We have fabricated ferromagnetic nanopillar arrays of $CoFe_2O_4$ (CFO), surrounded by a ferroelectric $BiFeO_3$ (BFO) and $BaTiO_3$ matrix. $90^0$ off-axis sputtering is used to deposit $SrRuO_3$ (SRO), followed by CFO on single surface $TiO_2$-terminated $SrTiO_3$ (001) substrates. SRO provides a good lattice match and electrode capabilities for the subsequent deposition of CFO. E-beam patterning defines pillar dimensions and spacing, while ion milling etches down to the SRO layer. The pillar dimensions range between 100 nm and 500 nm in diameter and are spaced 0.5 to 1 $\mu$m apart. Atomic force microscopy and scanning electron microscopy measurements confirm the structure of the pillars following the pattering and etching steps. The BFO ferroelectric matrix is then deposited by on-axis sputtering. Fabrication of these pillars along with piezo force micrcroscopy and magnetic force microscopy was used to understand the microstructure and domain switching. The detailed scanning probe measurements of domain switching in these novel oxide nanostructures will be discussed.

**B17 8 Structure and electronic properties of GeTe nanoparticles from ab initio calculations.*** GREGORY HAMMAD, *ENS, Strasbourg, France* PHILIPPE GHOSEZ, JEAN-YVES RATY, *University of Liege, Belgium* We use density functional theory to study the structure of small Ge-Te nanoparticles close to stoichiometry with various geometries. We particularly investigate the geometrical distortion of the rocksalt structure that gives rise to the ferroelectric effect in bulk GeTe. We observe that similar distortions appear in nanoparticles down to very small sizes (Ge15Te16). The electronic structure and the HOMO-LUMO states localization are shown to be in most cases related to the surface termination. Using linear response calculation (ABINIT code) we compute effective charges and compare these to the bulk value. We finally discuss the effect of the various factors (aspect ratio, facets, surface termination, stoichiometry) on the possibility that small (a few nm in size) Ge-Te nanoparticles could be ferroelectric.

**B18 1 Density gradient ultracentrifugation of single-walled nanotubes.**
MICHAEL ARNOLD, *Northwestern Univeristy*

We demonstrate the bulk separation and enrichment of single-walled carbon nanotubes (SWNTs) by diameter via density gradient ultracentrifugation.(1) Means for sorting SWNTs by their physical and electronic structures are essential for future electronic and optical applications where semiconducting SWNTs mono-disperse in diameter are necessary. The separation is driven by subtle variations in the buoyant density of these nanomaterials with small changes in their physical structure. After centrifugation in a density gradient, focused bands of various colors consisting of isolated SWNTs are clearly visualized by eye. By fractionating the centrifuge tube and characterizing the absorbance and photoluminescence spectra of the sorted SWNTs, it is apparent that SWNTs of decreasing diameter are increasingly more buoyant. This

scalable and non-destructive separation strategy uses centrifugation equipment already utilized in the solution-based processing of carbon nanotubes, and simultaneously separates isolated and aggregated SWNTs, which sediment to larger buoyant densities due the reduced solvation and surface-to-volume ratios of these larger structures. Along these lines, the removal of aggregates and spurious materials is evidenced by significantly lower background absorbencies in optical absorbance spectra. For the case of isolated SWNTs, we propose a geometric-based hydration model to describe the unexpected trend of increasing density with increasing diameter. The effectiveness of this technique is best demonstrated for SWNTs that are small in diameter. For example, in the small diameter regime, it is possible to sort the (6,5) and (7,5) tubes, which differ in diameter by only 0.7 Å. (1) M. S. Arnold et al. Nano Lett. 5 (2005) 713-718.

**B18 2 Determination of Diameter, Helicity, and Handedness of Carbon Nanotubes by Electron Diffraction** ZEJIAN LIU, LU-CHANG QIN, *University of North Carolina at Chapel Hill* We report a systematic procedure to determine the diameter, helicity and handedness of multiwalled carbon nanotubes by using nanobeam electron diffraction technique. Diameter and helicity of a nanotube can be measured directly from the scattering intensity distribution on the non-equatorial layer lines in its electron diffraction pattern, while the handedness information need be derived from several diffraction patterns of different orientations when if there exist concentric shells of the same helicities in the nanotube. Two selected examples of metallic triple-walled carbon nanotubes are presented to illustrate the detailed structure determination.

**12:03**

**B18 3 Diameter Recognition of Single Walled Carbon Nanotubes by Water-Soluble Proteins** KOJI MATSUURA, TAKESHI SAITO, TOSHIYA OKAZAKI, SATOSHI OHSHIMA, KOHEI MIZUNO, DON FUTABA, KENJI HATA, MOTOO YUMURA, SUMIO IIJIMA, *Res Ctr Adv Carbon Mat, Natl Inst of Adv Indust Sci and Technol (AIST)* The hybrid of proteins and single walled carbon nanotubes (SWCNT) is a promising advanced material that possesses both functions of associated proteins and SWCNTs. Using SWCNTs of varying diameter, synthesized by two distinct methods, Direct-Injection-Pyrolytic-Synthesis [1] (0.8- 1.2 nm) and super-growth chemical vapor deposition [2] (mean diameter of 3 nm), we observed diameter-selective dispersion for two differing proteins which is driven by the sizes of the hydrophobic pockets in the proteins. Hybrid solutions of both lysozyme (LYS) and bovine serum albumin (BSA) dispersed the smaller diameter SWCNTs as observed by absorbance and photoluminescence spectroscopy. The larger diameter SWCNTs were dispersed in the BSA solution, while not dispersed by LYS. A decrease in the mean molar ellipticity observed by far-UV circular dichroism spectroscopy following the removal of unadsorbed proteins suggests a loss in $\alpha$-helical contents of the proteins. These results, in addition to the difference in size of BSA and LYS (10 and 4 nm, respectively), indicate the hydrophobic pockets corresponding to the protein morphology can recognize the SWCNT diameters. **12:15**

**B18 4 Structure determination of a nine-wall carbon nanotube by nanobeam electron diffraction.** QI ZHANG, ZEJIAN LIU, *Department of Physics and Astronomy, the University of North Carolina at Chapel Hill* LU-CHANG QIN, *Department of Physics and Astronomy, Curriculum in Applied and Materials Sciences, the University of North Carolina at Chapel Hill* XINLUO ZHAO, YOSHINORI ANDO, *Meiji University, Japan* Multiwalled carbon nanotubes are composed of a series of coaxial single walled carbon nanotuebs. While great progress has been made in determining the atomic structure of single-walled carbon nanotubes, few direct measurements of the atomic structure of multiwalled carbon nanotubes have been available. Meanwhile, it is still a challenging task to determine the atomic structure of nanotubes with large diameter. In this work, the atomic structure of a nine-walled carbon nanotube was determined by nanobeam electron diffraction with the assignment of the chiral indices of each and every individual shell. The chiral indices of the innermost tubule has chiral indices [5,5], corresponding to the $C_{60}$ molecule. The diameters are from 0.678 nm to 6.445 nm with inter-shell spacings between the neighboring tubules in the range of 0.309 nm to 0.408 nm, the helical angles from $11.51^o$ to $30^o$, in which eight tubes are falling in the high helicity from $15^o$ to $30^o$.

**12:27**

**B18 5 Quantitative Characterization of Defect Densities in Single-Walled Carbon Nanotubes** YUWEI FAN, BRETT GOLDSMITH, PHILIP COLLINS, *Department of Physics and Astronomy, University of California Irvine, Irvine, CA 92697-4576* The prevailing conception of carbon nanotubes and particularly single-walled carbon nanotubes (SWNTs) continues to be one of perfectly crystalline wires. We have demonstrated a selective electrochemical method which labels point defects and makes them easily visible for quantitative analysis. High-quality SWNTs are confirmed to contain one defect per 4 um on average, with a distribution weighted towards areas of SWNT curvature. While this defect density compares favorably to high quality, silicon single crystals, the presence of a single defect can have tremendous electronic effects in one-dimensional conductors like SWNTs. We demonstrate a one-to-one correspondence between chemically-active point defects and sites of local electronic sensitivity in SWNT circuits, confirming the expectation that individual defects may be critical to understanding and controlling variability, noise, and chemical sensitivity in SWNT electronic devices. By varying the SWNT synthesis technique, we further show that the defect spacing can be varied over orders of magnitude. The ability to detect and analyze point defects, especially at very low concentrations, indicates promise of this technique for quantitative process analysis, especially in nanoelectronics development. This work is partly supported by NSF grant DMR-0239842.

**12:39**

**B18 6 Shape Engineerable Single Walled Carbon Nanotube Solid as a Flexible Conducting Mesoporous Material** DON N. FUTABA, KENJI HATA, TATSUKI HIRAOKA, TAKEO YAMADA, KOHEI MIZUNO, YUHEI HAYAMIZU, TATSUNORI NAMAI, YOZO KAKUDATE, OSAMU TANAIKE, HIROAKI HATORI, KOJI MIYAKE, SHINYA SASAKI, MOTOO YUMURA, SUMIO IIJIMA, *National Institute of Advanced Industrial Science and Technology (AIST)* We present a new form of carbon nanotubes (CNT) material where CNTs are aligned and packed densely in a bulk solid. This single-walled carbon nano-

tube (SWNT) solid is fabricated from liquid-induced collapse of the sparse as-grown SWNT forest synthesized by super-growth CVD [1], which results in a 20x increase in mass density and a 70x increase in the Vickers hardness while retaining alignment and high surface area. As such, SWNT solid is an ideal form of CNTs for material and energy storage. The high surface area and well-defined microscopic structure imply that SWNT solid can be regarded as a conductive and flexible mesoporous material. In addition, we can engineer shapes suitable to the application. These unique characters make SWNT solid as a valuable material for supercapacitor electrodes and flexible heaters. Furthermore, we show how partial shrinking of the as-grown material creates a ithandle for robust mechanical and electrical connection to demonstrate exceptional tribological character and wear rate. The SWNT solid promises to open new frontiers in within the carbon nanotube field. [1] K. Hata itet al, Science, **306**, 1241 (2004).

**12:51**

**B18 7 Filtration Patterning of Single Walled Carbon Nanotube Films** DAVID A. DALY, ZHUANGCHUN WU, ANDREW G. RINZLER, *Dept. of Physics, University of Florida, Gainesville, FL* Carbon nanotubes are increasingly being explored for applications exploiting the bulk electrical conductivity of aggregate nanotubes in the form of fibers and films. Attractive in this regard are electrical conductivities orders of magnitude greater than those of conducting polymers, while retaining many of the useful features of polymers, e.g. flexibility, transparency (in thin films) and alternative device fabrication strategies. Here we describe a novel, non-lithographic patterning technique that should also be applicable to other nano-materials. The technique is based on our method for forming thin, pure nanotube films on the surface of a filtration membrane followed by transfer of the film to the desired substrate.[1] To generate patterned films we block the pores of the filtration membrane in the inverse of the ultimately desired film pattern, prior to film formation on the surface of the membrane. The nanotubes only accumulate in the membrane regions that are not occluded, resulting in the desired pattern. Blocking of the membrane pores is accomplished with use of a commercial printer. Implementation and limitations of the technique will be discussed. 1. Z. Wu, Z. Chen, X. Du, J. M. Logan, J. Sippel, M. Nikolou, K. Kamaras, J. R. Reynolds, D. B. Tanner, A. F. Hebard, A. G. Rinzler, Science 305, 1273 (2004).

**13:03**

**B18 8 The Order in Vertically Aligned Carbon Nanotube Arrays** HOWARD WANG, ZHIYONG XU, *Department of Materials Science and Engineering, Michigan Technological University, Houghton, MI 49931* GYULA ERES, *Condensed Matter Sciences Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831* Vertically aligned carbon nanotube (CNT) arrays can exploit the remarkable properties of individual nanotubes in macroscopic applications. Here we report the first measurements of the degree of alignment order in as-grown vertically aligned CNT arrays using small angle neutron scattering. The scattering patterns reveal continuously varying alignment order along the growth and two distinctly different morphologies of CNTs. The observations are discussed in the light of growth mechanisms.

**13:15**

**B18 9 Physical properties of self-assembled monolayers of carbon nanotubes** V.A. SAMUILOV, *Dept. of Materials Sci., SUNYSB and Dept. of Physics, State Univ. of Belarus* J. GALIBERT, *Laboratoire National des Champs Magnetiques Pulses, France* V. KSENEVICH, N.A. POKLONSKI, *Dept. of Physics, State Univ. of Belarus* L. FORRO, *Ecole Polytechnique Federale de Lausanne, Switzerland* J. KOO, K. YOON, M. RAFAILOVICH, J. SOKOLOV, *Dept. of Materials Science, SUNYSB* The controlled method of self-assembly of functionalized carbon nanotubes into 2-D layers with highly regular structure and unique electronic properties has been developed. We use the Langmuir-Blodgett (LB) technique and newly developed inverted LB techniques. The alignment carbon nanotubes in the self-assembled 2-D layers was also introduced. The methods we propose, could be used for covering large surfaces with dense, molecularly ordered ultra-thin films of nanotubes of controlled thickness and orientation. The electrical, thermal conductivity and magneto-transport properties of the monolayers (arrays) of multi-wall and single-wall carbon nanotubes in the temperature range 1.8-300K and in magnetic fields up to 35 T have been tested.

**13:27**

**B18 10 Linear Dichroic Cell Based on Magnetic Alignment of Carbon Nanotubes** Y. J. LEE, J. SHAVER, S. ZARIC, J. KONO, *Rice University, Houston, TX 77005* Single-walled carbon nanotubes align with a magnetic field due to their anisotropic magnetic properties. A simple yet sensitive setup utilizing a balance detector has been constructed to study the alignment of micelle-suspended single-walled carbon nanotubes. We present alignment data in response to static and dynamic magnetic fields. The results of our ensemble measurements show that the amount of signal change depends on the strength and frequency of the applied magnetic field, thus allowing us to determine the minimum field required to align single-walled carbon nanotubes. This data can then be analyzed to characterize the physical parameters of the carbon nanotubes and to determine information about the time scale of the alignment process and local environment.

**13:39**

**B18 11 The Conformation of Polymers Dispersing Single-Walled Carbon Nanotubes in Water.** YAEL DROR, YACHIN COHEN, *Technion, Israel* WIM PYCKHOUT-HINTZEN, *Fz. Juelich, Germany* Amphiphilic polymers have been used to disperse single-walled carbon nanotubes (SWCNT) in water. The polymer conformation around the nanotube surface is important for understanding the nature of the interactions leading to successful dispersions. Two extreme cases are ''tight wrapping'' of the polymer around the nanotube and ''loose adsorption'' of solvated polymer coils on the nanotube surface. We studied aqueous dispersions of SWCNTs with an alternating copolymer of styrene and sodium maleate (PSSty) by small-angle neutron scattering (SANS) and cryo transmission electrons microscopy (cryo-TEM). Dispersion of long, isolated nanotubes and thin bundles was revealed by cryo-TEM. The SANS patterns (at different solvent contrasts) were evaluated by a modification of Pedersen's ''cylindrical block copolymer micelle'' model, depicting the nanotube-polymer complex as composed of a thin core, the radius of which is about 20 A thus containing about 3-4 nanotubes, surrounded by a thick corona of water-swollen polymer coils with a radius of gyration of 150-170 A. Long-term stabilization is achieved by the steric barrier provided by the adsorbed polymer coils reinforced by electrostatic repulsion due to charged groups distributed along the polymer.

**13:51**

**B18 12 High performance field emission in hybrid carbon nanotube-PDMS composite** CATERINA SOLDANO, *Department of Physics, Applied Physics and Astronomy, Rensselaer Polytechnic Institute, Troy, New York* SWASTIK KAR, *Department of Materials Science and Engineering, Rensselaer Polytechnic Institute, Troy, New York* YUNG J. JUNG, *Northeastern University, Boston MA* SAROJ K. NAYAK, *Department of Physics, Applied Physics and Astronomy, Rensselaer Polytechnic Institute, Troy, New York* OMKARAM NALAMASU, PULICKEL M. AJAYAN, *Department of Materials Science and Engineering, Rensselaer Polytechnic Institute, Troy, New York* We present a novel method of fabricating flexible carbon nanotube polymer composites by embedding aligned multi-walled carbon nanotube (MWNT) architectures into a polydimethylsiloxane (PDMS) polymer matrix. These structures are easily transferable, electromechanically robust and extremely flexible, and therefore suitable for applications as multifunctional flexible electronic devices. A combination of controlled placement of aligned multi-walled nanotubes on pre-patterned locations and an effective suppression of mutual screening gives these devices impressive field emission properties. With large field emission factors ($\beta \sim 10^4$) and low (sub 1V/$\mu$m) turn-on fields, these composites can easily operate at high current densities ( $>$ 1mA/cm$^2$) at relatively low voltages making them also suitable for applications in electrically and mechanically stable flexible sensors and display devices.

**14:03**

**B18 13 Thermal Oxidation Profiling of Single-Walled Carbon Nanotubes** BRIAN LANDI, CORY CRESS, CHRIS EVANS, RYNE RAFFAELLE, *NanoPower Research Labs, R.I.T.* A method of thermal oxidation profiling (TOP) to monitor the properties of single-walled carbon nanotube (SWNT)-containing samples has been developed. In the present analysis, the thermal decomposition of raw and acid-refluxed SWNT samples is evaluated by a systematic series of oxidative thermal treatments with subsequent calculation of the SWNT mass retention using a verified purity assessment technique. The TOP results indicate that there are no discernable regions of a raw soot TGA curve that can be ascribed to SWNT combustion independent of impurity influence. In contrast, the acid-refluxed SWNT sample shows that chemical oxidation of the metal can enable optimization of SWNT retention during thermal purification. The established understanding allows for purification efficiencies (the highest purity at the maximum retention) of 75% w/w to be achieved in laser-produced SWNTs, without modification to the diameter distribution.

## SESSION B19: FOCUS SESSION: TRANSITION METAL OXIDE FERROMAGNETIC SEMICONDUCTORS

**B19 1 Oxide Ferromagnetic Semiconductors.***
SATISHCHANDRA OGALE, *University of Maryland, College Park*

The field of oxide ferromagnetic semiconductors has witnessed tremendous interest and activity over the past few years, especially in the context of realization of intrinsic oxide based diluted magnetic semiconductors (O-DMS). In this talk I will review the important developments in this field, highlighting apparent successes, concerns and questions. Research results obtained by various groups on a number of systems such as transition element (especially Co, Mn, Cr) doped TiO2, ZnO, La1-xSrxTiO3, HfO2 will be discussed including some related device efforts involving spin transport and field induced modulation of magnetization. Some cases of undoped or dual doped oxide films will also be addressed. In the light of the potentially serious possibility of extrinsic effects in most systems the significance of the choice and implementation of an appropriate characterization scheme will also be highlighted. **B19 2 Model for vacancy-induced ferromagnetism in ''d0'' magnetic oxides** TIMOTHY ZIMAN, *Institut Laue Langevin and CNRS, Grenoble* GEORGES BOUZERAR, *Labo. Louis Neel, CNRS Grenoble* J. Coey has coined the term ''d0'' ferromagnetism to describe exciting but puzzling effects seen in HfO2, ZrO2 and other oxides. He has also postulated a connection to the occurrence of cation or anion vacancies, which, recent theories indicate, may reasonably lead to the formation of local moments. What has lacked has been a theory which explains why, and at what temperatures, one could expect ferromagnetism. Here we present a simple model for vacancy-based ferromagnetism which permits quantitative estimates of the Curie temperature. The model is based on a random Hubbard model for anions with potentials that represents the occurrence of cation vacancies. By an extension of techniques successfully used to model ferromagnetism in host substituted III-V diluted magnetic semiconductors, we calculate the Curie temperature and dynamical magnetic correlations as a function of the effective strength of the vacancy potential and doping properties, the density of vacancies, as well as the correlation and bandwidth of the host. For physically reasonable parameters this explains large Curie temperatures for rather small concentrations of vacancies.

**12:03**

**B19 3 Anisotropic magnetic properties of Co-doped $SnO_2$ thin films*** JUN ZHANG, RALPH SKOMSKI, *Dept. of Physics and Astronomy and Center for Materials Research and Analysis, Univ.*

*of Nebraska-Lincoln* YONGFENG LU, *Dept. of Electrical Engr. and Center for Materials Research and Analysis, Univ. of Nebraska-Lincoln* DAVID SELLMYER, *Dept. of Physics and Astronomy and Center for Materials Research and Analysis, Univ. of Nebraska-Lincoln* There is strong interest in oxide magnetic semiconductors, which show not only room-temperature ferromagnetism (FM), but also other interesting magnetic properties. Large magnetic moments and anisotropic FM have been observed in Co-doped $SnO_2$ [1] and Co-doped ZnO [2], respectively. Here we report the preparation and magnetic properties of Co-doped $SnO_2$ ($Sn_{1-x}Co_xO_2$, x=0.05) thin films. $Sn_{1-x}Co_xO_2$ thin films were grown on different substrates by pulsed-laser deposition and characterized by X-ray diffraction and SQUID magnetometry, and their magnetic properties depend on the substrates on which the films are grown. Interestingly, the films grown on R-plane-cut $Al_2O_3$ show strongly anisotropic magnetic properties, with [101] being the easy axis. The anisotropy also depends on the substrate on which the films are grown. The results will be discussed in terms of spin-orbit coupling and crystalline defects. [1]. S. B. Ogale, et al., Phys. Rev. Lett. 91, 077205 (2003). [2]. M. Venkatesan, et al., Phys. Rev. Lett. 93, 77206 (2004).

*This research is supported by NSF-MRSEC, W. M. Keck Foundation, NRI and CMRA.

**B19 4 Defect compensation determined magnetism in wide gap dilute magnetic semiconductors (DMS)** LIN-HUI YE, A.J. FREEMAN, DEPARTMENT OF PHYSICS & ASTRONOMY, NORTHWESTERN UNIVERSITY TEAM, Ferromagnetism (FM) in wide gap DMS is thought to be closely related to intrinsic defects; the F-center Bound Magnetic Polaron (FC/BMP) model proposes that it is mediated by shallow donor defects. Our first principles FLAPW calculations show that Cr:$TiO_2$ is a charge transfer insulator with strong defect compensation - which explains the insulating behavior and the Cr chemical valence. We predict different magnetic phases can form at different compensation levels, consistent with the $p-d$ hopping interaction model[1]. FM only exists with uncompensated $Cr^{4+}$, which explains the high $T_c$ FM initially reported[2]. Fully-compensated $Cr^{3+}$ is predicted NOT to be FM which has been verified recently[3]. Due to insufficient hybridization between dopant and impurity states, the FC/BMP mechanism does not apply, and oxygen vacancies destroy the FM instead of mediating it. Our theory extended to Mn:GaN is found to work equally well; it provides a new understanding of the correlation between defects and magnetism. This may explain why magnetism in wide gap DMS seems to be extremely sensitive to fabrication processes. Supported by NSF through the NU MRC.

**12:27**

**B19 5 Room temperature ferromagnetism in highly-resistive Ni-doped $TiO_2$ films prepared by sol-gel method** DONGHO KIM, JONGHO CHO, YOUNGGULL JOH, *Yeungnam University* KEEJOO LEE, *Choongnam National University* We investigated the magnetic and transport properties of Ni-doped $TiO_2$ films grown by a sol-gel method with Ni concentrations from 1% to 8%. All the samples exhibited ferromagnetism at room temperature identified by optical magnetic circular dichroism (MCD)along with SQUID measurement. For the samples with low Ni concentrations, both results argee each other, however, MCD results of 8% Ni-doped sample showed a noticeable difference in the temperature dependence of the coercive field and the saturation magnetization from the SQUID results. The Hall effect study showed that the carriers are electrons with densities lower than $10^{18} cm^3$ at room temperature, but no anomalous Hall effect has been observed due to the high resistivity of our samples. The observation of ferromagnetism in highly-resistive Ni-doped $TiO_2$ films questions the carrier-mediated exchange interaction as an origin of ferromagnetism in this material.

**12:39**

**B19 6 Niobium doping effects on the ferromagnetism and microstructure of anatase Co: $TiO_2$ films*** SHIXIONG ZHANG, SATISH OGALE, SANKAR DHAR, DARSHAN KUNDALIYA, WEGDAN RAMADAN, JOSHUA HIGGINS, RICHARD GREENE, THIRUMALAI VENKATESAN, *Center for Superconductivity Research, Department of Physics, University of Maryland, College Park, MD 20742-4111.* LIANFENG FU, NIGEL BROWNING, *Lawrence Berkeley National Laboratory, NCEM, 1 Cyclotron Road, MS 72-150, Berkeley, CA 94720* Niobium doping is shown to have a significant effect on the ferromagnetism and microstructure of dilutely cobalt-doped anatase $TiO_2$ films. Epitaxial films of anatase $TiO_2$ with 3% Co, with and without 1% niobium doping were grown by pulsed-laser deposition at 875 $^0$C at different oxygen pressures. For growth at $10^{-5}$Torr Niobium doping suppresses ferromagnetism, while it enhances the same in films grown at $10^{-4}$Torr. The results of High-resolution Z-contrast Scanning Transmission Electron Microscopy and Electron Energy Loss Spectroscopy study reveal uniform surface enrichment of cobalt in the form of $Ti_{1-x-y}Co_xNb_yO_{2-\delta}$g phase, without cobaltmetal clusters. The transport and Hall effect results will also be presented and discussed.

*Work Supported under DARPA SpinS program

**12:51**

**B19 7 Correlation between ferromagnetism and film structure in Co-doped ZnO films** SEBASTIAAN VAN DIJKEN, *Trinity College Dublin* R. BAUERSCHMIDT, *Trinity College Dublin* V. KARTHIK, *Trinity College Dublin* J.M.D. COEY, *Trinity College Dublin* An experimental study on reactively sputtered ZnO films with a fixed Co doping concentration of 6 percent is presented. The magnetic moment of these films is largest (about 0.7 Bohr magneton per Co) for deposition temperatures between 650 K and 800 K. The evolution of the magnetic moment with temperature correlates with an increase of the lattice parameter perpendicular to the film plane. For films on C-plane (0001) and R-cut (1-102) sapphire substrates the maximum elongation amounts to 2.5 percent and 1.3 percent, respectively. Annealing the films at 720 K for 6 hours in vacuum results in a relaxation of the lattice parameters towards the bulk values. In addition, the Co-doped films become electrically conducting during the annealing procedure. Both effects, however, do not drastically alter the magnetic moment of the Co-doped films: For films on C-plane sapphire the moment remains practically unchanged, while the magnetic moment increases only slightly for films on R-cut sapphire. These results and their implications for the understanding of ferromagnetism in Co-doped ZnO will be discussed.

**13:03**

**B19 8 Room Temperature Ferromagnetism in Transition Metal Doped CVD-Grown ZnO Films and Nanostructures*** D.H. HILL, R. GATEAU, R.A. BARTYNSKI, P. WU, Y. LU, L. WIELUNSKI, V. POLTAVETS, M. GREENBLATT, *Rutgers University* D.A. ARENA, *NSLS* J. DVORAK, *Montana State University* S. CALVIN, *Sarah Lawrence College* We have characterized the chemical, compositional, and magnetic properties of Mn- and Fe-ion implanted epitaxial ZnO films and single crystal nanostructures grown by MOCVD as candidate room temperature diluted magnetic semiconductors. X-ray absorption spectroscopy (SXAS) shows that Mn-implanted films contain $Mn^{2+}$ ions which convert to a mixture of $Mn^{3+}$ and $Mn^{4+}$ upon annealing. Fe-implanted films contain a mixture of $Fe^{2+}$ and $Fe^{3+}$ which converts to a higher concentration of $Fe^{3+}$ upon annealing. XAS and preliminary analysis of EXAFS data indicate that the TM ions are substitutional for Zn. SQUID magnetometry shows that as-implanted films are ferromagnetic at 5K and the annealed films are ferromagnetic at room temperature. X-ray diffraction shows that the annealed films remain epitaxial with excellent long range order. Rutherford backscattering spectrometry indicates a substantial recovery of local order upon annealing as well. The properties of in-situ Fe-doped MOCVD-grown ZnO epitaxial films and nanostructures will also be discussed.

**B19 9 Defect activated room temperature ferromagnetism in Co:ZnO films - micro-Raman studies** P. KHAREL, C. SUDAKAR, G. LAWES, R. NAIK, *Wayne State University, Detroit* R. SURYANARAYANAN, *LPCES,Université Paris-Sud, France* V.M. NAIK, *University of Michigan-Dearborn* Intense research for room temperature (RT) ferromagnetism (FM) in semiconductors doped with both magnetic and non-magnetic dopants is ongoing because of their potential applications in spin- & photo-electronics. We success fully employ a simple nonvacuum based spin−coating technique to prepare $Zn_{1-x}Co_xO$ films (0.5 to $1_{\mu}$m) on $Al_2O_3$ (001) substrate using precursor solutions of Zn and Co−ethylhexanoate. The films were annealed in air at 700 $^0$C/1h followed by annealing at 550 $^0$C/1h at $10^{-5}$–$10^{-6}$ Torr. X−ray and Raman spectrum indicate no change of wurtzite structure and no cluster formation due to the incorporation of Co in ZnO. Magnetic measurements reveal lack of RTFM in air annealed films, whereas on vacuum annealing films acquire FM ordering. Raman spectra gives a direct evidence on the influence of defect activated FM. The observed FM varies non−monotonically with cobalt concentration. Finally, the effect of annealing, role of oxygen defects, and concentration of $Co^{2+}$ ion on the magnetization properties will be discussed.

**B19 10 Annealing Temperature Dependence of the Magnetic Moment Observed in ZnO Nanotips Implanted with Mn** JEREMY RALEY,* *Air Force Institute of Technology* JEAN WEI, *Air Force Research Laboratory* YUNG KEE YEO, ROBERT HENGEHOLD, MICHAEL MARCINIAK, *Air Force Institute of Technology* PAN WU, YICHENG LU, *Rutgers, The State University of New Jersey* Magnetic properties of Mn ion-implanted ZnO nanotips grown on quartz substrates have been investigated as a function of anneal temperature. This work tracks the strength of the coercive ($H_C$) and remanent ($B_R$) fields of these samples as a function of anneal temperature over a range of 675 to 800 $^o$C for a period of 10 or 20 min in flowing $O_2$. The results show that the magnetic properties are highly dependent on anneal temperature. It has been found that 750 $^o$C is the optimal anneal temperature for producing the greatest values of $H_C$ and $B_R$, and a noticeable drop is observed when this annealing temperature is exceeded. This observation is true for magnetic moment measurements at both 5 and 300 K. The presence of an optimal temperature above which $H_C$ and $B_R$ decrease seems to indicate that post annealing causes magnetic activation and ordering in this material. These observations would not be expected if the ferromagnetic effects observed in this material were due purely to clusters, precipitates, or secondary phase formation.

**B19 11 Characterization of Mn and Fe diffusion into ZnO Films and single crystals for diluted magnetic semiconductor applications.*** R. GATEAU, D.H. HILL, R.A. BARTYNSKI, P. WU, Y. LU, *Rutgers University* There is growing interesting in the use of transition metal (TM) doped ZnO films as a diluted magnetic semiconductor for room temperature spintronics applications. Various methods of doping have been investigated including ion implantation and co-deposition during the growth process. In essentially all approaches, doping either accompanies, or is followed by, an annealing step intended to achieve a uniform distribution of the TM dopant, and/or encourage substitution of TM ions for Zn in the Wurtzite lattice. We have studied the diffusion of Mn and Fe into epitaxial and highly-oriented ZnO films, and into ZnO single crystals. The epitaxial films were grown on r-sapphire, exposing the (11-20) surface, while the highly oriented films were grown on a-sapphire exposing the (0001) surface of ZnO. The single crystal substrates were cut to the (0001) and (1100) orientations. Metallic films of $\sim$ 20nm thickness were deposited onto the ZnO substrates, which were subsequently annealed to 700C for between 10 and 40 minutes. We find that the diffusion rate for Mn is approximately an order of magnitude larger than for Fe under the same annealing conditions. Differences in diffusion rates associated with crystallographic orientation and film morphology will be discussed.

**B19 12 Magnetic Properties of Co-doped HfO2** Y.S. CHANG, W.C. LEE, M.L. HUANG, Z.K. YANG, M. HONG, *Dept. of Materials science and Engineering, National Tsing Hua University, Taiwan* S.F. LEE, *Inst. of Phys., Academia Sinica, Nankang, Taiwan* L. GONCHAROVA, T. GUSTAFSSON, *Physics Dept., Rutgers Univ., Piscataway, NJ, USA* M.C. HANG, Y.L. SOO, J. KWO, *Dept. of Physics, National Tsing Hua Univ., Taiwan* Dilutely doped Co in $HfO_2$ films were recently reported to show strong enhancement of Co magnetic moments. We have systematically studied the structural, chemical, and magnetic properties of $HfO_2$ epitaxial films $\sim$ 1000Å thick grown on YSZ with Co doping concentrations of 1, 2, 4, and 20 atomic percent. The crystal structures of these samples are predominantly monoclinic, and the XPS Co spectra also indicate the co-existence of cobalt metals and cobalt oxides. Tendency to form Co metal clusters in high doping concentrations was also observed by EXAFS. M-H loops at 10K and 300K by SQUID magnetometer were clearly seen for samples with Co doping of 4% and higher. But no evidence for

strong moment enhancement was found. However, our magnetic measurement do showed the unusual decay of magnetic moment with time, which was also seen in Co-doped $SnO_2$ films.

**B19 13 Local Environment Surrounding Co in MBE-grown $HfO_2$:Co Thin Films Probed by EXAFS and XMCD*** Y.L. SOO, S.C. WENG, W.H. SUN, S.L. CHANG, W.C. LEE, Y.S. CHANG, M. HONG, J. KWO, *National Tsing Hua University* Z.S. YANG, H.-J. LIN, D.G. LIU, J.F. LEE, C.T. CHEN, *NSRRC* Y.H. KAO, J.M. ABLETT, C-. C. KAO, *NSLS* Local structures in MBE-grown $HfO_2$:Co films with different Co concentration has been investigated using the EXAFS technique. The average local environment surrounding Co exhibited by our EXAFS data consists of two major near shells attributed to O and Co neighboring atoms at distances of 2.04 Å and 2.49 Å from the central Co atom, respectively. As the Co concentration increases, the average coordination number of the Co shell systematically increases while that of the O shell decreases. Our experimental results indicate that while chemically bonded with O at a most-likely interstitial location, Co impurity atoms may also form Co clusters even at a relatively low concentration of $\sim$ 1%. The progressive formation of Co clusters is also consistent with our XMCD results that demonstrate increasing magnetic moment with increasing Co concentration.

**B20 1 Phase Competition and Magnetotransport Phenomena in Manganite Films and Mesoscopic Structures.** TOM WU, *Materials Science Division and Center for Nanoscale Materials, Argonne National Laboratory*

The importance of competition between ferromagnetic metallic (FMM) and charge-ordered insulating (COI) phases in the physics of bulk manganites has been established through a wide variety of techniques. One exotic consequence of this phase competition is step-like features in magnetotransport observed in bulk and single-crystals of $Pr_{0.65}(Ca_ySr_{1-y})_{0.35}MnO_3$ (PCSMO) with $0.7 \leqslant y \leqslant 0.8$. The length-scale of the phase coexistence is $\sim$ 1 micron, motivating a study of structures with dimensions similar to this natural length scale where phenomenology distinct from that of bulk counterparts is expected. Toward that end, we have synthesized films and laterally confined mesoscopic bridges of PCSMO and studied their magnetotransport properties. In particular, we observed: (1) itIntrinsic ultrasharp magnetization steps below 5 K in both bulk and film samples and their dependence on the itextrinsic measurement protocols; (2) Spontaneous jumps of resistance during both the ramping of magnetic field and the relaxation after the field cycle; (3) I-V curves exhibiting negative differential resistance (NDR) in certain ranges of temperature and magnetic field. All of these phenomena can be explained in the context of interconversion between the COI phase and the FMM phase. As expected, this interconversion can be triggered by external magnetic field, as found in the case of the magnetization and resistance steps. Alternatively, in the mesoscopic structures with dimensions similar to the size of the competing FMM and COI domains, a local Joule heating-induced annihilation of conducting filaments causes the anomalous NDR.

**B20 2 Mapping nanometer-sized phase separation in La1-xCaxMnO3** JING TAO, M. VARELA, S.J. PENNYCOOK, *Oak Ridge National Lab* D. NIEBIESKIKWIAT, M.B. SALAMON, J.M. ZUO, *University of Illinois at Urbana-Champaign* W.D. LUO, S.T. PANTELIDES, *Vanderbilt University* It is well known that three phases dominate over a wide doping range in La1-xCaxMnO3: the paramagnetic (PM) phase is favored for all x at high temperatures, while at low temperatures, the ferromagnetic (FM) phase is favored for x less than 0.5, and the charge ordered (CO) phase for x greater than 0.5. The transitions between these phases are not simple in this system and the mechanism is still not fully understood [1-2]. Here we report direct observation of the formation and melting of CO droplets in the PM-FM regime (x less than 0.5) using in-situ electron microscopy. The distributions of the CO droplets are directly mapped in real space and show maximum density near the PM-FM transition temperature. This behavior contrasts strongly with the behavior in the PM-CO (x greater than 0.5) regime, where the CO clusters are found to nucleate as nanophase domains and percolate on cooling through the transition temperature [3]. We attribute the nanoscale phase separation observed in this system to the competition between electron mobility and localization. Free energies of the competing phases will be estimated using density-functional calculations to understand the nature of the observed phase separation phenomena. [1]. G.C. Milward, M.J. **B20 3 Implications of a dimeron magnetic pair model for CMR manganites.*** FRANK BRIDGES, LISA DOWNWARD, *UC Santa Cruz* Recently, based on extensive EXAFS data, we have proposed a magnetic pair model for clusters that exist above the ferromagnetic transition temperature, Tc [1]. The magnetic clusters must contain equal numbers of hole and electron Mn sites and have a reduced distortion compared to the remaining Jahn-Teller distorted electron sites. The smallest such unit (one electron and one hole site) we call a dimeron - it is an electron delocalized over two Mn sites. Here we consider why such a model might be stable, possible configurations of the local distortions for the site pair, and the implications for filamentary clusters throughout the sample when it is only partially magnetized. We also address

electrical transport via hopping dimerons and include the coulomb interactions between dimerons and the Ca(+2) dopants, which provides a quenched-in disorder. Several open questions such as the possible interactions between dimerons will also be discussed. [1] L. Downward et. al., Phys Rev Lett. 95, 106401 (2005).

**B20 4 Microscopic Ferromagnetic and Antiferromagnetic Clusters in $Pr0.7Ca_{0.3}MnO_3$** HAO SHA, JIANDI ZHANG, *Florida Intl. Univ.* FENG YE, JAIME FERNANDEZ-BACA, *ORNL* PENGCHENG DAI, *Univ. of Tenn. and ORNL* Y. TOMIOKA, *CERC, Japan* Y. TOKURA, *Univ. of Tokyo and CERC, Japan* ''Colossal'' magnetorestive manganite $Pr_{0.7}Ca_{0.3}MnO_3$ (PCMO30) is an ideal system to test the microscopic phase separation scenario because it has an inhomogeneous low-temperature insulating metastable state where ferromagnetic (FM), antiferromagnetic (AF), and charge/orbital (CO-OO) phases coexist. On cooling from room temperature, a CO-OO state occurs below $T_{CO-OO} \sim 200$ K, followed by AF ordering below $T_N \sim 140$ K. Below $T_C \sim 110$ K, the magnetic structure develops a FM component coexisting with AF ordering. We have used neutron scattering to study FM, AF and CO-OO phase transitions in a single-crystal PCMO30. The diffuse scattering of FM component demonstrates the presence of short-range ferromagnetic clusters both above and below $T_C$, while no diffuse component in the CO-OO scattering peaks has been observed near $T_{CO-OO}$. Interestingly, the short-range AF correlations associated with $Mn^{4+}$ sites but not with $Mn^{3+}$ sites are observed for both above and below $T_N$, indicating that the local AFM clustering is directly associated with doped holes in this system. The work was supported by NSF-DMR0453804, NSF-DMR0346826, DE-FG02-05ER46202, and DOE DE-FG02-04ER46125. ORNL is managed by UT-Battelle, LLC, for the U.S. DOE under contract DE-AC05-00OR22725.

**B20 6 Photoinduced phase-coexistence in $Bi_{0.4}Ca_{0.6}MnO_3$ thin films.** VERA SMOLYANINOVA, R. KENNEDY, E. TALANOVA, L. ALDACO, R.M. KOLAGANI, M. OVERBY, *Towson University* Doped manganites exhibit a wide variety of physical phenomena due to complex interplay of electronic, magnetic, orbital, and structural degrees of freedom. One of the most intriguing properties of manganites is coexistence of several distinct electronic phases. A photoinduced insulator to conductor transition in charge-ordered (CO) manganites is especially interesting from the point of view of creating photonic devices [1]. We have observed a photoinduced sub-micron phase coexistence of CO insulating phase and conducting phase via optical contrast in Near-field Scanning Optical Microscope images. Such phase coexistence is possible because of the presence of two local energy minima corresponding to CO insulating and charge-disordered conducting phases in the energy landscape [2]. To better understand the physics of phase coexistence in manganites we studied the dynamics of photoinduced conductivity changes. The temperature dependence of this process will be presented. The energy barrier separating the CO insulating and conducting states will be discussed. This work is supported by NSF grants DMR-0348939, DMR-04221141. [1] V. N. **B20 7 Electron-correlation induced phase separation in $Li_xFePO_4$** GERBRAND CEDER, *Department of Materials Science and Engineering, Massachusetts Institute of Technology* FEI ZHOU, *Department of Physics, Massachusetts Institute of Technology* $Li_xFePO_4$ is a promising rechargeable Li-ion battery cathode material. The $Li_xFePO_4$ system is known experimentally to phase separate into $FePO_4$ end $LiFePO_4$ up to $\sim$ 400 K, and form solid solutions above $\sim$ 600 K. Phase separation in this system is surprising as one would expect $Li^+$ ions to repel each other and form ordered compounds at compositions between those of the end members $FePO_4$ and $LiFePO_4$. This is exactly what is found in the local density or generalized gradient approximations to DFT, though it is in stark disagreement with experiments. The fact that the LDA+U method corrects this qualitative error points at the role of electron correlation in inducing phase separation in this material. We have thoroughly studied the LixFeO4 phase diagram with LDA+U. We found that the charge ordering of $Fe^{2+}/Fe^{3+}$ on the iron sub-lattice, induced by *d* electron localization, couples delicately with Li/vacancy ordering on the lithium sub-lattice. Although the repulsion within each sub-lattice favors compound formation, the Li-$e^-$ attraction favors phase separation. It is the balance of interactions within and between the two sub-lattices that gives rise to the unexpected phase behavior of $Li_xFePO_4$. Possible relevance of this novel phase transition mechanism to other alkali metal-intercalated materials will be discussed.

**B20 8 The electric field effect on the electronic soft matter in the manganite $(L_{1-y}Pr_y)_{0.67}Ca_{0.33}MnO_3$ ($y=0.4$, 0.5 and 0.6)** TARA DHAKAL, JACOB TOSADO, SUNGHEE YUN, AMLAN BISWAS, *Department of Physics, University of Florida* Hole-doped manganites are known for their colossal magnetoresistive (CMR) property and insulator to metal phase transition near their curie temperatures. For certain compositions of manganites a coexistence of a charge ordered insulating (COI) and ferromagnetic metallic (FMM) phases has been observed. Changing the temperature, magnetic field or strain modifies the spatial arrangement and relative proportions of these two phases, in this mixed phase state. This property suggests the existence of electronic soft matter in manganites. We have studied the properties of the electronic soft matter in one such material $(La_{1-y}Pr_y)_{0.67}Ca_{0.33}MnO_3$ (LPCMO, $y=0.4$, 0.5 and 0.6). We have grown thin films of LPCMO using pulsed laser deposition. To understand the dynamics of the local phase, we have experimentally mapped the temperature-magnetic field ($T-H$) phase dia-

gram of this material. The phase diagram shows 4 distinct regions, namely the COI state, the fluid phase separated state (FPS), the static phase separated state (SPS), and the FMM state. We have measured the effect of an electric field on this phase diagram and observed that the electric field can significantly modify the FPS state. We will explain the reason behind the electronic soft matter like behavior in the FPS state and the origin of the electric field effect in manganites.

**13:15**

**B20 9 High Temperature EXAFS Studies of $La_{1-x}Ca_xMnO_3$: New Evidence for Magnetic Dimers** L. DOWNWARD, F. BRIDGES, T.A. O'BRIEN, *Univ of California Santa Cruz* J.J. NEUMEIER, *Montana State University* We present Extended X-ray Absorption Fine Structure (EXAFS) data on the CMR perovskite manganites $La_{1-x}Ca_xMnO_3$ ($0.2 < x < 0.5$) to high-temperature (300-600 K) We have recently reported[1] changes in the Mn-O distortion (measured as a broadening, $\sigma$ of the Mn-O pair distribution function) as a function of magnetic field, temperature and Ca-concentration, $x$. Extensive data indicate that there is a universal relationship between changes in the local distortion ($\Delta\sigma^2$) and the sample magnetization. These data suggest that small magnetic clusters containing equal numbers of electron and hole sites must exist just above $T_c$. These clusters have little Jahn-Teller distortion and must form at some higher temperature; the smallest such unit would be an electron/hole site pair, which we call a dimeron. The new high temperature data presented here shows another significant step in the Mn-O distortion near 450 K, which we associate with the dimeron formation temperature, T*. This second step occurs at the same temperature for which other authors have observed a break in the inverse magnetic susceptibility. [1] L. Downward *et al.*, Phys Rev Lett **95**, 106401 (2005).

**B20 10 Origin of the non-thermal photoresponse in thin films of two-phase manganites*** ANTHONY DAVIDSON III, MASON OVERBY,[†] RAJEH MUNDLE, GRACE YONG, DAVID COX, ELENA TALANOVA, VERA SMOLYANINOVA, DAVID SCHAEFER, RAJESWARI M. KOLAGANI,[‡] *Towson University* TOWSON UNIVERSITY TEAM, Our studies of light-induced resistance changes (photoresponse) in thin films the colossal magnetoresistive manganite material $(La,Pr)_{0.67}Ca_{0.33}MnO_3$experiments have revealed a non-thermal component of the light-induced resistance change.This non-thermal component is also observed in thin films of oxygen deficient $La_{0.67}Ca_{0.33}MnO_3$.The common feature of both these material systems is the co-existence of metallic and insulating phases. Our results indicate that this component may be associated with the light-induced resistance decrease in the insulating regions through an electronic mechanism. Previous studies have shown insulator-metal transitions induced by magnetic fields as well as electric fields in these materials. We will present our studies of the correlation of the observed non-thermal photoresponse with magnetoresistance as well as current-voltage characteristics.

**B20 11 Charge Separation and Pre-percolation Regime in Manganites** ZSOLT MARTON, *University of Pennsylvania* TAKESHI EGAMI, *University of Tennessee/Oak Ridge National Laboratory* RINAT MAMIN, *Zavoisky Physical-Technical Institute of RAS, Kazan 420029, Russia* ZAVOISKY PHYSICAL-TECHNICAL INSTITUTE OF RAS COLLABORATION, Complex manganites have been intensively studied in the last decade since they are model objects for investigations of the collosal magnetoresistance. Temperature dependence of $La_{0.875}Sr_{0.125}MnO_3$ single crystals' dielectric and magnetic properties are investigated in the wide range of temperature and external magnetic field. In order to clarify the nature of the charge, spin and orbital ordering as well as the nanoscale inhomogeneity dynamics, we studied their low-frequency capacitances. It is found that giant dielectric permittivity arises in this manganite. The origin of this enormous dielectric response is believed to be connected with the fact that in the pre-percolation regime of charge separation there are very thin regions of insulator phase with large net surface embedded in metallic matrix. The features of the temperature and field dependence of these dielectric properties are explained by the nanoscale dynamic inhomogeneties appearing due to charge and spin ordering.

**13:51**

**B20 12 Magnetic Phase Diagram of $(NaMn_3)Mn_4O_{12}$** A. PRODI, F. BOLZONI, F. LICCI, E. GILIOLI, *IMEM-CNR* M. MAREZIO, *CRETA-CNRS* M. AFFRONTE, *U. Modena e Reggio Emilia* A. GAUZZI, *U. PM Curie* The double pervoskite $(NaMn_3)Mn_4O_{12}$ represents a model system to explore ordering phenomena usually sought after in half-doped manganites thanks to its unique crystal structure characterized by the absence of quenched disorder. We present here magnetization, transport and specific heat measurements performed under magnetic field aimed at characterizing the two distinct paramagnetic and two antiferromagnetic phases observed in $(NaMn_3)Mn_4O_{12}$ upon cooling. In particular, we investigated the change of paramagnetic regime associated with the structural phase transition at 176 K, the stability of the resulting charge ordered state as well as the peculiar magnetic response of the CE spin structure which orders below 125 K. Analysis of the corresponding specific heat anomalies confirms the nature of the transitions while at low temperatures specific heat data evidences a large Sommerfeld coefficient, unexpected for the insulating state, and reveals the presence of extra entropy with origin in nonmagnetic excitations.

**B20 13 Magnetic ordering of rare-earth compounds: first-principles studies** CHUN-GANG DUAN, *University of Nebraska Lincoln* R. F. SABIRIANOV, L LIU, W.N. MEI, *UNO* P.A. DOWBEN, *UNL* E.Y. TSYMBAL, *UNL* We report a systematic theoretical study on the magnetic ordering in heavy rare-earth compounds with face-centered cubic structure. Based on first-principles total energy calculations of Gd monopnictides, we deduced the exchange interaction parameters of these systems from fitting the total energies of different magnetic configurations to those computed from the Heisenberg model. Then we demonstrated the formation of different magnetic structures in these compounds by using the Monte Carlo simulations. The so obtained Curie (Néel) temperatures agreed well with experiments. Detailed analysis on the trend of exchange parameters changing with anion sizes and distances between neighboring magnetic sites clearly

demonstrate the co- existence of RKKY type metallic exchange interactions and anti- ferromagnetic superexchange interactions. We then propose a Bethe-Slater type curve which can qualitatively explain the behaviors of the exchange parameters in Gd monopnictides.

**B21 1 Phase diagram and direct mechanical measurements of colloidal gels** NA WANG, MARIA KILFOIL, We study the phase diagram of colloidal aggregates according to different salt concentration and particle volume fraction, in the absence of gravity. This phase diagram then helps us to locate the region to form strong colloidal gels, whose mechanical properties are studied with time-sharing optical tweezers.

**11:27**
**B21 2 Real Time Observations of Decaying Colloidal Clusters** MARCO POLIN, SANG-HYUK LEE, *Department of Physics and Center for Soft Matter Research, New York University* WILLEM KEGEL, *van 't Hoff Laboratories for Physical and Colloid Chemistry, Debye Research Institute Utrecht University* ANDREW HOLLINGSWORTH, DAVID GRIER, *Department of Physics and Center for Soft Matter Research, New York University* We have studied model colloidal dispersions characterized by long-range electrostatic repulsions and short-range entropically driven attractions. Through a combination of holographic optical trapping and precision digital video microscopy we can create nonequilibrium cluster configurations and track their decay fluctuations. These measurements reveal density and shape fluctuations that accompany the decay of the clusters. Such processes may cast additional light on decay of large atomic nuclei.

**11:39**
**B21 3 Length scale dependent relaxation in colloidal gels** EMANUELA DEL GADO, *Dipartimento di Scienze Fisiche, Universita' degli Studi di Napoli ''Federico II''* WALTER KOB, *Laboratoire des Cooloides, Verres et Nanomateriaux, Universite Montpellier II* Although gels are ubiquitous in fundamental science, technological applications and also in our daily life, their structural and dynamical properties are not well understood. In contrast to other systems that show a slow relaxation, such as glass-forming liquids, the structure of gels is given by an open network that is thought to be responsible for the unusual dynamical properties of these systems. We present the results of a recent study based on a simple model that does indeed have the characteristics of (colloidal) gel-forming systems at a finite temperature. By means of molecular dynamics computer simulations, we investigate the gel formation from the equilibrium sol phase. In particular we show that the strong length scale dependence of the dynamics in gel forming systems is tightly related to the formation of the gel structure and is therefore a general feature. This study allows for the first time to investigate on a microscopic level the relaxation processes in the incipient gel and to understand why they must strongly depend on the length scale investigated. In our model the mesh-size of the incipient gel network corresponds to a crossover length between dramatically different relaxation processes, from stretched to compressed exponentials. Moreover our results link the super-exponential relaxation at low temperature to the motion of pieces of the incipient gel structure.

**11:51**
**B21 4 Crossover from Intermittent to Continuum Dynamics for Locally Driven Colloids** CHARLES REICHHARDT, CYNTHIA J. OLSON REICHHARDT, *Theoretical Division and Center for Nonlinear Studies, Los Alamos National Laboratory* We simulate a colloid with charge $q_d$ driven through a disordered assembly of interacting colloids with charge $q$ and show that, for $q_d \approx q$, the velocity-force relation is nonlinear and the velocity fluctuations of the driven particle are highly intermittent with a $1/f$ characteristic. When $q_d \gg q$, the average velocity drops, the velocity force relation becomes linear, and the velocity fluctuations are Gaussian. We discuss the results in terms of a crossover from strongly intermittent heterogeneous dynamics to continuum dynamics. We also make several predictions for the transient response in the different regimes.

**12:03**
**B21 5 Evolving Bulk Properties of Collapsing Colloidal Gels** STEPHEN KAMP, MARIA KILFOIL, *McGill University* We present a study of the time evolution of the elastic properties of colloidal depletion gels. Silica colloids were suspended in NaCMC solutions and homogenized. Both the colloid volume fraction and the interaction strength (polymer concentration) were varied. The time evolution of the elastic properties of the suspensions was studied with a bulk rheometer in a double-wall Couette cell throughout the gel lifetime. The early lifetime is characterized by an elastic shear modulus that increases logarithmically with time, following which the gels experience catastrophic failure and the elastic modulus drops dramatically. As the gel collapses, various complex behaviors are seen, including a temporary stabilization against collapse, and reformation of a new gel with its own elastic properties which then follows its own trajectory to collapse. Time-lapsed images were taken of identical samples in a separate transparent cell of identical dimensions and the gel height was used to calibrate the measured shear modulus values. The visual cell also allows us to see the sample-spanning collective rearrangement involved in the collapse.

**12:15**
**B21 6 Experimental characterization of the interface of a colloidal suspension.** JESSICA HERNANDEZ-GUZMAN, ERIC R. WEEKS, We investigate experimentally the interface between liquids and solids by using a suspension of colloids as our model. Their size and slow motion makes colloidal suspensions experimentally accessible using 3D high speed confocal microscopy. We track the position of the particles over time, and characterize the spatial structure using bond order parameters as has been done by previous workers. We additionally measure the mobility of each particle. We study the thickness of the interface both in terms of the static structure (which changes from liquid-like disorder to crystal-like order across the interface) and the mobility of the particles with respect to distance from the interface. We find a transition region with a thickness of a few particle diameters.

**12:27**

**B21 7 Freezing and Melting of Colloidal Crystals with Short-Range Attractive Potential** J.R. SAVAGE, D.W. BLAIR, R.A. GUYER, A.D. DINSMORE, We study the kinetics of melting and freezing of colloidal crystals formed by a short-range attractive potential. We use aqueous suspensions of micron-sized latex spheres mixed with surfactant micelles, which create a depletion attraction among the spheres. Single- and multi-layer crystals appear on the glass surface. Upon uniformly heating or cooling, the micelles grow or shrink. Upon heating, the depletion attraction weakens by up to 0.7 kT, and the crystals melt. Optical microscopy is used to track the motions of hundreds of colloidal spheres for up to 8 hours, until crystals have melted. We initially observe a steady decrease in the size of the crystallites. When the size reaches approximately 20-30, however, crystallites rapidly shrink. Once the crystals have melted, we then supercool them and monitor the nucleation and growth of crystallites. The kinetics of individual bond-breaking events and the evolution of the crystalline order parameter in both melting and freezing will be presented. This work is supported by the NSF-DMR 0305395.

**12:39**

**B21 8 Melting of Temperature-Sensitive 3D Colloidal Crystals** AHMED ALSAYED, YILONG HAN, ARJUN YODH, *University of Pennsylvania* We employ thermally responsive monodisperse microgel colloidal spheres to study the melting mechanisms of colloidal crystals [1]. The particle diameter decreases with increasing temperature and leads to volume fraction changes that drive phase-transitions. We will describe observations of a variety of phenomena. Premelting, the localized loss of crystalline order near defects (e.g. grain boundaries) at volume fractions above the bulk melting transition, is directly observed by video microscopy, and is characterized by monitoring the first peak position of the particle pair correlation function. We find the position of the first peak shifts toward smaller particle separations at the onset of premelting. After Delaunay triangulation, mean square rotational and translational fluctuations of bonds were measured close to and away from defects. The behavior of all such quantities exhibits increased disorder near the defects. By locally heating the material within a crystal domain, we also studied the superheating and melting of a perfect 3D crystal. Finally, the introduction of weak attractions between spheres reveals free-floating 3D crystal 'blobs' which can be made to melt and recrystallize by tuning the temperature. [1] A. M. Alsayed, M. F. Islam, J. Zhang, P. J. Collings, A. G. Yodh, Science **309**, 1207 (2005). This work was supported by grants from NSF (DMR-0505048 and MRSEC DMR05-20020) and NASA (NAG8-2172).

**B21 9 Evolution of Particle-Scale Dynamics in Suspensions of Weakly Attractive Colloids Undergoing Structural Arrest** H. GUO, D. LIANG, *Johns Hopkins U.* S. RAMAKRISHNAN, C.F. ZUKOSKI, *UIUC* J.L. HARDEN, *U. of Ottawa* R.L. LEHENY, *Johns Hopkins U.* Suspensions of colloids with weak, short-range attractions can undergo an ergodic to nonergodic transition (ENT) as the strength of the attraction or the particle concentration increases. At low densities the transition corresponds to gelation, while at high densities it is identified as an attractive glass transition. We employ x-ray photon correlation spectroscopy (XPCS) to investigate the slowing dynamics associated the ENT in suspensions of nanometer-scale silica colloids coated with octadecyl-hydrocarbon-chains at wavevectors corresponding to interparticle length scales. At high temperatures the chains form a solvated brush that stabilizes the colloids. At low temperature, the brush collapses leading to a short-range attraction between colloids. Following a quench in temperature, the intermediate scattering function displays two features, a plateau value and a terminal relaxation time, that increase with time since the quench. A comparison between suspensions with concentrations of $\phi = 0.20$ and 0.43 shows qualitative differences in their temporal evolution, indicating a crossover from gelation-like to glass- like dynamical arrest. Further, a comparison with rheometry indicates how the slowing particle-scale dynamics correlates with the growth of the system's elastic modulus.

**13:03**

**B21 10 Microstructure and micromechanics of hard spheres with short-range attraction** MYUNG HAN LEE, ERIC M. FURST, *University of Delaware* We study the microscopic mechanical response of colloidal gels, such as yielding, compression and rearrangement, by manipulating single probe particles within the network. For this work, we use fluorescent polymethylmethacrylate (PMMA) dispersed in mixtures of decalin and cyclohexylbromide, with a refractive index and density close to that of PMMA. The strength of attraction is controlled by the concentration of a non-adsorbing polymer, polystyrene, which induces a depletion attraction between particles. In the presence of sufficiently strong attractive forces, particles form a colloidal gel. Confocal microscopy is used to observe the structural evolution in real time. This enables us to investigate the role of the local structure and particle interactions in the elasticity of the network. Specifically, we identify local elastic and plastic deformations in gels, which depend on the probe oscillation amplitude and strength of attractive interactions.

**13:15**

**B21 11 Deformation of Colloidal Glasses** PETER SCHALL, *WZI, University of Amsterdam* ITAI COHEN, *Physics Department, Cornell University* FRANS SPAEPEN, DAVID WEITZ, *DEAS, Harvard University* Amorphous colloidal suspensions are known to be powerful models for studying dynamical processes in glasses. Since the particles can be observed optically in real time, colloidal systems offer the unique opportunity of studying important mechanisms at the single particle level. We use confocal microscopy to investigate structural rearrangements in colloidal glasses under applied shear. Our setup allows us to track the motion of the individual particles in three dimensions while the suspension is sheared. We use the particle positions determined by confocal microscopy to calculate the local strain tensor and to identify regions of non-affine deformation. We observe ''shear zones'' that are accompanied by a complex strain field around them. Using the single particle data, we elucidate the particle rearrangements in the shear zones, and we investigate correlations between the location of these shear events and regions of high free volume.

**13:27**

**B21 12 Rotational perturbations of colloidal suspensions near the colloidal glass transition.** PIOTR HABDAS, *Dept. of Physics, Saint Joseph's University* ERIC R. WEEKS, *Dept. of Physics, Emory University* By increasing the concentration of small solid particles in a liquid (colloidal suspension) a colloidal glass transition is approached. This is due to the fact that the system becomes increasingly crowded and when it reaches the glass transition it becomes essentially jammed. Therefore, a colloidal suspension is a model system that exhibits a glass transition. There are a few

ways of locally perturbing a colloidal suspension. For example, one of the colloidal particles can be dragged through the colloidal suspension or a dimer made out of two small particles can be rotated. To perform the latter, we mix a small number of paramagnetic beads with dense PMMA particles. Some of the beads form dimers which can be put into rotation by rotating an external permanent magnet. Using confocal microscopy we study response of the system to such local perturbation. In particular, we investigate average spatial range of these perturbations and how it varies with the rotational rate and sample concentration.

**13:39**

**B21 13 Microscopy studies of the re-entrant glass transition.** ANDRZEJ LATKA, NORA GRANETO, PIOTR HABDAS, *Dept. of Physics, Saint Joseph's University* Colloidal suspensions are a model system for studying the glass transition. At the volume fraction $\phi_g \approx 0.58$ a glass transition occurs and a hard sphere colloidal glass is formed. The formation of hard sphere glass is attributed to the ''caging'' effect, in which the particles form cages around each other that restrict their movement. Introducing an attractive depletion force between the particles surprisingly causes the hard sphere glass to melt and the system becomes a liquid. Interestingly, by further increasing the attractive force an attractive glass is formed. Our system is a suspension of nearly hard-sphere colloidal particles and nonadsorbing linear polymer which induces a depletion attraction between the particles. We study the dynamics of the colloidal particles using microscopy techniques. In particular, our research is focused on the transition into the attractive glass phase.

**13:51**

**B21 14 Scaling of non-linear viscoelastic transitions in soft colloidal glasses** MATTHEW HELGESON, NORMAN WAGNER, *Center for Mol. and Eng. Thermodynamics, Dept. of Chemical Engineering, Univ. of Delaware, Newark, DE 19711* DIMITRIS VLASSOPOULOS, *FORTH, Inst. of Electronic Structure and Laser, Gr-71110, Heraklion, Crete, Greece* Soft colloidal particles undergo a transition to a glass-like state at sufficient concentration, due to kinetic trapping, similar to the glass transition in hard sphere systems. In this work we explore the use of rheological measurements as a tool to probe the mechanisms that lead to structure formation and breakage under shear in the glassy state for a monodisperse solution of multi-arm star polymers in an athermal solvent. Maxima in the loss moduli are observed with increasing strain amplitude at the onset of shear melting. We show that the transition to non-linear viscoelastic behavior and the onset of flow follow a systematic, rate-dependent trend. Specifically the critical strain increases with frequency. We discuss this trend in terms of phenomenological understanding of the kinetic trapping of soft colloids in the glassy state, leading to characterization of the softness of the colloidal glass as well as mechanisms of shear melting.

**B22 1 Reduction of the FMR damping in the nonlinear regime.** OLIVIER KLEIN, GREGOIRE DE LOUBENS, VLADIMIR V. NALETOV,* *CEA Saclay, Service de Physique de l'Etat Condense* It is well known in magnetic resonance, that the Gilbert damping coefficient cannot be extracted directly from the linewidth measurements. The later quantity only yields an upper bound value of the coupling to the lattice. In contrast simultaneous measurement of the microwave susceptibility and the longitudinal component of the magnetization gives directly the ratio between energy stored over the energy absorbed in the sample. This quantity is proportional to the spin-lattice relaxation rate of the excited system. We have recently measured the power dependence of this ratio in the nonlinear regime of YIG samples. Surprisingly, we find that the energy damping coefficient decreases dramatically above the Suhl's thresold while the linewidth increases.

*also at: Physics Department, Kazan State University.

**11:27**

**B22 2 The Periodic Table of Damping in Doped Permalloy Thin Films** JAMES RANTSCHLER, *NIST* DEEPTHI PULUGURTHA, *GWU* LAWRENCE MATTHEW CONNORS, *Rice Univ.* ANDREW CHEN, AUDI CASTILLO, ALEXANDER SHAPIRO, WILLIAM EGELHOFF, JR., ROBERT McMICHAEL, BRIAN MARANVILLE, *NIST* In a survey of thin film Permalloy doped with transition metals, we have constructed a periodic table of damping. We have co-sputtered 25 nm Permalloy films with twenty-one different dopants (Ti, V, Cr, Mn, Co, Cu, Zr, Nb, Mo, Ru, Rh, Pd, Ag, Hf, Ta, W, Re, Os, Ir, Pt, and Au) with at least ten cocnetrations. We measured damping with ferromagnetic resonance spectroscopy (FMR) and concentration with energy dispersive x-ray spectroscopy. Out-of-plane rotation FMR experiments were used to separate the extrinsic linewidth contributions produced by inhomogeneities in the sample from the intrinsic damping of the material. In all samples, doping increased damping, but the effect varied considerably. Trends in the periodic table include larger damping for the heavier elements and larger damping when the d shells are half-full. When using the dimensionless damping parameter of the Landau-Lifshitz-Gilbert equation to describe magnetization dynamics, undoped Permalloy is generally found to have a damping parameter of 0.008. In this study doping increased the damping parameter in all cases; the weakest effects were as little as 0.0001 per atomic percent of copper or silver, while the largest effect was measured to be 0.006 per atomic percent of osmium.

**11:39**

**B22 3 Enhanced Magnetic Damping in Spin-Transfer Excitation** E. M. RYAN, P. M. BRAGANCA, J. C. READ, N. C. EMLEY, G. D. FUCHS, J. C. SANKEY, D. C. RALPH, R. A. BUHRMAN, *Cornell University* While magnetic damping is understood to play a fundamental role in spin-torque phenomena, little experimental work has been done to study the effect of varying the damping parameter $\alpha$. Recently, light terbium (Tb) doping in thin films of permalloy (Py) has been shown to increase $\alpha$ by several orders of magnitude [1]. To directly study the effect of increased $\alpha$ on spin-transfer systems, we have fabricated 0.008 $um^2$ Py/Cu/Py nanopillar spin valves with Tb-doping between 0 and 2% in the free layer. We find that the critical currents for reversibly switching the free layer (proportional to $\alpha$) are several times larger on average in the 2% Tb samples than in pure Py samples. This substantial increase is still considerably less than the increase in $\alpha$ observed in the bulk film measurements of similar composition samples, suggesting that processes other than intrinsic spin-orbital coupling can dominate $\alpha$ in spin-transfer nanopillars, in agreement with simulation and pulsed measurements [2]. We compare this effect across a range of temperatures, and also discuss how the Tb doping affects the processional dynamics. These results suggest one approach for controllably reducing the negative impact of spin torque effects on nanoscale spin valve and tunnel junction read head sensors. [1] W. Bailey, P. Kabos, F. Mancoff, and S. E. Russek, IEEE Trans. Magn. 37, 1749 (2001). [2] P. M. Braganca, et al. Appl. Phys. Lett. 87, 112507 (2005).

**B22 4 Field and Current-Driven Domain Wall Motion in Permalloy Nanowires.***
GEOFFREY BEACH, *The University of Texas at Austin*

Ferromagnetic nanowires provide a well-defined conduit for domain walls, which may be manipulated and used in a variety of information storage and processing schemes. A domain wall may be displaced by a magnetic field or by an electric current traversing the wall via spin-momentum transfer. Many experiments have focused on the depinning of a domain wall by a current, but few have addressed the subsequent propagation of a depinned wall, whether driven by current [1], field [2,3], or both. Using high-bandwidth scanning Kerr polarimetry, we have studied time-resolved motion of field and current-driven domain walls in Permalloy nanowires. Domain dynamics models predict that above a threshold field, uniform wall translation gives way to turbulent wall motion, a dynamic internal wall structure, and a substantial drop in wall mobility. We have observed this transition at an unexpectedly low field [3], suggesting that in many experiments, wall motion is far more complex than the smooth translation typically assumed. The interaction of a dc current with a propagating domain wall is likewise more complex than existing spin-torque models predict. We find a nonlinear response of the wall velocity to a dc current, with velocity enhancements approaching 40 m/s at a current density of $\sim 6\times 10^{11}$ A/$m^2$. The response may be represented by a field-independent linear term, consistent with theory, and a field-dependent nonlinear term that overtakes the linear term at moderate currents. This latter term may arise from the interaction of the current with a vortex in the wall. [1] A. Yamaguchi, et al., Phys. Rev. Lett. **92**, 077205 (2004) [2] T. **B22 5 Direct observation of current driven domain wall distortions, transitions, and propagation in ferromagnetic wires.** W. CASEY UHLIG, JOHN UNGURIS, *National Institute of Standards and Technology, Gaithersburg, MD 20899-8412* Spin transfer torque induced domain wall distortions, transitions between vortex and transverse wall states, and defect-to-defect hopping of domain walls were all observed while flowing current through narrow ferromagnetic wires. Domain walls in 100 nm, 300 nm, and 1 um wide stripes fabricated from 12 nm and 24 nm thick NiFe films were directly imaged using scanning electron microscopy with polarization analysis (SEMPA). SEMPA images revealed that small current densities initially distort the domain walls which are fixed at random pinning defects along the wires. If the current density is increased above $5x10^{11}$ A/$m^2$, the wall is usually swept from the wire, but at smaller currents, the domain wall simply jumps a short distance to the next pinning site before stopping. For vortex type domain walls, the vortex core moves towards the stripe edge, perpendicular to the wall propagation direction. If the core reaches the edge, it is annihilated, thereby converting the vortex into a transverse wall. The direction of the vortex core motion and thus the chirality of the resulting transverse wall are dependent on the applied current direction. The observed domain wall distortions, transitions, and interactions with defects are all expected to play a significant role in spin torque driven magneto-electronics. Work supported in part by the Office of Naval Research.

**B22 6 Spin Transfer Torque for Continuously Variable Magnetization** JIANG XIAO, ANDREW ZANGWILL, *School of Physics, Georgia Institute of Technology* MARK STILES, *National Institute of Standards and Technology* We report quantum and semi-classical calculations of spin current and spin-transfer torque in a free-electron Stoner model for systems where the magnetization varies continuously in one dimension. Analytic results are obtained for an infinite spin spiral and numerical results are obtained for realistic domain wall profiles. The adiabatic limit describes conduction electron spins that follow the sum of the exchange field and an effective field produced by the gradient of the magnetization in the wall. Non-adiabatic effects arise for short domain walls but their magnitude decreases exponentially as the wall width increases. Our results cast doubt on the existence of a non-adiabatic contribution to the spin-transfer torque.

**12:51**

**B22 7 Nonlinear regimes of current-induced domain wall motion** YA. B. BAZALIY, M. HAYASHI, B. A. JONES, S. S. P. PARKIN, *IBM Almaden Research Center* A. JOURA, *Department of Physics, Georgetown University* We study theoretically the current-induced motion of a magnetic domain wall in a nanowire in the presence of external magnetic field and pinning potential. The wall is assumed to be rigid and is described by the one-dimensional model equations [1,2]. Both ''adiabatic'' and ''non-adiabatic'' spin-transfer terms are taken into account. The current-induced motion differs significantly below and above the Walker breakdown, i.e., in the regimes when the deflection angle is close to a particular value vs. when it makes the full circles. We find two novel phenomena. The first one is the existence of a stable auto-generation regime for a wall trapped in a shallow pinning center. The second is the ''reversed motion window'' regime in the situation when current and magnetic field push the domain wall in opposite directions. Both regimes are qualitatively different from the domain wall resonance regime studied in Ref. [1,3], or zero field current induced motion [1,2]. Reversal of the domain wall velocity by a relatively small current above the Walker breakdown was recently achieved in Ref. [4]. 1. Gen Tatara and H. Kohno, Phys. Rev. Lett. **92**, 086601 (2004). 2. A. Thiaville *et al.*, Europhys. Lett., **69**, 990 (2005). 3. E. Saitoh *et al.*, Nature, **432**, 203 (2004). 4. M. Hayashi *et al.*, submitted (2005).

**B22 8 Interactions between domain walls and spin currents** M. KLAUI, M. LAUFENBERG, D. BACKES, W. BUHRER, U. RUDIGER, *Fachbereich Physik, University of Konstanz, Germany* L. VILA, C. VOUILLE, G. FAINI, *LPN - CNRS, Maroussis, France* A promising novel approach for switching magnetic nanostructures is current-induced domain wall propagation (CIDP), where due to a spin torque effect, electrons transfer angular momentum to a head-to-head domain wall and thereby push it in the direction of the electron flow without any externally applied fields. This effect has been observed with a variety of techniques including MFM [1] and spin polarized scanning electron microscopy [2] to directly observe current-induced domain wall propagation in ferromagnetic nanostructures and magnetoresistance measurements to systematically probe the critical current densities as a function of the geometry [3]. The observed wall velocities and critical current densities, where wall motion sets in at room temperature, do not agree well with theoretical 0K calculations [4]. We have therefore measured the critical current densities as a function of the sample temperature. We find that the spin torque effect becomes more efficient at low temperatures, which could account for some of the observed discrepancies between the 300K experiment and the 0K simulation. [1] A. **B22 9 Current-Driven Resonance of Single Domain Wall in Permalloy Nanowires** SEOK-HWAN CHUNG, FRANK Y. FRADIN, AXEL HOFFMANN, *Materials Science Division and Center for Nanoscale Materials, Argonne National Laboratory* The manipulation of magnetic domain structures with electrical transport current is of fundamental interest for understanding the magneto-transport properties of spintronic devices. We measured current driven domain wall resonance by using a well-defined single domain wall in half-circle nanowires with 35 $\mu$m radius. Nanowires of 40 nm-thick and 250 nm-wide Permalloy with contact pads were fabricated by multi-step electron beam lithography and subsequent lift-off processes. A single ittransverse magnetic domain wall can be effectively introduced and pinned in the center of the nanowire, due to the strong shape anisotropy, by applying external field perpendicular to the center of the wire. This was confirmed with magneto-transport measurement, magnetic force microscopy and micromagnetic simulation. We observed single domain wall resonance by measuring the reflected power as a function of driving frequency and applied pinning field. From these measurements, we can obtain the domain wall inertia (Döring mass), which is $4\times\ 10^{-8}$g/cm$^2$ in our sample. The critical current density for the wall motion is $\sim\ 1\times\ 10^7$A/cm$^2$. We attribute the mechanism of the current driven wall motion in our sample to the spin and momentum transfer from *s* electrons in the conduction band to the local *d* electrons in the domain wall. * Supported by DOE, BES under contract W-31-109-ENG-38.

**B22 10 Spin accumulation and resistance due to a moving domain wall** J. IEDA, S. TAKAHASHI, *CREST, Japan Science and Technology Agency; Institute for Materials Research, Tohoku University* S. E. BARNES, *Physics Department, University of Miami* S. MAEKAWA, *CREST, Japan Science and Technology Agency; Institute for Materials Research, Tohoku University* The resistance of magnetic nanowires containing a moving domain wall (DW) is studied. The excess resistance due to the DW has been shown in a number of transport experiments [1]. Theoretically, the DW resistance is investigated along with the concepts of the spin dependent scattering with spin mistracking and the spin accumulation, where the DW is assumed static just producing the exchange field to conduction electrons. For a moving DW, however, the angular momentum transfer effect [2] should be incorporated to those mechanisms. In this presentation, we discuss this effect along with the spin accumulation mechanism. The frequency dependence of the spin accumulation is also presented. [1] J. F. Gregg et al., PRL77, 1580 (1996); U. Ebels et al., PRL84, 983 (2000); E. Saitoh et al., Nature432, 203 (2004). [2] S. E. Barnes and S. Maekawa, PRL95, 107204 (2005); cond-mat/0410021.

**B22 11 Theory of Antiferromagnetic Metal Spintronics** REMBERT DUINE, *The University of Texas at Austin* ALVARO NUNEZ, PAUL HANEY, ALLAN MACDONALD, *The University of Texas at Austin* Spintronics in ferromagnetic metals is built on a complementary set of phenomena in which magnetic configurations influence transport coefficients and transport currents alter magnetic configurations. In this talk I will argue that nanostructure circuits containing antiferromagnetic elements have large potential for applications, partly because the critical current for inducing magnetization dynamics may be smaller than for ferromagnets. This occurs in part because spin torques that lead to current-induced switching act through the entire volume of an antiferromagnet. I will explain how this follows from the special symmetry properties of antiferromagnets.

**13:51**
**B22 12 Towards ab-initio calculations for antiferromagnetic metal spintronic devices.** PAUL HANEY, DEREK WALDRON, ALVARO NUNEZ, REMBERT DUINE, HONG GUO, DEREK WALDRON, In conventional spintronics, the electron's spin degree of freedom is exploited to construct systems which exhibit behavior of practical importance and fundamental scientific interest. The prototypical system is a heterostructure which consists of alternating layers of ferromagnetic and paramagnetic materials. Such a system is used to study GMR and spin transfer torque, the two most important phenomena in spintronics today. In GMR, the relative orientation of magnetic layers affects the current flowing through a heterostructure, while in spin transfer the current flowing through the structure effects the orientation of the magnetic layers. It is of interest to consider what type of effects occur in structures containing antiferromagnetic materials. To this end, realistic calculations of GMR and spin transfer in antiferromagnetic heterostructures are presented. The calculations are carried out using ab-initio NEGF methods, using the LSDA extended to non-collinear magnetic configurations. Preliminary results of a Cr-Au-Cr structure are presented as an example of an experimentally realizable antiferromagnetic system.

**14:03**
**B22 13 Nonequilibrium Green's function calculations for antiferromagnetic metal spintronic nanocircuits** ALVARO NUNEZ, REMBERT DUINE, PAUL HANEY, ALLAN MACDONALD, *The University of Texas at Austin* In this talk I will present results of nonequilibrium Green's function calculations on toy-model heterostructures containing antiferromagnetic elements that are intended to illustrate some generic aspects of their spintronic properties. Using this formalism we calculate the nonequilibrium spin density of the electrons which, in a microscopic picture of spin transfer, gives rise to spin transfer torques. The main result is that, unlike the case of ferromagnets to ferromagnets, the spin transfer acts throughout the entire antiferromagnet, making current a very effective way to induce collective magnetization dynamics. Preliminary results on the influence of disorder and surface roughness will be presented.

**B23 1 Calculated And Experimental Exchange Interactions In A Strong-rail Spin Ladder** CHRISTOPHER LANDEE, A. SHAPIRO, M. M. TURNBULL, *Clark University, Worcester, MA 01610* J. NOVOA, J. RIBAS, *Departament de Quimica Fisica, Universitat de Barcelona, Barcelona, Spain.* Low-dimensional magnetic lattices with moderate exchange interactions can be conveniently formed by combining organic cations with tetrahalocuprates. In these compounds, the ultimate structure is ultimately determined by size, shape and hydrogen-bonding capacity of the cation with the magnetic interactions occurring through halide-halide contacts. A variety of these compounds have been studied [1] and techniques have been developed for calculating the magnetic exchange interactions from first principles [2,3]. We report on the synthesis, structure and magnetic properties of (2,3-dimethylpyridinium)$_2$CuBr$_4$, which is the second spin ladder to be found with a stronger rail interactions ($J_{rung}/k_B$ = 9 K, $J_{rail}/k_B$ = 17 K). Comparison will be made between the exchange constants calculated from first principles and those obtained from experimental data. 1. C. P. Landee itet al, itPhys. Rev. B **63** 100402 (2001). 2. M. **B23 2 Novel Raman resonance in ladder spin systems** ALEXANDER DONKOV, ANDREY CHUBUKOV, *UW-Madison* We consider Raman intensity in spin $S$ two-leg- spin-ladder, with the goal to understand recent experiments[1,2]. We argue that the Raman intensity has a pseudo-resonance peak whose width is very small at large $S$. The pseudo-resonance originates from the existence of a local minimum in the magnon excitation spectrum, and is located slightly below twice the magnon energy at the minimum. The physics behind the peak is surprisingly similar to that in the excitonic scenario for the neutron and Raman resonances in a $d-$ wave superconductor. We also consider mid-infrared X-ray scattering in 2D systems and compare the results with recent measurements [3]. [1] A. Gozar et al, Phys. Rev. Lett. **87**, 197202 (2001). [2] S. Sugai and M. Suzuki, Phys stat sol (b) **215**, 653 (1999). [3] J. P. Hill, G Blumberg et al, [unpublished]

**B23 3 Theory of spin gaps in the dimerized quarter-filled two-leg rectangular ladder*** YONGGUO YAN, SUMIT MAZUMDAR, *University of Arizona* Despite the extensive work on even-leg spin-ladders and 1/2- filled band electron-ladders[1] , little is known currently about commensurate non-1/2-filled band electron ladders. We report density-matrix renormalization group calculations of spin gaps in the 1/4-filled band correlated two-leg rectangular ladder with dimerization along the legs of the ladder. In contrast to the uniform ladder, spin gaps in the dimerized ladder can be significant. Very large spin gaps, as are found experimentally in quarter-filled band organic charge-transfer solids with coupled pairs of quasi-one-dimensional stacks[2], however, occur within the model only for large leg dimerization and electron hopping along the rungs that are nearly equal to the hopping along the legs.

**B23 4 Magnetic and electrical properties of the double chain-type compounds $NaRh_2O_4$ and $NaMn_2O_4$** K. YAMAURA, *NIMS (Japan)* Q. HUANG, *NIST* M. MOLDOVAN, D.P. YOUNG, *Louisiana SU* E. TAKAYAMA-MUROMACHI, *NIMS (Japan)* Both compounds share the same structure basis in which the 6- fold coordinated transition metal, $RhO_6/MnO_6$, forms a double chain-type unit by sharing the octahedra edges ($CaFe_2O_4$-type structure, not spinel-like). We were interested in the compounds because those magnetic and electrical properties might reflect nature of the correlated $4d/3d$ electrons on the anisotropic basis. The compounds were recently synthesized for the

first time. The structure, magnetic and electrical properties were investigated by neutron diffraction, magnetic susceptibility, and electrical transport measurements of those high-quality polycrystalline samples. The data indicate $NaRh_2O_4$ is metallic down to 1.8 K and the magnetic susceptibility shows a broad cusp around $\sim$ 100 K. $NaMn_2O_4$ is highly electrically insulating with and without presence of a magnetic field. The manganese oxide goes into an anti-ferromagnetically ordered state at low temperatures through two-steps process at $\sim$ 40 K and $\sim$ 10 K. We will give a detailed report about the properties of the two new compounds.

**12:03**

**B23 5 Spinless Fermionic ladders in a magnetic field** SAM CARR, BORIS NAROZHNY, ALEXANDER NERSESYAN, *The Abdus Salam ICTP, Trieste, Italy* We study a system of interacting spinless fermions hopping on a two-leg ladder subject to an external magnetic field perpendicular to the ladder. At 1/2-filling, we find a series of quantum phase transitions as a function of the magnetic field: these are either $U(1)$ Gaussian phase transitions between two phases with distinct types of long-range order or Berezinskii-Kosterlitz-Thouless transitions between ordered and gapless phases. At 1/4-filling, we also find long-range order: a bond density wave or a staggered flux phase, each supporting excitations with fractional charge.

**B23 6 Magnetic Susceptibility and Heat Capacity of Single Crystal $CaV_2O_4$ Containing $S = 1$ $J_1$-$J_2$ Antiferromagnetic Spin Chains*** A. NIAZI, D. C. JOHNSTON, S. BUD'KO, D. L. SCHLAGEL, T. A. LOGRASSO, *Ames Lab., Iowa State U., Ames, IA 50011, USA* A. HONECKER, *TU Braunschweig, Inst. Theor. Phys., 38106 Braunschweig, Germany* The compound $CaV_2O_4$ has an orthorhombic *Pnam* structure and contains spin $S = 1$ zig-zag ($J_1$-$J_2$) chains running along the crystallographic *b*-axis. Structural considerations suggest that $J_1 \approx J_2$, which would result in competing frustrating antiferromagnetic (AF) interactions in this low-dimensional system. Previous studies on powders have suggested collinear spin models, a gapless chiral phase, or spin freezing below 20 K@. We have grown single crystals of $CaV_2O_4$ for the first time and carried out magnetization and heat capacity measurements down to 1.8 K@. We observe long-range AF ordering at $T_N = 54$ K with the easy axis being the *c*-axis, as reflected by anisotropic susceptibility $\chi$ below $T_N$. The magnetic specific heat $C_p^{mag}(T)$ up to 100 K, obtained after subtracting the lattice contribution of nonmagnetic isostructural $CaSc_2O_4$, shows a clear signature of long-range magnetic order at $T_N$. However, the molar entropy attains only $\approx$ 1/4 of its maximum value 2Rln(3) by 100 K, indicating strong short range order above $T_N$ and large values $J_1, J_2 > 100$ K@. This is consistent with our estimates $J_1 \approx J_2 \sim$ 150–300 K obtained by comparison of our $\chi(T)$ data with exact diagonalization calculations of $\chi(T)$.

**B23 7 Profiles of magnons and spinons in a spin ladder** DAVID CLARKE, OLEG TCHERNYSHYOV, *Department of Physics and Astronomy, Johns Hopkins University* JEAN-BAPTISTE FOUET, *Institut Romand de Recherche Numérique en Physique des Matériaux* FRÉDÉRIC MILA, *Institute of Theoretical Physics, École Polytechnique Fédérale de Lausanne* We have studied quantum phase transitions between magnetization plateaux and gapless incommensurate states in a frustrated spin ladder placed in a magnetic field[1]. The transitions are triggered by a condensation of magnons (spinons) at the edge of an integer (half-integer) magnetization plateau. In this talk we will describe magnetization patterns formed in a finite ladder just off a magnetization plateau, i.e. at low concentrations of magnons or spinons. In these regimes the magnons and spinons behave as noninteracting fermions carrying spins $S^z = \pm 1$ and $\pm$ 1/2, respectively. The spinons also act as domain walls, thus causing a dramatically different magnetization pattern from that of the magnons. The analytical results obtained agree well with numerical data.

**B23 8 Ferromagnetic-antiferromagnetic alternating exchange spin-dynamics in the low-dimensional quantum magnet $DMACuCl_3$** MATTHEW STONE, *Oak Ridge National Laboratory* WEI TIAN, *University of Tennessee* MARK LUMSDEN, GARRETT GRANROTH, DAVID MANDRUS, *Oak Ridge National Laboratory* JAE-HO CHUNG, *National Institute for Science and Tecnology* STEPHEN NAGLER, *Oak Ridge National Laboratory* The spin magnet dimethylammonium trichlorocuprate, $DMACuCl_3$, has been considered both an alternating ferromagnetic-antiferromagnetic chain along the crystalline a-axis as well as a collection of isolated ferromagnetic and antiferromagnetic spin pairs. However, no spectroscopic probes have been applied until now to determine the underlying nature of the spin dynamics. We present results of single crystal inelastic neutron scattering measurements which clearly indicate that the magnetic excitations in $DMACuCl_3$propagate along the crystalline b-axis, not the proposed a-axis. A single magnetic excitation is observed with a gap of 0.98 meV and a bandwidth of approximately 0.67 meV. The quasi-one-dimensional excitation spectrum is dominated by a strongly coupled ferromagnetic spin-pair or dimer with weaker antiferromagnetic interdimer interactions. In light of this classification, we make comparisons to previously measured specific heat and magnetization measurements. We also place a limit on inter-dimer interactions perpendicular to the chain axis and propose a potential multi-chain model for $DMACuCl_3$.

**B23 9 Copper Phenazine Dichloride, a S=1/2 Heisenberg Antiferromagnetic Chain** R. T. SCHNEIDER, C. P. LANDEE, M. M. TURNBULL, *Clark University, Worcester, MA 01610* F. F. AWWADI, *Department of Chemistry, Washington State University, Pullman, WA 99164* Low-dimensional antiferromagnets provide good testing grounds for predictions of cooperative quantum behavior. S=1/2 copper ions bridged by organic ligands such as pyrazine form antiferromagnetic chains with exchange strengths weak enough to be overcome by available magnetic fields. [1] Phenazine (Phz) ($C_{12}H_8N_2$) is similar to pyrazine in its ability to form magnetic chains but has a different electronic structure resulting in different exchange strengths. We report on the synthesis, crystal structure, magnetic susceptibility, and high field magnetization of $Cu(Phz)Cl_2$. Its behavior can be described as that of a Heisenberg antiferromagnetic chain with an exchange constant $|J|/k_B = 33$ K. The exchange strengths of chains with pyrazine, quinoxaline, and phenazine will be compared. [1] M. B. Stone et al, Physical Review Letters **91**, 037205 (2003).

**B23 10 Real-Space Treatment of Spin-Peierls Transitions: Gap Equation of the S = 1/2 Heisenberg Antiferromagnetic Chain** ZOLTAN SOOS, SHARON BEWICK, *Princeton University* The spin-Peierls transition at $T_{SP}$ of s = 1/2 Heisenberg AF

chains with linear spin-phonon (sp-ph) coupling is modeled by exact solution up to 18 spins. Spin correlations alter the gap relation between $T_{SP}$ and the singlet-triplet gap, $E_{ST}$, from the free-fermion or mean-field (mf) result by 30%. Direct solution accounts for the spin-Peierls transition, magnetic susceptibility and magnetization of the prototypical $TTF^+$ (tetrathiafulvalene) spin chain in TTFCu(BDT). Strong sp-ph coupling is required for size convergence. Exact analysis of finite chains conserves total spin, while mf or bosonization approximations for spinless fermions in infinite chains only conserve the z component and have axial rather than spherical symmetry in spin space.

**13:15**

**B23 11 Phonon spectra in Spin-Peierls transitions** FRANZ MICHEL, *TU Graz, Austria* HANS GERD EVERTZ, *TU Graz, Austria* We present phonon and spin spectra from precise Quantum Monte Carlo simulations of Spin-Peierls systems, in one and two dimensions with acoustical and with optical phonons. We introduce a new technique which allows the direct integration of phonons for a given spin configuration. Together with cluster simulations for spins and a mapping from SSE to continuous time this allows efficient simulations of large systems at finite temperature and close to T=0.

**13:27**

**B23 12 Spin excitations in $S = 1/2$ AFM chains with alternating *g*-tensor and the Dzyaloshinskii-Moriya interaction.** S.A. ZVYAGIN, J. WOSNITZA, *Dresden High Magnetic Field Laboratory (HLD), Forschungszentrum Rossendorf, 01314 Dresden, Germany* A.K. KOLEZHUK, *Physics Dept., Harvard University, Cambridge, MA 02138* J. KRZYSTEK, *National High Magnetic Field Laboratory, Tallahassee, FL 32310* R. FEYERHERM, *Hahn-Meitner-Institute (HMI), 14109 Berlin, Germany* The magnetic excitation spectrum of copper pyrimidine dinitrate (Cu-PM), an $S = 1/2$ antiferromagnetic chain system with alternating *g*-tensor and the Dzyaloshinskii-Moriya interaction, is probed using ESR spectroscopy in magnetic fields up to 25 T. The field-induced gap is measured *directly*. Signatures of a soliton and three breather branches are identified, and their frequency-field dependences are described in frame of the quantum field sine-Gordon model. Furthermore, the ESR linewidth and shift behavior in Cu-PM in the *perturbativespinon* regime is studied as function of temperature and field. Excellent quantitative agreement between theoretical predictions (Phys. Rev. Lett. 82, 5136 (1999)) and experiment is obtained. The results are published in: S.A. Zvyagin *etal.*, Phys. Rev. Lett. 93, 027201 (2004); *ibid.* 95, 012707 (2005).

**B23 14 Meron and Haldane-Shastry spin chain states in quantum dots** MILICA MILOVANOVIC, ALEKSANDRA PETKOVIC, *Institute of Physics, Belgrade* We study solutions of the Coulomb interaction problem, in the lowest Landau level approximation, of a quantum dot with N = 4 and N = 6 electrons, without Zeeman term, and above the maximum density or filling factor one state. By making maps of spin correlations of the solutions we are able to connect excitations of the dot with states of the (one-dimensional) Haldane-Shastry spin chain. We also argue that the solutions of the problem without Zeeman term can be described as meron quasiparticle excitations analogous to vortex excitations in the completely polarized state. As a result we will describe how these meron excitations and states of the dot can be connected with spinon states of the Haldane-Shastry chain. This connection will enable us to associate orbital spin currents to quantum dot states.

**B26 1 Dynamics of molecular motors with finite processivity on heterogeneous tracks.**
DAVID NELSON, *Lyman Laboratory of Physics, Harvard University, Cambridge, Massachusetts 02138, USA*

The dynamics of molecular motors which occasionally detach from a heterogeneous track like DNA or RNA is considered.[1] Motivated by recent single-molecule experiments, we study a simple model for a motor moving along a disordered track using chemical energy while an external force opposes its motion. The motors also have finite processivity, i.e., they can leave the track with a position-dependent rate. We show that the response of the system to disorder in the hopping-off rate depends on the value of the external force. For most values of the external force, strong disorder

causes the motors which survive for long times on the track to be localized at preferred positions. However, near the stall force, localization occurs for any amount of disorder. To obtain these results, we study the complex eigenvalue spectrum of the time evolution operator. Existence of localized states near the top of the band implies a stretched exponential contribution to the decay of the survival probability. A similar spectral analysis also provides a very efficient method for studying the dynamics of motors with infinite processivity. 1. Y. Kafri D. K. Lubensky and D. R. Nelson, Phys. Rev. E 71, 041906 (2005).

**B26 2 DNA electrophoresis in Pluronic F127*** SEUNGYONG YOU, DAVID VAN WINKLE, *Center for Materials Research and Technology and Physics Department, Florida State University* Electrophoresis involves the separation of bio-molecules in a sieving medium by applying an electric field. DNA molecule fragments are separated in conventional gels and a several models have been successfully applied for understanding the separations. Recently, a pluronic gel was found to be an effective sieving medium for electrophoresis. However, the mobility of DNA in this gel cannot be described by the conventional theories. One reason is that Pluronic F127 is not a crosslinked gel, but a lattice of polymer micelles. The migration of single DNA molecules stained with various dye molecules was studied in slab gel electrophoresis by real-time fluorescence microscopy. Results for a variety of sizes will be presented.

**B26 3 Model for passage time of polymer trough a pore (weak external forces limit)** STANISLAV KOTSEV, ANATOLY KOLOMEISKY, *Rice University* Polymer translocation through a pore is an important problem in biophysics. Recent experiments measure the dynamics of the process with a single-molecule precision. In these experiments a single-stranded RNA or DNA molecule is driven trough a narrow pore by an external electric field. In our work we concentrate on theoretical modeling of polymer translocation when external forces are weak. In this regime the entropic forces are dominating. Then for long polymers the passage time scales with the number of monomers as $N^{\alpha}$. However, the exact value of $\alpha$ is still a matter of discussion. We are proposing a simple phenomenological model which can be solved exactly. Our results are in a good agreement with off-lattice $3D$ Monte Carlo simulations.

**12:15**

**B26 4 Driven DNA translocation through thin and long nanopores*** ANIKET BHATTACHARYA, WILLIAM H. MORRISON, *University of Central Florida* We utilize Brownian dynamics simulation to study polymer translocation through a nanopore driven by an electric field using a coarse-grained bead-spring model for the translocating DNA. We study mean translocation time $\langle \tau \rangle$ as a function of the chain length N, the width $w$ of the pore, and external bias F. Unlike many previous studies, we critically examine the scaling of $\langle \tau \rangle$ as a function of the ratio $N/w$ and F. For a thin pore, our preliminary results indicate that the mean translocation time $\langle \tau \rangle \sim N^{2\nu}$, where $\nu$ is the Flory exponent, although the slope shows a weak but non-negligible dependence on the external bias F for the chain lengths considered so far. Our simulation results are consistent with experiments done in solid-state nanopore*,+. *Work done in collaboration with Heath Morrison, Prof. Kurt Binder and Prof. Andrey Milchev. + A. J. Storm, C. **B26 5 Conformational Analysis of Single DNA Molecules Undergoing Entropically Induced Motion in Nanochannels.** JOHN MANNION, CHRISTIAN RECCIUS, JOSHUA CROSS, HAROLD CRAIGHEAD, *Cornell University* We have used the interface between a nanochannel and a microchannel as a tool for applying controlled forces on a DNA molecule. A molecule with a radius of gyration larger than a nanochannel width, that straddles such an interface, is subject to an essentially constant entropic force which can be balanced against other forces such as the electrophoretic force from an applied electric field. By controlling the applied field, we can position the molecule as desired and observe the conformation of the molecule as it stretches, relaxes and recoils from the nanochannel. We quantify and present models for the molecular motion in response to the entropic, electrophoretic and frictional forces acting on it. By determining the magnitude of the drag coefficients for DNA molecules in the nanostructure, we are able to estimate the confinement induced recoil force. Finally, we demonstrate that we can use a controlled applied field and the electrophoretic interfacial forces to unfold molecules, which can then be manipulated and positioned in their simple extended morphology.

**B26 6 The Physics of Nanoconfined DNA** WALTER REISNER, *Department of Physics, Princeton University* KEITH MORTON, *Electrical Engineering, Princeton University* ROBERT RIEHN, YANG MEI WANG, *Department of Physics, Princeton University* STEPHEN CHOU, *Electrical Engineering, Princeton University* JONAS TEGENFELDT, *Department of Physics, Lund University* ROBERT AUSTIN, *Department of Physics, Princeton University* Top-down approaches to nanotechnology have the potential to revolutionize biology by making possible the construction of chip-based devices that can not only detect and separate single DNA molecules by size but also–it is hoped in the future–actually sequence at the single molecule level. While a number of top-down approaches have been proposed, all these approaches have in common the confinement of DNA to nanometer scales, typically 5-200nm. Nanoconfinement effects the equilibrium conformation of the DNA. Here we present measurements of the static and dynamic properties of single DNA molecules confined in nanochannels using fluorescence microscopy techniques. In particular, we investigate the dynamics of DNA in novel structures, including structures with defects (bulges and constrictions) and channels that funnel in depth and width. We also discuss observations of possible topological structures on the confined DNA (knots or loops observed on the extended molecules).

**12:51**

**B26 7 DNA entropic elasticity for short molecules** JINYU LI, *University of Colorado* PHILIP C. NELSON, *University of Pennsylvania* M. D. BETTERTON, *University of Colorado* Single-molecule experiments in which force is applied to DNA or RNA molecules have enabled important discoveries of nucleic acid properties and nucleic acid-enzyme interactions. These experiments rely on a model of the polymer force-extension behavior to calibrate the experiments; typically the experiments use the worm-like chain (WLC) theory for double-stranded DNA and RNA. This theory agrees well with experiments for long molecules. Recent single-molecule experiments have used shorter molecules, with contour lengths in the range of 1-10 persistence lengths. Most WLC theory calculations to date have assumed infinite molecule lengths, and do not agree well with experiments on shorter chains. Key physical effects that become important when shorter molecules are used include (i) boundary conditions which constrain the allowed fluctuations at the ends of the molecule and (ii) rotational fluctuations of the bead to which the polymer is attached, which change the apparent extension of the molecule. We describe the finite worm-like chain (FWLC) theory, which takes into account these effects. We show the FWLC predictions diverge from the classic WLC solution for molecules with contour lengths a few times the persistence length. Thus the FWLC will allow more accurate experimental calibration for relatively short molecules, facilitating future discoveries in single-molecule force microscopy.

**13:03**

**B26 8 Single Molecule Visualization of DNA in Wicking Flows** CHAD DELONG, DAVID HOAGLAND, *University of Massachusetts - Amherst* An understanding of polymers in flow through micro- and nano-structured materials is critical to the success of bioseparations (proteins, DNA, etc.). An open, nanofluidic system has been developed to drive flow through a packed bed of colloidal particles using capillary forces (wicking), allowing the study of polymer dynamics in the absence of the electric field is typically used to drive micro- and nano-fluidic flows. This is especially important when dealing with charged molecules whose confirmation can be affected by the electric field or those insoluble in water. Single molecule imaging is performed in this system on fluorescently labeled DNA using an optical microscope equipped with a fluorescent light source, image intensifier, and CCD camera. Chain elongation in the flow depends sharply on flow rate, with fully relaxed configurations observed below a critical flow rate. At high flow rates, flow induced degradation can be seen. Molecular entanglements with the separation matrix cause molecular weight separation because longer molecules elongate in the flow and become entangled, leading to a longer retention time.

**13:15**

**B26 9 Abundance of pseudoknots in the RNA world*** DANIEL AALBERTS, EVAN MILLER, *Williams College* The pseudoknot fold is often seen in auto-catalytic RNA and in viruses. A recent polymer physics model and statistical-mechanical theory predicts relative probabilities of different pseudoknot folds consonant with a database of known folds. Now we extend that theory for a preliminary estimate of the abundance of pseudoknot folds in RNA sequences, finding approximately 1 per 40,000 nucleotides. This theoretical probability density compares favorably to what we infer from structure databases and has implications for genome organization, RNA folding algorithms, and the RNA World.

**B26 10 DNA sequencing via transverse electronic transport** JOHAN LAGERQVIST, *University of California - San Diego* MICHAEL ZWOLAK, *California Institute of Technology* MASSIMILIANO DI VENTRA, *University of California - San Diego* Recently, it was theoretically shown that transverse current measurements could be used to distinguish the different bases of single stranded DNA. [1] If electrodes are embedded in a device, e.g., a nanopore, which allows translocation of ss-DNA, the strand can be sequenced by continuous measurement of the current in the direction perpendicular to the DNA backbone. [1] However, variations of the electronic signatures of each base in a real device due to structural fluctuations, counter-ions, water and other sources of noise will be important obstacles to overcome in order to make this theoretical proposal a reality. In order to explore these effects we have coupled molecular dynamics simulations with transport calculations to obtain the real time transverse current of ss-DNA translocating into a nanopore. We find that distributions of currents for each base are indeed different even in the presence of all the sources of noise discussed above. These results support even more the original proposal [1] that fast DNA sequencing could be done using transverse current measurements. Work supported by the National Humane Genome Research Institute. [1] M. Zwolak and M. Di Ventra, ''Electronic Signature of DNA Nucleotides via Transverse Transport,'' Nano Lett. 5, 421 (2005).

**B26 11 Polymer effects in forced passage of DNA and macromolecules through nanopores** FRANCISCO SOLIS, *Integrated Natural Sciences* The forced passage of DNA, RNA and other linear molecules through nanopores has been proposed as a method to investigate the properties of these molecules and, in particular, as a sequencing method. This talk will discuss the polymer effects that arise when a macromolecule is pulled with constant velocity and with adjustable force through a pore. For homogeneous, strongly stretched molecules, the passage rate is proportional but slower than the pulling velocity. In addition, if the molecule contains a set of inhomogeneities that act as well defined obstacles, each of these will exhibit a waiting time for passage, and a relaxation period to return to the steady passage rate. These waiting and relaxation times increase with the length of the segment of already processed molecule.

**B26 12 Mapping the phase diagram of DNA force-induced melting in the presence of DNA intercalators** IOANA VLADESCU, MICAH McCAULEY, *Department of Physics, Northeastern University* MEGAN NUNEZ, *Department of Chemistry, Mount Holyoke College* IOULIA ROUZINA, *Department of Biochemistry Molecular Biology and Biophysics, University of Minnesota* MARK WILLIAMS, *Department of Physics, Northeastern University* The interactions between single DNA molecules and different non-covalent binding agents - the classical intercalator ethidium and compounds from the family of ruthenium complexes - are investigated using an optical tweezers instrument and their effects on the structure and mechanical stability of DNA molecules are quantitatively analyzed using a model of force-induced melting. When a single DNA molecule is stretched beyond its normal contour length, a melting phase transition is observed. Drug binding increases the dsDNA contour length, decreases the DNA elongation upon melting, and increases the DNA melting force. At concentrations of intercalator above critical, no force induced melting of dsDNA is possible. The DNA stretching

curves map out a phase diagram for DNA melting in the presence of intercalator, and define its critical point in the force-extension-drug concentration space. Our results allow for the complete thermodynamic characterization of the interaction of these intercalators with DNA.

**14:03**

**B26 13 DNA and RNA unzipping using nanopore force spectroscopy** AMIT MELLER, JEROME MATHE, MENI WANUNU, *Harvard University* BARAK AKABAYOV, IRIT SAGI, *Weizmann Institute for Science* DNA and RNA molecules can be electrophoreticaly threaded through nanoscale pores, such as the $\sim$ 1.5 nm alpha-Hemolysin. Information about their translocation dynamics is obtained by probing the ionic current flowing through the pore during their passage. We experimentally study the translocation process of unstructured and structured DNA molecules through a single nanopore. We find that the translocation process depends on DNA properties, such as its sequence and its direction of entry. With intense electrical field structured DNA and RNA can be unzipped in a controlled way, and the unzipping kinetics can be directly quantified. We study the unzipping kinetics of DNA and RNA molecules under a wide range of voltage gradients. We find that the unzipping kinetics is characterized by two limiting regimes: the strong field limit in which the system is unzipped in an irreversible process, and the weak field regime, in which it is in quasi equilibrium. Interestingly the unzipping kinetics of RNA molecules is very different from their DNA analogues. A theoretical model that accounts for our experimental results will be discussed.

**B28 1 Dual-beam Oscillating Optical Tweezers-Based 3-D Confocal Microrheometer** JING WANG, CHUAN PU, H. DANIEL OU-YANG, Optical tweezers are widely used in the studies of complex fluids and biological cells and tissues. Confocal microscopy visualizes detailed structures of sample specimen with high resolution in 3-D. In this report, we present the setup, calibration and application of a new powerful microrheometer that integrates a novel high temporal and spatial resolution dual-beam oscillating optical tweezers cytorheometer (DOOTC) with spinning disk confocal microscopy. The DOOTC uses the less photodamaging 1064nm laser, and detects the forced oscillatory particle motions by a lock-in amplifier. It can operate at single oscillating beam mode or the orthogonally polarized dual-beam mode to get large deflected forward scattering signals at both high and low frequencies. The system is demonstrated to identify granular structures trapped by optical tweezers with confidence, and at the same time measure dynamic mechanical modulus in the frequency range of 0.1-3000Hz at up to 10 data point per second and with sub-nanometer spatial resolution, while monitoring the sample structure and its transformation itin situ.

**11:27**

**B28 2 Integrated Fiber-optic Dipping-probe Microfluorometer** ROBERT W. GAMMON, *IPST, Univ. of Maryland* VILDANA HODZIC, CHRISTOPHER C. DAVIS, *Department of Electrical and Computer Engineering, Univ. of Maryland* An integrated fiber-optic device has been built that is with multimode fiber and found to exhibit exceptional performance as a dipping probe microfluorometer. This was discovered in the course of testing its performance using the device with simple, cleaved fibers. Thus the fiber both excites and collects fluorescence from the fluid along the axis direction in solutions of dye. The novel feature is that the light is restricted to coming from a region very near the end of the cleaved fiber. It then lends itself to testing very small volumes of sample fluid for fluorescence. Since the probe is a 200 micron diameter multimode fiber is can easily fit into small capillaries and also be stuck into small drops of sample fluid, i.e. drops sitting in microwell in multi-well test plates. Because the device uses an avalanche photodiode, the sensetivity is high and has a large dynamic range (4 to 6 orders of magnitude). The combination of small diameter, flexible fibers with high effeciency of exciting and collecting of fluorescence, and a sensitive detector makes this device unique. There is nothing on the commercial market or literature like it. Most devices that are called fiber-optic fluormeters use stiff fibers of diameter about 1 mm or larger (rods, really). They ususally excite through one of more fibers and collect through nearby fibers. The collection efficiency is low and the net diameters are far too large to allow use with microliter samples.

**11:39**

**B28 3 Characterization of RNase Immobilization at Surfaces by NEXAFS** XIAOSONG LIU, *Department of Physics, UW-Madison (DOP)* CHANG-HYUN JANG, *Department of Chemical and Biological Engineering, UW-Madison (DOCBE)* FAN ZHENG, *DOP* ASTRID JURGENSEN, *CSRF* NICHOLAS L. ABBOTT, *DOCBE* F.J. HIMPSEL, *DOP* Immobilization of proteins at surfaces plays an increasingly-important role for applications in biosensors and biochips, bioelectronics, bio-compatible implants, and biomimetic devices. In this study, Ribonuclease A (RNase A) is immobilized on silver surfaces in oriented and random form via self-assembled monolayers (SAMs) of alkanethiols as described previously.[1] The immobilization process is characterized step by step using chemically-selective near edge x-ray absorption fine structure spectroscopy (NEXAFS) at the C, N, and S K-edges. Oriented protein layers exhibit a small, but distinct polarization dependence of the N1s to $\pi^*$ orbital that is delocalized over O=C-NH, which is not seen for random orientation. They also have higher coverage. Oxidation and partial desorption of the alkanethiol SAMs are found to be predominant causes of imperfect immobilization. The results show how NEXAFS is able to provide feedback for optimizing the immobilization of proteins. [1] Luk, Y.-Y.; Tingey, M. L.; Dickson, K. A.; Raines, R. T.; Abbott, N. L. itJournal of the American Chemical Society **2004,** 126, (29), 9024.

**B28 4 Surface-enhanced Raman scattering of a hydrophilic ligand (tiopronin) adsorbed on gold nanoparticles.*** JOEL ST.AUBIN, *Dalhousie University* KEVIN HEWITT, *Dalhousie University* Surface enhancement of the Raman signal derived from tiopronin coated gold nanoparticles was observed. The gold nanoparticles were synthesized to mean diameters of 40 nm and 130 nm. Enhancement greater than 360 times was measured for the 40 nm gold nanoparticles and greater than 500 times for the 130 nm particles. New phonon modes appear that are possibly due to elec-

tric field gradient effects. Experiments to partially substitute tiopronin with a small fraction of hydrophobic thiols are underway. Surface-enhanced Raman scattering studies of these mixed (hydrophobic/hydrophilic) ligands will be reported.

**B28 5 Employing Grating Couplers in Biosensors** AMAL KASRY, WOLFGANG KNOLL, *Max Planck Institute for Polymer Research* Grating couplers have become very important tool in developing optical biosensors. In this work, surface plasmon polaritons excited by a dye molecule on the surface of a grating were studied. These polaritons can couple out to bulk radiation by scattering from the grating, and the emitted light comes off in certain well-defined directions. We focused here in studying how the coupling between the emitted light of a chromophore at the surface of a metallic grating and the scattered surface plasmons depends on the chromophore-metal separation. This was done using a protein layer-by-layer system as a spacer between the metal and the dye. The results show that the back coupling efficiency is maximum at distance about 30-50 nm, which is also the optimum distance for the fluorescence intensity. These results agree with the results determined on a planar metallic surface, and the behavior of the fluorescence was proved to be the same in different media (air or liquid). It was also proved that the back coupling could still be seen at the high distance reached here (106 nm), where the surface plasmon can scatter till this high distance.

**12:15**

**B28 6 15nm diameter upconversion nanophosphors as biolabels.** SHUANG FANG LIM, ROBERT RIEHN, CHIH-KUAN TUNG, ROBERT H. AUSTIN, *Department of Physics, Princeton University* NORA KHANARIAN, *University of Pennsylvania* WILLIAM S. RYU, DAVID TANK, *Lewis-Sigler Institute for Integrative Genomics, Princeton University* We have synthesized 15 nm diameter yttrium oxide based nanophosphors that are capable of visible to infrared upconversion. We show that these phosphors can be used for dual-mode imaging of biological systems by observing visible emission under both infrared excitation, and electron excitation in a scanning electron microscope. We have investigated the optical properties, confirmed the 2-photon nature of the upconversion process, and verified that similar narrow band emission spectra are obtained under electron and infrared excitation. We will also report on progress in surface functionalization for targeted bio-labeling. We demonstrate that biocompatibility is sufficient for in-vivo imaging in the nematode worm C. Elegans, and locate phosphors with high spatial resolution using energy dispersive X-ray imaging in scanning electron microscope.

**12:27**

**B28 7 Thermal Stability, and Curvature Dependence of Bovine Serum Albumin on Gold Nanoparticles Using Localized Surface Plasmon Resonance** JONATHAN TEICHROEB, *University of Waterloo* JAMES FORREST, *University of Waterloo* VALENTINA NGAI, Gold nanoparticles exhibit Surface Plasmon Resonance (SPR), whose absorption peak is strongly dependent on the index of refraction, and coating thickness of the near surface region. A macromolecule bound to the nanoparticle will typically undergo a shift in index of refraction as its conformation changes, leading to a shift in the peak wavelength. Nanospheres can be made with a large variety of diameters, and present a novel method of looking at curvature dependencies of stability. In this study, Bovine Serum Albumin (BSA) was conjugated to Au nanospheres. Using a visible absorption spectrometer, the peak wavelength vs. temperature for eight diameters from 5nm to 60nm, was collected. Diameters above 20nm exhibited a continual increase in peak wavelength with temperature. Theoretical calculations indicate that this is a thickening of the protein layer. Below 20nm, peak wavelength shifts indicated a thinning of the BSA layer, and possible a decrease in index of refraction, followed by thickening at higher temperatures. Additionally, the study indicates that the peak shifts are highly time dependent, and a kinetic study has been performed at several temperatures.

**B28 8 High Q RF Resonant Cavity for Detecting Biological Tissue Nonlinearities** VILDANA HODZIC, *Department of Electrical and Computer Engineering, Univ. of Maryland* ROBERT W. GAMMON, *IPST, Univ. of Maryland* QUIRINO BALZANO, CHRISTOPHER C. DAVIS, *Department of Electrical and Computer Engineering, Univ. of Maryland* To investigate whether biological cells exhibit nonlinearity in the radiofrequency (RF) region, a high quality factor resonant cavity has been built. The cavity is fitted with two loop antennas, one transmitting at 880-890 MHz and a second one receiving at 1760-1790 MHz. The antenna operating at the low frequency (LF) band actively excites the $TE_{111}$ cavity mode; the high frequency antenna must receive the energy of the $TE_{113}$ mode at twice the frequency of the LF antenna. The cavity and the two antennas have been built. The Q of the cavity is over 6000 for both the frequencies of operation. Experiments to detect nonlinear RF frequency conversion by biological tissue can be performed using this high quality factor device.

**12:51**

**B28 9 Micromachined piconewton force sensor for biophysics investigations*** STEVEN KOCH, GAYLE THAYER, ALEX CORWIN, GEORGE BACHAND, MAARTEN DE BOER, *Sandia National Laboratories* We describe a polysilicon surface-micromachined force sensor that is able to measure forces as small a few pN in both air and water. The simple device consists of compliant springs with force constants as low as 0.3 mN/m and Moire patterns for nanometer-scale optical displacement measurement. First, we measured the force field produced by an electromagnet on individual 2.8 micron magnetic beads glued to the force sensor. Forces matched predictions from finite element magnetic modeling and provided a calibration for future biophysical applications of the magnet. By repeating with several different beads, we measured a 9 percent standard deviation in saturation magnetization. We also demonstrated that the force sensor was fully functional when immersed in aqueous buffer and when performing the kinesin inverted motility assay on the sensor surfaces. These results show the force sensors can be useful for calibrating magnetic forces on magnetic beads and also for direct measurement of biophysical forces on-chip.

**B29 1 Direct measurement of the propulsion efficiency of bacterium Escherichia Coli** SUDDHASHIL CHATTOPADHYAY, RADU MOLDOVAN, *Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, PA 15260* CHUCK YEUNG, *School of Science, Pennsylvania State University at Erie, The Behrend College, Erie, PA 16563* XIAO-LUN WU, *Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, PA 15260* Swimming of flagellated bacterium in an aqueous medium is studied in vivo with the aid of optical tweezers and an imposed external flow. By trapping the bacterium perpendicular to the optical axis, the beating frequency of the flagellum $\omega$and the counter rotation of the cell body $\Omega$ can be measured simultaneously. Measurements of the trapping force $F$ and the two rotation speeds, $\omega$ and $\Omega$, enable us to determine all the elements of the propulsion matrix for individual cells as well as their statistics in a population. Further we obtain the propulsion efficiency, defined as the ratio of the input rotational power provided by the motors to the output propulsive power, to be $\sim 0.2\%$. Significant heterogeneities are observed among the bacteria despite their starting from a single colony.

**11:27**
**B29 2 Modeling the motion of microscale synthetic swimmers** ALEXANDER ALEXEEV, VICTOR YASHIN, ROLF VERBERG, ANNA BALAZS, *Chemical Engineering Department, University of Pittsburgh, Pittsburgh, PA* By direct numerical simulations, we study the motility of synthetic micro-swimmers in a quiescent fluid. The micro-swimmers examined here are composed of an elastic polymeric material and comprise one or more wiggling tails, which propel the swimmer through its low-Reynolds number environment. The tails are driven to move by a reactive gel, which constitutes part of the swimmer's body. The gel undergoes a periodic swelling and deswelling due to a reaction or an external stimulus. To model the interaction of this micro-swimmer with the surrounding fluid, we adopt our recently developed LBM/LSM approach, which integrates the lattice Boltzmann model (LBM) for fluid dynamics with the lattice spring model (LSM) for the micromechanics of an elastic solid. Using this model, we investigate different aspects of the swimmer's propulsion. In particular, we determine how the properties of the swimmer and the oscillatory gel affect the swimmer's velocity and efficiency. Our goal is to design autonomous micro-swimmers that can be guided along a particular direction in order to perform a specified task.

**11:39**
**B29 3 Detecting the gravitational sensitivity of itParamecium caudatum using magnetic forces*** KARINE GUEVORKIAN, JAMES M VALLES JR., *Brown University* Under normal conditions, itParamecium cells regulate their swimming speed in response to the pN level mechanical force of gravity. This regulation, known as gravikinesis, is more pronounced when the external force is increased by methods such as centrifugation. Here we present a novel technique that simulates gravity fields using the interactions between strong inhomogeneous magnetic fields and cells. We are able to achieve variable gravities spanning from 10 $\times$ $g$ to -8$\times$ $g$; where $g$ is earth's gravity. Our experiments show that the swimming speed regulation of itParamecium caudatum to magnetically simulated gravity is a true physiological response. In addition, they reveal a maximum propulsion force for paramecia. This advance establishes a general technique for applying continuously variable forces to cells or cell populations suitable for exploring their force transduction mechanisms.

*Supported by NASA OBPR under NAG3-2882. Experiments performed at National High Magnetic Field Laboratory.

**11:51**
**B29 4 Precise adaptation in chemotaxis through ''assistance neighborhoods''*** ROBERT ENDRES, NED WINGREEN, *Princeton University* The chemotaxis network in Escherichia coli is remarkable for its sensitivity to small relative changes in the concentrations of multiple chemical signals over a broad range of ambient concentrations. Key to this sensitivity is an adaptation system that relies on methylation and demethylation/deamidation of specific modification sites of the chemoreceptors by the enzymes CheR and CheB, respectively. These enzymes can access 5-7 receptors once tethered to a particular receptor. Based on these ''assistance neighborhoods,'' we present a model for precise adaptation of mixed clusters of two-state chemoreceptors. In agreement with experiment the response of adapted cells to addition/removal of attractant scales with the free-energy change at fixed ligand affinity. Our model further predicts two possible limits of precise adaptation: either the response to further addition of attractant stops through saturation of the receptors, or receptors fully methylate before they saturate and therefore stop adapting.

*We thank for financial support from HFSP.

**B29 5 Cellular individuality in the gradient sensing response of itDictyostelium** AZADEH SAMADANI, JEROME METTETAL, ALEXANDER VAN OUDENAARDEN, *MIT* It is generally assumed that single cells in an isogenic population exhibit the same behavior. However, it is becoming increasingly clear that even in a genetically identical population, gene expression levels can vary significantly from cell-to-cell. As a result of this variation, a physiological response such as gradient sensing might also display a significant variability from cell-to-cell. Although it is known that most cell populations are heterogeneous, the response of a typical cell or the average response of a population is often reported. However, quantitative information of cellular variability may contain important information on the intracellular signaling events. Here we explore the chemotactic response in single itDictyostelium cells in response to repeated spatio-temporal pulses of chemoattractant. We find that the response of a single cell is reproducible from pulse-to-pulse. In contrast, a large variability in the chemotactic response is observed from cell-to-cell even when different cells in the population are exposed to the same pulse. We propose a simple model, which allows for the broken symmetry of the chemotactic response and reproduces the cellular variability within the population fairly well.

**12:15**
**B29 6 How does Dicty find its way?** ERIN RERICHA, *University of Maryland College Park* CAROLE PARENT, *National Institute of Health* WOLFGANG LOSERT, *University of Maryland at College Park* As a cell chemotaxes, moves towards a chemical signal, it transduces external chemical signals into mechanical motion. Efficient chemotaxis is crucial for many biological processes from wound healing to the spread of cancer. We present our experimental investigations on itDictyostelium discodeum a model organism for chemotaxis. We expose cells to three types of external signals: a shallow background gradient of the signaling molecule cyclic-AMP a localized signal composed of cyclic-AMP attached to beads and a mechanical stimulus caused by pushing beads against the exterior of the cell. For each stimulus we ask: what is the stability of the gradient sensing pathway and how does it influence the mechanical response. We find that the cell speed increases with increasing concentration of cyclic-AMP. In addition, Dictyostelium cells relay the signal by releasing internally manufactured cyclic-AMP out of the back of the cell. A collection of cells moves in streams, where cells follow closely behind one another. We find that the cells moving in a stream move slower towards a source of attractant than cells that are chemically treated such that they do not stream.

**B29 7 Dictyostelium discoideum chemotaxis: threshold for directed motion.**
EBERHARD BODENSCHATZ, *Cornell University (LFPN) and Max Planck Institute for Dynamics and Self-Organization (Goettingen)*

The chemotactic response of Dictyostelium discoideum cells to stationary, linear gradients of cyclic adenosine 3′, 5′-monophosphate (cAMP) was studied using microfluidic devices. In shallow gradients of less than $10^{-3}$ nM/$\mu$m, the cells showed no directional response and exhibited a constant basal motility. In steeper gradients, cells moved up the gradient on average. The chemotactic speed and the motility increased with increasing steepness up to a plateau at around $10^{-1}$ nM/$\mu$m. In very steep gradients, above 10 nM/$\mu$m, the cells lost directionality and the motility returned to the sub-threshold level. In the regime of optimal response the difference in receptor occupancy at the front and back of the cell is estimated to be only about 100 molecules. The work is supported by the Biocomplexity Program of the NSF and the Max Planck Society.

**B29 8 Impact of Helicobacter Pylori on Mucus Rheology*** JONATHAN CELLI, *Boston University* SARAH KEATES, *Beth Israel Deaconess Medical Center* CIARAN KELLY, *Beth Israel Deaconess Medical Center* BRADLEY TURNER, *Beth Israel Deconess Medical Center* RAMA BANSIL, *Boston University Department of Physics* SHYAMSUNDER ERRAMILLI, *Boston University Department of Physics* It is well known that the viscoelastic properties of gastric mucin are crucial to the protection of the lining of the stomach against its own acidic secretions and other agents. Helicobacter Pylori, a rod shaped, gram-negative bacteria that dwells in the mucus layer of approximately 50% of the world's population is a class I carcinogen and is associated with gastric ulcers and severe gastritis. The structural damage to the mucus layer caused by H. Pylori is an important aspect of infection with this bacteria. We are examining the impact of H. Pylori on mucin and mucus rheology quantitatively using a combination of dynamic light scattering and multiple particle tracking experiments. Video microscopy data will also be presented on the motility of this bacteria in mucin at different pH and in other viscoelastic gels.

*We gratefully acknowledge support from the NSF, the NSF GK12 program, and the DOD.

**B29 9 The effect of viscosity on the contraction of the stalk of itVorticella Convallaria*** DEEPENDRA KANTHA, DAVID VAN WINKLE, *Center for Materials Research and Technology and Department of Physics, Florida State University* The contraction of the stalk of itVorticella Convallaria behaves as one of the most powerful single cell biological engines.Contractions in three different viscous mediums were recorded by a PhantomV5 camera (Vision Research) on a bright field microscope with 20X objective. The contractions were recorded as cines (image sequences) with the image resolution of 256 pixels X 128 pixels at 7000 pictures per second. The maximum variation in maximum velocity of one organism was 5.2 cm/s and the minimum variation for a different organism was 0.4 cm/s for the same viscous medium. It occurred at 2-3ms after the start of contraction. The force of contraction and the force constant were calculated as a function of the time to see the effect of viscosity on the contraction of the stalk. This experiment needs further investigation to see the net effect of viscosity on the contraction of the stalk.

**B29 10 Optimal Foraging Strategy: Angle Matters*** UDO ERDMANN, SEBASTIAN GÖLLER, IGOR M. SOKOLOV, LUTZ SCHIMANSKY-GEIER, *Insitut für Physik, Humboldt-Universität zu Berlin* We report a theory to describe the motion of zooplankton. In contrast to move just randomly like a classical Brownian particle, zooplankters like Daphnia or Copepods pick their turning angle from a distribution which is far from being Gaussian or equally distributed. This leads to different behavior in the motion compared to normal diffusion. The question which can be asked here is: Is there an evolutionary reason to forage for food in the aforementioned manner? The talk is planned to give an answer into that direction.

**B29 11 Nonlinear electromagnetic responses of active molecular motors in live cells and organelles** DHARMAKIRTHI NAWARATHNA, JEFFREY GARDNER, GUSTAVO CARDENAS, DAVID WARMFLASH, JOHN MILLER, WILLIAM WIDGER, *University of Houston* JAMES CLAYCOMB, *Houston Baptist University* The response of biological cells to an oscillatory electric field contains both linear and nonlinear (eg. induced harmonic) components. At low frequencies (about 10Hz), harmonic generation by budding yeast cells is observed. These induced harmonics are sensitive to sodium metavanadate, an inhibitor, and glucose, a substrate, respectively, of P-type ATPase membrane pumps. At higher frequencies, two peaks, around 3kHz and 12kHz, are observed in the frequency-dependent harmonic responses. These are sensitive to potassium cyanide, a respiratory inhibitor that blocks cytochrome c oxidase, an enzyme of the mitochondrial respiratory chain. We have also measured the response of uncoupled mitochondria extracted from bovine heart cells, for which a second harmonic sensitive to pericidin A and carboxin is detected at applied frequencies of 3-4kHz. Finally, in coupled mouse mitochondria, an ADP sensitive peak (12-15kHz) is observed, likely due to the F0 domain of ATP synthase, which acts as a molecular turbine.

**13:51**

**B29 12 Mechanism of formin-associated actin filament elongation** DIMITRIOS VAVYLONIS, *Columbia University, Yale University* DAVID R. KOVAR, *University of Chicago* BEN O'SHAUGHNESSY, *Columbia University* THOMAS D. POLLARD, *Yale University* Formins control the kinetics of actin filament polymerization by remaining processively attached at the growing filament end. The FH2 formin domain associates with the barbed end while FH1 interacts with profilin and is thought to mediate profilin-actin polymerization. We combined TIR microscopy (Kovar et al., Cell, in press) with theoretical modeling to study the dependence of the rate of formin-associated actin filament elongation on profilin and actin concentrations. We assume a transfer mechanism of profilin-actin from FH1 to the barbed end, gated by FH2 as described by the gating parameter p measuring the accessibility of the barbed end. The model explains the main experimental trends and rationalizes (i) how filaments associated with formin mDia1 elongate more rapidly than formin-free filaments due to the the large number of profilin binding sites and p 1, and (ii) how filaments associated with formins with $p<1$ elongate slowly in the absence of profilin but more rapidly in the presence of profilin. High profilin concentrations suppress elongation and in the model this is attributed largely to the saturation of FH1 by profilin. Consistent with our ADP-actin experiments, the proposed mechanism does not require ATP hydrolysis though we cannot exclude the possibility that formin translocation accelerates ATP hydrolysis for ATP-actin.

**B29 13 Spreading of neutrophils: from activation to migration** HELIM ARANDA-ESPINOZA, *Department of Chemical and Biomolecular Engineering, University of Maryland* KHEYA SENGUPTA, *Forschungzentrum Julich, Germany* LEE SMITH, *Department of Chemical and Biomolecular Engineering* PAUL JANMEY, *Institute for Medicine and Engineering* DANIEL HAMMER, *Department of Bioengineering, University of Pennsylvania* Reflection Interference Contrast Microscopy was used to study the dynamics of neutrophil spreading. The images were analyzed to identify simultaneously the changes in the overall cell adhesion and the zones of close contact with the substrate. We show that for neutrophils, cell spreading is anisotropic and directional from the very initial stage. The curve describing the spreading area of the cell as a function of time can be fitted piecewise as power laws. Different spreading regimes are identified and related to the adhesion state and/or dynamical state of the cell. All cells follow a slow spreading, fast spreading and finally area saturation. After saturation the adhesion area of the cell fluctuates as the neutrophil migrates. Close contacts occur at opposite sides of the cell where the uropod and lamellipodium develop. The apparition of close contacts seems to indicate a change in adhesion regime.

## SESSION B31: INSULATING NANOSTRUCTURES

**B31 1 Structural and electronic properties of aluminate nanotubes** KEE JOO CHANG, YONG-JU KANG, *Department of Physics, Korea Advanced Institute of Science and Technology* Recently, lithium containing aluminate nanotubes have been synthesized by the surfactant templating method. However, their structural and electronic properties have not been clearly understood yet. In this work, using first-principles theoretical calculations, we present a stable tubular structure in the form of $AlO_2$, which is energetically stable with fewer strain energies, compared with $MoS_2$ nanotubes with similar diameters. All the $AlO_2$ nanotubes are metallic with pseudogaps, independent of chilality. For small diameter zigzag tubes, more electron conduction occurs through the outer O shell with longer Al-O bonds, while the whole tube wall contributes to electron conduction for large diameter tubes or armchair tubes, which have similar inner and outer Al-O bond lengths. We find that an AlO tubular form can be stabilized by hole doping.

**11:27**

**B31 2 Formation of SiOx nanoflowers during the VLS growth of silicon nanowires** JOONHO BAE, REBECCA THOMPSON-FLAGG, MICHAEL MARDER, *Physics Department, University of Texas* JOHN EKERDT, *Department of Chemical Engineering, University of Texas* CHIH-KANG KEN SHIH, *Physics Department, University of Texas* We report the formation of SiOx nanoflowers at the tip of the VLS grown silicon nanowires. The morphology and complexity of the flowers can be reproducibly controlled by varying the growth conditions. Structural and compositional analysis of the nanoflowers formed at different stages (from open geometry to close geometry) using TEM and SEM with energy dispersive spectroscopy reveal that the flower results from selective oxidation of silicon at the interface between nanowire and the gold catalyst. There is no detectable oxidation in the wire region. The underlying mechanism and the intriguing pattern formation will be discussed.

**11:39**

**B31 3 Ferromagnetism of MnO and Mn3O4 nanowires** MYUNG-HWA JUNG, *Quantum Materials Research Team, Korea Basic Science Institute, Daejeon 305-333, Korea* JEUNGHEE PARK, *Department of Chemistry, Korea University, Jochiwon 339-700, Korea* KOREA BASIC SCIENCE INSTITUTE COLLABORATION, KOREA UNIVERSITY COLLABORATION, The MnO and Mn3O4 nanowires were grown by thermal evaporation of MnCl2 under the Ar flow. The diameter is in the range 50-100 nm and the length is about 20 ?m. The MnO and Mn3O4 nanowires consist of single-crystalline cubic MnO and tetragonal Mn3O4 crystals, respectively, grown uniformly with the [100] direction. The XPS data suggest that the majority of nanowires could be MnO nanowires. The temperature-dependent FC and ZFC magnetization curves with H=0.1-30 kOe, and the hysteresis curves measured at 5-300 K provide an evidence for the ferromagnetism with TC = 12 K and 43 K, for the MnO and Mn3O4 nanowires, respectively. The hysteresis curves at low temperatures were resolved well by two ferromagnetic components based on Brillouin function form, confirming the ferromagnetism of both MnO and Mn3O4 nanowires. We conclude that the single- crystalline MnO and Mn3O4 nanowires could be excellent ferromagnetic nanomaterials.

**11:51**

**B31 4 Metal-insulator transition in vanadium oxide nanowires** JIANG WEI, ZENGHUI WANG, YUJIE XIONG, YOUNAN XIA, DAVID COBDEN, The oxides of vanadium are strongly correlated electronic materials. In the form of nanostructures, the correlations and the phenomena associated with them should be modified. For instance, in sufficiently thin nanowires the metal-insulator transition, which is first-order in the bulk, should become a crossover. We report on our synthesis of vanadium oxide nanowires and preliminary measurements of their transport properties. The nanowires as grown by vapor phase deposition on $SiO_2$ appear to be mainly $V_2O_5$, a semiconductor, and their conductance shows no features as a function of temperature. After annealing in hydrogen, hysteresis is seen in the conductance within a limited temperature range above room temperature, consistent with partial reduction to $VO_2$ which undergoes a metal-insulator transition in the bulk at $67^o$ C. After further annealing, the conductance increases by two orders of magnitude and the hysteresis disappears, consistent with further reduction of the nanowires to $V_2O_3$ which is a correlated metal at room temperature.

**12:03**

**B31 5 Magnetoresistive Core-Shell Nanowires** BO LEI, CHAO LI, CHONGWU ZHOU, *University of Southern California* Magnetoresistive La0.67Sr0.33MnO3 nanowires have been synthesized and studied using pulsed laser deposition with MgO nanowires working as the template. Transport studies on these novel nanowires revealed a remarkable metal-insulator transition at 325 k, accompanied by room-temperature colossal magnetoresistance 10 percent under 1 T magnetic field. Furthermore, shape-induced magnetoresistance was observed for magnetic fields applied parallel or perpendicular to the nanowire. In addition, polycrystalline La0.67Sr0.33MnO3 have been obtained by tuning the synthesis condition, leading to a low-field magnetoresistance up to 16 percent at 0.06 T.

**12:15**

**B31 6 Table Salt's New Application in High Throughput Growth of Zinc Oxide Nanowires from Zinc Powder** JIAN YANG, *Boston College* WENZHONG WANG, *Boston College* YI MA, *Boston College* D.Z. WANG, *Boston College* ZHIFENG REN, *Boston College* Table salt was found to be very helpful in producing single crystal zinc oxide (ZnO) nanowires in grams quantity with a conversion efficiency of about 60-80%. The growth process involves heating the mixture of zinc powder and table salt at about 600-700C in flowing gases of oxygen and argon. A conversion efficiency of only 5-10% was achieved when salt was not used. The salt was completely removed by a few times water rinse. The as-grown ZnO nanowires are about 40 – 100 nm in diameter and 5 – 10 micrometer in length, and are grown on either zinc oxide particles or on the surfaces of the table salt crystals. Transmission electron microscope studies showed that these ZnO nanowires are highly crystallized single crystals. Photoluminescence spectra of the as-grown and salt-free ZnO nanowires using excitation of 325 nm showed that the ZnO nanowires have a very strong emission in the visible frequency without any emission from the band edge, meaning that surface states dominate the emission. The important role of the salt plays in the high conversion efficiency is discussed.

**12:27**

**B31 7 Growth of Ultra-long Horizontally Grown Zno NWs, their Photoluminescence and Electrical Properties** BABAK NIKOOBAKHT, MICHAEL BEVERSLUIS, MARK VAUDIN, STEPHAN STRANICK, *National Institute of Standards and Technology* In this presentation a technique for growth of very long horizontal ZnO NWs on $(11\bar{2}0)$ sapphire surface is discussed, which is a modification to our previously published work (**Appl. Phys. Lett. 2004, 85(15), 3244**). This technique provides the in situ alignment, predictable positioning, large scale assembly, diameter control, and production of quantum wires. A crystallographic model explaining the unique growth direction of $[11\bar{}00]$ is proposed, which is supported by electron-back scattering diffraction results. Two photon photoluminescence microscopy of oriented NWs with diameter about 5 nm as well as electrical characterization of individual NWs are discussed.

**12:39**

**B31 8 $W_3O$ Nanowires as Gas Sensors** SHARVIL DESAI, *University of Louisville, Department of Physics* BISWAPRIYA DEB, *University of Louisville, Department of Chemical Engineering* GAMINI SUMANASEKERA,* *University of Louisville, Department of Physics* MAHENDRA SUNKARA, *University of Louisville, Department of Chemical Engineering* $N_2O$ interaction on thin films of $W_3O$ nanowires and nanoparticles at different temperatures and concentrations was investigated. $W_3O$ nanowire and nanoparticle films were synthesized on quartz substrates by Hot Filament Chemical Vapor Deposition. DC resistance measurements in the Van der Pauw geometrical methods were conducted on the films. It was observed that the $W_3O$ nanowire thin film as a gas sensor resulted in an improved sensitivity as compared to the $W_3O$ nanoparticle thin film. Impedance Spectroscopy measurements (1mHz - 100kHz) were also performed in both films to understand the underlying mechanism for these different responses. Measurements on single $W_3O$ nanowire will also be presented.

**B31 9 Semiconducting Oxide Nanobelt Field Effect Transistors: Characteristics and Applications** YI CHENG, P. XIONG, *MARTECH/Physics Department, Florida State University* LENWOOD FIELDS, J.P. ZHENG, *Department of Electrical and Computer Engineering, FAMU/FSU College of Engineering* R. YANG, Z.L. WANG, *School of Materials Science and Engineering, Georgia Institute of Technology* Single-crystalline ZnO and $SnO_2$nanobelts with thickness of 10 -150 nm were synthesized by thermal evaporation of oxide powders without any catalyst. Field-effect transistors have been fabricated based on these oxide nanobelts, using a doped-Si/$SiO_2$ substrate. Multi-terminal electrical contacts to individual nanobelts were defined by photolithography, which enabled us to correlate the FET characteristics with the behavior of the contacts. FETs with nonohmic high-resistance contacts showed enhancement mode Schottky barrier FET behavior. In contrast, in devices with low-resistance ohmic contacts, characteristics of an n-channel depletion-mode FET were observed, with ON/OFF ratio as high as $10^3$ (ZnO) and $10^5$ ($SnO_2$), and well-defined linear and saturation regimes. Electrical measurements also revealed high transconductance and field-effect mobility for these nanobelt FETs. Effects of surface oxygen adsorption and desorption have been studied by monitoring the transport properties of $SnO_2$ nanobelt FET in different gas flow. Importantly, the FET characteristics of the $SnO_2$ device showed significant modification by a 2% hydrogen gas flow at room temperature. *This work is supported by NSF NIRT grant ECS-0210332.

**13:03**

**B31 10 Electromechanical Properties of GaN Nanowires** CHANG-YONG NAM, PAPOT JAROENAPIBAL, DOUGLAS THAM, DAVID E. LUZZI, JOHN E. FISCHER, *Dept. of Materials Science and Engr., University of Pennsylvania* STEPHANE EVOY, *Dept. of Electrical and Computer Engr., University of Alberta* GaN, an important wide and direct bandgap semiconductor for optoelectronic devices, also possesses excellent thermal stability, chemical inertness, and a high piezoelectric constant, making it suitable for high temperature chemical sensors and transducers. While one-dimensional GaN nanowires have attracted extensive research recently for nano-scale optoelectronic devices, their high aspect ratio, straightness and smooth surfaces suggest potential in nanoelectromechanical system (NEMS) applications such as high sensitivity mass sensing. In spite of such importance, electromechanical properties of GaN nanowires have not been accessed so far. Here, we investigate Young's modulus $E$ and resonance quality $Q$ of GaN nanowires by itin-situ detection of electromechanical resonances in a transmission electron microscope. For the largest nanowire diameter observed (84 nm), $E$ is close to the theoretical value of bulk GaN ( $\sim$ 300 GPa) and gradually decreases for smaller diameters. Also we find $Q$ generally higher than that of conventionally micromachined nano-scale Si resonators despite the larger surface-to-volume ratio, implying significant advantage of GaN nanowires in NEMS applications. Most nanowires display two closely-spaced resonances, which we attribute to low-symmetry triangular cross-sections.

**B31 11 Electronic and Transport Characteristics of Two-Phase Coaxial Gallium Nitride Nanowires** V.M. AYRES, B.W. JACOBS, M.A. CRIMP, *Michigan State University, East Lansing, MI 48824* R.E. STALLCUP, A. HARTMAN, *Zyvex Corporation, Richardson, TX, 75081* M.A. TUPTA, *Keithley Instruments, Cleveland, OH 44139* J.B. HALPERN, M.Q. HE, *Howard University, Washington, DC 20059* We will present results of investigations of electronic and transport characteristics of two-phase coaxial gallium nitride nanowires. The$\sim$ 50-100 nm gallium nitride nanowires grown in a direct reaction of metal gallium vapor with flowing ammonia at 850-900[r]C without a catalyst have a two phase coaxial zinc-blende/wurtzite structure, shown by high resolution TEM and nanodiffraction experiments. The electronic characteristics were investigated by STM. The transport characteristics were investigated in 2-point and 4-point probe configurations using a Keithley-Zyvex KZ100 Nanoprobing System, in which specially sharpened $\sim$ 30 nm radius tungsten nanoprobes were coupled to an ultra low noise semiconductor characterization system. The transport experiments were performed under direct SEM observation. Results indicating coaxial transport with different transport characteristics will be presented.

**B31 12 In-situ STM-TEM Studies of Individual GaN Nanowires** MITRA TAHERI, *Materials Science and Technology (Code 6360), Naval Research Laboratory, Washington, D.C. 20375* BLAKE SIMPKINS, *Surface Chemistry (Code 6170), Naval Research Laboratory, Washington, D.C. 20375* PEHR PEHRSSON, *Surface Chemistry (Code 6170), Naval Research Laboratory, Washington, D.C. 20375* RHONDA STROUD, *Materials Science and Technology (Code 6360), Naval Research Laboratory, Washington, D.C. 20375* The electronic and structural properties of individual GaN nanowires were studied using a scanning tunneling microscopy (STM) stage that operates inside a high-resolution transmission electron microscope (TEM) allowing simultaneous evaluation of electrical, compositional, and structural properties with nm-scale resolution. The GaN nanowires were prepared by atmospheric CVD on $SiO_2$/Si substrates. Catalyst metal deposition consisted of electron-beam lithography patterned Ni dots, enabling diameter- and position-controlled nanowire growth for device-compatible processing. A focused ion beam- scanning electron microscope with an in situ micromanipulator was used to extract single GaN nanowires from the substrate and attach them to copper TEM supports. Analysis of I-V characteristics of individual wires, and any correlation with microstructure, such as wire dimensions, growth habit and defect concentration will be presented.

**13:39**

**B31 13 Spatially Resolved Luminescence from CdSe Nanowires** YONG-JOO DOH, KRISTIN N. MAHER, LIAN OUYANG, *Department of Chemistry and Chemical Biology, Harvard University* JIWOONG PARK, *The Rowland Institute at Harvard* HONGKUN PARK, *Department of Chemistry and Chemical Biology, and Department of Physics, Harvard University* We report photoluminescence (PL) and electroluminescence (EL) from devices incorporating single cadmium selenide (CdSe) nanowires. Electrical measurements and spatially resolved optical measurements are carried out simultaneously at room temperature, and under constant uniform illumination ($\lambda$ = 480 nm). At low bias voltages ($V$), photoluminescence is observed along the length of the wire, with a spectral peak at 706 nm. Once $V$ exceeds $\pm$ 1V, the PL intensity begins to decrease, and above $V = \pm 2.5$V localized emission can be seen at one of the contacts (at the positively biased electrode). The EL spectrum shows a peak that is broadened and blue-shifted in comparison to the PL. A mechanism for the observed light emission will be discussed.

**13:51**

**B31 14 Compositional and magnetic ordering in $Mo_6S_{9-x}I_x$ nanowires*** TENG YANG, SHINYA OKANO, DAVID TOMANEK, *Michigan State University* We investigate the effect of atomic ordering and geometry on the relative stability and electronic as well as magnetic structure of $Mo_6S_{9-x}I_x$ nanowires using *ab initio* Spin Density Functional calculations. The skeleton of these unusually stable nanowires consists of Mo octahedra, which are decorated with S and I atoms and connected by sulfur bridges. These sulfur bridges turn out to be bi-stable, providing the nanowires with the unusual capability to stretch by 20% at no energy cost. Depending on the degree the nanowires have been stretched, they may reversibly acquire or lose their magnetic moment. The ordering of the decorating atoms, observed in these nanowires, reflects our finding that the total energy depends sensitively on the atomic arrangement at a given stoichiometry.

**B32 1 Losses due to phonon-phonon interactions in nanotube oscillators: From classical potentials through one-dimensional elasticity and many-body perturbation theory.**
DAVID ROUNDY, *Cornell University*

Phonon-phonon losses are an intrinsic loss mechanism and it is therefore important to calculate their magnitude as an upper bound on the quality factor of any nano-oscillator. We will present an approach to handling the problem of phonon-phonon interactions in nanotube oscillators which uses an empirical interatomic potential to compute the input parameters for a fully quantum-mechanical green function-based method. This approach allows us to compute losses at temperatures comparable to or below the Debye temperature ( $>$ 500K), allowing comparison with experimental results.

**B32 2 Scalable Linear Electronic Structure Method for Free Standing Clusters** KAB SEOK KANG, JAMES DAVENPORT, DAVID KEYES, JAMES GLIMM, *Brookhaven National Laboratory* We have developed a Scalable Linear Augmented Slater Type Orbital (LASTO) method for electronic-structure calculations on free standing clusters. As with other linear methods we solve the Schrodinger equation using a mixed basis set consisting of numerical functions inside atom centered spheres matched onto tail functions outside. The tail functions are Slater type orbitals which are localized, exponentially decaying functions. To solve the Poisson equation between spheres, we use a finite difference method replacing the rapidly varying charge density inside the spheres with a smoothed density with the same multipole moments. We use multigrid techniques on the mesh which are well-known scalable solvers. This yields the Coulomb potential on the spheres which in turn defines the potential inside via a Dirichlet problem. To solve the linear eigen-problem, we use SCALAPACK, a well-developed package to solve large eigen-problems with dense matrices. We have tested the method on finite clusters of palladium and palladium hydride. Supported by the US Department of Energy under contract DEA02-98CH10886.

**12:03**

**B32 3 ONETEP: linear-scaling density-functional theory with plane waves** PETER HAYNES, *Cavendish Laboratory, University of Cambridge, UK* CHRIS-KRITON SKYLARIS, *Physical and Theoretical Chemistry Laboratory, University of Oxford, UK* ARASH MOSTOFI, *Department of Materials Science and Engineering, Massachusetts Institute of Technology* MIKE PAYNE, *Cavendish Laboratory, University of Cambridge, UK* Plane waves are a popular choice of basis set for first-principles quantum-mechanical simulations based on density-functional theory because the implementation is straightforward and the completeness can be controlled systematically with a single parameter. The resulting simulations require a computational effort which scales as the cube of the system-size, which makes the cost of large-scale calculations prohibitive. Extended basis functions would appear to be an inappropriate choice for expanding the localized orbitals of linear-scaling methods or for embedding the calculation within a larger model. In spite of these apparent difficulties, the ONETEP linear-scaling method can achieve the same accuracy as traditional plane-wave calculations and overcomes the apparent difficulties mentioned above. An outline of the ONETEP method will be presented, focusing on its distinctive features and primarily the ability to optimize the localized orbitals in each particular environment. These optimized orbitals are known as non-orthogonal

generalized Wannier functions within ONETEP, and justification for this term will be presented, in addition to results that demonstrate the scaling and accuracy of the method.

**12:15**

**B32 4 Acceleration of the Convergence in *ab initio* Atomic Relaxations*** ZHENGJI ZHAO, LIN-WANG WANG, JUAN MEZA, *LBNL* Atomic relaxations is often required to accurately describe the properties of nanosystems. In *ab initio* calculations, a common practice is to use a standard search algorithm, such as BFGS (Broyden-Fletcher-Goldfarb-Shanno) or CG (conjugate gradient) method, which starts the atomic relaxations without any knowledge of the Hessian matrix of the system. For example, the initial Hessian in BFGS method is often set to identity, and there is no preconditioning to CG method. One way to accelerate the convergence of the atomic relaxations is to estimate an approximate Hessian matrix of the system and then use it as the initial Hessian in BFGS method or a preconditioner in CG method. Previous attempts to obtain the approximated Hessian were focused on the use of classical force field models which rely on the existence of good parameters. Here, we present an alternative method to estimate the Hessian matrix of a nanosystem. First, we decompose the system into motifs which consist of a few atoms, then calculate the Hessian matrix elements on different motif types from *ab initio* calculations for small prototype systems. Then we generate the Hessian Matrix of the whole system by putting together these motif Hessians. We have applied our motif-based Hessian matrix in *ab initio* atomic relaxations in several bulk (with/without impurity) and quantum dot systems, and have found a speed up factor of 2 to 4 depending on the system size.

**12:27**

**B32 5 Electric field polarization calculations using charge patching method*** LIN-WANG WANG, *Lawrence Berkeley National Lab, Berkeley CA 94720* XAVIER CARTOIXA SOLER, *Universidad Autonoma de Barcelona, Barcelona, SPAIN* Charge patching method has been used to calculate the electronic structures of thousand atom nanosystems with ab initio accuracy. Within the charge patching method, the ab initio charge density of a nanostructure is patched together using charge motifs which are calculated from small prototype systems. However, the current charge patching method can only be used for systems without long range electric field. In this talk, we will present results which include the polarizations of charge motifs. These polarization motifs accurately describe the charge responses of a nanosystem under external electric fields, and the results agree well with direct ab initio calculations, including part of the local field effects. This motif polarization method enables us to calculate nanosystems such as charged impurities, quantum dots with permanent dipole moments, or charged quantum dots. It also makes it possible to calculate the charge density of a nanosystem selfconsistently when combined with the folded spectrum method in solving a few band edge electronic states.

**12:39**

**B32 6 A divide and conquer method for Bader decomposition** JUN-ICHI HOSHINO, KAZUO TSUMURAYA, *Meiji University* The ionicity of atoms in crystals or molecules is a measure of the bonding states among the atoms. There have been several methods to evaluate the electron charges that belong to each atom. Bader analysis is a direct method and divides up into atomic regions where the dividing surfaces are at a minimum in the charge density. [1] The algorithm, however, has computational difficulties to find the critical points for complex circumstance of atoms. A Henkelmans algorithm [2] is free of the points, assign each point on a regular grid to one of the regions by following a steepest ascent (SA) method contrary to the Baders steepest descent (SD) algorithm. We have found the SA method separates the regions more precisely than the SD method, although they are reverse relation. The SA method however requires much memory capacity for all-electron densities which are oscillating in the core regions. We implement a divide and conquer method to calculate the core region separately from the other region, assess the proposed method, and compare it with the Henkelmans decomposition.

**B32 7 Direct enumeration of alloy configurations for semiconductor electronic structure properties*** SIRICHOK JUNGTHAWAN, SUKIT LIMPIJUMNONG, *National Renewable Energy Laboratory, U.S.A. and Suranaree University of Technology, Thailand* PETER A. GRAF, KWISEON KIM, WESLEY B. JONES, *National Renewable Energy Laboratory, Golden, CO 80401* GUS L. W. HART, *Department of Physics and Astronomy, Northern Arizona University, Flagstaff, AZ 86011-6010* We present an approach to directly enumerating the electronic structure of all possible zincblende-based alloy configurations whose unit cell contains up to a specified number of atoms. This method allows us to map the space of bandgaps and effective masses versus alloy composition and atomic configuration. We demonstrate for GaInP alloys that a large range of bandgaps and masses are available for a given composition. By decomposing the space of possible atomic configurations into categories based on superlattice structure, we can identify trends in bandgap extrema. For example, bandgap maxima typically occur in [0 h k] superlattices where h is not equal to k, and minima typically occur in [1 1 1] superlattices. We focus on dilute alloys where the minority composition is below 10 percent. The empirical pseudo potential method (EPM) and folded spectrum method are used to solve the single particle Schrödinger equation. The results from the EPM are compared with first- principle calculations.

**B32 8 Surface passivation optimization using DIRECT*** KWISEON KIM, PETER A. GRAF, WESLEY B. JONES, *National Renewable Energy Laboratory, Golden, CO 80401* LIN-WANG WANG, *Lawrence Berkeley National Laboratory, Berkeley, CA, 94720* The calculation of the electronic structure of a nanostructure must take into account surface effects. In experiments, the dangling bonds at the surface of a semiconductor nanostructure are passivated by other semiconductors or by organic ligands. In either case, photoluminescence measurements reveal that the emission comes from bulk-like, dot-interior states. These observations suggest that an approach to passivating a simulated nanostructure would be to attach pseudo-atoms to each dangling

bond. Here we present an automated methodology for generating surface passivating pseudo potentials for bulk empirical pseudo potentials. Our method is based on the global optimization method DIRECT. We apply it to two materials, CdSe and InP. Incorporated into a larger computational nanoscience infrastructure, our work represents a much needed improvement in the usability of the empirical pseudo potential method.

**B32 9 Non-linear dynamics of the electron wave packet propagating through the resonant tunneling structure under the presence of the electron-photon and inter-electron interactions** MASAKAZU MURAGUCHI, KYOZABURO TAKEDA, *Waseda University* We solved the TD Schrodinger equation numerically in the framework of the TD Hartree-Fock (HF) approach both in the real space and time, and studied the TD phenomena of an electron wave packet propagating through the time-modulated resonant tunneling structure (TMRTS). We suppose that a single electron Gaussian wave packet is injected into the TMRTS by varying its group velocity. For the inter-electron interaction in the TMRTS, we combine Poisson's equation with TD-HF equation. We found that the TD features of the wave function confined in the TMRTS (e.g., lifetime) strongly depend on the choice of the resonant states as well as the frequency and strength of the applied electric field. Furthermore, TD non-linear processes based on the multi-photon interaction are recognized. For extracting characteristics of these TD phenomena, we expanded the resulting wave function in terms of the RTS resonant sates at each time-step. This projection approach enables us not only to estimate the lifetime precisely but also provides a guiding principle to control the wave packet artificially.

**13:27**

**B32 10 Multi-Scale Modeling of Carbon Nanotube/Carbon Fiber/Epoxy Lamina** S.J.V. FRANKLAND, *National Institute of Aerospace* J.C. RIDDICK, *Army Research Laboratory* T.S. GATES, *NASA Langley Research Center* A carbon fiber/epoxy lamina in which the carbon fibers are coated with single-walled carbon nanotubes is modeled with a multi-scale method. The multi-scale model is designed to predict the effect of the carbon nanotubes on the constitutive properties of the lamina. Within the model both the nanotube volume fraction and nanotube distribution are varied. The multi-scale analysis links results from molecular dynamics and equivalent-continuum techniques with micromechanics and strength of materials models. The multi-scale method will be used in a parametric study to examine the relative effect of nanotube concentration, orientation, and distribution on the constitutive properties of the lamina.

**13:39**

**B32 11 Tight binding models derived from k-dot-p theory** C. E. PRYOR, *Dept. of Physics and Astronomy, University of Iowa* M.-E. PISTOL, *Dept. of Physics, Lund University, Sweden* Calculations of the electronic properties of semiconductor nanostructures rely on one of three different methods: tight-binding, pseudopotentials, or k-dot-p theory. The first two are well suited to modeling small scale structures, however their parameters must be fitted to bulk properties, which can be a complicated procedure, especially for tight-binding. In contrast, k-dot-p theory is best at describing large nanostructures in which the placement of individual atoms is not important, and the parameters of k-dot-p theory are directly related to experimentally determined quantities. To bridge the gap between atomistic and large scale models, we will present a method for constructing tight-binding models directly from k-dot-p theory by considering a real-space representation of k-dot-p theory with finite differences on a grid which matches the desired crystal lattice. Conversely, given a tight-binding model it is also possible to construct an equivalent k-dot-p theory in the long wavelength limit

**13:51**

**B32 12 Mobility of Lithium and Hydrogen Ions in Nanotubes in Terms of Fokker-Plank Equation** ANDREW KINCHEN, YURIY MALOZOVSKY, *Southeastern Louisiana University* We present the theory of mobility of Li and H ions in metallic nanotubes. We derived the mobility of ions in terms of the kinetic Fokker-Plank equation with the consideration of both the motion of an ion in the cylindrical periodic potential of a nanotube and interaction of an ion with lattice vibrations of the tubule. We argue that there is an optimum diameter of the tubule below which the mobility of ions is significantly reduced.

## SESSION B33: FINANCIAL MARKETS AND OTHER APPLICATIONS OF STATISTICAL PHYSICS

**Monday Morning, 13 March 2006**
**336, Baltimore Convention Center at 11:15**
**Victor Yakovenko, University of Maryland, presiding**

**11:15**

**B33 1 What physicists should learn about finance (if they want to)** ANATOLY SCHMIDT, *EBS Dealing Resources, Parsippany, NJ* There has been growing interest among physicists to Econophysics, i.e. analysis and modeling of financial and economic processes using the concepts of theoretical Physics. There has been also perception that the financial industry is a viable alternative for those physicists who are not able or are not willing to pursue career in their major field. However in our times, the Wall Street expects from applicants for quantitative positions not only the knowledge of the stochastic calculus and the methods of time series analysis but also of such concepts as option pricing, portfolio management, and risk measurement. Here I describe a synthetic course based on my book ''Quantitative Finance for Physicists'' (Elsevier, 2004) that outlines both worlds: Econophysics and Mathematical Finance. This course may be offered as elective for senior undergraduate or graduate Physics majors.

**11:27**

**B33 2 Relation between bid-ask spread and volatility in financial markets** JEAN-PHILIPPE BOUCHAUD, *Service de Physique de l'Etat Condense, CEA-Saclay, France* J. KOCKELKOREN, M. POTTERS, M. WYART, We establish empirically a linear relation between the bid-ask spread and the volatility per trade in stock markets. We give a theoretical argument explaining this relation and why it should hold on all electronic markets.

**11:39**

**B33 3 An equation of state for the financial markets: connecting order flow to price formation.** AUSTIN GERIG, *University of Illinois at Urbana-Champaign* SZABOLCS MIKE, *Budapest University of Technology and Economics* J. DOYNE FARMER, *Santa Fe Institute* Many of the peculiarities of price formation in the financial marketplace can be understood as the result of a few regularities in the placement and removal of trading orders. Based on a large data set from the London Stock Exchange we show that the distribution of prices where people place orders to buy or sell follows a surprisingly simple functional form that depends on the current best prices. In addition, whether or not an order is to buy or sell is described by a long-memory process, and the cancellation of orders can be described by a few simple rules. When these results are combined, simply by following the rules of the continuous double auction, the resulting simulation model produces good predictions for the distribution of price changes and transaction costs without any adjustment of parameters. We use the model to empirically derive equations of state relating order flow and the statistical properties of prices. In contrast to previous conjectures, our results demonstrate that these distributions are not universal, but rather depend on parameters of individual markets. They also show that factors other than supply and demand play an important role in price formation.

**11:51**

**B33 4 An empirical analysis of waiting times for price changes and orders in a financial market** NAOYA SAZUKA, *Sony Corporation* We discuss an empirical analysis of waiting time distribution for price changes and orders in a financial market and its Weibull approximation. It is widely assumed that trades in financial markets occur independently and the waiting time distribution is exponential. However, recent empirical results [Raberto et al 2002, Scalas et al 2005 etc] of high frequency financial data show that the distribution is non-exponential. Therefore, in order to understand market behavior quantitatively and systematically, it is important to check the validity of the exponential distribution hypothesis and which non-exponential distribution is appropriate. In this talk, we analyze the waiting times of Sony bank USD/JPY rate and orders. We show that the waiting time distribution for not only price changes, but also orders, is non-exponential by using non-double auction market data. We also measure exactly how much better the Weibull distribution is as an approximation by using the Weibull paper and divergence measurements. Moreover, the estimated value of the shape parameter in Weibull distribution is similar in both price changes and orders waiting time distributions.

**12:03**

**B33 5 Dynamics of the return distribution in the Korean financial market** JAE-SUK YANG, SEUNGBYUNG CHAE, WOO-SUNG JUNG,*HIE-TAE MOON, *Korea Advanced Institute of Science and Technology* In this paper, we studied the dynamics of the log-return distribution of the Korean Composition Stock Price Index (KOSPI) from 1992 to 2004. Based on the microscopic spin model, we found that while the index during the late 1990s showed a power-law distribution, the distribution in the early 2000s was exponential. This change in distribution shape was caused by the duration and velocity, among other parameters, of the information that flowed into the market.

*Present address: Boston University

**12:15**

**B33 6 Grouping in the stock markets of Japan and Korea** WOO-SUNG JUNG,*OKYU KWON, *Korea Advanced Institute of Science and Technology* TAISEI KAIZOJI, *International Christian University* SEUNGBYUNG CHAE, *Korea Advanced Institute of Science and Technology* WOONG LEE, *Yonsei University* HIE-TAE MOON, *Korea Advanced Institute of Science and Technology* We investigated the temporally evolving network structures of the Japanese and Korean stock markets through the minimum spanning trees composed of listed stocks. We tested the validity of conventional grouping by industrial categories, and found a common trend of decrease for Japan and Korea. This phenomenon supports the increasing external effects on the markets due to the globalization of both countries. At last the Korean market are grouped with the MSCI Korea Index, a good reference for foreigners' trading, in the early 2000s. In the Japanese market, this tendency is strengthened more and more by burst of the bubble in 1990's.

*Present address: Boston University

**12:27**

**B33 7 Dynamical Structures of High-Frequency Financial Data** KYUNGSIK KIM, *Department of Physics, Pukyong National University, Pusan 608-737, Korea* SEONG-MIN YOON, *Division of Economics, Pukyong National University, Pusan 608-737, Korea* SOO YONG KIM, *Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon 305-701, Korea* YUP KIM, *Department of Physics, Kyung Hee University, Seoul 130-701, Korea* We study the dynamical behavior for high-frequency data of the Korean stock price index (KOSPI) using the movement of returns in Korean financial markets. It is shown that the dynamical behavior for a binarized series of our models is not completely random. The conditional probability are numerically estimated from a return series of tick data in the KOSPI. Non-trivial probability structures can be constituted from binary time series of the autoregressive (AR), logit, and probit models for which the Akaike Information Criterion (IC) value shows a minimum value at the 15th-order. From our result, the value of correct match ratio for the AR model is found to relatively have slightly larger than calculated findings of other models.

**12:39**

**B33 8 Systematic Analysis of Group Identification in Stock Markets** DONG-HEE KIM, HAWOONG JEONG, *Department of Physics, KAIST* We propose improved methods to identify stock groups using the correlation matrix of stock price changes. By filtering out the marketwide effect and the random noise, we construct the correlation matrix of stock groups in which nontrivial high correlations between stocks are found. Using the filtered correlation matrix, we successfully identify the multiple stock groups without any extra knowledge of the stocks by the optimization of the matrix representation and the percolation approach to the correlation-based network of stocks. These methods drastically reduce the ambiguities while finding stock groups using the eigenvectors of the correlation matrix.

**12:51**

**B33 9 Virtual Volatility, an Elementary New Concept with Surprising Stock Market Consequences** RICHARD PRANGE, A. CHRISTIAN SILVA, *University of Maryland* Textbook investors start by predicting the future price distribution, PDF, of a candidate stock (or portfolio) at horizon T, e.g. a year hence. A (log)normal PDF with center (=drift =expected return) $\mu$T and

width (=volatility) $\sigma\sqrt{T}$ is often assumed on Central Limit Theorem grounds, i.e. by a random walk of daily (log)price increments $\Delta s$. The standard deviation, stdev, of historical (itex post) $\Delta s$ 's is usually a fair predictor of the coming year's (itex ante) stdev($\Delta s$) $= \sigma_{daily}$, but the historical mean E($\Delta s$)it at bestroughly limits the true, to be predicted, drift by $\mu_{true}T \sim \mu_{hist}T \pm \sigma_{hist}\sqrt{T}$. Textbooks take a PDF with $\sigma \sim \sigma_{daily}$ and $\mu$ as somehow known, as if accurate predictions of $\mu$ were possible. It is elementary and presumably new to argue that an average of PDF's over a range of $\mu$ values should be taken, e.g. an average over forecasts by different analysts. We estimate that this leads to a PDF with a 'virtual' volatility $\sigma \sim 1.3\sigma_{daily.}$ It is indeed clear that uncertainty in the value of the expected gain parameter increases the risk of investment in that security by most measures, e. g. Sharpe's ratio $\mu T/\sigma\sqrt{T}$ will be 30% smaller because of this effect. It is significant and surprising that there are investments whichit benefit from this 30% virtual increase in the volatility

**13:03**
**B33 10 Volatility, Persistence, and Survival in Financial Markets** MAGDALENA CONSTANTIN, SANKAR DAS SARMA, *Condensed Matter Theory Center, University of Maryland, College Park* We study the temporal fluctuations in time-dependent stock prices (both individual and composite) as a stochastic phenomenon using general techniques and methods of nonequilibrium statistical mechanics. In particular, we analyze stock price fluctuations as a non-Markovian stochastic process using the first-passage statistical concepts of persistence and survival. We report the results of empirical measurements of the normalized $q$-order correlation functions $f_q(t)$, survival probability $S(t)$, and persistence probability $P(t)$ for several stock market dynamical sets. We analyze both minute-to-minute and higher frequency stock market recordings. We find that the fluctuating stock price is multifractal and the choice of the sampling time has no effect on the qualitative multifractal behavior displayed by the $1/q$-dependence of the generalized Hurst exponent $H_q$. The probability $S(t)$ of the stock price remaining above the average up to time $t$ is very sensitive to the total measurement time $t_m$ and the sampling time. The probability $P(t)$ of the stock not returning to the initial value within an interval $t$ has a universal power-law behavior, $P(t) \sim t^{-\theta}$, with a persistence exponent $\theta$ close to 0.5 that agrees with the prediction $\theta = 1 - H_2$. The empirical financial stocks also present an interesting feature found in turbulent fluids, the extended self-similarity. This work is partially supported by the NSF and U.S. ONR.

**B33 11 Comparing Extremal and Hysteretic Optimization on the Satisfiability Problem*** BRUNO GONÇALVES, *Emory University* STEFAN BOETTCHER, *Emory University* We apply physically inspired optimization methods to the classical combinatorial Satisfiablity problem. Treating the usual boolean variables as Ising spins and each clause as a p-spin interaction we can use the pre-existing physical intuition about spin glasses and magnetic systems to find the optimal solution for this problem (the ground state energy). We compare the performance of Extremal Optimization[1] ($\tau EO$) and Hysteretic Optimization[2] ($HO$) and determine the parameter values that provide the best results. Comparisons with previously published results on well known benchmarks[3] are also made.

*This work has been supported by grant 0312510 from the Division of Materials Research at the National Science Foundation.

**B33 12 What is the most interesting team sport?** FEDERICO VAZQUEZ, *Boston University* ELI BEN-NAIM, *Los Alamos National Laboratory* SIDNEY REDNER, *Boston University* What is the most interesting team sport? We answer this question via an extensive statistical survey of game scores, consisting of more than 1/4 million games in over a century. We propose the likelihood of upsets as a measure of competitiveness. We demonstrate the utility of this measure via a comparative analysis of several popular team sports including soccer, baseball, hockey, basketball, and football. We also develop a mathematical model, in which the stronger team is favored to win a game. This model allows to us conveniently estimate the likelihood of upsets from the more easily-accessible standings data.

**13:39**
**B33 13 Diagnosis of weaknesses in modern error correction codes: a physics approach*** MIKHAIL STEPANOV, MICHAEL CHERTKOV, *Los Alamos National Laboratory* VLADIMIR CHERNYAK, *Wayne State University* BANE VASIC, *University of Arizona* One of the main obstacles to the wider use of the modern error-correction codes is that, due to the complex behavior of their decoding algorithms, no systematic method which would allow characterization of the bit-error-rate (BER) is known. This is especially true at the weak noise where many systems operate and where coding performance is difficult to estimate because of the diminishingly small number of errors. We show how the instanton method of physics allows one to solve the problem of BER analysis in the weak noise range by recasting it as a computationally tractable minimization problem. The material is based on Phys. Rev. Lett. 95 (22) 228701 (2005).

**B35 1 Electromigration Forces on Ions in Carbon Nanotubes.**
STEFAN HEINZE, *Institute of Applied Physics, University of Hamburg, Jungiusstrasse 11, 20355 Hamburg*

Due to their unique structural, electronic, and optical properties carbon nanotubes (CNs) are promising candidates for future nanoelectronic devices. Recently, field-effect transistors (FETs) from single-wall CNs have been a research focus. In particular, ballistic transport has been demonstrated [1] and key transport parameters compare well with state-of-the-art silicon FETs. In many cases improved CN-FET performance has been achieved by the use of dopants such as alkali metal atoms (see e.g. [2]). However, during transistor operation a current-induced, *electromigration*, force will be exerted on the alkali metal ions. Due to the low diffusion barriers the alkali ions may move along the CN which can influence the FET characteristics. On the other hand, electromigration forces can be used to intentionally transport atoms along a CN [3]. Here, we present self-consistent non-equilibrium Greens function calculations to treat a ballistic CN-FET within a tight-binding approximation. We use a cylindrically symmetric device and calculate the current-induced forces on ions located either inside or outside of the CN. We observe that the forces are especially large in the turn-on regime of the transistor, and much smaller in the off- and on-states. The electromigration forces are mainly due to momentum transfer from the charge carriers, i.e. due to the ''wind'' forces. The sign of the ''effective valence'' $Z^*$ is independent of the actual charge sign, but can be reversed with gate voltage, providing a dramatic illustration of the quantum character of the wind force. **B35 2 Molecular Dynamics Simulations of the Thermal Conductivities of Group IV Bulk Materials and Nanowires** JOHN REED, ANDREW WILLIAMSON, *Lawrence Livermore National Laboratory* GIULIA GALLI, *University of California, Davis* We present the results of equilibrium molecular dynamics simulations of the thermal conductivities of bulk C, Si, Ge, and SiC using the Green-Kubo formalism. We use an empirical interatomic potential developed by Tersoff [1] and investigate the effects of modifications to this potential suggested by Porter et al [2]. We also investigate the effects of choosing a symmetric versus nonsymmetric definition of the local heat. A generalization of this approach to study the dependence of the thermal conductivity of SiGe nanowires on their size and composition will also be presented. [1] J. Tersoff, PRB 39 (8), 5566-5568 [2] L. Porter, J. Li, S. Yip, J. Nuc. Matl. 246 (1997) 53-59 This work was performed under the auspices of the U.S. Dept. of Energy at the University of California/Lawrence Livermore National Laboratory under contract no. W-7405-Eng-48.

**B35 3 The Nanocomposite Approach to Enhanced Thermoelectric Performance** G. CHEN, R. YANG, H. LEE, Q. HAO, M. TANG, M. S. DRESSELHAUS, *MIT, Cambridge, MA* D. WANG, Z. REN, *BC, Chestnut Hill, MA* J. P. FLEURIAL, P. GOGNA, *JPL, Pasadena, CA* Model calculations and experimental results confirm that a nanocomposite approach leads to an enhancement in the thermoelectric performance of a bulk nanocomposite sample based on Si-Ge relative to its 3D alloy counterpart, though the predictions are quite general and should be applicable to a variety of nanocomposite systems. Modeling and experimental results here are reported for nanocomposites of Si-Ge made of Si and Ge nanoparticles (typically the particles are 20 nm or less in size prepared from the liquid phase or by ball milling or other techniques) and consolidated by hot press in an inert argon atmosphere to theoretical density. Most important is the large decrease in the thermal conductivity, well below that of the alloy of the same composition, both at room temperature and up to 1000K. Although the electrical conductivity decreases somewhat, the selective filtering of the high energy electron carriers enhances the Seebeck coefficient much more than the decrease in electrical conductivity, resulting in a gain in the power factor as well over a large temperature range. Emphasis is given to physical phenomena associated with nanostructures that serve to enhance the thermoelectric performances generally, and can be used for other Nanocomposite systems. The authors acknowledge support from NASA under the Radio Isotope Power Conversion program.

**12:15**
**B35 4 Theory of the thermoelectric properties of semiconductor-matrix nanocomposites** NATALIO MINGO, *NASA-Ames Center for Nanotechnology* DAVID BROIDO, *Boston College* We theoretically investigate the thermoelectric properties of a nanocomposite nanowire array where the matrix material is a semiconductor. We take InSb to be the nanocomposite matrix that surrounds an array of cylindrical holes, and we calculate the density-optimized power factor, P, and the lattice thermal conductivity, k, employing a relaxation time approach and including band nonparabolicity. For fixed aspect ratio of wire diameter to cylindrical-hole period, we obtain universal curves for P. For small period, we find that P is enhanced above the bulk value with the magnitude of this enhancement increasing with the aspect ratio. For k, we model the phonon scattering by a frequency-dependent relaxation time [1] and use a boundary-scattering ge-

ometry introduced by Prasher [2]. For fixed aspect ratio and small periods we find reductions in k of around 50%. Our results for P and k suggest that choosing a thermoelectric material as the matrix of a nanowire composite can contribute to enhance the composites ZT. [1] N. Mingo and D. A. Broido, Phys. Rev. Lett. 93, 246106 (2004). [2] R. Prasher, submitted.

**B35 5 Molecular dynamics simulation of shock-induced chemical, mechanical and thermal processes in Ni/Al nanolaminates** SHIJIN ZHAO, TIMOTHY GERMANN, ALEJANDRO STRACHAN, *Los Alamos National Laboratory* Nanostructured metastable intermolecular composites (MICs) are a new class of energetic materials with a wide range of applications. MICs can be made to react to form a more stable compound while releasing a large amount of energy and exhibit several unique properties, for example, extremely fast propagation of the chemical reactions when the initial components are intermixed at the nanometer scales. The fundamental molecular-level mechanisms that govern the unique properties of these materials are to a large extent unknown. We employ molecular dynamics to characterize the chemical and mechanical response of MICs induced by shock loading. We use detailed analysis methods to characterize the atomic level processes responsible for the initiation and propagation of the chemical reactions. Our simulations are designed to characterize the role of composition and nanostructure on the initiation and subsequent ultra-fast propagation of chemical reactions in nanostructured MICs as well as their mechanical and thermal properties.

**12:39**

**B35 6 Vibrations and thermal conductivity in inorganic and polymeric glasses.** SERGEI SHENOGIN, ARUN BODAPATI, PAWEL KEBLINSKI, *Rensselaer Polytechnic Institute* The mechanism of thermal transport in amorphous materials was studied by means of vibrational mode analysis and classical nonequilibrium molecular dynamics (MD) simulations. We studied four different model systems of (a) Lennard-Jones glass, (b) bead-spring model of an amorphous polymer, (c) amorphous silicon with Stillinger-Weber potential; and (d) all-atom model of glassy polystyrene with PCFF-type force field. For all structures we evaluated thermal conductivity from the harmonic theory of disordered solids [P.B.Allen, and J.L.Feldman, Phys.Rev.B 48, 12581 (1993)] and from direct MD simulations. We found that for all models but polystyrene, the harmonic theory accurately predicts thermal conductivity. By contrast, in the case of polystyrene, only $\sim$ 1/2 of thermal conductivity can be explained within the harmonic approximation. Consequently, a major part of the transport has to be attributed to anharmonic coupling between vibrational modes. The reasons for the failure of harmonic theory of disordered solids to model amorphous glassy polymers will be discussed.

**12:51**

**B35 7 Anomalous thermal transport in the low-conductivity phase of granular metals** VIKRAM TRIPATHI, *University of Cambridge, U.K.* YEN LEE LOH, *Purdue University, U.S.A.* We study the thermal conductivity of a nonmagnetic, nonsuperconducting granular metal in the low-conductivity phase using the Kubo formula approach, and compare it with the electrical conductivity. We find that the physical mechanisms and the temperature dependences of the two are very different. In a regular granular array, electrical transport, which takes place through the intergrain hopping of quasiparticles, obeys an Arrhenius law due to Coulomb blockade of quasiparticle hopping. Certain many-particle processes such as particle-hole cotunneling do not suffer Coulomb blockade due to their charge-neutrality and show a much slower power-law decrease with temperature; however, because of their charge-neutrality, these processes make no qualitative difference to the electrical conductivity. Cotunneling of particle-hole pairs does transport heat, and therefore, the thermal conductivity decreases only algebraically with temperature. This picture is reminiscent of excess thermal transport in disordered semiconductors due to low-energy excitons.

**B35 8 Molecular heat pump** DVIRA SEGAL, *Department of Chemical Physics Weizmann Institute of Science Rehovot 76100 Israel* ABRAHAM NITZAN COLLABORATION, A heat pump is a device that transfers heat from a low to a high temperature reservoir by applying an external work that modulates the system's parameters. In this work we discuss a novel molecular machine of this kind. The system consists of a molecular element connecting two thermal reservoirs that are characterized by different spectral properties. The pumping action is achieved by applying an external force that periodically modulates molecular levels. This modulation affects periodic oscillations of the internal temperature of the molecule and the strength of its coupling to each reservoir resulting in a net heat flow in the desired direction. The heat flow is examined in the slow and fast modulation limits and for different modulation waveforms, thus making it possible to optimize the device performance.

**13:15**

**B35 9 Transport and Noise in Mesoscopic Conductors Coupled to Quantized Electro-Magnetic Fields.** A.D. STONE, M.G. VAVILOV, *Yale University* Previous analyses of the effects of electro-magnetic (EM) fields on transport through mesoscopic systems have employed a classical treatment of the fields. To describe experiments on circuit electrodynamics [A. Wallraff et al., Nature 431, 162 (2004)] this treatment is no longer applicable. In this talk we discuss how the current and current noise through mesoscopic conductors are modified by the presence of such non-classical EM fields. For example when the EM field corresponds to a thermal state with temperature different from the electron temperature typically a steady-state current will flow through the system at zero bias due to the lack of detailed balance. The magnitude and direction of this current can be used to measure the temperature of the EM field. More generally, this current and its noise will allow measurement of non-classical properties of the EM field coupled to the system.

**B35 10 Elastomeric Network/Air Structures for Mechanically Tunable Hypersonic Phononic Crystals** TARAS GORISHNYY, JI-HYUN JANG, CHAITANYA K. ULLAL, EDWIN L. THOMAS, *Massachusetts Institute of Technology* Hypersonic phononic crystals allow control over high frequency phonons, which is crucial for a whole range of applications from acousto-optics to thermal management and high resolution nondestructive evaluation techniques. The ability to fabricate phononic crystals with a band diagram that can be modified reversibly and repeatedly opens an interesting possibility to create tunable acoustic devices. In this talk we will describe the use of submicron elastomeric PDMS (poly(dimethylsiloxane))/air network structures as tunable phononic crystals operating in hypersonic frequency re-

gime. The structures were fabricated from interference lithography templates, which were infiltrated with PDMS precursor and then after crosslinking the photoresist template was removed in water-based basic solution. Brillouin light scattering was used to monitor the modification of the phononic band diagram of these elastomeric structures as a function of the direction and degree of reversible mechanical deformation. The influence of symmetry and anisotropic sound velocities on the features of the phononic band diagram will be discussed.

**B36 1 1D-1D Tunneling in Vertically Coupled Quantum Wires** E. BIELEJEC, S. K. LYO, J. A. SEAMONS, J. L. RENO, M. P. LILLY, *Sandia National Laboratories* We report tunneling measurements between two vertically coupled quantum wires in a GaAs/AlGaAs double quantum well structure with a 7.5 nm barrier. Split gates above and below the electron bilayer define each quantum wire and allow separately controlled 1D densities. Separate contacts are achieved with additional depletion gates. Parallel conductance as a function of split gate voltages provides a map of the 1D subband occupation; tunneling measurements can be made with any combination of subbands occupied in each wire. The full tunneling spectroscopy is measured using both a voltage between the wires and parallel magnetic field to explore the energy and momentum dependence of the tunneling. We observe a number of features, such as resonance peaks at high parallel magnetic fields, that can be explained within the framework of non- interacting 1D systems. These resonance features change in a systematic way as the number of occupied subbands changes. Other characteristics of the data such as very broad tunnel resonances as a function of the interwire voltage may require many-body interactions for a complete description of the tunneling physics. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy under contract DE-AC04- 94AL85000.

**11:27**
**B36 2 Tunable double quantum dots in InAs nanowires defined by local gate electrodes.** CARINA FASTH, ANDREAS FUHRER, LARS SAMUELSON, *Lund University* We present low-temperature transport measurements on quantum dots induced in homogeneous InAs quantum wires 50 nm in diameter. Quantum dots are induced by electrical depletion of the wire using local gate electrodes with down to 30 nm electrode spacing. This scheme has permitted the realization of fully gate-defined multiple quantum dots along the nanowire [1]. Tunability in double quantum dots is a prerequisite for the system to be operated as a quantum gate. We demonstrate control over the lead tunnel barrier transparencies and, in the case of double quantum dots, the interdot coupling. Using the local gate electrodes also as plunger gates we measure double dot honeycomb stability diagrams which show the transition from a single large dot to two weakly coupled dots at 4.2K. The induced quantum dots can be tuned into the few-electron regime which is shown from Coulomb blockade measurements. We extract values of orbital energy-level spacings, capacitances and capacitive and tunnel interdot coupling for this system. [1] C. Fasth et al., NanoLett 5, 1487 (2005).

**11:39**
**B36 3 Orbital and Spin Effects in Single- and Double-Quantum Dots Defined in InAs/InP Nanowire Heterostructures.** ANDREAS FUHRER, LINUS FROBERG, LARS SAMUELSSON, *The Nanometer Structure Consortium, Lund Universtity, Lund, Sweden* Heterostructures in semiconducting nanowires are highly promising in terms of their potential for novel physics and device applications. We present measurements on single (double) quantum dots fabricated using InP double (triple) barrier heterostructures in InAs nanowires. Transport spectroscopy measurements on single dots show that we can design few-electron quantum dots in nanowires where the well defined geometry leads to shell structure effects. We also show that the Zeeman splitting of the first few electrons can be engineered to any desired effective g-factor between $|g^*|=2.5$ and values close to the bulk value of InAs $|g^*|=13$ [1]. In extension of this, transport spectroscopy in the few- electron regime of double quantum dots consisting of two InAs islands in series have been performed. These double dots are tuned using a single homogenous backgate, which together with a source-drain bias allows us to controllably empty both dots down to the last electron. Again we observe a shell-structure which can be linked to the geometric cross-section of the wire and an orbital blockade effect is observed depending on the character of the wavefunctions in each dot. **11:51**
**B36 4 Ultra-dense nanowire arrays*** EZEKIEL JOHNSTON-HALPERIN, J.E. GREEN, D.W. WANG, E. DEIONNO, J.W. CHOI, Y. LUO, A. BOUKAI, Y. BUNIMOVICH, B.A. SHERIFF, J.R. HEATH, *Division of Chemistry and Chemical Engineering, The California Institute of Technology, Pasadena, CA* The development of the superlattice nanowire pattern transfer (SNAP) technique has allowed for the fabrication of highly ordered arrays of hundreds of nanowires (both metallic and semiconducting) at pitches down to 16 nm and aspect ratios up to $10^6$. Applications of these nanowire arrays range from bridging length scales via binary-tree demultiplexing [1], to the development of ultra-dense arrays of molecular switch tunnel junctions ( $\sim$ 1 TBit/in$^2$), to the integration of complementary logic arrays within a crossbar architecture. In addition, at the narrowest pitches the periodicity of the SNAP array is only a few tens of atoms, allowing access to length scales compatible with coherent electronic transport and opening the door to fundamental studies. These topics will be discussed within the context of the flexibility of the SNAP fabrication technique and its wide applicability to a number of both basic and applied challenges in nanoscience/nanotechnology. [1] Science, 310, 465 (2005).

**B36 5 Ag nanowires on Cu(110) and Ni(110): atomic structure and electronic dimensionality*** RICHARD KURTZ, PHILLIP SPRUNGER, WEICHANG ZHAO, YAROSLAV LOSOVYI, *Louisiana State University* Epitaxial Ag nanowires have been found to self-assemble on Cu(110) or on Ni(110) at Ag coverages exceeding 1.2 ML. The atomic and electronic structure of these nanowires have been characterized by scanning tunneling microscopy (STM) and angle-resolved photoemission spectroscopy (ARPES). STM shows that the Ag(110)-oriented nanowires that are straight and parallel to the [110] direction with a uniform width (height) ranging between 10-30 nm (2-3 nm) depending on coverage. The nanowires have a triangular cross-section and expose two sides of facets that slope at an angle of approx 25 deg with respect to the surface. Overall length-to-width aspect ratios up to 20:1 have been observed. The substrate-wire lattice mismatch induces an anisotropy in the nanowire with a strained lattice match in the [001] (across-wire) direction and an incommensurate periodicity, essentially decoupled from the substrate, in the [110] (along-wire) direction. Angle-resolved photoemission data reveals Ag d-band dispersion in the vertical (or (110)) and the lateral [110] (or along-wire) direction, but absence of dispersion in the lateral [001] (or across-wire) direction because of the limited dimension of the nanowire width. This anisotropic electronic dimensionality correlates with the structural asymmetry.

**12:15**

**B36 6 Electronic structure of self-assembled Si nanowires on Ag(110) surfaces** TAISUKE OHTA, *Fritz Haber Institute/LBNL* ELI ROTENBERG, *Lawrence Berkeley National Laboratory* KARSTEN HORN, *Fritz Haber Institute* Much attention has recently been paid to the physics of one- dimensional (1-D) systems, since exotic properties are predicted from basic theoretical consideration. However, it is not easy to realize such one-dimensional systems experimentally. Recently, Leandri et al.[1] have reported the growth of self-assembled 1D linear structures of silicon on Ag(110), perfectly aligned along [-110] direction and 16Å wide. We have investigated the electronic structure of such self-assembled Si nanowires using angle resolved photoemission spectroscopy. The Si 2p core level line shows two narrow components in agreement with earlier work [1]. Silicon-induced features in the valence band region are observed, most clearly within the band gap of the Ag s-p states. The silicon-induced band exhibits a sizeable dispersion only in the direction along the linear structure, i.e. the [- 110] azimuth of the Ag(110) substrate. Details of the experimentally observed bands will be presented and related to the atomic structure within the 1D structure and its arrangement on the silver substrate. T.O. acknowledges financial support from Max Planck Society. Experiments were performed at the Advanced Light Source, Lawrence Berkeley National Laboratory operated by the U.S. DOE under Contract No. DE-AC03-76SF00098. [1] C. Leandri et al., Self-aligned silicon quantum wires on Ag (110), Surface Science 574 (2005) L9L15

**12:27**

**B36 7 One-dimensional Pt induced chains on Si(337)** JESSICA MCCHESNEY, *Montana State University* A. BOSTWICK, E. ROTENBERG, *Advanced Light Source* GERALD LAPEYRE, *Montana State University* The use of high index Si surfaces as templates for the formation of adsorbate induced one-dimensional chain structures have attracted considerable interest. These systems have been used as a test bed in which to study low-dimension physics and components of nanoelectronics. In addition to the Ag and Au induced chains reported to form on the Si(337) surface, Pt also produces one-dimensional chains. Angle-resolved photoemission spectroscopy was used to investigate the electronic structure of these new Pt chains. The valence band mapping confirms the one-dimensional nature of these chains as seen in LEED. Supported by ONR and DOE.

**12:39**

**B36 8 The Coulomb blockade regime in disordered AlAs cleaved-edge overgrown quantum wires** JOEL MOSER, *Walter Schottky Institut, TU Muenchen, Am Coulombwall 3, D-85748 Garching, Germany* DIETER SCHUH, *Walter Schottky Institut, TU Muenchen, Am Coulombwall 3, D-85748 Garching, Germany* MAX BICHLER, *Walter Schottky Institut, TU Muenchen, Am Coulombwall 3, D-85748 Garching, Germany* MATTHEW GRAYSON, *Walter Schottky Institut, TU Muenchen, Am Coulombwall 3, D-85748 Garching, Germany* STEFANO RODDARO, *Scoula Normale Superiore, Via della Faggiola 17/19, I-56126 Pisa, Italy* VITTORIO PELLEGRINI, *Scoula Normale Superiore, Via della Faggiola 17/19, I-56126 Pisa, Italy* We present transport measurements on AlAs quantum wires in the pinch-off regime, where the wire breaks up into zero-dimensional islands of electrons and Coulomb blockade sets in. Conductance resonances as a function of gate bias vanish at low temperature T, and a gap bounded by two peaks opens up in the differential conductance as a function of source-drain dc bias V. We propose two interpretations for these results: (i) low T, low V transport is limited by incoherent tunneling through 2 asymmetric quantum dots in series; (ii) at pinchoff the wire carries a collective mode that is pinned by disorder, but can be depinned by a finite threshold bias V.

**12:51**

**B36 9 The transition from a one-dimensional to a quasi-one-dimensional state in interacting quantum wires*** JULIA S. MEYER, *The Ohio State University* KONSTANTIN A. MATVEEV, *Argonne National Laboratory* ANATOLY I. LARKIN, *W.I. Fine Theoretical Physics Institute, University of Minnesota* Upon increasing the density of electrons in a quantum wire, the system undergoes a transition from a one-dimensional to a itquasi-one-dimensional state. In the absence of interactions between electrons, this corresponds to filling up the second subband of transverse quantization. On the other hand, strongly interacting one-dimensional electrons form a Wigner crystal, and the transition corresponds to it splitting into two chains (zig-zag crystal). While the two subbands in the non-interacting case represent two gapless electron modes, in the Wigner crystal the two chains are locked, i.e., the relative motion is gapped, and only one gapless mode remains. We study the evolution of the system as the interaction strength changes. In particular, we establish that only one gapless mode exists near the transition at any interaction strength.

**B36 10 Exciton Energy Transfer between Asymmetric Quantum Wires** S.K. LYO, *Sandia National Laboratories, U. S. A.* K.F. KARLSSON, H. WEMAN, K. LEIFER, A. RUDRA, E. KAPON, *Ecole Polytechnique Federale de Lausanne (EPFL), Switzerland* We present theoretical result and data for the Stokes exciton transfer rate from a narrow quantum wire (n-QWR) to a parallel wide QWR (w-QWR) separated by a wide barrier and also to an array of parallel w-QWRs. The transfer rate is calculated as

a function of the distance $d$ between n-QWR and w-QWR and also the array. The dependence of the rate on the temperature and the localization radius is studied for free and localized excitons, respectively. Both the resonant and non-resonant rates are considered. We find that, for energy transfer between two QWRs, the Förster dipole-dipole transfer dominates the transfer rate at short and intermediate distances. The photon-exchange transfer prevails only at an extremely long distance where the rate is negligibly small. This behavior is in contrast with the two-dimensional quantum wells, where the photon-exchange mechanism is dominant except at a very short distance. However, the photon-exchange transfer rate continues to increase as the array size grows to a macroscopic scale due to its slow range dependence while the dipolar rate saturates quickly with the array size. The prediction of the theory is consistent with the data from V-groove $GaAs/Al_xGa_{1-x}As$ double QWRs. Supported by the US DOE (SKL), Swedish Foundation for Strategic Research, Swedish Research Council, and Ericsson's Research Foundation.

**B36 11 Spin excitation velocities in multi-channel quantum wires** EUGENE PIVOVAROV, MICHAEL FOGLER, *UC San Diego* We investigate how an external magnetic field affects the interaction corrections to the velocities of spin collective modes in quantum wires. We show that both many-body and single- particle effects are important. The former generate logarithmic field dependence that can alter the Hartree-Fock results by up to a factor of two. On a single-particle level, the field modifies the subband wavefunctions and therefore the effective interaction strength. This theory is applied to quantum wires fabricated by the recently introduced cleaved edge overgrowth technique and the results are compared with experiments [Auslaender *et al.* Science **308**, 88 (2005)].

**13:27**

**B36 12 Junctions of Three Quantum Wires of spin-1/2 Electron System** CHANG-YU HOU, *Department of physics, Boston University* CLAUDIO CHAMON, *Department of physics, Boston University* MASAKI OSHIKAWA, *Department of Physics, Tokyo Institute of Technology* IAN AFFLECK, *Dept. of Phys. and Astro., University of British Columbia* We study a junction of three interacting quantum wires which are joined by a ring enclosing a magnetic flux. The wires are modeled as single channel spin-1/2 Tomonaga-Luttinger Liquids (TLL). We study the problem by identifying the boundary conditions corresponding to the low energy fixed points through both Delay Evaluation Boundary Condition and Boundary Conformal Field Theory method. We obtain a rich phase diagram as the function of the TLL interacting parameter, $g_c$ and $g_s$, including a chiral regime in which the asymmetric current flow is highly sensitive to the sign of the flux and a phase in which electron pair tunneling dominates.

**13:39**

**B36 13 Effect of electron-electron interaction on linear and nonlinear optical phenomena in quantum dot systems in interlevel resonance region** VICTOR BONDARENKO, *WSU* MIROSLAW ZALUZNY,* *IF UMCS* YANG ZHAO, *WSU* We theoretically investigate linear and nonlinear optical phenomena in quantum dot (QD) systems caused by interlevel transitions. Effect of electron-electron (e-e) interaction in the systems on the optical phenomena is in the focus of the work. The e-e interaction is taken into account by employing the self-consistent field approach in the quasistatic limit. We show that presence of metal surface, and especially another resonant system, can dramatically enhance the effect of the e-e interaction on the optical phenomena. We discuss the conditions for the intrinsic optical bistability in QD systems caused by the e-e interaction. The obtained results can find applications for design, fabrication, and exploiting nanooptoelectronics devices, in part, all-optical components like QD-based optical switches and optical transistors.

**B37 1 Signatures of strong correlations in the tunneling spectra of superconducting doped Mott insulators** TIAGO C. RIBEIRO, *University of California, Berkeley* XIAO-GANG WEN, *Massachusetts Institute of Technology* We compare the tunneling spectra from BCS mean-field theory and from a mean-field theory of superconducting doped Mott insulators to address the signatures of strong correlations in tunneling experiments, namely the bias sign asymmetry, the generic lack of evidence for the Van Hove singularity and, in some cases, the absence of coherence peaks. We also establish the connection between tunneling spectroscopy and ARPES observations in the cuprate superconductors. Thus, we provide a consistent description of these two experimental techniques which probe the single electron microscopic physics of the cuprates.

**11:27**

**B37 2 Controlling hole concentration in superconducting $YBa_2Cu_3O_{7-\delta}$ thin films for spectroscopic studies*** MATTHEW BRINKLEY, WAN KYU PARK, XIAOFANG ZHAI, JAMES ECKSTEIN, LAURA GREENE, *University of Illinois at Urbana-Champaign* UNIVERSITY OF ILLINOIS AT URBANA-CHAMPAIGN COLLABORATION, One of the remaining controversial issues in the high-$T_c$ cuprate superconductors is whether the $d$-wave order parameter is robust over the whole doping range. As an essential first step to address this, we optimize a growth procedure for high-quality sputter-deposited $YBa_2Cu_3O_{7-\delta}$ thin films with various hole concentrations by controlling the oxygen content (and by cation doping in the future). Two different approaches have been attempted successfully: annealing in an oxygen-controlled environment and ozonization. We have developed an itin-situ annealing procedure employing two-step post-deposition anneals in vacuum and $O_2$. The oxygen content is estimated from high-resolution x-ray diffraction data. This procedure produces high-quality thin films, optimally doped (e.g., $7\text{-}\delta \approx 6.88$, $T_{c,on}=91.8$ K, and $\Delta T_c < 0.9$ K) and underdoped (e.g., $7\text{-}\delta \approx 6.43$, $T_{c,on}=55.1$ K, and $\Delta T_c < 2.9$ K). Preliminary ozonization experiments show that varying the oxygen content in a controlled manner is feasible, especially in the overdoped regime. We will present detailed transport measurements, materials characterizations, and some initial conductance spectra from planar tunneling and Andreev reflection spectroscopies. *Supported by the U.S. DoE Award No. DEFG02-91ER45439 through the FSMRL and the CMM at UIUC.

**B37 3 Point-contact spectroscopy of the electron-doped cuprate superconductor $Pr_{2-x}Ce_xCuO_4$ in magnetic fields up to 32 tesla*** SUNGHEE YUN, TARA DHAKAL, JACOB TOSADO, AMLAN BISWAS, *Department of Physics, University of Florida, Gainesville, FL* BING LIANG, RICHARD GREENE, *Center for Superconductivity Research, University of Maryland, College Park, MD* Tunneling spectra of the normal state of electron-doped cuprates at low temperatures and in magnetic fields higher than the upper critical field ($H_{c2}$) have shown evidence of a pseudogap. However, to understand if the origin of this pseudogap is the same as the pseudogap observed in hole-doped cuprates and to determine the theoretical model it supports, it is necessary to study the effect of high magnetic fields on this pseudogap. Point contact spectroscopy (PCS) was carried out on junctions between electron doped cuprate $Pr_{2-x}Ce_xCuO_4$ (PCCO, $0.13 < x < 0.17$) single crystals and normal metal (Pt-Rh). To probe the normal state at low temperatures ($T \sim 1.5$ K), the superconductivity was suppressed by applying high magnetic fields (up to 32 T). These experiments showed that the normal state gap is present for all the dopings, including the overdoped one. These results at high magnetic fields can be interpreted as a combined effect of precursor superconductivity and the presence of disorder in these materials.

**11:51**

**B37 4 Density of state correlations in pseudogap systems** MARIANNA MALTSEVA, *Rutgers University* PIERS COLEMAN, *Rutgers University* Developments in the scanning tunneling microscopy and spectroscopy (STM/STS), make it possible to probe the detailed position and energy- dependent density of states in electronically inhomogenious media [1,2]. Theoretical analysis to date has focused on the spatial autocorrelations of the density of states as a probe of the quasiparticle spectrum. In this work we discuss how correlations between the density of states above and below the Fermi energy can be used to discern the underlying nature of the pseudogap order. We can divide the density of states fluctuations into components that are symmetric and antisymmetric about the Fermi energy. Density waves produce a signal in the antisymmetric channel whereas superconductors produce a signal in the symmetric channel. Moreover, a careful analysis of the momentum dependence can be used to discern between off-diagonal and diagonal disorder [3]. We will present our theory of these topics. [1] H. C. Fu, J. C. Davis, and D.-H. Lee, cond-mat/0403001. [2] J.-X. Zhu, K. McElroy, J. Lee, T. P. Devereaux, Qimiao Si, J.C. Davis, and A.V. Balatsky, cond-mat/0507621. [3] T.S. Nunner, B.M. Andersen, A. Melikyan, and P.J. Hirschfeld, Phys. Rev. Lett. 95, 177003 (2005).

**B37 5 Observation of the pseudogap features in overdoped Bi2Sr2CaCu2O8+d by breakjunction tunneling spectroscopy*** Y. XUAN, H. J. TAO, Z. Z. LI, B. R. ZHAO, Z. X. ZHAO, *National Laboratory for Superconductivity, Institute of Physics and Center for Condensed Mater Physics, Chinese Academy of Sciences, China* C.T. LIN, *Max-Planck-Institut für Festkörperforschung, 70569 Stuttgart, Germany* Tunneling measurements of Bi2Sr2CaCu2O8+d single crystals with different oxygen doping have been carried out by using break-junction technique to study the pseudogap in the overdoped regime. The normal-state pseudogap has been observed clearly in the three overdoped crystals with Tc = 90 K, 82 K, and 72 K, respectively. Furthermore, direct measurements on the pseudogap opening temperature T*, by tracing the disappearance of the tunneling conductance peak, reveal that the relationship of T* versus hole concentration is linear and its extrapolation just crosses the end of the superconducting phase boundary.

**12:15**

**B37 6 Gap Inhomogeneity-Induced Electronic States in Superconducting $Bi_2Sr_2CaCu_2O_{8+\delta}$** ALAN FANG, *Stanford University* LUCA CAPRIOTTI, *Credit Suisse First Boston, Ltd. (Europe)* DOUG SCALAPINO, *University of California, Santa Barbara* STEVE KIVELSON, *Stanford University* NOBU KANEKO, *National Institute of Advanced Industrial Science and Technology (Japan)* MARTIN GREVEN, AHARON KAPITULNIK, *Stanford University* We use STM to measure nearly optimally doped $Bi_2Sr_2CaCu_2O_{8+\delta}$ in zero field. Focusing on the superconducting gap, we find patches of what appear to be two different phases in a background of some average gap, one with a relatively small gap and sharp large coherence peaks and one characterized by a large gap with broad weak coherence peaks. We compare these spectra with calculations of the local density of states for a simple phenomenological model in which a $2\xi_0 \times 2\xi_0$ patch with an enhanced or supressed d-wave gap amplitude is embedded in a region with a uniform average d-wave gap.

**12:27**

**B37 7 Electronic modulations in the pseudogap state of $Bi_2Sr_2CaCu_2O_{8+d}$ and $Ca_{2-x}Na_xCuO_2Cl_2$*** ABHAY PASUPATHY, AAKASH PUSHP, KENJIRO GOMES, *Princeton University* SHIMPEI ONO, *CRIEPI* YASUSHI ABE, *AIST* YOICHI ANDO, *CRIEPI* HIROSHI EISAKI, *AIST* KYUNG HEE KIM, HYE KYONG LEE, SUNG-IK LEE, *POSTECH* ALI YAZDANI, *Princeton University* The nature of the local modulations of the density of states (DOS) found in the pseudogap regime of the cuprates is still a mystery. Using variable-temperature scanning tunneling spectroscopy we observe non-dispersive spatial DOS modulations in the pseudogap state of $Bi_2Sr_2CaCu_2O_{8+d}$ (1) and $Ca_{2-x}Na_xCuO_2Cl_2$ (2). We will compare the nature of modulations found in these materials to various models such as those arising from interference effects due to impurity scattering or from local electronic organization. We will also discuss the spatial variation of the pseudogap in $Bi_2Sr_2CaCu_2O_{8+d}$ and $Ca_{2-x}Na_xCuO_2Cl_2$. **12:39**

**B37 8 Influence of vortex quantum fluctuations on the electronic spectra of superconductors** LORENZ BARTOSCH, *Harvard University* SUBIR SACHDEV, *Harvard University* We compute the influence of the zero point motion of vortices on the electronic quasiparticle spectra of two-dimensional *s*- and *d*-wave superconductors. In the core region the zero point motion of the vortices leads to a shift of spectral weight away from the Fermi level and thereby reduces the zero bias conductance peak. We discuss the relationship of our results to STM measurements on the cuprates and the observed 7 meV LDOS peaks near the core of vortices.

**12:51**

**B37 9 Local effects of impurities on the Pseudogap State of Bi-2212*** KENJIRO GOMES, *Princeton University* AAKASH PUSHP, *Princeton University* ABHAY PASUPATHY, *Princeton University* SHIMPEI ONO, *CRIEPI* YASUSHI ABE, *AIST* YOICHI ANDO, *CRIEPI* HIROSHI EISAKI, *AIST* ALI YAZDANI, *Princeton University* Some of the most surprising properties of the cuprates are found in the pseudogap state, above the superconducting transition temperature Tc on underdoped samples. Modifications of the local density of states (LDOS) due to the presence of atomic impurities can unveil clues about the nature of the pseudogap. Using atomically resolved scanning tunneling spectroscopy we map the LDOS near Zn and Ni impurities in Bi-2212 above Tc. We find modifications of the pseudogap LDOS near both Ni and Zn sites. We will report on the spatial dependence of these variations and how they relate to the underlying pseudogap state.

**B37 10 Scanning Tunneling Spectroscopy Studies of Current-Carrying Superconductors*** J. NGAI, P. MORALES, J. Y. T. WEI, *Department of Physics, University of Toronto* Understanding how a superconducting order parameter evolves in the current-carrying state is of fundamental physical importance. In this talk we present novel applications of scanning tunneling spectroscopy (STS) on current-carrying superconductors, with the current either directly applied [D. Zhang et al., Phys. Rev. B 70, 172508 (2004)] or induced by a magnetic field [G. Deutscher, Rev. Mod. Phys. 77, 109 (2005)]. We will discuss STS measurements on YBa2Cu3O7 thin-film strips under directly-applied current, showing suppression of the d- wave Andreev states [J. Ngai et al. Phys. Rev. B 72, 054513 (2005)]. We will also discuss more recent STS experiments on high-Tc and other superconductors, performed under magnetic field-induced currents.

**B37 11 High Precision Spectroscopic Imaging of Single Layer Cuprate: $Bi_2Sr_{1.6}La_{0.4}CuO_{6+x}$** A.M. WANG, J. LEE, J. SLEZAK, *LASSP, Dept. of Physics, Cornell University* K. FUJITA, *Dept. of Adv. Mater. Sci., University of Tokyo* H. EISAKI, *AIST, Japan* S. UCHIDA, *Dept. of Physics, University of Tokyo* J.C. DAVIS, *LASSP, Dept. of Physics, Cornell University* We present high spatial resolution scanning tunneling spectroscopy (STS) study of single layer cuprate $Bi_2Sr_{1.6}La_{0.4}CuO_{6+x}$. The sample is optimally doped, with $T_c = 34$K. We focus on two main points: (1) Quasiparticle interference pattern obtained by Fourier transform of high resolution local density of states (LDOS) map, (2) LDOS map shows even stronger nanoscale electronic disorder than double layer cuprate $Bi_2Sr_2CaCu_2O_{8+x}$ of similar doping. Inside the primary energy gap, at very low energies, small LDOS peaks emerge and exhibit short range modulations in their heights. Scattering by La substitution on Sr sites may be key to these new phenomena.

**13:27**

**B37 12 Atomic-resolution tunneling asymmetry mapping in $Ca_{2-x}Na_xCuO_2Cl_2$: charge distribution, crystal distortion and superconducting electronic structure properties of glassy electronic nanodomains** Y. KOHSAKA, C. TAYLOR, *LASSP, Cornell University* C. LUPIEN, *Universite de Sherbrooke* T. HANAGURI, H. TAKAGI, *RIKEN* M. AZUMA, M. TAKANO, *Kyoto Univerisity* J. C. DAVIS, *LASSP, Cornell University* We report spectroscopic imaging on the electronic state in a lightly-doped high-$T_c$ superconductor $Ca_{2-x}Na_xCuO_2Cl_2$. Conductance maps at $|E| < 100$ mV show $4a_0$ correlation 'checkerboard' patterns ($a_0$: in-plane lattice constant) [1]. At higher energies, the electronic state shows strong hole-electron asymmetry changing with the doping levels. The asymmetry integrated up to 600 mV changes at atomic scale and exhibits spatial patterns with $4a_0$ correlation, consistent with spatial modulation of hole density [2]. At intermediate energies, the asymmetry structures locally break rotational symmetry of background lattice, forming uni-directional and glassy nano-domains with $4a_0$ correlation. In-plane oxygen atoms appear electronically inequivalent, implying oxygen orbitals are key for physics in this energy range. We also discuss atomic motions and relationship of superconductivity to the glassy electronic nano-domains. [1] T. Hanaguri *et al.*, Nature 430, 1001 (2004). [2] M. Randeria *et al.*, PRL 95, 137001 (2005).

**13:39**

**B37 13 Low energy spectroscopic mapping study on $(Ca,Na)_2CuO_2Cl_2$** T. HANAGURI, *RIKEN (Inst. Phys. and Chem. Research)* Y. KOHSAKA, J. C. DAVIS, *LASSP, Cornell University* I. YAMADA, M. AZUMA, M. TAKANO, *Inst. Chem. Research, Kyoto University* K. OHISHI, *Japan Atomic Energy Agency* H. TAKAGI, *RIKEN (Inst. Phys. and Chem. Research) / University of Tokyo* Spatial variations of the low energy ( $<$ 50 meV) local density of states (LDOS) spectra of $(Ca,Na)_2CuO_2Cl_2$ ($T_c \sim$ 25 K) have been studied using scanning tunneling microscopy/spectroscopy (STM/STS) in the temperature range between 0.4 K and 20 K. Previous STM/STS studies revealed the checkerboard-like glassy electronic order which is associated with a V-shaped pseudogap $\sim$ 150 mV. [1] We have found another small gap ( $\sim$ 10 mV) with LDOS peaks at the gap edges. The gap-edge peak is spatially inhomogeneous and tends to disappear at elevated temperatures, suggesting that the small gap is related to superconductivity. [1] T. Hanaguri *et al.*, Nature **430**, 1001 (2004).

**13:51**

**B37 14 Many-Impurity Effects in Fourier Transform Scanning Tunneling Spectroscopy** WILLIAM ATKINSON, *Trent University* Fourier transform scanning tunneling spectroscopy (FTSTS) is a useful technique for extracting details of the momentum-resolved electronic band structure from inhomogeneities in the local density of states due to disorder-related quasiparticle scattering. To a large extent, current understanding of FTSTS is based on models of Friedel oscillations near isolated impurities. Here, a framework for understanding many-impurity effects is developed based on a systematic treatment of the variance $\Delta\rho^2(\mathbf{q},\omega)$ of the Fourier transformed local density of states $\rho(\mathbf{q},\omega)$. One important consequence of this work is a demonstration that the poor signal-to-noise ratio inherent in $\rho(\mathbf{q},\omega)$ due to randomness in impurity positions can be eliminated by configuration averaging $\Delta\rho^2(\mathbf{q},\omega)$. Furthermore, we develop a diagrammatic perturbation theory for $\Delta\rho^2(\mathbf{q},\omega)$ and show that an important bulk quantity, the mean-free-path, can be extracted from FTSTS experiments.

**B37 15 Atomic-resolution Inelastic Electron Tunneling Spectroscopy studies of doping dependence of electron-boson interaction in Bi-2212** JINHO LEE, *Cornell University* K. MCELROY, *Lawrence Berkeley Laboratory* J. SLEZAK, *Cornell University* K. FUJITA, *University of Tokyo, Japan* J.-X. ZHU, *Los Alamos National Laboratory* A.V. BALATSKY, *Los Alamos National Laboratory* S. UCHIDA, *University of Tokyo, Japan* H. EISAKI, *University of Tokyo, Japan* J.C. DAVIS, *Cornell University* Inelastic Electron Tunneling Spectroscopy(IETS) has been one of the most powerful tool to probe collective modes in the solids. We use the recently developed itSTM-based Atomic-resolution Inelastic Electron Tunneling Spectroscopy(IETS) technique to study the doping dependence of the electron-boson interactions(EBI) in Bi-2212 high-Tc cuprates. According to our results, the distribution of the bosonic mode energy($\Omega$) does not change as doping level changes, while the gap distribution changes greatly. Also $\Omega$-maps show nano-scale disorder. We will discuss the possible origin of this doping independent EBI.

**SESSION B38: SUPERCONDUCTING DEVICES AND APPIICATIONS**

**B38 1 Transition-edge sensors based on superconducting nanowires.** MATTHEW BELL, ANDREI SERGEEV, *University at Buffalo* GREGORY GOLTSMAN, *Moscow State Pedagogical University* JONATHAN BIRD, ALEKSANDR VEREVKIN, *University at Buffalo* We present our experimental study of superconducting NbN nanowire-based sensor. The responsivity of the sensor is strongly affected by the superconducting transition width of the nanostructure, which, in turn, is determined by the phase slip centers (PCSs) dynamics. The fluctuations and noise properties of the sensor are also discussed, as well as the devices' behavior at high magnetic fields. The ultimate performance of the sensor and prospects of the devices will be discussed, as well.

**11:27**

**B38 2 Frequency Noise in Superconducting Thin-Film Resonators** SHWETANK KUMAR, *Caltech* PETER DAY, HENRY LEDUC, BENJAMIN MAZIN, *JPL* MEGAN ECKART, JIANSONG GAO, *Caltech* JONAS ZMUIDZINAS, *Caltech* We present the results of low temperature (120 – 1200 mK) noise measurements performed on thin-film superconducting niobium resonators fabricated on a silicon substrate. The devices studied use coplanar waveguide (CPW) transmission lines and have resonance frequencies of around 4 GHz and quality factors in the range of Q $\sim$ $10^4$ to $10^6$. These resonators are similar to those used to make novel photon detectors and read out charge qubits. These resonators show excess frequency noise which varies as approximately $f^{-1/2}$. This excess noise limits the sensitivity of our photon detectors and likely effects the qubit performance as well. Two level systems (TLS) in amorphous thin-film dielectrics and oxide tunnel barriers have been shown to cause dissipation and decoherence in phase qubits. We suggest that noise in our resonators is also caused by TLS most likely near the surfaces of the substrate and metal films. To test this idea, we have measured the frequency shift, the quality factor and the frequency noise as a function of the device temperature and the microwave readout power. The frequency shift data agrees well with existing weak field TLS theory. We also find that the frequency noise decreases with increasing readout power and temperature and that decreased noise at higher powers is not due to simply device heating.

**11:39**

**B38 3 Measurement of environmental impedance at plasma frequency of Josephson junctions with microwave induced escapes** BO MAO, SIYUAN HAN, *Department of Physics and Astronomy, University of Kansas* Impedance of electromagnetic environment of a Josephson junction is critical to its dynamics. We show that microwave induced escape rate of Josephson junctions as a function of microwave frequency and power provides an excellent quantitative measurement of the environmental impedance at plasma frequency of the junction. It is shown that in strong microwave fields the effect of anharmonicity of the junction's potential well must be taken into account. Direct comparison of experimental result with numerical simulation allows one to extract environmental impedance at junction's plasma frequency.

**11:51**

**B38 4 Probing superconducting samples using a two-superconducting-nanowire device** DAVID PEKKER, *University of Illinois at Urbana-Chanmpaign* ALEXEY BEZRYADIN, DAVID S. HOPKINS, PAUL M. GOLDBART, An NQUID (nanowire SQUID) is a device featuring two thin-film superconducting leads connected by a pair of parallel narrow superconducting wires [1,2]. Thermal fluctuations of the order parameter in the superconducting wires endow the device with a nonzero lead-to-lead resistance ($R$). For short wires, $R$ also depends on the phase profile of the order parameter in the leads. Here, we consider the situation in which one of the leads carries a supercurrent perpendicular to the wires (a cross-current). We show that $R$ is a periodic function of this cross-current. Minima of $R$ occur whenever the phase-gain between the wire attachment-points along the lead carrying the cross-current is an integer multiple of $2\pi$. NQUID devices such as these may be useful for probing superconducting order in the leads or determining current-phase relations in various settings. The results of experiments on devices carrying cross-currents will be presented in a companion talk by Hopkins et al. [1] Hopkins et al., Science 308, 1762 (2005). [2] Pekker et al., Phys. Rev. B 72, 104517 (2005).

**12:03**

**B38 5 Measurement of superconducting phase gradients using a DNA-templated nanowire interference device** DAVID S. HOPKINS, DAVID PEKKER, PAUL M. GOLDBART, ALEXEY BEZRYADIN, *University of Illinois at Urbana-Champaign* We have fabricated an NQUID (i.e., a Nanowire SQUID) [1,2] in which two thin ( $\sim$ 15 nm) superconducting nanowires templated by DNA molecules are used to directly measure phase gradients of the Ginzburg-Landau order parameter along a superconducting strip of width $\sim$ 1 $\mu$m. A supercurrent flowing along the strip creates a phase difference between the contact-points of the nanowires. This causes the resistance of the two-wire device to oscillate as a function of the current flowing along the strip with a period equal to the amount of current required to create a $2\pi$ phase difference between the contact-points of the wires. We find that the period increases with decreasing

temperature, due to the increase in superfluid density in the film. Using this device we are able to study the process of superconductivity suppression in the thin film strip caused by a high bias-current and/or a magnetic field. A theory of the operation of such NQUIDs will be presented in a companion talk by Pekker et al. [1] Hopkins et al., Science 308, 1762 (2005). [2] Pekker et al., Phys. Rev. B 72, 104517 (2005).

**12:15**

**B38 6 Impedance matching using superconducting planar spiral inductors** UTKU KEMIKTARAK, *Physics Department, Boston University* KEITH SCHWAB, *Laboratory for Physical Sciences* KAMIL L. EKINCI, *Department of Aerospace and Mechanical Engineering, Boston University* We discuss the use of superconducting Nb inductors for impedance matching. The micro-fabricated inductors we used in our experiments had submicron line-widths with 50 to 200 turns. We first characterized these inductors by measuring their inductances, quality factors and self resonance frequencies. Then we compared these results with existing models. With the measured parameters, we showed that these inductors could be used for matching impedances on the order of megaohms to 50 $\Omega$.

**12:27**

**B38 7 Microstrip SQUID amplifiers with cooling fins*** DARIN KINION, *LLNL* JOHN CLARKE, *UC Berkeley and LBNL* Amplifiers based on dc SQUIDs (superconducting quantum interference devices) with integrated input coils configured as a microstrip resonator operate at frequencies between 50 MHz and 2 GHz, and in principle are capable of reaching the Standard Quantum Limit (SQL) for linear amplifiers. The SQUIDs are fabricated with Nb-AlOx-Nb tunnel junctions with Pd shunt resistors to eliminate hysteresis. In practice, Johnson noise in the shunt resistors often limits the noise temperature before the SQL is reached. To reduce this noise contribution we have attached large area cooling fins to the shunts to minimize hot- electron effects when the amplifier is operated at miilikelvin temperatures. Previous measurements were performed at frequencies corresponding to peak gain, but theory predicts that the lowest noise temperature should be attained at a slightly lower frequency. We have measured the noise temperature of a number of devices as a function of frequency and bath temperature. We compare our results to the predicted frequency dependence of the noise temperature and to the predicted value of the SQL.

**B38 8 RF Amplifiers Based on DC SQUID for 3-4 GHz Band*** G.V. PROKOPENKO, K.D. OSBORN, *National Inst. of Standards and Tech. - Boulder* S.V. SHITOV, *Inst. of Radio Engineering and Electronics, Moscow, Russia. Natl. Astronomical Observatory of Japan, Mitaka, Japan.* M. MAEZAWA, *Natl. Inst. of Advanced Industrial Science and Technology, Tsukuba.* A.J. SIROIS, K. CICAK, R.W. SIMMONDS, *National Inst. of Standards and Tech. - Boulder* DC SQUID based RF Amplifiers (SRFAs) are known to dissipate very little power and can be integrated on-chip with existing micro-fabricated circuits for low-noise, low temperature measurements. The SRFA chip has 4 independent channels, which amplify at different signal frequencies and have integrated output filters, which prevent the leakage of high frequency resonances associated with the Josephson frequency. A compact two-layer input signal coil is integrated with the washer of the SQUID (L=20 pH) and planar capacitors for tuned frequency and impedance matching. The input reflected power is further reduced using proven balanced configuration on the SQUID. The shunt resistors are made from a multilayer film Ti(2 nm)/Pd(55 nm)/Ti(2 nm), which allow the SRFA to operate down to 0.4 K. Low-noise SRFAs have been tested with an operating frequency range of 3-4 GHz.

**12:51**

**B38 9 SQUID-detected magnetic resonance imaging in zero static magnetic field** N. KELSO, S-K. LEE, L. BOUCHARD, V. DEMAS, A. PINES, J. CLARKE, *UC Berkeley and LBNL* Conventional magnetic resonance imaging (MRI) is performed in a static homogenous magnetic field $B_0$ in the presence of applied field gradients that generate a magnetic field change $\Delta B << B_0$ across the sample. In this case, the concomitant gradients can be ignored and the applied gradients are unidirectional. When $\Delta B \sim B_0$, this approximation breaks down and the concomitant gradients distort the image. In the limit $B_0 \rightarrow 0$ these distortions can be eliminated by means of a pulse sequence consisting of a train of short, spatially uniform magnetic field pulses. Between the pulses, the spins evolve in a pure gradient field (with zero spatial average). The effect of the pulse train is to average out the concomitant terms to leave an effectively unidirectional gradient field (Meriles itet al., itPNAS 102, 1840 (2005)). We acquire magnetic signals with a superconducting gradiometer coupled to the input loop of a low-transition temperature superconducting quantum interference device. Using this pulse sequence we have acquired undistorted two-dimensional images of methanol phantoms in a residual static field $< 1\ \mu$T. Supported by USDOE.

**13:03**

**B38 10 Fast Non-Destructive Evaluation of Superconducting Magnet Wires using a Flow-Through SQUID Microscope*** JOHN MATTHEWS, FREDERICK WELLSTOOD, *University of Maryland* HAROLD WEINSTOCK, *Air Force Office of Scientific Research* We have developed a cryocooled high-Tc SQUID microscope for fast non-destructive evaluation (NDE) of long wires, designed for detecting defects in superconducting magnet wire. A feedthrough mechanism pulls the wire at speeds of up to 20 cm/s through a thin mylar tube that separates the room temperature wire from the SQUID. We present results on test wires where we detect defects down to about 0.3 mm diameter. We discuss how we extract information from the data, such as defect size and location, and also outline a method for fast automated detection of defects in long wires.

*Supported by the Center for Superconductivity Research, and Air Force Office of Scientific Research

**13:15**

**B38 11 Low-field SQUID MRI: To tune or not to tune?** MICHAEL HATRIDGE, WHITTIER MYERS, MICHAEL MÖßLE, NATHAN KELSO, JOHN CLARKE, *UC Berkeley / LBNL* BEN INGLIS, *UC Berkeley* ANDREAS TRABESINGER, *110 Stapleton Hall Rd., London N4, UK* Our magnetic resonance imaging (MRI) system detects protons precessing at 5.6 kHz in a 132-$\mu$T field using a superconducting quantum interference device (SQUID) coupled to an untuned superconducting second-order gradiometer with 65-mm diameter coils. The magnetic flux noise of the SQUID corresponds to a magnetic field noise of 0.4 fT $Hz^{-1/2}$. We consider whether the use of a tuned input circuit could

reduce the noise. The high intrinsic quality factor of the superconducting circuit must be damped to obtain the bandwidth required for MRI. The simplest approach is to insert a resistor in series with the gradiometer. However, the associated Nyquist noise causes this configuration to underperform the untuned version at frequencies below 100 kHz. In a more sophisticated approach Seton and coworkers damped the input circuit by coupling the SQUID output to the pickup coil. In principle, such feedback damping enables the tuned detector to achieve a field noise of 0.05 fT $Hz^{-1/2}$ at 5.6 kHz. The relative merits of these approaches over a wide frequency range are discussed. Work supported by USDOE.

**13:27**

**B38 12 SQUID-detected microtesla MRI: a new modality for tumor detection?** MICHAEL MÖßLE, SARAH BUSCH, MICHAEL HATRIDGE, WHITTIER MYERS, ALEXANDER PINES, JOHN CLARKE, *UC Berkeley and LBNL* LARS SCHMITT, JEFF SIMKO, *UC San Francisco* We are investigating the use of low-field magnetic resonance imaging with enhanced longitudinal-relaxation-time ($T_1$)-weighted contrast to detect tumors. Our technique involves prepolarizing the sample in a magnetic field up to 0.3 T and detecting the nuclear magnetic resonance (NMR) signal at microtesla fields using a superconducting quantum interference device. This technique enables us to obtain $T_1$ dispersion curves and $T_1$-weighted contrast images in fields from 1.4 $\mu$T to 0.3 T. We have shown that for materials such as agarose gel the $T_1$-weighted contrast is greatly enhanced in microtesla fields. To investigate the use of this enhancement for tumor imaging we measured the $T_1$ relaxation times of healthy and cancerous tissue specimens, maintained at 4[r]C, shortly after their surgical removal. To minimize artifacts we measured normal and cancerous tissues simultaneously and separated their NMR signals by applying a magnetic field gradient. We present $T_1$ dispersion curves for several sets of samples, and discuss the applicability of this technique to itin vivo imaging. Work supported by USDOE.

**B39 1 Low temperature penetration depth measurements as a probe of anisotropic superconductivity in $NbSe_2$** ANTONY CARRINGTON, *University of Bristol, U.K.* JON FLETCHER, *University of Bristol, U.K.* PIERRE RODIERE, *CRTBT, Grenoble, France* Measurements of the field dependent thermal conductivity [1] and angle resolved photoemission spectroscopy (ARPES) [2] have provided evidence for strong gap anisotropy in $NbSe_2$ ($T_c \simeq 7.2$ K). A key result of the ARPES study was that one of the sheets of Fermi surface has a much smaller energy gap than the others. Here we investigate the gap structure of $NbSe_2$ using measurements of the temperature dependence of the magnetic penetration depth in single crystal samples at temperature down to less than 0.1 K. Although there is evidence for moderate gap anisotropy (around a factor two) we do not find any evidence for the energy gap being as small as suggested by the ARPES measurements on any sheet of Fermi surface. We will compare these $\lambda(T)$ measurements to specific heat measurements on the same samples. [1] Boaknin *et al.*, Phys. Rev. Lett. **90**, 117003 (2003) [2] Yokoya *et al.* Science **294**, 2518 (2001).

**B39 2 Phase-sensitive measurements of harmonic response in high-Tc superconducting thin films by means of local microwave microscopy** DRAGOS MIRCEA, STEVEN ANLAGE, *Center for Superconductivity Research, Department of Physics, University of Maryland* The microscopic origins of Meissner-state nonlinearities in superconductors are still not clear. Traditionally, microwave nonlinear measurements of superconducting thin films employ a spectrum analyzer to measure the power carried by the harmonic signals ($P_{2f}$and $P_{3f}$). Such measurements have provided strong evidence for the Nonlinear Meissner Effect (NLME) at the critical temperature $T_c$ in cuprates [PRB 71, 014507 (2005)]. Investigations of the NLME in underdoped $YBa_2Cu_3O_{7-\delta}$ (YBCO) thin films have revealed the existence of an additional nonlinear mechanism that onsets at $T_c$ and leads to the persistence of $P_{3f}$ above $T_c$, a feature which has not been observed in optimally-doped samples. A possible nonlinear source active at and slightly above $T_c$ is the current-dependent normal conductivity, as proposed earlier by Mishonov and co-workers [PRB 65, 064519 (2002)]. The measurements performed with a spectrum analyzer do not provide phase information about the harmonic signals and therefore the nature of the nonlinear source (inductive vs. resistive) remains undetermined. However, nonlinear phase-sensitive measurements can be carried out with a network analyzer in the frequency offset mode and such data are instrumental in disentangling the effects of different types of nonlinear mechanisms. **B39 3 Doping Dependence of the Magnetic Penetration Depth and Coherence Length in $YBa_2Cu_3O_y$** JEFF SONIER, FERGAL CALLAGHAN, *Simon Fraser University* JESS BREWER, WALTER HARDY, DOUG BONN, RUIXING LIANG, *University of British Columbia* While linear scaling of $T_c$ with superfluid density has been inferred from early muon depolarization rate ($\sigma$) measurements on high-temperature superconductors, this interpretation of $\mu$SR data assumes an invalid relation between $\sigma$ and the in-plane magnetic penetration depth $\lambda_{ab}$. From detailed measurements and analysis of the $\mu$SR line shapes in $YBa_2Cu_3O_y$ single crystals, we have accurately determined the doping dependence of $\lambda_{ab}$ and the superconducting coherence length $\xi_{ab}$. We find that $T_c$ exhibits a sublinear dependence on $1/\lambda_{ab}^2$, and that $\xi_{ab}$ increases with decreasing hole doping. In addition, the $\mu$SR line shapes for $y = 6.50$ are found to be consistent with $y = 0$ antiferromagnetism in and around the vortex cores, compatible with static stripes. We find that the antiferromagnetic order occurs only where superconductivity is suppressed, indicating that the ordering of copper spins competes with high-temperature superconductivity.

**B39 4 A magnetic analog of the isotope effect in cuprates** RINAT OFER, GALINA BAZALITSKY, AMIT KANIGEL, AMIT KEREN, ASSA AUERBACH, *Technion - Israel Institute of Technology* JAMES LORD, *Rutherford Appleton Laboratory, UK* ALEX AMATO, *Paul Scherrer Institute, Switzerland* Since the discovery of superconductivity in the cuprates, it has been speculated that their pairing mechanism is due to magnetic inter-

actions. However, this was never proven. Such a proof would require an experiment similar to the isotope effect in metallic superconductors, namely, a measurement of $T_c$ versus the in-plane super-exchange J, with no other structural changes. We have done this experiment using the $(Ca_xLa_{1-x})(Ba_{1.75-x}La_{0.25+x})Cu_3O_y$ system with its 4 different families having different $T_c^{max}$. For each family, we measured the Néel Temperature $T_N$, the anisotropies of the magnetic interactions, the spin glass temperature $T_g$ of underdoped samples, and, of course, $T_c$ from under to overdoped compounds. These properties were determined using the zero field muon spin resonance ($\mu$SR) technique, where one injects polarized muons into the sample and measures the time evolution of their spin polarization. Our measurements allow us to demonstrate that $T_c^{max} J_f^{-1}$ =const where f is a family index, and to prove experimentally that pairing in the cuprates stems from magnetic interactions.

**B39 5 Magnetization curves in underdoped cuprates measured at low T in fields up to 45 Tesla** LU LI, *Physics Department, Princeton University* YAYU WANG,* *Physics Department, Princeton University* MIKE NAUGHTON, *Boston College* S. ONO, *Central Research Inst., Electric Power Industry, Tokyo* YOICHI ANDO, *Central Research Inst.,Electric Power Industry, Tokyo* NAI PHUAN ONG, *Physics Department, Princeton University* Torque magnetometry is capable of resolving the weak diamagnetic which extends to temperatures $T \gg T_c$ in hole-doped cuprate crystals. Recently, we reported[1] that the magnetization $M$ above $T_c$ scales accurately as the Nernst signal $e_N$ and remains robust to fields of 33 T. The results strongly support the scenario in which thermally created vortices destroy long-range phase coherence at $T_c$. We have extended these studies to explore the fluctuation magnetization to 45 T in underdoped LSCO and Bi 2201 in a series of samples doped near the critical value $x_c \sim 0.055$. We investigate the loss of phase coherence as we decrease $x$ below $x_c$ keeping $T$ as low as 0.5 K. We use the $M$-$H$ curves to explore how singular phase fluctuations occur as superfluidity is destroyed when $x$ approaches the insulating Mott limit at low $T$. *Supported by NSF grant (DMR 0213706). 1. **B39 6 Superconductivity and Glassiness in Strongly Underdoped $Y_{1-x}Pr_xBa_2Cu_3O_{7-\delta}$*** C. C. ALMASAN, V. SANDU, P. GYAWALI, *Kent State University* B. J. TAYLOR, M. B. MAPLE, *University of California at San Diego* We performed magnetic investigations on single crystals of $Y_{0.47}Pr_{0.53}Ba_2Cu_3O_{7-\delta}$ ($T_c$ = 7.0 K) at temperatures $4 < T < 80$ K. Magnetization $M$ vs field $H$ data measured at $T > 6.3$ K exhibit an evolution from a hysteretic loop ty pical for superconducting mixed state at low $H$ to one typical for a spin glass state at high $H$. The latter opens as a separate loop above the irreversible field and expands on the account of the superconducting loop with which overlaps at $T < T_c$. This second loop survives up to temperatures higher than 40 K and shows positive magnetization. The $M$ vs $T$ dependence displays also a hysteresis above $T_c$ for fields between 10 and 60 mT with a maximum width at about 30 mT. Magnetic susceptibility $\chi$ vs $T$ data follow a Curie dependence $\chi(H,T) = C(H)/[T + \theta(H)]$ at low fields with field-dependent $C$ and $\theta$, as for an antiferromagnetic glass. These findings are consistent with the previously reported intrinsic inhomogeneity of the underdoped cuprates, where superconducting and antiferromagnetic nano-droplets coexist over a large $T$ range, while the latter droplets persist up to $T >> T_c$.

**12:27**

**B39 7 FFLO surface bound state** SHI-HSIN LIN, PAWEL REDLINSKI, BOLDIZSAR JANKO, *University of Notre Dame* DANIEL AGTERBERG, *University of Wisconsin - Milwaukee* Here we study the inhomogeneous superconducting phase of heavy fermion superconductor CeCoIn5. Specifically, we propose a possible existence of FFLO surface bound states. We anticipate that the node of FFLO superconducting state would coincide with the surface to lower the energy. The order parameter vanishes at the interface and increases towards the bulk. This is similar to the case in vortex core of type II superconductor in that the normal region is confined by superconducting wall, except that one side now is vacuum. We thus anticipate bound states to exists at the surface, just as the Caroli-de Gennes-Matricon states exist in the vortex core. We will perform a self-consistent calculation using Bogoliubov-de Gennes equation to obtain the bound surface state spectrum, which can be directly compared to scanning tunnelling microscope (STM) measurements.

**12:39**

**B39 8 Current driven FFLO state in unconventional superconductors** MATTHEW SONG, HYEONJIN DOH, HAE-YOUNG KEE, *Dept. of Physics, Univ. of Toronto, Canada* The typical Fulde-Farell-Larkin-Ovchinnikov (FFLO) state is known as the superconducting state with periodic spatial variation of order parameter which becomes stable under a Zeeman magnetic field. Here, we suggest that a kind of FFLO state, Cooper pair with a finite center of mass momentum, can be induced without a magnetic field. We investigate the FFLO state in $d$-wave superconductivity with an external current. In this case, the direction of the induced center of mass momentum of FFLO state is orthogonal to the direction of the external current. We discuss the detail conditions of the gap function for the current driven FFLO state.

**12:51**

**B39 9 Formation of non-unitary state near the upper-critical field of $Sr_2RuO_4$** MASAFUMI UDAGAWA, YOUICHI YANASE, MASAO OGATA, *Dept. of Physics, School of Science, Univ. of Tokyo* We have studied the superconducting state of $Sr_2RuO_4$ under a magnetic field parallel to the superconducting plane. On the basis of quasiclassical analysis, we show that non-unitary $k_y(\hat{\mathbf{z}} - i\alpha\hat{\mathbf{y}})$ state is stabilized right at $H_{c2}$ as a result of the competition between spin-orbit interaction and Zeeman energy. As a magnetic field is lowered, this state changes to unitary $k_y\hat{\mathbf{z}}$ state. On the basis of this crossover, we address the origin of the observed double peaks of specific heat and the disappearance of the double peaks at low fields. We have also investigated the position of the phase transition line proposed by Agterberg in terms of the quasiclassical theory, and determined the magnetic field-temperature phase diagram of $Sr_2RuO_4$.

**B39 10 Conductance characteristics between a normal metal and a two-dimensional Fulde-Ferrell-Larkin-Ovchinnikov superconductor** QINGHONG CUI, *Physics Department, Florida State University* CHIA-REN HU, *Physics Department, Texas A&M University* J.Y.T. WEI, *Physics Department, University of Toronto* KUN YANG, *Physics Department, Florida State University* The Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state has received renewed interest recently due to the experimental indication of its presence in $CeCoIn_5$. In this work we explore the possibility of detecting the phase structure of the order parameter directly using conductance spectroscopy through microconstrictions, which probes the phase sensitive surface Andreev bound states of *d*-wave superconductors. We employ the Blonder-Tinkham-Klapwijk formalism to calculate the conductance characteristics between a normal metal and a 2-dimensional *s*- or *d*-wave superconductor in the Fulde-Ferrell state, for all barrier parameter $z$ from the point contact limit ($z=0$) to the tunneling limit ($z \gg 1$). We find that the zero-bias conductance peak due to these surface Andreev bound states observed in the uniform *d*-wave superconductor is split and shifted in the Fulde-Ferrell state. This work was supported by NSF grant No. DMR-0225698, NSERC, CFI/OIT, MMO/OCE and CIAR. Reference: cond-mat/0510717.

**B39 11 A novel homogeneous superconducting state to compete with the inhomogeneous FFLO states in conductors with exchange or Zeeman split Fermi surfaces** CHIA-REN HU, *Texas A&M University* The Fulde-Ferrell-Larkin-Ovchinikov (FFLO) states have been proposed as the states to replace the usual BCS state when the Fermi surfaces of spin-up and down electrons are sufficiently different due to exchange or Zeeman splitting. The FF state has a space-varying phase and the LO state has an oscillating order-parameter magnitude. Thus both are inhomogeneous states. Here I propose a novel homogeneous state to compete with the FFLO state: Instead of forming Cooper pairing of one spin-up electron of momentum $\mathbf{k}$ and one spin-down electron on momentum $-\mathbf{k}$, this new state involves a generalized Cooper pair which is actually a triplet: One spin-up electron of momentum $(1+\delta)\mathbf{k}$, one spin-down electron of momentum $-(1-\delta)\mathbf{k}$, AND one boson of momentum $-2\delta\mathbf{k}$, which can be a phonon, or a magnon, etc. (This state might also form in Fermion-Boson atomic mixtures, and in quark-gluon plasma.) The value of $\delta$ is such that $(1+\delta)k_F$ is the spin-up Fermi momentum, and $(1-\delta)k_F$ is the spin-down Fermi momentum. Since the boson involved does not have a fixed momentum $\mathbf{q}$, this state is not a density wave state of any sort coexisting with superconductivity. A mean field theory of this state will be presented.

**13:27**

**B39 12 The Fulde-Ferrell-Larkin-Ovchinnikov state in two-dimensional *s*-wave and *d*-wave superconductors*** QIAN WANG, HONGYI CHEN, *Texas Center for Superconductivity, University of Houston, Houston, Texas 77204* CHIA-REN HU, *Department of Physics, Texas A&M University, College Station, Texas 77843* CHIN-SEN TING, *Texas Center for Superconductivity, University of Houston, Houston, Texas 77204* We study the Fulde-Ferrel-Larkin-Ovchinnikov (FFLO) states for two-dimensional superconductors under a strong magnetic field at low temperature. Using a tight-binding model, the spatial variation of the superconducting order parameter is self-consistently determined by solving Bogliubov-de-Gennes equations iteratively. We then calculate the magnetization and the LDOS of the FFLO state. When the magnetic field is parallel to the superconducting plane, our results show that for 2D s-SC (d-SC), 1D stripe (2D lattice) solutions are more energetically favorable. At certain symmetric sites, we find that the features in the local density of states can be ascribed to two types of bound states. We also investigate the effect of impurities on the FFLO state and the vortex structure when the FFLO state is subjected to an orbital magnetic field.

**B39 13 Quantum fluctuations in LOFF superconductors*** KIRILL SAMOKHIN, MAXIM MAR'ENKO, *Department of Physics, Brock University* We study the order parameter fluctuations near the phase transition into the Larkin-Ovchinnikov-Fulde-Ferrell superconducting state at zero temperature. In contrast to the usual normal metal-to-uniform superconductor transition, the fluctuation corrections are dominated by the modes with the wave vectors away from the origin. We find that the superconducting fluctuations lead to a divergent spin susceptibility and a breakdown of theFermi-liquid behavior at the quantum critical point in the clean limit.

**B39 14 Helical phases in broken parity superconductors*** RAMINDER KAUR, *University of Wisconsin-Milwaukee* DANIEL AGTERBERG, *University of Wisconsin-Milwaukee* KAORI TANAKA, *University of Saskatchewan* PAOLO FRIGERI, *ETH, Zurich* MANFRED SIGRIST, *ETH, Zurich* The recently discovered broken inversion superconductors, $CePt_3Si$, $Li_2Pt_3B$, and $Li_2Pd_3B$, have provided a unique opportunity to study the role of broken parity in the superconducting state. In these superconductors, a magnetic field leads to a novel inhomogeneous superconducting state, a helical phase. Although the origin of the helical phase is quite different from another well known inhomogeneous superconducting phase, Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state, the consequences of both phases are similar, for example; a relative enhancement of transition temperature as a function of magnetic field over that of a uniform state. FFLO states are quite unstable and hard to observe experimentally as that exist only in the low temperature and high field regime. Until now, the FFLO state has only been identified in $CeCoIn_5$ as an unusual magnetic field enhanced superconducting state near a quantum critical point. We argue that the helical phases is more stable than the FFLO state and will exist in all broken parity superconductors. We present results on the microscopic quasiparticle structure and the stability of the helical phase in broken inversion superconductors.

**B39 15 Superconductivity in $PrRu_4As_{12}$ single crystals** W. M. YUHASZ, P. -C. HO, T. A. SAYLES, T. YANAGISAWA, N. A. FREDERICK, M. B. MAPLE, *University of California San Diego* Single crystals of the filled skutterudite compound $PrRu_4As_{12}$ were characterized by magnetization, specific heat, and electrical resistivity measurements. These measurements reveal the occur-

rence of superconductivity below $\sim$ 2.4 K. The magnetic susceptibility exhibits behavior consistent with a $Pr^{3+}$ ninefold degenerate $J = 4$ Hund's rule ground state multiplet split in a tetrahedral crystalline electric field with either a nonmagnetic singlet or doublet ground state. Fits to the specific heat data indicate an electronic contribution to the specific heat $\gamma$ of $\sim$ 70 mJ/mol $K^2$ and a Debye temperature $\Theta_D$ of $\sim$ 344 K. The value of $\Delta C/\gamma T_c \approx 1.53$ for $PrRu_4As_{12}$ is close to the weak-coupling BCS value of 1.43. Electrical resistivity measurements in field were used to determine $H_{c2}$ as a function of temperature from which the zero temperature value of the orbital critical field $^*H_{c2}(0)$ was calculated and used to estimate the coherence length $\xi_0$ of $PrRu_4As_{12}$. In contrast to $PrRu_4As_{12}$, the compound $PrOs_4As_{12}$ displays two phase transitions at 2.2 K and 2.3 K in zero field, one of which is antiferromagnetic and the nature of the other is yet to be determined. $PrOs_4As_{12}$ also displays heavy fermion behavior with an enhanced electronic specific heat coefficient $\gamma$ on the order of 200 mJ/mol $K^2$ and a $\Theta_D$ of only 260 K. This research was supported by the U.S. DOE (No. DE-FG02-04ER46105) and NSF (No. DMR 0335173).

**11:15**
**B40 1 Bell's inequalities: derivation, violation, and implications** LOUIS SICA, *Naval Research Laboratory (Retired)* Cross-correlations among jointly present data sets satisfy the Bell inequality as a fact of mathematics. Violation of Bell's inequalities by data correlations obtained in independent trials of quantum mechanical correlation experiments shows that a wide-sense spatially stationary (in angle) process cannot account for the Bell cosine correlation. Since the correlations usually measured are cosinusoidal, at least one variable pair of those constrained by a Bell's inequality must have a correlation function different from the usual cosine in order to satisfy the inequality. When nonlocal information is used to construct correlations among real and counterfactual measurements, the correlation functions obtained are not all of the simple cosine form, and the set of correlations satisfies the Bell inequalities. Thus, the resulting correlations are not based on a wide-sense stationary process. The same conclusion holds for properly correlated experimental data. These considerations may be extended to the domain of well-known inequalities in probabilities that follow from the correlational inequalities upon assuming a simple symmetry condition. Such results imply that a proof of nonlocality based on Bell's inequality violation must use different reasoning from that used historically.

**11:27**
**B40 2 Correlated observables in field theoretic terms: single- and multi-particle systems** IAN DURHAM, *Saint Anselm College* In recent years correlations between two degrees of freedom for a single particle have been experimentally demonstrated and further experiments have been suggested. This has presented a more direct test of non-contextuality. The results indicate that quantum mechanical entanglement is a more complex process than non-local theories generally suggest. The nature of both the single-particle and multi-particle entanglement processes suggest that perhaps a field theoretic solution is tenable where measurements actually transform the entire field.

**11:39**
**B40 3 Differences between the Measurement Process and Schrödinger Evolution** STEINER MICHAEL, *NRL* An overview of the Measurement Problem is given and an argument is presented that reduces the measurement problem to a 2-qubit problem of entanglement. In current experiments, the measurement problem has not been a limitation on what can be predicted. If the problem were to continue to not be a limitation for all future experiments of interest, then the problem may be interesting from a philosophical perspective, but is not limiting in terms of physical predictions. However, the author will show examples to illustrate why this is not the case. Certain experiments would be incorrectly predicted if the measurement process were replaced by Schrödinger evolution. Hence understanding the reason for measurement is of primary interest. A new direction toward developing a comprehensive theory will be proposed.

**11:51**
**B40 4 Inference of Schrödinger Equation from Classical-Mechanics Solution*** JX ZHENG-JOHANSSON, *IOFPR, SWE* P-I JOHANSSON, *Uppsala Univ, SWE* We set up the classical wave equation for a particle formed of an oscillatory massless charge, traveling at velocity $v$ in a potential $V(X)$ in a one-d box along $X$ axis, and its electromagnetic waves $\{\varphi_p^j\}$ (as virtual or ''hidden'' processes) as: $[c^2 - V/m]\partial^2\psi/\partial X^2 = \partial^2\psi/\partial T^2$ (1). Where $\psi = \Sigma\varphi_p^j$; $p =$ *incident* or *reflected*, $j = \dagger$ or $\ddagger$ for $\angle[c,v] = 0$ or $\pi$, $c$ velocity of light, $M = m\sqrt{1-(v/c)^2} = h\Omega/2\pi c^2$ the particle's rest mass, $\Omega/2\pi$ wave frequency for $v = 0$, and $h$ Planck constant. For $V =$ const, Eq (1) has the plane wave solutions: $\{\varphi_p^j = C_1 e^{i(K^jX-\Omega^jT)}\}$; $K^j(j = \dagger\ddagger) = K/1 \mp v/c$ is a Doppler-displaced wavevector; $\Omega^j = K^jc$. From $\Sigma\varphi_p^j$, we get a standing beat, or de Broglie phase wave for the particle total motion: $\psi = 4C_1\cos(KX)e^{i(\Omega+\Omega_d/2)T}\Psi$. Where $\Psi = C\sin(K_dX)e^{-i\Omega_d/2T}$ describes the particle motion, and $K_d = \sqrt{(K^\dagger-K)(K-K^\ddagger)} = (v/c)K$ the de Broglie wavevector; $\Omega_d = vK_d$. For $V$ varying, we get similarly a $\psi$ and $\Psi$ from sums of partial plane waves from all of infinitesimal $(X_i, X_i + \Delta X)$. We can in turn subtract (1) by itself but with $v = 0$, getting an equation for $\Psi$: $[ - \hbar^2/2M\ \partial^2/\partial X^2 + V(X)]\Psi = i\hbar\,\partial\Psi/\partial T$, which is equivalent to the Schrödinger equation. (The so represented QM invites not the so-called EPR paradox.)

**B40 5 Aton, Relativity, and Quantum Mechanics** ALFRED PHILLIPS, JR., *Source Institute* In the mechanics of the Aton, we have shown that the Davisson-Germer experiments and other crystal based experiments can be modeled without recourse to particle-wave notions. We have also shown that the energy levels of the hydrogen atom and the helium atom can be calculated accurately

with Atonic Mechanics, subject to the limits of three-body effects in the latter atom. Using the Aton concept, we now provide a way to unify Einstein's Relativity with what we commonly refer to as quantum mechanics. We note that entanglement is an intrinsic part of the mechanics of the Aton.

**12:15**
**B40 6 Vortex Theory and Photon Acceleration Effect** KONSTANTIN GRIDNEV, RUSSELL MOON, VICTOR VASILIEV, Using the principles of the Vortex Theory, it was theorized that when a photon encounters an electromagnetic field, both the velocity and the frequency of the photon will change. To prove this idea an experiment was devised using a laser interferometer and electromagnets. The electromagnets were arranged so that when the beam splitter divided the initial beam of laser light into two secondary beams; one of the two secondary beams passed back and forth between the magnets. With the DC current to the electromagnets turned off, the two beams formed an interference pattern on the target screen. When the current to the electromagnets was suddenly turned on, the pattern fluctuated wildly until the two beams again reached a quiescent state creating a stable pattern on the screen; when the current to the electromagnets was suddenly turned off, again the pattern fluctuated wildly until it reached a quiescent state forming the initial stable pattern on the screen. It was determined that this new effect was a phenomenon created by the changing frequency of the laser light whose velocity is increasing as it passes between the expanding electromagnetic field of the magnets. Because it is a new phenomenon in science revealing that the speed of light is not a constant but indeed can be varied.

**12:27**
**B40 7 The classical – quantum border at $10^{11}$ Hz and Cosmic Microwave Background** SIMON BERKOVICH, *George Washington University* Findings of non-trivial anisotropy of CMB challenge current cosmology. Notably, this has been predicted by our model of the Universe – a cellular automaton with a rule of distributed fault-tolerant synchronization (http://arxiv.org/abs/astro-ph/0509743). This model yields spectrum of elementary 'quasi-particles' and fast operational background: 'action-at-the-distance' for gravitation, underlying mechanism for Bohm-Hilley's interpretation of quantum phenomena and holographic reference waves for biological information. Matter creation is accompanied with 'shock wave' and synchronization-desynchronization undulations of $10^{-11}$ sec that form CMB. Its structurization is due to eccentric observation, the $2.72^0$K 'temperature' of black body spectrum is indicative of $10^{11}$frequency. Quantum strangeness stems from multiplexing of synchronized and desynchronized stages resulting in sophisticated behavior at the former and loose motion at the latter. The relative stage durations are determined by placing in the Universe, and propagation front may impact large molecules depending on their orientation. Quantum and Life mysteries being interrelated, both can be affected by the border frequency. Millimeter waves cause biological effects neither by heating nor direct action, but as a trigger. Mesoscopic quantum phenomena, like, e.g. superconductivity, can be destroyed by $10^{11}$ Hz. Thus, there is a possibility for a $10^{11}$ Hz threshold in disrupting quantum entanglement through the suggested multiplexed machinery.

**B42 1 Interferometric studies of a piano soundboard** SARAH ZIETLOW, THOMAS MOORE, *Department of Physics, Rollins College, Winter Park, Fl 32789* Electronic speckle pattern interferometry has been used to study the deflection shapes of a piano soundboard. During the experiments the soundboard remained attached to the piano, providing, to our knowledge, the first optical examination of soundboard movement itin situ. The lowest modes have been studied in detail, and the interferograms have been compared to predictions of a simple model that assumes the soundboard is well approximated by an isotropic plate clamped at the edges. Analysis indicates that this model is insufficient to explain the deflection shapes associated with the resonances of the soundboard. It is shown that a finite element model results in more accurate predictions of the mode shapes, and provides insight into the parameters that are important in determining the final sound of the instrument.

**11:27**
**B42 2 Acoustical study of the Nigerian slit log gong.** JACOB SKUBAL, ZACH HACKETT, THOMAS MOORE, *Department of Physics, Rollins College, Winter Park, FL 32789* The acoustically important resonances of a Nigerian slit gong consist of two significant mechanical resonances and a Helmholtz acoustical resonance. Beating in the acoustical signal from the struck gong suggests that energy is cyclically transferred between the acoustical and mechanical resonators, as is known to happen in similar idiophones. However, we have determined that in the slit log gong there is no significant two-way exchange of energy. Rather, the beating occurs as a result of interference between the frequencies associated with the mechanical and acoustic resonances. The relationship between these resonances has an impact on the tuning and sound quality of the gong.

**11:39**
**B42 3 Visualizing the sound field of an acoustic fire extinguisher*** DMITRIY PLAKS, ELIZABETH NELSON, NESHA HYATT, ZADE COLEY, GARY HUNTER, PATRICIA SAPONARI, JAMES ESPINOSA, *University of West Georgia* Our objective is to study the effects of acoustics on flames for the purpose of encouraging new research that will provide a different approach to reducing and extinguishing a combustion reaction. Through experiment, we have already demonstrated that it is possible to extinguish fire with sound. Our apparatus uses 12'' subwoofer speakers in order to generate the necessary acoustic field. By placing dry ice at the bottom of the apparatus, this field becomes visible. We give visual data of how various sound patterns affect the flame and combustion reaction and provide qualitative explanations of the physical phenomena responsible for the effects.

**B42 5 Construction of an apparatus to characterize the early evolution of ultracold neutral plasma*** LUCAS WILLIS, *Rowan University* MICHAEL LIM, *Rowan University* A magneto-optical trap was constructed for the purpose of charting early atomic recombination rates in an ultracold neutral plasma, which is created by photo-ionizing laser cooled rubidium atoms. Planned experiments will focus primarily on the first 100 nanoseconds of plasma evolution, during which a ramped electric field will be applied to Rydberg atoms that recombine from the plasma components. The ramped field will ionize loosely-bound states, liberating electrons at times that are correlated with binding energy. An electron beam comprised of a series of electrostatic lenses enables the transport of these electrons from the MOT region to a multichannel plate electron detector (MCP). We devised a system to raster the beam across the MCP to prevent detector saturation and the loss of signal due to electron multiplier recovery times. We will also discuss other apparatus features that allow flexible electric and magnetic field configurations.

**B42 6 Mode shapes of the American five-string banjo** LAURIE STEPHEY, ISAAC CODREY, THOMAS MOORE, *Rollins College Department of Physics, Winter Park, FL 32789* Experimental studies of the mode shapes of the American five string banjo have revealed the importance of properly tuning the membrane that comprises the head of the instrument. Electronic speckle pattern interferometry has been used to visualize the deflection shapes of the banjo head at several frequencies. Although the off-center placement of the bridge results in asymmetric forces on the head, the mode shapes of a properly tuned banjo head appear symmetric. The implication is that the preferred sound results only when asymmetric pressure is applied to the rim of the membrane to compensates for the off-center placement of the bridge.

**12:27**

**B42 7 Electrical Characterization of Organic Conducting Polymers** LINDSAY WINDSOR, *Cornell University* As Moore's Law drives the silicon semiconductor industry to its limits, organic conducting polymers have been explored on a small scale as a possible solution to the breakdown of silicon. Here, the electrical properties of two organic polymers were measured using nanopore and micron-sized devices. In this electrical characterization, polypyrrole was found to exhibit hopping conduction, and both polypyrrole and polyaniline yield nonlinear I-V curves and degradation after sweeps of high voltage. Consequently, these organic polymers and possibly others may have only limited applications in the future semiconductor industry.

**12:51**

**B42 8 Contact Potential Difference Measurements of Self Assembled Monolayers** BRIDGER ANDERSON, *Society of Physics Students, NIST* In this work, the metal work function and its evolution with systematic chemical changes were studied using an Atomic Force Microscope. A technique, Scanning Kelvin Probe Microscopy, was used to measure the metal work function of various surface dipoles. This metal-molecule interface is also known as a Helmholtz double layer. We expect that this work will lead to a fundamental way of understanding and rationalizing the electrical characteristics of select metal-molecule-metal systems.

**13:15**

**B42 9 Nonlinear Optical Properties of CdSe Quantum Dots** CHARLES ANDERSON, SEAN BENTLEY, JOHN DOOHER, *Adelphi University* Detailed research into the nonlinear optical properties of several quantum dot samples is conducted. Data from the research is being used to investigate applications for the quantum dots. Possible applications may include quantum encryption for more secure forms of communication, lithography techniques for improved capabilities of writing computer chips, and the generation of entangled photons through the use of a four-wave mixing process. Other applications may also include more efficient and cheaper photovoltaic cells. Evident Technologies has provided several different samples of quantum dots, each with distinct nonlinear properties. Using z-scan techniques, absorptive and refractive information are extracted for each of the samples. The absorptive natures are observed by scanning the dot sample through varying intensities and measuring their transmission values with an open aperture. Comparing these values with the same process, but utilizing a closed aperture, allows extraction of values of $n_2$, the nonlinear refractive index.

**B42 10 Bond Angles in the Crystalline Silicon/Silicon Nitride Interface** ROBERT H. LEONARD, MARTINA E. BACHLECHNER, *West Virginia University, Physics Dept.* Silicon nitride deposited on a silicon substrate has major applications in both dielectric layers in microelectronics and as antireflection and passivation coatings in photovoltaic applications. Molecular dynamic simulations are performed to investigate the influence of temperature and rate of externally applied strain on the structural and mechanical properties of the silicon/silicon nitride interface. Bond-angles between various atom types in the system are used to find and understand more about the mechanisms leading to the failure of the crystal. Ideally in crystalline silicon nitride, bond angles of 109.5[r] occur when a silicon atom is at the vertex and 120[r] angles occur when a nitrogen atom is at the vertex. The comparison of the calculated angles to the ideal values give information on the mechanisms of failure in silicon/silicon nitride system.

**B43 1 Superfluidity without Symmetry-Breaking: The Time-Dependent Hartree-Fock Approximation** H.A. FERTIG, CHANG-HUA ZHANG, *Indiana University* We develop a time-dependent Hartree-Fock approximation that is appropriate for Bose-condensed systems. In order to explicitly capture the exchange energy for interactions between the condensate and single-particle excitations, we work with an ensemble with a fixed condensate particle number, so that there is no breaking of gauge symmetry in our approach. Defining a ''depletion Green's function'' allows the construction of condensate and depletion particle densities from eigenstates of a single time-dependent Hamiltonian, guaranteeing that our approach is a conserving approximation. We show that its application to the infinite uniform system produces the expected superfluid mode, and discuss the structure of the density response function.

**11:27**
**B43 2 Number-of-Particle Fluctuations and Stability of Bose-Condensed Systems** CHANG-HUA ZHANG, *Physics Department, Indiana University* In this paper we show that a normal total number-of-particle fluctuation can be obtained consistently from the static thermodynamic relation and dynamic compressibility sum rule. In models using the broken $U(1)$ gauge symmetry, in order to keep the consistency between statics and dynamics, it is important to identify the equilibrium state of the system with which the density response function is calculated, so that the condensate particle number $N_0$, the number of thermal depletion particles $\tilde{N}$, and the number of non-condensate particles $N_{nc}$ can be unambiguously defined. We also show that the chemical potential determined from the Hugenholtz-Pines theorem should be consistent with that determined from the equilibrium equation of state. The $N^{4/3}$ anomalous fluctuation of the number of non- condensate particles is an intrinsic feature of the broken $U(1)$ gauge symmetry. However, this anomalous fluctuation does not imply the instability of the system. Using the random phase approximation, which preserves the $U(1)$ gauge symmetry, such an anomalous fluctuation of the number of non-condensate particles is completely absent.

**B43 3 Measuring Correlations by Single Atom Detection in Quantum Degenerate Gases** ANTON ÖTTL, STEPHAN RITTER, TOBIAS DONNER, THOMAS BOURDEL, MICHAEL KÖHL, TILMAN ESSLINGER, *Institute for Quantum Electronics, ETH Zurich, Switzerland* We observe single atoms by means of cavity QED detection in a quantum degenerate gas. Starting from a magnetically trapped $^{87}$Rb BEC of 5 million atoms we coherently output couple a continuous atom laser by means of a local radio-frequency induced spin-flip into a magnetically untrapped hyperfine state. These atoms propagate freely downward due to gravity and enter the detector which is placed 36 mm below the BEC. Our single atom detector consists of an ultra-high finesse ($\mathcal{F} = 3 \cdot 10^5$) optical cavity in the strong coupling limit of cavity QED. We record the transmission of a weak resonant probe laser through the cavity with a single photon counter and detect single atom transits by their significant reduction of transmission. We measured the second order correlation function of an atom laser beam in a Hanbury Brown & Twiss type experiment. Analyzing the correlations in the arrival time of individual atoms reveals the second order coherence of the atom laser. The high quantum efficiency and fast response time of our single atom detector enables us to extract the full counting statistic of atomic beams. We verified a poissonian distribution for the atom laser whereas a pseudo-thermal atomic beam showed a bunching behavior corresponding to a Bose-Einstein statistical distribution function.

**B43 4 Casimir-like drag force in a slow-moving superfluid** DAVID ROBERTS, YVES POMEAU, *Ecole Normale Superieure* It is widely accepted that a superfluid flow exhibits a critical velocity below which there is no dissipation. However, the often-neglected zero-temperature quantum fluctuations have implications for the existence of this critical velocity. The drag force on an object created by the scattering of these quantum fluctuations in a three-dimensional, weakly interacting Bose-Einstein condensate is discussed. A non-zero force at low velocities is found to exist for two specific experimentally realizable examples, which suggests that the effective critical velocity in these systems is zero.

**B43 5 Berry Phase Effect on Semiclassical Dynamics of Bogoliubov Quasiparticles*** CHUANWEI ZHANG, *Department of Physics & Center for Nonlinear Dynamics, The University of Texas at Austin* ARTEM DUDAREV, *Max-Planck-Institut für Physik Komplexer Systeme, Dresden, Germany* QIAN NIU, *Department of Physics, The University of Texas at Austin* We develop a semiclassical theory for Bogoliubov quasiparticles in a superfluid by following the center of mass motion of a quasiparticle wavepacket. Berry phase arises when the underlying condensate moves, invalidating the usual canonical relation between the mechanical momentum and position variables. The equations of motion become non-canonical, and the quantization rule and the density of states are also modified. We study quasiparticles in a condensate with a vortex to show explicitly the Berry phase effects and their experimental observation.

**B43 6 Collective modes of a spherical shell condensate** COURTNEY LANNERT, *Wellesley College, Wellesley, Massachusetts 02481* TZU-CHIEH WEI, SMITHA VISHVESHWARA, *University of Illinois at Urbana-Champaign, Urbana, Illinois 61801* Dilute ultracold bosonic atoms in three-dimensional optical lattices with a harmonic confining potential are expected to exhibit inhomogeneous phases – in particular phases containing superfluid regions confined to a spherical shell. It may also be possible to confine superfluids in this geometry using a special trap designed for this purpose. We explore the low-energy collective modes of a superfluid confined to a thin spherical shell analytically. In particular, in the limit of strong interactions we find two breathing modes with frequencies distinct from the spherical condensate breathing mode.

**12:27**

**B43 7 Expansion of spherical shell condensates** SMITHA VISHVESHWARA, TZU-CHIEH WEI, *University of Illinois at Urbana-Champaign, Urbana, Illinois 61801* COURTNEY LANNERT, *Wellesley College, Wellesley, Massachusetts 02481* Bose-condensed atoms in traps of novel geometries can show dramatic features in time-of-flight measurements that are absent in conventional spherical trap settings. The specific case of a trap creating a spherical condensate shell is presented. The dynamics of such a shell can yield a significant accumulation of mass at the center upon release of the trapping potential. Morever, the expanded cloud can undergo self- interference and exhibit the associated interference fringes. These features are substantiated by numerical simulations and studied for a range of interaction strength between constituent atoms.

**12:39**

**B43 8 Bose-Einstein condensation and superfluidity in finite sized systems.** ALI SHAMS, *Department of Physics and Astronomy, University of Delaware, Newark, Delaware 19716* HENRY GLYDE, *Department of Physics and Astronomy, University of Delaware, Newark, Delaware 19716* We present results on the relationship between the superfluid fraction and the condensate fraction in finite sized systems of hard-core bosons. The systems are investigated using path integral Monte Carlo methods over a wide range of densities. While it is well known that in strongly interacting bose systems like liquid helium the condensate fraction is much smaller than the superfluid fraction, our results indicate that for finite sized systems and weak interaction, condensate fraction can actually exceed superfluid fraction. This is especially the case as we get closer to the superfluid transition temperature. Condensation in an interacting system can be suppressed both through increased correlation effects and decreased exchange effects. Our investigation also sheds light on the relative importance of these two depletion mechanisms.

**B43 9 Bose Einstein Condensation in a Box Trap: A Monte Carlo Study** CHONGSHAN ZHANG, KWANGSIK NHO, D. P. LANDAU, *Center for Simulational Physics, University of Georgia, Athens, GA 30602* Using the path-integral Monte Carlo method, we have investigated Bose-Einstein condensates in an optical box trap which has been produced very recently[1]. We have used the same geometry as the experiment, and approximated the trapping potential with Gaussian functions at the boundary in order to mimic such a trap. The two-body interaction was described by a hard-sphere potential whose radius equals the *s*-wave scattering length. We have studied the temperture dependence of the equilibrium properties such as the total energy, the total density profiles, and the superfluid fraction. In addition, we have calculated the equilibrium properties as a function of the strength of the two-body interaction. We will compare our simulation results with those for harmonic and hard wall traps. *Research supported by NASA

**B43 10 Transistor like behavior of a Bose Einstein condensate in triple well potential** JAMES STICKNEY, *Department of Physics, Worcester Polytechnic Institute* DANA ANDERSON, *Department of Physics and JILA, University of Colorado and National Institute of Standards and Technology* ALEX ZOZULYA, *Department of Physics, Worcester Polytechnic Institure* The availability of cold atom-based analogs of building blocks of electronic circuits, especially with the ability to integrate them into larger devices, may be extremely valuable in applications. We demonstrate that a device based on a BEC in a triple well potential can show behavior similar to a field effect transistor. The left well is coupled only to the middle and is equivalent to the source in a transistor, the middle is coupled to both the left and right wells and is the equivalent of a gate, and the right well is the drain. The potential is designed so that the chemical potential of the atoms in the empty middle well is sufficiently smaller than in the left or right wells to block tunneling. A small number of atoms placed in the middle well switches the device and enables strong tunneling from the left to the right. This tunneling, controlled by the middle well, is due the atom-atom interactions which increase the chemical potential in the middle well and remove the energy mismatch. We show that the number of atoms tunneling into the right well can be much larger than the number of controlling atoms in the middle well. The three well structure demonstrates both absolute and differential gain. Estimates of the switching time and parameters for the potential are presented.

**B43 12 The three-body recombination of a condensed Bose gas near a Feshbach resonance*** LAN YIN, *School of Physics, Peking University* We study the three-body recombination rate of a homogeneous dilute Bose gas with a Feshbach resonance at zero temperature. The ground state and excitations of this system are obtained. The three-body recombination in the ground state is due to the break-up of an atom pair in the quantum depletion and the formation of a molecule by an atom from the broken pair and an atom from the condensate. The rate of this process is in good agreement with the sodium experiment in a wide range of magnetic fields. The three-body recombination at finite temperatures is also discussed.

**B43 13 The Vortex Phase Qubit: Generating Arbitrary, Counter-Rotating, Coherent Superpositions in Bose-Einstein Condensates via Optical Angular Momentum Beams** KISHOR KAPALE, *Jet Propulsion Laboratory, California Institute of Technology* JONATHAN DOWLING, *Department of Physics and Astronomy, Louisiana State University* We propose a scheme for generation of arbitrary coherent superposition of vortex states in Bose-Einstein condensates (BEC) using the orbital angular momentum (OAM) states of light. We devise a scheme to generate coherent superpositions of two counter-rotating OAM states of light using known experimental techniques. We show that a specially designed Raman scheme allows transfer of the optical vortex superposition state onto an initially non-rotating BEC. This creates an arbitrary and coherent superposition of a vortex and anti-vortex pair in the BEC. The ideas presented here could be extended to generate entangled vortex states, design memories for the OAM states of light, and perform other quantum information tasks.

**B46 1 Interaction of the N vacancy with H and Mg acceptors in *p*-type GaN.***
A.F. WRIGHT,† *Sandia National Laboratories*

Results from recent experimental studies suggest that the N vacancy ($V_N$) may compensate Mg acceptors in GaN in addition to the compensation arising from H introduced during growth. To investigate this possibility further, density-functional-theory calculations were performed to determine the interactions of $V_N$ with H, Mg, and the MgH center in GaN, and modeling was performed to determine the state populations at elevated temperatures. The results indicate that $V_N$H and Mg$V_N$H complexes with H inside the vacancy are highly stable in *p*-type GaN and act to compensate or passivate Mg acceptors. Furthermore, barriers for formation of these complexes were investigated and the results indicate that they can readily form at temperatures $>$ 400[r] C, which is well below temperatures typically used for GaN growth. Overall, the results indicate that the $V_N$ compensation behavior suggested by experiments arises not from isolated $V_N$, but rather from $V_N$H and Mg$V_N$H complexes with H located inside the vacancy.

**B46 2 First Principles Green's Function Calculations of the Electronic and Optical Properties of Point Defects in GaN** SOHRAB ISMAIL-BEIGI, *Yale University* Despite the successful use of GaN in light-emitting and laser diodes, its materials properties are not well understood or controlled: typical samples have high densities of point and extended defects. A wealth of experimental information exists on these defects, but disentangling the contributions of individual defects from aggregated measured signals requires theoretical input. To date, first principles studies of these defects have used density functional theory (DFT) to study their formation energies, charge states, and structures. However, DFT provides poor predictions of electronic excitations and thus optical and luminescence properties, whereas many experiments probe these very properties. We apply state-of-the-art first principles Green's functions methods (based on the *GW* approximation and the Bethe-Salpeter Equation) to GaN point defects. These methods have proven accurate enough to provide direct comparisons to experiments for a variety of materials. We report mainly on the properties of the gallium and nitrogen vacancies, $V_{Ga}$ and $V_N$, native defects with favorable formation energies in typical GaN samples.

**B46 3 Electron paramagnetic resonance of a donor in aluminum nitride crystals.** SEAN EVANS, *West Virginia University* NANCY GILES, LARRY HALLIBURTON, GLEN SLACK, *Crystal IS* SANDRA SCHUJMAN, LEO SCHOWALTER, Electron paramagnetic resonance (EPR) and electron-nuclear double resonance (ENDOR) have been used to characterize a dominant donor in single crystals of aluminum nitride (AlN). A broad EPR signal, with g (parallel) = 2.002 and g (perpendicular) = 2.006, is observed in the as-grown crystals. Exposure to x-rays (i.e., ionizing radiation) increases the concentration of this center by a factor of five to ten (depending on sample), thus indicating that most of these centers are initially present in the crystals in a nonparamagnetic charge state. ENDOR identifies a strong hyperfine interaction with one aluminum neighbor along the c axis (described by A (parallel) = 111.30 MHz, A (perpendicular) = 54.19 MHz, and P = 0.289 MHz) and weaker equivalent hyperfine interactions with three additional aluminum neighbors in the basal plane. These aluminum interactions indicate that the responsible center is a deep donor at a nitrogen site. The observed paramagnetic defect is either a neutral oxygen substituting for nitrogen or a neutral nitrogen vacancy. This work was supported at West Virginia University by the National Science Foundation (Grant DMR-0508140). One of the authors (SME) received support from the WV EPSCoR STEM fellowship program.

**12:15**

**B46 4 Comparison of point defects in 4H SI SiC grown by halide chemical vapor deposition and physical vapor transport*** M.E. ZVANUT, *University of Alabama at Birmingham* H.J. CHUNG, ALEXANDER POLYAKOV, *Carnegie Mellon University* Semi-insulating (SI) SiC may be produced by chemical vapor deposition using halides (HCVD) or physical vapor transport (PVT). Our electron paramagnetic resonance (EPR) studies address the point defects detected in PVT and HCVD 4H SI SiC substrates. EPR measurements are made 'in equilibrium' prior to illumination and after exposure to light. All samples reported here have resistivity of $10^{10}$ ohm-cm and activation energy greater than 0.8 eV. PVT samples exhibit the positively charged carbon vacancy ($V_c^+$) before illumination, which may be quenched by 1.5 eV light and revived at energies greater than 1.9 eV. The 'equilibrium' EPR measurement of the HCVD samples reveals an intrinsic defect which can be quenched by bandgap illumination. The amount of this unidentified defect is estimated to be an order of magnitude greater than that of $V_c^+$ typically observed in PVT substrates.

*The UAB work is supported by NSF

**12:27**

**B46 5 Observation of a three-site defect in SI 4H-SiC** N.Y. GARCES, W.E. CARLOS, E.R. GLASER, *Naval Research Laboratory, Washington, DC 20375* M.A. FANTON, *Electro-Optics Center, Freeport, PA 16229* High temperature anneals were used to study the evolution of native defects in semi-insulating 4H-SiC grown by PVT or HTCVD methods. The samples were annealed in an argon atmosphere for 30 min at temperatures from 1400$^o$C to 2100$^o$C. Using electron paramagnetic resonance (EPR), we observe a defect that is tentatively identified as $V_C$-$C_{Si}$-$V_C$. This spin S=1 defect is characterized by $g_{||}$=2.0029; $g_{\perp}$=2.0038, a fine structure splitting D$\sim$ 96G, and several hyperfine interactions with the low abundant Si (A$\sim$ 5.5G) and C (A$\sim$ 30G) neighboring nuclei. This center is diamagnetic in the ground state but can be excited into a paramagnetic triplet state by sub-bandgap light. The EPR intensity of this center increases significantly with annealing. This defect could result during annealing by the movement of an adjoining C atom onto the $V_{Si}$ site of the divacancy ($V_C$–$V_{Si}$) whose intensity decreases. This may be the simplest of a family of more complex defects that play a role in the SI character. A search for optical signatures associated with this defect from 0.7-3.2 eV PL studies will also be discussed.

**12:39**

**B46 6 Defects Controlling the Minority Carrier Lifetime in n$^-$ 4H-SiC epitaxial layers.*** P.B. KLEIN, B.V. SHANABROOK, *Naval Research Laboratory* S.W. HUH, A.Y. POLYAKOV, M. SKOWRONSKI, *Carnegie Mellon University* J.J. SUMAKERIS, M.J. O'LOUGHLIN, *Cree Inc.* The relationship between the minority carrier lifetime (MCL) and the concentration of deep trapping centers in n$^-$ 4H-SiC was investigated by low-injection time-resolved photoluminescence (TRPL) and by deep level transient spectroscopy (DLTS) and minority carrier transient spectroscopy (MCTS). Layers of varying layer thicknesses were studied in order to enable the separation of bulk lifetimes from surface recombination effects. A linear dependence of the inverse bulk MCL on the concentration of the Z1/Z2 defect, and the lack of significant correlation of the MCL on the concentration of any other traps, suggests that the Z1/Z2 defect controls the MCL. The results of DLTS measurements in 4H-SiC p-i-n diodes under forward bias reinforce the idea that Z1/Z2 alone is the lifetime killer in this material.

*Work supprted in part by DARPA and ONR.

**12:51**

**B46 7 Transition metal doped SiC: defect levels and magnetism*** M.S. MIAO, WALTER R.L. LAMBRECHT, *Case Western Reserve University* The properties of transition metal substitutions and interstitials in 3C and 4H SiC are studied by first principles supercell calculations. The defect levels change slightly for different polytypes or for different layers in 4H SiC. The calculated defect levels are generally in good agreements with DLTS results. Ti in 4H SiC has two acceptor levels close to the conduction band minimum, corresponding to cubic and hexagonal layers.V, Cr and Mn are amphoteric and have both donor and acceptor levels in the gap. We found Mn has deep trap levels which may be useful to achieve semi-insulating SiC, as is also well-known to be the case for V. The Cr and Mn acceptor levels are deep in the gap. They are unlikely to induce holes at the valence band maximum. Therefore the well-known hole-mediated ferromagnetic mechanism does not apply to Cr and Mn doped SiC. However, our calculations showed ferromagnetic coupling for Cr or Mn doped at neighboring sites. The ferromagnetic coupling is very strong but localized for Cr:SiC. However, it is relatively weak but long range for Mn:SiC. Such features are determined by the nature of the impurity bands. The highest occupied defect state of Cr:SiC is antibonding *e* which is localized whereas the state of Mn:SiC is *t*2 which is delocalized and strongly couples with the surrounding C dangling bonds.

*This work is supported by the Office of Naval Research. The calculations are run on Ohio Superconputer Center.

**B46 8 Heat Capacity of ZnO: Isotope Effects** MANUEL CARDONA, *Max-Planck-Institut für Festkörperforschung* JORGE SERRANO, *European Synchrotron Radiation Facility* REINHARD K. KREMER, GISELA SIEGLE, *Max-Planck-Institut für Festkörperforschung* ALDO H. ROMERO, *CINVESTAV, Departamento de Materiales, Unidad Querétaro* RUDOLF LAUCK, *Max-Planck-Institut für Festkörperforschung* We have measured the heat capacity of zinc oxide for several single crystals with different isotopic composition in the 5 – 350 K temperature range. In order to analyze the dependence of the heat capacity on the isotope mass of the oxygen and zinc atoms, we have performed first-principles calculations within the harmonic approximation. The Zn mass affects mainly the acoustic phonons, thus leading to isotopic effects on the heat capacity mostly at low temperatures, whereas the O mass affects mainly the optic phonons, which become thermally active at higher temperatures. This behavior is reproduced quantitatively by the calculations, and is also in agreement with theoretical predictions reported for wurtzite GaN, an isostructural semiconductor. The possibility of using these data to obtain the density of phonon states projected on the corresponding atoms will be discussed.

**13:15**

**B46 9 Unambiguous identification of an OH-Li center in ZnO: Experiment** G.A. SHI, M. STAVOLA, W.B. FOWLER, *Lehigh University* Theory has found that isolated H is always a donor in ZnO [1] and has led to a number of studies of the properties of H in this promising wide bandgap semiconductor. Of interest here is an OH vibrational line at 3577.3 $cm^{-1}$ that is dominant in ZnO grown by the hydrothermal method [2,3]. We show that the two naturally abundant isotopes of Li [$^6$Li (7.5%) and $^7$Li (92.5%)] cause the D-stretching counterpart of the 3577.3 $cm^{-1}$ IR line to be split into two components that can be separately resolved, even though the 3577.3 $cm^{-1}$ line itself shows no Li-related splitting. This unexpected result establishes unambiguously that the 3577.3 $cm^{-1}$ IR line is due to an OH-Li complex. Overtone and oxygen isotope data for the OH-Li center provide an unusually complete picture of the vibrational properties of this defect. Because isotope splittings for elements heavier than Li will be more difficult to detect, this OH-Li center may be considered a model system for H trapped by impurities in ZnO. [1] C. G. Van de Walle, Phys. Rev. Lett. **85**, 1012 (2000). [2] L. E. Halliburton itet al., J. Appl. Phys. **96**, 7168 (2004). [3] E. V. Lavrov itet al., Phys. Rev. B **71**, 035205 (2005).

**13:27**

**B46 10 Unambiguous identification of an OH-Li center in ZnO: Theory*** W.B. FOWLER, G.A. SHI, M. STAVOLA, *Lehigh University* Three structures[1] have been suggested for the OH-Li complex in ZnO whose Li isotope shift has been observed by Shi, Stavola, and Fowler: (a), an O-H-second neighbor Li; (b), Li-O-H; and (c), O-H-Li (a bond-centered hydrogen), with all three atoms along the c-axis. Wardleit et al. [2] have theoretically investigated the energies of two of these structures. They found (c) to be the ground state and (b) to be 0.5 eV higher in energy. We have used[3] CRYSTAL2003 to evaluate the structural and vibrational properties of this defect. We also find the ground state to be bond centered, with structure (b) higher in energy by 0.5 eV and structure (a) higher by 0.7 eV. We have then moved the O, H, and Li atoms by hand along the c-axis to obtain harmonic force constants and anharmonic constants and have used the harmonic force constants to predict the Li-related isotope shifts. Li-related isotope shifts for OD are predicted to be only 0.3 % and 25% of the experimental value, respectively, for structures (b) and (a). Structure (c), the bond-centered structure, is favored both by its stability and by a predicted Li-related isotope shift for OD of 76% of the experimental value. 1. L. E. Halliburton itet al., J. Appl. Phys. **96**, 7168 (2004). 2. M. G. Wardle itet al., Phys. Rev. B **71**, 155205 (2005). 3. V. R. Saunders itet al., itCrystal2003 User's Manual, University of Torino, Torino, 2003.

**B46 11 Vibrational properties of a Li − OH complex in ZnO*** K. R. MARTIN, *Lehigh University, University of Pittsburgh at Johnstown* P. M. BLANEY, G. A. SHI, M. STAVOLA, W. B. FOWLER, *Lehigh University* Considerable interest has developed on the potential use of II-VI oxides as electronic and optical materials. In several cases alkali atoms have been suggested as dopants. We report on the theoretical and experimental investigation of infrared and vibrational properties of a Li-OH complex in ZnO. Earlier infrared experiments[1] revealed a broad OH-like band centered at 3577.3 $cm^{-1}$ (12K), with full width at half maximum ranging from 0.4 $cm^{-1}$ (12K) to 41.3 $cm^{-1}$ (300K) and a corresponding shift in peak position of - 29 $cm^{-1}$, suggesting a significant coupling of the OH stretch with other modes. We have performed similar experiments on the OD version of this defect and have theoretically investigated[2,3] the coupling of these stretch modes to other modes. The lack of a significant isotope dependence of the resulting parameters suggests that the defect couples to the host rather than the large-amplitude motion of the H or D itself. 1. L. E. **B46 12 Oxygen vacancies and titanium interstitials in rutile and anatase*** JOHN JAFFE, MICHAEL HENDERSON, *Pacific Northwest National Laboratory* Native point defects in reduced $TiO_2$, namely the oxygen vacancy and Ti interstitial, were investigated computationally for both the rutile and anatase structures. The generalized gradient approximation to density functional theory was used along with a plane-wave expansion and ultrasoft pseudopotentials. Defect formation energies were calculated after geometry relaxation from O vacancies created in the bulk rutile and anatase lattices, from the experimental Ti interstitial position in rutile, and from several trial initial geometries for the Ti interstitial in anatase. Contrary to traditional assumptions but consistent with much recent evidence, the Ti interstitial was found to be predominant over the O vacancy in rutile under most conditions. Donor ionization energies in rutile were consistent with experiment. Surprisingly, the calculations also indicate a dominant role for the Ti interstitial in anatase (lower formation energy than the O vacancy, though not by as much as in rutile, and much shallower ionization levels.) We evaluate these findings against experimental data on pure n-type $TiO_2$, and discuss possible implications for transition metal cation doping as well as anion doping of $TiO_2$.

## C1 1 DPOLY POSTER SESSION I

**C1 2 A Multi-Sample Melt Micro-Rheometer** KALMAN MIGLER, *NIST* ANTHONY BUR, We have developed a multi-sample melt micro-rheometer (M3R) based on pressure driven channel flow and designed for simultaneous measurement of multiple polymer melts. The required sample size is less than 100 mg. The driving force for the rheometer is pressurized gas from a nitrogen tank that forces polymer melt into a slit. The melt flow is monitored using a video camera that views the flow front through a sapphire window. The device contains no moving parts and no gaskets or O-rings. Measurements of polyethylene and polycarbonate are presented.

**C1 3 Collection of an electrospinning jet** TAO HAN, DARRELL RENEKER, Electrospinning [1, 2] of polymer nanofibers involves an electrically driven bending instability of the elongating jet. If the jet is collected on a stationary surface immediately before or after the bending instability occurs, the jet buckles as it stops. Bending and buckling are distinct phenomena. The determination of the behavior of the jet path in the vicinity of the onset of the first bending instability is important for the orderly collection of the nanofiber. Precise adjustment of the fluid flow, the electrical current, and the shape of the region from which the jet issued, produced a very stable jet which was observed with a high frame rate, short exposure time camera. The fluid jet and the resulting nanofibers were collected on a solid, electrically conducting substrate which was moved laterally, and simultaneously, away from the tip. This collected material preserved a record of the straight segment and the bending and buckling instabilities with a minimum of overlapping. The occurrence of a second bending instability was sometimes observed in the dry fiber. 1. Doshi, J.; Reneker, D.H., itJournal of Electrostatics; **35**, 151, **1995** 2. Reneker, D.H. ;Yarin,A.L.Fong, H.; Koombhongse, S., it Journal of Applied Physics, **87**, 4531, **2000**

**C1 4 Electrospun Nanofiber Yarn** SPHURTI DOIPHODE, DARRELL RENEKER, *The Maurice Morton Institute of Polymer Science, The University of Akron* Electrospinning creates an electrically charged jet of polymer solution or melt, which elongates dries and solidifies to give very long fibers with nanometer-scale diameters [1]. The yarn manufacturing method [2,3] involves collecting the electrically charged fibers between two parallel and electrically grounded collector surfaces separated by a distance commensurate with the diameter of the loops formed by the electrically driven bending instability [1]. One of the collector surfaces is rotated around its axis at an appropriate rate to twist the fibers into a nanofiber yarn. The yarn was extended, for example by translating the other collector away from the rotating collector. Properties such as yarn diameter, fiber count, and twist per unit length were controlled by changing the rotation rate of the disk. It appears that yarns of nanofibers can be produced from all polymer solutions that can be electrospun. References: [1] Reneker, D.H.; Yarin, A.L.; Fong, H. Koombhongse, S. itJ. **C1 5 Branching in electrospinning of nanofibers** A. L. YARIN, *University of Illinois, Chicago* W. KATAPHINAN, D. H. RENEKER, *reneker@uakron.edu* Z. ZHONG, *The Maurice Morton Institute of Polymer Science, The University of Akron* . A sequence of secondary jet branches sometimes emanates from the electrically charged primary fluid jet during electrospinning experiments. This process was observed during the electrospinning of solutions of polycaprolactone dissolved in acetone [1]. Branching occurred both in the straight segment of the jet and after the onset of the bending instability. Jets with larger diameters, associated with higher voltages, tend to have more branches. Stereographic, stopped motion images of the path of the jet showed that the branches grow in all azimuthal directions around the jet with a smaller component of their growth along the direction of the applied electric field. An electrohydrodynamical model of the branching process showed that the surface of a conducting fluid jet can acquire complicated static equilibrium undulations which become unstable and are capable of transforming into branches. 1. Yarin, A. L.; Kataphinan, W.; Reneker, D. H. itJ. App. Phys., 98, 2005, 064501.

**C1 6 Developments of Novel Polymer Electrolyte Fuel Cell Membranes*** TOMOMI IRITA, *Polymer Science & Engr. Dept. UMass* MASAHIRO KONDO, HIROKAZU AOYAMA, *Fundamental Research Dept., Chemical Div. Daikin Industries, Ltd Osaka* THOMAS RUSSELL, *Polymer Science & Engr. Dept. UMass* Perfluorinated polymer electrolyte membranes (PEM), such as Nafion, are considered to be the most promising candidate for the development of the next generation fuel cell technology. The key technological challenges facing PEMs are their performance, durability and cost. In this research, the polymer electrolyte emulsions (PEE) were obtained by a simple hydrolysis reaction of the precursor polymer emulsion. PEMs are obtained by solvent casting the PEE. The PEE obtained here has a very low viscosity even at high solution concentrations. Using high concentration emulsions greatly reduces the amount of the waste, which makes this technology superior to the conventional ones. Casting conditions were optimized to enhance the mechanical properties, e.g. the tensile strength and viscoelastic properties, of the membrane. The PEMs obtained possessed better ionic conductivity than Nafion while their mechanical properties are comparable. Finally, the cost evaluation for this process was conducted and it was shown that the contribution to the cost reduction becomes bigger. **C1 7 Abstract Withdrawn**

**C1 8 Non-halogen Flame retardant High Impact Polystyrene Composites** MIRIAM RAFAILOVICH, MAYU SI, JONATHAN SOKOLOV, *Dept. of Materials Science and Engr., Stony Brook Univ.* JOSHIA OTAIGBE, *School of Polymers and High Performance Materials, Univ. of Southern Miss.* VLADIMIR E. YUDIN, *Head of Polymer Composites Lab, Inst. of Macromolecular Compounds, Russian Academy of Sciences* In recent years, driven by the health issues and the incurred banning policy of bromine compounds, it is a great demand to find an alternate to replace brominated compounds in polymer flame retardant industry. High impact polystyrene (HIPS), a popular materials widely used for electrical appliances and electronic instruments, attracts extensive attention for its dominant flame retardant agent, decabromodiphenyl ether. Here we propose a novel idea to prepare non-halogen HIPS self-extinguishing composites based on the combination of phosphorus compounds and clay. The combustion behavior was thoroughly investigated by UL 94 V-0, LOI, and cone calorimeter measurements. The addition of Cloisite 20A dramatically decreases the value of LOI and the resulted HIPS composites could not pass UL 94 V-0. On the other hand, the introduction of thermal stable clay significantly increases the value of LOI and the corresponding HIPS composites can successfully self-extinguish. These results strongly demonstrate that the thermal stability of clay is the key factor to determine the final flame retardant performance. The synergy between the clay and phosphorus compounds is further studied.

**C1 9 An ''Alternating-Curvature'' Model for the Nanometer-scale Structure of the Nafion Ionomer, Based on Backbone Properties Detected by NMR** KLAUS SCHMIDT-ROHR, Q. CHEN, *Ames Laboratory and Department of Chemistry, Iowa State University, Ames, IA* The perfluorinated ionomer, Nafion, which consists of a $(-CF_2-)_n$ backbone and charged side branches, is useful as a proton exchange membrane in $H_2/O_2$ fuel cells. A modified model of the nanometer-scale structure of hydrated Nafion will be presented. It features hydrated ionic clusters familiar from some previous models, but is based most prominently on pronounced backbone rigidity between branch points and limited orientational correlation of local chain axes. These features have been revealed by solid-state NMR measurements, which take advantage of fast rotations of the backbones around their local axes. The resulting alternating curvature of the backbones towards the hydrated clusters also better satisfies the requirement of dense space filling in solids. Simulations based on this ''alternating curvature'' model reproduce orientational correlation data from NMR, as well as scattering features such as the ionomer peak and the $I(q) \sim 1/q$ power law at small q values, which can be attributed to modulated cylinders resulting from the chain stiffness. The shortcomings of previous models, including Gierke's cluster model and more recent lamellar or bundle models, in matching all requirements imposed by the experimental data will be discussed.

**C1 10 Dynamics of Sulfonated Polystyrene Copolymers and Ionomers using Broadband Dielectric Spectroscopy** PORNPEN ATORNGITJAWAT, JAMES RUNT, *The Pennsylvania State University* The dynamics of sulfonated polystyrene (SPS) copolymers in acid and neutralized forms were investigated using broadband dielectric relaxation spectroscopy. SPS copolymers were synthesized by sulfonation of a monodisperse polystyrene to 1 and 7 mol %. Neutralization was achieved by exchanging the protons of the acid functionality with Na, Cs and Zn cations. Multiple relaxation processes were observed above the glass transition temperature of the neutralized and unneutralized materials. For the unneutralized copolymers, a 'chemical relaxation' was observed at temperatures above the segmental process, arising from the presence of hydrogen bonding. For the ionomers, a Maxwell-Wagner-Sillars process was observed due to the presence of ionic clusters. The 'chemical relaxation' followed Arrhenius behavior and its relaxation strength decreased significantly with increasing temperature. The relaxation times of the MWS process of all ionomers followed a VFT form. A local relaxation in the glassy state was observed for unneutalized copolymers and ionomers neutralized with monovalent cations, while it was suppressed for ionomers neutralized with divalent cations.

**C1 11 Molecular Dynamics Simulations of Polyelectrolyte Adsorption at Oppositely Charged Surfaces** JAN-MICHAEL CARRILLO, ANDREY DOBRYNIN, *University of Connecticut* We have performed molecular dynamics simulations of polyelectrolyte adsorption at oppositely charged surface from dilute polyelectrolyte solutions. In our simulations polyelectrolytes are modeled by chains of charged Lennard-Jones particles with explicit counterions. We have studied the effects of surface charge density, surface charge distribution, solvent quality for the polymer backbone, strength of the electrostatic and short-range interactions on the polymer surface coverage and thickness of the adsorbed layer. We have observed surface undercharging by adsorbing polyelectrolyte in most systems except for systems with low surface charge densities. This undercharging is due to partial screening of the surface charge by surface counterions however this effect is negligible at low surface charge densities. Surface overcharging was also observed for the so-called ''salt-free'' systems in which only counterions necessary for neutralization of the charge difference between surface charge and polyelectrolytes were kept in the system. Hydrophobic polyelectrolytes cover higher percentage of the adsorbing surface forming a thinner polymeric layer in comparison with those observed in the systems with hydrophilic polyelectrolytes. However, the polymer surface coverage is close for both these systems.

**C1 12 Molecular Dynamics Simulations of Polyelectrolyte-Polyampholyte Complexes. Effect of Solvent Quality and Salt Concentration.** JUNHWAN JEON, ANDREY DOBRYNIN, *Polymer Program, Institute of Materials Science, Department of Physics, University of Connecticut* Using molecular dynamics simulations we have studied complexation in polyelectrolyte-polyampholyte mixtures in poor solvent conditions for the polyelectrolyte backbone. In a poor solvent a polyelectrolyte form a necklace-like structure. Upon forming a complex with both random and diblock polyampholytes a polyelectrolyte chain changes its necklace conformation by forming one huge bead. The collapse of the polyelectrolyte chain occurs due to neutralization of the polyelectrolyte charge by polyampholytes. In the case of the random polyampholyte the more positively charged sections of the chain adsorb on the surface of the globular bead while more negatively charged chain sections form loops surrounding the collapsed core of the aggregate. In the case of diblock polyampholyte the positively charged block and a part of the negatively charged block wraps around the collapsed polyelectrolyte with a substan-

tial section of the negatively charged block sticking out from the collapsed center of the aggregate. These structures appear as a result of optimization of the net electrostatic energy of the complex and short-range attractive interactions between monomers of the polyelectrolyte chain.

**C1 13 Surface Treatment for Improved Mobility in Poly(3-hexylthiophene) Thin-Film Transistors*** ADRIAN SOUTHARD, MICHAEL FUHRER, *Department of Physics and Center for Superconductivity Research, University of Maryland* Thin films of poly(3-hexylthiophene), an organic semiconductor, were spin-coated from chloroform onto a self-assembled monolayer of octyltrichlorosilane (2 nm thick) and yielded an order of magnitude higher field-effect mobility than similar films deposited directly onto the $SiO_2$/Si substrate. Mobility was measured using the polymer as the conducting channel of a field-effect transistor with Au top contacts as the source and drain electrodes and the doped silicon as a gate. The higher mobility is presumed to be due to the increased order of the semiconducting layer. Evidence for this ordering and the effect of other self-assembled monolayers will be discussed along with the effect of various contact geometries. This work was supported by the Laboratory for Physical Sciences.

**C1 14 Age old antipodes united: stable *and* low-work-function surfaces are generic** M.A. UIJTTEWAAL, G.A. DE WIJS, R.A. DE GROOT, *Radboud University Nijmegen/Electronic Structure of Materials* Both a low work function and a stable surface are crucial for the application of cathodes in *e.g.* microwave ovens, organic photoconductors and displays as CRTs and OLEDs. Until recently they were considered antipodes. In previous work[1] we showed a stable low-work-function surface to be realised for the compound $BaAl_4$ and even predicted that stable, low-work-function surfaces would be generic for metals with polar surfaces. Now, *ab initio* calculations confirm the prediction for the compounds $CaAl_4$, $BaAuIn_3$ and $LaB_6$. [1] M.A. Uijttewaal, G.A. de Wijs, R.A. de Groot, R. Coehoorn, V. van Elsbergen, and C. H. L. Weijtens, *Chem. Mater.* **17**, 3879 (2005)

**C1 15 Effects of Local Dielectric Property on the Chain Conformation Distribution of Poly (vinylidene fluoride-hexafluoropropylene) Copolymers.** GUOLIN WU, SURIYAKALA RAMALINGAM, SHAW LING HSU, *Polymer Science & Engineering, Univ of Massachusetts* Poly(vinylidene fluoride) (PVdF) is a well known polymer possessing various polymorphic structures. Local dielectric property is known to affect the relative amount of polymorphic phases. The copolymer of PVdF and hexafluoropropylene units is especially fascinating. In this copolymer, changes in structure need to consider both localized dielectric property and steric effects of the comonomer units. The copolymer structure possesses smaller remnant polarization and fewer polar crystalline states in comparison to the homopolymer. Solution NMR studies reveal that the relative population of various rotational isomeric states has been changed in comparison to the homopolymer. This change in single chain structure obviously propagates into the condensed state yielding polar structure, that is, $\beta$ and $\gamma$ phases. NMR, Raman spectroscopy, wide-angle X-ray diffraction, and calorimetric methods were utilized in these studies. The steric effects of the comonomer units driving away from the $\beta$ phase have also been established.

**C1 16 The Effects of Surface Interactions and Confinement on the Melting Point of Semi-crystalline Polymer Thin Films** YANTIAN WANG, MIRIAM RAFAILOVICH, JONATHAN SOKOLOV, DILIP GERSAPPE, *State University of New York at Stony Brook, NY 11794-2275* ASHISH BAKSHI, *Manhasset High School, Manhasset, NY 11030* RAJESH ATLURI, *Herricks High School, New Hyde Park, NY 11040* TOHRU ARAKI, YING ZOU, HARALD ADE, *North Carolina State Univeristy, Raleigh, NC27695* DAVID LEWIS KILCOYNE, *Advanced Light Source, LBNL, Berkeley, CA94720* GAD MAROM, *The Hebrew University of Jerusalem, Jerusalem 91904, Israel* ARNOLD LUSTIGER, *ExxonMobil Research and Engineering Company, Annandale, NJ 08801* A decrease in melting temperature for semi-crystalline polyethylene thin films in the vicinity of a substrate was observed. The depression in the melting point increases with increasing surface interaction. The biggest $T_m$ depression is 38°C. We propose a model where the depression is attributed to the attractive force between the substrate and the polymer chains which competes with the ordering force among the polymer chains. In order to determine the universality of the effect, experiments were conducted on other polymers, i.e. polycaprolactone and poly(ethylene oxide) where similar results were obtained. The effects of confinement were then studied by crystallizing the films on patterned surfaces where the dimensionality of the patterns was continuously varied for nanometer to micron scale.

**C1 17 Oriented Lamellar Structure and Pore Formation Mechanism in CSX-Processed Porous High-Density Polyethylene** SHUJUN CHEN, SAMUEL P. GIDO, *Dept. of Polymer Sci. and Eng., Univ. of Massachusetts, Amherst, MA 01003* SOUVIK NANDI, H. HENNING WINTER, *Dept. of Chem. Eng., Univ. of Massachusetts, Amherst, MA 01003* Characterization of pore structure and pore wall crystal structure was performed on porous high-density polyethylene (HDPE) using SEM, TEM, and electron diffraction. The porous HDPE material was obtained through crystallization from swollen crosslinked polyethylene gels (CSX process) in supercritical propane. SEM showed an open pore structure of micron-sized pores, large void fraction and surface area, as well as thin yet rigid pore walls, making this material a good candidate for a variety of applications. TEM revealed oriented lamellar structure in the pore walls which was much different from structures found in typical bulk HDPE as well as that of the crosslinked HDPE before CSX processing. Electron diffraction results confirmed the presence of oriented lamellar stacking. Based on this oriented lamellar structure, possible mechanisms for crystallization and pore formation in the CSX process are suggested.

**C1 18 Melting Point Measurement of Polycaprolactone Thin Films*** CLIVE LI, *SUNY at Stony Brook* VICTOR WANG, *Great Neck South High School* JONATHAN SOKOLOV, *SUNY at Stony Brook* MIRIAM RAFAILOVICH, *SUNY at Stony Brook* GARCIA TEAM, GREAT NECK SOUTH HIGH SCHOOL COLLABORATION, We investigated the melting point of Polycaprolactone (PCL) thin films as a function of film thickness by using three different techniques, namely, Shear Modulation Force Microscopy (SMFM) technique, Atomic Force Microscopy (AFM) topographic technique, and optical birefringence technique which consisted of laser, polarizers, photoelasitc modulator (PEM), and a lock- in amplifier. The optical and the AFM topography results show PCL to behave similarly for film thicknesses of 215.8 and 37.0 nm, both melting around 331 - 335 K. However, the SMFM

show an approximate 8 K decrease in melting point, suggesting that the polymer may get softer at this lower temperature before it changes in structure for 37.0 nm PCL films. Possible explanations for the differences are discussed.

*This work is supported by the NSF

**C1 19 Effects of Residual Crystallinity on the Crystallization Behavior of Random Polypropylene-Polyethylene Copolymer** SAMUEL AMANUEL, *Materials Science and Engineering* XIAOFENG CHEN, *Chemical and Biological Engineering* RAHMI OZISIK, SANFORD S. STERNSTEIN, *Materials Science and Engineering, Rensselaer Polytechnic Institute* Differential scanning calorimeter measurements revealed that blends of isotactic polypropylene and random polypropylene- polyethylene copolymer have two separate melting peaks, with a peak at 45 $^{o}$C attributed to the copolymer and another peak at 160 $^{o}$C attributed to the homopolymer. Annealing at temperatures below and above the melting of the homopolymer, 145 $^{o}$C and 200 $^{o}$C, resulted in changes of the melting temperature and melting enthalpy of the copolymer. This suggests that the crystallization behavior of the copolymer has been influenced by the residual crystallinity of the homopolymer. Furthermore, this crystalline memory has significant influence on the aging process of the blend. For instance, dynamic measurements, at room temperature, revealed that samples annealed at 120 $^{o}$C have lower shear storage modulus compared to those that were annealed at 200 $^{o}$C. Although physical aging increases the storage modulus in both cases, the rate at which it changes is also dependent on the presence of residual crystallinity.

**C1 20 Disk, Cylinders, Stack-of-Disks, and Vesicles Morphologies from Amphiphilic Block Copolymer Solution-State Assemblies** ZHIBIN LI, ZHIYUN CHEN, HONGGANG CUI, KELLY HALES, KAI QI, KAREN WOOLEY, *Washington University in Saint Louis* DARRIN POCHAN, *University of Delaware* Disk formation has been examined through self-assembly of poly(acrylic acid)-*b*-poly(methyl acrylate)-*b*-polystyrene (PAA-*b*-PMA-*b*-PS) amphiphilic triblock copolymer with polyelectrolyte PAA as corona block and organic diamines as counterions in water/THF solvent mixtures. It was found that by using the same triblock copolymer but varying the type and amount of diamines, disk or cylindrical micelles could be selectively formed and intermediate structures between discs and cylinders were observed. Under certain solution conditions, disks were prefer to stacking together to form stack-of-disks, and stack-of-disks could also transfer to organized rods by increasing the counterion concentration. Discs within the stacks could be uniform in size, and organized rods had the same geometry while they changed from stack-of-disks. It was interesting to see the long range (microns) interactions between discs or organized-rods. By using diblock (PAA-*b*-PS) copolymer analogues, vesicles were obtained with the presence of diamine counterions. The stability of disc vs. vesicle will also be discussed, and the experimental results will be used to compare with the theoretical predictions. The system was investigated by means of transmission electron microscopy, cryogenic transmission electron microscopy, DLS and SANS.

**C1 21 Nanoporous Membrane with Ultrahigh Selectivity and Flux Suitable for Filtration of Viruses*** JIN KON KIM, *Department of Chemical Engineering, Pohang University of Science and Technology* SEUNG YUN YANG, *Department of Environmental Science and Engineering, Pohang University of Science and Technology* IN CHEOL RYU, SUNG KEY JANG, *Department of Life Sciences, Pohang University of Science and Technology* THOMAS P. RUSSELL, *Polymer Science and Engineering Dept., Univ. of Massachusetts at Amherst* We introduce a new double layered nanoporous membrane suitable for virus filtration. One layer is an 80 nm thick film having cylindrical pores with diameters of 15 nm and a narrow pore size distribution. This layer is prepared by using a thin film of the mixture of a block copolymer and a homopolymer, and mainly acts to separate viruses. The support layer is a conventional micro-filtration membrane with a broad pore size distribution. This asymmetric membrane showed very high selectivity and flux for the separation of human rhinovirus type 14 which has a diameter of $\sim$ 30 nm and is a major pathogen of the common cold in humans.

*This work was supported by the Creative Research Initiative Program (KOSEF).

**C1 22 Effect of Selective Solvent on the Morphological Phase Behavior of PS-b-PEO** PRACHUR BHARGAVA, XIAOLIANG ZHENG, YINGFENG TU, STEPHEN Z.D. CHENG, MAURICE MORTON INSTITUTE OF POLYMER SCIENCE, THE UNIVERSITY OF AKRON TEAM, Amphiphilic block copolymers with glassy cores can be self -assembled in solution to form various nanoscale morphologies by using a two solvent process. In the first step the block copolymer is dissolved in a common solvent and then a selective solvent for one of the blocks is added to induce micellization. We have used this method to obtain nanoscale morphologies for PS-b-PEO. We have used DMF as the common solvent and have investigated two selective solvents for PEO, water and acetonitrile. The morphologies obtained by using both these selective solvents are similar. Spheres, rods/worm and vesicles can be obtained by varying only the solvent composition in both the systems. However a 'worm network' can be obtained only by using water as a selective solvent. Also in case of water all the morphologies can be obtained in a very narrow range of water content while in case of acetonitrile the morphologies can be obtained only in a broad range of acetonitrile content. The difference in the behavior with water and acetonitrile can be attributed to their solubility parameters which affects the polymer solvent interaction parameter $\chi$.

**C1 23 Effect of Annealing Temperature on the Surface Composition of Block Copolymers with Semifluorinated Side Chains** K.E. SOHN, A. HEXEMER, *UCSB* S. KRISHNAN, M. PAIK, C.K. OBER, *Cornell* E.J. KRAMER, *UCSB* D. FISCHER, *NIST* The effect of the annealing temperature on the surface composition and orientation of semifluorinated side chains in styrene-isoprene based block copolymers has been studied using NEXAFS spectroscopy, angle resolved XPS, and AFM. Annealing brings the fluorogroups to the surface due to their lower surface energy, resulting in a decrease in styrene content at the surface. NEXAFS experiments on samples annealed in high vacuum and slowly cooled show orientation of the $CF_2$ helix of fluorinated side chains as characterized by a helix orientational order parameter, $S_{helix}$, (relative to the surface normal) that is increased by annealing at the optimum temperatuer. NEXAFS measurements during heating in-situ heating reveal how the orientation progresses at the annealing temperature.

**C1 24 Polystyrene Freeze Dried from Dilute Solution:Ê Tg Depression and Residual Solvent*** WEI ZHENG, SINDEE SIMON, *Texas Tech University* The calorimetric glass transition temperature, Tg, was measured for both linear and cyclic polystyrenes freeze-dried from dilute solution in benzene for concentrations of 0.10%, 0.05% and 0.02% polymer by weight. Upon freeze-drying, Tg was found to be depressed by 4 to 15 K depending on the sample, solvent concentration, and freezing conditions. Annealing under vacuum (0.05 torr) at moderate temperatures, 40 to 140° C, resulted in the shifts of Tg back to its bulk value and was accompanied by a decrease in sample weight. The observed weight loss is presumably due to residual solvent. The amount of solvent present in the original freeze-dried samples was determined from the weight loss observed after annealing under vacuum (0.05 torr) for one hour at 100° C and one hour at 140° C. The calorimetric glass temperature was measured as a function of the fraction of the residual solvent. A linear correlation was found between the Tg depression and the residual solvent concentration, in agreement with data in the literature. In addition, the structure of the freeze-dried polystyrene was examined using Fourier transform infrared spectroscopy. Results show that the recovery of Tg is not due to the structure change during annealing. We conclude that the residual solvent has a significant effect on the Tg depression observed for polymers freeze-dried from dilute solution; no depression or even a slight increase in Tg was observed in the absence of residual solvent.

*Funding from NSF DMR 0304640 is gratefully acknowledged.

**C1 25 Enthalpy Recovery of Polymeric Glasses: Is the Theoretical Limiting Liquid Line Reached?** QINGXIU LI, SINDEE SIMON, *Texas Tech University* Glasses are inherently non-equilibrium materials, and consequently, their properties evolve toward equilibrium in a process known as structural recovery or physical aging. Recently, several authors have suggested that the equilibrium liquid line is not reached even when properties have ceased to evolve. In this work, we present measurements of the enthalpy recovery of polystyrene (PS) at temperatures ranging from the vicinity of glass transition temperature to 10[r]C below Tg (90[r]C), for aging times up to 200 days. The results are analyzed in the context of the TNM model of structural recovery. In addition, we analyze data in the literature to determine whether enthalpy recovery ceases prior to the material reaching the equilibrium liquid line obtained by extrapolation of the liquid line above Tg. The results suggest that, in fact, the liquid enthalpy line is reached at temperatures below Tg when equilibrium is reached, i.e., when properties cease to evolve.

**C1 26 Universal Aspects of Macromolecules in Polymer Blends, Solutions, and Supercritical Mixtures*** YURI MELNICHENKO, *Oak Ridge National Laboratory* GEORGE WIGNALL, *Oak Ridge National Laboratory* DIETMAR SCHWAHN, *Kernforschungsanlage, Julich* ?We demonstrate that macromolecules in miscible polymer blends may behave as poor, theta and good polymeric solvents for each other. We construct a conceptual phase diagram, indicating the range of validity of the random phase approximation, outside of which molecules contract or expand beyond their unperturbed dimensions, contrary to common assumptions. Similarly, the concentration fluctuation correlation length collapses onto a master curve for polymeric, liquid and supercritical solvents, indicating that macromolecules behave uni-versally in these media over a wide range of thermodynamic variables.

**C1 27 Associative polymers bridging between layers of multilamellar vesicles.** SEO CHOI, *University of Massachusetts Amherst* SURITA BHATIA, *University of Massachusetts Amherst* Multilamellar vesicles can be found in a variety of pharmaceutical formulations, personal care products, and home care products. Hydrophobically modified associative polymers are often used to stabilize the vesicles or to control the rheological properties of these formulations. The hydrophobic groups are expected to insert themselves into the vesicle bilayers. Recent experimental work shows that hydrophobically modified polymers may from bridges between vesicles or may bridge between layers of a single vesicle. The latter configuration forces an interlayer spacing roughly equal to the radius of gyration of the backbone between associative groups. We have performed simple mean-field calculations on ideal telechelic associative polymers between concentric spherical surfaces. We find that the free energy per chain has an attractive minimum when the layer spacing is approximately $N^{1/2}l$, which is consistent with experimental results. The depth of the minimum depends on both chain length and curvature, and as expected when the curvature becomes small, the result for telechelic chains between flat surfaces is recovered.

**C1 28 Synthesis and characterization of thermoreversible hydrogels from associating polymers** JUN JIANG, CHUNHUA LI, *State University of New York at Stony Brook* MICHAEL RUBINSTEIN, *University of North Carolina at Chapel Hill* RALPH COLBY, *Pennsylvania State University* DANIEL COHN, *Hebrew University of Jersualem* MIRIAM RAFAILOVICH, JONATHAN SOKOLOV, *State University of New York at Stony Brook* STATE UNIVERSITY OF NEW YORK AT STONY BROOK TEAM, UNIVERSITY OF NORTH CAROLINA AT CHAPEL HILL COLLABORATION, PENNSYLVANIA STATE UNIVERSITY COLLABORATION, HEBREW UNIVERSITY OF JERSUALEM COLLABORATION, Multiblock copolymers of poly(ethylene oxide)$_{99}$-poly(propylene oxide)$_{69}$-poly(ethylene oxide)$_{99}$ were synthesized by coupling with hexamethylene diisocyanate (HDI). The rheological, morphological and structural properties of the gel were characterized as a function of temperature, composition and block number. Mixtures of multiblock and single block copolymers were also studied. Using neutron scattering we found that a large degree of alignment could be induced in the single block gel, but no order could be found in the multi-block or homopolymer multiblock mixture. The yield strain in samples with 3.2 of multiblocks was nearly an order of magnitude higher than the single bock gel. This was interpreted in terms of an ordered layered state of micelles being formed by steady shear. A model based on the competition between forming non-interacting micelles and forming bridges will be presented.

**C1 29 Design, Synthesis, and Evaluation of Non-Porous, Hydrophilic Membranes** SADIE WHITE, *University of Pennsylvania Department of Materials Science and Engineering* MICHAEL FRYD, *University of Pennsylvania Department of Chemistry* BRADFORD WAYLAND, *University of Pennsylvania Department of Chemistry* RUSSELL COMPOSTO, *University of Pennsylvania Department of Materials Science and Engineering* KAREN WINEY, *University of Pennsylvania Department of Materials Science and Engineering* The use of membranes in biological sciences, electrochemistry, and separation technologies is widely expanding. In this investigation, the water flux and filtra-

tion capacities of polyacrylamide-based hydrogel membranes were studied under gravity- and forced filtration processes. The crosslinked membranes were prepared via room-temperature aqueous free radical polymerization, initiated with ammonium persulfate. The crosslinker hydrophilicity and concentration (between 0.5 and 10 mole percent), as well as the membrane thickness, were varied to determine the dependence of gel swelling and water flux on these factors. Suspensions of narrowly-dispersed pigment particles (with a diameter of approximately 200 nanometers) were analyzed with light scattering before and after filtration to determine how effectively the membranes remove particulate matter in this size range. Ongoing work will broaden the investigation to include similar water throughput and filtration studies on crosslinked poly(acrylic acid) membranes.

**C1 30 Small angle neutron scattering study to determine the structure of high strength hydrogels.*** TAIKI TOMINAGA,† *Graduate School of Science, Hokkaido University, Japan* VIJAY R. TIRUMALA, ERIC K. LIN, WEN-LI WU, *Polymers Division, National Institute of Standards and Technology* JIAN PING GONG, HIDEMITSU FURUKAWA, YOSHIHITO OSADA, *Graduate School of Science, Hokkaido University* Hydrogels are swollen polymer networks containing more than 90% water. Most hydrogels, however, are mechanically too weak to be used as load bearing devices. Gong itet al. have overcome this problem by synthesizing hydrogels with a double network (DN) structure. Modifying the polyelectrolyte network structure by polymerization of high molecular weight uncharged polymer itin situ, resulted in orders of magnitude increase in their load bearing ability. Despite 90% water, these tough gels exhibit a fracture stress of 170 kg/cm$^2$, similar to that of articular cartilage found in the bone-joints of human body. In this work, we determined the structure of DN-gels using small angle neutron scattering. Structural origins for high toughness found in DN-gels were then examined by comparing the structure of DN-gels with that of pure polyelectrolyte network and polyacrylamide solution.

**C1 31 Quantitative analysis of interfacial reaction and interfacial thickness by FTIR and Ellipsometry.** MANORANJAN PRUSTY, HAN GOOSSENS, GERT DE WIT, PIET LEMSTRA, *Technical University Eindhoven* MATRIN VAN DUIN, *DSM Research, Geleen* We have studied the development of interface and also interfacial reaction in Polyethylene-co-methacrylic-acid (PE-co-MA) and Styreneacrylonitrile-oxazoline (SAN-Oxaz) bilayer film. The interfacial reaction was studied in-line at different temperatures for the bilayer sample. A decrease in oxazoline and increase in amide and ester was observed. The intensity of amide I was found to have a plateau at higher time indicating that the reaction is diffusion limited. The growth of interface was also studied with the ellipsometer. The retardation, $\Delta$ and reflection ratio, tan$\psi$ data were recorded for the bilayer sample at three angles of incidence (60[r], 70[r] and 80[r]) and at different temperatures. These data were fitted according to a 4-layer model. The time variations of interfacial thickness in SAN-Oxaz/PE-co-MA bilayer was found to increase with time and finally go to a plateau at higher temperatures.

**C1 32 Confinement Effects on the Phase Separation of Polymer Dispersed Liquid Crystals** JIANFENG XIA, JUN WANG, ZHIQUN LIN, *Department of Materials Science and Engineering, Iowa State University, Ames, IA 50011600* FENG QIU, YULIANG YANG, *Department of Macromolecular Science, Fudan University, Shanghai 200433, China* The phase separation kinetics of polymer dispersed liquid crystals (PDLC) confined between two parallel, smooth walls are numerically studied for the first time. The time evolution of two order parameters (i.e., composition order parameter, it$\phi$ and orientational order parameter, $Q$) are calculated by solving coupled time-dependent Ginzburg–Landau (TDGL) model C equations. The external confinement is found to accelerate the ordering of LC. The results presented in the study may provide insights into the experiments on the control of LC domain morphology under nanoscopic confinement.

**C1 33 Crystallization of Ethylene Vinyl Acetate (EVA) and Polyethylene (PE) /deuterated Polystyrene (dPS) Blends in Supercritical Carbon Dioxide (scCO$_2$)** CHRISTOPHER PYNN, *Hals Hollow Hills High School West, NY* PAYVAND AHDOUT, *Rosyln High School, NY* JOHN JEROME, YANTIAN WANG, VLADIMIR ZAITSEV, JOHNATHAN SOKLOV, MIRIAM RAFAILOVICH, *Dept. of Mat. Sci. and Engr,, State Univ. of New York at Stony Brook* STEVEN SCHWARZ, *Dept. of Physics, CUNY Queens College* Thin films of EVA or PE and dPS were spun cast onto Si wafers and crystallized in supercritical carbon dioxide at pressures and temperatures corresponding to the density fluctuation ridge[1] or thermally annealed using standard protocols. The morphology composition and melting points of the films were studied using scanning force microscopy and imaging time-of-flight secondary ion mass spectrometry as function of film thickness and homopolymer concentration. The results showed that exposure to scCO$_2$ produced highly crystalline films. Furthermore, in contrast to the thermally annealed films, the homopolymer was fully incorporated into the crystalline phase. The surface morphology of the films after crystallization showed either island or hole structure, depending on the relation between the film thickness and the lamellar height. Supported in part by the NSF-MRSEC program and by a grant from the SRC-NYS consortium. Reference: [1]Koga T., Seo Y.S., Shin K., Zhang Y., Rafailovich M., Sokolov J., B. Chu, Satija, S.K. Macromolecules. Vol. 36. 2003: 5236-5243.

**C1 34 Phase structures of block copolymers blended with small molecules** KISHORE TENNETI, *Drexel University* XIAOFANG CHEN, *Peking University* CHRISTOPHER LI, *Drexel University* XINHUA WAN, QI-FENG ZHOU, *Peking University* IGORS SICS, BENJAMIN HSIAO, *University of Stony Brook* DREXEL UNIVERSITY TEAM, PEKING UNIVERSITY COLLABORATION, UNIVERSITY OF STONY BROOK COLLABORATION, We report our observations on the influence of blending small molecules on the phase structures of a block copolymer (BCP) system. Poly(styrene-b-4vinyl pyridine) (PS-b-P4VP) BCP was blended with 4-(3,4,5-tris(alkyloxy)benzoyloxy)phenyl 4- hydroxyphenyl isophthalate (BCLCn where n = 6-16) small molecule in different weight ratios. The terminal hydroxyl group of the BCLC is expected to form hydrogen bonding with the P4VP and thus alter the phase structure of the BCP. Thermal analysis, X-ray analysis and transmission electron microscopy were conducted and it was observed

that BCLCs with n = 6 and 8 did not have any influence on the BCP morphology and those with n = 14 and 16 have phase separated. There was a substantial decrease in the d-spacing of BCPs blended with BCLCs with n = 10 and 12 and a bilayer structure was evident.

**C1 35 Structure and Nanomechanical Properties of Well-aligned Electrospun PS/MWCNT Composite Nanofibers** YUAN JI, SHOUREN GE, JASEUNG KOO, BINGQUAN LI, *Department of Materials Science, SUNY at Stony Brook* BATYA HERZBERG, TOBY KLEIN, *SKA High School for Girls* JONATHAN SOKOLOV, MIRIAM RAFAILOVICH, *Department of Materials Science, SUNY at Stony Brook* SKA HIGH SCHOOL FOR GIRLS COLLABORATION, Carboxyl-functionalized multi-wall carbon nanotubes (MWCNT) were incorporated into polystyrene/DMF solutions and electrospun to form PS/MWCNT composite nanofibers. The nanofibers were spun onto a high speed rotator where they became well aligned. Scanning electron microscopy (SEM) and transmission electron microscopy (TEM) were used to investigate the surface morphology and interior structure of the electrospun nanofibers. A three-point bending test, using atomic force microscopy (AFM), was utilized to measure the Young's moduli of the nanofibers as a function of fiber diameter and MWCNT concentration. Shear modulation force microscopy (SMFM) was employed to measure the surface glass transition temperature of the composite nanofiber. The existence of MWCNT enhanced the Young's moduli of fibers and increased the glass transition temperature by nearly 10 degrees. Supported by NSF-MRSEC.

**C1 36 Spherical nanoparticle ordering in block copolymer systems** JOHN PAPALIA, MARY GALVIN, *University of Delaware* In recent years, nanoparticles and self-assembled systems have both been areas of extensive research. Our work combines the unique properties of both fields into a single system by investigating the ordering of nanoparticles in block copolymers (BCPs). Balazs et al. put forth an expansive set of theories which predict the behavior of hard nanoparticle inclusions in BCP systems. These composites combine the natural drive of the BCPs to self-assemble with the physical properties of the particles, yielding complex systems. Our goal is to methodically investigate the theories via model experimental systems. Silica nanoparticles ( $<$ 25nm have been incorporated into the styrene phase of a polystyrene-b-poly(ethylene-co-propylene) BCP. Parameters such as particle size, surfactant coverage, and particle volume fraction are varied in a controlled fashion with their effects on particle ordering studied. Results show surfactant use is almost mandatory to provide the particles with the energetic advantage needed to integrate them into the BCPs. Integrated particles show definitive ordering within discrete BCP domains. Our current and future systems seek to further investigate these results and trends. The combination of these result sets, along with experimentation related to domain size, will aid the design of multi-size particle systems potentially suited for improved photonic devices or nanoscale waveguides.

**C1 37 Dependence of Tg Upon Fiber Orientation in Epoxy-Matrix Composites** KRISTY VISCONTI, PATRICK BURTON, JOHN D. McCOY, *New Mexico Institute of Mining and Technology* SANDIA NATIONAL LABORATORIES COLLABORATION, Epoxy-matrix glass-fiber reinforced composites were tested using a Rheometrics RMS to investigate the dynamic complex shear modulus. The samples were constructed from woven prepreg tape with all layers layed-up at a single weave orientation. Rectangular samples were cut at various angles relative to the fiber direction. The material was found to be rheologically simple. Consequently, a single master curve was constructed for each sample orientation. From this master curve the corresponding shift factors were extracted and plotted against temperature. The WLF equation was used to estimate the glass transition temperature, Tg. An apparent shift in the glass transition temperature was observed as the orientation of the fiber weave relative to the torsional axis was varied.

**C1 38 One Dimensional Nanocomposites** NIKHIL SHARMA, DARRIN POCHAN, *Univ of Delaware, Dept of Materials Science & Engineering* Tailoring the structure of hybrid materials at the nano-scale in order to enhance their properties could produce advanced materials with remarkable attributes and poses significant research challenges. One- dimensional nanoparticle assemblies are an interesting class of materials that may provide an insight into the fundamentals of quantum mechanics of nanomaterials and have potential applications as sensors, in drug-delivery, and in the conduction of novel signals such as phonons and spin states. Experimental work with electrospinning of polyethylene oxide fibers with inorganic particles (silica and iron) is underway that utilizes a coaxial capillary electrospinning apparatus for the formation of one- dimensional assemblies of nanoparticles. The effect of change in solution concentrations and relative flow rates in internal and external channels of the coaxial electrospinning apparatus on the inter-particle distance are being investigated.

**C1 39 Structure, Morphology and Properties of Carbon Nanotube Containing Polymeric Materials** LINGYU LI, STEVE KODJIE, CHRISTOPHER LI, Carbon nanotubes (CNTs) are considered an ideal reinforcing fillers in polymer nanocomposites because of their high aspect ratio, nanosize diameter, very low density and excellent physical properties (such as extremely high mechanical strength, high electrical and thermal conductivity), However, in order to achieve homogeneous dispersion of CNTs without damaging their extraordinary properties, non-covalent functionalization is an essential step. Our study of functionalization of CNTs via controlled polymer crystallization method has resulted in the formation of ''nano hybrid shish-kebab'' (NHSK), which is CNT periodically decorated with polymer lamellar crystals. By tuning the experimental parameters such as concentration of polymer and crystallization temperature, hybrid polymer spherulite with CNT inside was achieved. This can be considered as CNT reinforced composite with ideally controlled CNT dispersion. Both Nylon 6, 6 and PE were used as the matrix materials. Excellent dispersion of CNTs in polymer matrix was achieved and the nanocomposites showed improved thermal stability.

**C1 40 Organic Photonic Crystal Lasers from Holographic Polymer Dispersed liquid Crystals (H-PDLCs)** TIMOTHY BUNNING, RACHEL JAKUBIAK, DEAN BROWN, RICHARD VAIA, *Air Force Research Laboratory* PAMELA LLOYD, *UES* VINCENT TONDIGLIA, LALGUDI NATARAJAN, RICHARD SUTHERLAND, *Science Applications International Corp.* Holographic polymerization of liquid crystal containing photopolymerizable resins enables one-step, rapid formation of multi-phase structures that exhibit partial photonic band gaps. These holographic polymer dispersed liquid crystals (H-PDLCs) provide a versatile platform for diffractive optical elements because the structures are not limited by multi-phase equilibrium but are con-

trolled by the interference of multiple lasers at discrete angles. Incorporation of laser dyes into H-PDLCs form 1-D and 2-D optically pumped distributed feedback lasers. Linewidths as narrow as 1.8 nm are observed with laser thresholds below 1 mJ/cm$^2$ in 2-D columnar structures compared to 9 nm and 25 mJ/cm$^2$ exhibited by 1-D H-PDLC Bragg stack lasers. In the 2-D lattices the energy of the laser action can be tuned within the gain spectrum of the lasing medium by an applied electric field.

**C1 41 Single-layer white-light polymeric luminescent film by plasma polymerization for light emitting diodes** CHUN-CHIH CHANG, YI-HSING CHANG, YING-CHU CHEN, ARNOLD CHANG-MOU YANG, *Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan* KUO-CHU HWANG, *Department of Chemistry, National Tsing Hua University, Hsinchu, Taiwan* Efficient white polymeric light-emitting diodes (PLED) were fabricated with a single active layer consisted of three-dimentional crosslinking $\pi$-conjugated system by plasma polymerization from conjugated monomers. As indicated by the FTIR, XPS UV-vis and PL spectra, the plasma polymer chains were constructed by various chromophores including naphthalene, phenyl, polyene and alkyl groups. Upon optical excitation, the light emission was characterized with a broad peak (FMHW $\sim$ 100 nm) located at 430 nm. In a PLED device, however, the energy transfer by Foster processes (FRET) between multiple host-guest pairs give rise to white emission located in CIE coordinates of (0.3439, 0.3369). This result illustrated the feasibility of large area contour coating of single-layer white-light luminescent polymers for LEDs by simple plasma polymerization methods. This work is supported by National Science Council of Taiwan.

**C1 42 Evaporation induced hierarchical structure formation using diblock copolymers** SUCK WON HONG, JUN XU, ZHIQUN LIN, *Material Science and Engineering Department, Iowa State University, Ames, IA 50011* We present a study of the formation of the hierarchically ordered structures produced from the combination of two self-assembling processes on different length scales, i.e., the dynamic self-assembly via irreversible solvent evaporation in restricted geometries at the microscopic scale and the spontaneous self-assembly of diblock copolymer (e.g., PS-b-PMMA) at the nanoscale. This approach utilizes concurrent self-assemblies as a means to organize unique nanomaterials into spatially ordered structures.

**C1 43 A Unique Two-Stage Dewetting of Ultrathin Films of Entangled Chains Solution-Cast on a Deformable Surface** TONY MING-HSUN YANG, S.Y. HOU, ARNOLD CHANG-MOU YANG, *Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan* F.C. CHANG, C.F. WANG, *Department of Applied Chemistry, National Chiao Tung University, Hsinchu, Taiwan* Stability of polystyrene (PS) thin films ($200\text{ki} \leqslant M_w \leqslant 2M, 20nm \leqslant h \leqslant 80nm$) on a deformable surface of low energy at 170 °C was investigated. A unique two-stage dewetting process was discovered and the magnitude of total forces driving the dewetting was determined from the strong substrate interaction. The film dewet by first nucleating small holes which grew rapidly but subsequently ran into a complete rest. Additional annealing of more than 4.5 hours, however, induced a second stage dewetting initiated from the intact region. The newly initiated holes were characterized with fingers growth that broke down into tiny droplets concurrent to holes expansion. The dewetting force was estimated to be around 0.036 N/m and decrease with aging time. Substrate interactions appeared to have a significant effect of increasing surface energy, hampering the rate of dewetting. This work is supported by Air Force (AFOSR-04-4074) and National Science Council of Taiwan.

**C1 44 Investigation of atomic force microscopic image resolution of organic molecules** MASANORI HARADA, MASARU TSUKADA, *Waseda University* NARUO SASAKI, *Seikei University* We simulated atomic force microscopic images of organic molecules using MM3 force field. Especially we investigated how higher the resolution of images can change using single atom tip compared with realistic tip model. This investigation was motivated by the fact that the resolution of the AFM images of organic molecules is not as good as the images of inorganic surfaces. The difference of the image resolutions can be seen for different element atom, which means using different van der Waals parameter. We also investigated the relation between resolution and mobility of molecules.

**C1 45 Surface Plasmon Resonance Studies of Hydroxypropyl Xylan Self-Assembly on Cellulose** DANIEL A. DRAZENOVICH, ABDULAZIZ KAYA, ALAN R. ESKER, *Virginia Tech Department of Chemistry (0212) Blacksburg, VA 24061* WOLFGANG G. GLASSER, *Virginia Tech Department of Wood Science and Forest Products (0323) Blacksburg, VA 24061* Wood is a multiphase material consisting of cellulose crystals embedded within a non-crystalline hetereopolysaccharide (hemicellulose) and lignin rich phase. The hierarchial arrangement of these three chief components in wood produces excellent properties like resistance to fracture and toughness. Through the study of self-assembly of hemicellulose onto a model cellulose surface, further insight into the interactions between hemicelluloses and cellulose can be gained. In our study, we used xylans with different degrees of substitution of hydroxypropyl groups. Surface plasmon resonance measurements (SPR) probe the self-assembly behavior of hydroxypropyl xylans (HPX) onto a cellulose coated gold surface. In addition, tensiometry provides the critical aggregation concentration (CAC) of different HPX samples. CAC results can be correlated to adsorption observed by SPR. Increasing the degree of hydroxypropyl substitution decreases the CAC and increases adsorption onto cellulose surfaces.

**C1 46 Microfluidic interfacial tensiometry** JAI PATHAK, *NIST* STEVEN HUDSON, *NIST* JOAO CABRAL, *Imperial College, London* A microfluidic instrument to measure interfacial tension of multicomponent immiscible liquids is reported. The instrument measures deformation and retraction dynamics of drops under extensional flow, and is accurate within a few percent. Binary and ternary mixtures have been examined. Surfactant transport phenomena and the effects of viscosity ratio and bounded flow have also been explored.

**C1 47 The Effect of Humidity on the Ordering of Block Copolymer Thin Films** JOONA BANG, BUMJOON J. KIM, *UCSB* THOMAS P. RUSSELL, *UMass* EDWARD J. KRAMER, CRAIG J. HAWKER, *UCSB* Solvent cast diblock/triblock copolymer films of poly(styrene-*b*-ethylene oxide) (PS-PEO) and poly(styrene-*b*-methyl methacrylate-*b*-ethylene oxide) (PS-PMMA-PEO), with cylindrical microdomains of PEO or PMMA-PEO, have a high degree of long-range lateral order after solvent

annealing. Relative humidity of the vapor during the solvent annealing has been shown to play an important role in achieving this order yet the origin of the humidity effect is has been the subject of debate. This work focuses on understanding the role of humidity on the ordering of block copolymer thin films. We find that PS-PMMA-PEO triblock copolymers that show a lamellar morphology in bulk develop a hexagonal array of PMMA-PEO domains on the film surface after solvent annealing in a humid environment. To study the effect of humidity further, hydrophilic nanoparticles, such as PEO-coated gold nanoparticles and PEO-star polymers, were incorporated into nonhydrophilic block copolymers, i.e., poly(styrene-*b*-methyl methacrylate) (PS-PMMA) diblock copolymers that exhibit PMMA cylinders. By controlling the relative humidity and the volume fraction of hydrophilic nanoparticles, it was found that lateral ordering of these PS-PMMA diblock copolymers can also be achieved. The thin film morphologies were investigated in detail using AFM, GISAXS, and TEM.

**C1 48 Surface Modification Using Photo-Crosslinkable Random Copolymers** JOONWON BAE, *UMass* JOONA BANG, *UCSB* PETER LOWENHIELM, *UCSB* CHRISTIAN SPIESS-BERGER, *UCSB* THOMAS P. RUSSELL, *UMass* CRAIG J. HAWKER, *UCSB* We recently reported that poly(styrene-*r*-methyl methacrylate) (PS-*r*-PMMA) random copolymers containing benzocyclobutene (BCB) group can be used to modify the surface effectively by thermal crosslinking. It was demonstrated that this method is simple, rapid, and robust, and can be applied to various surfaces. However, it requires the large amount of heat for processing, and the BCB monomer itself involves a hard chemistry. An alternative way that can replace BCB with easier chemistry and lower cost, if possible, is highly desirable. We introduce the new functional group, azide group, which can be crosslinked simply by UV irradiation, for this purpose. PS-*r*-PMMA random copolymers, containing various amounts of azide groups, were synthesized via controlled living-radical polymerization. It was demonstrated that even after 1 minute of the UV irradiation can crosslink the materials effectively, so that they can be used as crosslinked random copolymer mat to control the surface energy. However, it was observed that the longer irradiation time causes the damages on the surface due to the other side reactions. Depending on the UV intensity, the UV irradiation time, and the amount of azide group, the effective processing window that leads to the crosslinking without any surface damages was optimized.

**C1 49 Mean-field Description of Spinodal Growth of Surface Waves on Rupturing Films*** YONG JIAN WANG, OPHELIA K.C. TSUI, *Department of Physics and Institute of Nano Science and Technology, Hong Kong University of Science and Technology* We examine the extent to which the mean-field theory is applicable to the description of the experimentally observed growth of surface waves on a rupturing polystyrene film coated on an oxide-covered silicon that is known to be spinodal unstable. We find that good agreement between theory and experiment is obtainable if corrections due to non-linear effects and stochastic thermal fluctuations are considered.

*We acknowledge financial support of the Research Grant Council of Hong Kong through the projects HKUST6070/02P and 603604.

**C1 50 The Interface between Two Incompatible Polymers in Density Fluctuating Supercritical Carbon Dioxide*** J.S. KOO, T. KOGA, M. RAFAILOVICH, J. SOKOLOV, *SUNY at Stony Brook* The X-ray reflectivity was used to investigate an effect of $CO_2$ sorption on interface between two immiscible polymers, polystyrene (PS) and poly(methylmethacrylate) (PMMA). Thin films of PS and PMMA were spun cast onto Si wafers and the interfacial width was measured as a function of the film thickness of both PS and PMMA layers. The samples were then exposed $CO_2$ gas at pressures and temperature corresponding to the density fluctuation ridge (1). The relative dilation of the two layers and the change in the interfacial width was then determined. The results showed that the dilation was nearly independent of the PMMA film thickness, and maximal at thickness less than 3Rg of the PS layers. The interfacial width in all cases was almost twice as large after exposure. These results will be interpreted in terms of the interfacial reduction induced by the $CO_2$ and capillary wave theory. (1) Koga, T. itet al. Phys. Rev. Lett. **2002**, 89, 125506 ; Koga, T. itet al. Macromolecules **2003**, 36, 5236.

*Work supported in part by the NSF-MRSEC and the SRC-NYS consortium.

**C1 51 Trisilanolphenyl-POSS as an Adhesion Promoter** SARAH HUFFER, *Department of Chemistry (0212), Virginia Tech Blacksburg, VA 24061* UFUK KARABIYIK, ALAN ESKER, *Department of Chemistry (0212), Virginia Tech Blacksburg, VA 24061* Polyhedral oligomeric silsesquioxanes (POSS) have been an innovative research area for over twenty years. Potential aerospace applications include space-survivable coatings and ablative insulation. Recent studies showed that trisilanol-POSS derivatives form monolayers at the air/water interface. The purpose of this study was to improve adhesion between ceramics and metals and metals and polymers by preparing multilayer films at various pH values and metal ion concentrations using trisilanolphenyl-POSS (TPP). Multilayer systems were created by spincoating polystyrene, using the Langmuir-Blodgett technique for TPP, and physical vapor deposition of aluminum oxide. The resulting films were characterized for quality and stability using atomic force microscopy, optical microscopy, X-ray photoelectric spectroscopy, and dewetting experiments. Initial experiments demonstrated that TPP-aluminum ion complexes facilitated smooth aluminum oxide film formation on silicon wafers while TPP alone yielded a blistered aluminum oxide surface.

**C1 52 Interface Behavior in Diblock Copolymer Brushes** GOKCE UGUR, BULENT AKGUN, WILLIAM J. BRITTAIN, MARK D. FOSTER, *Maurice Morton Institute of Polymer Science,The University of Akron, Akron, OH 44325* XUEFA LI, DONG RYEOL LEE, JIN WANG, *Experimental Facilities Division, Argonne National Laboratory, Argonne, IL 60439* A polymer brush is an assembly of polymer chains with one end tethered to a surface or an interface with a tethering density high enough that the polymer chains are forced to stretch away from the substrate. This stretching of polymer chains along the direction normal to surface is different from the typical behavior of flexible chains. The study of surface and interface properties of polymer brushes is important for their use in nano-scale applications. We investigated the surface and interface structure of polystyrene-b-polymethylacrylate (PS-*b*-PMA) diblock copolymer brushes that have been synthesized using atom transfer radical polymerization (ATRP). Grazing incidence small angle X-ray scattering (GISAXS) was used to probe the structure of the surface as well as the buried interfaces of

the brushes. It showed that there are lateral correlations inside the brush and that the spacing of these structures is on the order of the top layer thickness of the brush. Analysis of the GISAXS data provides information for values of the in-plane scattering vector that are larger than those accessible using a conventional transverse scan.

**C1 53 Exciton Emission in PTCDA Thin Films under Uniaxial Pressure** A. DESILVA, V.R. GANGILENKA, H.P. WAGNER, *Department of Physics, University of Cincinnati, Cincinnati, Ohio 45221-0011, USA* R.E. TALLMAN, B.A. WEINSTEIN, *Department of Physics, SUNY at Buffalo, NY 14260-1500, USA* R. SCHOLZ, *Institut für Physik, Technische Universität Chemnitz, 09107 Chemnitz, Germany* We study the strain dependent photoluminescence (PL) of a 90 nm thick polycrystalline PTCDA film on Si(001) between 20 and 300 K. Uniaxial pressure up to 1 kbar is applied along the molecular stacking direction using a home made pressure cell. With increasing pressure we find a quenching of the total PL intensity which is mainly attributed to the creation of defects. At low temperature the charge transfer exciton emission (CT2) gains intensity relative to the Frenkel exciton emission. Furthermore the CT2 transition reveals a shift to lower energies by approximately 5 meV. At room temperature the PL is dominated by the excimer transition which shows a redshift of 5 meV at highest uniaxial pressure. The increase of the CT2 transition at low temperature and the redshift of the emission bands are attributed to an increased exciton trapping probability and enhanced binding energy with reduced distance between stacked molecules.

**C1 54 Evidence for Capillary Contributions to Gecko Adhesion from Single Spatula Nanomechanical Measurements** GERRIT HUBER, STANISLAV GORB, EDUARD ARZT, *Max Planck Institute for Metals Research, Heisenbergstrasse 3, D-70569 Stuttgart, Germany* RALPH SPOLENAK, *ETH Zurich, Laboratory for Nanometallurgy, Department of Materials, CH-8093 Zurich, Switzerland* KLAUS MECKE, *Erlangen University, Dept. of Theoretical Physics, D-91058 Erlangen, Germany* HUBERT MANTZ, KARIN JACOBS, *Saarland University, Dept. of Experimental Physics, D-66041 Saarbruecken, Germany* The hairy attachment system on a geckos toes, consisting of one billion spatulae in the case of Gekko gecko allows it to adhere to nearly all surface topographies. The mechanistic basis for gecko adhesion has been intensely investigated, but the lowest hierarchical level, that of the spatula, has become experimentally accessible only recently. This study details measurements of the adhesion force exerted by a single gecko spatula for various atmospheric conditions and surface chemistries. Through judicious choice and modification of substrates, the short- and long-range adhesive forces are separated. In contrast to previous work, our measurements clearly show that humidity contributes significantly to gecko adhesion on a nanoscopic level. These findings are crucial for the development of artificial biomimetic attachment systems.

**C1 55 The Influence of Stereoerrors on the Crystallization of Isotactic Polypropylene*** XIAOFENG CHEN, SANAT K. KUMAR, *Chemical and Biological Engineering* RAHMI OZISIK, *Materials Science and Engineering, Rensselaer Polytechnic Institute* Crystallization behavior of four isotactic polypropylenes (iPP) with stereoerrors was studied by Monte Carlo simulation. All systems were equilibrated above the melting temperature ($T_m$) and then cooled systematically to temperatures below the $T_m$. The conformations of the iPP chains were analyzed to characterize the crystallinity development in each system. The probability of helix formation, the average length of helices, and the fraction of repeat units involved in helical structures all increased as temperature decreased. As expected, the stereoregular iPP had the longest helical structures and the highest overall crystallinity compared to the other systems with stereoerrors. The overall crystallinity decreased with increasing number of stereoerrors. The influence of stereoerrors on the ability of iPP repeat units participation in helical structures was also investigated. The results showed that the stereoerrors can exist in helices but they strongly influence the ability of their neighbors to exist in helices.

*This material is based upon work supported by the National Science Foundation under Grant 0310596.

**C1 56 Investigation of the Structure and Dynamics of Polyethylene Nanocomposites*** PETER J. DIONNE, *Mechanical, Aerospace and Nuclear Engineering* RAHMI OZISIK, *Materials Science and Engineering* CATALIN R. PICU, *Mechanical, Aerospace and Nuclear Engineering, Rensselaer Polytechnic Institute* The structure and dynamics of linear, monodisperse polyethylene (PE) melts ($C_{160}H_{322}$ and $C_{440}H_{882}$) containing homogenously distributed spherical nanoparticles were investigated. The PE chains were simulated using a coarse grained model and a Monte Carlo algorithm. Two variables were considered: (i) the wall-to-wall distance between particles (itd), and (ii) the interaction energy between monomers and particles. The various chain structures changed greatly with itd while the monomer-particle interaction had little effect. The average size, shape, and orientation of PE chains did not differ significantly from those of a neat melt. Bridge segments were more stretched relative to segments in the neat melt and the stretch increased with increasing itd. However, the number of bridge segments decreased markedly with increasing itd. Chain dynamics was monitored by computing the Rouse relaxation modes and the mean-square displacement of the center of mass. The dynamics were slowed by both geometric effects (confinement by fillers) and energetic effects (monomer-particle energetic interaction).

**C1 57 Extensions of an analytical coarse-grained description for polymer liquids: thermodynamic determinations and an intermediate length-scale description** EDWARD SAMBRISKI, MARINA GUENZA, *Department of Chemistry, Institute of Theoretical Science, University of Oregon, Eugene, Oregon 97403* We extend our previous analytical coarse-graining (CG) procedure[1], which maps polymer liquids onto a system of interacting soft-colloidal particles. First, we present an optimized representation of the effective pair potential, $v_{cc}(r)$ [initially determined via the hypernetted-chain closure], by carrying out an interative predictor-corrector (PC) scheme. Then, we compare the thermodynamics obtained through the virial and compressibility routes, for which we observe an improvement in their consistency when using the PC result. Finally, we present an intermediate length-scale CG treatment for polymers by performing an analytical remapping of the chain onto ''blobs'' (monomer aggregates). The derived expression for the blob-blob total correlation function,

$h_{bb}(r)$, is seen to be in agreement with data from united-atom molecular dynamics simulations.

**C1 58 A Novel Approach for Understanding the Effect of Nano-Fillers on the Conformational Properties of a Polymer Matrix: Dimensions go up or down?** FATIH M. ERGUNEY, WAYNE L. MATTICE, *The University of Akron* MC simulations of a polymer matrix composed of linear POE chains and nano-fillers were performed on a 2nnd lattice to reveal the change in the $< s^2 >$ of matrix chains perturbed by nano fillers. Nano-fillers are obtained by the collapse of a desired number of linear chains by increasing the contribution of the attractive core of discretized intramolecular LJ potential. The resulting change in $< s^2 >_{matrix}$ is case sensitive in such a way that it might either go up or down depending on the size of both species. It tends to increase in the presence of nano-fillers when both kinds are represented by a small number of beads. There's a peak point observed in this case after which the dimensions start to decrease as the filler fraction is further increased. The contraction of chains is also of concern provided that chains have a larger number of beads. On the contrary, there's no peak point observed in such a case, but a plateau region is acquired at high filler fraction. Magnitude of the change depends on several parameters like mobility and compactness of fillers.

**C1 59 Density functional and molecular dynamics study of conducting polymers** Y. DAI, E. BLAISTEN-BAROJAS, *School of Computational Sciences, George Mason University, Fairfax, VA 22030* Polypyrrole belongs to the important class of conducting polymers and is a good candidate for photonic devices and chemical sensors. In this work we performed electronic structure calculations of pyrrole oligomers containing 6 to18 rings at the density functional (DFT) level and searched for the charge distribution in the oxidized and neutral phases. The description of bipolaron given in terms of charge localization over domains along the pure polymer chain by semiempirical methods could only be confirmed by DFT studies in the oxidized phase when dopants are present. A model potential for polypyrrole was developed based on the first principles calculations of the structure and charge distribution. Several finite temperature and dynamical properties were studied with molecular dynamics.

**C1 60 Structure and Spectra in Mutated Green Fluorescent Protein: A Combined Molecular Dynamics and QM/MM Study** SOUMYA PATNAIK, STEVEN TROHALAKI, RUTH PACHTER, *Air Force Research Laboratory* Recently, several Green Fluorescent Protein (GFP) mutants have been developed with red-shifted absorptions. The molecular structures of two such mutants with S65G and S65T mutations have been studied with an aim towards understanding the shift in their absorption spectra. A combined approach of molecular dynamics (MD) and Quantum Mechanics/Molecular Mechanics (QM/MM) has been used. Time dependent density functional theory (TDDFT) based absorption spectra calculations were found to be of excellent agreement with experimental data. These calculations were carried out on chromophore structures derived from QM/MM and MD studies, thus taking into account, both the effects of thermal fluctuations and the protein and solvent environment. In addition to providing information regarding the variation of the geometrical parameters due to temperature effects, the MD simulations also identify residues around the chromophore which are associated with conformational change on mutation. By using QM/MM to systematically analyze significant structural features that were identified by MD simulations, a detailed understanding of the energetics of the optimized chromophore conformations was achieved.

**C1 61 Biodegradable Epoxy Networks Cured with Polypeptides** SHIGEO NAKAMURA, *Ajinomoto Co., Inc.* EDWARD J. KRAMER, *University of California, Santa Barbara* Epoxy resins are used widely for adhesives as well as coatings. However, once cured they are usually highly cross-linked and are not biodegradable. To obtain potentially biodegradable polypeptides that can cure with epoxy resins and achieve as good properties as the conventional phenol novolac hardeners, poly(succinimide-co-tyrosine) was synthesized by thermal polycondensation of L-aspartic acid and L-tyrosine with phosphoric acid under reduced pressure. The tyrosine/succinimide ratio in the polypeptide was always lower than the tyrosine/(aspartic acid) feed ratio and was influenced by the synthesis conditions. Poly(succinimide-tyrosine-phenylalanine) was also synthesized from L-aspartic acid, L- tyrosine and L-phenylalanine. The thermal and mechanical properties of epoxy resins cured with these polypeptides are comparable to those of similar resins cured with conventional hardeners. In addition, enzymatic degradability tests showed that Chymotrypsin or Subtilisin A could cleave cured films in an alkaline borate buffer.

**C1 62 A novel Generalized Langevin approach to bridge different timescales of relaxation in Protein Dynamics** ESTHER CABALLERO MANRIQUE, *Department of Chemistry, University of Oregon* JENELLE BRAY, *Department of Chemistry, California Institute of Technology* MARINA GUENZA, *Department of Chemistry, University of Oregon* The derivation of a Generalized Langevin Equation (GLE) for the long-time dynamics of biological systems presents several challenges as hydrogen bonding, secondary and tertiary structure, Coulombic interactions, and hydrophobic effects come into play. Here we propose a novel GLE approach where the internal friction is explicitly included in the protein dynamics, allowing the distinction between hydrophobic and hydrophilic effects. The protein is described as a linear chain of beads (centered at the alpha carbons) that are connected by harmonic springs. Input for our theory is short time (ns) molecular dynamics simulations of a single protein (or complex) in solution, in this case the bacterial signal transduction protein CheY. Effective inter-bead potentials and local friction coefficients are obtained from the simulations. A comparison of the bond autocorrelation function predicted from the theory and calculated directly from the simulation affords the test of the theory in the short timescales (ns). In the long timescales (ms), the theory is tested against experimental NMR $T_1$ relaxation values. Our results show a remarkable agreement in both cases, indicating that our GLE correctly bridges from the short- to the long-time scale of protein dynamics.

**C1 63 Quantitative prediction for two-dimensional bacterial genomic displays** JEAN-FRANCOIS MERCIER, CHRISTINE KINGSBURRY, *University of Ottawa* BÉNÉDICTE LAFAY, *CNRS-IRD* GARY W. SLATER, *University of Ottawa* Two-dimensional bacterial genomic display (2DBGD) is a simple technique that allows one to directly compare complete genomes of

closely related bacteria. It consists of two phases. First, polyacrylamide gel electrophoresis (PAGE) is used to separate the DNA fragments resulting from the restriction of the genome by appropriate enzymes according to their size. Then, temperature gradient gel electrophoresis (TGGE) is used in the second dimension to separate the fragments according to their sequence composition. After these two steps, the whole bacterial genome is displayed as clouds of spots on a two-dimensional surface. 2DBGD has been successfully used to distinguish between strains of bacterial species. Unfortunately, this empirical technique remains highly qualitative. We have developed a model to predict the location of DNA spots, as a function of the DNA sequence, the gel electrophoresis and TGGE conditions and the nature of the restriction enzymes used. This model can be used to easily optimize the procedure for the type of bacteria being analyzed.

**C1 64 Osmotic Pressure induced by Poly(ethylene glycol) at High Salt Concentrations** SUNGKYUN SOHN, HELMUT STREY, SAM GIDO, *Polymer Sci. & Eng., Univ. of Massachusetts Amherst* The osmotic pressure method is one of the most effective tools that can be used in controlling self-assembly of polymers in solution, especially of water-soluble biopolymers. This study investigated if there is a noticeable synergistic osmotic pressure increase between co-existing polymeric osmolyte and salt when extremely highly concentrated salt molecules are present both at sample subphase and stressing subphase. PEG 8,000 and LiBr were chosen as osmolyte and salt, respectively, since this model system can be directly applied to the case of silk protein self-assembly, where hydrogen bonding plays a major role. In addition to the conventional methods for measuring osmotic pressure, such as membrane osmometry, vapor pressure osmometry, and ultracentrifuge, an 'equilibration method' that measures osmotic pressure relative to a reference with known osmotic pressure, was introduced. PEG 400 solution was chosen as the reference for this method. Osmotic pressure of aqueous LiBr solution up to 2.75M was measured and it was found that the synergistic effect was insignificant up to this salt concentration. Solution parameters and Arrhenius kinetics based on time-temperature relationship during the equilibration process were derived as well.

**C1 65 The Effect of Polymer-Clay Nano-Composites on Human Dermal Fibroblasts** LOURDES COLLAZO, HILANA LEWKOWITZ-SHPUNTOFF, MARY CATHERINE WEN, MIRIAM RAFAILOVICH, *Stony Brook University* The effect of polymer-clay nano-composites on the proliferation of Human Dermal Fibroblasts (HDF) as a function of clay content was investigated. Polybutadiene with different clay concentrations were spun cast on glass substrates. HDF cells were cultured on these substrates and growth curves were generated for a period of 2 weeks. The results show that the optimal growth occurred on Polybutadiene films with nano-composites that consisted of 90% polymer and 10% clay. The relative modulus of these polymer-clay nano-composites films were measured by Scanning Modulus Force Microscopy (SMFM) 1 and showed a linear increase with clay concentration, indicating that the nano-composites became harder with increased clay concentration.Confocal microscopy revealed that the morphology of the F-Actin fibrils is a function of the matrix modulus. In addition more focal adhesion points were found on the harder substrates. This adaptation of normal fibroblasts will be compared to cancer fibroblasts as well as protein distribution by western blotting. Reference: Shouren Ge et al. PRL (2000) 85(11) 2340-2343

**C1 66 Receptor/Ligand Interactions at an Oil/Water Interface** DANIEL CARVAJAL, *Northwestern University* CHI-YANG CHAO, *Northwestern University* KENNETH SHULL, *Northwestern University* The strength of the interaction between biotin and avidin has sparked major research interests as the system serves as a vehicle for both targeted drug delivery and the simulation of surface recognition processes. Interfacial tension measurements (IFT) using R-PEO-biotin[1] were used to obtain dynamic information on the avidin-biotin interaction. Real time IFT data was gathered from the liquid-liquid interface by monitoring the shape of the drop via a drop shape analysis (DSA) instrument. A drop, containing dissolved R-PEO-biotin block copolymers in an ''oil like'' phase, was formed in an immiscible embedding ''water like'' phase. The block copolymers were specially designed to segregate to the liquid-liquid interface and cover the drop surface. By adding avidin to the surrounding water phase, changes in the drop shape provided dynamic data on the avidin-biotin interaction, as avidin binds to biotin only at the drop surface. This is the first study to show that DSA can be applied to the dynamic study of the interaction between avidin and biotin. [1]Biotin-functionalized block copolymers with a hydrophobic aliphatic block and a hydrophilic PEO block

**C1 67 Theoretical Comparative Study of the Structure, Dynamics and Electronic Properties of Five Ally Molecules: Allicin, Methyl Propyl Disulfide (MPD), Allyl Methyl Sulfide (AMS), S-allyl cysteine (SAC) and S-allyl mercaptocysteine (SAMC)*** EMINE DENIZ CALISIR, SAKIR ERKOC, *Department of Physics, Middle East Technical University, 06531 Ankara, Turkey* HANDAN YILDIRIM, ABDELKADER KARA, TALAT S. RAHMAN, *Department of Physics, Kansas State University, Manhattan, USA* MAHMUT SELVI, FIGEN ERKOC, *Department of Biology Education, Gazi University, 06500 Ankara, Turkey* The structural, dynamics and electronic properties of five allyl molecules have been investigated theoretically by performing semi-empirical molecular orbital (AM1 and PM3), ab-initio (RHF) and density functional theory calculations. The geometry of the molecules have been optimized, the vibrational spectra and the electronic properties of the molecules have been calculated in their ground states in gas phase. For each molecule, we found that the optimized geometries resulting from calculations based on the three levels of accuracy, to be very similar. However, we found that an accurate description of the vibrational properties of these molecules necessitates calculations at the ab-initio level. The electronic structures of these molecules were performed at the DFTlevel, resulting in an accurate description of the HOMO-LUMO gap and the local charges.

*Work supported in part by NSF under grant No: INT_0244191

**C1 68 Spheres-to-vesicles morphological transition in polymer micelles** ZHIJUN HU, ALAIN JONAS, JEAN-FRANÇOIS GOHY, CERMIN COLLABORATION, Self-assembly of block copolymers in solution and the resultant nano-objects such as spheres, rods, and vesicles, have been the focus of much interest during the last 20 years. The ability to tune the micellar morphology and trigger the morphological transitions still remains a central challenge in this field. Here we present the possibility to control the micellar morphologies in poly(styrene)-itblock-poly(4-vinylpyridine)/surfactant complexes by dilution, which is believed to be due to the changes of order in the insoluble blocks. These complexes, that form spherical micelles at a concentration of 1 g/L, rearrange into vesicles when the solutions are diluted, as

confirmed by combined dynamic light scattering, atomic force microscopy and transmission electron microscopy investigations. This morphological transition can be further used as a tool to encapsulate molecules of interest in the interior of block copolymer vesicles.

**C1 69 Osmotic Pressure Measurements of the Order Disorder Transition in Acrylic Triblock Copolymer Gels** RAFAEL E. BRAS, *Northwestern University* KENNETH R. SHULL, *Northwestern University* Semi-dilute solutions of PMMA-PnBA-PMMA triblock co-polymers in alcohols are excellent binder materials for a novel ceramics processing method, thermo-reversible gel casting. Processing methods based on this technology offer a low cost alternative to traditional slip and gel casting techniques. The rapid transition of these gels from freely flowing liquids to elastic solids has been attributed to the aggregation of the PMMA endblocks to form small spherical domains. We have recently begun to examine the order disorder transition of the PMMA endblocks with vapor pressure osmometry. This technique measures osmotic pressure by monitoring the equilibrium temperature of a solution droplet relative to the temperature of a pure solvent droplet. Measurements of solutions consisting of 15 vol % acrylic triblock copolymer in butanol show a significant drop in osmotic pressure between 80 and 85 [r]C. This result indicates that the relaxation times of the ordered gels can be quite low, so that the order-disorder transition of the triblock copolymer occurs at temperatures higher than the rheologically determined gelation temperature of about 65 [r]C.

**C1 70 Scaling of Avrami Kinetics of Growing Anisotropic Grains** SAMUEL GIDO, ASHOUTOSH PANDAY, *University of Massachusetts, Amherst MA 01003* The kinetics of phase transformations proceeding by nucleation and growth are commonly modeled with the Avrami equation. In its most general form, the Avrami equation is expressed as $V(t) = 1- \exp[-V_e(t)]$, where $V(t)$ and $V_e(t)$ denote actual volume transformed and itextended volume respectively, as a function of time t. The extended volume, $V_e(t)$ is the imaginary volume of all the grains if they did not stop at impingement and grew into one another. We report an observation about the growth of anisotropic grains obtained through simulations. We have found that for both simultaneous and continuous nucleation of elliptical grains, of aspect ratio L, the extended volume is reduced by a factor of $L^{1/2}$ in random orientation as compared to unidirectional orientation. In other words, $V_e(t)_{,\ random} = [\ V_e(t)_{,\ unidirectional}] \ / \ L^{1/2}$.

**C1 71 Block Copolymer Nanotemplates for Biomolecular Arrays** JUNG HYUN PARK, YALE E. GOLDMAN, RUSSELL J. COMPOSTO, *NBIC, University of Pennsylvania* The controlled positioning of biomolecules on surfaces is important for applications such as high-throughput proteomic arrays as well as fundamental biological research. However, the development of biomolecule arrays requires well-ordered nanosize platforms. The perpendicular lamellar structure of diblock copolymer films deposited on silicon substrates is a good candidate as a nanotemplate because of their spatial dimensions and orientation. Using scanning probe microscopy, a nearly symmetric poly(styrene-b-methyl methacrylate) P(S-b-MMA) diblock copolymer spin coated on silicon and annealed at 175[r]C for 2 days exhibits a perpendicular lamellar morphology with a periodicity of 70nm. To further constrain biomolecules or proteins, topographical variations were etched into the film by exposure to UV radiation for varying times. This exposure was found to preferentially etch the MMA phase resulting in ''trenches'' of MMA stripes separated by hills of PS. Studies are underway to investigate the controlled attachment of biomolecules on both the perpendicular lamellar morphology and the same morphology with trenches.

**C1 72 X-ray Photon Correlation Spectroscopy Studies of Dynamics in a Polymer Bicontinuous Microemulsion** KRISTIN BRINKER, WESLEY BURGHARDT, *Northwestern University* SIMON MOCHRIE, *Yale University* Polymer bicontinuous microemulsions are ternary blends of otherwise immiscible homopolymers that are compatibilized with their corresponding diblock copolymer, leading to an equilibrium spongy interconnected morphology with domain sizes typically on the order of 10 - 100 nm. Recent research has demonstrated that the dynamics of this interconnected structure leads to rich and complicated linear and nonlinear viscoelastic behavior. Direct probing of the equilibrium dynamics of order parameter fluctuations within bicontinuous microemulsion phases has been achieved using dynamic light scattering; however, the range of accessible scattering vector in light scattering is poorly matched to the intrinsic length scale of the microemulsion morphology. Here we report experiments using small-angle X-ray Photon Correlation Spectroscopy, performed using facilties at Sector 8 of the Advanced Photon Source, to make direct measurements of the dynamic structure factor in a polystyrene- polyisoprene microemulsion sample in the vicinity of the Teubner-Strey scattering peak associated with the dominant length scale of the bicontinuous phase.

**C1 73 Morphology of Fluorinated and Sulfonated diblock Copolymers** TOMONORI HOSODA, SAM GIDO, *Polymer Sci. & Eng., Univ. of Massachusetts Amherst* TIANZI HUANG, JIMMY MAYS, *Univ. of Tennessee Knoxville* We have studied the microphase separation of Fluorinated and Sulfonated diblock Copolymers. The polymer was synthesized by post-polymerization fluorination and sulfonation of PI-b-PS diblocks. THF containing different weight fraction of water was used as solvents for the diblock copolymers to solution casting films. From the dry THF, we obtained a coexistence morphology of well-ordered lamella and cylinders. As the water content in the solvent was increased, the morphology changed from well-ordered to disordered. In addition, it was to be found that thermal annealing at 120C of the well ordered samples caused the morphology become disordered. The progressive disordering of the structure upon annealing was directly observed with TEM and SAXS. The results are very different the usual behavior or uncharged diblock copolymers in which annealing generally results in improvements in long range order. The disordering upon annealing may be the result of ion cluster formation which interferes with the normal block copolymer morphology.

**C1 74 Stereocomplex Formation in Incompatible Racemic Chiral Polylactide Block Copolymers** LU SUN, LEI ZHU, *Polymer Program, Institute of Material Science and Department of Chemical Engineering, University of Connecticut, Storrs, CT 06269-3136* Stereocomplexes in incompatible racemic chiral polylactide (PLA) block copolymers have not been widely studied. In this work, we synthesized PLLA and PDLA containing block copolymers by ring opening polymerization of L- and D-lactides from hydroxyl-terminated hydrophilic [poly(ethylene oxide)

(PEO)] and hydrophobic [poly(ethylene-itco-1,2-butylene) (PEB)] oligomers, respectively. Two samples PEO-*b*-PLLA (2,000-5,400) and PEB-*b*-PDLA (4,200-5,400) were chosen. The stereocomplexes were cast from equal molar blends of above two block copolymers in chloroform solution, followed by two different thermal treatments before stereocomplex formation; The blend was either heated to 250 [r]C and quickly quench to 160 [r]C or heated to 250 [r]C for 15 min and quench to 160 [r]C for stereocomplex crystal growth. Before the formation of stereocomplexes, lamellar and cylindrical morphologies were observed in blends for the first and second thermal treatments, respectively, as evidenced by small-angle X-ray scattering (SAXS). After complete crystal growth, the 100% stereocomplexes was confirmed by differential scanning calorimetry and wide-angle X-ray diffraction (WAXD). The morphologies of stereocomplexes grown from these two pre-existing microphases (lamellar vs. cylindrical) were studied by time-resolved SAXS and transmission electron microscopy (TEM).

**C1 75 Effect of local point group symmetry on self-assembly in thin films of block copolymers on topographically patterned substrates.*** ION BITA, *Department of Materials Science and Engineering, Massachusetts Institute of Technology* JOEL KANG, *Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology* KARL BERGGREN, *Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology* EDWIN THOMAS, *Department of Materials Science and Engineering, Massachusetts Institute of Technology* We have investigated the self-assembly of a diblock copolymer with spherical morphology on novel topographically patterned substrates. Poly(styrene)-b-poly(ferrocenyldimethylsilane), PS-*b*-PFS, was spin casted to form thin films with a PFS monolayer of spheres morphology. Topographically patterned silicon substrates were fabricated by both electron-beam and interference lithographies. To vary the local point group symmetry, a number of topographical patterns were designed and fabricated. Quasiperiodic arrays of posts allows access to multiple types of local symmetries with the average distance between posts an order of magnitude or more larger than the BCP period. Results for controlling long-range correlations of the BCP morphology and local 4-, 6-, 8-, and 12-fold rotational symmetries will be presented.

*Acknowledge support from NSF DMR 02-13282, NSF DMR-0308133.

**C1 76 Spectroscopy of the Primary Photoexcitation and the Origin of the Photocurrent in Rubrene Single Crystals** HIKMAT NAJAFOV, IVAN BIAGGIO, *Lehigh University* VITALY PODZOROV, MATT CALHOUN, MICHAEL GERSHENSON, *Rutgers University* By studying and correlating the photoexcitation spectra of several observables connected with excitons and charge transport we are able to gain new insights into the nature of the primary photoexcitation in organic molecular crystals. By simultaneously measuring the excitation spectra of the transient luminescence and of the transient photoconductivity after picosecond pulsed excitation in rubrene single crystals we show that free excitons are photoexcited starting at photon energies larger than 2.0 eV. We observed a competition between photoexcitation of free excitons and photoexcitation into vibronic excited states that subsequently decay into free carriers, while self-trapped molecular excitons are instead formed predominantly through the free exciton. At photon energies smaller than 2.25 eV free charge carriers are only created through a long-lived intermediate state with a lifetime of up to 0.1 ms and no free carriers appear during the exciton lifetime.

**C1 77 Exciton Dissociation by a Static Electric Field Followed by Nano-scale Charge Transport in PPV Polymer** HIKMAT NAJAFOV, *Lehigh University* IVAN BIAGGIO, *Lehigh University* TA-KO CHUANG, *Lehigh University* MILTIADIS K. HATALIS, *Lehigh University* The nature of the photoinduced generation of charge carriers in conjugated polymers is still the subject of an intense discussion. We investigate the main question of weather photoexcitation results in localized excitons or directly leads to mobile charge carriers by simultaneously studying the electric field dependence of the photoluminescence and the photoinduced charge-transport in a phenyl-substituted PPV derivative. We show that charge-carriers are created indirectly through field-induced ionization of excitons, and by quantitatively estimating the amount of carriers created by ionization of the exciton we identify a free-carrier mobility larger than $\sim 3.0\times 10^{-6}\mathrm{cm}^2\mathrm{V}^{-1}\mathrm{s}^{-1}$ that is valid for transport over a few nm during an apparent free-carrier lifetime of $\sim$ 50 ns. The time-dynamics of the photoluminescence and its temperature-quenching behavior indicate the presence of two species of excitons, which can be interpreted as intra-chain and inter-chain excitons.

**C1 78 Temperature Dependent Electroluminescence of $Alq_3$ Based OLEDs** AJITH DESILVA, H. P. WAGNER, *Deptartmet of Physics, University of Cincinnati, OH 45221* R. A. JONES, W. LI, A. STEKL, *Deptartment of ECECS, University of Cincinnati, Cincinnati OH 45221* The temperature dependent I-V characteristics and electroluminescence (EL) of an ITO/PEDOT/NPD/$Alq_3$/LiF–Al OLED is investigated. The I-V measurements reveal a trap charge limited current behavior with characteristic trap energy of 53 meV. The EL of the device is compared with the photoluminescence (PL) of a 50 nm thick $Alq_3$ film on Si (001) in the range from 10 to 320 K. The EL efficiency of the device shows similar temperature dependence as the PL intensity obtained from the $Alq_3$ film. The OLED brightness saturates at 10,000 cd/m$^2$ (T = 300 K; V = 15 V). For a constant forward bias (8 V) the maximum EL efficiency of the device is 2.2 cd/A obtained at 180 K. The maximum PL efficiency of the $Alq_3$ film is observed at the same temperature (180 K). Furthermore, both the EL and PL spectra reveal a maximum redshift at 180 K which is tentatively attributed to the formation of self-trapped excitons within the $Alq_3$ layer.

**C1 79 Multiplicative luminescence enhancement induced by chain relaxation in ultrathin films of a conjugated polymer (MEH-PPV)** CHIH-WEI YANG, JUO-HUEI JOU, ARNOLD CHANG-MOU YANG, *Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan* A surprising multiplication of light-emitting efficiency was observed in dewetting process of the conjugated luminescent polymer of poly (2-methoxy- 5-(2'-ethyl-hexyloxy)-1,4-phenylene vinylene] (MEH-PPV). The luminescent efficiency increased with the dewetting process and became about six-fold when the polymer film ruptured into tiny droplets. This enhancement appeared to be related to the carrier transport mechanisms and the motions of polymer chains. The effects of inter-molecular energy transport and

molecular deformation of polymer chains were studied by examining the emission behavior in liquid and solid solutions. It was found that the molecular movements during stretching in the glassy state were quite different from that in the dewetting process. The latter was dominated by disengagement of intermolecular entanglements while the former was strongly influenced by trapping mechanisms of chain entanglements due to rapid local molecular strains. This work is supported by National Science Council of Taiwan.

**C1 80 How Fast Should Polymer/Drug Nanocrystal Dispersions Be Frozen?** JONGHWI LEE, *Chung-Ang University, Dept. of Chemical Engineering and Materials Science, Seoul, Korea* CHUL HO PARK, *Chung-Ang University* Recent advances in nanoparticle technologies have significantly enhanced the oral and parenteral delivery of poorly water-soluble active pharmaceutical ingredients (APIs). However, reports have been limited on the various drying procedures to convert a liquid nanocrystal dispersions into solid dosage forms. The solid dosage form should consist of nanocrystals that can readily reconstitute into their original size upon dissolution in water. Herein, the freeze drying process of nanocrystal dispersions was examined at varying freezing rates (speed of freezing interface). As freezing rate decreases, more particle-particle aggregation developed. A critical freezing rate, below which the dried nanocrystals cannot be re-dispersed, was identified based on the plot of the particle size of reconstituted nanocrystals versus freezing rate. Freeze drying at a freezing rate near the critical value produces dry powders of bimodal particle size distribution after re-dispersion. In addition, API concentration was found to significantly affect the critical freezing rate and therefore the re-dispersibility of dry powders. The concept of critical freezing rate is critical for the development of solid dosage forms of liquid nanocrystal dispersions. [1] J. Lee, Drug nano- and microparticles processed into solid dosage forms: physical properties, J. Pharm. Sci., 92(10) (2003) 2057-2068.

**C1 81 Equilibrium interactions and phase behavior of nanoparticles in solutions of adsorbing polymers** MEGHA SURVE, VICTOR PRYAMITSYN, VENKAT GANESAN, *University of Texas at Austin* We present the polymer mediated pair-interaction potentials, phase and percolation behavior of nanoparticles in presence of adsorbing polymers. We propose a ''saturable'' adsorption model to capture the effect of the finite surface saturation capacity for adsorption, and use polymer self-consistent field theory in combination with a McMillan-Mayer framework to compute the pair interaction potentials. Our results demonstrate novel size effects that distinguish the adsorption characteristics of nanoparticles from that of larger particles. Specifically, we predict that the nanoparticle regime is characterized by a significant adsorbance of polymers, distributed predominantly in the form of tails. We also demonstrate that an interplay between the surface saturation, polymer-to-particle size ratios and the polymer concentrations governs the overall effective interactions between nanoparticles in presence of adsorbing polymer. Our results show that the percolation threshold for smaller particles are significantly smaller (and overall correspond only to a few volume percent) compared to that of the larger particles. Further, with a decrease in the size of the particles, we also predict a considerable increase in the miscibility of the polymer-particle mixtures. The importance of surface saturation considerations is highlighted by comparing our results with the previous approaches.

**C1 82 How do colloidal particles rotate? New Materials and New Physics** LIANG HONG, *Materials Science and Engineering Department, University of Illinois at Urbana-Champaign* STEPHEN ANTHONY, *Department of Chemistry, University of Illinois at Urbana-Champaign* HUILIN TU, *Materials Science and Engineering Department, University of Illinois at Urbana-Champaign* STEVE GRANICK, *Materials Science and Engineering Department, Department of Chemistry, Physics and Chemical Engineering University of Illinois at Urbana-Champaign* Surface modification of colloidal particles to a Janus (asymmetric) chemical composition affords an opportunity to measure the rotational dynamics of colloidal particles in suspension as well as at interfaces. Using a metal deposition technique, we make particles half-covered by metal, and generate geometrically symmetric but chemically and fluorescently asymmetric materials. The rotational dynamics of single colloidal particles as well as rod-like structures have been measured utilizing imaging and tracking techniques. Increasing the concentration of polyelectrolytes in the solution results in the retardation of the rotational diffusion of single colloidal particles. This decrease, however, is not proportional to the viscosity of the solution. Moreover, we formed a metal-welded rod-like tetramer with this approach; for the first time, the rotational dynamics along the long-axis is measured. Research in progress includes chemical modification of the metal surface to form new colloid based materials and Brownian dynamics studies of these new materials.

**C1 83 The Prospects of Nanorods as Blending Agents in Immiscible Binary Polymer Blends** MICHAEL J. A. HORE, MOHAMED LARADJI, *Dept. of Physics, The University of Memphis* Systematic, large scale dissipative particle dynamics computer simulations performed in three dimensions indicate that the dynamics of phase separation of polymer blends containing rigid nanorods can be substantially slower than that of a pure binary blend, and that the dynamics depend greatly on the aspect ratio, i.e length/diameter, of the nanoparticles. When compared with spherical nanoparticles, it is also found that nanorods with the same volume fraction, or same surface area, are more effective in slowing down the dynamics of the blend – an indication that the anisotropy of the nanoparticles plays an important role in the phase separation kinetics. For a given volume fraction of rods, the domain growth exponent decreases (and growth may become non-algebraic) as the aspect ratio of the rods is increased. Growth is also slowed as the volume fraction of the nanorods is increased for a given aspect ratio. Additionally, it is found that the effect of lengthwise polydisperse rods is similar to that of monodisperse rods with a length equal to the mean length of the polydisperse rods. In cases with high aspect ratio rods or high volume fractions of rods, systems often proceed to micro-phase separated states – results not seen for nanospheres. The upshot of these results is that nanorods may potentially be used as effective emulsifiers of immiscible binary polymer blends. The thermodynamic stability of these micro-phase separated states will be discussed.

**C1 84 Adhesion and Release Mechanisms for Nanoimprint Lithography** DOUGLAS HOLMES, *University of Massachusetts, Amherst* JOHN WHANG, EDWIN CHAN, *University of Massachusetts, Amherst* ALFRED CROSBY, *University of Massachusetts, Amherst* Nanoimprint lithography is a leading candidate for fabricating next generation devices with features smaller than 50nm. A fundamental challenge with this emerging technology is the generation of defects during the release of the template

from the cured polymer pattern. This release process is dependent not only on the surface energetics of the template and the cured polymer, but also on the local mechanical properties of both materials – similar to the propagation of a crack at an interface. Here we present results on the investigation of adhesion and release properties of several polydimethylsiloxane-based polymer templates using UV-based imprint lithography techniques. We demonstrate that the framework of fracture mechanics and the theory of Johnson, Kendall, and Roberts (JKR) allows the separation of bulk and interfacial contributions to the overall release process. This decoupling of material properties guides the future development of both templates and imprintable resists for the success of nanoimprint lithography.

**C1 85 Nanotransfer printing for patterning conductive copper features** KIMBERLY DICKEY, YANGMING SUN, YUEH LIN LOO, *University of Texas at Austin* The drive for low-cost electronics creates a need for new techniques to directly and inexpensively pattern copper features in the 1-100$\mu$m range. We have developed a solventless, additive approach for printing permanent, conductive copper features at ambient conditions. Our technique is analogous to previously established nanotransfer printing (nTP) procedures for patterning gold with one marked difference. When copper is deposited onto a poly(dimethylsiloxane), PDMS, stamp, residual oligomers from the stamp penetrate between copper grains. This penetration disrupts the conductive pathway between copper grains; the printed copper patterns are electrically insulating as a consequence. This phenomenon is not observed with nanotransfer printing of gold features. A simple modification to the patterning procedure – leaching the PDMS stamps in boiling toluene for 2-3 days to remove uncrosslinked oligomers – results in printed copper patterns that are electrically conductive, with an average resistivity of 31$\mu$ohms-cm.

**C1 86 Surface grafting of carbon nanotubes with conjugated polybenzoxazole polymer** CHIH-WEI LIN, JEN-YOU LIN, ARNOLD CHANG-MOU YANG, *Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan* CHEN-CHI M. MA, *Department of Chemical Engineering, National Tsing Hua University, Hsinchu, Taiwan* Surface-grafted carbon nanotubes impart extraordinary mechanical reinforcement to the polymer nanocomposites but considerably reduce the superior electrical conductivity of the neat carbon nanotubes. The conjugated polymer of polybenzoxaole (PBO) for grafting carbon nanotube therefore is very interesting as it may warrant reinforcement of both electrical and mechanical performances. The PBO-grafted carbon nanotubes was obtained from graft polymerization on nanotubes of polyhydroxyamide (PHA), the precursor of PBO, via condensation of 2,2'-bis(3-amino-4- hydroxyphenyl)-hexafluropropane ($BisPF_6$) and isophthaloyl chloride (IC) at low temperatures. The microstructure of the hybrid nanocomposites was investigated by FTIR, SEM, and TEM. The PBO/MWNT nanocomposites demonstrated excellence electronic (resistivity 0.374 $\Omega$-cm) and thermal (decomposition temperature 590 °C) properties. This work is supported by Air Force (AFOSR-04-4074) and National Science Council of Taiwan.

**C1 87 Modification of Nanocomposite POSS-PMMA Surfaces by Exposure to Reactive Oxygen.** REBEKAH ESMAILI, JACOB FORSTATER, BRIAN H. AUGUSTINE, WM. CHRISTOPHER HUGHES, *James Madison University* Thin films of the nanocomposite copolymer polymethylmethacrylate-polyhedral oligomeric silsequixane (PMMA-POSS) have been deposited onto glass and polymeric substrates and modified by exposure to reactive oxygen. The source of the oxygen was either a remote capacitively coupled plasma or UV-generated ozone. A change from hydrophobic to hydrophilic was observed after exposure to oxygen for time periods greater than 20 seconds. This change was quantified by measuring water contact angles on the surface which varied from greater than 90[r] before plasma exposure to less than 10[r] afterwards. A model for this behavior in which the isobutyl groups around the POSS cage are selectively removed by the oxygen plasma leaving a SiOx-rich surface is proposed. Time-of-flight secondary ion mass spectroscopy (ToF-SIMS) data were performed to test this model and show that the number of isobutyl groups on the surface does decrease with exposure time. Ongoing experiments involving the effect of oxygen exposure on the electro-osmotic flow in microfluidic structures which incorporate these films will be discussed.

**C1 88 Polypeptide-Based Silicate Layered Nanocomposite: Effect of Poly(L-lysine) Secondary Conformation on Physical Properties of the Hybrid** ROHAN HULE, *Dept of Mat. Sci. and Engg. and Del. Biotech Inst., Univ of Delaware, Newark, DE 19716* JEFFREY THOMPSON, *Dept of Mat. and Chem., UCSB, CA, 93106* TIMOTHY DEMING, *Dept of Bioengg., UCLA, CA 90095* DARRIN POCHAN, *Dept of Mat. Sci. and Engg. and Del. Biotech Inst., Univ of Delaware, Newark, DE 19716* The formation of nanocomposites from poly(L-lysine) (PLL) as the matrix and reinforced by $Na^+$- MMT clay is discussed. By varying solution conditions such as pH, temperature and concentration in the presence of MMT, the secondary conformation of PLL was controllably altered into $\alpha$-helical, $\beta$-sheet and random coil. Investigations were made into the PLL secondary conformation using FTIR, XRD and Circular Dichroism (CD). CD and FTIR revealed a strong propensity to fold into $\beta$-sheet when cast as films, irrespective of the initial secondary structure in solution. Two principles were observed for nanocomposite behavior: better mechanical properties at high molecular weight and controllable secondary structure at low molecular weight. Local morphology, observed using TEM and XRD confirmed the coexistence of intercalated and exfoliated MMT platelets over a wide range of compositions. Nanocomposite material properties relative to the secondary conformation of the matrix revealed significant enhancement in composite elastic modulus over neat polypeptides, with values comparable to traditional engineering polymers.

**C1 89 Oriented Mesoporous Inorganic Thin Films Using Laterally Confined Swellable Block Copolymer Templates.** SE GYU JANG, *UCSB* EDWARD J. KRAMER, *UCSB* SEUNG-MAN YANG, *KAIST* KAIST (SNL) COLLABORATION, UCSB (KRAMER) COLLABORATION, The control of grain orientation and long-range ordering of mesoporous inorganic materials produced by a sol-gel reaction of an inorganic precursor in self-assembling amphiphilic template systems have been limited due to the restrictions both on the time-scale and conditions for processing imposed by network formation of the inorganic component. Our goal is to form ordered mesoporous inorganic thin films by starting with a crosslinkable block copolymer template with long range order. A cylindrical poly(styrene-2-vinylpyridine) (PS-P2VP) diblock copolymer with Mn = 32.7 kg/mol and $f_{PS} = 0.21$ was spin-cast onto a set of 30 nm high and 2000 nm wide SiOx channels on Si substrates produced by optical lithography. An ordered PS-P2VP monolayer[1] is achieved via slow cooling after heating above its bulk order-disorder transition temperature (212

C), measured by small angle X-ray scattering. Hybrid inorganic/organic structures are fabricated by incorporation of inorganic precursor into the chemical cross-linked P2VP matrix.[2] Cylindrical pores within the inorganic matrix are then obtained by removal of the organic component using UV-ozone treatment. [1]M.R.Hammond, E. Cochran, G.H. Fredrickson, E.J. Kramer Macromolecules **38** 6575 (2005). [2]R.C. Hayward, B.F. Chmelka, E.J. Kramer Macromolecules **38** 7768 (2005).

**C1 90 Chemical composition effects on the crazing of PS-PMMA block copolymers** WON KIM, *Rensselaer Polytechnic Institute, Department of Chemistry and Chemical Biology* JUN-WON HAN, *Rensselaer Polytechnic Institute, Department of Chemical and Biological Engineering* HOICHANG YANG, *Rensselaer Polytechnic Institute, Rensselaer Nanotechnology Center* CHANG RYU, *Rensselaer Polytechnic Institute, Department of Chemistry and Chemical Biology* Using a large scale separation technique adopting interaction chromatography, we have fractionated as-synthesized PS-PMMA block copolymers in terms of the average chemical composition difference, while maintaining the same average molecular weight. Copper grid technique with optical, atomic force and transmission electron microscopy has been employed for the fracture study to reveal how the composition-dependent morphology affect the crazing of the glassy-glassy block copolymers, while maintaining the same level of Chi*N. In addition, we study how the thermal annealing affects the median strains for crazing and catastrophic failure.

**C1 91 Impact of Nanotube Addition on Stress Recovery of Thermoplastic Elastomer Nanocomposites.** DANIEL POWERS, MAX ALEXANDER, RICHARD VAIA, *Air Force Research Laboratories* MICHAEL ARLEN, *University of Akron* HILMAR KOERNER, *University of Dayton Research Institute* Recent extension of polymer nanocomposite concepts to shape memory polymers has demonstrated potential to substantially improve recovery stress and provide novel triggering options, while still maintaining large deformations. One such example is multi wall carbon nanotubes (MWCNT)s in thermoplastic polyurethane (PU), where the MWCNTs increase modulus and modify strain induced crystallization leading to improved strain set and recovery force relative to unfilled PU as well as conventionally-filled PU. The impact of MWCNT alignment on the stress recovery rate depends on MWCNT concentration and the procedure used to 'set' the deformation. Differences in response time upon shape recovery are observed whether the nanocomposites are 'set' above the melting point of soft segment crystallites or at room temperature (RT). A detailed dynamic mechanical analysis protocol reveals that recovery rate and shape fixity are increasing as a function of MWCNT volume fraction and that RT processed nanocomposites show overall superior results. Recovery times can be described with a modification of the Kohlrausch-Williams-Watt equation, indicating a contribution from elasticity of the carbon nanotubes or chain scission of the matrix PU.

**C1 92 Long DNA Molecules at Liquid-Solid Interfaces** VLADIMIR SAMUILOV, B. LI, J. SOKOLOV, M. RAFAILOVICH, *Dept. of Materials Science, SUNYSB, Stony Brook* B. CHU, *Dept. of Materials Science, Dept. of Chemistry, SUNY at Stony Brook* The electrophoresis of long DNA molecules was studied using a newly developed method of electrophoresis on flat surfaces [1] in the regime of strong electrostatic interaction. The mobility of lambda- DNA molecules on this surface was found to scale as the square root of the persistent length with the ionic strength at high buffer. This experimental result indicates that at high buffer concentration the separation mechanism of solid-liquid interface electrophoresis is expected to be due to surface friction rather than biased reptation [2-4]. At low buffer concentrations the DNA chains are stretched.The electric double layer is responsible for a velocity profile of the electroosmotic flow. The net electrophoretic mobility of longer DNA, being trapped closer to the surface as found to be higher then for the shorter ones in the electric field. [1]. N. Pernodet, V. Samuilov, K. Shin, et al. Physical Review Letters, 85 (2000) 5651-5654. [2] Y.-S. Seo, V.A. Samuilov, J. Sokolov, et al. Electrophoresis, 23 (2002) 2618-2625. [3] Y.-S. Seo, H. Luo, V. A. Samuilov, et al. DNA Electrophoresis on nanopatterned surfaces, Nano Letters, 4, 2004, 659-664.

**C1 93 Closed-Loop Phase Behavior: Is it Universal Phenomenon for Block Copolymers with Lower Critical Transition Temperature?*** JIN KON KIM, CHAOXU LI, DONG HYUN LEE, *Department of Chemical Engineering, Pohang University of Science and Technology* A closed-loop phase behaviour was found for Polystyrene-block- poly(n-pentyl methacrylate) (PS-PnPMA) copolymer having a weak interaction between two segments. On the other hand, PS-block- poly(n-butyl methacrylate) (PS-PnBMA) exhibited only lower disordered-to-ordered transition (LDOT). Then, a question might be raised: Is it possible that PS-PnBMA has the closed-loop phase behaviour, although the upper ordered-to-disordered transition (UODT) could not be detected in the experimentally accessible temperature. In this study, we clearly demonstrate that PS-PnBMA exhibits the closed-loop phase behaviour, where both LODT and UODT were measured at experimentally accessible temperatures (100 ~ 280°C) by using special solvents.

*This work was supported by the Creative Research Initiative Program (KOSEF).

**C1 94 Acoustic modes and elastic properties of polymeric nanostructures*** RYAN D. HARTSCHUH, A. KISLIUK, A.P. SOKOLOV, *University of Akron* V. NOVIKOV, *U of A and IA&E, Russian Academy of Sciences* P.R. HEYLIGER, *Colorado State University* C.M. FLANNERY, W.L. JOHNSON, *NIST, Boulder* C.L. SOLES, W.-L. WU, *NIST, Gaithersburg* Very few experimental techniques exist to quantify the mechanical properties of nanoscale photoresist structures. This inadequacy is going to become increasingly important as the rigidity of such structures is expected to change as the feature sizes approach the characteristic dimensions of the macromolecules and size-dependent material properties begin to compromise device fabrication and performance. Phonon spectra of polymeric linear nanostructures have been characterized using Brillouin light scattering. In addition to phonon modes similar to those present in uniform thin films, the phonon spectra of the nanolines reveal a new mode with a lower frequency that depends on the width of the nanolines. Classic wave theory and finite element analysis were combined to identify this new mode as a flexural vibration of the nanolines. Analysis of the phonon spectra gave estimates of elastic constants in the nanostructures and indicated that there is no significant deviation from bulk mechanical properties and no mechanical anisotropy in structures as small as 88 nm.

*This material is based upon work supported under a National Science Foundation Graduate Research Fellowship

**C1 95 Polymeric Micro/Nanostructures Fabricated through a Novel Method with Optical Microscopy** CHAO-MIN CHENG, BIN LI, PHILIP LEDUC, *Department of Mechanical Engineering, Carnegie Mellon University* We present a technique for building three-dimensional structures using optical methods with photocuring chemistry. This method merges an optics-based approach with chemical restructuring through the transition of materials from distinct phases. By activating a photocurable material in combination with controlling the intensity distributions that are inherent in optical patterns, in-situ fabrication of three-dimensional polymeric microstructures is demonstrated. Furthermore, polymeric nanostructures can be also obtained based on this method through combining this technique with Al2O3 nanopores. This experimentally simple approach combined with thermal control can create complex shapes including curved and asymmetric profiles. This method has potential applications in a variety of fields including optical technique, micro/nanoelectromechanical systems and microfluidics.

**C1 96 Nanoparticle arrays controlled by polymeric ligands** CHUN-KWEI WU, JEFFREY T. KOBERSTEIN, *Columbia University* Ligand chemistry on nanoparticles plays an important role in applying their unique properties to the real world. The original capping ligands on nanoparticles, i.e. oleic acid, limit their compatibility with some bulk materials of interest and can restrict some potential applications. We have successfully exchanged the original oleic acid ligands on $\gamma$-$Fe_2O_3$ nanoparticles with $\omega$-poly(dimethylsiloxane) (PDMS). A high grafting density of PDMS on iron oxide nanoparticles has been achieved by this ''grafting to'' method. $Fe_2O_3$ nanoparticles with PDMS ligands self-assemble with hexagonal packing when deposited on substrates. The interparticle spacing can be controlled by varying the molecular weight of the PDMS. The PDMS-modified $Fe_2O_3$ nanoparticles are totally compatible with bulk PDMS allowing nanocomposites to be formed. The PDMS components in resultant thin films can subsequently be converted to silicon oxide by room temperature UV/ozone treatment to fabricate $Fe_2O_3$-silica composite thin films. The use of such nanocomposite films in gas separation and catalyst membranes is being studied.

**C1 97 Crosslinked nanoparticle assemblies at liquid-liquid interfaces** RAVISUBHASH TANGIRALA, HABIB SKAFF,*YAO LIN,†THOMAS RUSSELL, TODD EMRICK, *University of Massachusetts, Amherst, MA* The assembly of nanoparticles at the interface of immiscible fluids holds promise for the preparation of new materials that benefit from both the physical properties of the nanoparticles and the chemistry associated with the ligands. The weak confinement of nanoparticles to the liquid-liquid interface enables the formation of particle-based assemblies that possess unique features relative to assemblies of micron-scale particles. Crosslinking of nanoparticles at a liquid-liquid interface lends greater stability to the interfacial assembly, leading to ultrathin nanoparticle-based capsules which possess mechanical integrity even after removal of the interface. Norbornene-functionalized CdSe/ZnS core/shell quantum dots are used in this study to afford facile capsule visualization by fluorescence confocal microscopy, as well as ease of crosslinking in mild conditions by means of ring-opening metathesis polymerization (ROMP) using a unique amphiphilic ruthenium benzylidene metathesis catalyst. The crosslinked capsules display a size-selective encapsulation capability, dictated by the interstitial spaces between the nanoparticles. The porosity of the capsules can be further tuned by the addition of small amounts of uncrosslinkable nanoparticles prior to crosslinking.

†Currently at Argonne National Laboratories

**C1 98 Gold nanoparticle self-assembly and gold patterning using thin film polymer blend templates.** RANJAN D. DESHMUKH, RUSSELL J. COMPOSTO, *Materials Science and Engineering, University of Pennsylvania* In this study we have used thin films of polymer blend of Poly(methyl methacryalate), PMMA, and Poly(styrene-ran-acrylonitrile), SAN, as templates for patterning gold as well as gold nanoparticles on silicon substrate. PMMA/SAN phase separate above lower critical solution temperature, LCST, and form cylindrical and bi-continuous morphologies in 50/50 and 70/30 blend compositions. Selectively etching out PMMA phase by UV and acetic acid treatment results in a template, which is used for patterning. Gold is sputtered on these templates followed by removal of SAN in a solvent, leaving gold patterns on the substrate. Unique cylindrical island-like and bi-continuous patterns were observed by AFM. We also selectively patterned the etched region (PMMA) with a self-assembled monolayer, SAM, of 3-aminopropyl-triethoxysilane, APTES, followed by SAN removal and coating the exposed region with 3-mercaptopropyl-trimethoxysilane, MPTMS. Further, deposition of colloidal citrate-stabilized gold nanoparticles resulted in the selective deposition of gold nanoparticles on APTES (island-like and bi-continuous patterns), because of the charge-charge interactions between nanoparticles and SAM.

**C1 99 Organometallic Polymer-Derived Catalyst Dispersion Effects on SWNT Growth** SARAH LASTELLA, PULICKEL M. AJAYAN, CHANG Y. RYU, *Rensselaer Polytechnic Institute* DAVID RIDER, IAN MANNERS, *University of Toronto* Catalyst formation kinetics of a ferrocene-containing homopolymer, polyferrocenylethylmethylsilane or PFEMS, is investigated as it relates to the catalysis of single walled carbon nanotubes (SWNTs) and is compared with that of the corresponding diblock copolymer, poly(styrene-b-ferrocenylethylmethylsilane) or PS-b-PFEMS. The polystyrene blocks in the PS-b-PFEMS form a matrix to uniformly disperse discrete nanoscale iron domains that enhance the uniformity of nanotube diameters compared to the homopolymer. PFEMS homopolymer contains 23 percent iron by weight, while PS-b-PFEMS with a 25 vol percent PFEMS is only 6 percent iron, respectively. It is concluded that iron present in a block copolymer film is two times more active than a PFEMS film, and in turn, leaves a lower iron density on the substrate surface relative to its nanotube yield.

## C1 100 BIOLOGICAL PHYSICS POSTER SESSION

**C1 101 Elastic and osmotic properties of articular cartilage** DAVID LIN, EMILIOS DIMITRIADIS, IREN HORKAYNE-SZAKALY, FERENC HORKAY, *National Institutes of Health (NIH)* The pathophysiology of osteoarthritis involves cellular and biochemical processes linked to mechanical stress. A better understanding of the mechanism of these processes and how they cause

changes in the composition, macro- and micro-structure, and mechanical properties of cartilage is necessary for developing effective preventative and treatment strategies. In this study, elastic and osmotic swelling properties of tissue-engineered cartilage were explored using atomic force microscopy (AFM) and a tissue osmometer. AFM was also used to image the surface of the specimens while chemical composition was determined by biochemical analysis. Estimation of the Young's moduli of the tissue from AFM force-indentation data was performed using an optimization approach to fit appropriate models to the data. Force-indentation data were acquired both with sharp, pyramidal and with microspherical probes. The procedure has been validated by making measurements on model gel systems of known elastic properties. This approach is presented as a robust method of optimally extracting Young's moduli of soft, crosslinked materials from AFM data. Gross inhomogeneities at different scales in the cartilage tissue are manifested in the high degree of variance in local Young's moduli values obtained from both AFM and osmotic swelling data. These findings suggest that the mechanical properties of cartilage are affected by the local macromolecular composition.

**C1 102 The Influence of Environment Geometry on Injury Outcome: II. Lumbosacral Spine** SAAMI J. SHAIBANI, *Independent Modeling, Algorithms & Analytical Studies (IMAAS)* It is widely agreed that the type of motor vehicle in which an occupant is situated can sometimes make a noticeable difference in injury potential even when the insult suffered is the same. A simple example might be the same occupant being in a sports car as opposed to a minivan, but such anecdotal experience does not usually help to distinguish the effect of particular features within the same category of vehicle. Other research has addressed the role of environment geometry in neck injury,[1] and this paper adopts the same methodology for the low back. The heights, lengths and angles of the seat cushion and seat back (including head rest) are all examined as descriptors of passenger compartment geometry, and any changes caused by these are determined. Useful results are feasible with the large patient population available even if clear patterns in these are not always present. As in earlier work, there is still the option of finding individual outcomes on a case-by-case basis. [1] The influence of environment geometry on injury outcome: I. Cervical spine, Bull Am Phys Soc, in press (2006).

**C1 103 Analysis of a 2D simulation model of biofilms with autonomous cells** ANAND BHANDAR, YERGOU TATEK, GARY SLATER, *University of Ottawa* Biofilms are substances consisting of a large number of microorganisms that grow on surfaces in contact with liquids. They can be found growing in water pipes, on surgical instruments or on tooth surfaces. Mathematical models have been used for the last three decades in order to improve our understanding of their growth and behavior. We have designed and implemented a new Monte Carlo model based on the life of autonomous cells and investigated the static and dynamic characteristics of the resulting bacterial populations. Each cell is modeled as an autonomous agent whose behavior is controlled by thermodynamic parameters, mechanical properties, physiological rules and environmental conditions. In the 2D version studied, a cell is represented by a closed chain of self-avoiding beads linked together using the bond fluctuation algorithm. The cell is controlled both by the rigidity of its membrane and a pressure difference. The model is complemented by key features such as the processes of cell division, growth and death, attractive interactions between the cell and the surface, and the explicit presence of nutrient diffusion. Tuning model parameters leads to the growth and maturation of various types of biofilms. Typical colonies incorporating these and other important characteristics of biofilms such as the exopolymeric substance (EPS), metabolism and waste production, cell motility and chemotaxy, and cell mutation will be presented.

**C1 104 A physiologically-based spatiotemporal model of fMRI hemodynamic responses.** JACKIE HUBER, *School of Physics, University of Sydney, Australia* PETER DRYSDALE, PETER ROBINSON, *School of Physics, University of Sydney, Australia; Brain Dynamics Center, Westmead Hospital, Australia* A 3D cerebrovascular model is developed to describe the spatiotemporal Blood Oxygen Level Dependent (BOLD) functional MRI (fMRI) response. Modelling spatial effects is particularly important as technology improves, shrinking image voxels and thereby increasing voxel interdependence. Specifically, poroelastic theory, originally developed in geophysics, is used to model the brain tissue and vasculature as a porous continuum. The model yields equations describing conservation of mass, momentum, and deoxyhemoglobin, plus the effect of neuronal activity on blood flow. The equations reproduce existing, non-spatial, hemodynamic models in the relevant limit. Imposition of continuity of flow between adjacent points enables potential investigation of spatial phenomena such as 'blood steal' which has been proposed to account for negative BOLD signals abutting sites of positive BOLD responses. This model will enable future study of spatiotemporal relationships between stimuli and experimental fMRI BOLD responses.

**C1 105 BOLD Responses to Stimuli: Dependence on Frequency, Stimulus form, Amplitude, and Repetition Rate.** PETER ROBINSON, PETER DRYSDALE, *School of Physics, University of Sydney, Australia; Brain Dynamics Center, Westmead Hospital, Australia* HELENA VAN DER MERWE, ELIZABETH KYRIAKOU, MICHELLE RIGOZZI, BILJANA GERMANOSKA, *School of Physics, University of Sydney, Australia* CHRISTOPHER RENNIE, *School of Physics, University of Sydney, Australia; Brain Dynamics Center, Westmead Hospital, Australia* A quantitative theory is developed for the relationship between stimulus and the resulting Blood Oxygen Level Dependent (BOLD) functional MRI signal in the brain. The relationship of stimuli to neuronal activity during evoked responses is inferred from recent physiology-based modeling of evoked response potentials (ERPs). A hemodynamic model is then used to calculate the BOLD response to neuronal activity. The predicted response is analyzed vs. form, frequency, and amplitude of stimulus. The BOLD frequency response is very nearly linear in the parameter ranges of interest, with the form of a low-pass filter with a weak resonance at 0.07 Hz. For short stimuli, the response is closely proportional to the time-integrated stimulus-evoked activity, rather than the peak amplitude, as often assumed. There can thus be widely differing proportionalities between BOLD and peak activity, a likely reason for the weak expected correlation between ERPs and BOLD.

**C1 106 Measurement of the Mechanical Properties of Intact Collagen Fibrils** H. MERCEDES, A. HEIM, W.G. MATTHEWS, *Department of Physics, University of South Florida* T. KOOB, *Shriners Hospital for Children* Motivated by the genetic disorder Ehlers-Danlos syndrome (EDS), in which proper collagen synthesis is interrupted, we are investigating the structural and mechani-

cal properties of collagen fibrils. The fibrous glycoprotein collagen is the most abundant protein found in the human body and plays a key role in the extracellular matrix of the connective tissue, the properties of which are altered in EDS. We have selected as our model system the collagen fibrils of the sea cucumber dermis, a naturally mutable tissue. This system allows us to work with native fibrils which have their proteoglycan complement intact, something that is not possible with reconstituted mammalian collagen fibrils. Using atomic force microscopy, we measure, as a function of the concentration of divalent cations, the fibril diameter, its response to force loading, and the changes in its rigidity. Through these experiments, we will shed light on the mechanisms which control the properties of the sea cucumber dermis and hope to help explain the altered connective tissue extracellular matrix properties associated with EDS.

**C1 107 Design and use of an artificial capillary in the study of metastatic cell adhesion** ADAM RAFI, ANTONIO PERAMO, REBECCA BOREN, AUGUST HEIM, WILLIAM G. MATTHEWS, *Department of Physics, University of South Florida* To improve the quality of life of patients with cancer, treatments will need to both minimize existing tumors and reduce the metastasis of cancer cells. The effectiveness of potential treatments on existing tumors can be directly probed, but anti-metastasis treatments are difficult to quantify. Therefore, a detailed understanding of the metastatic process is required for drug design. Details of the metastatic deposition of tumor cells in the circulatory system are not well understood. We are investigating the binding of tumor cells to an artificial endothelium. The model system allows for control over molecular composition at the interface, presenting the proteoglycans (PGs) found in the glycocalyx to tumor cells under shear flow conditions. Whether rolling or static adhesion is preferred, as well as what mechanical properties of the interaction between the cells and the PGs are important is to be determined. The outcomes of these experiments will help guide the search for pharmaceuticals that can disrupt the metastatic process at the endothelial adhesion step.

**C1 108 Study of Native Type I Collagen Fibrils** AUGUST HEIM, *University of South Florida* Presented in this work is direct imaging and force microscopy of native, intact type I collagen fibrils extracted from the sea cucumber itCucumaria frondosa dermis with affiliated proteoglycan molecules. The prototypical collagen fibril structure is well conserved through higher mammalian species and presents a model for study of the mechanical properties of the primary individual components of the dermis and skeletal ligature. Common practice is to use reconstituted fibrils which lack the precise conformal structure and affiliated proteoglycans. We have performed force microscopy to probe the mechanical properties of native fibrils and extract the elastic modulus under natural conditions. This knowledge is combined transmission and atomic force imaging, in conjunction with applied computation models, to demonstrate an inherent semitubular structure of these fibrils.

**C1 109 Conformational analysis of tripeptides: a molecular dynamics study of rigid and non-rigid tripeptides** JOHN SHIBATA, MARK MOCHEL, *The University of the South* Molecular dynamics simulations have been performed on different tripeptides classified as structurally rigid and non-rigid (1). The simulations were run using the OPLS-AA force field (2) with and without explicit solvent. Two modeling programs, Tinker (3) and Macromodel (4), were used to simulate the dynamics. The accessible conformations were analyzed using Ramachandran plots of the dihedral angles. The results of this study are compared to the rigidity classification scheme (1), and differences in the results using explicit solvent and a continuum solvent model are noted. **C1 110 Examination of the Interface Formed from Protein Interactions in Gels** PERUMAL RAMASAMY, *Dept. Of Materials Science and Engineering, SUNY Stony Brook* LISA M. MILLER, *National Synchrotron Light Source, Brookhaven National Laboratory* M. RAAFAT EL-MAGHRABI, *Department Of Physiology And Biophysics, SUNY Stony Brook* MIRIAM RAFAILOVICH, *Dept Of Materials Science and Engineering, SUNY Stonybrook* Understanding the interaction of proteins with one another in confined environments serves as an important step for developing faster protein separation methods. To understand proteinprotein interaction of oppositely charged proteins, fluorescently-labeled Albumin and poly-L-Lysine were subjected to electrophoresis in Agarose gels, in which the cationic albumin and the anionic poly-lysine were allowed to migrate towards each other and interact. Confocal microscopy was used to image the fluorescently-tagged proteins in the gel. The secondary structure of the proteins was studied using FTIR microspectroscopic imaging. Results showed that sharp interfaces were formed where the proteins met. Protein-protein interactions were observed through fluorescence quenching. The migration of the interface in the gel was found to be dependent upon the relative concentration of the proteins. The structure of the proteins at the interface, the fluorescent intensity modifications, and the mobility of the interface for different pore sizes are currently under investigation.

**C1 111 Simple Model for Phase Diagram of Lysozyme as a Function of Salt Type and Salt Concentration** NATHANIEL WENTZEL, JAMES D. GUNTON, *Lehigh University* The liquid-liquid phase separation curves for lysozyme are known to depend on the salt type and salt concentration. For the case of monovalent cations, the cloud point temperature typically increases with increasing salt concentration, for fixed lysozyme concentration. For the case of divalent cations, however, a maximum in the cloud point temperature is observed that has been interpreted as being due to ion binding to the protein surface and subsequent water structuring. In this paper we use a simple square well model due to Grigsby et al (Biophys. Chem. 91, 231 (2001)), whose well depth depends on salt type and salt concentration, to determine the phase diagram for both monovalent and divalent cations. The phase diagrams are calculated using standard Monte Carlo simulations and compared with known experimental results.

**C1 112 Computationally Efficient Method of Simulating Creation of Electropores** JOHN NEU, *University of California, Berkeley* WANDA KRASSOWSKA, *Duke University* Electroporation, in which electric pulses create transient pores in the cell membrane, is an important technique for drug and DNA delivery.

Electroporation kinetics is described by an advection-diffusion boundary value problem. This problem must be solved numerically with very small time and space steps, in order to resolve very fast processes occurring during pore creation. This study derives a reduced description of the pore creation transient. This description consists of a single integrodifferential equation for the transmembrane voltage V(t) and collateral formulas for computing the number of pores and the distribution of their radii from V(t). For pulse strengths corresponding to those used in drug and DNA delivery, relative differences in predictions of the reduced versus original problem are: voltage V(t), below 1%; number of pores, below 10%; pore radii, below 6%. Computational efficiency increases with the number of pores and thus with the pulse strength. For the strongest pulses, the run time of the reduced problem was below 1% of the original one. Such time savings can bridge the gap between problems that can be simulated on today's computers and problems that are of practical importance.

**C1 113 Hydrophobic Mismatch and Phase Transition in a Membrane Composed by a Mixture of Linear and Bola Phospholipids** GABRIEL LONGO, IGAL SZLEIFER, *Department of Chemistry, Purdue University* Archeobacteria are microorganisms that can survive and proliferate in extreme habitats, such as high salt concentration environments, anaerobic conditions, and high or low temperatures. A membrane composed of bolaform phospholipids is what gives these unique survival qualities to the bacteria. The nature and composition of this membrane has not yet been elucidated. In this work, a membrane composed by a mixture of linear and bola phospholipids is studied using a molecular theory. The effect of changing the fraction of bolaform phospholipids, as well as the length of the hydrocarbon chain of the linear lipid are studied. A phase separation in the mixture between a thin bola rich membrane and a thick linear rich membrane is found. The thin membrane is mainly composed by ''spanning'' bola molecules whose polar heads are in opposed hydrophilic regions of the membrane. The phase separation is only present when the hydrocarbon chains of both molecular species have comparable sizes. The driving force for the phase separation is the size matching between the hydrophobic chains of the linear phospholipid and the spanning bola lipid.

**C1 114 Renormalized Elasiticity of Lipid Membranes with Adsorbed Polymers** JOEL D. REVALEE, *Physics Department, University of Memphis* MOHAMED LARADJI, *Physics Dept., University of Memphis* Renormalized elastic moduli of self-assembled lipid membranes, with anchored polymers that interact attractively with the membrane, are determined by means of large scale dissipative particle dynamics simulations. We show that the effective surface tension and the bending modulus of the membrane behave non-monotonically with the molecular weight or/and polymer coverage. At low molecular weight or grafting densities, the surface tension increases, while the bending modulus decreases, with increasing molecular weight or grafting density of the polymer chains. However, at high molecular weight or grafting densities, when the polymers are in the brush regime, we found that the surface tension decreases while the bending modulus increases with increasing grafting density or molecular weight of the polymers. We will also present results on the pearling instability of the lipid membrane due to grafted polymers.

**C1 115 On the Registry of Lipid Domains in Multicomponent Lipid Membranes** CLAYTON H. DAVIS, *Physics Department, University of Memphis* MOHAMED LARADJI, *Physics Dept., University of Memphis* Recent experiments on multicomponent lipid vesicles, composed of a saturated lipid, unsaturated lipid and cholesterol, have shown that the liquid-ordered domains in the two leaflets of the bilayer are in strong registry [1,2]. In order to understand the reasons behind this domain registry, we propose a simple lattice model, where the two leaflets are represented by two spin-half Ising surfaces, where the up and down spins represent the saturated and unsaturated lipids, respectively. Since lipid flip-flops are very rare events, spins in the two Ising lattices are only allowed to diffuse within each leaflet through spin-exchange Kawasaki dynamics. In addition each lattice point can also be occupied by a cholesterol particle which is allowed to both diffuse within each lattice and flip-flop between the two lattices. We found that registration can occur even for small concentrations of cholesterol. We will discuss the effects of cholesterol saturation and intra-layer and inter-layer lipid-cholesterol interaction on domains registration. [1] S.L. Veatch and S.L. Keller, Phys. Rev. Lett. 89, 268101 (2002) [2] T. Beaumgart, S.T. Hess, and W.W. Webb, Nature 425 (2003)

**C1 116 Cubic Phase Formation in Peptide/Lipid Systems*** BRANDON SCUFFINS, BETH CUNNINGHAM, *Bucknell University* DAVID WOLFE, *Lycoming College* Previous studies have shown that the phenomena of spontaneous membrane self-assembly can be used to incorporate membrane peptides into lipid bilayers. Once a peptide is incorporated in these peptide/lipid systems they may then be crystallized through the process of itin meso crystallization. In this study, we used x-ray diffraction and $^{31}$P NMR to show that a system of dioloeoylphosphatidylethanolamine (DOPE), monoolein (MO), and DOPE with polyethylene glycol covalently attached to the headgroup (PEG-lipid) can create a system with a higher concentration of peptide incorporated into the cubic phase then previously reported. We have observed that DOPE:MO:PEG-lipid at a molar ratio of 97.5:100:2.5 naturally forms the Im3m cubic phase at room temperature. Furthermore, we found that the DOPE:MO:PEG-lipid system can incorporate a concentration of up to 25 mole % peptide at room temperature. Preliminary results indicate that the lipid/peptide system requires a stable cubic phase for peptide crystallization to occur.

*We acknowledge support from NSF grant PHY-0097424

**C1 117 Conformational Change in Fibrinogen on Langmuir Blodgett Clay Monolayer*** J.S. KOO, T. KOGA, M. RAFAILOVICH, J. SOKOLOV, *SUNY at Stony Brook* We have studied the adsorption of the plasma protein, fibrinogen, on two different clay monolayers. Surface pressure-molecular area ($\pi - A$) isotherm measurements, atomic force microscopy (AFM), X-ray reflectivity and grazing incident X-ray diffraction (GID) were used to characterized formation of organo-clay and sodium clay monolayers. These clays serve as model hydrophobic and hydrophilic surfaces, respectively. The overall conformational structure of fibrinogen is dramatically different on organo-clay and sodium clay surfaces. On the sodium clay surface, individual fibrinogen molecules appear globular in shape whereas, on orgnoclay, the trinodular structure is most commonly observed. Time dependent studies were also conducted. The results show that uniform multilayer formation occurred only on the hydrophobic surfaces. Fibrillar fibrinogen structures are observed over their uniform bilayers. Non-uniform adsorption occurred on the hydrophilic surfaces.

**C1 118 pH-dependent conformational changes of diphtheria toxin adsorbed to lipid monolayers by neutron and X-ray reflection** MICHAEL KENT, *Sandia National Labs* HYUN YIM, *Sandia National Labs* SUSHIL SATIJA, *National Institute of Standards and Technology* IVAN KUZMENKO, *Argonne National Labs* Several important bacterial toxins, such as diphtheria, tetanus, and botulinum, invade cells through a process of high affinity binding, internalization via endosome formation, and subsequent membrane penetration of the catalytic domain activated by a pH drop in the endosome. These toxins are composed of three domains: a binding domain, a translocation domain, and an enzyme. The translocation process is not well understood with regard to the detailed conformational changes that occur at each step, To address this, we performed neutron reflectivity measurements for diphtheria toxin bound to lipid monolayers as a function of pH. While the final membrane inserted conformation will not be reproduced with the present monolayer system, important insights can still be gained into several intermediate stages. In particular, we show that no adsorption occurs at pH = 7.6, but strong adsorption occurs over at a pH range from 6.5 to 6.0. Following binding, at least two stages of conformational change occur, as the thickness increases from pH 6.3 to 5.3 and then decreases from pH 5.3 to 4.5. In addition, the dimension of the adsorbed layer substantially exceeds that of the largest dimension in the crystal structure of monomeric diphtheria, suggesting that the toxin may be present as multimers.

**C1 119 Topology based theory of helix-coil transition** KINGSHUK GHOSH, *Dept of Pharm Chem, UCSF 2240* KEN DILL, *Dept of Pharm. Chem, University of California, San Francisco* We revisit the problem of helix-coil transition. We propose a new theory based on topology, significantly different from Zimm-Bragg theory. Our model predicts the cooperativity and is in excellent agreement with available experimental data. The model can be extended to study the thermodynamics of other structures as well. It also provides a framework to understand the kinetics of formation for different structures.

**C1 120 An Inside Look at Traube's Rule: A Molecular Dynamics Study** ALLISON DICKEY, ROLAND FALLER, *UC Davis* According to Traube's Rule [1], the alcohol concentration required to maintain the interfacial tension ($\gamma$) of a bilayer is reduced by a factor of three for each additional $CH_2$ group that is added to the alkyl chain of the alcohol. Recent experimental work confirmed that Traubes Rule applies to 1-stearoyl, 2-oleoyl phosphatidylcholine (SOPC) lipid bilayers that are exposed to alcohol solutions of methanol, ethanol, propanol, and butanol [2]. To examine the molecular mechanisms leading to Traubes Rule, we use molecular dynamics simulations to study the interactions between a dipalmitoylphsphatidylcholine (DPPC) bilayer and ethanol, propanol, and butanol solutions. We first examine how the bilayer structure variation depends on alcohol chain length via the area per lipid headgroup, lipid chain disorder, and electron distribution functions. We also study the alcohol dynamics within the bilayer by monitoring the time length, number, and location of hydrogen bonds. Lipid mean squared displacements are also calculated to determine the extent to which lipid mobility is affected by alcohols. [1] I. Traube Liebigs Annalen (1891) [2] H. Ly, M. Longo Biophys J (2004)

**C1 121 Optimum pH for protein-protein complexes.** PETRAS KUNDROTAS, EMIL ALEXOV, *Dept. of Physics & Astronomy, Clemson University, Clemson, South Carolina* The structure and function of proteins are influenced by external parameters such as pH of the environment. The pH at which proteins are most stable is the optimum pH of stability and the pH at which the binding affinity of protein-protein complexes is maximal is called optimum pH of the complexes. Therefore it is plausible to suggest that two proteins forming a complex in a particular environment should have their optimum pH's correlated as well as they should be correlated with the optimum pH of the complex. In order to test this hypothesis, we have calculated the pH dependencies of electrostatic folding free energy and total net charge for a set of 60 protein complexes previously used for protein-protein docking benchmark. The calculations have been performed for the entire complex and for each individual molecule separately. It was shown that there exists a clear correlation between optimum pH of the complex and optimum pH's of its components. In addition, the correlations between the net charges of the individual molecules and between the charges of the interfaces were also studied. The above findings could be used as additional criteria in evaluating models of protein-protein complexes.

**C1 122 Excited state of peptide nanorings** TETSUO YAMADA, HIROSHI MIYAZAKI, HAJIME OKAMOTO, KYOZABURO TAKEDA, *Waseda University* Peptide nanorings (PNRs) has a closed ring form composed of alternating D- and L-$\alpha$-amino acid residues. Much interest has been attracted owing to their function as a selective ion receptor. Here, based on itab initio molecular orbital theory, the excited as well as the ground state structures have been theoretically studied and discussed how the photoexcitation changes the ion-capturing ability with regarding on the two ring skeletons of Extended (E)- and Bound (B)-type PNR geometries. Because the HOMO-LUMO transition is optically allowed, we took into account this single excitation via the unrestricted Hartree-Fock (UHF/6-31G**) calculations. Our results reveal that the HOMO-LUMO single electron transition expands the bore of E-type PNR while narrows that of B-type one. This itad hoc treatment, however, causes an overestimation, because the electronic states both near the HOMO and LUMO are itpseudo-degenerated. An inclusion of other configurations due to the single electron excitation (CIS) relaxes the above geometrical changes predicted by the UHF HOMO-LUMO single excitation. Thus, the ring molecular geometry in the first optical excitation is rather indistinguishable compared with that in the ground state.

**C1 123 Free energy versus potential energy landscapes of drug-like molecules*** YONAS ABRAHAM, *Wake Forest University* REBECCA HARRIS, PHILIP S. HAMMOND, JEFFREY D. SCHMITT, *Targacept Inc* To gain information about molecular shape tendencies, the life science community has traditionally focused primarily on conformational search methodologies that explore the Potential Energy Surface (PES). The output of these methods is a collation of so-called minimum energy conformers. In our effort to gain more insight into molecular shape and overall behavior, we have used both PES conformational search techniques and *ab initio* molecular dynamics to study a set of neuronal nicotinic receptor (NNR) ligands that possess a non-trivial structure-affinity relationship. This latter method, properly executed, provides the free energy landscape. In this poster we show the sometimes dramatic difference in predicted behavior between these two methods. Significantly, conformers predicted to be

highly populated in one method are disallowed in the other method. This work constitutes our first exploration into the use of an *ab initio* derived free energy landscape to better understand small molecules of biological interest.

**C1 124 Surface Charge Method Calculation of Biomolecular Electrostatic Force with Application to a Model System*** TIMOTHY DOERR, YI-KUO YU, *National Center for Biotechnology Information, NLM, NIH* Due to the presence of ions, a high dielectric constant solvent (water with $\varepsilon = 80$), and significant charges and polarizabilities associated with many biomolecules, electrostatic forces play a crucial role in biomolecular interactions. It is particularly important to adequately account for the effects of the solvent. The surface charge method presented here has been applied to a system of an arbitrary number of charged dielectric spheres embedded in an infinite dielectric medium (the solvent). The surface charge method allows calculation (to any accuracy desired) of the energy and the various forces using only matrix inversion. The energy and forces are relatively insensitive to the value chosen for the dielectric constant inside the spheres. For the special case of two isolated charged dielectric spheres in an infinite medium, the results are not obvious: The repulsive force for like-charged spheres is strengthened (compared to point charges in the solvent medium) at short distances, while the attractive force for oppositely-charged spheres is to a lesser degree weakened at short distances. In the limit that the charges associated with a biomolecule are point-like, the excess repulsion and suppressed attraction found here might play a role in minimizing the effect of energetic traps.

**C1 125 Gamma Oscillations and Visual Binding** PETER A. ROBINSON, JONG WON KIM, *School of Physics, University of Sydney, Australia. Brain Dynamics Center, Westmead Hospital and University of Sydney, Australia* At the root of visual perception is the mechanism the brain uses to analyze features in a scene and bind related ones together. Experiments show this process is linked to oscillations of brain activity in the 30-100 Hz gamma band. Oscillations at different sites have correlation functions (CFs) that often peak at zero lag, implying simultaneous firing, even when conduction delays are large. CFs are strongest between cells stimulated by related features. Gamma oscillations are studied here by modeling mm-scale patchy interconnections in the visual cortex. Resulting predictions for gamma responses to stimuli account for numerous experimental findings, including why oscillations and zero-lag synchrony are associated, observed connections with feature preferences, the shape of the zero-lag peak, and variations of CFs with attention. Gamma waves are found to obey the Schroedinger equation, opening the possibility of cortical analogs of quantum phenomena. Gamma instabilities are tied to observations of gamma activity linked to seizures and hallucinations.

**C1 126 Experimental Study of the Dynamics of Foraging Ants** J. I. WALKER,*R. P. FETZNER, G. W. BAXTER, *Penn State Erie, The Behrend College* We study the search paths of foraging ants in order to describe their behavior mathematically. Ants have become popular as simple agents in models of artificial life. Here, the ant is presented the problem of finding food when no food cues are present. In this experiment, individual ants (Formicinae lasius flavus) are allowed to forage on a two-dimensional textured surface in the absence of a food source. The position of the ant as a function of time is determined with a high resolution digital camera. The scaling properties of the resulting foraging paths compare favorably with those of certain types of random walk.

*Supported by a Penn State Behrend Undergraduate Summer Research Grant

**C1 127 Coarse-grained dynamics of alignment in animal group models** SUNG JOON MOON, SIMON LEVIN, YANNIS KEVREKIDIS, Coordinated motion in animal groups, such as bird flocks and fish schools, and their models gives rise to remarkable coherent structures. Using equation-free computational tools we explore the coarse-grained dynamics of a model for the orientational movement decision in animal groups, consisting of a small number of informed ''leaders'' and a large number of uninformed, nonidentical ''followers.'' The direction in which each group member is headed is characterized by a phase angle of a limit-cycle oscillator, whose dynamics are nonlinearly coupled with those of all the other group members. We identify a small number of proper coarse-grained variables (using uncertainty quantification methods) that describe the collective dynamics, and perform coarse projective integration and equation-free bifurcation analysis of the coarse-grained model behavior in these variables.

**C1 128 Assigning p-values to complex biological systems** NATALIE ARKUS, MICHAEL BRENNER, *Harvard University* Models of complex biological systems with many free parameters do not describe a unique data set, nor is a data set uniquely described by one of them. Their conclusions may therefore not reveal an underlying biological phenomenon, but rather be model or parameter specific. We propose a method of assigning p-values to these models and their conclusions. As an example, we consider feedback and open loop models of the e. coli heat shock response system. We determine to what degree properties associated with the feedback loops are a result of the loops themselves or of the model and its specific parameter regime.

**C1 129 Applications of non-equilibrium thermodynamics to signaling and metabolic pathways** DAWEI HU, ENSHENG LIU, JIAN-MIN YUAN, *Drexel University* Signaling transduction pathways play important roles in regulating cell functions, such as growth, differentiation, and apoptosis. Metabolic pathways, on the other hand, generate many metabolites utilized by human body. Abnormal regulations of the enzymes and metabolites associated with these pathways may be related to diseases. In view of their importance, we are interested in applying non-equilibrium thermodynamics to investigate the properties and dynamic behaviors of these two types of pathways. The systems of concentration are the MAPK, coupled MAPK-PI3K, and insulin metabolic pathways. In the case of signaling pathways we study the properties of thermodynamic variables, such as the affinities and fluxes of individual reaction steps, as affected by the perturbations of rate constants, protein-protein interactions, and cross talks. In the case of metabolic pathways, we study the system dynamics, the stability of steady states, and the flux-affinity relations as functions of constant inputs and outputs as well as the parameters of feedback loops. Our goals are to shed light on the design principles of the biological pathways and to rank the most vulnerable nodes of these pathways.

**C1 130 Discovering Fuzzy Motifs in Yeast Genome through a generalized REDUCE algorithm** XING ZHENG, CAIYI LANG, WEIQUN PENG, CHEN ZENG, *George Washington University* Chromatin immunoprecipitation followed by cDNA microarray hybridization (ChIP-on-Chip) has become a popular procedure for studying genome-wide protein-DNA interactions and transcription regulation. We present here a fuzzy REDUCE computational method on the genes subgroup significantly associated with each of 203 DNA-binding transcriptional regulators, based on the model in which upstream motifs contribute additively to the logRatio of chip fluorescent intensities between the enriched sample and the control sample. Statistically significant motifs are deduced from the analysis of publicly available ChIP data for Saccharomyces cerevisiae and compared to the motifs obtained using other approaches. Interactions and formations of multi-transcription activation complex are discussed.

**C1 131 Recovery of Elasticity of Aged Human Epithelial Cells itIn-Vitro** IGOR SOKOLOV, SWAMINATHAN IYER, *Dept. of Physics, Clarkson University* CRAIG WOODWORTH, *Dept. of Biology, Clarkson University* We recently found a considerable increase in rigidity of human epithelial cells during ageing itin-vitro. This is important because the loss in elasticity of epithelial tissues with ageing contributes to many human diseases. We also found that cultured cells had three distinct regions of rigidity, and that the increase in rigidity correlated with an increase in density of cytoskeletal fibres. However, it was not clear which type of fibre was important. Atomic Force Microscopy (AFM) and imunofluorescence microscopy were used in this study to characterize aging human epithelial cells in vitro, both before and after treatment with cytochalasin B. We found that the fibres associated with increased rigidity were mostly F-actin microfilaments. Furthermore, using cytochalasin B, a chemical that inhibits polymerization of F-actin, we restored the rigidity of old cells to the young level in all three areas of rigidity simultaneously. In conclusion, these results clarify how the cell mechanics changes during aging itin vitro, and they may be relevant for treatment of age-related loss of elasticity in epithelial tissues. The trials of this new treatment are in progress.

**C1 132 The Effect of Polybutadiene Polymer on Cell Aging In Vitro.*** YING LIU, LOURDES COLLAZO, MIRIAM RAFAILOVICH, JONATHAN SOKOLOV, *Dept. Mat. Sci. & Eng., SUNY Stony Brook, NY 11794* Cell experimentation often undergoes several weeks of culturing. The most common problem that scientists face is the variability of cell behavior due to subculturing. Most cells have a limited lifespan in vitro, changing their cell characteristic after just a few passages. Here we focus on the changes in cell function with passage. We used human CRF31 dermal fibroblasts initially cultured from lower passages (P11) to higher passages (P20) at a density of 5000/cm2. We first generated a series of cell growth curves for the different passages. We observed that as cell passage number increased, cell proliferation decreased significantly. Western Blot analysis indicated that the composition of the extracellular matrix proteins changed with increasing passage. The effect of these changes on migration and actin production will be presented.

*Supported by NSF-MRSEC program

**C1 133 Regulation of an Actin Spring** BARNEY TAM, *Dept. of Physics, MIT* JENNIFER SHIN, *Dept. of Mechanical Engineering, KAIST* RICARDO BRAU, *Div. Biol. Eng., MIT* MATTHEW LANG, *Div. Biol. Eng. & Dept. of Mech. Eng., MIT* L. MAHADEVAN, *DEAS & Dept. of Systems Biol., Harvard* PAUL MATSUDAIRA, *Whitehead Institute, Dept. of Biol., & Div. of Biol. Eng., MIT* To produce motion, cells rely on the conversion of potential energy into mechanical work. One such example is the dramatic process involving the acrosome reaction of itLimulus sperm, whereby a 60 $\mu$m-long bundle of actin filaments straightens from a coiled conformation to extend out of the cell in five seconds. This cellular engine and the motion it produces represent a third type of actin-based motility fundamentally different from polymerization or myosin-driven processes. The motive force for this extension originates from stored elastic energy in the overtwisted, pre-formed coil—much like a compressed mechanical spring. When the actin bundle untwists, this energy is converted to mechanical work powering the extension. We report on experiments probing the regulation of this actin spring by extracellular calcium. We find that extracellular calcium needs to be present for the spring to activate, and that calcium regulates the velocity of the extension.

**C1 134 Radiation Hazard from Galactic Cosmic Rays** ASHRAF FARAHAT, *Department of Physics and Technology, Edinboro University of Pennsylvania* Space radiation is a major hazard to astronauts in long-duration human space explosion. Astronauts are exposed to an enormous amount of radiation during their missions away from the Earth in outer space. Deep space is a rich environment of protons, gamma rays and cosmic rays. A healthy 40 years old man staying on Earth away from large doses of radiation stands a 20% chance of dying from cancer. If the same person travels into a 3- year Mars mission, the added risk should increase by 19%. This indicates that there is 39% chance of having cancer after he comes back to Earth. Female astronaut chances to get cancer is even almost double the above percentage. The greatest threat to astronauts en route to the red planet is galactic cosmic rays (GCR). GCRs penetrate through the skin of spaceships and people like tiny firearm bullets, breaking the strands of DNA molecules, damaging genes, and killing cells. Understanding the nature of the GCRs, their effect on biological cells, and their interactions with different shielding materials is the key point to shield against them in long space missions. In this paper we will present a model to evaluate the biological effects of GCRs and suggestion different ways to shield against them.

**C1 135 A Comparative Study of Different Monte Carlo Modeling Techniques for Proton Dose in Biological Materials*** DAN FRY, WILFRED SEWCHAND, JOHN O'CONNELL, *Walter Reed Army Medical Center, Radiation Oncology, Washington, DC 20307* We have performed a comparison of the Monte Carlo simulation tools SRIM, PTRAN, and GEANT 4.7.0. The comparative parameters were chosen according to the degree of flexibility, ability to handle complex simulation geometries and physical processes modeled. Proton depth-doses in water have been compared with experimental measurements at 72 MeV, 110 MeV 158.5 MeV and 250 MeV. At the lowest incident proton energy all tools are in agreement with measurement. With increasing energy, SRIM underestimates the entrance and plateau dose. PTRAN and GEANT consistently predict the measured depth-dose over all energies simulated. Comparison was also done by simulating the depth-dose distribution in aluminum, tissue equiva-

lent plastic (A-150) and graphite. The entrance ($D_0$) and peak doses ($D_m$), and the FWHM $\sigma_{50}$ were simulated with both SRIM and GEANT at incident proton energies of 70 MeV, 100 MeV, 150 MeV, 200 MeV and 250 MeV. Comparison was made with the extended PTRAN-X code results of Palmans *et al.* (Phys. Med. Biol., 42, 1175, 1997). Neither SRIM nor GEANT are in agreement with PTRAN-X. Differences range from a few to over 100%.

*This work was supported by the US Army Medical Research and Materiel Command under Contract Agreement No. DAMD 17-W81XWH-04-2-0022. Opinions and conclusions are those of the authors.

**C1 136 Mössbauer Spectroscopy on Compounds of Biomedical Interests** F. OLIVER, *Morgan State University* N. EWING, E. HOFFMAN, A. KINYUA, F. OLADEINDE, A. MURDOCK, *Morgan State University* MORGAN STATE UNIVERSITY COLLABORATION, MORGAN STATE UNIVERSITY TEAM, MORGAN STATE UNIVERSITY TEAM, MORGAN STATE UNIVERSITY TEAM, MORGAN STATE UNIVERSITY TEAM, Mössbauer spectroscopy (nuclear gamma resonance spectroscopy)[1] has been used in our laboratory for many biomedical applications. This presentation will demonstrate uses of Mössbauer spectroscopy to obtain qualitative and quantitative information about the electronic and magnetic properties of various systems. Information is obtained related to the electronic spin, electric quadrupole interaction, and magnetic hyperfine interactions. This technique has a very broad spectrum of applications, most of them in solid state physics and chemistry. Experiments may be done using transmission or backscattering geometry. For the past fifteen years we have successfully applied this technique to investigate materials of biomedical interest. Materials investigated include porphyrins containing europium[2], plants, over the counter medicines, hemoglobin, and ion implanted implant materials. Results of these experiments and other possible applications will be reported. 1. Leopold May, An Introduction to Mössbauer Spectroscopy, Plenum Press Z(1971). 2. Oliver, et al., Inorganica Chimica Acta, Vol. 186, 119 (1991). * Partially supported by NIH, ** Partially supported by NSF-SEM program.

**C1 137 Chlorophyll-a self-assembly: A low temperature STM investigation** VIOLETA IANCU, SAW-WAI HLA, *Quantitative Biology Institute, and Department of Physics and Astronomy, Ohio University, Athens, Ohio, 45701, USA* We investigate self-assembly of chlorophyll-a molecules on a Au(111) surface by using a low temperature scanning tunneling microscope (LT-STM) at 4.6 K. Chlorophyll-a is a vital resource for the sustenance of life on Earth and responsible for the green color in plant leaves. Chlorophyll-a forms hexagonal close-packed structures that grow epitaxially on Au(111). The STM images show the detailed structure of the self-assembled molecular (SAM) layer where the molecules are positioned in pairs with the heads facing each other. Within a single row along the long-molecular axis direction, the molecules are assembled in an alternating head-tail-tail-head arrangement. The tunneling spectroscopy of single chlorophyll-a molecules inside this SAM layer reveals that their lowest unoccupied molecular orbital (LUMO) is located at 2.8eV above the Au(111) Fermi level. This investigation provides detailed structural and electronic properties of self-assembled chlorophyll-a and may be useful for the development of bio-molecular electronic devices. This work is supported by a US-DOE grant, DE-FG02-02ER46012 and Ohio University Nanobio Technology Initiative program BNNT

**C1 138 A statistical model for bacterial speciation triggered by lateral gene transfer** SUNJEET SIDHU, WEQUIN PENG, *Physics Department at The George Washington University* The process of bacterial speciation has been a major unresolved issue in the study of bacterial evolution. It has been proposed that lateral gene transfer and homologous recombination play critical and complementary roles in speciation.[1] We introduce a statistical model, of a population, for the evolution under lateral gene transfer and local homologous recombination. We examine the evolutionary dynamics and its dependence on various evolutionary operators.

[1]J. G. Lawrence, Theor. Popul. Biol. **61**, 449(2002).

**C1 139 Three Laws in Darwinian Evolutionary Theory** PING AO, *University of Washington* Recent works to formulate laws in Darwinian evolutionary dynamics will be discussed. Specifically, three laws which form a consistent mathematical framework for the evolutionary dynamics in biology will be spelt out. The second law is most quantitative and is explicitly expressed in the unique form of a stochastic differential equation. Salient features of Darwinian evolutionary dynamics are captured by this law: the probabilistic nature of evolution, ascendancy, and the adaptive landscape. Four dynamical elements are introduced in this formulation: the ascendant matrix, the transverse matrix, the Wright evolutionary potential, and the stochastic drive. The first law may be regarded as a special case of the second law. It gives the reference point to discuss the evolutionary dynamics. The third law describes the relationship between the focused level of description to its lower and higher ones, and defines the dichotomy of deterministic and stochastic drives. It is an acknowledgement of the hierarchical structure in biology. A new interpretation of Fisher's fundamental theorem of natural selection is provided in terms of the F-Theorem. Ref. P. Ao, Physics of Life Reviews 2 (2005) 117-156.

**C1 140 Impact of Stability on Random and Small-World Brain Networks*** RICHARD GRAY, PETER ROBINSON, CANDY FUNG, *School of Physics, University of Sydney* The dynamics and stability of networks of brain components are studied to determine the role stability plays in constraining the network structure of the brain. The linear stability of a brain network is determined from a physiologically based continuum model of the brain's electrical activity. If instabilities correspond to neurological disorders such as seizures, stability is an important constraint on network structure and, hence, brain physiology and anatomy. Results for random brain networks and small-world networks are presented, showing that stability sharply constrains random network structure to satisfy $npg < 1$, where $n$ is the number of components, $p$ the probability of connection, and $g$ the connection gain. In contrast, small-world networks have a stability boundary independent of $n$ with a connectivity similar to experimentally determined cortical networks. Implications of these results to brain structure and its evolution are made, along with comparisons with cortical connection networks.

**C1 141 Large-scale simulation of the primary visual cortex*** JIM WIELAARD, PAUL SAJDA, *Columbia University, New York* We have developed a large-scale computational model of a 4x4 $mm^2$ patch of a primary visual cortex (V1) input layer. The model is constructed from basic established anatomical and physi-

ological data. Based on numerical simulations with this model we are able to suggest neural mechanisms for a wide variety of classical response properties of V1, as well as for a number of extra-classical receptive field phenomena. The nature of our model is such that we are able to address stationary as well as dynamical behaviour of V1, both on the single cell level and on a population level of up to about $10^5$ cells.

**C1 142 Comparative Genomic Study of Plant Putative Glutamate Receptors** YOSHIHISA ISHIZUKA, *The George Washington University, Department of Physics* MIMMIE HUANG, *The George Washington University, Department of Computer Science* SHERI CHURCH, *The George Washington University, Department of Biological Sciences* FRANK TURANO, *The George Washington University, Department of Biological Sciences* WEIQUN PENG, *The George Washington University, Department of Physics* Glutamate receptors are ion channels that were first discovered in vertebrates and found to play a vital role in the mediation of signal transmission in the central nervous system. Recently, sequence homologs of these receptors were found in Arabidopsis, which was a surprise, as plants do not have a true nervous system. These putative glutamate receptors (GLRs) have been shown to play a critical physiological role in the regulation of carbon and nitrogen metabolism in Arabidopsis. However, their functions at the molecular and biochemical levels are not known. The newly completed genome of a second plant, rice, presents an opportunity to investigate the functions of the GLRs via a comparative genomic approach. Using phylogenetic and bioinformatics analysis, we identify the important residues, functional specificity, and potentially interacting sites and domains.

**C1 143 Modeling phototaxis in complex networks** OLGA KUKSENOK, ANNA C. BALAZS, *University of Pittsburgh* Phototaxis is the movement of organisms towards or away from light. It is one of the most important photo-biological processes, which in turn are responsible for light reception and the use of photons as a source of information. We briefly review current models of phototaxis of biological organisms and we develop a simple, minimal model for synthetic microscale units that can undergo phototactic motion. We then use this model to simulate the collective motion of such photosensitive artificial objects within a complex network, which is illuminated in a non-uniform manner by an external light.

**C1 144 Energy Flow Analysis of Photoactive Yellow Protein** TAKAKAZU ISHIKURA, KAZUTOMO KAWAGUCHI, HIROSHI WATANABE, *Nagoya Univ* TAKAHISA YAMATO, *Nagoya Univ / CREST, JST* The signal transduction of photosensory receptors is intimately related to the energy relaxation associated with the relevant functional motion. To understand this energy conversion process, it is useful to analyse the energy flux vector field in a polypeptide chain matrix. Recently, we developed a new formalism for energy flux, $J_{AB}$, between two different sites A and B in a protein. Flexibility is one of the attractive points of this method, namely, sites A/B can be consisted of an atom or any groups of atoms. In addition, huge computation resource is not required for this method. Since this method is based on the linear response theory, the energy flux, $J_{AB}$, can be obtained from a classical molecular dynamics simulation trajectory. We can define energy conductivity between the sites A and B in terms of the time-correlation function of $J_{AB}$. This quantity corresponds to the transport coefficient of heat and potential energy, representing the strength of the direct energetic coupling between the two sites. We applied this method to a photosensory receptor, photoactive yellow protein (PYP). We calculated the energy conductivity between the chromophore and the surrounding amino acid residues, Tyr42, Glu46, Thr50, Arg52, and Tyr98. As a result, we observed the values of energy conductivity decreased in this order. We will discuss the possibility of finding energy transfer pathway in PYP with this method.

**C1 145 IRMPD Spectroscopic Analysis of Peptides and Oligosaccharides Using FTICR With Mid-Infrared Free-Electron Laser*** KAZUHIKO FUKUI, KATSUTOSHI TAKAHASHI, *National Institute of Advanced Industrial Science and Technology (AIST)* The fragmentation in gas-phase peptides and oligosaccharides has been investigated by using electrospray ionization (ESI) Fourier-Transform Ion Cyclotron Resonance (FTICR) mass spectrometry (MS) with a laser cleavage infrared multiphoton dissociation (IRMPD) technique. In order to cleave the ionized sample introduced in the FTICR cell, an infrared free electron laser (FEL) is used for the technique of IRMPD as a tunable infrared light source. The gas-phase infrared spectra of protonated peptides (Angiotensin II, Substance P) and sodiated ologosaccharide (Sialyl Lewis X) are obtained in the range from 5.7 $\mu$m to 9.5 $\mu$m. The results of the IRMPD spectra of the peptides show that the peaks for the photoproducts are observed as y/b type fragment ions in the IR range from 5.7 $\mu$m to 7.5 $\mu$m, corresponding to the cleavage of backbone in the parent amino acid sequence, while the spectra of the oligosaccharide have the peaks for the B/Y type in the range from 7.1 $\mu$m to 9.3 $\mu$m.

**C1 146 Divergence of protein structure in solvent from that in X-ray quality crystals: probing the local environment of Chl *a* in the cytochrome $b_6f$ complexes by ultrafast spectroscopy** SERGEI SAVIKHIN, NARANBAATAR DASHDORJ, HANYOUP KIM, JOHN SCHAIBLEY, *Department of Physics, Purdue University* HUAMIN ZHANG, JIUSHENG YAN, EIKI YAMASHITA, WILLIAM CRAMER, *Department of Biological Sciences, Purdue University* The cytochrome $b_6f$ complex in oxygenic photosynthesis mediates electron transfer between the reaction centers of photosystems I and II, and coupled proton translocation across the membrane. High-resolution X-ray crystallographic structures of the $b_6f$ complex show a single chlorophyll $a$(Chl $a$) molecule as an intrinsic component of the complex. Using ultrafast optical spectroscopy, we have shown that the excited state lifetime of the Chl $a$ in dissolved complex is unusually short ( $\sim$ 200 ps) and attributed the observed quenching to the electron transfer exchange with a nearby amino acid. Similar optical time resolved experiments performed on single crystals of the $b_6f$ complex reveal significant changes in the lifetime of the excited state and suggest structural dissimilarities between the complexes within crystals and in solvents. The extent of the structural variations is discussed and modeled using molecular dynamic simulation methods (NSF MCB-0516939, NIH GM-38323).

**C1 147 Raman study of CaDNA films as a function of water content and excess $CaCl_2$ concentration: Stability of the B conformation.** MEGAN SCHWENKER, *University of Toledo* ROBERT MARLOWE, *University of Tennessee at Chattanooga* SCOTT LEE, *University of Toledo* ALLAN RUPPRECHT, *University of Stockholm* Highly oriented, wet-spun films of CaDNA expand in the direction perpendicular to the helical axis as the hydration of the film is increased. CaDNA films with a high $CaCl_2$ content show an unexpected shrinkage at a relative humidity of about 93%. We have performed Raman experiments on CaDNA films as a function of both water content and excess $CaCl_2$ concentration in order to determine if this unexpected shrinkage might be related to a conformational transition of the DNA molecules. We find that the DNA molecules remain in the B conformation for all salt contents down to a relative humidity of 59%.

**C1 148 High pressure mid-infrared study of deoxyadenosine** SCOTT LEE, IAN LAWSON, *University of Toledo* LAUREN LETTRESS, ANTHONY ANDERSON, *University of Waterloo* Crystalline deoxyadenosine has been studied via infrared spectroscopy at room temperatures up to about 10 GPa of pressure. Samples, typically 250 microns in diameter and roughly 25 microns in thickness, were loaded into a piston-cylinder type diamond anvil cell supplied by Diacell Ltd. and fitted with type IIa diamonds. To avoid saturation of strongly absorbing modes, the deoxyadenosine sample was diluted with KBr powder, which also served as an isotropic pressure-transmitting medium. A number of changes in the infrared spectra are noted near 2 GPa, suggesting a phase transition.

**C1 149 Multivariate statistical analysis of Raman spectra to distinguish normal, tumor, lymph nodes and mastitis in mouse mammary tissues** H. DAI, J.S. THAKUR, G.K. SERHATKULU, A.K. PANDYA, G. W. AUNER, R. NAIK, D. C. FREEMAN, *Wayne State University* V.M. NAIK, *University of Michigan-Dearborn* A. CAO, M.D. KLEIN, R. RABAH, *Childrens Hospital of Michigan, Detroit, MI* Raman spectra ( $>$ 680) of normal mammary gland, malignant mammary gland tumors, and lymph node tissues from mice injected with 4T1 tumor cells have been recorded using 785 nm excitation laser. The state of the tissues was confirmed by standard pathological tests. The multivariate statistical analysis methods (principle component analysis and discriminant functional analysis) have been used to categorize the Raman spectra. The statistical algorithms based on the Raman spectral peak heights, clearly separated tissues into six distinct classes, including mastitis, which is clearly separated from normal and tumor. This study suggests that the Raman spectroscopy can possibly perform a real-time analysis of the human mammary tissues for the detection of cancer.

**C1 150 Influence of Temperature and Hydration on Protein dynamics** J.H. ROH, *University of Akron, USA* J.E. CURTIS, *NIST, USA* S. AZZAM, *Kent State University, USA* V.N. NOVIKOV, *Russian Academy of Sciences, Russia* I. PERAL, Z. CHOWDHURI, V. GARCIA-SAKAI, *NIST, USA* R.B. GREGORY, *Kent State University, USA* A.P. SOKOLOV, *University of Akron, USA* Protein dynamics and function are strongly influenced by temperature and hydration. Dynamic transition is believed to be closely related to onset of protein function since protein function activates at dynamic transition temperature, $T_d$. However, understanding of correlation between protein dynamics and function and of microscopic mechanism of the dynamics activated above $T_d$ is sill a subject of discussion. We used neutron and light scattering measurements to study temperature and hydration dependence of protein-lysozyme dynamics in the frequency range from 100 MHz to 1 THz. Our detailed analyses of protein dynamics provide i) two onsets of anharmonicity: methyl group rotation that activates regardless of hydration at 100 K and slow relaxation process that appears only in wet proteins at 200 K, ii) slow relaxation process is the mode that activates dynamic transition and enzymatic activity, and iii) temperature dependence of slow relaxation process exhibits Arrhenius-like behavior at $T > T_d$.

**C1 151 A new Monte Carlo approach for exact calculation of polymer translocation time through a channel** MICHEL G. GAUTHIER, GARY W. SLATER, *Univerity of Ottawa* Molecular Dynamics simulations are useful to study the impact of hydrodynamic interactions on the translocation process, but this technique requires large computer resources (both time and memory) which limit the size of the systems that we can study. We propose a new Monte Carlo algorithm that integrates various effects such entropic forces, external force fields frictional effects, and polymer-channel interactions. Our novel approach allows us to study the polymer as a single Brownian particle diffusing on a one-dimensional lattice in a non-constant force field. The calculation technique we suggest gives us the exact value of the translocation time via the resolution of a simple system of linear equations. This Monte Carlo approach can be used to obtain scaling laws of polymer translocation through a channel much faster than by using fluctuating-bond simulation models.

**C1 152 Kinetics of Protein Adsorption at liquid/solid interfaces** MARKUS BELLION, LUDGER SANTEN, *FR 7.1 Theoretische Physik, Universität des Saarlandes, 66041 Saarbrücken* ARMIN NAGEL, HUBERT MANTZ, ANTHONY QUINN, KARIN JACOBS, *FR 7.2 Experimentalphysik, Universität des Saarlandes, 66041 Saarbrücken* Protein adsorption processes are of crucial importance in many biomedical processes. From a physical point of view these processes raise a number of challenging questions, e.g.: How does the surface influence the conformation of proteins at the surface? What are the characteristics of the protein film at the liquid/solid interface? In this work we investigate the adsorption kinetics of salivary proteins on different kinds of surfaces in a liquid environment. The adsorbed protein layers are analyzed by means of ellipsometry, plasmon resonance, and SPM. It turns out that the adsorbed amount of proteins is sensitive to the long ranged interactions of the solid surface. The experimental data are compared to extensive Monte Carlo simulation of a colloidal protein model. The Monte Carlo results strongly suggest that induced conformal changes lead to the experimentally observed three step kinetics of amylase.

## C1 153 CHEMICAL PHYSICS POSTER SESSION

**C1 154 Thermally activated escape rate for a Brownian particle in a tilted periodic potential for all values of the dissipation: classical and quantum regimes** WILLIAM COFFEY, *Dept. of Electronic and Electrical Engr., Trinity College* YURI

KALMYKOV, *MEPS, Université de Perpignan, France* SERGEY TITOV, *Inst. of Radio Engr. and Electronics of the Russian Academy of Sciences, Russia* B. MULLIGAN, *Dept. of Electronic and Electrical Engr., Trinity College* The translational Brownian motion of a particle in a tilted periodic potential is considered. The classical and semiclassical escape rates of a particle out of the well are estimated both numerically and analytically. In order to accomplish this, the continued-fraction method of solving classical Fokker–Planck equations is adapted to treat quantum master equations of the Caldeira–Leggett type using the phase-space (Wigner) representation of the quantum density matrix as suggested by Garcia-Palacios [J. Phys. A: Math. Gen. **37,** 10735 (2004)]. The numerical escape rates are compared with those obtained in the context of the Kramers theory of the escape rate of a Brownian particle from a potential well as extended by Mel'nikov [Physica A **130**, 606 (1985); Phys. Rep. **209**, 1 (1991).] and Rips and Pollak [Phys. Rev. A **41**, 5366 (1990)] for all values of the dissipation including the very low damping, very high damping, and turnover regimes. It is shown that in the low temperature limit, the universal expressions for the escape rate provide a good estimate of escape rates both in classical and quantum regimes.

**C1 155 Nonequilibrium phase transition of a model of diffusion, aggregation and fragmentation on complex networks** YUP KIM, SUNGMIN LEE, SUNGCHUL KWON, *Department of Physics, Kyung Hee University* We investigate condensation phase transitions of symmetric conserved-mass aggregation (SCA) model on random networks (RNs) and scale-free networks (SFNs) of degree distribution $P(k) \sim k^{-\gamma}$. In SCA model, masses diffuse with unite rate, and unit mass chips off from mass with rate $\omega$. The dynamics conserves total mass density $\rho$. In the steady state, on RNs and SFNs of $\gamma > 3$ for $\omega \neq \infty$, we numerically show that SCA model undergoes the same type condensation transitions as those in regular lattice. However the critical line $\rho_c(\omega)$ depends on network structures. On SFNs of $\gamma \leqslant 3$, the fluid phase of exponential mass distribution completely disappears and no phase transitions occurs. Instead, the condensation with exponentially decaying background mass distribution always takes place for any non- zero density. For the existence of the condensed phase for $\gamma \leqslant 3$ at the zero density limit, we investigate one lamb-lion problem on RNs and SFNs. We numerically show that a lamb survives indefinitely with finite survival probability on RNs and SFNs of $\gamma > 3$, and dies out exponentially on SFNs of $\gamma \leqslant 3$. The finite life time of a lamb on SFNs of $\gamma \leqslant 3$ ensures the existence of the condensation at the zero density limit on SFNs of $\gamma \leqslant 3$. At $\omega = \infty$, we numerically confirm that complete condensation takes place for any $\rho > 0$ on RNs.

**C1 156 Adsorption on an Equilateral Triangular Terrace Three Atomic Sites in Width: Application to Chemisorption of CO on Pt(112).*** ALAIN PHARES, *Villanova University* DAVID GRUMBINE, JR., *St. Vincent College* FRANCIS WUNDERLICH, *Villanova University* The study of monomer adsorption on equilateral triangular terraces three atomic sites in width is presented. Adsorbate-substrate interactions at the terrace edges differ from those at bulk sites. Adsorbate-adsorbate interactions up to second neighbors are included. Phase diagrams for all possible interactions whether attractive or repulsive are obtained at low temperature. The effect of increasing temperature is also investigated. Results of the model are applied to chemisorption of CO on Pt(112).

*This research is supported in part by grant number PHY910014P from the Pittsburgh Supercomputing Center, supported by several federal agencies, the Commonwealth of Pennsylvania and private industry.

**C1 157 Single Walled Carbon Nanotubes as Macroscopic Surfactant Molecules** ERIK K. HOBBIE, BARRY J. BAUER, *NIST* Single-walled carbon nanotubes (SWNTs) are made hydrophyllic through coating and wrapping with short segments of single-stranded DNA (ssDNA) containing alternating guanine (G) and thymine (T) units. Small-angle neutron scattering (SANS) measurements on dilute to semi-dilute aqueous suspensions of these colloidal SWNTs raise interesting questions about the degree of nanotube dispersion, with power-law exponents suggestive of weak attractive interactions. The SWNT-ssDNA complexes also act as nanoparticle surfactant, stabilizing the interface between water and toluene, for example. We exploit this to make hydrophillic cross-linked polymer particles coated and stabilized by the ssDNA-SWNT complex. Near-infrared fluorescence microscopy demonstrates the band-gap fluorescence of these SWNT-coated particles, suggesting potential routes to novel platforms and applications. Light scattering and optical microscopy from index-matched suspensions of the SWNT-coated colloids are compared with similar measurements on colloids made with conventional surfactants.

**C1 158 Rotational Energy Exchange in Molecule-Surface Collisions*** HAILEMARIAM AMBAYE, JOSEPH MANSON, *Clemson University* A theoretical approach that combines classical mechanics for treating translational and rotational degrees of freedom and quantum mechanics for describing the excitation of internal molecular modes is applied to the scattering of diatomic molecules from metal surfaces. Calculations are carried out for determining the extent of energy transfer to the rotational degrees of freedom of the projectile molecule. For the case of observed spectra of intensity versus final rotational energy, quantitative agreement with available experimental data for the scattering of NO and $N_2$ from close packed metal surfaces is obtained. It is shown that such measurements can be used to determine the average rotational energy of the incident molecular beam. Measurements of the exchange of energy between translational and rotational degrees of freedom upon collision are also well described by calculations for these same systems.

**C1 159 Understandings of Formation of N-Ntrosoamine in Smoke.*** YI-LEI ZHAO,[†] CARLOS GONZALEZ,[‡] *NIST* MANUEL MARQUEZ,[§] *PMUSA Research Center, 4201 Commerce Rd., Richmond, VA 23234* INEST TEAM,[‖] CTCN TEAM, Formation of N-nitrosoamine compounds is highly concerned in combustion and past-combustion. In chemical laboratory, nitrosylation of amine toward N-nitrosoamine generally requires nitrosonium donor and acidic condition. Recently, an unexpected reaction was observed to be relevant to nitrogen dioxide, a common component of past-combustion gas; an alternative non-ionic pathway must lead to the rapid nitrosylation. Here, we proposed a radical mechanism, by which amino-radical is formed by H-abstraction of nitrogen dioxide, followed by radical scavenging with nitric oxide.

Relatively low activation energy of 10-11 kcal/mol (ca., CBS-QB3) of the radical mechanism rationalized the feasibility of N-nitrosoamine formation in colloids after combustion of biomaterials. Acid-catalyzed nitrosylation in aqueous solution was also computed.

**C1 160 Classical nucleation theory based method for computing the crystal-melt interfacial free energy** XIAN-MING BAI, MO LI, *School of Materials Science and Engineering, Georgia Institute of Technology* The crystal-melt interfacial free energy is a fundamental thermodynamic parameter governing phase transformations. It is very weak and extremely difficult to obtain experimentally. Here we present a simple approach, which is based on classical nucleation theory, for calculating the solid-liquid interfacial free energy. Using molecular-dynamics simulations, we construct spherical crystal nuclei embedded in the supercooled liquids to create an ideal model of homogeneous nucleation. The interfacial free energy is extracted by fitting the relation between the critical nucleus size and the reciprocal of the critical undercooling temperature. The orientationally averaged interfacial free energy is found to be 0.301 with errors of 0.002 (in standard LJ unit). The temperature dependence of interfacial free energy is also obtained in this work. We find that the interfacial free energy increases slightly with increasing temperature. The positive temperature coefficient of interfacial free energy is in good agreement with Spaepen's analysis [Solid State Phys. **47**, FS181, (1994)] and Turnbull's empirical estimation [J. Appl. Phys. **21**, 1022 (1950)].

**C1 161 Polarization Model for the Hydration Forces.** OSCAR CALVO, MARIAN MANCIU, *Physics Department, University of Texas at El Paso* ELI RUCKENSTEIN, *Chemical and Biological Engineering, State University of New York at Buffalo* The interactions between hydrophilic surfaces in water cannot be always explained on the basis of the traditional DLVO theory, and an additional repulsion, the ''hydration force'' is sometimes required to accommodate the experimental data. While this force is in general associated with the organization of water in the vicinity of the surface, different models for the hydration were typically required to explain different experiments. We will show that the polarization model for the double layer/ hydration, which account for the correlations between neighboring dipoles, is consistent with a number of experiments, such as (i) the repulsion almost independent of the electrolyte concentration between neutral lipid bilayers, with a short decay length ( $\sim$ 2Å), (ii) the repulsion between weakly charged mica surfaces, with a longer decay length ( $\sim$ 10 Å), exhibiting not only a dependence on the ionic strength, but also strong ion specific effects. (iii) the repulsion between silica surfaces. It is shown that, for a particular structuring of water in the vicinity of a flat surface (in ice-like layers)., the polarization model leads to an oscillatory behavior of the polarization and a non-local dependence on the local electric field, as suggested by Molecular Dynamics simulations.

**C1 162 A particle-based simulation technique for fluid flow: applications to binary mixtures, microemulsions and colloids** ERKAN TUZEL, *School of Physics and Astronomy, University of Minnesota* THOMAS IHLE, GUOAI PAN, DANIEL KROLL, *Department of Physics, North Dakota State University* Particle-based simulation techniques provide an attractive alternative to traditional methods for the coarse-grained modeling of a fluctuating solvent. A particularly appealing algorithm was introduced by Malevanets and Kapral[1]. The algorithm has been successfully applied to study the behavior of polymer solutions, colloids and vesicles in shear flow. We present generalizations of this algorithm to fluids with non-ideal equations of state and binary mixtures with a miscibility gap[2]. We show the thermodynamic consistency of the model by measuring the pressure and density fluctuations and compare with analytical results. Results for the demixing of a binary mixture are presented such as the phase diagram and measurements of interface fluctuations and the surface tension of a droplet as well as the coarsening of domains during spinodal decomposition. Preliminary results for the lowering of the surface tension in microemulsions and the onset of emulsification are presented. Furthermore, colloids are included in the solvent and results for colloidal suspensions driven by external forces will be shown. [1] A. Malevanets, R. Kapral, J. Chem. Phys. 110, 8605 (1999). [2] T. Ihle, E. Tuzel, D. M. Kroll, cond-mat/0509631.

**C1 163 Thermodynamic Investigation of Ar, $CH_4$, and $D_2O$ Adsorption on ZnO surfaces** SAMI CHANAA, M. FARINELLI, A. FREITAG, M. ROSS, *University of Tennessee* JOHN Z. LARESE, *Oak Ridge National Laboratory, University of Tennessee* ZnO nanoparticles of different shape and exposed crystal face have raised considerable interest in the recent past, because their potential use for electronic and photonic devices, etc. Understanding the relationship between the macroscopic particle shape and the surface morphology, structure and polarity will play a crucial role in developing technologically useful devices. Using a recently developed synthetic method we have been able to produce large quantities of high quality pure and doped ZnO nanomaterial with shapes including plates, nanowires and tetrapods as observed by TEM. High resolution adsorption is otherms were used to investigate the interaction of the nanoparticle surfaces with different probe molecules. The shape of the resulting adsorption isotherms varies as the distribution of nanoparticle shapes and surfaces used as substrate is changed. Results of thermodynamic investigation of argon and methane adsorption below the respective triple points show the formation of 3 distinct adsobate layers before the onset of bulk adsorbate formation. $D_2O$ isotherms show weak evidence of different mono and multi layer capacities depending on previous exposure of the nanoparticle surface to UV radiation.

**C1 164 The non-dominance of counterions in the spherical electrical double layer: an integral equation and simulational study** ENRIQUE GONZÁLEZ-TOVAR, IVÁN GUERRERO-GARCíA, MARTíN CHÁVEZ-PÁEZ, *Instituto de Física, Universidad Autónoma de San Luis Potosí, México.* The ionic cloud around a charged colloid (or electrode) immersed in an electrolyte is known as the electrical double layer (EDL). An important amount of theoretical and simulational work in this topic has been done in the frame of the restricted primitive model (RPM) of an electrolyte, in which the ionic size correlations are taken into account considering equal-sized ions. Ionic size asymmetry, on the other hand, has been explored to much less extent. One possible explanation to this can be found in the common belief that coun-

terions dominate the EDL, i.e., that away from the zero-charge point the properties of the EDL are essentially equal for size-symmetric and size-asymmetric electrolytes if the counterions are the same in both cases. Recent developments, however, clearly show that size asymmetry can induce dramatic effects on the structure and properties of EDLs. In the present work we report Monte Carlo simulations and theroretical results that exhibit that the counterions not always rule the properties of the EDL, e.g. the ionic size asymmetry enhances the phenomenon of charge reversal (i.e., the overcompensation of the bare charge of the macroion) and the screening due to the electrolyte. Additionally, we find that the predictions of the HNC/HNC and HNC/MSA integral equations are in good agreement with simulations in a wide range of conditions.

**C1 165 Optical detection of sub-micron and nanoscale particles in liquids** SUBECHHYA PRADHAN, MATTHEW McGRATH, TOBIAS HERTEL, *Vanderbilt University* We discuss a scheme for detection of submicron and nanoscale particles using light scattering in combination with lock-in filtering for increased sensitivity and signal-to-noise ratio. In this experiment, suspended submicron and nanoscale particles flow downstream a microfluidic cell until they enter the detection volume where particles are subjected to forced oscillatory motion perpendicular to the flow direction. Scattered light can then be detected in the forward direction by a position sensitive detector or in backscattering geometry using an interferometric confocal setup. The signal to noise ratio is improved over previous experiments making use of low pass filtering by lock-in amplification. We explore the potential of this technique for nanoparticle detection in liquid environment and present preliminary results on the detection of low and high index spherical particles such as polystyrene beads or colloidal gold as well as of high aspect ratio particles such as carbon nanotubes and tobacco mosaic virus.

**C1 166 Coexistence curve of a near-critical, eight-arm star polystyrene in methylcyclohexane** MARK WELLONS, MARK LIGHTFOOT, D.T. JACOBS, *Physics Department, The College of Wooster, Wooster OH 44691* The coexistence curve of eight-arm star polystyrene in methylcyclohexane has been measured and used to determine the coexistence curve amplitude B. An automated measurement of the minimum deviated angle in each phase provides the refractive index and thus the composition in each phase. By exploring temperatures from a few milliKelvins to two Kelvin below the critical temperature, the shape of the coexistence curve is determined and compared to a simple power law of amplitude B and exponent $\beta$. The exponent should be independent of molecular weight while the amplitude should vary as a power-law in molecular weight. We report the results of one molecular weight (228,000) and compare them to published values for a smaller molecular weight (74,000) and to the results for a linear polystyrene in the same solvent. We acknowledge the support from the donors of the American Chemical Society Petroleum Research Fund.

**C1 167 Investigation of Gas Phase Gold Oxide Cations Towards the Oxidation of CO** NELLY MOORE, GRANT JOHNSON, A. WELFORD CASTLEMAN, JR., *Pennsylvannia State University* Studies are underway in our laboratory aimed at providing information to aid in the design of more efficient and selective catalysts. Gas phase metal oxide cluster studies are becoming a valuable complementary technique to surface methods for elucidating the mechanistic details and active sites of catalytic systems. It is our present goal to uncover possible species responsible for the increased activity and selectivity of gold oxide catalysts utilizing gas phase studies. To gain insight into the bonding properties and structures of gold oxide clusters, collision induced dissociation experiments were undertaken. In addition, reactivity studies of gold oxide clusters with CO provided information into different reaction pathways based on size, stoichiometry, and charge state. Reactions of gold oxide cations with CO were explored and compared to anionic cluster reactions previously conducted in our laboratory. These studies have provided evidence of various reaction mechanisms including oxidation, replacement, and association which will be presented.

**C1 168 Stern-Gerlach molecular beam deflection studies of magnetic sandwich clusters*** MARK KNICKELBEIN, *Argonne National Laboratory* KEN MIYAJIMA, ATSUSHI NAKAJIMA, *Keio University* Stern-Gerlach studies of transition metal-benzene $[M_n(bz)_m]$ and lanthanide-cyclooctatetarene $[Ln_n(COT)_m]$ sandwich clusters and related sandwich compounds have identified several systems that are ferromagnetically ordered. Such ordered organometallic systems are promising candidates as building blocks for spintronic and information storage applications: their quasi-one-dimensional molecular structures introduce the spatial anisotropy required for magnetic bistability. Magnetic moment measurements of representative magnetically ordered $M_n(bz)_m$ (M=Sc and V) and $Ln_n(COT)_m$ (Ln=Eu, Tb, Ho) systems will be presented.

*This work is supported by the US Department of Energy, Office of Basic Energy Sciences, Division of Chemical Sciences, under Contract W-31-109-ENG-38 and by the CREST program of the Japan Science and Technology Agency (JST).

**C1 169 Reactivity of Size-Selected Gas-Phase Transition Metal Sulfide Clusters with CO and $NH_3$*** JAMES LIGHTSTONE, MELISSA PATTERSON, *Stony Brook University* MICHAEL WHITE, *Brookhaven National Lab* Our current focus has been the production of early transition metal sulfide and carbide clusters for reactivity studies in both the gas-phase and deposited on well defined surfaces. The transition metal sulfides are particularly interesting due to their catalytic properties and their ability to form fullerene-like nanostructures that reflect the S-M-S layered structure of the bulk material. Gas-phase $M_xS_y^+$ clusters (M=Mo, Nb, Ta, W) were produced in a cluster deposition apparatus by reactive sputtering via a magnetron cluster source. Mass spectroscopy results show that Mo, Ta, and W preferentially produce clusters of similar stoichiometry (x/y = 2/6, 3/7, 4/6, 5/7, and 6/8) while all the metals are found to form the ''magic'' cluster, $M_4S_6^+$ . Several prominent $M_xS_y^+$ clusters in the mass spectra were size-selected and reacted with CO and $NH_3$ in a hexapole collision cell. In general, CO adsorbs sequentially on exposed metal sites, while the results for $NH_3$ appear to suggest the formation of solvation shells. These results and how they may relate to cluster structure and reactivity will be discussed. In addition, we will discuss current progress towards deposition of these nanomaterials on well-defined substrates.

**C1 170 Simulations of vapor water clusters at vapor-liquid equilibrium*** KIM BOLTON, *School of Engineering, University College of Boras, SE-501 90, Boras, Sweden; Physics Department, Goteborg University, SE-412 96, Goteborg, Sweden* PETER AHLSTROM, ERIK JOHANSSON, *School of Engineering, University College of Boras, SE-501 90, Boras, Sweden* ARNE ROSEN, *Physics Department, Goteborg University, SE-412 96, Goteborg, Sweden* Clustering of water molecules is important, for example, in the nucleation of water drops and in the penetration of water into hydrophobic polymers where water trees can be formed. Monte Carlo methods have been used to study the clustering of water under vapour-liquid equilibrium conditions between 300 and 600 K. The number of clusters, as well as the cluster size, increases with increasing temperature. In addition, due to entropic effects, the percentage of clusters that have linear (or open) topologies increases with temperature and dominate over the minimum-energy cyclic topologies at the temperatures studied here.

**C1 171 An Atom in a Golden Ring: M@$Au_6$(M = Ti, V, Cr)** KIRAN BOGGAVARAPU, *Virginia Commonwealth University* XI LI, LI-FENG CUI, LAI-SHENG WANG, *Washington State University* The electronic structure and magnetic properties in a series of transition metal doped Au clusters, $MAu_6^-$ (M = Ti, V, Cr), are investigated experimentally using photoelectron spectroscopy (PES) and density functional calculations. PES features due to the impurity atoms and the $Au_6$ host are clearly observed. It is found that all the $MAu_6^-$ and $MAu_6$ clusters possess a planar structure, in which the transition metal atom is located in the center of an $Au_6$ ring and carries large magnetic moments (2, 3, and 4 $\mu_b$ for $MAu_6$, M = Ti, V, and Cr, respectively).

**C1 172 Abstract Withdrawn**

**C1 173 Small Metallized Carbon Clusters.** A. PATRICK, P. WILLIAMS, E. BLAISTEN-BAROJAS, *School of Computational Sciences, George Mason University, Fairfax, Virginia 22030* Studies of carbon clusters with 1-4 Ca atoms metallized with Li and Be were performed within the density functional theory approach (DFT). Structures of the ground state and first 3 or 4 excited states where systematically calculated for $C_mLi_n$ and $C_mBe_n$ with $n$, $m$=1, 2, 3, and 4. Several of these clusters have ground states of high multiplicity, which make them interesting for magnetic applications. Overall, most stable structures are either linear or planar in the ground state for the smaller clusters, whereas larger clusters acquire 3D structures. Charge transfer in these compounds is notorious, showing no indication of covalent bonding. Calculations were done with DFT the gradient corrections and large basis sets, and compared for several excited states with CASSCF calculations.

**C1 174 Size-Evolution of the Structural and Energy Characteristics of Magnesium Clusters*** PAULO H. ACIOLI,[†] JULIUS JELLINEK, *Chemistry Division, Argonne National Laboratory, Argonne, IL 60439* The most fascinating and important from the applied point of view attribute of the cluster phase of matter is the unique and often unexpected variation of properties with the cluster size. The structural forms, electronic properties, nature and strength of bonding, and other physical characteristics all change as the clusters grow. The rate of change in different properties is, however, nonuniform and element/material dependent. The goal of this study is to investigate and characterize qualitatively and quantitatively the size evolution of the structural and energy characteristics of magnesium clusters. These include the transition from a tetrahedral- to pentagonal- to capped trigonal prism-based motif as the energetically most preferred one. The analysis will include also the higher energy isomers of the clusters and will address the issue of the transition to the bulk lattice.

**C1 175 Catalytic water formation on free platinum and palladium clusters** MATS ANDERSSON, ARNE ROSEN, *Göteborg University* A pulsed beam of neutral metal clusters is generated with a laser vaporization source. The cluster beam passes through two reaction cells, in which the clusters make from less than one up to a few collisions with the reactive molecules. The clusters are detected with laser ionization and time-of-flight mass spectrometry. By measuring the abundance of pure clusters and reaction products as a function of reaction cell pressure, the reaction probability in a cluster-molecule collision can be determined. Platinum clusters with more than 6 atoms form stable reaction products with both oxygen and hydrogen. When the clusters first react with oxygen and then with hydrogen we measure a decreasing number of oxygen atoms adsorbed on the clusters as the number of cluster-hydrogen collisions is increased. The interpretation for this is that water molecules form on the clusters and desorb. The efficiency of the reaction is high on all cluster sizes measured (7-30 atoms), with only a weak size dependence. The water formation reaction also proceeds on palladium clusters in the same size range.

**C1 176 Size, charge, and isomer specific vibrational spectroscopy of isolated metal clusters in the far infrared** ANDRE FIELICKE, GERT VON HELDEN, GERARD MEIJER, *Fritz-Haber-Institut der MPG, Berlin, Germany* CHRISTIAN RATSCH, *Dep. of Mathematics, UCLA* We report on the vibrational spectra of neutral and charged metal clusters in the far infrared. These spectra are obtained via far infrared resonance enhanced multiple photon dissociation (FIR-MPD) of the complexes of metal clusters with rare gas atoms. The experiments make use of the Free Electron Laser for Infrared eXperiments (FELIX) in Nieuwegein, The Netherlands, as an intense and widely tunable far-infrared radiation source. The measured FIR-MPD spectra of the complexes represent the infrared absorption spectra of the bare metal clusters. These spectra are unique for each cluster size and are true fingerprints of the cluster's structure. This FIR-MPD technique has been applied to cationic vanadium clusters and cationic and neutral niobium clusters containing 3 to more than 20 atoms. For smaller sized clusters ($n < 15$), theoretical infrared spectra have been calculated using density functional theory and a comparison with the experimental spectra allows for the structure determination.

**C1 177 Multiphoton control of an electrocyclic ring-opening** ELIZABETH CARROLL, *FOCUS Center, Department of Physics, and Department of Chemistry, University of Michigan, Ann*

*Arbor* BRETT PEARSON, *Department of Physics, SUNY Stony Brook, Stony Brook, NY* JAMES WHITE, ANDREI FLOREAN, PHILIP BUCKSBAUM, ROSEANNE SENSION, *FOCUS Center, Department of Physics, and Department of Chemistry, University of Michigan, Ann Arbor, MI* We have investigated optical control over the photoisomerization of 1,3-cyclohexadiene to 1,3,5-cis-hexatriene via multiphoton excitation. Sub-80fs pulses at 800nm were shaped with an acousto-optic modulator. A closed-loop genetic algorithm (GA) searched for optimal excitation pulses while the effectiveness of each pulse was evaluated using differential absorption of a time-delayed, broadband, ultraviolet probe pulse. Reaction products were subsequently identified in an ultraviolet spectrophotometer. The GA identified pulses that increased the formation of hexatriene by a factor of two over the transform-limited pulse. Detailed analysis of the pulses in the GA search set has identified negative quadratic spectral phase and cubic phase as important control parameters. Multiphoton control mechanisms will be discussed.

**C1 178 Ultrafast Proton Transfer Driven by a Femtosecond Strong-Field Laser Pulse** ALEXEI MARKEVITCH, *Temple University, Department of Chemistry* DMITRI ROMANOV, *Temple University,Department of Physics* STANLEY SMITH, *Wayne State University, Department of Chemistry* ROBERT LEVIS, *Temple University, Department of Chemistry* TEMPLE UNIVERSITY COLLABORATION, WAYNE STATE UNIVERSITY COLLABORATION, Kinetic energy distributions of protons ejected from a polyatomic molecule, anthraquinone, subjected to 60 fs, 800 nm laser pulses of intensity between 0.2 and 4.0x10[1]4 W/cm[2], reveal field-driven restructuring of the molecule (intramolecular proton migration) prior to its Coulomb explosion. Model calculations demonstrate that proton migrates into a field-dressed metastable potential energy minimum. Isomerization mediated by strong field is an important novel phenomenon in coupling of polyatomic molecules with intense laser pulses.

**C1 179 Synthesis of anatase $TiO_2$ nanocrystals by low temperature sol-gel method modified with a hydrophobic ionic liquid** YEN-HUI LIU, CHIH-WEI LIN, ARNOLD CHANG-MOU YANG, *Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan* MIN-CHAO CHANG, HSIN SHAO, *Center for Environmental, Safety and Health Technology Development, ITRI, Hsinchu, Taiwan* CHIH-JEN LIN, LI-JIAUN LIN, *Materials Research Laboratories, ITRI, Hsinchu, Taiwan* Anatase $TiO_2$ nanocrystals of uniform sizes were synthesized via low temperature sol-gel reaction of titanium tetraisopropoxide (TIP) with water in the presence of small amount of hydrophobic ionic liquid (IL) molecules. It was found that the IL molecules did not actively participate in precursor hydrolysis and $TiO_2$ nucleation. However, the IL molecules strongly screened the abundant remaining hydroxylic bonds on the surfaces of the primordial $TiO_2$ particles, giving rise to low temperature transition to anatase phase at 100 °C and impeded inter-particle sintering. The former was believably induced by self-organization of the IL molecules that adsorbed on the hydroxylic bonds. This IL-modified sol-gel reaction resulted in uniform sized ( $\sim$ 10 nm) anatase $TiO_2$ nanocrystalline particles, useful for high efficiency photo-catalytic applications.

**C1 180 Semi-Classical Quantization of a [2] Rotaxane** KARL SOHLBERG, ARI SILVER, *Chem. Dept., Drexel University* Rotaxanes show tantalizing potential for functional nanosystems. A [2]rotaxane is a molecular complex consisting a long dumbbell-shaped chain molecule, (called the shaft) which threads a ring molecule, typically a crown-ether or cyclodextrin. The chain component is terminated on each end by a bulky substituent to prevent unthreading of the ring. The components are therefore chemically independent but mechanically interlocked. When such complexes are synthesized with two inter-component binding stations, bistability results, hinting at potential for switching or data storage applications. We have investigated the quantum-mechanical eigenstates associated with the shuttling motion between these co-conformations. The state density is very high because nanosystems exist at the transition/interface between molecular systems, which are dominated by quantum phenomena, and macroscopic systems where matter is essentially continuous and classical physics provides the best description. We show that state density is ithighest where quantum mechanical tunneling is most important.

**C1 181 Single molecule fluorescence investigates the heterogeneity of liquid crystal matrix.** YU-TSU CHUANG, JUI-HUNG HSU, *National Sun Yat-sen University* Liquid crystals are attracted for their existence of unique meso-phase between solid state and liquid state. We perform the single-molecule (SM) fluorescence investigation on the thermotropic liquid crystal matrix. Using the nm size fluorescent quantum dots as a probe, it allows us to investigate the local structural and dynamic heterogeneity in the liquid crystal matrix. Controlling the temperature allows us to probe how the local behaviors differ at different meso-phases. Fluorescence correlation spectroscopy (FCS) as well as the intensity time trace analysis indicate the much more heterogeneity in the liquid crystal phase than the other phases.

**C1 182 Synthesis and Characterization of Rectangular Palladium Nanoparticles.*** YUAN SUN, *Dept. Mat. Sci. & Eng., SUNY at Stony Brook* LIHUA ZHANG, ELI SUTTER, YIMEI ZHU, *Center for Functional Nanomaterials, Brookhaven National Laboratory* MIRIAM RAFAILOVICH, JONATHAN SOKOLOV, *Dept. Mat. Sci. & Eng., SUNY at Stony Brook* The optical, magnetic and catalytic and electronic properties of nanoparticles are affected not only by their size, but also by their shape. We have used a mild reducing agent, ascorbic acid, in the presence of sodium citrate and a surfactant, cetyltrimethylammonium bromide, at ambient conditions to prepare colloidal rectangular palladium nanoparticles, including nanocubes and nanorods. Our procedure requires no seed-mediated growth or nanoporous template so that it is more practical for large-scale synthesis. Upon changing the concentration of sodium citrate from $0.2 \times 10^{-3}$ M to $1.0 \times 10^{-3}$ M, TEM measurements indicate that the average size of the nanocubes decreases slightly from $31.8 \pm 3.2$ nm to $29.4 \pm 4.2$ nm and the aspect ratio of the nanorods increases from $2.48 \pm 1.42$ to $3.94 \pm 2.50$. HRTEM images and diffraction patterns indicate that the particles are highly crystalline and have strong (100) faceting. Being exposed to air for $\sim$ 100 days, the particles are oxidized to form 2$\sim$ 4 nm-thick amorphous shells.

**C1 183 Nucleation, composition and morphology of ALD $HfO_2$ films** JUSTIN C. HACKLEY, THEODOSIA GOUGOUSI, *University of Maryland Baltimore County* A hot wall Atomic Layer Deposition flow reactor equipped with a Quartz Crystal Microbalance (QCM) has been used in the development of a

$HfO_2$ process from tetrakis-ethylmethylamino hafnium (TEMAH) and $H_2O$ precursors. We have studied the nucleation, composition and morphology of $HfO_2$ films deposited on H- terminated Si, native oxide and SC1 chemical oxide. Ellipsometry and QCM measurements confirm linear growth of the films ( $\sim$ 1.2Å/cycle at 250[r]C). Similar incubation periods ( $\sim$ 10 cycles) are found for depositions on the H-terminated Si and native oxide starting surfaces in agreement with recently published results.[1] AFM measurements show rms roughness of the as deposited films below 4% of the total film thickness. FTIR measurements show some OH and carbonate content in the films that are corroborated by XPS measurements. Rapid Thermal Anneal of the films in Ar (500 to 900[r]C, 2 min) results in the destabilization of the $HfO_2/SiO_2$ interface, increased rms roughness and crystallization of the film. FTIR and XPS analysis of the films annealed at 900[r]C in Ar confirm removal of the OH and carbonate species from the films. Finally, we present QCM measurements for the nucleation of $HfO_2$ films on Si and H-terminated surfaces.

**C1 184 Ranked solutions to a class of combinatorial optimizations - with applications in mass spectrometry based peptide sequencing*** TIMOTHY DOERR, GELIO ALVES, YI-KUO YU, *NCBI/NLM/NIH* Typical combinatorial optimizations are NP-hard; however, for a particular class of cost functions the corresponding combinatorial optimizations can be solved in polynomial time. This suggests a way to efficiently find approximate solutions —find a transformation that makes the cost function as similar as possible to that of the solvable class. After keeping many high-ranking solutions using the approximate cost function, one may then re-assess these solutions with the full cost function to find the best approximate solution. Under this approach, it is important to be able to assess the quality of the solutions obtained, *e.g.*, by finding the true ranking of $k$th best approximate solution when all possible solutions are considered exhaustively. To tackle this statistical issue, we provide a systematic method starting with a scaling function generated from the fininte number of high- ranking solutions followed by a *convergent* iterative mapping. This method, useful in a variant of the directed paths in random media problem proposed here, can also provide a statistical significance assessment for one of the most important *proteomic* tasks—peptide sequencing using tandem mass spectrometry data.

## C1 185 STATISTICAL AND NONLINEAR PHYSICS POSTER SESSION

**C1 186 Loschmidt echo decay in hard-disk billiards*** ARSENI GOUSSEV, KLAUS RICHTER, *Institute for Theoretical Physics, University of Regensburg* The Loschmidt echo (LE) quantifies the sensitivity of quantum dynamics to perturbations of system's Hamiltonian. In a chaotic system it is known to exhibit exponential time decay, for a certain range of perturbation strengths, with the decay rate given by the mean Lyapunov exponent of the counterpart classical system. This phenomenon makes the LE an attractive tool for quantifying *Quantum Chaos*. To date, all existing theories for the LE strongly rely on averaging over different realizations of the Hamiltonian and/or averaging over an ensemble of initial states. Thus, a theory for the LE in pure individual chaotic systems is needed. We attempt to fill in this gap by addressing the LE in pure open quantum hard-disk billiards. We find that in such systems the LE time decay is intimately connected to Lyapunov exponents as well as to quantities characterizing escape of classical trajectories from the system's chaotic repellor. Our theoretical findings are supported by results of numerical simulations.

**C1 187 Random Walk Model with Waiting Times Depending on the Preceding Jump Length** VASILY ZABURDAEV, *Max Planck Institute for Dynamics and Self-Organization* In the present work the generalized continuous time random walk model with a coupled transition kernel is considered. The coupling occurs through the dependence of the waiting time probability distribution on the preceding jump length. The method, which involves the details of the microscopic distribution over the waiting times and arrival distances at a given point, is suggested for its description. In the particular case of coupling, when a waiting time is a simple function of a preceding jump length, a close analogy to the problem of a random walk with finite velocity is demonstrated. With its help an analytical solution for the generalized random walk model, including both effects (finite velocity and jump dependent waiting times) simultaneously, is found. Considered examples indicate a possibility to apply the developed approach to the biological problems where the random walk together with the recovery processes and the finite velocity are present, such as e.g. the foraging movements of animals or the motion of zooplankton.

**C1 188 Diameter of Random Cluster Models** D. W. BLAIR, J. MACHTA, *University of Massachusetts at Amherst* The diameter of critical clusters of the $q$-state Potts model in the random cluster representation is measured in numerical simulations. The diameter of a graph is the maximum over all pairs of connected sites of the minimum path length between the sites. Although the diameter of Fortuin-Kasteleyn clusters is not a thermodynamic quantity, it is expected to display power law critical behavior since the size of the largest cluster diverges at the critical point. The Swendsen-Wang algorithm is used for both for equilibrating the spin model and for identifying clusters. An efficient algorithm is employed to measure the diameter. The exponent characterizing the divergence of the diameter is obtained for $q = 1, 2, 3$ and 4. The relation to other critical exponents is discussed. This work is supported by NSF (DMR-0242402).

**C1 189 Empirical and model study on Travel-entering China*** XUE-FANG HAN, QI-JUAN CHEN, HUI CHANG, DA-REN HE, *Yangzhou University, China* We have done an empirical investigation on the travel-entering China from abroad to 31 regions of Chinese Mainland in recent ten years, including the development of the traveler's number, the traveler's number distribution for the traveler's home regions, the traveler's number distribution for the traveler's destination regions in Chinese mainland, and so on. We also suggest a dynamic model for simulating the competition between the 31 regions in the traveling market by considering two main influence factors, the attracting factor of the travel

destinations and the distance between the destination and the home regions of the travelers. The simulation results show a good agreement with the empirical data. We expect the model could suggest some advice and thoughts to the travel-entering management departments in China and may be also for other countries.

**C1 190 An empirical and model study on automobile market in Taiwan*** JI-YING TANG, RONG QIU, YUEPING ZHOU, DA-REN HE, *Yangzhou University, China* We have done an empirical investigation on automobile market in Taiwan including the development of the possession rate of the companies in the market from 1979 to 2003, the development of the largest possession rate, and so on. A dynamic model for describing the competition between the companies is suggested based on the empirical study. In the model each company is given a long-term competition factor (such as technology, capital and scale) and a short-term competition factor (such as management, service and advertisement). Then the companies play games in order to obtain more possession rate in the market under certain rules. Numerical simulation based on the model display a competition developing process, which qualitatively and quantitatively agree with our empirical investigation results.

*supported by Chinese National Natural Science Foundation, No. 70371071

**C1 191 Stochastic Synchronization in Lattices of Model Neurons** ANDY MUELLER, KLAUS LEHNERTZ, *Helmholtz-Institute for Radiation and Nuclear Physics and Dept. of Epileptology, University of Bonn* It has been shown recently that a wide class of uncoupled limit-cycle oscillators can be fully synchronized by a common weak additive white noise. We study the influence of noise on the dynamics of mutually uncoupled lattices that are composed of periodically spiking model neurons with an increasing complexity. In order to approximate characteristics of noise found in empirical data we use an Ornstein Uhlenbeck process (OUP) as the driving force. Varying the correlation time and the intensity of the OUP we study the time to full synchronization (ST) and the largest Lyapunov exponent (LLE) of the systems. For all investigated correlation times LLE is negative indicating the convergence of the trajectories of the systems. For a constant noise intensity we observe that both ST and LLE exhibit a minimum for a particular correlation time of the OUP. We discuss the possible relationship between the correlation time of the OUP and the time scales of the investigated systems.

**C1 192 Score Statistics of Global Sequence Alignment and a Modified Directed Polymer Problem*** MIHAELA SARDIU, *Stowers Institute* GELIO ALVES, YI-KUO YU, *NCBI/NLM/NIH* Sequence alignment is one of the most important bioinformatics tools for modern molecular biology. Using a variant of the directed path in random media model, we investigate the score statistics of global sequence alignment taking into account the compositional bias of the sequences compared. To accommodate the compositional bias, we introduce an extra parameter $p$ indicating the probability for positive matching scores to occur. When $p$ is large, the highest scoring point within a global alignment tends to be close to the end of both sequences, in which case we say the system percolates. By applying finite-size scaling theory on percolating probability functions of various sizes (sequence lengths), the critical $p$ at infinite size is obtained. For alignment of length $t$, the score fluctuation $\sim \chi t^{1/3}$ is confirmed via scaling of the alignment score. Using the Kolmogorov-Smirnov statistics test, we show that $\chi$ follows the Tracy-Widom distributions: Gaussian Orthogonal Ensemble for $p$ slightly larger than $p_c$ and Gaussian Unitary Ensemble for larger $p$. The possibility of characterizing score statistics for modest system size (sequence lengths), via proper reparametrization of alignment scores, is illustrated.

*This work was supported by the Intramural Research Program of the NLM at the NIH/DHHS

**C1 193 Nonequilibrium phase transition on a randomly diluted lattice** MAN YOUNG LEE, THOMAS VOJTA, *Department of Physics, University of Missouri-Rolla* We show that the interplay between geometric criticality and dynamical fluctuations leads to a novel universality class of the contact process on a randomly diluted lattice. The nonequilibrium phase transition across the percolation threshold of the lattice is characterized by unconventional activated (exponential) dynamical scaling and strong Griffiths effects. We calculate the critical behavior in two and three space dimensions, and we also relate our results to the recently found infinite-randomness fixed point in the disordered one-dimensional contact process.

**C1 194 Numerical Studies of the Edwards-Wilkinson interface equation: the influence of short-range time-correlated noise** MIKA SAUKKONEN, TEEMU LAURILA, TAPIO ALANISSILA, *Helsinki University of Technology* COMP TEAM, We study the properties of the Edwards-Wilkinson equation with finite temporal correlations of duration $t_d$. Two limiting cases can be calculated analytically, namely, the thermal white noise limit, where $t_d \to 0$, and the purely columnar limit, when $t_d \to \infty$. The surface growth exponents are $\beta = 1/4$ for the thermal white noise case and $\beta = 3/4$ for the columnar noise case. Correspondingly, the rougness exponents are $\chi = 1/2$ and $\chi = 3/2$. We study the crossover scaling of the surface width and the dynamical structure factor between these two limits by introducing a scaling ansatz and numerically verifying it. Furthermore, we present results from a comparison between the time correlated case and the case with quenched noise, which has the same effective correlation length. The scaling behavior in these two cases is similar exept close to the pinning transition for the quenched noise case.

**C1 195 A study of SOC models by the use of joint distributions** ESPEN JETTESTUEN, ANDERS MALTHE-SORENSSEN, JENS FEDER, *Centre for Physics of Geological Processes, University of Oslo* A precise characterization of scaling behavior is important for the further development of self-organized criticality. This has been achieved for models that display finite size scaling, but is lacking for systems that have more complicated scaling form. We propose that scaling of structures in joint probability densities can be used to identify the underlying structure in systems that show multi-scaling behavior. Here, we will study two simple models by the use of joint probability distributions. One is the BTW model that have multi-scaling behavior and the other is a randomized version of the Olami-Feder-Christensen earthquake model which has a simple finite size scaling form. We will also relate the scaling of the joint probability density to other well-known measures.

**C1 196 Glassy dynamics in interface growth: aging, fluctuation disipation and thermal avalanches** JOSE J. RAMASCO, *Emory University* JUAN M. LOPEZ, MIGUEL A. RODRIGUEZ, *Inst. de Fisica de Catabria (Spain)* In this work we study the KPZ interface growth equation subjected to both quenched and anealed disorder. We find that the interface dynamics shows a glassy behavior in the regime of low temperatures and low external force, a regime commonly known as creep in the superconductor literature. We also describe how the temperature affects to the avalanches in the front development.

**C1 197 Delayed Feedback and Chaos on the Driven Diode-Terminated Transmission Line** VASSILI DEMERGIS, STEVEN ANLAGE, *Dept of Physics, Univ of Maryland, College Park* EDWARD OTT, THOMAS ANTONSEN, *Institute for Research in Electronics and Applied Physics, Univ of Maryland, College Park* ALEXANDER GLASSER, MARSHAL MILLER, A simple model of a distributed, non-linear circuit that produces chaos at GHz frequencies is introduced and tested experimentally. The model circuit is a driven, diode-terminated transmission line with the transmission line impedance mismatched to that of the source. This model is motivated by the need to understand the mechanisms for RF upset in computer circuits. Experimental tests of the model were performed with driving frequencies of 10 MHz to 1.2 GHz, driving powers of -30 to +50 dBm, and delay times from 3 to 20 ns. Diode reverse recovery times (/tau/) ranged from 4 to 100 ns. Experimentally, it was found that chaotic behavior was strongly dependent on the reactance of the system as seen by the driving source, and influenced by an applied DC voltage-bias across the diode. In the experiments that showed period-doubling and / or chaos, the /tau/ was on the order of both the driving period and the delay time of the circuits. Comparisons between theory and experiment are in general agreement.Work supported by the DOD MURI AFOSR Grant F496200110374 and DURIP Grants FA95500410295, FA95500510240.

**C1 198 Geometrically induced nonlinear dynamics in one-dimensional lattices** MERLE D. HAMILTON, O.F. DE ALCANTARA BONFIM, *University of Portland* We present a lattice model consisting of a single one-dimensional chain, where the masses are interconnected by linear springs and allowed to move in a horizontal direction only, as in a monorail. In the transverse direction each mass is also attached to two other linear springs, one on each side of the mass. The ends of these springs are kept at fixed positions. The nonlinearity in the model arises from the geometric constraints imposed on the motion of the masses, as well as from the configuration of the springs, where in the transverse direction the springs are either in the extended or compressed state depending on the position of the masses. Under these conditions we show that solitary waves are present in the system. In the long wavelength limit an analytic solution for these nonlinear waves is found. Numerical integrations of the equations of motion in the full system are also performed to analyze the conditions for the existence and stability of the nonlinear waves.

**C1 199 Stochastic qualifyers of brain dynamics** JENS PRUSSEIT, *Helmholtz Institute for Radiation and Nuclear Physics, University of Bonn* KLAUS LEHNERTZ, *Department of Epileptology, University of Bonn* Despite the fact that both linear and nonlinear analyses of EEG time series have provided valuable insights into the complex spatio-temporal dynamics of physiological and patho-physiological brain functions, these processes are far from being fully understood. We here investigate the applicability of a previously proposed analysis method to characterize EEG time series from epilepsy patients using concepts from the theory of Markov-processes. To estimate the coefficients of a corresponding Fokker-Planck equation we adopt the method of Siegert et al (Phys. Lett. A **243**, 275 (1998)) to the problem at hand. To check the validity of our approach we reconstruct the driving noise force via the associated Langevin equation and show that the noise is approximately delta-correlated and Gaussian. We then integrate our model to compare the stationary probability distribution function (PDF) as well as the conditional PDFs on different time scales with the PDFs derived from the EEG data. Applying the analysis method to long-lasting multichannel EEG recordings we discuss the possible relevance for diagnostic purposes.

**C1 200 Berry curvature contributions to the density fluctuation spectrum of Bloch electrons** M. J. RAVE, W. C. KERR, *Wake Forest University* Recent work has shown that the equations of motion (EOM) for semiclassical Bloch electrons must be modified in the presence of a non-zero Berry curvature [1]. These corrections to the EOM have implications for many physical quantities: effective mass, electron orbits in a magnetic field, de Haas-van Alphen oscillations, etc. In addition the Boltzmann transport equation is also modified with possible ramifications for calculations of transport phenomena. We investigate these issues for a gas of spinless Bloch electrons in an external electric field. We find modifications to the traditional dispersion relation for density fluctuations; in particular we find a shift in the plasma frequency and an anisotropic sound velocity. [1] M.-C. Chang and Q. Niu, Phys. Rev. B 53, 7010 (1996)

**C1 201 Correlation functions and anisotropy in the XY model with a magnetic field*** WEI ZHANG*, H.A. FERTIG, *Department of Physics, Indiana University* Recent studies have demonstrated that the classical XY model with a magnetic field has three phases: a linearly confined vortex-antivortex phase, a logarithmically (Log) confined phase, and a free vortex phase. We calculate correlation functions in this model by making use of duality transformations and numerical simulations. In all three phases, the order parameter is nonzero and $< \cos(\theta(r_1))\cos(\theta(r_2)) > \rightarrow$ const., for $|\mathbf{r}| = |\mathbf{r}_1 - \mathbf{r}_2| \rightarrow \infty$, indicating true long range order, when the ordering field favors $\theta = 0$. A renormalization group analysis suggests that the Log phase may be distinquished from the other two in the correlation function $C(r) = < \sin(\theta(\mathbf{r}_1))\sin(\theta(\mathbf{r}_2)) >$, which is short-ranged with a correlation length that depends on the direction of $\mathbf{r}_1 - \mathbf{r}_2$ with respect to the lattice axes. However, it is shown that a directional anisotropy also enters all the phases through a prefactor. Our numerical simulations support the existence of these anisotropies, but the the anisotropy in the prefactor is generically relatively strong while the correlation length anisotropy is rather weak, making it difficult to distinquish the different phases from these correlation functions. *Present address: Department of Physics and Astronomy, Ohio University

**C1 202 Emergent Structures in Dissipative Wave-Particle Systems*** DAVIT SIVIL, ALFRED HUBLER, *Center for Complex Systems Research, Department of Physics, University of Illi-*

*nois at Urbana-Champaign* We study the motion of a particle with mass m on a vibrated string of length L. We assume there is no friction force between the particle and the string. The string is sinusoidally forced at both ends. We find that the particle has attractors located at $x=L/2 - n\pi c/2\omega$, where $\omega$ is the frequency of the waves on the string, and $n \in \mathbf{Z}$. We also study the same system with friction and multiple driving frequencies. We also compared our results with numerical simulations

*The research is supported by the National Science Foundation Grant No. NSF PHY 01-40179, NSF DMS03-25939. ITR, and NSF DGE 03-38215.

**C1 203 Scaling in a cellular automaton model of earthquake faults with long-range stress transfer** JUNCHAO XIA, *Clark University* HARVEY GOULD, *Clark Unversity* M. ANGHEL, WILLIAM KLEIN, *Boston University* JOHN RUNDLE, *U. C., Davis* We present simulation data indicating that the scaling of earthquake events in models of faults with long-range stress transfer is composed of at least three distinct regions, corresponding to earthquakes with different underlying physical mechanisms. We discuss the interpretation of these events as fluctuations in the vicinity of a spinodal critical point. In addition to the scaling events, there are larger ''breakout'' events that do not scale. The nature of the stress density profile before an event is investigated and a possible way of predicting breakout events is discussed.

**C1 204 Time-Evolution of the Wigner Function in Phase-Space using Finite Differences** SHUBHABRATA RATH, TOMAS MATERDEY, *University of Massachusetts Boston* Phase-space density holes are vortex-like nonlinear structures that have been observed in the magnetosphere. To study the time evolution of these structures we evolve the Wigner function in time by solving the quantum Vlasov equation using finite-differences.

**C1 205 The Structural Database*** NIKOLAI ZARKEVICH, D.D. JOHNSON, *Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign.* A Structural Database can be used as a universal tool for global accumulation and integration of structural and energy data from different methods, people, and places. It allows data mining and data validation by direct comparison of structural data from different sources. Being combined with multi-scale methods (e.g., ThermoToolkit), it can significantly reduce the cost of materials design. We exemplify these and other benefits of the Structural Database, and demonstrate its working prototype, available at http://data.mse.uiuc.edu. This database is a product of multi-disciplinary research involving Physics, Computer Science, and Materials Science and Engineering.

*Development is supported in part by the U.S. Department of Energy through grant DE-FC36-05GO15064.

**C1 206 Interacting Cracks in an Environmentally Assisted Fracture** ARTEM LEVANDOVSKY, ANNA BALAZS, *University of Pittsburgh* We perform the study of environmentally assisted fracture within the framework of a lattice model. Formation of an ensemble of environmentally assisted microcracks, their coalescence and formation of crack ''avalanches'' lead to a very rich dynamical picture. Under specific condition crack healing can occur due to cohesive forces, which hold material together and tend to pull atoms together even if they are separated by a crack over several lattice units. We investigate the dynamical interplay between crack formation, arrest, healing and re-cracking. The goal here is to provide an understanding of the conditions leading to the phenomena of crack healing that happens along with the crack formation. We study the morphology of crack patterns with the intentions to establish a way to enhance the healing property of a material sample.

**C1 207 Structure and Nonlinear dynamical response of Pinned Lattice systems: Application of the Phase Field Crystal Model to Pinned Lattices** MIKKO KARTTUNEN, CRISTIAN ACHIM, *Helsinki University of Technology* KEN ELDER, *Oakland University* TAPIO ALA-NISSILA, *Laboratory of Physics, Helsinki University of Technology* ENZO GRANATO, *Instituto Nacional de Pesquisas Espaciais, Sao Jose dos Campos, SP Brazil* S.C YING, *Department of Physics, Brown University* We present analytic and numerical results for the structure and dynamics of a lattice system in 2D in the presence of a pinning potential. We employ a new approach via the Phase Field Crystal (PFC) model which describes phenomena on atomic length and diffusive time scales. It can be used for modeling elastic and plastic deformation, free surfaces and multiple crystal orientations in non-equilibrium processes, and enables access to time scales much longer than conventional atomic methods. The competition between the length scales associated with the intrinsic ordering and the pinning potential leads to commensurate-incommensurate transitions. The dynamical response of the system in the presence of a driving force has also been studied via the time dependent Landau Ginzberg equation. Dynamically induced phases, mobility thresholds and hysteresis behavior have been observed. We will discuss the application of this model to physical problems such as the I-V characteristics of 2-D vortex lattices and sliding friction in interfaces with boundary lubricants.

**C1 208 Piconewton force measurement with a scanning tunneling microscope** KAI-FELIX BRAUN, APARANA DESHPANDE, SAW HLA, *Ohio University* The magnitude of force required to move a single atom across a crystal surface has been measured for the first time. During atomic manipulation experiments with a scanning tunneling microscope the tip heigth curve is recorded. Analysis of shape and period has yielded detailed knowledge about atomic movement while it is shown here that the amplitude of the manipulation curve is a measure of the interaction force between the microscopes tip and the manipulated atom on the surface. This interaction force has been measured for single Ag atoms on a Ag(111) substrate as a function of distance and amounts to several hundred piconewton.

**C1 209 Theory of the Effects of Multiscale Surface Roughness and Stiffness on Static Friction*** JEFFREY SOKOLOFF, *Northeastern University* It is shown on the basis of simple scaling arguments that an interface between two three dimensional elastic solids, consisting of completely flat disordered surfaces, which interact with interatomic hard core interactions, will be in a weak pinning regime, and hence exhibit negligibly small static friction. It is argued, however, that the presence of roughness on multiple length scales can lead to much larger friction (i.e., static friction coefficients not too much smaller than 1), as is characteristic of most solid surfaces. This approach suggests a possible way of understanding why coatings of materials with high elastic constants are often excellent lubricants.

**C1 210 Electrospinning frozen in time*** MATIJA CRNE, *Georgia Institute of Technology* JUNG OK PARK, *Georgia institute of Technology* MOHAN SRINIVASARAO, *Georgia Institute of Technology* Electrospinning is known to produce microfibers with small diameter and/or high surface area. Often times, the high surface area of these fibers is associated with their surface structures, consisting of nanometer-sized holes, droplets, or microcups, whose formation depends on the spinning condition and the type of the solutions used. A mixture of isotactic and syndiotactic PMMA in dimethyl formamide was used in our study to produce helical microfibers by electrospinning at elevated temperatures. Rapid cooling during electrospinning allows for fast physical gelation to take place and trap helical microstructures arising from instabilities due to electrostatic, capillary and viscous forces. The formation of these helices was considered in terms of stability theory for electrically forced jets.

*The authors would like to acknowledge the National Science Foundation (DMI-0423619) for supporting this research.

**C1 211 Response to disturbance*** WEN-XIU WANG, DAN SHEN, YU-MEI JIANG, YING-MEI WANG, DA-REN HE, *Yangzhou University, China* PEI-PEI ZHANG, *Jiangsu University, China* YUE HE, *Wuxi No.1 Middle School, China* We suggest a new concept named response to disturbance for describing a character of dynamic systems. In relatively simple systems the evolution usually tends to a final state, which may be an equilibrium state, a periodic oscillating state, a quasi-periodic state, or a chaotic state. A disturbance, which always exists in practical systems, sometimes vanishes gradually and indicates the final state is stable, while it sometimes grows up very quickly and indicates the final state is unstable. However, in a relatively complex system disturbance may cause emergence of (may be a very large number of) new structures and very long evolution processes. So, we are trying to suggest a parameter with suitable function form so that the different responses to disturbance in different type of systems can be quantitatively distinguished. We hope that the parameter can be useful for understanding complexity of the practical systems. The details will be presented elsewhere.

**C1 212 A model study on dyad act-degree distribution in some collaboration networks*** YUE-PING ZHOU, HUI CHANG, DA-REN HE, *Yangzhou University, China* We (and cooperators) have suggested extending the conception collaboration network to some non-social networks, which have structures as sets of completed graphs [1]. A dyad is composed of two nodes, which are connected by one edge. In social network studies dyad often is considered as the basic units in networks. It should be more important in the extended collaboration networks. We suggest emphasizing the importance of dyad in organizing a network and studying the evolution of the extended collaboration networks by a dyad-act organizing model. The analytic and numeric studies of the model lead to a conclusion that most of the collaboration networks should show a dyad act-degree distribution (how many acts a dyad belongs to) between a power law and an exponential function, which can be described by a shifted power law. We have done an empirical study on dyad act-degree distribution in some collaboration networks. The results show good agreement with this conclusion. The details will be published elsewhere. [1] P-P Zhang, K. Chen et al., to appear on Physica A.

*Supported by Chinese National Natural Science Foundation, No. 70371071.

**C1 213 Empirical study on dyad act-degree distribution in some collaboration networks*** HUI CHANG, *Yangzhou University* PEI-PEI ZHANG, *Jiangsu University* YUE HE, *Wuxi No.1 Middle School* DA-REN HE, *Yangzhou University, China* We (and cooperators) suggest studying the evolution of the extended collaboration networks by a dyad-act organizing model. The analytic and numeric studies of the model lead to a conclusion that most of the collaboration networks should show a dyad act-degree distribution (how many acts a dyad belongs to) between a power law and an exponential function, which can be described by a shifted power law. We have done an empirical study on dyad act-degree distribution in some collaboration networks. They are: the train networks in China, the bus network of Beijing, and traditional Chinese medical prescription formulation network. The results show good agreement with this conclusion. We also discuss what dyad act-degree implies in these networks and what are the possible applications of the study. The details will be published elsewhere.

*Supported by Chinese National Natural Science Foundation, No. 70371071.

**C1 214 Empirical study on assortativity in some collaboration networks*** BEI-BEI SU, HUI CHANG, DA-REN HE, *Yangzhou University, China* We (and cooperators) have suggested extending the conception collaboration network to some non-social networks, which have structures as sets of completed graphs [1]. In this view of point, we may divide practical networks into four groups: a) social collaboration networks, b) social non-collaboration networks, c) non-social collaboration networks, and d) non-social non-collaboration networks. We have done an empirical study on assortativity in some practical networks, which belong to the four groups. The results show that all the networks of a) and b) groups show positive assortativity, all the networks of d) group show negative assortativity. This is in agreement with the conclusion obtained by Newman [2]. However, for some of the networks belonging to group c), we obtained positive assortativity, but obtained negative one for other networks belonging to the same group. The details will be published elsewhere. Now we are trying to find the difference in the structure properties of these networks, which may be responsible for different sign of assortativity. [1] P-P Zhang, K. Chen et al., to appear on Physica A. [2] M. E. J. Newman, PRE 67, 026126 (2003).

**C1 215 Dynamical Stochastic Processes of Returns in Financial Markets** KYUNGSIK KIM, *Department of Physics, Pukyong National University, Pusan 608-737, Korea* SOO YONG KIM, *Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon 305-701, Korea* GYUCHANG LIM, *Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon 305-701, Korea* JUNYUAN ZHOU, *Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon 305-701, Korea* SEUNG-MIN YOON, *Division of Economics, Pukyong National University, Pusan 608-*

*737, Korea* We show how the evolution of probability distribution functions of the returns from the tick data of the Korean treasury bond futures (KTB) and the S&P 500 stock index can be described by means of the Fokker-Planck equation. We derive the Fokker-Planck equation from the estimated Kramers-Moyal coefficients estimated directly from the empirical data. By analyzing the statistics of the returns, we present the quantitative deterministic and random influences on both financial time series, for which we can give a simple physical interpretation. Finally, we remark that the diffusion coefficient should be significantly considered to make a portfolio.

## C1 216 ARTIFICIALLY STRUCTURED MATERIALS POSTER SESSION

**C1 217 Diffusion and binding of CO on Pt nanowires** NURI ONCEL, WOUTER J. VAN BEEK, JEROEN HUIJBEN, HAROLD J.W. ZANDVLIET, BENE POELSEMA, *Solid State Physics, MESA + Research Institute for Nanotechnology, University of Twente* Room temperature scanning tunneling microscopy (STM) has been used to study the diffusion and binding of CO molecules on Pt nanowires. The perfectly straight Pt nanowires (with a cross-section of only one atom) are grown on Ge(001) surfaces. CO molecules bind on a bridge position of the Pt dimers and they are mobile at room temperature. The interaction between adsorbed CO molecules is strongly repulsive, which leads to low saturation coverage and ''restricted'' 1D Brownian motion along the nanowires.

**C1 218 Phononic crystals for the mode conversion of elastic waves.*** BETSABE MANZANARES-MARTINEZ, *División de Ciencias e Ingeniería, Unidad Regional Sur de la Universidad de Sonora* FELIPE RAMOS-MENDIETA, *Departamento de Investigación en Física de la Universidad de Sonora* We have studied theoretically the transmission of elastic waves in an Epoxy/Sn superlattice with Si and Epoxy as media of incidence and transmission, respectively. We found that this is a good system for conversion of the elastic mode polarization. Within some ranges of frequencies the incident longitudinal waves are converted to transverse waves with efficiency of 85%. In order to understand this effect the polarization states of the sagittal bands need be considered. The modes of sagittal bands can be mainly transverse or mainly longitudinal. We found that as higher the density of transverse modes, higher the conversion. The effect depends strongly on the sound velocity of the medium of incidence - high velocity as possible is required. For calculations we also include absorption effects.

**C1 219 X-ray Studies of Ultrathin Wires and Tubes in Nanoscale Confinement.** JONATHAN M. LOGAN, OLEG G. SHPYRKO, ERIC D. ISAACS, *Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL and JFI/Physics Department, University of Chicago, Chicago, IL* RAFAEL JARAMILLO, YEJUN FENG, *JFI/Physics Department, University of Chicago, Chicago, IL* JEFFREY W. ELAM, *Energy Systems Division, Argonne National Laboratory, Argonne, IL* DAVID J. COOKSON, *Australian Synchrotron Research Program, Argonne, IL* MICHAEL J. PELLIN, *Materials Science Division, Argonne National Laboratory, Argonne, IL* Nanoporous Anodized Aluminum Oxide (AAO) membranes are composed of self-assembled, densely packed, co-aligned cylindrical pores. The pore diameter of these membranes can be controllably reduced to as little as $\approx$ 1 nm through Atomic Layer Deposition (ALD) process. AAO pores have been used as templates for formation of metallic nanotubes and nanowires through ALD or thermal vapor deposition. These embedded structures have been characterized by small- and wide-angle x-ray scattering (SAXS, WAXS). The penetrating ability of x rays provides a non- destructive structural characterization technique for materials confined within AAO matrix, on both atomic (WAXS) and nanometer (SAXS) length scales.

**C1 220 Electric Field Effects on Motion of a Charged Particle Through a Saddle Potential in a Magnetic Field** V. FESSATIDIS, *Fordham University* K. SABEEH, *Quaid-i-Azam University, Pakistan* N.J.M. HORING, *Stevens Institute of Technology* M.L. GLASSER, *Clarkson University* Electron transmission through a quantum point contact (QPC) in the presence of both electric and magnetic fields is examined. The QPC is modeled as a saddle potential. The first part of the paper is devoted to deriving the relevant Green's function including the effects of arbitrarily time dependent electric and constant magnetic fields. The derivation is carried out using Schwinger's operator equation of motion approach. In the second part of the paper we apply it to determine transmission of the electron guiding center through the QPC in constant electric and magnetic fields.

**C1 221 Hofstadter's butterfly with Rashba spin-orbit coupling*** SUKEY SOSA Y SILVA SALGADO, FERNANDO ROJAS, *Centro de Ciencias de la Materia Condensada, UNAM* We study the energy spectrum of an electron in a two-dimensional periodic lattice in a perpendicular magnetic field in the tight-binding approximation including the Rashba spin-orbit coupling. We have investigated how the fractal spectrum known as Hofstadters butterfly is modified if one includes the spin-orbit coupling. We find a set of decoupled Harper-like equations for each spinor by restricting the Rashba coupling along one direction. We solve the set of equations and evaluate the energy spectrum for each spinor. In order to characterize the energy spectrum we calculate its fractal dimension, in particular, we analyze the capacity and the correlation dimension of each spin-subbands buttlerfly as a function of the spin-orbit coupling parameter and magnetic field.

*Support by DGAPA project IN114403 and CONACyT project 43673-F

**C1 222 Ground state energy of an electron in a GaAs pillbox immersed in a GaAlAs substrate** GERARDO JORGE VAZQUEZ-FONSECA, MARCELO DEL CASTILLO-MUSSOT, *Instituto de Fisica, UNAM* SANDRA MILENA RAMOS-ARTEAGA, NELSON PORRAS-MONTENEGRO, *Universidad del Valle, Colombia* In this work we have studied the ground state energy behavior for a GaAs pillbox immersed in a system of GaAlAs as a function the thickness of the barrier potential when the length of the pillbox is fixed, as function the length of the pillbox when the thickness of the barriers remained

constant, and as a function of the pillbox position in the host of GaAlAs. Also, we studied the behavior of the energy of the ground state in this system for different Al concentrations. It is important to stress that for small lengths of the pillbox the energy of the ground state as function de relative position to the barrier potential presents a similar behavior as the binding energy of a hydrogenic impurity in quantum wells, quantum wires and quantum dots. We also found that there are critical values of the pillbox length for which there are no bound states.

**C1 223 Photoconductivity for an Array of Nanowires and Dots*** PAULA FEKETE, GODFREY GUMBS, *Hunter College, CUNY* We present a model calculation for the photoconductivity of a two-dimensional electron gas in an ambient perpendicular magnetic field. An electrostatic modulation which produces quantum wires or dots is also applied. The system is then subjected to a weak radiation field. The Landau eigenstates in the periodically modulated system are first obtained numerically and then used in the Kubo formula to obtain the conductivity. We analyze the frequency-dependent transport coefficients for their dependence on frequency and strength of modulation. The calculation is restricted to the low-frequency regime where the system is assumed to be in or close to equilibrium.

*Mailing Address: Department of Physics and Astronomy, Hunter College of the City University of New York, 695 Park Avenue New York, NY 10021

**C1 224 Dissipation Stabilized Superconductivity in Quantum Wires** HENRY FU, *University of California, Berkeley* ALEXANDER SEIDEL, *Lawrence Berkeley National Laboratory* JOHN CLARKE, DUNG-HAI LEE, *University of California, Berkeley* We present a theory of a superconducting wire dissipatively coupled to an environment. We show that due to the finite extent of the wire, in the absence of dissipation quantum phase slips always destroy superconductivity, even at zero temperature. Dissipation stabilizes the superconducting phase. We apply this theory to understand the ''anti-proximity effect'' recently seen by Tian et. al. [Phys. Rev. Lett. 95, 076802 (2005)] in Zinc nanowires.

**C1 225 Readout of single spins via Fano resonances in quantum point contacts** LEV MOUROKH, *Stevens Institute of Technology* ANATOLY SMIRNOV, VADIM PULLER, JONATHAN BIRD, We examine the feasibility of performing single-spin readout in a small quantum dot (SQD), using a quantum point contact (QPC) that is coupled to it by a larger dot with a quasi-continuous spectrum. When the Fermi energy in the QPC is approximately equal to one of the discrete levels of the SQD, a Fano resonance is observed in its conductance. We propose a procedure that uses such Fano peaks to determine the spin projection of a single electron in the SQD, in the presence of an external magnetic field that causes Zeeman splitting of its levels. We also show that this structure can exhibit Rabi oscillations when subject to microwave irradiation.

**C1 226 Fabrication of 3D-Ordered Nanoporous Gold for Chemical Sensors** DAVID HUNG, NEEPA SHAH, ZHU LIU, *Department of Materials Science and Engineering, Johns Hopkins University* YAOWU HAO, *Materials Science and Engineering Program, University of Texas at Arlington* PETER SEARSON, *Department of Materials Science and Engineering, Johns Hopkins University* 3D ordered nanoporous materials provide high surface-to-volume ratio and controlled nano-scale periodic architecture, making them attractive for applications such as energy storage, catalysis, separations, chemical sensing, and tissue engineering. 3D-ordered nanoporous gold structures were fabricated by electrodeposition of gold into colloidal crystal templates formed by self-assembly. The structures are replicas of the colloidal crystal and have pore sizes and feature sizes that are dependent on the particle size. When the dimensions of a conductor are sufficiently small the resistance is dominated by surface scattering. A prototype chemical sensor was created exploiting this architecture. Molecules with sulfhydryl groups adsorb strongly to gold surfaces and can be monitored by the change in resistance. A resistance change of approximately 2 percent was achieved and a chemical sensor based on surface scattering has been demonstrated.

**C1 227 Electronic and Magnetic Properties of Novel III-V-(M) Superlattices** J. RUFINUS, *Widener University* We present the results of computational works on the electronic and magnetic properties of ''novel'' III-V-(M) (where M is transition metals) superlattice. The calculations were performed using ABINIT and Gaussian 03 codes. The objective of this work is to determine the possibility of ferromagnetism in this type of superlattice.

**C1 228 Intersubband magnetophonon resonance in InAs/AlSb quantum cascade structures.** GEORGY FEDOROV, *National High Magnetic Field Laboratory* AARON WADE, *National High Magnetic Field Laboratory* DMITRY SMIRNOV, *National High Magnetic Field Laboratory* ROLAND TESSIER, *CEM2, University of Montpellier II* ALEXEI BARANOV, *CEM2, University of Montpellier II* Application of an external magnetic field offers a sensitive experimental tool to study and control basic processes which determine the performance of quantum cascade lasers – quantum confinement and intersubband relaxation. A strong magnetic field applied parallel to the confinement direction resonantly modulates the lifetime of the upper state of the laser transition, which is controlled by electron-optical phonon scattering. This effect of the intersubband magnetophonon resonance (ISMPR) allows for the investigation of the electronic structure and electron scattering mechanisms. We report on the observation of ISMPR in quantum cascade lasers based on InAs/AlSb heterostructures. Our experiments have been done under a magnetic field up to 33 T. We observe pronounced quantum oscillations in both the magnetoresistance and the intensity of the intersubband laser emission. Analysis of the obtained data is provided.

**C1 229 Development of Low-Temperature Scanning Capacitance Microscopy for Measurement of Single Quantum Dots*** GUANGLEI CHENG, *Department of Physics and Astronomy, University of Pittsburgh* JEREMY LEVY, *Department of Physics and Astronomy, University of Pittsburgh* GILBERTO MEDEIROS-RIBEIRO, *Laboratorio Nacional de Luz Sincrotron* COSMQC COLLABORATION,† Self-assembled single quantum dots are widely considered to be leading candidates for spin-based quantum bits. The characterization of such systems requires local information about both charge and spin degrees of freedom as a function of temperature and magnetic field. We describe an extension of a working low-temperature AFM/optical microscope to enable scanning capacitance measurements of quantum dots. Our system relies on the sensitivity of a microwave resonator to perturbations from the scanning probe (similar to RCA's CED technology), using a quartz tuning fork with an etched tungsten tip. The expected sensitivity of the instrument ($10^{-21}$ F) is much be-

low the capacitance of a single self-assembled quantum dot ($10^{-18}$ F). To measure the capacitance, we first use the AFM to locate a single quantum dot, and then collect local C-V information using the measured frequency shift of the resonator.

*This work was supported by the DARPA QuIST program (DAAD-19-01-1-0650).

**C1 230 Abstract Withdrawn**

**C1 231 Wigner Function for an Impurity in a Parabolic Quantum Dot** GARY SNYDER, *University of Massachusetts Boston* PRAVEEN NITTALA, *University Massachusetts Boston* TOMAS MATERDEY, *University of Massachusetts Boston* High sensitivity of quantum dots with impurities can be linked with phase space high sensitivity to initial conditions. We present the Wigner function for an impurity in a parabolic quantum dot obtained from a variational wavefunction.

**C1 232 Optical and phonon spectra of wurtzite ZnO quantum dots and nanocrystals** VLADIMIR A. FONOBEROV, KHAN A. ALIM, ALEXANDER A. BALANDIN, *Nano-Device Laboratory (http://ndl.ee.ucr.edu), Dept. of Electrical Engineering, University of California, Riverside, CA 92521* ZnO nanostructures have recently attracted attention due to the proposed optoelectronic and spintronic applications. Envisioned applications require accurate knowledge of exciton states and optical phonons. We report results of the investigation of wurtzite ZnO nanostructures with diameters from 2 nm to 20 nm (quantum dots to nanocrystals). The calculated size dependence of the exciton states and UV photoluminescence spectra of ZnO nanostructures is in agreement with the experimental data [1]. In addition, both interface and confined polar optical phonon modes in ZnO quantum dots and nanocrystals have been calculated and identified in the resonant and non-resonant Raman spectra [2]. It was found that the phonon confinement resulted in phonon frequency shifts of few $cm^{-1}$ in the non-resonant Raman spectra. We also show that UV laser excitation in resonant-Raman spectroscopy leads to large red shifts of phonon peaks (up to 14 $cm^{-1}$) due to heating. The authors acknowledge the support of MARCO and its Functional Engineered Nano Architectonics (FENA) Focus Center. [1] V.A. Fonoberov and A.A. Balandin, Appl. Phys. Lett. 85, 5971 (2004); [2] V.A. Fonoberov and A.A. Balandin, Phys. Rev. B 70, 233205 (2004); K.A. Alim, V.A. Fonoberov, and A.A. Balandin, Appl. Phys. Lett. 86, 053103 (2004).

**C1 233 A Study Of CdSe/ZnS Core-Shell Quantum Dots For Use in Luminescent Solar Concentrators** MEREDITH HYLDAHL, SHELDON BAILEY, PAUL FONTECCHIO, BRUCE WITTMERSHAUS, *Pennsylvania State University, Erie* A Luminescent Solar Concentrator (LSC) is a translucent plate that uses embedded fluorescent materials to absorb sunlight. The fluorescence that is produced is then transferred to the edges of the plate via total internal reflection where it is absorbed by photovoltaic cells. We compare a LSC made of CdSe/ZnS core-shell quantum dots (QD) (Evident Technologies) embedded in a transparent epoxy to a LSC made with the fluorescent organic dye Lumogen Red (BASF) cast in a thin polymer film. Fluorescence and absorption spectra and edge light output measurements are reported in this study. The Lumogen Red LSC outperforms the QD LSC suggesting a lower fluorescence quantum yield for the QDs. QDs are also easily oxidized, whereas the Lumogen Red dye is relatively more stable in the presence of oxygen. The merits of QDs as a fluorescent material for a LSC are discussed in terms of light output, photostability, and cost.

**C1 234 Effects of magnetic and electric fields on the excitonic properties of quantum rings** ZDENKA BARTICEVIC, MONICA PACHECO, *Universidad Santa María* JORGE SIMONIN, CESAR PROETTO, *Centro Atómico Bariloche and Instituto Balseiro,C.P. 8400, San Carlos de Bariloche, Argentina* We have studied the effects of an external electric field on the excitonic and optical spectra of a semiconductor quantum ring threaded by a magnetic flux. We have make a detailed analysis of the ground-state properties of radially polarized excitons and its dependence with magnetic fields applied perpendicular to the ring plane and electric fields parallel to the ring plane. In the absence of the electric field, the total angular momentum of the polarized exciton remains a good quantum number, even in the interacting regime, as a consequence of the Coulomb interaction only depends on the relative coordinate and the azimuthal rotational symmetry of the structured rings. The electric field breaks the azimuthal symmetry and mixes the eigenfunctions with differents angular momentum. For the extended regimen we have found that the electric field destroys the oscillations of the ground-state energy as a function of the magnetic field. The low-lying energy levels are almost independent of the magnetic field up to a region in energy where periodic Aharonov-Bohm-type oscillations appear.

**C1 235 Strong Blue Photoemission from Au/ZnO Nanocomposite Material** AKIRA UEDA, *Fisk University* ESOSA EJOMO, ROBERTO AGA, WARREN COLLINS, RICHARD MU, Several layers of Au (5 nm) and ZnO (20 nm) were alternatively deposited on Si and $SiO_2$ substrates with an electron beam evaporator. With post-annealing of the samples in air, the samples were characterized with XRD, RBS, SEM, AFM, and PL. The samples annealed at higher temperatures ($> 700^oC$) exhibit the growth of ZnO nanocrystals in the system. Along with these observations, the samples annealed at higher temperatures emit strong blue photons due to an electric field.

**C1 236 Faraday rotation in one-dimensional magnetic photonic crystals in electric field** I.L. LYUBCHANSKII, N.N. DADOENKOVA, M.I. LYUBCHANSKII, E.A. SHAPOVALOV, A.E. ZABOLOTIN, *Donetsk Physical and Technical Institute of the National Academy of Sciences of Ukraine, Donetsk, Ukraine* Y.P. LEE, *q-Psi and Department of Physics, Hanyang University, Seoul, Korea* TH. RASING, *IMM, Radboud University Nijmegen, Nijmegen, The Netherlands* In the last few years, magnetic photonic crystals (MPCs) or magnetic photonic bandgap materials, are the objects of intensive investigations because of promising application in photonics [1]. A large enhancement of the Faraday rotation (FR) in one-dimensional (1D) MPC was reported [2,3]. In this report, the influence of external electric field on the FR in 1D MPC with magnetic and non-magnetic defect layers is theoretically studied. For the theoretical description of FR we introduce electrical polarization, which depends on magnetization and external electric field. Numerical calculations of the dependence of FR on the strength and the direction of electric field is done for the 1D MPC based on yttrium-iron garnet. [1] I. L. Lyubchanskii, N. N. Dadoenkova, M. I. Lyubchanskii, and Th. Rasing, J. Phys. D: Appl. Phys. 36, R277 (2003). [2] M. Inoue and T. Fujii, J. Appl. Phys. 81, 5659 (1997). [3] M. Steel, M. Levy, and R. M. Osgood, J. Lightwave Technol. 18, 1298 (2000).

**C1 237 Optical and magneto-optical properties of 1-D dielectric and magnetic photonic crystals.** M.D. HUANG, Y.H. LU, P.J. KIM, S.Y. PARK, Y.P. LEE, *Quantum Photonic Science Research Center and Department of Physics, Hanyang University, Seoul, 133-791 Korea* The optical properties of one-dimensional (1-D) photonic crystals (PCs) and magnetic PCs (MPCs), composed of dielectric $TiO_2$ and $Al_2O_3$ as well as magnetic Bi:YIG layers deposited on a glass substrate, are investigated in this work. The structure of dielectric 1-D PCs was optimized and a narrow omni – photonic bandgap (PBG) is found away from the designed wavelength. When a Bi:YIG layer with an optical thickness of quarter wavelength is inserted, no defect mode is found within the PBG despite the structural defect. However, when the thickness becomes half wavelength, a defect mode can be obtained at the designed wavelength, revealing the localization of light. More magnetic defect layers induce correspondingly more defect modes within the PBG. Large Faraday rotation angles, indicating strong magneto-optical (MO) effects, are obtained at the defect modes in the MPCs. A considerable amount of coupled light, whose polarization is perpendicular to that of incident light, confirms the enhanced MO effects at the defect modes.

**C1 238 Band gap of a 3D dyed polystyrene photonic crystal from optical absorption.** NA YOUNG HA, *University of Pennsylvania* JEONG WEON WU, *Ewha Womans University* Three-dimensional (3D) photonic crystals (PCs), fabricated from colloidal spheres doped with organic dye and whose optical absorption overlaps with the photonic band gap (PBG), have been studied to determine the relation between the PBG widening and the increased contrast in refractive indices. In this work, we report on the identification of the role of the optical absorption of the dye in determining the PBG shape of a 3D dyed PC, which is fabricated from colloidal dyed-polystyrene spheres consisting of an inner core and an outer shell. In analyzing the optical reflection spectra of 3D dyed PCs, an analytical electromagnetic wave scattering theory was rigorously employed, with the dispersive and absorptive optical responses of the composite dyes fully taken into account. It was subsequently found that the characteristic PBG shape of the 3D dyed PC, when measured in the reflection spectra, results from two superimposed contributions with distinct origins, i.e., a Bragg reflection and a high reflection associated with the strong dye absorption.

**C1 239 Faraday effect of 1-D magnetic photonic crystals for normal and parallel incidence to the periodic direction** Y. H. LU, M. D. HUANG, S. Y. PARK, P. J. KIM, Y. P. LEE, *q-Psi and Dept. of Physics, Hanyang Univ., Seoul 133-791, Korea* J. Y. RHEE, *BK21 Physics Research Division and Institute of Basic Science, Sungkyunkwan Univ., Suwon 440-746, Korea* We calculated the Faraday rotation of one-dimensional (1-D) magnetic photonic crystals (MPCs), which are based on the dielectric $Ti_2O_3$ and $Al_2O_3$, and the magnetic Bi:YIG, by employing 4 x 4 transfer-matrix method for the general case that the linearly polarized incident beam is parallel to their periodic direction, as mostly studied for the 1-D MPCs. Furthermore, even for a special case of normal incidence, the calculation of Faraday rotation was also carried out for such discontinuous thin films with a 1-D array structure and the existence of rotation was proved, which had been scarcely studied yet. The magneto-optical Faraday effects obtained for these two cases are compared and discussed in detail.

**C1 240 Modeling and fabrication of photonic bandgap waveguiding structures*** M.Y. TEKESTE, *Physics Department, Miami University, Oxford, OH* P.R. RICE, *Physics Department, Miami University, Oxford, OH* J.M. YARRISON-RICE, *Physics Department, Miami University, Oxford, OH* Novel photonic devices based on the idea of photonic bandgap (PBG) crystals are poised to make contributions in modern optoelectronic and telecommunication applications. These nanophotonic devices have the ability to guide light with very low loss even around tight corners. Several PBG waveguide structures are modeled using using the finite difference time domain technique in EMlab software. The resulting electric field distributions allow us to study single line defect waveguiding and a wavelength demultiplexer structure for single mode propagation, the depth of light leakage into the lattice, and transmission coefficients. These models inform the experimental fabrication process where a 2D triangular lattice is etched into the silicon nitride on silicon dioxide planar wafer which has been patterned via e-beam lithography. SEM micrographs record the various fabrication steps. Optical characterization of the structures will include bulk transmission measurements, as well as near field scanning microscopy.

*We gratefully acknowledge computer support of OAST, Miami University

**C1 241 Fano Resonance in Photonic Crystals and Quantum Mechanics** SOLOMON DUKI, FRANCESC FERRER, H. MATHUR, *Case Western Reserve University* We study the resonant transmission through a photonic crystal channel dope device. The frequency dependence of the resonant transmission is shown to have an asymmetric Fano line shape. In contrast to previous work[1] we find the symmetric Lorentzian line shape results only under special conditions of high device symmetry. We also study quantum systems in which the resonant scattering cross section has an asymmetric Fano line shape as a function of energy. Surprisingly the associated long-lived quasi-bound state under goes simple exponential decay, just as it would in the symmetric Lorentzian case.

**C1 242 Raman Spectroscopy from Optical Trapped Nano Coated Microsphere Complexes** EMANUELA ENE, CHUCK BLACKLEDGE, JAMES WICKSTED, *Oklahoma State University* The Raman measurements from optically trapped gold nanowires and from nanoparticles coated on microspheres, under various visible laser excitation wavelengths, are being studied. Changes in the Raman spectra for the trapped coated microspheres when they were positioned at different distances from an immersed photonic crystal (PC) are being investigated. We are also developing a method which has the potential of detecting certain molecules present in biological environments.

**C1 243 Abstract Withdrawn**

**C1 244 Inelastic cotunneling current and shot noise of an interacting quantum dot with ferromagnetic correlations** BING DONG, *Shanghai Jiaotong University, China* NORMAN J. M. HORING, *Stevens Institute of Technology* V. FESSATIDIS, *Fordham University* We explore inelastic cotunneling through a strongly Coulomb-blockaded quantum dot attached to two ferromagnetic leads in the weak coupling limit using a Langevin equation approach.[1] We first develop a Bloch-type equation to describe the cotunneling-induced spin relaxation dynamics, and then derive explicit analytical expressions for the local magnetization, current,

and its fluctuations. On this basis, we predict a novel zero-bias anomaly of the differential conductance in the absence of a magnetic field for the anti-parallel configuration, and asymmetric peak splitting in a magnetic field, which are ascribed to rapid spin-reversal due to underlying spin-flip cotunneling.[2] [1] B. Dong, N. J. M. Horing, and H. L. Cui, Phys. Rev. B **72**, 165326 (2005). [2] B. Dong, X. L. Lei, and N. J. M. Horing, cond-mat/0509098.

**C1 245 Electron transport properties in InAs ballistic devices** MASATOSHI KOYAMA, MASATAKA INOUE, MASASHI FURUKAWA, HIROSHI TAKAHASHI, TOSHIHIKO MAEMOTO, SHIGEHIKO SASA, *New Materials Research Center, Osaka Institute of Technology* A ballistic rectifier is one of the applications using ballistic electron transport properties, and has been fabricated by using high quality compound semiconductor heterostructures. We have observed a rectification for the first time in InAs triangular anti-dot structures at 77K and room temperature [1]. InAs/AlGaSb heterostructures provide relatively long mean free path for ballistic electron transport because of its high carrier density ($1.0 * 10^{12}$ $cm^{-2}$ at 77K) and high electron mobility (200,000 $cm^2$/Vs at 77K). In the present report, we will focus on nonlinear electron transport properties in InAs asymmetric anti-dot structures as well as ballistic rectification effects at higher temperatures. In addition, the observed magnetotransport properties in the InAs ballistic rectifiers will be also presented at the conference. [1] M. Koyama et al., presented at the $14^{th}$ Int. Conf. on Nonequilibrium Carrier Dynamics in Semiconductors, 2005.

**C1 246 Electrode fabrication and attachment of organometallic molecules for conductivity measurements*** S. RAJAGOPAL, *Physics Department, Miami University, Oxford, OH* N. SMITH,† *Physics Department, Miami University, Oxford, OH* J.M. YARRISON-RICE, *Physics Department, Miami University, Oxford, OH* C. URIG, T. SCOTT, S. ZOU, H. ZHOU, *Department of Chemistry and Biochemistry, Miami University, Oxford, OH* The primary goal of this research is to understand the bonding and electronic structure within this class of compounds and the influence of a gated electric field on their conductivity. We report an approach for connecting a single molecule containing di-metal units to electrodes with nanometer gaps. We have succesfully fabricated pairs of terminal electrodes with intial gaps of $\sim$ 75 nm which we then close using electrodepostion and re-open with electromigration to nanometer gaps. The results of the time resolved voltage curve during the electrodepostion process show that most of electrodes have a very short closing time. We have also fabricated lateral three terminal devices for studying the influence of a gated third electrode. The present results show that a gap to gate distance of less than 50nm is acheivable. Our next step is to deposit molecules on the thin gap, and to measure the electrical conductivity when a single molecule bridges the gap and conducts current.

*We gratefully acknowledge NSF through the NER - award #0403669.

**C1 247 Correlating Internal Chemical and Physical Structure with Electrical Data for Nanoscale Molecular-Electronic Devices** JASON J. BLACKSTOCK, *Quantum Science Research, HP Labs* WILLIAM F. STICKLE, *HP Labs Corvallis* CARRIE L. DONLEY, DUNCAN R. STEWART, R. STANLEY WILLIAMS, *Quantum Science Research, HP Labs* The critical limitation for most nanoscale molecular-electronic devices is the lack of physical/chemical characterization accompanying electrical data. Present most device geometries and fabrication processes are incompatible with conventional photon and electron spectroscopies and scanning probe microscopies – critical layers and interfaces are frequently inaccessibly buried inside the as-built device structures. We present the fabrication of a new stencil-based nanopore device geometry, along with techniques for studying the in-situ characterization of the as-build internal properties of these devices. These methods were developed in combination to allow the cleaving of completed device stacks at internal inorganic/organic interfaces in a UHV environment. This cleaving process exposes the uncontaminated and unaltered internal nanoscale chemical and physical structure in UHV for examination with a range of conventional tools. We specifically present on XPS, IR and STM data from several metal/organic-monolayer/metal device stacks of interest, and conclude by correlating temperature-dependant and IETS electrical data on nanoscale devices with the physical/chemical characterization.

**C1 248 Thermoelectric Properties of a Nanocontact** KEIVAN ESFARJANI, MONA ZEBARJADI, *Department of Physics, Sharif University of Technology, Tehran, Iran* Thermoelectric properties of a nanocontact made of two capped single wall carbon nanotubes (SWCNT) are calculated within the tight-binding approximation and by using Green's function method. It is found that doped semiconducting nanotubes can have high Seebeck coefficients. This in turn leads to very high figures of merit(ZT) for p-doped tubes which turn out to have also a large electrical to thermal conductivity ratio. Transport in the nanocontact device is dominated by quantum interference effects, and thus it can be tuned by doping (charge transfer and/or impurity potential) or application of a (nano-)gate voltage, or a magnetic field. Another reason for high ZT in this device is the absence of phonon transport as there is barely a contact between the two sides.

**C1 249 Microscopic Investigations of Phonon Thermal Conductivity in SiGe Superlattices with Rough Interfaces** SHANGFEN REN, *Illinois State University* WEI CHENG, *Illinois State University and Beijing Normal University* GANG CHEN, *Massachusetts Institute of Technology* Phonon thermal conductivity in semiconductor superlattices (SLs) has attracted a great research attention in recent years due to the potential applications of SLs in thermoelectric devices and other applications [1]. By using a microscopic model developed to investigate phonon properties in semiconductor nanostructures [2], we have calculated thermal conductivities of SiGe SLs with rough interfaces in both the growth and in-plane directions. The results are compared with SLs with perfect smooth interfaces as well as bulk random alloys. Our results show that thermal conductivities of SLs with rough interfaces are much lower than SLs with the same thickness but smooth interfaces in both directions. In the in-plane direction, the thermal conductivities of SLs with rough interfaces are about the same as random alloy but lower than random alloy in the growth direction. Our results indicate that the interface roughness is a true mechanism of thermal conductivity reduction in SLs. References: [1] Partially Coherent Phonon Heat Conduction in Superlattices, B. Yang and G. Chen, Phys. Rev. B 67, 195311 (2003). [2] A Microscopic Investigation of Phonon Modes in SiGe Alloy Nanocrystals, S. F. Ren, W. Cheng, and P. Y. Yu, Phys. Rev. B 69, 235327 (2004).

**C1 250 Semiconductor Nanocomposites for Direct Energy Conversion Applications** JEFF URBAN, *IBM/MSU* DMITRI TALAPIN, ELENA SHEVCHENKO, CHRIS MURRAY, *IBM* MERCOURI KANATZIDIS, *MSU* Novel materials for thermoelectric and photovoltaic applications may be rationally designed by assembling quantum dots with distinct thermal, optical, and electronic characteristics into nanocomposite superlattices and glassy thin films. Here we present the synthesis and initial thermoelectric characterization of semiconductor nanocomposites composed of lead chalcogenide (PbX = PbS, PbSe, PbTe) nanocrystals. Monodisperse nanocrystals of all PbX materials varying in size from $\sim$ 4-10nm are synthesized, and their structural, optical, and electronic properties are presented. Well-ordered nanocomposites composed of two different types of PbX nanocrystals are synthesized and their basic thermoelectric characteristics are studied. The strategy of using nanocrystal composites for thermoelectric applications will, in principle, provide an opportunity to independently tune the desired electronic and phonon scattering characteristics of these materials.

**C1 251 Crossover in Thermal Transport Mechanism in Nanocrystalline Silicon** ARUN BODAPATI, PAWEL KEBLINSKI, *Rensselaer Polytechnic Institute* PATRICK SCHELLING, *University of Central Florida* SIMON PHILLPOT, *University of Florida* Using vibrational mode analysis of model structures we demonstrate that lattice vibrations in small grain ( $<$ 3 nm) structurally inhomogeneous nanocrystalline silicon are almost identical to those of homogeneous amorphous structures. In particular, the majority of the vibrations are delocalized and unpolarized. As a consequence the principal thermal conductivity mechanism in such nanocrystalline materials is essentially the same as in the amorphous material. With increasing grain size the ability of vibrations to ''homogenize'' over the nanocrystalline structure is gradually lost and the phonon spectra and polarization become progressively more like that of a crystalline material; this is reflected in a crossover in the mechanism of thermal transport. Interestingly, a few of the vibrational modes are localized either on the grain boundary and the grain interiors.

**C1 252 Switching Light through Arrays of Sub-wavelength Holes in Vanadium Dioxide*** E. U. DONEV, J. Y. SUH, R. LOPEZ, R. F. HAGLUND, L. C. FELDMAN, *Vanderbilt University, Nashville, Tennessee, USA* Transmission of near- and far-field light through periodic arrays of sub-wavelength holes is a subject of intense interest. We present the first studies on perforated vanadium dioxide ($VO_2$) thin films that can modulate the transmission of near-infrared light by virtue of their semiconductor-to-metal transition. Modulation arises because of the marked difference in dielectric contrast between the holes and the surrounding material in the two phases of $VO_2$. In perforated structures consisting of a silver (or gold) layer atop a $VO_2$ layer, the modulation effect constitutes a novel kind of dynamical control of the enhanced optical transmission through sub-wavelength holes in opaque metal films. Surprisingly, such double-layer structures exhibit a reversal in the optical switching of $VO_2$, as the near-infrared transmission during the metallic phase exceeds its semiconducting-phase counterpart—opposite of the transmission behavior of plain $VO_2$ films. We explain this by accounting for the loss of transmitted intensity due to leaky evanescent waves inside the holes and scattering at the entrance and exit apertures.

**C1 254 Magnetic resonance study of nanoparticles systems** NATALIA NOGINOVA, FENG CHEN, TRACEE HARRIS, *NSU* EMMANUEL GIANNELIS, ATHANASIOS BOURLINOS, *Cornell University* VADIM ATSARKIN, *IRE, Moscow* Magnetic nanoparticles of gamma-$Fe_2O_3$ coated by organic molecules and suspended in liquid and solid matrices, as well as non-diluted magnetic fluid have been studied by ESR in the dependence on temperature and relative concentration. The ESR spectrum demonstrates an interesting double feature shape, with narrow peak at g=2 growing in intensity with increase in temperature. Angular dependence of the ESR signal in field cooled samples unambigously points to the dominating uniaxial magnetic anisotropy of the nanoparticles, suggesting a strong surface effect. The interpretation based on the FMR equations with account made for thermal fluctuations of the magnetic moment is compared with ''paramagnetic'' model suggesting a discrete energy spectrum of the lowest high-spin multiplet. Consideration of the superparamagnetic nanoparticles as intermediate between paramagnetic and ferromagnetic entities allows us to explain most of the obtained experimental results and estimate parameters of the magnetization, particle interactions and magnetization dynamics.

**C1 255 Interface effects in modulation-doped manganite superlattices** MARIA E. GOMEZ, G. CAMPILLO, P. PRIETO, *Excellence Center for Novel Materials. Universidad del Valle, A.A. 25360 Cali, Colombia* A. HOFFMANN, *Argonne National Laboratory, Materials Science Division, Argonne, Illinois 60439* A. BERGER, *Hitachi Global Storage Technologies, San Jose Research Center, San Jose, CA* J. GUIMPEL, N. HABERKORN, A. CONDO, *Centro Atómico de Bariloche Instituto Balseiro 8400 Bariloche, Argentina* Epitaxial superlattices of antiferromagnetic $La_{1/3}Ca_{2/3}MnO_3$ and ferromagnetic $La_{2/3}Ca_{1/3}MnO_3$ were grown using a high-pressure sputtering technique. Structural analysis was performed by simulation of X-ray diffraction data using the SUPREX program and Transmission Electron Microscopy. Both techniques confirmed interfacial roughness in the range of one unit cell. Magnetization measurements showed that magnetization

depth profile is incommensurate with the doping profile, such that the ferromagnetic order extends into the antiferromagnetically doped region beyond the chemical doping interface. Thermal demagnetization in the low temperature range obtained from the temperature dependence of the saturation magnetization shows an $\alpha=5/2$ power law dependence, independent of the ferromagnetic layer thickness. The $T^{5/2}$term is associated with long-wave length spin waves, and corresponds to the anharmonic second-order expansion of the magnetization. This work was supported by COLCIENCIAS contract 043-2005, and U.S. DOE-BES under contract W-31-109-ENG-38.

**C1 256 Isolated hollow nano-spheres of Co on the surface** TOSHIFUMI TERUI, TAKASHI NAGASE, HIROYUKI HASEGAWA, SHINRO MASHIKO, *National Institute of Information and Communications Technology* YASUHARU KODUKA, YE QUAN-LIN, HIROFUMI YOSHIKAWA, MOTOTAKA ONISHI, KUNIO AWAGA, *Department of Chemistry, Nagoya University* In magnetic materials of sub-micron and the nano-meter size, peculiar magnetic structures and characteristics are expected. The hollow sphere of Co is an interesting material in such nano magnetic materials because of the unique structure. The diameter and the thickness of shell of the hollow sphere of Co can be accurately controlled between 100-500nm and 40nm respectively. It is necessary to examine the physical properties about isolated hollow sphere of Co to apply this material as nano-spin material. Therefore, we combined the top down and the bottom up technique to isolate the sample on the surface. For example, the nanogap electrode and patterns were fabricated by EB lithography and FIB, and manipulation and the conduction measurement were performed by SEM with probe.

## C1 257 INSTRUMENTATION AND MEASUREMENTS POSTER SESSION

**C1 258 Low-Cost Cavity Ring-Down System For Measurement Of High Reflectivity Semiconductor Mirrors** DANIEL TREMBLAY, SUSAN LEHMAN, *The College of Wooster* A cavity ring-down system consisting of a half-symmetric optical resonator with a swept cavity design has been constructed from off-the-shelf components in order to investigate ultra-high reflectivity distributed Bragg reflectors (DBRs). Cavity ring-down is a sensitive technique often used for spectroscopy that measures the buildup and decay of laser light within a high finesse optical cavity. Once light is resonant in the cavity, the resonance is interrupted so that the light within the cavity decays. From this measured decay time, the amount of light lost per pass to mirror losses or absorptive and scattering losses is determined. As a measurement of time rather than absolute intensity, cavity ring-down has the advantage of not requiring calibration since it is unaffected by drifts in laser intensity or detector sensitivity. This low-cost ring-down system was designed with one planar mirror and one concave mirror to allow simple conversion to DBR measurement. The concave mirror is mounted on a piezoelectric modulator to enable rapid sweeping of the cavity length, eliminating the need for an acousto-optic modulator to shutter the light off, but increasing the analysis complexity due to Doppler shifting of the light by the moving mirror. A cw-laser tunable over 30 nm is used to probe the cavity and DBR system.

**C1 259 Potentiometric Sensing of the Organic Molecules*** YANTIAN WANG, *State University of New York at Stony Brook* VIJAY JAIN, *Herricks High School* HARRIMAN LEE, *The Wheatley School* KALLE LEVON, *Polytechnic University* MIRIAM RAFAILOVICH, JONATHAN SOKOLOV, *State University of New York at Stony Brook* A prototype detector was constructed for the detection of complex biomolecules, such as viruses and complete chromosomes. The technology is based on Ref. [1], where the technique was demonstrated for small molecules. A monolayer of 11-mercapto-1-undocanol (thiol) is coabsorbed with the organic molecules on a gold plated electrode. The thiolated molecules self assemble into a highly organized crystalline film chemically anchored to the surface. The biomolecules which are not attached and can then be removed by washing in water, leaving behind templated regions, or cavities in the monolayer with specific size and shape. The electrochemical response between the modified electrode and the Ag/AgCl reference electrode was measured by the potentiometer. When the electrode was exposed to the solution containing the template molecules, in a concentration as low as $10^{-6}M$, a sharp potential response was observed, while very slight response was observed when exposed to other kind of molecules. This was attributed to the selective absorption of the molecules onto the electrode. Reference: [1]. Zhou Y., Yu B., Shiu E., Levon K., itAnal. Chem. 2004, 76, 2689.

*Supported by the NYS Center for Maritime and Port Security

**C1 260 Magnetic Domain Wall Motion as a Basis for a New Type of Sensor.** SEONG-JAE LEE, YEVGEN MELIKHOV, *Center for NDE, Iowa State University, Ames, Iowa 50011, USA* CHOON-MAHN PARK, *Dept. of Physics, Seonam University,Namwon 590-711, Korea* HANS HAUSER, *Institute of Sesnor and Actuator Systems, Vienna Univ. of Technology, A-1040 Vienna, Austria* DAVID JILES, *Wolfson Centre for Magnetics, Cardiff University, Cardiff CF24 3AA, United Kingdom* It has been found that the periodic motion of a magnetic domain wall under the action of a magnetic field can be used as a basis for linear and angular displacement sensor. The domain wall between two opposite domains is created by the field from two opposite permanent magnets and the periodic motion is excited by an external ac current. When the up-domain covers both the incident and reflected laser beam paths, the Faraday rotation reaches a positive maximum and when the down-domain covers both beams, the Faraday rotation reaches a negative maximum. If when the domain wall is between the incident and reflected laser beams, the Faraday rotation cancels and a reference or nominal ''zero'' rotation occurs. The sensor system consists of a laser, magneto-optic film, magnets, and a detector. By observation of the pattern of detected light intensity as a result of periodic movements of magnetic domain wall, we can extract information about linear or angular displacement a surface with resolution down to 3 $\mu$m or 0.01 deg, respectively.

**C1 261 The challenge of characterizing an inefficient antenna field for health protection purposes** MARJORIE LUNDQUIST, *The Bioelectromagnetic Hygiene Institute* Growing evidence that the electromagnetic field around electrical wires is harmful to human health prompted a 1990s National Academy of Sciences study of power-frequency (50-60 Hz) fields; results for power-frequency fields were negative but data suggested that fields from *transients* may be hazardous.[1] Transients represent high frequencies that can reach into the radiofrequency (RF) range. What in-

strument can be used to measure an RF field around electric wires carrying RF current? Such an RF field is that of an *inefficient antenna*, which lacks the pure far-field region characteristic of an *efficient antenna field* for which standard RF measuring instruments are calibrated, making it impossible to obtain a properly calibrated measurement with such instruments. The *magnetic induction current* d**B**/d*t* is explored as an alternative way to characterize the *inefficient antenna RF field* sheathing electric wires carrying RF due to *poor power quality* ( *e.g.*, switching transients) or to utility use of *power line carrier* [2] or of FCC-approved *broadband on power lines*. [1]National Research Council, **Possible Health Effects of Exposure to Residential Electric and Magnetic Fields**, Washington, DC: National Academy Press, 1997. [2]M. Vignati & L. Giuliani, Environ. Health Perspect. **105** (Suppl 6):1565-1568(1997).

**C1 262 Current Status of LANSCE Single Crystal Diffractometer - SCD** ALICE I. ACATRINEI, LUKE L. DAEMEN, MONIKA A. HARTL, *Los Alamos National Laboratory, LANSCE-12, MS H805, Los Alamos, NM 87545* JACOB URQUIDI,* *New Mexico State University, Department of Physics, MSC 3D, Las Cruces, NM 88003* The Single Crystal Diffractometer (SCD) at LANSCE, Los Alamos National Laboratory, represents a powerful tool for many crystallographic and magnetic structure determinations. The instrument is located at the Lujan Neutron Scattering Center and utilizes the time-of-flight (TOF) Laue technique for neutron scattering data collection. This technique, combined with a 25 cm × 25 cm multi-wire 3He position-sensitive detector and the possibility of two axis of rotation for sample orientation yield to an 80% sphere of coverage in reciprocal space. The redesign and status of the Single Crystal Diffractometer at LANSCE are reported. We give an overview of the instrument characteristics and of the of calibration and data evaluation activities (higher intensity, lower background, better profile shape, improved resolution).

*Los Alamos National Laboratory, LANSCE-12, MS H805, Los Alamos, NM 87545

**C1 263 Effects of asphericity in charge distribution on electron scattering amplitude.*** JIN-CHENG ZHENG, LIJUN WU, YIMEI ZHU, *Brookhaven National Laboratory, Upton, NY 11973* The sensitivity of atomic scattering factors to valence-charge distributions has been compared quantitatively for x-ray and electron diffraction. It is found that electron diffraction provides information about valence charge densities via the low-order structure factors, which are relatively insensitive to thermal vibrations, but sensitive to the charge distribution that characterizes the chemical bonding properties in materials. The effects of asphericity in charge distribution on electron scattering amplitude have been examined using both analytical and numerical methods. We show that the aspheric effects are dominated in low-order scattering region, where the electron scattering factor of Bragg reflections can be measured very precisely by quantitative electron diffraction, and therefore enables us to quantitatively determine the spherical and aspherical orbital ordering. The applications of quantitative electron diffraction in strongly correlated materials are discussed.

*This work was supported by DOE under Contract No. DE-AC02-98CH10886

**C1 264 Analytical form for the tip-sample interaction in liquid for Atomic Force Microscopy** FREDY ZYPMAN, *Yeshiva University* Knowledge of the functional form of force-separation curves in Atomic Force Microscopy (AFM) is necessary to develop reconstruction algorithms to predict the morphology and chemical activity of the sample under study. In vacuum, the tip and the sample can be modeled as a collection of atoms. The tip-sample force can thus be evaluated from the appropriate atom-atom forces. These elemental forces have been modeled via Morse, 6-12 pair potentials, and more detailed quantum approaches with non pair-wise forces. Nevertheless, a large section of the AFM community is interested in tip-sample interactions in the presence of fluids. The production of theoretical expressions for colloidal interactions relevant to AFM has been hampered by the fact that analytical solutions to the Poisson-Boltzmann equation (PBE) are restricted, thus far, to planar geometries. Numerical solutions for other geometries do exist, but they are computationally expensive. We present a simple theoretical expression for the interaction forces between the Atomic Force Microscope tip, and a sample immersed in an electrolytic solution. Our result is based on the Surface Element Integration of the Dejarguin-Landau-Verwey-Overbeek interaction between flat surfaces. We apply our results to the Van der Walls and to the electrostatic double layer cases. Finally, we use our expression to show how it simplifies the analysis of extant experimental data. Acknowledgment. Work supported by Research Corporation through grant CC5786.

**C1 265 3D ESR-MRI with A Sub-Micrometer Resolution Using Magnetic Resonance Force Microscopy** SHIGENORI TSUJI, YOHSUKE YOSHINARI, *JEOL Ltd. and CREST-JST, Japan* KOSUKE INOMATA, *Kyoto Univ. and CREST-JST, Japan* We will present our progress of ESR Magnetic Resonance Force Microscopy (MRFM). In order to improve our previously achieved resolution (2∼ 3 micrometer), we used an electropolished magnetic tip made of a sintered Nd2Fe14B permanent magnet, which generated a larger magnetic field gradient (8000 T/m) in the very vicinity of the magnetic tip. To avoid a collision between a sample glued on a cantilever and the magnetic tip placed on a 3D stage, the tip-sample direction was set parallel to the cantilever long axis. Magnetic resonance force signals were induced by a cyclic saturation technique. In this setup, the observed signals had an anti-symmetrical phase with respect to a plane that contains a specimen and is perpendicular to the vibrational direction of the cantilever. MRFM image was then reconstructed from the force map through FT deconvolution. At present, our MRFM can produce 3D ESR-MRI with a sub-micrometer spatial resolution.

**C1 266 Optical properties of the tips for apertureless near-field microscopy*** DISHA MEHTANI, N. LEE, R. D. HARTSCHUH, A. KISLIUK, M. D. FOSTER, A. P. SOKOLOV, I. TSUKERMAN, *The University of Akron* Apertureless near-field optical microscopy is based on the enhanced optical signal in the vicinity of a metal or metal-coated tip via surface plasmon generation in the metal. Resonant excitation of the plasmons is crucial for maximizing enhancement under the tip. However, it remains a challenge to measure the optical properties of the nanoscale apex of a tip with a radius much smaller than the wavelength of light. We have developed a system to measure optical properties of tips based on the principle of total internal reflection microscopy. Optical resonance spectra of silver- and gold-coated tungsten and silicon nitride tips exhibit a dependence on the metal deposited. We also measured the wavelength dependence of tip-enhanced

Raman signal. The enhancement of the Raman signal for silicon with gold-coated silicon nitride tips was found to be ~ 3 times stronger for a wavelength of 647 nm than for 514.5 nm. The former is closer to the plasmon resonance observed for this tip at ~ 680 nm. Additional examples correlating enhancement with resonance excitation will be presented.

*This research was supported by an NSF-MRI grant (DMR-0215966) and Air Force Research Laboratory

**C1 267 High contrast nano-Raman spectroscopy with optimized polarization** NAM-HEUI LEE, RYAN HARTSCHUH, DISHA MEHTANI, ALEXANDER KISLIUK, MARK FOSTER, ALEXEI SOKOLOV, *Department of Polymer Science, The University of Akron, Akron, OH 44325, USA* JOHN MAGUIRE, *Materials and Manufacturing Directorate/MLBP, Wright-Patterson AFB, OH 45433, USA* For nanoscale characterization of chemical composition, structure, stresses and conformational states, tip-enhanced Raman spectroscopy (TERS) is an attractive tool. A TERS spectrometer based on side illumination geometry that shows reproducible enhancement of the order of $10^3$-$10^4$, for a variety of molecular, polymeric and semi-conducting materials using silver- and gold-coated silicon nitride tips, will be presented. The radius of the spot from which the Raman signal comes is estimated to be 20nm for CdS thin films. For thick samples, such as a silicon wafer, polarization was optimized to achieve high contrast between the near- and far-field Raman signals. Additionally, systematic studies to estimate the localization volume of the detected near-field Raman signal with the optimized polarization are being performed. Raman imaging with sub-wavelength lateral resolution will be demonstrated on several nano-structures.

**C1 268 UHV LT-STM system with Sample and Tip Exchange** MICHAEL DREYER, *Lab for Physical Sciences, Dept. of Electrical and Computer Engineering, University of Maryland* JONGHEE LEE, HUI WANG, DAN SULLIVAN, *Lab for Physical Sciences, Dept. of Physics, University of Maryland* BARRY BARKER, *Lab for Physical Sciences, National Security Agency* We developed and built a low temperature scanning tunneling microscope system with ultra high vacuum sample and tip preparation capabilities. The STM is mounted inside an UHV can which is submerged in a He bath cryostat. The cryostat is equipped with two superconducting magnets allowing a maximum in plane field of 2 T and a maximum out of plane field of 9 T. The two fields can be combined to a 1 T vector field. The vacuum can is connected to an UHV system at room temperature consisting of two chambers: One dedicated to transferring samples and tips to the STM, and the other chamber used for tip/sample preparation. It is equipped with two electron beam evaporators, an argon ion sputter gun as well as sample heaters. The whole system is supported by an optical table to decouple the STM from building vibrations. The system was successfully used to study standing electron waves on gold (111) as well as vortices on NbSe2. Details of the microscope, sample and tip handling system, as well as the UHV system will be presented.

**C1 269 Modification of Tips for Use With Tip-Enhanced Raman Spectroscopy (TERS)** SCOTT HAMILTON, NAM-HEUI LEE, DISHA MEHTANI, RYAN HARTSCHUH, ALEXEI SOKOLOV, MARK FOSTER, *Maurice Morton Institute of Polymer Science, University of Akron* In tip-enhanced Raman spectroscopy (TERS) the Raman signal is enhanced only in the vicinity of a probe tip that can be positioned near the surface of a sample. TERS tips were made by vapor-depositing gold onto AFM tips. These tips create plasmon resonances in the focal spot of the incident laser beam. Variation in the enhancement provided by the tips with the morphology of the metal surface was studied. Enhancement was found to be a function of film thickness and roughness. Deposition of metal nanoparticles on the tip surface was also studied as an alternative method of modification. Optical properties of various nanoparticles are being determined experimentally, allowing comparison with theoretical calculations.

**C1 270 Digitally Controlled Quad Sine Wave Generator.** MOHAMMED Z. TAHAR, *SUNY College at Brockport* Square, triangular, and sine and cosine waves of same frequency are generated with single digital command, using off the shelf components. This method does not synthesize the waves using the continuous digital control of the out put(s), as for arbitrary wave functions. The frequency ranges from below one to thousands of Hz, with the use of one capacitor. Also, the method lends itself to the use of embedded microcontrollers for frequency and independent amplitude control through the use of multiplying digital to analog converters. Because of the omnipresence of microcontrollers, the method is an inexpensive computer controlled frequency quad sine wave generation. With the addition of an analog-to-digital converter, one can use such a generator for systems studies in control and measurements.

## SESSION D1: FLUCTUATION AND RELAXATION NEAR JAMMING
**Monday Afternoon, 13 March 2006; Ballroom IV, Baltimore Convention Center at 14:30**
**Sharon Glotzer, University of Michigan, presiding**

**14:30**
**D1 1 Dynamic model of super-Arrhenius relaxation rates in glassy materials.***
J. S. LANGER, *University of California, Santa Barbara*

The principal theme of this talk is that anomalously slow, super- Arrhenius relaxation processes in glassy materials may be activated by chains of atomic displacements. The entropy of critically long excitation chains can enable them to grow without bound, thus stabilizing thermal fluctuations in the local density or atomic coordination of the material. I argue that the intrinsic atomic-scale disorder in a glass plays an essential role in determining the activation rate for such chains, and show that the resulting rate formula is essentially the same as the Vogel-Fulcher law. A key feature of this theory is that

the spatial extent of critically long excitation chains diverges at the Vogel-Fulcher temperature. I speculate that this diverging length scale implies that ergodicity is partially broken in the super-Arrhenius region above that temperature, and point out how this partially broken ergodicity may explain the vanishing entropy at that point and other observed relations between dynamics and thermodynamics of the glass transition.

*Research supported by U.S. Department of Energy Grant No. DE-FG03-99ER45762.

**15:06**
**D1 2 Experimental studies of jamming in colloids, grains and emulsions.**
HERNAN MAKSE

We review experimental progress towards the development of a statistical mechanics description of jamming in colloids, granular matter and emulsions. The approach is to consider the application of equilibrium concepts such as temperature, entropy and thermalization to this variety of jammed systems. We first present a study of the correlation and response functions to external fields in an aging colloidal glass. Our analysis reveals that even though the system is aging far from equilibrium, it behaves as if it were equilibrated at a constant temperature, independent of its age. This temperature is larger than the bath, and can be rationalized by the cage dynamics of the system and also in terms of theoretical descriptions of mean field models of spin-glasses. A scaling theory is shown to describe the global and local fluctuations of the observables. We then investigate the effective temperature of jammed granular matter. The measurement of the effective temperature is realized in the laboratory by slowly shearing a closely-packed ensemble of spherical beads confined by an external pressure in a Couette geometry. All the probe particles, independent of their characteristic features and the shear rate, equilibrate at the same temperature, given by the packing density of the system. This suggests that the temperature reveals the ''thermalization'' of the jammed system. Finally, jammed emulsions are investigated under the confocal microscope. Owing to a new technique to identify the contact network in a 3D assembly of droplets, we reveal new signatures of jamming from micromechanics to statistical mechanics.

**15:42**
**D1 3 Onset of jamming for gas-fluidized grains.***
ADAM ABATE, *University of Pennsylvania, Department of Physics*

Upon approach to jamming, whether for molecular liquids or colloidal particles or grains of sand, the microscopic dynamics can develop dramatic long-ranged correlations while the microscopic structure remains relatively unchanged. Experimentally, it has been difficult to study such phenomena in full detail due to the range of temporal and spatial scales involved. Here we introduce a new model system that is both easier to image and to manipulate at the microscale: a bidisperse system of steel beads rolling stochastically due to a nearly-levitating upflow of air. At fixed air flow, we demonstrate that this system exhibits all the hallmarks of a jamming transition as spheres are added and the area fraction increases toward close-packing. In terms of structure, the pair correlation function and the Voronoi cell shape distribution functions exhibit peak splitting. In terms of dynamics, the mean-squared displacement develops a plateau separating the short-time ballistic from the long-time diffusive motions; in this plateau the displacement distribution is non-Gaussian, due to spatial heterogeneities. While this phenomenology is familiar, one feature observed previously only in simulation is the presence of string-like swirls of rearranging grains. We highlight these by movies of an appropriately time-averaged velocity field. We hope to connect such dynamics both to a microscopic measure of effective temperature and to the macroscopic viscosity of the system.

*This work was done in collaboration with D.J. Durian.

**16:18**
**D1 4 Force heterogeneity and stress propagation inside 3D granular materials.**
LEONARDO SILBERT

The effect of increasing structural disorder on the (re)distribution of contact stresses inside three dimensional particle assemblies is systematically studied using computer simulations of granular packings. Starting from a face-centred cubic array, where all contact forces are identical, particles are removed at random and the system is then allowed to relax into a new mechanically stable state. Various measures are used to quantify the amount of disorder, including distributions of the coordination number, three-particle contact angle, and normal contact forces. Upon applying a localised, perturbative force within the central region of the packings, the resulting stress response is mapped inside the different particle assemblies, covering several orders of magnitude in the particle friction coefficient. There is a clear change in the propagative response between frictionless and highly-frictional packings, with an intermediate, crossover regime for packings with lower values of the friction coefficient.

**16:54**
**D1 5 Transitions from jammed to flowing granular matter.***
WOLFGANG LOSERT, *University of Maryland*

In static and slowly flowing granular materials forces are transmitted through a network of direct particle contacts. We experimentally examine how the contact networks fails and rearranges as granular matter starts to flow. Through surface measurements and 3D imaging of particle motion and forces we deduce how a granular contact network breaks and re-forms under shear forcing and point forcing. At small forcing, in the jammed state, we observe that low probability ''jumps,'' in which a grain moves significantly more relative to the others, play a significant role in the relaxation of the jammed state [1]. Under larger local forcing, the jammed state fails and grains rearrange locally. The characteristics of this rearrangement sensitively depend on the number density of particles and direction of forces that had been applied to jam the material (history dependence). If the direction of principal stress is changed (e.g. by changing the shear stress direction), the contact network breaks everywhere. The material is transiently weaker, more compact, and exhibits linear strain until a new contact network forms cooperatively[2]. [1] WL and M. Toiya with P. Ribiere, P. Richard, R. Delannay and D. Bideau to appear in Phys Rev. Lett. (2005). [2] M. Toiya, J. Stambaugh, and WL, Phys Rev Lett. 83, 088001-1 (2004).

**SESSION D2: QUANTUM HALL EFFECT IN GRAPHENE**
**Monday Afternoon, 13 March 2006; Ballroom III, Baltimore Convention Center at 14:30**
**Gene Mele, University of Pennsylvania, presiding**

**14:30**
**D2 1 Experimental Observation of Quantum Hall Effect and Berry's Phase in Graphene.**
PHILIP KIM, *Department of Physics, Columbia University*

When electrons are confined in two-dimensional (2D) materials, quantum mechanically enhanced transport phenomena, as exemplified by the quantum Hall effects (QHE), can be observed. Graphene, an isolated single atomic layer of graphite, is an ideal realization of such a 2D system. Its behavior is, however, expected to differ dramatically from the well-studied case of quantum wells in conventional semiconductor interfaces. This difference arises from the unique electronic properties of graphene, which exhibits electron-hole degeneracy and vanishing carrier mass near the point of charge neutrality. In this talk I will present an experimental investigation of magneto transport in a high mobility single layer of graphene. Adjusting the chemical potential using the electric field effect, we discovered an unusual half integer QHE for both electron and hole carriers in graphene, which originates from the quantum mechanical phase associated with the topologically unique graphene Fermi surface. The existence of a non-zero Berry's phase in magneto-oscillations will be discussed in the connection to Dirac Fermion description in graphitic systems. In addition, I will discuss our recent results in transport measurement in strong quantum limit and spin transport in graphene samples.

**15:06**
**D2 2 QED in Graphene.***
ANDRE GEIM, *University of Manchester*

Electronic properties of materials are commonly described by quasiparticles that behave as non-relativistic electrons with a finite mass and obey the Schrödinger equation. I will describe our experimental studies of graphene (a free-standing single layer of carbon atoms) in which electron transport is essentially governed by Dirac's (relativistic) equation and charge carriers mimic relativistic particles with zero rest mass and an effective ''speed of light'' of $\approx 10^6$m/s. We have found a variety of unusual quantum phenomena characteristic of two-dimensional Dirac fermions. In particular, we have observed that a) the integer quantum Hall effect in graphene is anomalous in that it occurs at half-integer filling factors; b) graphene's conductivity never falls below a minimum value corresponding to the conductance quantum, even when carrier concentrations tend to zero; c) the cyclotron mass of massless carriers in graphene is described by Einstein's equation $E=mc^2$; and d) Shubnikov-de Haas oscillations in graphene exhibit a phase shift of $\pi$ due to Berry's phase. I will also explain another, third type of the integer quantum Hall effect that happens in bilayer graphene and accompanied by Berry's phase of $2\pi$.

*In collaboration with K. Novoselov.

**15:42**
**D2 3 Dirac fermions as a cause of unusual Quantum Hall Effect in Graphene.***
SERGEI SHARAPOV, *McMaster University*

The graphite films with a single atomic layer of carbon (graphene) have the low-energy ''relativistic-like'' quasiparticle excitations which can be described by two-dimensional Dirac equation. It is demonstrated that due to the Dirac-like character of carriers the quantization of the Hall conductivity is unusual: it occurs at half-integer filling factors. In addition, the phases and amplitudes of the de Haas - van Alphen and Shubnikov de Haas quantum magnetic oscillations in graphene differ drastically from the patterns observed in a more conventional materials with a parabolic dispersion.

*In collaboration with V.P. Gusynin.

**16:18**
**D2 4 Electronic coherence and confinement in patterned epitaxial graphene.**
WALT DE HEER, *Georgia Institute of Technology*

I will present very recent results from our studies of ultrathin graphite films that are epitaxially grown on single crystal silicon carbide. The quasi-two dimensional films consisting of a few to a few dozen graphene layers are patterned ($\geqslant 0.1\mu$m) using standard e-beam lithography methods. Relatively high mobilities ($\mu$ up to 10,000 $cm^2$/Vs) are deduced from transport measurements. Patterned structures reveal a variety of mesoscopic effects (i.e. universal conductance fluctuations and anomalous Shubnikov de Haas oscillations) from which coherence lengths of the order, or greater than $1\mu$m at cryogenic temperatures are deduced. Evidence for size dependent resistivities even at room temperature is observed. Changes the magnetoresistive properties at about 2K provide evidence for an unusual, first order phase transition. The properties of this new patternable quasi-2D material are promising for sub-micron electronics applications.

## SESSION D3: SCIENTISTS FROM DEVELOPING COUNTRIES: IS THERE AN EFFECTIVE WAY TO SUPPORT MEANINGFUL RESEARCH?

**Monday Afternoon, 13 March 2006; Ballroom I, Baltimore Convention Center at 14:30**
**Katepalli Sreenivasan, The Abdus Salam International Centre for Theoretical Physics, presiding**

**14:30**
TIMOLEON CREPIN KOFANE, *University of Yaounde*

**15:06**
**D3 2 Scientists in Developing Countries: Is there an effective way to support meaningful research?**
ZOHRA BEN LAKDAR, *Faculty of Sciences, Tunis, Tunisia*

Nations in the developing countries are in front of barriers for progress, but without progress how can they exist and take place in the society of 21 eme century, knowledge society or new technology society? Research in science suppose competivness in a specific area of science and at the same time exchange of ideas between researchers. Researchers shoud be good scientists, be in a scientific environment, have financial support and have possibility to direct their research. Competivness has never been as hard as in knowledge society! About 90% of human knowledge is produced during the last 50 years! African countries get independance in 1950-60.! At their independance they are in mean age and yet in the civilization of new technology! They never know industrial revolution. Thanks to pioneers scientits, in some developing countries, who begin from nothing, found solutions to built laboratories and conduct research activities.These solutions among which are principally -cooperation with laboratories from developed countries—regular training of researchers and —good vision for choice of research subjet- offer an example of an effective way to support meaningful research.

**D3 4 Physics at Universities in Congo and Central Africa: Problems, Needs, hopes and solutions.**
BERNARD M'PASSI-MABIALA, *Université Marien NGouabi (Brazzaville)*

We present Teaching and Research Activities in Science, and that of Physics in particular, at Universities in Congo and in Central Africa. Although the number of Physics Students is increasing and that the Progress in Physics in a reality today also in some developing countries, problems that could promote this science remain in this geographic area of the world and are listed. Needs and hopes have to be exposed and Solutions are proposed to the international scientific community.

## SESSION D4: ORGANIC ELECTRONICS
**Monday Afternoon, 13 March 2006; 308, Baltimore Convention Center at 14:30**
**Chang Yeol Ryu, Rensselaer Polytechnic Institute, presiding**

**14:30**
**D4 1 Excited states at polymer semiconductor heterojunctions.**
RICHARD FRIEND, *University of Cambridge*

Excitons in bulk organic semiconductors are generally strongly bound due to the weakly-screened electrostatic electron-hole interaction, but can be de-stabilized at heterojunctions between semiconductors with substantial band-edge offsets. The charge-transfer states that then forms at the heterojunction (exciplexes) can still show radiative emission (with strongly increased radiative lifetimes and large red-shifts), and still require an external field to enable long-range charge separation as required in a photovoltaic diode. The effect of DC field on this process of charge separation, will be discussed, as measured by the suppression of exciplex luminescence and photocurrent. The strength of interchain interactions can be increased under pressure, and measurements of absorption and time-resolved luminescence under hydrostatic pressure will be reported. These reveal the changing character of the exciplex at the heterojunction.

**15:06**
**D4 2 Defects and Deformation in Organic Molecular Semiconductors.***
DAVID MARTIN,† *The University of Michigan*

We have been investigating microstructural defects in crystalline organic molecular semiconductors such as pentacene and soluble pentacene derivatives. We have examined the structure of grain boundaries, dislocations, and vacancies in these materials by polarized optical microscopy, X-ray diffraction, transmission electron microscopy, electron diffraction, low voltage electron microscopy, and low dose high resolution electron microscopy. We have quantified the nature and extent of local relaxations that occur near these structural defects. We have also studied the micromechanisms of plasticity using nanoindentation and scratching. Our microstructural studies provide detailed information about the defect-mediated mechanisms of plastic flow. We have also examined pentacene derivatives that can be processed from solution, and have found information about solid-state phase transformations that result in internal cracking within the organic semiconductor crystals. We have also examined the relationship between the type and density of these defects and the macroscopic properties in devices such as thin-film transistors.

**15:42**
**D4 3 Solution-Processable Organic Semiconductors and Conductors: Viable Materials for Functional Thin-Film Transistors.***
YUEH-LIN LOO, *University of Texas at Austin*

Large-area displays based on organic materials promise low-cost fabrication, lightweight construction, mechanical flexibility and durability. To truly realize the low-cost aspects of organic electronics, however, conventional high-vacuum deposition technologies will have to be replaced by solution processing methodologies. This need has in turn driven the development of solution-processable organic semiconductors and conductors. We have focused on fabricating thin-film transistors with triethynylsilyl antradithiophene (TES ADT), a solution-processable p-type organic semiconductor. Subjecting the as-cast thin films of TES ADT to short solvent vapor annealing dramatically increases the device characteristics: we observe three orders of magnitude increase in carrier mobility and current on/off ratio, and a decrease in current hysteresis and threshold voltage. The improvement in the electrical characteristics can be directly correlated with

morphological transformations during solvent vapor annealing. Our efforts in solution-processable organic conductors focus on water-dispersible polyaniline (PANI). We have fabricated bottom-contact thin-film transistors with PANI electrodes, which function as effectively as gold electrodes, when on-characteristics are concerned. Examination of the linear source-drain voltage regime suggests that PANI devices exhibit markedly less contact resistance than gold devices.

*In collaboration with Kimberly Dickey, Kwangseok Lee, Joungeun Yoo, University of Texas at Austin; and John Anthony, University of Kentucky.

**16:18**
**D4 4 Structural Effects on the Performance of Polymeric Thin Film Transistors.**
MICHAEL CHABINYC, *PARC*

Semiconducting polymers are currently being researched for use in thin-film transistors (TFTs) in large-area electronic devices such as displays. Most high performance semiconducting polymers form semicrystalline thin films, but the details of the connection between their structure and the field-effect mobility of charge carriers in these materials in TFTs are poorly understood. We have used a variety of techniques to reveal the connection between the microstructure of semiconducting polymers and their electrical performance. We have used synchrotron x-ray scattering to determine the molecular ordering in thin films of several high-performance poly(thiophene)-based semiconducting polymers including poly[5,5'-bis(3-dodecyl-2-thienyl)-2,2'-bithiophene], known as PQT-12, and poly(2,5-bis(3-alkylthiophen-2-yl)thieno[3,2-*b*]thiophene). These materials show evidence of thermotropic liquid crystalline phases that can be used to improve the ordering in the films. We have used a delamination technique to transfer these films between substrates without substantially perturbing their structure to help disaggregate the contributions of film structure and of interfacial structure to device characteristics. Using films of constant morphology, we have found that chemically modified dielectrics can have a strong influence on the threshold voltage of TFTs, but have little impact on mobility. These results suggest that the field-effect mobility is mainly controlled by the structure of the first few molecular layers of the semiconducting films at the interface with the gate dielectric.

**16:54**
**D4 5 NEXAFS measurements of the development of interfacial order in organic semiconductor thin films.**
ERIC K. LIN, *National Institute of Standards and Technology*

Interest in organic semiconductors has increased because of their potential use in new electronics applications such as radio frequency identification tags, biosensors, or photovoltaics. The development of solution processable organic semiconductors has made it possible to take advantage of low-cost processing methods such as spin coating, dip coating, or ink-jet printing onto flexible substrates. However, the performance of these materials in devices is difficult to control and new processing methods can deliver unexpected results. These deviations are often due to variability in film microstructure that leads to variability in carrier transport properties. The microstructure is sensitive to processing variables because they influence the dynamic assembly process of the material as it dries from a solution to a solid thin film that is crystalline or semicrystalline. To quantify structural changes, we employ synchrotron-based near-edge X-ray absorption fine structure (NEXAFS) spectroscopy, which measures the soft X-ray excitation of 1s electrons to unfilled molecular orbitals. For a polymer semiconductor, regioregular poly(3-hexylthiophene) (P3HT), we show that variations in the spin-coating process may be a source of differences in the P3HT microstructure because of changes in complex balance of inertial forces and solvent evaporation during the solidification of the film from solution. The morphology of semicrystalline polymers such as P3HT is affected by the rate of solidification; slower solvent removal rates result in materials closer to their equilibrium structure. For thermally convertible, oligomeric organic semiconductors, we show that the formation of interfacial order of the molecules is affected by the oligomer length.

## SESSION D5: CATALYSIS AND COMPLEXITY: KEN HASS MEMORIAL
**Monday Afternoon, 13 March 2006; 309, Baltimore Convention Center at 14:30**
**Willes Weber, APS, presiding**

**14:30**
**D5 1 Environmental Catalysis from First Principles.**
WILLIAM SCHNEIDER, *University of Notre Dame*

Innovation in environmental catalysis—catalysis related to sustainable production and consumption of energy and materials—is one of the most pressing societal needs of the day. Fuel cells, fuel reforming, hydrogen generation, emissions control, and many other processes all rely on effective catalysts to facilitate the transformation of chemicals into more desirable forms. Historically these heterogeneous catalysts, most often consisting of active transition metal

particles dispersed on a high surface area support, have advanced in a largely evolutionary fashion. Today, the increasing demands for more capable catalysts have dovetailed with a revolution in experimental and computational techniques available for preparing and studying these materials at the nanoscale to create the potential for unprecedented advances in catalyst research and discovery. Three central questions have emerged in nanoscale environmental catalysis: First, how does the structure and catalytic function of transition metal catalysts evolve as particles decrease in size from the micro to the nanoscale? Second, how do these particles interact and communicate with supports, and what are the effects on structure and catalytic function? Third, how does the particle/support system respond to realistic and dynamic reaction environments? Density functional theory (DFT) simulations provide a means to interrogate these questions independently and have proved a powerful complement to experiment in the investigation and development of nanocatalysis. In this talk we will review recent progress in studying these questions using DFT methods, with a particular emphasis on the connection between oxidation environment, catalyst composition, and activity for CO and NO oxidation with Pt and Ru catalysts.

**15:06**
**D5 2 Density functional calculations in the automotive industry: Catalyst supports and hydrogen storage materials.**
CHRISTOPHER WOLVERTON, *Ford Motor Company*

In my talk, I will describe some uses of density functional theory (DFT) calculations in the research laboratory at Ford, and particularly highlight work that was inspired by, or performed in collaboration with Ken Hass. I begin with a discussion of past work on $\gamma$-$Al_2O_3$ catalyst support materials, but also discuss the current main focus of our group's activities: hydrogen storage materials. Catalyst Supports: In current three-way automotive catalysts, precious metals are often supported by the phase of aluminum oxide known as $\gamma$-$Al_2O_3$. Despite the ubiquitous nature of this oxide in current automobile catalysts, and a considerable amount of effort expended to understand this material, many questions about the phase stability and even crystal structure of $\gamma$-$Al_2O_3$ remain. DFT calculations have made significant progress in unraveling these unanswered questions, allowing one to construct realistic models of the supported catalysts materials. Hydrogen Storage Materials: One of the major bottlenecks to the widespread use of hydrogen-fueled vehicles is the ability to store sufficient energy on-board to enable vehicle attributes acceptable to customers. I will give a general introduction to the topic of hydrogen storage, and a broad survey of the various classes of hydrogen storage technologies, and point out some pros and cons associated with each class. Currently known technologies have insufficient usable energy densities, and I will describe how DFT calculations are aiding the search for improved high density storage materials.

**15:42**
**D5 3 From Condensed Matter Theory to Complex Biological Structures.**
ANDERS CARLSSON, *Washington University*

Condensed matter theory has given us many successful examples of the combination of analytic theory and numerical modeling in treating microscale and nanoscale physical phenomena. The methods of condensed-matter theory are increasingly being applied to biological problems. We will describe recent work modeling the growth of actin networks in biological cells. Actin, an abundant intracellular protein, polymerizes into semiflexible filaments which are important for many processes, including cell motion and shape changes. The growth of the filaments is regulated by intracellular proteins that can, for example, cap the growing ends of filaments, cause new branches to grow on existing filaments, or sever filaments. These activities generate a dynamic actin filament network at the cell edge. The filaments' growth can generate forces large enough to move the cell and change its shape. The talk will describe Brownian-dynamics simulations of the growth of single filaments against an obstacle, and stochastic-growth modeling of the growth of the actin network. The single-filament growth simulations show that even filaments attached to an obstacle can grow and push it forward, at rates comparable to free-filament growth rates. This result is consistent with experimental observations of filament-obstacle attachments. The network-growth simulations use a minimal stochastic growth model including capping, branching, and severing. Simulation studies of this model yield a network structure quite similar to that seen by electron microscopy. Surprisingly, the growth velocity of the network is almost independent of the opposing force. Analytic theory shows that this effect is due to the autocatalytic nature of the branching route to filament generation. Studies of the polymerization dynamics of this model reveal a ''branching explosion'' in which large clusters of branched filaments form at short times, but the filaments are nearly unbranched at long times.

**16:18**
**D5 4 The Physics of Traffic.**
L. CRAIG DAVIS

Congestion in freeway traffic is an example of self-organization in the language of complexity theory. Nonequilibrium, first-order phase transitions from free flow cause complex spatiotemporal patterns. Two distinct phases of congestion are observed in empirical traffic data–wide moving jams and synchronous flow. Wide moving jams are characterized by stopped or slowly moving vehicles within the jammed region, which widens and moves upstream at 15-20 km/h. Above a critical density of vehicles, a sudden decrease in the velocity of a lead vehicle can initiate a transition from metastable

states to this phase. Human behaviors, especially delayed reactions, are implicated in the formation of jams. The synchronous flow phase results from a bottleneck such as an on-ramp. Thus, in contrast to a jam, the downstream front is pinned at a fixed location. The name of the phase comes from the equilibration (or synchronization) of speed and flow rate across all lanes caused by frequent vehicle lane changes. Synchronous flow occurs when the mainline flow and the rate of merging from an on-ramp are sufficiently large. Large-scale simulations using car-following models reproduce the physical phenomena occurring in traffic and suggest methods to improve flow and mediate congestion.

**SESSION D6: SIMULATING HYDROGEN STORAGE: FROM CURRENT CHALLENGES TO FUTURE PROMISES**
**Monday Afternoon, 13 March 2006; 310, Baltimore Convention Center at 14:30**
**Shengbai Zhang, National Renewable Energy Laboratory, presiding**

**14:30**
**D6 1 Computational Study of Metal Hydride Destabilization.**
KARL JOHNSON, *University of Pittsburgh*

The safe and efficient on-board storage of hydrogen in fuel cell vehicles is one of the major road-blocks for utilization of hydrogen in transportation. This talk will illustrate the use quantum molecular modeling techniques for investigating atomic- level details of hydrogen storage in new materials. Metal hydrides of period 2 and 3 materials have high volumetric and gravimetric hydrogen storage capacities. However, these materials typically have very high heats of reaction, meaning that high temperatures are required to dissociate the hydrides. Likewise, hydrogenation reactions evolve very large quantities of energy, making thermal management during refueling a impractical. Recent experimental work has focused on chemical destabilization of metal hydrides as a means of decreasing the heats of reaction. We have carried out quantum mechanical calculations, using the electronic density functional theory (DFT) formalism, for various metal hydride systems. The heats of reaction for over 300 different reactions have been computed. We have compared our calculations with experimental and tabulated data where available and find reasonable agreement. Our calculations demonstrate the utility of DFT for screening reactions and for identifying promising materials for further computational and experimental studies. We have also studied the hydration of $Mg_2Si$, a destabilized hydride of MgH2. Experiments have failed to hydrogenate this material in the laboratory under high pressures of $H_2$. We examine adsorption of H2 and dissociation on the $Mg_2Si(110)$ surface to see if kinetic limitations are responsible for the failure to observe hydrogenation of this material.

**15:06**
**D6 2 The potential of hydrogen storage in hydrate and graphitic systems.**
JOHN TSE, *University of Saskatchewan*

Many methods have been proposed for efficient storage of molecular hydrogen for fuel cell applications. Recently, it was found that molecular hydrogen can be stored in large quantity approaching the U.S. Department of Energy goals of 6.5% mass ratio in ice clathrate under high pressure and low temperature [1]. Attempts were made to increase the stability of the clathrate. Unfortunately, so far the modified hydrates failed to meet the elusive goal [2,3]. To understand the thermodynamic stability and storage capacity, hydrogen occupancy in clathrate hydrate was examined with a statistical mechanical model in conjunction with first−principles quantumchemistry calculations [4]. The theoretical approach is extended to graphitic systems [5]. It is shown that insufficiently accurate carbon–$H_2$ interaction potentials, together with the neglectand incomplete treatment of the quantum effects in previous theoretical investigations led to incorrect conclusions for the absorption capacity. A proper account of the contribution of quantum effects to the free energy and the equilibrium constantfor hydrogen adsorption suggest that the U.S. Department of Energy specification can be approached in a graphite−based physisorptionsystem. [1] W.L. Mao, H.-K. Mao, A.F. Goncharov, V.V. Struzhkin, Q Guo, Q., *et al. Science* 297, 2247–2249 (2002) [2] H.Lee, J. Lee, D.Y. Kim, J. Park, Y. Seo, H. Zeng, I.L. Moudrakovski, C.I. **D6 3 Theory of Hydrogen Storage: A New Strategy within Organometallic Chemistry.**
YUFENG ZHAO, *National Renewable Energy Laboratory*

As one of the most vigorous fields in modern chemistry, organometallic chemistry has made vast contributions to a broad variety of technological fields including catalysis, light emitters, molecular devices, liquid crystals, and even superconductivity. Here we show that organometallic chemistry in nanoscale could be the frontier in hydrogen storage. Our study

is based on the notion that the 3d transition metal (TM) atoms are superb absorbers for H storage, as their empty d orbital can bind dihydrogen ligands (elongated but non-dissociated $H_2$) with high capacity at nearly ideal binding energy for reversible hydrogen storage. By embedding the TM atoms into a carbon-based nanostructures, high H capacity can be maintained. This presentation contains four parts. First, by comparing the conventional hydrogen storage media, e.g., metal hydrides and carbon-based materials, the general principles for designing hydrogen storage materials are outlined. Second, organometallic buckyballs are studied to demonstrate the novel strategy. The amount of $H_2$ adsorbed on a Sc-coated fullerene, $C_{48}B_{12}$ $[ScH]_{12}$, could approach 9 wt%, with binding energies of 30-40 kJ/mol. Third, the method is applied to the transition-metal carbide nanoparticles that have been synthesized experimentally. The similar non-dissociative $H_2$ binding is revealed in our calculation, thereby demonstrating the resilience of the overall mechanism. Moreover, a novel self-catalysis process is identified. In the fourth part, transition-metal functionalization of highly porous carbon-based materials is discussed heuristically to foresee macroscopic media for hydrogen storage. Finally follows the summary and discussion of the remaining challenges to practical hydrogen storage. Work in collaboration with A. C. Dillon, Y.-H. Kim, M. Heben & S. B. Zhang and supported by the U.S. DOE/EERE under contract No. DE-AC36-99GO10337.

**D6 4 Materials for Hydrogen Storage: From Nanostructures to Complex Hydrides.**
PURU JENA, *Virginia Commonwealth University*

The limited supply of fossil fuels, its adverse effect on the environment, and growing worldwide demand for energy has necessitated the search for new and clean sources of energy. The possibility of using hydrogen to meet this growing energy need has rekindled interest in the study of safe, efficient, and economical storage of hydrogen. This talk will discuss the issues and challenges in storing hydrogen in light complex hydrides and discuss the role of nanostructuring and catalysts that can improve the thermodynamics and kinetics of hydrogen. In particular, we will discuss how studies of clusters can help elucidate the fundamental mechanisms for hydrogen storage and how these can be applied in Boron Nitride and Carbon nanocages and how metallization of these nanostructures is necessary to store hydrogen with large gravimetric density. We will also discuss the properties of complex light metal hydrides such as alanates and magnesium hydrides that can store up to 18 wt % hydrogen, although the temperature where hydrogen desorbs is rather high. Using first principles calculations, we will provide a fundamental understanding of the electronic structure and stability of these systems and how it is affected due to catalysts. It is hoped that the understanding gained here can be useful in designing better catalysts as well as hosts for hydrogen storage.

**16:54**
**D6 5 First Principles predictions of Hydrogen Storage Materials.***
WILLIAM GODDARD, *Caltech*

A grand challenge in materials technology is the development of materials capable of reversible storage of $H_2$ at ambient temperatures and pressures capable of mass densities greater than 6% by weight. We report here the results of first principles calculations on several classes of materials including: Carbon-alkali based systems, Metal oxide framework systems, Metal alloy systems. These simulations indicate that the DOE goals for 2010 are achievable in materials that could be manufactured today.

**D7 1 Spin liquids and spin dynamics in kagome antiferromagnets.**
PHILIPPE MENDELS, *Universite Paris-Sud*

Among all the corner sharing highly frustrated magnets, only a few experimental systems are good candidates for a low-T fluctuating state, ie fulfilling the important conditions of the pure Heisenberg lattice with nn couplings. The combination of the weakness of the single-ion anisotropy and of a direct overlap antiferromagnetic exchange are certainly the major advantages of the chromate S=3/2 kagome bilayer $Ba_2Sn_2ZnGa_{10-7p}Cr_{7p}O_{22}$- BSZCGO(p)- and the long studied $SrCr_{9p}Ga_{12-9p}O_{19}$ - SCGO(p). Beyond the absence of ordering well below the Curie-Weiss temperature, the unusual large value of the specific heat unveils a high density of low lying excitations and its field independence suggests that the excited states are mostly singlets. Moreover, their ground state is found essentially fluctuating although an intrinsic spin

glass (SG) signature is observed in susceptibility measurements. Through a review of our past years work, I'll illustrate all the potential of local studies (NMR and $\mu$SR) to reveal some key aspects of the physics of these compounds: susceptibility, fluctuations, impact of dilution defects which generate an extended response of the spin-lattice ... as well as the puzzling spin-glass state. More recently we also investigated new series of compounds, among them volborthite and delafossites which feature S=1/2 spins on a corner sharing antiferromagnetic lattice. I'll introduce these compounds and shortly discuss their relation to ideal Hamiltonians and novel features. D. Bono et al.Phys. Rev. Lett. 93, 187201 (2004), 92, 217202 (2004) ; Cond-mat/0503496. F. **D7 2 Frustrated dipolar interactions – why spin ice obeys the ice rules.**
RODERICH MOESSNER, *CNRS and ENS Paris*

The low temperature entropy of the the spin ice compounds, such as $Ho_2Ti_2O_7$ and $Dy_2Ti_2O_7$, is well described by the nearest-neighbor antiferromagnetic Ising model on the pyrochlore lattice, i.e. by the ''ice rules.'' This is surprising since the dominant coupling between the spins is their long ranged dipole interaction. We show that this phenomenon can be understood rather elegantly: one can construct a model dipole interaction, by adding terms of shorter range, which yields *precisely* the same ground states, and hence $T = 0$ entropy, as the nearest neighbor interaction. A treatment of the small difference between the model and true dipole interactions reproduces the numerical work by Gingras et al in detail. We are also led to a more general concept of projective equivalence between interactions.

**D7 3 Neutron studies of 3D Highly Frustrated Magnetism.**
JASON GARDNER, *BNL/NIST*

Because of their low propensity to order antiferromagnetic materials based on a pyrochlore lattice appear to be excellent systems for studying exotic ground states. It has also been shown that ferromagnetically coupled spins can be frustrated on such a lattice, if there is considerable local Ising anisotropy. I will review several neutron scattering studies on pyrochlore compounds done in the past couple of years, focusing on the study of spin dynamics. Evidence for large, dynamical spins at low temperatures in several antiferromagnets and a crossover from classical to quantum regime in the spin ices will be discussed. If time permits I will discuss new areas of neutron research in frustrated magnetism. [1] Magnetic Systems with Competing Interactions, edited by H.T. Diep (World Scientific, Singapore, 1994), Can. J. Phys. **79**, (2001) and Frustrated Spin Systems, ed H T Diep (World Scientific, Singapore, 2004). [2] S. T. Bramwell and M. P. Gingras, Science, **294**, 1495, (2001).

**D7 4 Natural and Artificial Spin Ice.***
PETER SCHIFFER, *Pennsylvania State University*

Geometrical frustration among spins in magnetic materials can lead to exotic low temperature states including ''spin ice,'' in which the local moments mimic the frustration of hydrogen ion positions in frozen water. We have performed extensive studies of spin ice materials and related compounds, and recently have begun study of an itartificial geometrically frustrated magnet which shares many of the properties of the spin ice materials. This artificial frustrated system is based on an array of lithographically fabricated single-domain ferromagnetic islands. The islands are arranged such that the dipolar interactions between them are analogous to those in spin ice. Images of the magnetic moments of individual elements in this correlated system allow us to study the local accommodation of frustration. We see both ice-like short range correlations and an absence of long range correlations, behavior which is very similar to the low temperature state of spin ice. These results demonstrate that artificial frustrated magnets can provide a rich new arena in which to study the physics of frustration. References: J. Snyder et al. (PRL 2003, and PRB 2004); R. F. Wangit et al. (Nature, in press). This research was supported by the Army Research Office and the National Science Foundation.

**D7 5 Colossal magnetocapacitive effects in geometrically frustrated chalcogenide spinels.**
PETER LUNKENHEIMER, *Center for Electronic Correlations and Magnetism, University of Augsburg, Germany*

It is well known that the spinel structure is susceptible to the occurrence of geometrical frustration, which in the past was invoked to explain a number of unusual observations concerning the magnetic and orbital degrees of freedom in these materials. We demonstrate that several chalcogenide spinels also exhibit very unusual dielectric behavior, especially an extremely strong coupling of magnetic and dielectric properties and the simultaneous occurrence of magnetic and polar

order. Especially, in $CdCr_2S_4$ a colossal magnetocapacitive effect is observed, which shows up as a sharp upturn of the dielectric constant it$\varepsilon$' when the sample becomes ferromagnetic and as a variation of it$\varepsilon$' up to a factor of 30 when the sample is subjected to external magnetic fields. As revealed by linear and non-linear dielectric measurements, this material shows the typical signatures of relaxor ferroelectrics, i.e. a strong increase of the static dielectric constant with decreasing temperature and considerable frequency dispersion of the complex permittivity. While in most relaxor ferroelectrics the freezing of polar moments is driven by frustrated interactions related to substitutional disorder, in the present pure system geometrical frustration seems a plausible mechanism to explain the relaxor behavior. However, one may also speculate on completely different mechanisms of ferroelectric polarization, e.g., the ordering of electronic degrees of freedom. The concomitant occurrence of polar and magnetic order makes $CdCr_2S_4$ another example of the rare species of multiferroic materials. In contrast to other members of this group of materials, it has sizable ordering temperatures and moments. A detailed investigation of the relaxational dynamics in this material provides clear evidence that the observed magnetocapacitive effect stems from an enormous acceleration of the relaxation dynamics induced by the development of magnetic order. In addition, recent results reveal even larger magnetocapacitive effects in In-doped $CdCr_2S_4$. In addition to $CdCr_2S_4$, we found similar effects also in ferromagnetic $CdCr_2Se_4$ and, most astonishing, in $HgCr_2S_4$, which exhibits a complex type of antiferromagnetic magnetic order at low temperatures. In the latter system, the magnetocapacitive effect, exemplified by the relative increase of it$\varepsilon$' in a field of 5 T, reaches values up to $8\times 10^5$ %.

**D8 1 Nonlinear Analysis of the Self-assembly of Nanostructures** SHAOWEN HU, *University of Houston* GIRISH NATHAN, GEMUNU GUNARATNE, DONALD KOURI, We investigate properties of a model of nanoscale pattern formation on a uniform substrate. The coefficients of the Ginzburg-Landau equations are concentration dependent. We find that, above the threshold, there are two branches of solutions corresponding to the up and down hexagonal structures; their appearance is related to the initial concentration of the system. The stability of such structures is confirmed by the analysis of the phase dynamics. When system is away from the threshold, the theory predicts a competition of stripe and hexagonal structures. The predicted stability domain of the stripe structures is consistent with numerical simulations. This provides a framework to understand the guided self-assembly technology, e.g., by the photolithography, at a coarse scale. The possible interaction of a large scale mode with the pattern mode is also discussed.

**14:42**
**D8 2 Shear band instability in the presence of convection*** SEBASTIEN AUMAITRE, J.P. GOLLUB, *Haverford College* One of the main features of the atmospheric motion of giant gas planets, like Jupiter and Saturn, is their remarkably stable shear band structure. The stability and internal structure of this flow, and the consequences for the internal heat transport, are not fully understood. Here we present a flexible device to study in a laboratory experiment the stability of a shear band flow in the presence of convective heat transport. The shear band flow is generated in layer of conductive fluid by spatially periodic Lorentz forces resulting from an electric current passing through the fluid in the presence of a network of magnets placed under the cell. Moreover, a convective flow is created by an imposed temperature gradient across the fluid layer. By changing the current through the fluid, and the temperature difference across the layer, we are able to adjust independently the velocity fields resulting from the shear and thermal forcing. Heat transport, flow patterns, and velocity fields are monitored. Initial results on the threshold for the instability of the shear band flow, and the resulting flow patterns, will be presented.

**D8 3 Surfactant-enhanced thermocapillary flow in two-dimensional slots.** RAM HANUMANTHU, KATHLEEN STEBE, *Department of Chemical & Biomolecular Engineering; Johns Hopkins University; Baltimore, MD 21218* An insoluble surfactant at an aqueous-gas interface can assume a variety of surface states including gaseous (G), liquid expanded (LE), and liquid condensed (LC) states. The surface pressure-surface area isotherm for such monolayers is well established; however, their thermocapillary behavior has received less attention. Recently, Nguyen & Stebe reported surfactant-enhanced Marangoni-Benard flows in evaporating aqueous drops, created by the strong dependence of surface tension on temperature in LE-LC co-existence. In this work, flow in a two-dimensional slot in the presence of insoluble surfactant is modeled. The time-dependent, incompressible Navier-Stokes equations, coupled with energy conservation and surface convection-diffusion equations are solved using Galerkin's method of weighted residuals on a finite element mesh. The model is verified against the results of Sen & Davis for steady thermocapillary flows in two-dimensional slots; and of Homsy & Meiburg for surfactant effects in a linear limit. Finally, both steady-state and dynamic flow patterns are presented that evolve when a constitutive equation that captures the full, non-linear, concentration- and temperature-dependent phase-change behavior is used. Predicted flow patterns are compared qualitatively to the experimental observations.

**D8 4 Weakly nonlinear dynamics of the longwave Marangoni instability in a binary-mixture layer in the presence of the Soret effect.*** ALEXANDER ORON, *Mechanical Engineering* ALLA PODOLNY, *Mathematics* ALEXANDER A. NEPOMNYASHCHY, *Mathematics* TECHNION-ISRAEL INSTITUTE OF TECHNOLOGY TEAM, We consider a system consisting of a layer of an incompressible binary liquid with a deformable free surface. We investigate the long-wave Marangoni instability in the case of small Lewis and Galileo numbers for finite capillary and Biot numbers in the case of a specified heat flux at the solid

substrate. The Soret effect is taken into account. Both long-wave monotonic and oscillatory modes of instability are found in various parameter domains of the Biot and Soret numbers. We have derived a set of strongly nonlinear evolution equations describing the spatio-temporal dynamics of the layer in three dimensions in the case of the oscillatory instability. The weakly nonlinear analysis based on these equations demonstrates the presence of several kinds of stable supercritical standing and travelling waves.

**15:18**

**D8 5 Convection onset in a supercritical pure fluid** HORST MEYER, *Duke University* The convection onset of a pure supercritical fluid -$^3$He - in a Rayleigh-Bénard cell has been investigated along the critical isochore by measuring the temperature drop $\Delta T(t)$ across the fluid layer as a function of time $t$ after starting the heat current $q$. The measurements showed after the initial sharp rise in $\Delta T(t)$ a first maximum at the time $t_p$, which indicates that the convection has developed and that plumes have reached the upper plate. It was found empirically that $t_p$, scaled by the thermal diffusion relaxation time $\tau_D$, could be expressed as $t_p/\tau_D = F([Ra - Ra_c])$, where $Ra_c$ is the critical Rayleigh number[1]. A model is proposed which reproduces this observed scaled representation. It uses the instability criterion of the bottom (hot) boundary fluid layer and the calculated Nusselt and Ra numbers for the steady-state convection. The perturbations leading to the convection development, after the fluid instability point has been reached, are unknown. Therefore $t_p/\tau_D$ is determined within a constant multiplicative factor, the only fit parameter of this model. There is then good agreement over more than four orders of magnitude of $[Ra - Ra_c]$ between the calculations and the experiments. The fit parameter is a phenomenological measure for the effectiveness of the perturbations, and will be discussed. 1. A. Furukawa et al. Phys. Rev. E 68, 056309 (2003), Fig.5a.

**D8 6 The Resolution of the Domain Chaos Puzzle for Rotated Rayleigh-Bénard Convection*** NATHAN BECKER, GUENTER AHLERS, *UC Santa Barbara* Due to the Küppers-Lortz instability, Rayleigh-Bénard convection-patterns exhibit spatio-temporal chaos at the onset of convection when the sample rotates fast enough about a vertical axis. Previous work showed that the scaling of the correlation length $\xi$ determined from the experimental chaotic patterns disagreed with the prediction from a Ginzburg-Landau weakly-nonlinear model.[1] Commonly the power spectrum of the pattern images (the structure factor) is used to extract $\xi$ from the half-width of its peak. Past experiments and simulations used standard Fourier techniques to calculate the power spectrum. On the basis of simulations using the Swift-Hohenberg equation, we show that those results are influenced strongly by the finite image-size available from experiment. The disagreement between experiment and theory was resolved by using the maximum-entropy method to calculate the power spectra. The maximum-entropy method is not as sensitive to the finite image-size effect. When applied to new experimental images, it yielded results for $\xi$ that were in agreement with the theory.

**D8 7 Revealing the buidling blocks of chaos: Deviations from extensivity** DAVID A. EGOLF, *Dept of Physics; Georgetown University* MATTHEW P. FISHMAN, *Dept of Physics; Georgetown University & Medical College of Wisconsin* Researchers have made relatively little progress in developing a predictive theory of far-from-equilibrium, spatially-extended chaotic systems. Even descriptions of the fundamental degrees of freedom and the nature of their interactions — central elements of statistical mechanics — are lacking. Using high- precision studies of the fractal dimension as a function of system length for the complex Ginzburg-Landau equation, we have uncovered deviations from extensivity on a length scale consistent with the chaotic length scale, indicating that this spatiotemporal chaotic system is composed of weakly-interacting building blocks, each containing about two degrees of freedom. Our results also suggest an explanation of some of the 'windows of periodicity' found in spatiotemporal systems of moderate size.

**15:54**

**D8 8 Estimating the State of Large Spatio-Temporally Chaotic Systems: Application to a Rayleigh-Benard Convection Experiment** MATTHEW CORNICK, EDWARD OTT, BRIAN HUNT, *University of Maryland* Data Assimilation (DA) refers to the estimation of a dynamical system's state from the combined knowledge of past observations (possibly incomplete and noisy) and knowledge of an approximate model for the systems time evolution. Here we consider DA for spatio-temporally chaotic systems, and, in particular, we study the Local Ensemble Kalman Filter DA technique. We have applied this technique to Rayleigh-Benard convection undergoing spiral defect chaos. Using a system model (Boussinesq equations) and time series of noisy shadowgraphs we obtain estimates of the temperature and velocity field everywhere in a convection cell. This technique provides us with an indirect measurement of quantities previously inaccessible such as mean flow. We also demonstrate the utility of this method for forming initial conditions and producing 'forecasts' from the model.

**16:06**

**D8 9 Competition between left and right spiral vortices and their combinations with different or equal amplitudes** MANFRED LÜCKE, ALEXANDER PINTER, CHRISTIAN HOFFMANN, *University Saarbrücken* Stability, bifurcation properties, and the spatiotemporal behavior of different nonlinear combination structures of spiral vortices in the counter rotating Taylor-Couette system are investigated by full numerical simulations and by coupled amplitude equation approximations. Stable cross-spiral structures with continuously varying content of left and right spiral modes are found. Their solution provides a stability transferring connection between the initially stable, axially counter propagating wave states of pure spirals and the axially standing waves of so-called ribbons that become stable slightly further away from onset of vortex flow.

**16:18**

**D8 10 An Accurate Mode Selection Mechanism for Magnetic Fluids** DAVID JACKSON, *Dickinson College* JOSÉ MIRANDA, *Universidade Federal de Pernambuco* When a ferrofluid is trapped in a Hele-Shaw cell and subjected to a perpendicular magnetic field a fingering instability results in the droplet evolving into a complex branched structure. This fingering instability depends on the magnetic field ramp rate but it also depends critically on the

initial state of the droplet. Small perturbations in the initial droplet can have a large influence on the resulting final pattern. By simultaneously applying a stabilizing azimuthal magnetic field, we gain more control over the mode selection mechanism. In fact, a linear stability analysis predicts that any mode can be selected by appropriately adjusting the strengths of the applied fields. We present the results of numerical simulations that demonstrate that this mode-selection mechanism is quite robust and ''overpowers'' any initial perturbations on the droplet. This provides a predicable way to obtain patterns with any number of fingers whatsoever.

**16:30**

**D8 11 Controlling Interfacial Instabilities in Hele-Shaw Cells: Theory** SHUWANG LI, JOHN LOWENGRUB, *University of Californa at Irvine* JAKE FONTANA, PETER PALFFY-MUHORAY, *Liquid Crystal Institute, KSU* The growth of crystals in an undercooled melt and interface evolution in Hele-Shaw cells are governed by similar underlying mathematics. Hele-Shaw experiments can therefore give valuable insights into crystal growth. In the context of crystal growth, Li, Lowengrub and co-workers have demonstrated (e.g. see J. Crystal Growth, Physica D) that by varying the temperature conditions in the far-field in a prescribed way without feedback, interface instabilities (e.g. Mullins-Sekerka) can be suppressed and crystals may be grown with desired symmetries. Interestingly, at long times nonlinear stabilization is observed and leads to the existence of universal crystal shapes that depend only on the far-field temperature conditions. Here, this work is adapted to interface evolution in Hele-Shaw cells where the control parameter is the injection pressure. Namely, we consider the displacement of oil by air and we demonstrate that by varying the injection pressure in a prescribed, time-dependent way (without feedback) that the Saffman-Taylor instability can be suppressed and controlled such that bubbles of desired symmetries can form. This is in agreement with recent experimental predictions (presented separately in this session). We further predict the existence of universal bubble shapes that depend only on the injection pressure; the experimental confirmation of such universal shapes is the subject of ongoing studies.

**16:42**

**D8 12 Controlling Interfacial Instabilities in Hele-Shaw Cells: Experiments** JAKE FONTANA, *Liquid Crystal Institute, KSU* PETER PALFFY-MUHORAY, *Liquid Crystal Institute, KSU* SHUWANG LI, *University of California at Arvine* JOHN LOWENGRUB, *University of California at Arvine* LIQUID CRYSTAL INSTITUTE TEAM, UNIVERSITY OF CALIFORNIA AT ARVINE TEAM, The growth of crystals in an undercooled melt and interface evolution in Hele-Shaw cells are governed by similar underlying mathematics. Hele-Shaw experiments can therefore give valuable insights into crystal growth. We have constructed radial Hele-Shaw cells where oil between parallel glass plates could be displaced by air whose injection pressure is a function of time. Here we describe our experimental apparatus and present results for the interface evolution for different driving schemes. We have found that, in agreement with recent theoretical predictions (presented separately in this session), we can prevent the onset of the Saffman-Taylor instability, or we can select and grow a particular unstable mode and drive the interface towards a corresponding universal shape. Varying the injection pressure during growth thus allows control over interfacial instabilities.

**16:54**

**D8 13 Liquid manipulation via morphological transitions*** RALF SEEMANN, MARTIN BRINKMANN, EVGENY GUREVICH, STEPHAN HERMINGHAUS, *MPI for Dynamics and Self-Organization, D-37073 Goettingen* JEAN-CHRISTOPHE BARET, MICHEL DECRE, *Philips Research Laboratories, NL-5656AA Eindhoven* Liquid deposited on rectangular grooves, has a variety of possible liquid morphologies determined by the contact angle, $\theta$, and the exact channel geometry. In our experiments, electrowetting is used to tune $\theta$ reversibly from 100 to 50 °, leading to a reversible transition between a drop-like morphology at large $\theta$ and extended liquid filaments for small $\theta$. The transition is capillarity-driven but the behavior of the liquid above the transition is influenced by the electrical properties of the liquid. The static length of the liquid filament is a function of the applied Voltage and is in perfect agreement with a simple transmission-line model. Emphasis is put on the dynamic aspects of the filling and the draining behavior that follow a modified Washburn law. In case of thin and elastic ridges separating two grooves the cross talk of the liquid morphologies with the elastic substrate has an ordering effect on the position of the droplets.

**17:06**

**D8 14 Diffusion-induced spontaneous pattern formation on gelation surfaces** HIROAKI KATSURAGI, *University of Pennsylvania, Kyushu University* Polymer gels make various kinds of surface patterns, which are typical non-equilibrium phenomena, under the volume phase transition. Mechanical instabilities due to swelling or shrinking of polymer gels play an essential role in such pattern formations. However, there is no report on diffusion-induced spontaneous pattern formation in polymer gels. Here we report the diffusion-induced (not caused by the mechanical instability) macroscopic pattern formation on gelation surfaces. We experimented on two-dimensional poly-acrylamide gelation that is governed by free radical polymerization. Gel slabs were made on Petri-dishes with free upper surface boundary condition. Then, random and straight stripe patterns (surface deformations) were observed, depending on gelation conditions. We consider a reaction-diffusion dynamics to describe this pattern formation. Acrylamide is considered as an activator and oxygen works as an inhibitor in the gelation reaction-diffusion system. We found the scaling relation between the characteristic wavelength and the gelation time. This scaling is consistent with the reaction-diffusion dynamics.

**17:18**

**D8 15 Using Capillary Flows to Pattern Lines*** SAURABH VYAWAHARE, KATE CRAIG, AXEL SCHERER, *California Institute of Technology, Pasadena CA 91125* One can appreciate how capillary forces cause unexpected patterns and shapes by looking at a soap bubble. Pattern formation by surface tension is seen in ring patterns of coffee stains, fingering patterns in Hele-Shaw cells, ordering of two dimensional micro-sphere crystals, combing of DNA and skeleton formation in marine creatures called radiolarians. Though comman, problems involving the understanding and control of the self-assembly mechanism need to be resolved before using capillary forces as a practical lithographic tool. Here, we report capillary flows create line patterns in evaporating liquids between closely spaced parallel plates. The widths of these lines range from a few microns to a few nanometers. Delib-

erate patterning of such lines requires pinning of the contact line and the presence of foaming surfactants. The position and type of line can be controlled with artificial pinning points and varying solutes respectively, and large-scale photolithography can be used to guide and control the definition of nanostructures. We provide ''proof of principle'' demonstrations of this method's application by creating lines of colloidal quantum dots and micro-spheres. This represents the first step in using capillary phenomena to create controlled, self–assembling, one-dimensional wire-like structures

**D9 4 Mapping Protein Transport in Living Cells with Quantum Dots and Spatio-Temporal Image Correlation Spectroscopy.**
PAUL WISEMAN, *McGill University*

We will present recent advances in image correlation methods and recent use of this technique in combination with luminescent quantum dots for measurements of protein transport in living cells. The talk will focus on the development of image correlation spectroscopy (ICS) as an imaging extension of fluorescence correlation spectroscopy (FCS). The ICS technique is ideally suited to measure transport and clustering of fluorescently tagged proteins in cellular membranes where transport is slow and static proteins abound. The image correlation methods are based on the measurement of fluorescence intensity fluctuations as a function of space and time collected as image time series using a laser scanning microscope (either confocal or two-photon). Spatial and temporal variants of the basic ICS method will be introduced and the power of these approaches to measure both aggregation and transport of cell surface proteins will be demonstrated. The use of luminescent quantum dots as labels for image correlation studies will be discussed including the effects of quantum dot blinking on the fluctuation based image correlation measurements. We will discuss appropriate models and image correlation analysis approaches for dealing with the quantum dot blinking including a new reciprocal space image correlation technique. Finally we will present experimental results from image correlation experiments using quantum dots for mapping protein transport fluid flows in living migrating cells.

**D9 5 STM Manipulation of Nanoscale Biomolecules.**
SAW-WAI HLA, *Ohio University*

The fascinating advances in single molecule manipulations with the scanning-tunneling-microscope (STM)-tip allow scientists to fabricate artificial atomic scale structures, to study local quantum phenomena or to investigate and control properties of molecules at an atomic limit. The STM manipulation is facilitated by a precise control of tip-molecule interactions, or tunneling electrons, or the electric field between the tip and sample. By combining STM manipulation with imaging and tunneling spectroscopy, powerful experimental schemes can be developed, which opens novel routes to investigate or induce molecular conformation changes with atomic level control. In this talk, various cutting-edge STM manipulation techniques relevant to the biological systems will be introduced and our recent results on manipulation of nanoscale biological molecules including chlorophyll-a, $\beta$-carotene and amyloid $\beta$/A4 precursor protein on a Au(111) substrate will be presented.

**D10 1 Chemical Imaging and Lasing of Nanoparticle Systems.**
STEPHEN LEONE, *University of California, Berkeley*

Scanned probe microscopy techniques are developed to investigate nanoscale materials and time-domain processes in nanostructured devices. These include apertureless near field microscopy probing of islanded semiconductor films, confocal microscopy ultrafast pump-probe experiments to interrogate stimulated emission processes in ZnO tetrapod species, and single pulse CARS microscopy using phase-shaped ultra-broad-band pulses for rapid spatial and spectral analysis of soft condensed matter. Apertureless near field microscopy studies of InN islands have revealed contrast mechanisms due to the real and imaginary parts of the index of refraction, providing measurements of nanometer size Ga metal islands and InGaN and InN islands on GaN. Pickup of gold nanoparticles permits tip enhancements with resolution of the electric field phase in the images. Ultrafast laser, differential gain experiments on ZnO stimulated emission in nanowires and tetrapods are performed to measure the timescales and ratios of the electron-hole plasma and exciton mechanisms during lasing in nanostructured materials. Two novel types of measurements are addressed, stimulated emission dumping and upconversion probing methods. A single pulse CARS microscopy instrument using an ultrafast laser and phase control with interferometric detection produces complete Raman spectra while spatially scanning. Polymer domains have been analyzed with vibrational spectral sensitivity. The merger of optical techniques with scanned probe methods to investigate nanoscale features is considered in relation to the scientific requirements for measurements and the results for each system.

**D10 2 Spectroscopic Near-Field Imaging of Flat Gold Nanoparticles*** L.A. BUMM, D.H. DAHANAYAKA, D.W. KELLE, D.J. WASIELEWSKI, E.S. DAY, D.R. WHITE, *Center for Semiconductor Physics in Nanostructures, Homer L. Dodge Department of Physics and Astronomy, University of Oklahoma, Norman, OK 73019, USA* B.S. PRALL, M. ACHERMANN, V.I. KLIMOV, *Chemistry Division, C-PCS, Los Alamos National Laboratory, Los Alamos, NM 87545, USA* Using a white-light near-field scanning optical microscope (NSOM) we demonstrate near-field imaging and local plasmon spectroscopy of flat gold nanoparticles (FGNPs). These nanoparticles are atomically-flat single crystal plates with well defined shapes ranging from equilateral triangles to regular hexagons, which include intermediate truncated triangle shapes. NSOM images reveal the FGNP plasmon mode structure and its dependence on FGNP size and shape. Moreover, spatially resolved spectroscopy shows position dependent coupling to different plasmon modes.

**D10 3 Characterization of Palladium and Gold Nanoparticles Using X-ray Reflectivity, EXAFS and Electron Microscopy.*** YUAN SUN, *Dept. Mat. Sci. & Engr., SUNY at Stony Brook* ANATOLY FRENKEL, *Dept Phys, Yeshiva Univ., New York, NY* REBECCA ISSEROFF, CHERYL SHONBRUN, MICHELLE FORMAN, *Stella K Abraham High School, Hewlett, NY* KWAN-WOO SHIN, *Dept Mat Sci & Engr, K-JIST, Korea* TADANORI KOGA, HENRY WHITE, MIRIAM RAFAILOVICH, JONATHAN SOKOLOV, *Dept. Mat. Sci. & Engr., SUNY at Stony Brook* We compared the characteristics of thiolate Pd and Au nanoparticles synthesized by 1-phase and 2-phase methods. HRTEM showed that the 1-phase Pd particles had an ordered core

surrounded by a disordered shell structure while the 2-phase Pd particles appeared to be crystalline throughout; and multiple twinning existed in both the 1-phase and 2-phase Au particles. EXAFS measurements revealed that Pd particles contained large amount of disordered Pd-S compounds while the 1-phase Au particles have a larger fraction of amorphous or defective structures and higher grafting density of thiol chains than the 2-phase Au particles. Lattice expansion was found in the Pd particles, compared with lattice contraction in the Au particles. Only the 2-phase Pd and Au particles spread at the air/water interface and formed Langmuir films, which were deposited onto solid substrates and examined by x-ray reflectivity and EXAFS.

**D10 5 Probe single cyanine dye molecules' photo isomerization.** ZIH-HAO CHEN, CHANG-YEH LEE, CHAO-KUEI LEE, YU-TSU CHUANG, JUI-HUNG HSU, *National Sun Yat-sen University* Cyanine dyes are interested in the photosensitization, nonlinear optics, and their photophysical and photochemical behaviors. In particular, cyanine molecules, like DiI, plays an important role in single molecule fluorescence investigations. The high photo-stability, good QE, and low inter-system crossing rates, make it an good example for the single molecule investigations. We present the single molecule fluorescence investigation on the DiI molecules. In the investigation, we observe some (but not all) molecules exhibits reversible and quasi-stepwise polarization change. The decay dynamics is also changed correspondingly. Clear on-off blinking behaviors indicate the change in polarization from a single molecule, rather than the background noise, and we speculate it as the photo isomerization of the dye molecule. More detail analysis indicates some isomerization occurred at the singlet excited states, and it takes longer timescale ( $>$ ms) than expected.

**16:18**
**D10 6 Conductive probe AFM investigation on monolayer films of colloidal CdSe quantum dots** ITARU KAMIYA, *Toyota Technological Institute* ICHIRO TANAKA, *Wakayama University* RISA WADA, *Wakayama University* MASAYO ARIMOTO, *Wakayama University* KAZUYUKI UNO, *Wakayama University* TOMOHIRO HAYASHI, *Tokyo Institute of Technology* MASAHIKO HARA, *Tokyo Institute of Technology* The opto/electronic properties of single quantum dots (QDs) have attracted much attention due to their potential for applications to various future devices. We have been employing conductive probe AFM for measuring quantized energy levels of single QDs prepared by colloidal synthesis [1]. In contrast to measurements on QDs prepared by MBE [2], a difficulty we suffered was interaction between the probe and the colloidal QDs. We have shown that the use of conductive CNT tips can prevent such problems [3]. Here, we show that the use of monolayer films of close-packed colloidal QDs allows us to perform stable conduction measurements even with standard probes. Thin films of 1-2nm of Ti followed by 20nm of Pt were sputtered on Si(001) substrates, whereon monolayer CdSe QD films were prepared by horizontal adsorption. The nearly close-packed QDs are stably attached to the substrate, enabling us to perform local conduction measurement using AFM without tip-QD interaction. We report the film formation, and the conduction features due to the single QDs. [1] I.Tanaka, itet al., Surf.Sci. **532-535**, 801 (2003). [2] I.Tanaka, itet al., Appl.Phys-.Lett. **74**, 844 (1999). [3] I.Tanaka, itet al., Jpn.J.Appl.Phys. **44**, L249 (2005).

**16:30**
**D10 7 Ballistic Electron Emission Spectroscopy Studies of Gold Nanocrystals** SAMEH DARDONA, JIANFEI SHAO, RYAN PRICE, ROBERT WHETTEN, PHILLIP FIRST, *School of Physics, Georgia Institute of Technology* We report experimental measurements of ballistic electron emission spectroscopy (BEES) on single gold nanocrystals. Nanocrystals with core diameters from 1 nm to 3 nm were chemically attached to a 10-nm thick gold film that was vapor-deposited on a silicon substrate. Low temperature (77 K) scanning tunneling microscopy and spectroscopy were used to image and identify nanocrystals prior to BEES measurements. A comparison of BEES spectra acquired by tunneling through a nanocrystal with those acquired by tunneling directly to the gold film, shows attenuation of the BEES signal by a factor of typically 4-10. From a simple rate equation, electron relaxation times in these gold nanocrystals are estimated to be of order 10 picoseconds.

**16:42**
**D10 8 Neutron diffraction and thermodynamics of deuterium adsorption in amorphous carbon materials with a uniform pore network.** LILLIAN FRAZIER, *University of Tennessee* TOM ARNOLD, *ORNL CSD* THOMAS HANSEN, MIGUEL GONZALEZ, *ILL* DAVID MARTIN Y MARREO, *ISIS* SHENG DAI, ZUOJAIN LI, DAVID BEACH, *ORNL CSD* JOHN Z. LARESE, *University of Tennessee/ ORNL CSD* A coordinated thermodynamic and neutron diffraction investigation of the sorption properties of D2 within an amorphous carbon material with a uniform, close-packed network of open pores has been undertaken. The volumetric adsorption studies are used to determine the gas capacity, the heat of adsorption and as a guide to the neutron diffraction experiments. By combining the results of the thermodynamic measurements with the findings in the structural measurements a precise description of structure of the adsorbed phase as a function of gas filling is possible. Because the pores in these carbon materials are unequivocally open these findings have a direct impact on the interpretation of earlier adsorption and diffraction experiments involving carbon nanotubes.

**16:54**
**D10 9 Adsorption properties of amorphous carbon materials with a uniform pore network.** RICHARD E. COOK, LILLIAN FRAZIER, SAMI CHANAA, ANDREA E. FREITAG, *University of Tennessee* SHENG DAI, ZUOJIANG LI, DAVID BEACH, *ORNL CSD* JOHN Z. LARESE, *Univ of Tennessee / ORNL CSD* There has been increasing interest in various forms of high surface area carbon materials, such as buckyballs, nanotubes, and carbon black, because of their potential applications as support for catalysts, electrode materials in fuel cells, gas storage devices and as a component of nano-composites. The underlying mechanism for most of these applications involves adsorption and transport of molecules on the carbon surface. Understanding the details of the interaction potential for different adsorbate molecules with these carbon materials is an important step for tailor-making application-specific materials. The adsorption properties of a carbon material with a uniform, close packed pore distribution of approximately 2.5nm were examined using high resolution adsorption isotherms with different adsorbates. By varying the size of the adsorbate molecule we hope to learn about the potential energy surface offered by these materials and gain a keen insight into the role played by the relative surface curvature on the adsorption properties. Volumetric adsorption isotherms of H2, D2, Ar, N2, H2O, CH4, and Xe were recorded and the results will be presented. Thermodynamic properties derived from these adsorption isotherms will also be discussed.

**17:06**
**D10 10 Sonoelectrochemical Approach Towards Nanostructures** CLEMENS BURDA, XIAOFENG QIU, *Case Western Reserve University* We will report on the sonoelectrochemical synthesis of nanostructured semiconductor materials. The talk will focus on the control of the nanostructure size, shape, and composition using sonolectrochemistry as a versatile synthesis tool. The synthesis of targeted nanostructures requires thorough control of the redox chemistry during the growth process. The composition of the product can be controlled by changing the initial metal-ligand concentration. Futhermore, the properties of the novel materials will be discussed. Powder X-ray diffraction of the products confirmed the compositional change in the nanomaterials. Control of the involved sonoelectrochemistry also allows for the formation of highly monodispersed 1-D Nanorods. Qiu, Xiaofeng; Lou, Yongbing; Samia, Anna C. **17:18**
**D10 11 Optical properties of single solution based semiconductor nanowires** MASARU KUNO, VLADIMIR PROTASENKO, *University of Notre Dame* The optical properties of solution based nanowires are studied using single molecule microscopy. Particular emphasis is placed on CdSe nanowires with diameters at or below 10 nm and lengths exceeding 1-10 microns. For comparison the bulk exciton Bohr radius is 5.6 nm. These wires therefore exhibit confinement effects as seen by blueshifts, both in the ensemble linear absorption and band edge emission. No deep trap emission is seen. Furthermore, branched nanowires with tripod, v-shape and y-shape morphologies can be made using the same solution based chemistry. In all cases, unusual intrawire spectral heterogeneity is observed in both the spectral position and linewidth. Fluorescence intermittency within the wire is also observed and has been shown to exhibit power law on-time and off-time probability densities. Possible explanations for this intrawire heterogeneity include dielectric contrast effects as well as more intrinsic causes due to zincblende/wurtzite phase admixtures present in the wires. However, such explanations do not explain any of the observed fluorescence dynamics. Complicating these (and other) possible explanations are recent experiments we have conducted, which show that external electric fields can modulate both the spatial position and intensity of the nanowire emission.

**D11 1 Photodissociation of water ice and adsorbed molecules.**
MASAHIRO KAWASAKI, *Department of Molecular Engineering, Kyoto University*

The TOF spectra of photofragment hydrogen atoms from the photodissociation of amorphous ice at 193 nm have been measured. The spectra consist of both a fast and a slow components characterized by translational temperatures of 2300 and 120 K, respectively. The photoabsorption of a branched cluster, $(H_2O)_{6+1}$ that is a $(H_2O)_6$ cyclic cluster attached by a water molecule with the hydrogen bond, is expected to appear at around 200 nm. The source of the hydrogen atoms is attributed to the photodissociation of the ice surface molecules that are attached by the $(H_2O)_6$ water structure with the hydrogen bond. Atmospheric implications are estimated for the photodissociation of the ice particles at 190-230 nm in the region between 80 and 85 km altitude. The photodissociation of ice has also performed at 157 nm. Since the bulk ice absorbs vacuum UV light, hydrogen atoms are produced from both the surface and bulk photodissociation processes. A difference in the UV photodissociation dynamics of chlorine and tricholorofluorocarbon has been observed when those molecules were adsorbed on water ice surfaces. In the photodissociation of $Cl_2$ at 300 to 414 nm, the branching ratios of the formation of $Cl(^2P_{1/2})$ with respect to $Cl(^2P_{3/2})$ are different from those reported in the gas phase photodissociation.

However, in the photodissociation of $CFCl_3$ at 193 nm, the ratio is in good agreement with that reported in the gas phase photodissociation. These results are mostly attributable to the difference in the interaction of the adsorbed molecule with surface water molecules of ice. The kinetic energy distributions of the photofragment chlorine atoms reflect the interaction between the adsorbed molecules and the surface water molecules. The photofragment spectroscopy developed by late Prof. Richard Besohn has been used in this work.

**D11 2 Photodissociation dynamics of ethyl ethynyl ether: A ketenyl radical precursor** MARIA KRISCH, JOHANNA MILLER, LAURIE BUTLER, *University of Chicago* HONGMEI SU, RICHARD BERSOHN,* *Columbia University* JINIAN SHU, *Lawrence Berkeley National Laboratory* We investigate the photodissociation dynamics of ethyl ethynyl ether at 193.3 nm with crossed laser-molecular beam photofragment translational spectroscopy and laser-induced fluorescence. We establish ethyl ethynyl ether as the first clean precursor to the ketenyl radical, a key species in combustion reactions. One major bond fission channel was observed for the system, cleavage along the HCCO-$C_2H_5$ bond, leading to ground state $C_2H_5$ (ethyl) radicals and HCCO (ketenyl) radical products in two distinct electronic states. We observed neither cleavage of the other C-O bond nor molecular elimination to form $C_2H_4$ + $CH_2CO$ (ketene). Ketenyl radicals formed in the higher recoil kinetic energy channel could be either $\tilde{X}(^2A'')$ or $\tilde{A}(^2A')$ state ketenyl radical. We assign the lower recoil kinetic energy channel to the spin forbidden $\tilde{a}(^4A'')$ state of the ketenyl radical, reached through intersystem crossing. Laser-induced fluorescence from the ketenyl radical peaks after a 20 $\mu$s delay, indicating that it is formed with a significant amount of internal energy and subsequently relaxes to the lowest vibrational level of the ground electronic state, a result consistent with the product assignment.

*Deceased

**15:18**

**D11 3 Multiphoton Photodissociation of Several Halocarbons.** BOB QUANDT, *Department of Chemistry Illinois State University* The 2 x 193 nm photodissociations of $CHCl_3$, $CFCl_3$, $CF_3CCl_3$, $CCl_4$, $CH_3$-$CCl_3$ and $CH_3CH_2$-$CCl_3$have been examined using dispersed fluorescence. It was found that the initial photodissociation of $CHCl_3$ forms large amounts of $CH(A^2\Delta)$ while the photodissociation of $CCl_4$ forms lesser but still significant amounts of $CX(A^2\Delta)$ The photodissociations of $CH_3$-$CCl_3$ and $CH_3CH_2$-$CCl_3$ produce $CH_3$-C and $CH_3CH_2$-C presumably in the $A^2\Delta$ state. The exact photoproducts of the fluorinated species are currently unknown. Fluorescence rise time measurements show that the $CH(A^2\Delta)$ and $CCl(A^2\Delta)$ photoproducts quickly react to form $C_2(d^3\Pi_g)$. However, formation of $C_2(d^3\Pi_g)$ is attenuated when the primary photoproducts are $CF_3C$, $CH_3$-C and $CH_3CH_2$-C and disappears completely when it is CF. In addition, the atomic and molecular halogen photoproduct channels were investigated using ab initio calculations. Intrinsic Reaction Coordinate calculations were performed at the MP2 level of theory using the LANL2DZ basis set in order to characterize the dissociation pathways for all of species investigation. The results of the calculations show the presence of three transition states and an ion-pair isomer intermediate for all molecules. The broken symmetry structure of the transition states for the formation of molecular bromine is in agreement with the first step of the addition mechanism proposed by Cain and co-workers for $CX_2+Y_2$ reactions.

**15:30**

**D11 4 Thick and thin slices of photoproducts: correlated state distributions in ketene dissociation*** GREGORY HALL, *Brookhaven National Laboratory* ANATOLY KOMISSAROV, *JPL* MIKE MINITTI, *Stony Brook University* ARTHUR SUITS, *Wayne State University* We have revisited the correlated product distribution of $CH_2$ + CO in the photodissociation of ketene at an energy 2350 $cm^{-1}$ above the barrierless singlet dissociation threshold. Using time-sliced ion imaging, we find the speed distribution of state-selected CO fragments to be quite different from previous measurements. For each CO rotational state observed, the deviations of the coincident $CH_2$ distribution from a statistical Phase Space Theory can be accurately described with a single parameter in the spirit of a linear surprisal. The distributions are consistent with calculations of exit channel rotational dynamics starting at a variational transition state.

*Work performed under DOE Contracts DE-AC02-98CH10886 at Brookhaven National Laboratory and DE-FG-02-04ER15593 at Wayne State University.

**15:42**

**D11 5 State-resolved reactive scattering by slice imaging: A new view of the Cl+ethane reaction** ARTHUR SUITS, WEN LI, CUNSHUN HUANG, *Wayne State University* The reactions of chlorine atoms with alkanes have been the subject of intense scrutiny as model systems for the detailed investigation of polyatomic reaction dynamics. Interest in these systems has accelerated in recent years as new experimental methods have provided the means of gaining insight into the reaction with quantum state specificity. In this presentation, we will show state-resolved crossed beam scattering results for the reaction Cl + $C_2H_6 \rightarrow$ HCl + $C_2H_5$, obtained using DC slice imaging. The HCl (v=0, J) images, recorded at a range of well-defined collision energies, show strongly coupled angular and translational energy distributions revealing features of the reaction not seen in previous studies. The overall distribution is mainly forward-sideways scattered with respect to the Cl beam, with a translational energy distribution peaking near the collision energy. However, there is a substantial backscattered contribution that is very different. It shows a sharp peak near the energetic limit, but extending to much lower energy, implying substantial internal excitation in the ethyl radical co-product. These results provide new insight into the reaction, and they are considered in terms of alternative models of the dynamics. This work represents the first genuine crossed-beam study in which a product other than the methyl radical was detected with quantum state specificity, showing the promise of the approach generally for high resolution state-resolved reactive scattering.

**15:54**

**D11 6 Propargyl Radical: ab initio Anharmonic Modes and the Polarized Infrared Absorption Spectra of Matrix-Isolated HCCCH2** BARNEY ELLISON, *University of Colorado* XU ZHANG, *University of Colorado* EVAN JOCHNOWITZ, *University of Colorado* MARK NIMLOS,* *University of Colorado* JOHN STANTON, *University of Texas* MYCHEL VARNER, *University of Texas* Propargyl Radical: ab initio Anharmonic Modes and the Polarized Infrared Absorption Spectra of Matrix-Isolated HCCCH2 The propargyl radical has twelve fundamental vibrational modes, Gamma(vib)(HCCCH2) = 5a1 + 3b1 + 4b2, and nine have been detected in a cryogenic matrix. Ab initio coupled-cluster anharmonic force field calculations were used to help guide the assignments. The experimental HCCCH2 matrix frequencies (cm-1) and polarizations are: a1 modes - 3308.5 +/- 0.5, 3028.3 +/- 0.6, 1935.4 +/- 0.4, 1440.4 +/- 0.5, 1061.6 +/- 0.8; b1 modes - 686.6 +/- 0.4, 483.6 +/- 0.5; b2 modes - 1016.7 +/- 0.4, 620 +/- 2. We recommend a complete set of gas-phase vibrational frequencies for the propargyl radical, HCCCH2 X 2B1.

**16:06**

**D11 7 H-atom elimination of *n*-propyl and itiso-propyl radicals: a photodissociation study*** JINGSONG ZHANG, WEIDONG ZHOU, YAN YUAN, *University of California, Department of Chemistry* The H-atom elimination channels in the UV photodissociation of jet-cooled *n*-propyl and itiso-propyl radicals are studied in the region of 237 nm using the high-*n* Rydberg-atom time-of-flight technique. Upon excitation to the 3*p* state by the UV photolysis radiation, *n*-propyl radical and itiso-propyl radical dissociate into the H atom and propene products. The product center-of-mass translational energy release of both *n*-propyl and itiso-propyl radicals have bimodal distributions. The H-atom product angular distribution in *n*-propyl is anisotropic (with it$\beta \sim 0.5$), and that in itiso-propyl is isotropic. The overall average translational energy release is $\langle E_T \rangle \sim 0.27 E_{avail}$ for *n*-propyl and $\langle E_T \rangle \sim 0.21 E_{avail}$ for itiso-propyl. The bimodal translational energy distributions indicate two dissociation pathways: (i) a unimolecular dissociation pathway from the ground-state propyl after internal conversion from the 3*p* state, and (ii) a repulsive pathway directly connected with the excited state of the propyl radical. Isotope labeling has also been carried out. The possible photodissociation mechanisms will be discussed.

**16:18**

**D11 8 Photoinitiated decomposition of hydorxyalkyl radicals: Rydberg-valence interactions** HANNA REISLER, JIE WEI, BORIS KARPICHEV, LAURA EDWARDS, *University of Southern California* The photoinitiated dynamics of hydroxyalkyl radicals is investigated on the ground and excited surfaces. Overtone excitation of four quanta of OH stretch vibration of the hydroxymethyl radical gives rise to O-H bond fission via tunneling, without prior isomerization to the methoxy radical. Excitation of hydroxyethyl radicals to the lowest *s* and *p* Rydberg excited states accesses dissociative states lying as low as 2.5 eV above the ground state. These states undergo conical intersections with each other and the ground state, which are much more efficient than comparable interactions in the hydroxymethyl radical, and display increased opportunities for accessing crossing seams. Both O-H and C-H bond fission channels are observed. Dissociation mechanisms involving direct and indirect bond fission, isomerization and nonadiabatic interactions will be discussed. Research supported by DOE.

**D11 9 Determining the Products and Mechanism of the $C_2Cl_3+O_2$ Reaction by Time-Resolved FTIR Emission Spectroscopy** HONGMEI SU, TIANCHENG XIANG, SHAOLEI ZHAO, CONGYUN SHI, The reaction products and mechanism of the $C_2Cl_3$ radical with $O_2$ have been studied by time-resolved FTIR emission spectroscopy. The chlorinated vinyl radical, $C_2Cl_3$, was generated by 248 nm photolysis of a $C_2Cl_4$ precursor. Vibrationally excited CO, $CO_2$ and ClCO products were observed. The time evolution of the emission intensity shows that $CO_2$ and ClCO are primary reaction products. In contrast, CO emission does not decay until itms time scale indicating that CO products are due to secondary reactions, most likely, the further dissociation of ClCO. Two primary reaction channels are identified: $C_2Cl_3 + O_2 \diamond CO_2 + CCl_3 \diamond ClCO + COCl_2$ When reacting with $O_2$, the observed products and channels of the chlorinated vinyl radical, $C_2Cl_3$, turned out to be very similar to its counterpart, vinyl radical $C_2H_3$. Morokuma's DFT study[1] of the reaction $C_2H_3+O_2$ shows that the main reaction path proceeds through a three-membered CCO ring adduct. The question is, does $C_2Cl_3$ go through the same reaction path as $C_2H_3$? Does the substitution of H atom by heavier Cl atom make any difference in regard to the reaction mechanism? Further investigation combining itab initio calculation is under way. [1] A.M.Mabel, E.W.G.Diau, M.C.Lin, and K.Morokuma, J.Am.Chem.Soc. 118, 9759 (1996)

**D11 10 Experimental and Theoretical Investigation of the Electronic Spectroscopy of $H_2CN$** PAUL J. DAGDIGIAN, *Johns Hopkins University* ALEXEY TESLJA,* *Columbia University* MICHAEL BANCK, WOLFGANG EISFELD, *Technische Universität M|"unchen* The electronic spectrum of $H_2CN$, recorded through cavity ring-down spectroscopy, is reported. The radical was prepared by 193 nm photolysis of monomeric formaldoxime vapor. Two diffuse features are observed in the 34800-35800 $cm^{-1}$ spectral range, along with the $A - X$ (1,0) band of the OH co-fragment. These are assigned as vibronic transitions to the ground and $2b_1$ (umbrella mode) levels of the second excited, $^2A_1$ state from the ground $^2B_2$ state. Experimental and simulated rotational profiles of these bands agree extremely well with each other for an assumed type-B electric-dipole allowed $^2A_1 \leftarrow {}^2B_2$ transition appropriate to this transition. A theoretical investigation of the dissociation pathways for electronically excited $H_2CN$ is also presented. The upper states of the observed bands cannot dissociated directly, but higher $b_1$ levels are above the excited-state dissociation limit.

**D11 11 Ab initio analysis of the BCN, NBC and CNB fragments formation** ROBERT JARA, VLADIMIR MAKAROV, GERARDO MORELL, BRAD WEINER, The Laser Ablation technique applied to the synthesis of nano-structured materials produce unique compositions, with correspondingly unique physical and chemical properties. In order to do smart utilization of this method, fundamental understanding of the precursor formation and incorporation mechanisms for the growth of different materi-

als is crucial. Particularly important is to know what fragments are formed during the ablation process, in order to understand its dynamic evolution and eventual incorporation in the synthesized material. In connection to the synthesis of Boron Carbonitride, we have focused our attention on the dynamic evolution of the primary reactions upon BCN ablation using the itab initio method (Gaussian-98 software pack). The results (including the formation energy, direct and inverse rate constants, etc.) were estimated by considering the elementary reactions as bimolecular reactions: reactions between atoms, and atoms with diatomic molecules. The temperature dependence of the dissociation rate constant of three-atomic fragments by different channels was also analyzed using the RRKM theory. It was found that BCN and NBC are the most thermodynamically stable fragments. This theoretical analysis helps understand the strong tendency for BCN to grow stoichiometrically under a variety of experimental conditions.

**17:06**

**D11 12 Variable (itT$_g$ , itT$_s$) Measurements of Alkane Dissociative Sticking Coefficients** LETICIA VALADEZ, KRISTY DEWITT, HEATHER ABBOTT, KURT KOLASINSKI, IAN HARRISION, *Dept. of Chemistry, University of Virginia* Dissociative sticking coefficients $S(T_g, T_s)$ for $CH_4$ and $C_2H_6$ on Pt(111) have been measured as a function of gas temperature ($T_g$) and surface temperature ($T_s$) using an effusive molecular beam. Microcanonical unimolecular rate theory (MURT) was employed to extract transition state characteristics [e.g., $E_0(CH_4) = 52.5 \pm 3.5$ kJ/mol$^{-1}$ and $E_0(C_2H_6) = 26.5 \pm 3$ kJ/mol$^{-1}$]. MURT allows our $S(T_g, T_s)$ values to be directly compared to other supersonic molecular beam and thermal equilibrium sticking measurements. The $S(T_g, T_s)$ depend strongly on $T_s$, however, only for $CH_4$ is a strong $T_g$ dependence observed. The fairly weak $T_g$ dependence for $C_2H_6$ suggests that vibrational mode specific behavior and/or molecular rotations play stronger roles in the dissociative chemisorption of $C_2H_6$ than they do for $CH_4$. Interestingly, thermal $S(T_g = T_s)$ predictions based on MURT modeling of our $CH_4$/Pt(111) data are three orders of magnitude ithigher than recent thermal equilibrium measurements on supported Pt nanocrystallite catalysts [J. M. Wei, E. Iglesia, J. Phys. Chem. B **108**, 4094 (2004)].

**D12 1 Langevin Equation for the Morphological Evolution of Strained Epitaxial Films*** DIMITRI VVEDENSKY, *Imperial College London* CHRISTOPH HASELWANDTER, *Imperial College London* A stochastic partial differential equation for the morphological evolution of strained epitaxial films is derived from an atomistic master equation. The transition rules in this master equation are based on previous kinetic Monte Carlo (KMC) simulations of a model that incorporates the effects of strain through local environment-dependent energy barriers to adatom detachment from step edges. The morphological consequences of these rules are seen in the transition from layer-by-layer growth to the appearance of three-dimensional islands with increasing strain. The regularization of the exact Langevin description of these rules yields a continuum equation whose lowest-order terms provide a coarse-grained theory of this model. The coefficients in this equation are expressed in terms of the parameters of the original lattice model, so a direct comparison between the morphologies produced by KMC simulations and this Langevin equation are meaningful. Comparisons with previous approaches are made to provide an atomistic interpretation of a similar equation derived by Golovin *et al.* based on classical elasticity.

**D12 2 Crystal Surfaces out of Equilibrium: Instabilities, Multiscaling and Non-locality** ALBERTO PIMPINELLI, *LASMEA, U. Blaise Pascal Clermont-2, France, & U. of Maryland* FLORIN NITA, *U. of Genoa, Italy* We have recently proposed a novel scenario for the step meandering instability on vicinal surfaces, in which the instability is ascribed to unhindered diffusion of atoms along the step edges.[1] Then, in a rather counterintuitive way, step meandering appears due to the very mechanism - step edge diffusion - which may be expected to oppose it. We discuss the detailed comparison of the scaling properties of unstable surfaces driven by different atomistic mechanisms. We have discovered an unsuspected richness of behaviors: anomalous scaling, multiaffinity, ... We discuss a number of continuum equations that share several features with the simulations. Implications for experiments are also discussed.

**D12 3 Criticality of morphological instability of a strained film growing on a patterned substrate*** HANGYAO WANG, FENG LIU, *University of Utah* We show that the morphological instability of a strained film on a patterned substrate is fundamentally different from that on a flat substrate. It exhibits a film thickness ($t$) dependent critical wavelength, which takes a simple form as $\lambda_c = \lambda_0/2 + \pi t$ for a very thin film, where $\lambda_0$ is the critical wavelength on a flat substrate. It also defines three distinct regimes of growth stability depending on the wavelength of substrate undulation ($\lambda_s$): for $\lambda_s \leqslant \lambda_0/2$, growth is stable; for $\lambda_s \geqslant \lambda_0$, growth is unstable; in between, growth is unstable below a critical film thickness $t_c$, and stable above it.

**D12 4 First-principles Investigation of the Stability of Surface Gold Oxides on Au(111)** HONGQING SHI, CATHERINE STAMPFL, *The University of Sydney* In contrast to the long held view that gold is catalytically inert and as such uninteresting, it is now well known that Au is significantly more active than Pt in the catalytic oxidation of CO under basic environments. Au can also promote many other reactions in the form of nanoparticles on metal oxide and activated carbon supports [1].This has simulated huge efforts in an attempt to understand the mechanisms responsible for the high activity, including investigations into the nature of oxygen on gold surfaces[2]. In the present work we have investigated the relative stability of oxygen adsorbed on and under the Au (111) surface, as well as thin surface oxides. We identify structures in which the binding of atomic oxygen is stronger than

that at under−coordinated surface Au atoms (e.g. at steps). To determine the stability of the structures for different pressure and temperature conditions, we use the approach of *ab initio* thermodynamics [3], which indicates that these structures should be stable under certain catalytic conditions.[1] Haruta, Catal. J. New. Mater. Electro. Sys. **7**, 163 (2004). [2] R. Meyer, *et al.*, Gold Bull. **37**, 72 (2004), and references therein. [3] K. Reuter, C. Stampfl and M. **D12 5 Modeling Nanoscale Dynamics for Film Growth** ALEXANDRA TEN BOSCH, *CNRS, Lab. Phys. Mat. Cond., Parc Valrose, 06108 Nice, France* Small scale particle motion controls the onset of a phase transition. A general method is developed which links atomic and mesoscopic dynamics in a nanoscale description reminiscent of the classical theory of fluid flow. Derived from a Fokker Planck equation for the non-equilibrium particle distribution, the dynamic equation includes inertia terms essential for high frequency fluctuations. Film nucleation and growth are modeled by the spatially inhomogeneous evolution of the instantaneous density profile which measures the average number of particles at a given time and position. The method is used to show how an alteration in the equilibrium distribution of particles at the boundary between parent and product phases induces transient film growth and/or damped vibrations at the surface. To illustrate, condensation of a simple fluid on a surface is considered.

**15:30**

**D12 6 Interface Roughening Dynamics of Spreading Droplets** HAIM TAITELBAUM, AVRAHAM BE'ER, INBAL HECHT, AVIAD FRYDMAN, *Department of Physics, Bar-Ilan University, Ramat-Gan 52900, Israel* YOSSI LEREAH, *Faculty of Engineering, Tel-Aviv University, Tel-Aviv 69978, Israel* We review our recent experimental data of interface roughening dynamics of spreading mercury droplets on thin films (silver or gold), obtained using optical microscopy and other techniques (AFM, SEM). We discuss the various results obtained for the roughness and growth exponents associated with the interface dynamics, and their universality classes. We analyze the temporal width fluctuations, obtained for single interfaces, and show that these fluctuations contain information on the lateral correlation length of these interfaces. We show how to extract this length from experimental data, and demonstrate the validity of this method in a wide range of growing interfaces (droplet spreading experiments as well as water imbibition on paper). **D12 7 Evolution of the morphology and composition of metal germanosilicide thin films** MATHIEU BOUVILLE, DONGZHI CHI, *Institute of Materials Research and Engineering, Singapore* DAVID J. SROLOVITZ, *Princeton University* Metal germanosilicide thin films, formed from the reaction of metals on silicon-germanium substrates, are attractive for use in advanced metal-oxide-semiconductor field-effect transistors (MOSFETs). However, metal germanosilicide films are less stable than silicides films at elevated temperatures, easily agglomerating into isolated islands following severe grain boundary grooving. The resultant germanosilicide islands are noticeably different from both silicides and germanides. Agglomerated germanosilicide films consist of small, regular islands with faceted interfaces, whereas agglomerated silicides form irregular islands and uniformly curved island/substrate interfaces. Experimental observations show that the germanium composition is inhomogeneous both in the film and in the substrate. We use phase-field simulations to study the interplay between morphology, composition inhomogeneities, and strain during grain boundary grooving and agglomeration of polycrystalline metal germanosilicide films on silicon-germanium alloy substrates. By simulating the evolution of germanosilicide films on compressive and relaxed substrates, we demonstrate the important role played by misfit stress on agglomeration morphologies.

**D12 8 Effects of shadowing in oblique incidence epitaxial growth*** J.G. AMAR, Y. SHIM, V. BOROVIKOV, *University of Toledo* The results of kinetic Monte Carlo simulations of a simplified model of oblique incidence epitaxial growth on a metal fcc(100) surface are presented. Results for the effects of shadowing on the mound morphology, surface roughness, and nanoscale pattern formation as a function of the angle of incidence $\theta$ relative to the surface normal as well as the azimuthal angle $\phi$ relative to the high-symmetry direction are presented. In good agreement with experiment, we find that shadowing has little effect for deposition angles up to approximately $55^o$. However, for higher angles there is a significant effect. In particular, the formation of ripples perpendicular to the incident beam is found at $\theta \simeq 78^o$ while at even higher angles the formation of ripples parallel to the incident beam is observed. The coarsening behavior of the resulting ripple structures is also studied. Results are also presented for azimuthal angles away from the high-symmetry directions.

**D12 9 Multiscale simulations of oblique-incidence Cu/Cu(100) epitaxial growth*** V. BOROVIKOV, Y. SHIM, J.G. AMAR, *University of Toledo* We present an improved method for multiscale simulations of homoepitaxial growth of metal thin films in which the effects of oblique incidence on the deposition process may be accurately taken into account. Our method combines a kinetic Monte Carlo (KMC) simulation for the thermal surface diffusion with a small scale molecular-dynamics simulation of every deposition event, in order to account correctly for both shadowing as well as the detailed atom-surface interaction of depositing atoms. To speed-up the simulations, that are very time consuming computationally, we have utilized a parallel algorithm that involves simultaneous depositions in different areas of the surface along with parallel kinetic Monte Carlo. Simulation results for the growth of Cu/Cu(100) at 160 and 200 K are presented and compared with both ordinary KMC simulations and experiments. Results will be presented for the case of both normal incidence as well as oblique angle incidence.

**D12 10 Evolution of Roughness and Wavelength Selection during Fluorocarbon Plasma Etching of Nanoporous Silica*** TAESOON KWON, HUNG-CHIH KAN, XUEFENG HUA, GOTTLIEB OEHRLEIN, RAY PHANEUF, *University of Maryland* Nanoporous silica is a technologically appealing candidate as a low-k dielectric material for high speed nano device applications. A crucial issue during plasma pattern transferring processes is the stability of the plasma/NPS interface. Induced surface/interface roughness may ultimately limit the minimum feature sizes attainable in devices using this material. Our results show a monotonic increase with porosity in the roughening rate, and pronounced disagreement with the predictions of simple models based upon self-affine behavior. In addition we find direct evidence for spontaneous pattern formation during etching.

**D12 11 Wavelength Tunability of Ion-bombardment Induced Surface Ripples on Sapphire** HUA ZHOU, LAN ZHOU, YIPING WANG, RANDALL L. HEADRICK, *Department of Physics, University of Vermont* AHMET S. OZCAN, YI-YI WANG, GOZDE OZAYDIN, KARL F. LUDWIG JR., *Department of Physics, Boston University* DAVID P. SIDDONS, *National Synchrotron Light Source, Brookhaven National Laboratory* Energetic particle bombardment on surfaces is known to produce well ordered 2-D (ripples or wires) and 1-D (dots) structures at submicron/nanoscale by a self-organization process. Recently, significant experimental and theoretical effort has been expended to develop methods to produce self-organized nanostructures on diverse substrates from semiconductors to metals. These studies have shown potential in tailoring surface morphology in order to exploit novel physical properties, and contributed much to reveal the mechanisms of the instability-driven self-organization process. In this work, a study of ripple formation on sapphire surfaces by ion sputtering is presented. Surface characterization by in-situ synchrotron grazing incidence small angle x-ray scattering (GISAXS) and ex-situ atomic force microscopy (AFM) for the wavelength, shape and amplitude of sapphire ripples is performed. The wavelength can be varied over two orders of magnitude by changing the ion incidence angle. The linear Bradley-Harper (B-H) theory with ion induced viscous flow (IVF) relaxation fits the general trends of the data. However, anomalous smoothing not predicted by current models is observed near normal incidence.

**16:42**

**D12 12 Atomistic calculations of mass redistribution and surface morphology evolution due to medium energy ion bombardment** HARLEY JOHNSON, *University of Illinois at Urbana-Champaign* NAGARAJAN KALYANASUNDARAM, *University of Illinois at Urbana-Champaign* BENJAMIN DAVIDOVITCH, *Harvard University* MICHAEL BRENNER, *Harvard University* MIKE AZIZ, *Harvard University* JONATHAN FREUND, *University of Illinois at Urbana-Champaign* Nanoscale mass redistribution mechanisms and dynamics near a surface due to ion bombardment are studied using molecular dynamics (MD). In addition to sputter erosion, as described by the well-known Bradley-Harper theory, ion assisted surface mass redistribution is identified as an important contributor to surface morphology changes. MD simulations yield a response function based on the change in surface height at any point on the surface due to impact at an arbitrary point on the surface. We derive a linear continuum equation for surface morphology evolution using the new response function and relate the results to pattern formation. We conclude that consideration of both sputtering and mass redistribution could explain the experimentally observed limits on the slopes of ripples formed in this process.

**16:54**

**D12 13 Measurement and modeling of temperature-dependent step bunching on Si(111)** BRIAN GIBBONS, JONATHAN PELZ, *The Ohio State University* Direct Current (DC) induced step bunching on Si(111) is a long-standing puzzle, with the required DC direction for bunching (relative to the ''step-down'' vicinal surface direction) reversing multiple times with increasing temperature. It was recently proposed [1,2] that this could be explained if step attachment is itfaster (slower) than terrace diffusion in Temperature Regime II (Regimes I and III). We have numerically simulated a similar model and directly compared with measurements of how the step bunching depends on the initial terrace width $l_0$ in all three regimes [3]. Using realistic parameter values for terrace diffusion and step attachment, this model can account for the bunching behavior in all three temperature regimes, provided there indeed exist modest (0.2 – 0.4 eV) temperature-dependent variations in the relative activation barriers for attachment and diffusion, and/or modest changes in the respective activation attempt rates. **D12 14 Oxygen-induced faceting of NiAl(111)** E. LOGINOVA, W. CHEN, N. M. JISRAWI, *Department of Physics and Astronomy, Rutgers University* F. COSANDEY, *Materials Science and Engineering, Rutgers University* T. E. MADEY, *Department of Physics and Astronomy, Rutgers University* Our research is focused on the adsorption of oxygen and oxygen-induced faceting of NiAl(111), as studied by means of LEED, AES, SEM, AFM and high-resolution soft XPS (HRSXPS, using synchrotron radiation at NSLS). The atomically rough NiAl(111) surface remains planar at room temperature when exposed to oxygen. However, the surface changes its morphology and becomes faceted upon annealing at 1100K and higher; nucleation and growth of facets are studied. The adsorption and reaction of oxygen are characterized by HRSXPS measurements of Al 2p and Ni 3p core levels for the faceted and planar surfaces. The data indicate that a well-ordered thin aluminum oxide film can be formed on the faceted NiAl surface. After extensive annealing in oxygen, symmetric oxide features of micrometers in length are observed on the surface. We investigate the stoichiometry of these features by X-Ray mapping and propose a model for their formation. Our work is motivated by the possibility that alumina thin-film-covered NiAl facets might be used as templates for growth of metallic nanostructures with controlled size and spacing. The $Al_2O_3$/NiAl(111) system is a good model for studying catalytic reactions over $Al_2O_3$-supported metal catalysts.

**D12 15 Faceting of Re (11$\bar{2}$1) induced by oxygen** HAO WANG, WENHUA CHEN, THEODORE E. MADEY, *Department of Physics and Astronomy and Laboratory for Surface Modification, Rutgers University, Piscataway, NJ 08854* The oxygen-induced nanoscale faceting of Re (11$\bar{2}$1) has been studied by low energy electron diffraction (LEED) and Auger electron spectros-

copy (AES); the results are compared with recent STM and LEED studies of O-induced faceting of Re(12$\bar{3}$1). The evolution of surface morphology depends on oxygen exposures and deposition temperatures. Re(11$\bar{2}$1) remains planar after oxygen deposition at 300K. Annealing O-covered Re(11$\bar{2}$1) between 800K-1200K leads to the formation of (01$\bar{1}$0) and (10$\bar{1}$0) facets that coexist with the (11$\bar{2}$1) surface. Under oxidation conditions, i.e. dosing a large amount of oxygen at high temperatures (900-1000K), the (11$\bar{2}$1) surface is completely covered by 4-sided nanoscale pyramidal structures whose facets are identified as (01$\bar{1}$0), (10$\bar{1}$0), (01$\bar{1}$1) and (10$\bar{1}$1). The fact that the (11$\bar{2}$1) surface becomes completely faceted only after oxidation is consistent with our previous data for O-induced faceting of Re(12$\bar{3}$1), where one facet has the (11$\bar{2}$1) orientation and is unstable against oxidation. The faceted O/Re surfaces may be potential templates to grow nanostructures with narrow size distribution, and may also be substrates to study structural sensitivity in catalytic reactions.

**D13 1 Imaging of protein partitioning in plasma membranes with coexisting fluid phases.**
TOBIAS BAUMGART, *University of Pennsylvania*

The membrane raft hypothesis postulates the existence of lipid bilayer membrane heterogeneities, or domains, important for cellular membrane functioning, including lateral sorting, signaling and trafficking. The itin vivo characterization of lipid membrane heterogeneities thus far has been challenging. Lipid membrane rafts have been suggested to be enriched in lipids that confer fluid ordered phase like character to these compositional heterogeneities. Lipid model membranes, on the other hand, allow fluorescence imaging of lipid domain coexistence, but so far micron-size coexisting fluid phases have been demonstrated only in simple, including ternary, lipid mixtures. We found that giant itplasma membrane itvesicles (PMVs) obtained from cultured rat basophilic leukemia cells can phase segregate into optically resolvable micron-size phases that are identified as both being fluid. We examined the partitioning of fluorescent lipid analogs and hydrophobic membrane markers and found them to be similar to the partitioning behavior in model membrane systems that show coexisting fluid ordered and fluid disordered phases. Significant temperature dependence of the tendency of PMVs to phase separate was found and analyzed. An advantage of these PMVs is that they contain, at least a large subfraction, of proteins associated with native plasma membranes. We are therefore able to study the partitioning of membrane proteins redistributing between coexisting fluid membrane phases. Trans-membrane proteins, outer leaflet associated peripheral and cytosolic peripheral membrane proteins were examined for their fluid phase partitioning. We suggest our method as a new approach for studying aspects of biological membrane heterogeneity.

**D13 2 Spectroscopic Characterization of ssDNA Brushes** D. Y. PETROVYKH, *University of Maryland, College Park, MD and Naval Research Laboratory, Washington, DC* A. OPDAHL, H. KIMURA-SUDA, M. J. TARLOV, *NIST, Gaithersburg, MD* L. J. WHITMAN, *Naval Research Laboratory, Washington, DC* We use X-ray photoelectron (XPS) and Fourier transform infrared (FTIR) spectroscopies to quantitatively characterize the structure and conformation of single-stranded DNA (ssDNA) brushes on gold surfaces. Self-assembly of these brushes exploits an intrinsic affinity between blocks of adenine nucleotides and gold surfaces. Using brushes of model block oligonucleotides, d(Tm-An), with systematically varied lengths of the thymine and adenine blocks [d(T) and d(A)], we demonstrate that this immobilization strategy enables independent and deterministic control of the grafting density (lateral spacing) and brush conformation. Quantitative analysis of XPS and IR spectroscopic signatures of the model d(Tm-An) brushes confirms that the d(T) blocks extend away from the surface in a brush-like conformation, at lateral spacing 2-3 times larger (grafting density 5-10 times lower) than in analogous films immobilized via standard thiol linkers. The conventional S-Au attachment strategy requires near-saturation grafting densities to adopt this upright conformation, therefore ssDNA immobilization via d(A) blocks offers a unique pathway to achieve a brush-like conformation at low grafting density.

**15:18**
**D13 3 Detection of $\beta$ − Amyloid Peptide Dimer in Solution by Fluorescence Resonance Energy Transfer** JUN HAN, *Department of Chemistry, University of Pennsylvania, Philadelphia, PA 19104* ERWEN MEI, *Regional Laser and Biotechnology Laboratory, University of Pennsylvania, Philadelphia, PA 19104* MEI-PING KUNG, HANK KUNG, *Department of Radiology, University of Pennsylvania, Philadelphia, PA 19104* HAI-LUNG DAI, *Department of Chemistry, University of Pennsylvania, Philadelphia, PA 19104* Studies have suggested that there is a connection between ß-amyloid-derived diffusible ligands (ADDLs), small oligomers formed from clustering of peptides with 39-42 amino acid units, and pathogenicity of Alzheimer's disease. It is believed that the soluble ADDL oligomers eventually coagulate and precipitate into fibrils that cause neurotoxicity. Although there have been studies characterizing the fibrils structure and the large coagulate

formation kinetics, little experimental information exists for the oligomers in the solution phase. We report here the use of fluorescence resonance energy transfer detected through a confocal microscope under single molecule conditions for the detection of the $\beta$-amyloid (1-40) peptide dimer in solution. The structure of the dimer is characterized in terms of the distance of the two N-terminals.

**D13 4 Nanolaser Spectroscopy of Genetically Engineered Yeast: New Tool for a Better Brew?** PAUL L. GOURLEY, JUDY K. HENDRICKS, *Sandia National Laboratories* ROBERT K. NAVIAUX, MICHAEL P. YAFFE, *UC San Diego* A basic function of the cell membrane is to selectively uptake ions or molecules from its environment to concentrate them into the interior. This concentration difference results in an osmostic pressure difference across the membrane. Ultimately, this pressure and its fluctuation from cell to cell will be limited by the availability and fluctuations of the solute concentrations in solution, the extent of inter-cell communication, and the state of respiring intracellular mitochondria that fuel the process. To measure these fluctuations, we have employed a high-speed nanolaser technique that samples the osmotic pressure in individual yeast cells and isolated mitochondria. We analyzed 2 yeast cell strains, normal bakers yeast and a genetically-altered version, that differ only by the presence of mitochondrial DNA. The absence of mitochondrial DNA results in the complete loss of all the mtDNA-encoded proteins and RNAs, and loss of the pigmented, heme-containing cytochromes. These cells have mitochondria, but the mitochondria lack most normal respiratory chain complexes. The frequency distributions in the nanolaser spectra produced by wild-type and modified cells and mitochondria show a striking shift from Gaussian to Poissonian distributions, revealing a powerful novel method for studying statistical physics of yeast.

**15:42**
**D13 5 The Influence of Environment on the Reactivity, Dynamics and Spectroscopy of B12 Coenzymes.*** ROSEANNE SENSION, *University of Michigan* D. AHMASI HARRIS, ELIZABETH CARROLL, ANDREW STICKRATH, Adenosylcobalamin (AdoCbl) dependent enzymes catalyze a variety of chemically difficult reactions that proceed by mechanisms involving organic radicals. In these enzymes radicals are initially generated by homolysis of the cobalt-carbon bond to produce an adenosyl radical and a cob(II)alamin radical. This radical pair may also be generated by optical excitation of the AdoCbl cofactor with visible light. In the work presented here, time-resolved spectroscopic measurements spanning the time range from 10 fs to 10 ns are used to investigate the energetics and dynamics of AdoCbl and other cobalamins as a function of environment. These studies probe the influence of environment on the energy of the low-lying charge transfer states of the cobalamin and on the barriers for dissociation and for recombination of the geminate radical pair. When the AdoCbl coenzyme is bound to the enzyme glutamate mutase, the protein environment is found to stabilize the charge transfer state of AdoCbl relative to observations in water and ethylene glycol. However, the intrinsic rate constant for recombination is only slightly smaller than the rate constant measured in free solution, suggesting the protein does not greatly perturb the ground state stability of the cobalt-carbon bond.

**D13 6 Single molecule views of Nature's nano-machines.**
TAEKJIP HA, *University of Illinois at Urbana-Champaign*

We are interested in the perturbational analysis of biological molecules to better understand their mechanisms. Our redout is the fluorescence signal from individual biomolecules, mainly in the form of single molecule fluorescence resonance energy transfer (FRET). We are pioneering approaches to perturb and control biomolecular conformations using external force (combination of single molecule FRET and optical trap) or other biological motifs (DNA hybridization, G-quadruplex, aptamers). In this talk, I will present out latest results on mapping the conformational energy landscape of the Holliday junction through simultaneous fluorescence and force measurements. In addition, a new nanomechanical device called single molecule nano-metronome will be discussed with an outlook toward controlling protein conformations using nucleic acids motifs.

**D13 7 Time-Resolved Protein Superstructure Disassembly at the Single Particle Level** JASON PUCHALLA, KELLY KRANTZ, JULIE VIEHWEG, HAYS RYE, *Princeton University, Dept. of Mol. Biology* PETER GALAJDA, ROBERT AUSTIN, *Princeton University, Dept. of Physics* Many proteins are able to spontaneously self-organize itin vivo into large, complex structures. These superstructures are often disassembled through the action of key enzymes to fulfill a specific biological role. Yet, the mechanisms of disassembly of such complex structures are poorly understood. We demonstrate the ability to monitor the kinetics of the enzyme assisted disassembly of fluorescently labeled clathrin-coated vesicles in a micro-fluidic flow cell using photon burst and correlation spectroscopy.

**16:42**
**D13 8 Study of DNA uptake locations in single itE. coli cells** C. SHAN XU, L. MEADOW ANDERSON, *Department of Chemistry, University of California at Berkeley* HAW YANG, *Department of Chemistry, University of California, Physical Biosciences Division, Lawrence Berkeley National Laboratory* Artificial gene transfer of bacteria, such as itE. coli, has become the main stream technique in genetic engineering and molecular cell biology studies. In spite of the great improvements in transformation effi-

ciency, some fundamental questions remained to be answered. For instance, what are the DNA uptake channels and how do they form and function under external stimuli? Furthermore, where are these channels located on the cell membrane? Here we report a study aimed at DNA uptake locations in the two widely used gene transformation techniques: electroporation and heat shock. A direct visualization of the settling location of single DNA molecules inside individual itE. coli cells was obtained by fluorescence imaging and spectroscopy. Electroporation and heat shock exhibit two distinct characteristics of DNA uptake locations. A preferential distribution toward cell poles during electroporation is consistent with earlier experiments and previously proposed models. However, the result from heat shock is unanticipated in which the majority of DNA enters the cell near the center. Such observation suggests that uptake channels form preferentially where newly-synthesized membrane is located under cation and low temperature treatment

**D13 9 Real-Time, Nonlinear Optical Probe of Molecular Transport across Living itEscherichia coli Cell Membranes** JIA ZENG, HEATHER ECKENRODE, HAI-LUNG DAI, *Department of Chemistry, University of Pennsylvania, Philadelphia, PA 19104-6323* We will demonstrate for the first time that a nonlinear optical technique- Second Harmonic Generation- can be used to monitor, with real time resolution, the transport of a molecule across the membranes of a living cell. The transport of the hydrophobic ionic dye molecule malachite green (MG) through both membranes of the gram-negative bacteria itEscherichia coli, the outer membrane and the cytoplasmic membrane, has been studied. A kinetic model, assuming that the MG molecules penetrate the bacteria outer membrane through classic porin channels while transport across the cytoplasmic membrane is by diffusion through the phospholipid bilayer, is proposed to account for experimental observations. Analysis of the SHG data enables quantitative determination of the transport rate constants and the adsorption equilibrium constants for the itEscherichia coli cells living in different environments.

**17:06**
**D13 10 Photon-by-Photon Determination of Emission Bursts from Diffusing Single Chromophores** KAI ZHANG, HAW YANG, *University of California at Berkeley* Diffusing-type single molecule experiment is expected to provide rich information such as protein conformational distribution, DNA sequencing, ultrasensitive detection, to name a few. However, its application is greatly limited by the difficulty of extracting the useful information out of the noisy data because of the embedded Poissonian noise. Conventional analysis of such trajectories involves further smoothing the data followed by artificially setting a threshold to distinguish the signal, risking the chance of ignoring the fast transition events along the trajectory. Here we report a statistically robust algorithm, which operates on the trajectory photon by photon, based on the well established sequential test model. A demonstration experiment with the gold nanoparticle diffusing throuth the detection volume shows that our algorithm indeed retrieves more information, relieving the incertitude of artificial placement of bin width and threshold.

**17:18**
**D13 11 Quantum cooperative process in living cells** ROBERT FINKEL, *St. John's University* A model of a quantum cooperative process has accurately accounted for various quantitative observations.[1] That investigation considered chemical oscillations to be generated by generic quantum oscillators producing discrete quanta with well-defined energy and wavelength. The current work extends the theory by postulating that these oscillations arise from repetitive electron transfers in membranes. We find this produces a limit cycle completely consistent with the hypothetical generic oscillators, accurately reproduces the results of microwave irradiation experiments on yeast, and addresses limits for the smallest possible cell sizes. Questions of coherence in cells and implications for molecular information transfers are briefly considered. [1]R.W. Finkel, itJ. Theor. Biol. in press.

## SESSION D15: FOCUS SESSION: ATOMIC TUNNELING, FILMS, NANOSTRUCTURES
**Monday Afternoon, 13 March 2006; 311, Baltimore Convention Center at 14:30**
**Daniel Finkenstadt, Naval Research Laboratory, presiding**

***Invited Papers***

**14:30**
**D15 1 Dephasing of Atomic Tunneling by Nuclear Quadrupoles.**
CHRISTIAN ENSS, *Universität Heidelberg*

A few years ago strong magnetic field effects have been observed in low-temperature dielectric susceptibility measurements and in coherent polarization echo experiments on certain glasses and disordered crystals. The low-temperature dielectric properties of such materials are dominated by atomic tunneling systems. It has been suggested that the surprising magnetic field dependence is caused by tunneling particles with nuclear quadrupole moment. For such systems there exists a coupling of the tunneling motion with the nuclear quadrupole moments experiencing the electric field gradients in the localized states. This coupling gives rise to a quadrupole splitting of the energy levels of the tunneling systems. The applied magnetic field then leads to an additional Zeeman splitting of the nuclear levels. We review the results of polarization echo experiments in magnetic fields and discuss the role of the nuclear spins in such experiments.

**D15 2 Electronic Structures of Quasiperiodically Modulated Thin Ag films** D. EOM, J. SHI, Q. NIU, C.-K. SHIH, *The University of Texas at Austin* When electrons move in crystalline solids, the coherent scattering with the periodic potential enables them to sneak by all ions uninhibited, forming Bloch electrons with their own E vs. k dispersion relationship. This ''Bloch description'' underlies the electronic structures of all crystalline solids. In quasicrystals, however, such a description encounters conceptual difficulties since the Bloch theorem no longer applies. While theoretical investigations showed exotic characteristics such as the Cantor-set energy spectrum early experiments did not reveal such exotic properties. Recent attempt to measure E vs. k relation in a quasicrytal using angle-resolved photoemission revealed free-electron like states. Nevertheless, critical questions remain as how electronic states in a quasiperiodic solid differ from those in a periodic solid. By using low-tempeature scanning tunneling spectroscopy (STS) to probe a quasiperiodically modulated Ag metallic thin film, and by using Fourier analysis, we unravel the influences of individual Fourier components of the scattering potential (periodic vs. quasiperiodic) on the electronic structures.

**15:18**

**D15 3 Theoretical study of the morphology of stretched gold nanowires** FRANCESCA TAVAZZA, ANNE CHAKA, LYLE LEVINE, *National Institute of Standard and Technology* Gold nanowires (NW) have been proposed for a variety of applications, including as intrinsic force standards in the nanoregime. To determine if they are effectively suitable for such an usage, we analyzed the dependence of the evolving NW morphology on different strain rates and directions, using semi-static, density functional (DFT) calculations. The NW under examination are very thin, initially fcc and have the wire axis along the (110) crystallographic orientation. The uniqueness of the necking pathway and the corresponding pre- failure structure are analyzed. The structure evolution and the ultimate length of the NWs are shown to be extremely sensitive to the tensile direction, and possibly on the strain rate as well, indicating that the corresponding energy surface is complex and that any experimental quantitative evaluation of the forces necessary to break the NW should keep parameters such as stretching direction and strain rate under careful control.

**15:30**

**D15 4 Optical Properties of Silver Nanowires** ARIC SANDERS, MARK REED, *Yale University* We report on the propagation of light through silver nanowires mediated by plasmons. Light is observed to couple through crossed nanowires and around soft bends. Farfield Emission is observed from multiple bends in the nanowire. Propagation lengths of several microns are observed through structures less than 100nm in diameter. Light is coupled into silver nanowire fibers with a focused laser beam at both 830nm and 532nm.

**15:42**

**D15 5 Computer Simulation of Copper Nanowires*** EDISON Z. DA SILVA, E.P. AMORIM, *Instituto de Física ''Gleb Wataghin,'' UNICAMP,CP 6165, 13083-970, Campinas - SP, Brazil* A.J.R. DA SILVA, A. FAZZIO, *Instituto de Física, USP, CP 66381, 05315-970, São Paulo - SP, Brazil* Any device to operate, no matter how large or small, needs metallic contacts. The trend towards nano-miniaturization, with the development of nanodevices, will require the understanding of the behavior of metals at the nanoscale, especially gold and copper. Gold has received a lot of attention, while copper, also an important metal has not been studied as much. Recently the dynamical evolution of copper nanowires was observed with high resolution transmission electron microscopy (HRTEM) experiments [1]. We have performed tight binding molecular dynamics (TB-MD) simulations of copper nanowires under stress along some directions until their rupture. The TB-MD calculations have been show to be an excellent tool to study gold nanowires [2]. We present the time evolution of the structures, the formation of defects and the forces sustained by the nanowires. We discuss the possibility of the formation of short linear atomic chains before the breaking. Our results are in good agreement with experimental results. [1] J. C. Gonzalez, et al., Phys. Rev. Lett. **93**, 126103-1 (2004). [2] E. Z. da Silva, A. J. R. da Silva and A. Fazzio, Phys. Rev. Lett. **87**, 256102 (2001).

**D15 6 Measurement of Temperature-Dependent Conductivity and Seebeck Coefficient of Self-assembled Gold Nanoparticle Wires** J.W. SUN, J.B. HUTCHISON, J.A. HOFFMANN, M.E. REEVES, *Department of Physics, The George Washington University* We are exploring the electrical and thermoelectrical properties of wires composed of 12nm diameter gold nanoparticles. The wires are deposited on glass substrates via evaporation-driven vertical colloidal deposition (VCD). We then measure the temperature-dependence of the resistance and thermopower (Seebeck coefficient) between 30 and 120K. We will discuss these measurements in the context of the constituent nanoparticle size and the preparation of the deposited wire; we also make comparisons to similar measurements of bulk gold and gold-iron alloys.

**16:06**

**D15 7 Electrical Detection of Surface Plasmon Resonance in Individual Gold Nanowires** CHRISTOPHER LAFRATTA, *Univeristy of Maryland College Park* DANIEL LIM, JULIET ZNOVENA, *University of Maryland College Park* LINJIE LI, *University of Maryland College Park* JOHN FOURKAS, *University of Maryland College Park* Plasmon absorption in individual gold nanowires has been detected electrically. Gold nanowires, electrochemically synthesized in polycarbonate templates with diameters of 40 nm and lengths of 5 $\mu$m, are connected under an optical microscope using multiphoton absorption polymerization (MAP). MAP uses a prepolymer acrylic based resin and a focused ultrafast laser to stereolithographically pattern with sub-micron resolution. For this experiment, nonconducting acrylate leads are made by MAP to connect to a single gold nanowire. These polymer leads can then be made conductive by surface modification followed by electroless copper enhancement. In this way the resistance of a single nanowire can be measured in a four-probe scheme. The gold rod can then be optically excited near its plasmon absorption peak. The excitation is quickly converted to heat, which is observed as an increase in resistance. This electrically detected plasmon absorption has been found to be linearly dependent on light intensity and is also sensitive to the direction of the polarization with respect to the rod. This non-optical plasmon detection is of basic interest but may be applicable for intrabeam polarization detection or electrical detection of biomolecules.

**16:18**

**D15 8 The Metal-Insulator Transition in Metal Transition Granular Films** N.E. MASSA, *Lanais EFO-CEQUINOR, U.N.L.P., C. C. 962, (1900) La Plata, Argentina* J.C. DENARDIN, *Depto de Fisica, USACH, Santiago, Chile* L. SOCOLOSKY, M. KNOBEL, *Inst de Fisica, UNICAMP, 13083-970, Campinas-SP, Brazil* X.X. ZHANG, *Inst. of Nanoscience and Technology, UST, Hong Kong, China* We study with infrared reflectivity the concentration and temperature dependence of the regime change from metallic to insulating in granular films made of transition metals embedded in $SO_2$. The $TM_x(SO_2)_{1-x}$ (TM=Fe, Ni, Co), ($0.25 \leqslant x \leqslant 0.85$) systems yield spectra typical of conducting oxides where hopping carriers undergo electron-phonon interactions with localization enhanced by nanoparticles and substrate roughness. The distinct Drude component, extending beyond 1.3 eV in the metallic state, undergoes a dramatic change in intensity due to the progressive reduction of carriers critical paths as the transition temperature is reached in the glassy matrix. At the intermediate conducting state for $x \sim 0.55$, about the percolation threshold, a well defined reflectivity edge and band, considered fingerprint for small polarons, emerges in addition to the vibrational bands. A very good agreement is found between the measured optical conductivity and current small polaron models. This, in addition to underlying the importance of polarization effects, provides grounds toward a quantitative microscopic description of transport properties. It also adds toward an understanding of a non-magnetic factor in the magnetoresistance and extraordinary Hall coefficient enhancements.

**16:30**

**D15 9 Jahn-Teller distortion mediated phase separation in spinel thin films** S. PARK, N. LEE, S. GUHA, S-W. CHEONG, *Department of Physics and Astronomy, Rutgers University, Piscataway, NJ 08854, USA* Self-assembled nano-structures have been acquired in various forms, giving significant impacts both on industrial and academic realms. Recently, nano-structures in spinel oxides have been observed in bulk materials by harnessing the Jahn- Teller distortions. Realization of magnetic nano-stuructures could give a breakthrough in the magnetic recording industry. We have grown chemically phase separated spinel films utilizing pulsed laser deposition method, and the inter- relationship between structural and magnetic properties will be discussed.

**16:42**

**D15 10 Synthesis and properties of multiferroic Bi(Fe,Cr)$O_3$ thin films** S. FUJINO, M. MURAKAMI, S.-H. LIM, C. LONG, L. SALAMANCA-RIBA, *Univ. of MD* H. SUGAYA, *Tokyo Inst. of Technology* T. HASEGAWA, *Univ. of Tokyo* S. LOFLAND, *Rowan Univ.* M. WUTTIG, I. TAKEUCHI, *Univ. of MD* Bi based magnetic oxide systems, including $BiFeO_3$ and $BiCrO_3$, have spontaneous magnetization and display charge polarization. Bi(Fe,Cr)$O_3$ system has been predicted to be a new candidate of multiferroic materials. In this study, we will present systematic investigation of multiferroic properties of Bi(Fe,Cr)$O_3$ thin films. The films are fabricated by pulsed laser deposition under various deposition conditions. We have succeeded in synthesizing single phase epitaxial $BiCrO_3$ films on $LaAlO_3$ (001), $SrTiO_3$ (001) and $NdGaO_3$ (110) substrates. It shows weak ferromagnetic behavior with the Curie temperature at 120 K. Pseudo-binary epitaxial thin film composition spreads of $BiFe_{1-x}Cr_xO_3$ have been fabricated using the combinatorial pulsed laser deposition technique in order to investigate their changing multiferroic properties as a function of composition. Their magnetic and dielectric properties mapped using low temperature scanning SQUID microscopy and microwave microscopy will be discussed. This work was supported by ONR N000140110761, ONR N000140410085, NSF DMR 0094265 (CAREER), NSF DMR 0231291, MRSEC DMR-00-0520471, and W. M. Keck Foundation.

**16:54**

**D15 11 Domains in Multiferroic Films** JULIA SLUTSKER, *NIST* A. ARTEMEV, *Carleton University* ALEXANDER ROYTBURD, *University of Maryland* The theory and modeling of equilibrium self-assembling nanostructures based on concept of elastic domains in multiphase epitaxial films successfully explained the morpholgies of $CoFe_2O_4$-$PbTiO_3$ films grown on differently oriented substrates. It is shown that it is possible to design the different nanostructure architectures: cobalt ferrite rods in lead titanate matrix and vise versa as well as differently oriented laminar structures. The elastic interactions between the phases determine the mutual change of order parameters: magnetization and polarization, that allow one to estimate the magneto-electric coupling through the study of constrained polarization and magnetization.

**17:06**

**D15 12 Schottky-Barrier height at Si(001)/PtSi(010) and Si(111)/$ErSi_2$(001) interface** M.K NIRANJAN, S. ZOLLNER, L. KLEINMAN, A.A DEMKOV, According to the Si roadmap (ITRS) one of the most pressing concerns of CMOS technology beyond the 65 nm node is the contact resistances in source/drain regions between the doped silicon and silicide. For the 45 nm node it is expected to amount to one-fourth of the total parasitic resistance. This contribution will clearly only rise as the scaling continues. Thus the roadmap calls for a new contact technology by the 45 nm node. A monosilicide would have an additional advantage in lower Si consumption. The transition from $CoSi_2$ to NiSi is a step in that direction. Physically, the contact resistance comes from a relatively high Schottky-barrier between Si and silicide. For both $CoSi_2$ and NiSi the barrier is about 0.5 eV. Thus, it is desirable to identify new metals or alloys that will have lower Schottky barrier to n- and p- type Si for use in NMOS and PMOS, respectively. In deep submicron regime, PtSi, $ErSi_2$ and NiSi have been shown to be prospective candidates for replacing conventional silicides. We have studied the electronic structure of bulk PtSi and $ErSi_2$ within the framework of density functional theory. We then calculate work functions and surface energies for different surface orientations and come up with plausible interface structures with Si. Our calculated valance band Schottky-barrier height of 0.26 eV at Si(001)/PtSi(010) is in excellent agreement with the experiments. We have, also, calculated the valance band Schottky-barrier height of 0.29 eV at Si(111)/$ErSi_2$(001) interface.

**17:18**

**D15 13 Magnetic Resonance Force Microscopy investigations of a continuous ferromagnetic thin film** J. KIM, *The Ohio State University* T. MEWES, *University of Alabama* F. YANG, *The Ohio State University* P. WIGEN, *The Ohio State University* YU. OBUKHOV, *The Ohio State University* D. PELEKHOV, *The Ohio State University* P. C. HAMMEL, *The Ohio State University* The ferromagnetic resonance of a 50nm thick Permalloy film has been investigated using a magnetic resonance force microscope operated at UHV and 4K. A low boron doped silicon cantilever with a hardmagnetic SmCo tip attached to its end was used to detect the locally excited ferromagnetic resonance in the film. The high coercivity of the tip magnet enables the measurement of FMRFM spectra with the tip magnetization aligned either parallel

or antiparallel to the external magnetic field, while saturating the Permalloy film perpendicular to the film plane. The variation of the spectra as a function of the tip-film separation reveals a bulk resonance and the excitation of spin waves originating where the magnetic resonance condition is locally met. This local resonance may be used to characterize the dynamic properties of ferromagnetic thin film samples with high spatial resolution.

**SESSION D16: FOCUS SESSION: NEGATIVE REFRACTIVE INDEX I**

**14:30**
**D16 1 Single Superconducting Split-Ring Resonator Electrodynamics** MICHAEL C. RICCI, STEVEN M. ANLAGE, *University of Maryland, College Park* In order to create compact metamaterial devices in the microwave frequency range, current designs must be scaled down to smaller dimensions. However, at such scales, normal metal losses dominate, and desirable device properties (*e.g.* negative index of refraction) are lost. We investigate the properties of superconducting Nb metamaterials that do not suffer from these limitations. The experiments are performed in an all-Nb waveguide, with Nb wires and Nb thin film split-ring resonators (SRRs). Transmission experiments performed in vacuum show a narrow, deep notch for a single Nb SRR (quality factor $\sim$ 50,000), and no notch for a Cu resonator of similar dimensions. Adding SRRs increases the notch bandwidth, but decreases the insertion loss of individual resonators. In addition, placing a single superconducting SRR into an array of superconducting wires produces a single negative-index passband 40 dB above the noise floor, with a quality factor of $\sim$ 22,000. Models based on the permeability of individual SRRs and the effective dielectric response of a wire array are used to fit the data. This work is supported by the NSF through Grant No. NSF/ECS-0322844, and the DI Outreach Program.

**D16 2 Experiments on the Goos-Hänchen shift with negative and positive index of refraction materials** NATHAN ORLOFF, MICHAEL RICCI, *Univ. of Maryland, College Park* COLLIN ANDERSON, *Yale University* CHRISTIAN LONG, SUDEEP DUTTA, STEVEN ANLAGE, *Univ. of Maryland, College Park* The negative Goos-Hänchen shift occurs when a beam of radiation having a finite transverse extent undergoes total internal reflection at a positive to negative index of refraction interface, hence the reflected beam experiences a negative lateral shift. This phenomenon has been predicted for materials with a negative index of refraction. We investigate a composite wire and split-ring resonator medium between 8-12 GHz, based on that first implemented by [1]. In addition, we present an experiment to investigate the Goos-Hänchen shift and show preliminary results on transmission, refraction, and total internal reflection. Work supported by NSF/ECS-0322844. **14:54**
**D16 3 Optical properties of Ag nanoparticle arrays: Tuning the plasmon resonance*** J.R. SIMPSON, H.D. DREW, S.H. GUO, R. PHANEUF, *Department of Physics, University of Maryland, College Park, MD 20742 and Laboratory for Physical Sciences, College Park, MD 20740* Potential applications in the optical spectral range of meta-materials displaying negative permittivity and negative permeability has driven recent interest in nanostructured materials. Electromagnetic radiation incident on metallic nanoparticles induces a collective electronic excitation, or plasmon, which results in a detectable optical resonance. We report polarization-dependent transmission measurements of Ag nanoparticle arrays in the near-infrared to visible frequency range. E-beam lithography patterns arrays of nanoparticles from Ag deposited on transparent ITO-glass substrates. The array grid spacing is several hundred nanometers and the nanoparticle thickness and width are approximately 75 nm. We vary the length to provide an in-plane aspect ratio (length to width) from 1 : 1 to 4 : 1. The resonance shifts to lower (higher) energy with increasing aspect ratio for polarizations parallel to the long (short) axis. This work demonstrates the ability to tune optical resonance energies and widths in nanostructured materials with quality factors $Q$ exceeding 10. Additionally, we discuss the effects of radiation damping, carrier scattering, and inhomogeneous broadening on the resonance widths.

**15:06**
**D16 4 Large-Area Infrared Metamaterials using Interferometric Lithography.***
STEVEN BRUECK, *University of New Mexico*

Large area (several $cm^2$) mid- and near-infrared metamaterial samples including analogs to split ring resonators and negative index materials have been fabricated using interferometric lithography and standard integrated circuit fabrication techniques. The split ring resonators are vertical structures with the smallest dimensions defined by deposition rather than by lithography. The negative index material is a Au-$Al_2O_3$-Au stack structure perforated with a 2D hole pattern. Both the amplitude and phase of the transmission and reflectivity are measured with phase-mask, zero-path-length difference, interferometric techniques and the refractive index is deduced by inverting these measurements. A rigorous coupled wave

analysis (RCWA) is in excellent agreement with the measurement. Improvements in the original structure to provide a lower loss and an improved transmission for the structure are presented. Prospects for continued reduction in the loss and an improved figure of merit, [$|\mathrm{Re}(n)|/\mathrm{Im}(n)$], are discussed. Interferometric lithography provides an inexpensive, facile, large-area technology for the fabrication of visible/infrared metamaterials with a 2D array patterning capability extending to as small as 30-nm features.

**15:42**

**D16 5 Zero-n band-gap in 1D periodically layered photonic superlattices*** NICOLAE PANOIU, RICHARD OSGOOD, *Columbia University* SHUANG ZHANG, STEVEN BRUECK, *University of New Mexico* COLUMBIA UNIVERSITY TEAM, UNIVERSITY OF NEW MEXICO TEAM, We demonstrate that photonic superlattices consisting of a periodic distribution of alternating layers of materials with positive and negative index of refraction present a photonic band-gap at a frequency at which the spatial average of the index of refraction is zero (these stop bands are called zero-n band-gaps). We prove that these results can be generalized to two cases, namely i) a superlattice of alternating layers, one layer made of a homogeneous material with positive index of refraction and the other layer consisting of a photonic crystal, with negative index of refraction and ii) a superlattice consisting of alternating photonic crystal slabs, which, have positive and negative index of refraction. We demonstrate that, in both cases, the central frequency of the zero-n band-gap corresponds to the frequency at which the spatial average of the refractive index, taken over the unit supercell, is zero. We also show that, unlike the Bragg gaps, these zero-n band-gaps are invariant to the geometrical scaling of the superlattice or the direction of wave propagation in the superlattice.

**D16 6 Negative Refraction in One-Dimensional Photonic Crystal*** PLARENTA VODO, *Northeastern University* WENTAO LU, *Northeastern University* PATANJALI PARIMI, *Northeastern University* SRINIVAS SRIDHAR, *Northeastern University* We demonstrate experimentally negative refraction of plane waves by a one-dimensional Photonic crystal (PhC) prism at microwave frequencies. The prism was fabricated from a microwave alumina PhC acting as a left-handed metamaterial. Focusing of plane waves from a one-dimensional PhC plano-concave lens is predicted theoretically and realized experimentally. The focal point is observed to move with the radius of curvature of the lens. The measured values of refractive index are in complete agreement with those determined from band structure calculations.

*Work supported by NSF and Hanscom Air Force Lab

**16:06**

**D16 7 Determination of Refractive Indices of Photonic Crystals: Theory and Experiments*** WENTAO LU, SRINIVAS SRIDHAR, *Northeastern University* We develop a method to calculate the refractive indices of photonic crystal based on plane wave expansion. The appearance of surface waves and subwavelength imaging is explained within this frame. Numerical simulations of 1D and 2D crystals are performed to support our theory. Comparisons are presented with experimental results on microwave photonic crystals.

*Work supported by NSF and Hanscom Air Force Lab.

**16:18**

**D16 8 Free space microwave focusing by a negative-index gradient lens** TOM DRISCOLL, PATRICK RYE, DIMITRI BASOV, SIA NEMAT-NASSER, *University California, San Diego* TONY STARR, *Sensormetrix, inc.* DAVID SCHURIG, DAVID SMITH, *Duke University* The complexity of left-handed metamaterials has advanced rapidly to the point where direct applications are now viable. We present a radial gradient-index lens with an index-of-refraction ranging from -2.67(edge) to -0.97(center). Experimentally, we find the lens can produce field intensities at the focus that are greater than that of the incident plane wave. These results are obtained at 10.3 GHz and are in excellent agreement with full-wave simulations. We also discuss the design and construction of this lens - which involved an advanced fabrication technique using conventional printed circuit board technology. This technique offers significant design, mechanical, and cost advantages over other microwave lens constructions.

**16:30**

**D16 9 Dynamical Electric and Magnetic Metamaterial Response at Terahertz Frequencies** WILLIE PADILLA, ANTOINETTE TAYLOR, *Los Alamos National Laboratory* CLARK HIGHSTRETE, MARK LEE, *Sandia National Laboratories* RICHARD AVERITT, *Los Alamos National Laboratory* Utilizing terahertz time domain spectroscopy, we have characterized the electromagnetic response of a planar array of split ring resonators (SRRs) fabricated upon a high resistivity GaAs substrate. The measured frequency dependent magnetic and electric resonances are in excellent agreement with theory and simulation. For two polarizations the SRRs yield negative electric response ($\epsilon < 0$). We demonstrate, for the first time, dynamical control of the electrical response of the SRRs through photoexcitation of free carriers in the substrate. An excited carrier density of $\sim 4 \times 10^{16}\mathrm{cm}^{-3}$ is sufficient to short the gap of the SRRs thereby turning off the electric resonance demonstrating the potential of such structures as terahertz switches. Due to the universality of metamaterial response over many decades of frequency, these results have implications for other regions of the electromagnetic spectrum.

**16:42**

**D16 10 Nanofabricated materials with negative refractive indices at optical wavelengths** WENSHAN CAI, *School of Electrical and Computer Engineering, Purdue University, W. Lafayette, IN 47907* UDAY CHETTIAR, HSIAO-KUAN YUAN, VLADIMIR DRACHEV, ALEXANDER KILDISHEV, ANDREY SARYCHEV, VLADIMIR SHALAEV, The efforts to construct media exhibiting negative refraction have been extended to the optical range. In this work we present examples of structures with negative refraction at optical frequencies, including paired

nanorods arrays and coupled metal strips. The negative refractive indices in such nanofabricated metamaterials result from plasmon resonances for both the electric and magnetic components of light at overlapping wavelength ranges. Simulations and experimental verification of the negative indices are demonstrated. The agreement between simulations and experimental data is excellent, confirming the validity of the proposed structures as negative index materials. Optimization of the parameters of the nanostructure is also discussed.

**16:54**

**D16 11 Negative static dielectric constant in a nano-colloid** JASON SHULMAN, STEPHEN TSUI, FENG CHEN, YUYI XUE, C. W. CHU,* *TcSUH/University of Houston* We have investigated the dielectric properties of assemblies of urea-coated $Ba_{0.8}Rb_{0.4}TiO(C_2O_4)_2$ nanoparticles. The effective dielectric constant, $\varepsilon$', is negative below a certain bias dependent frequency. $\varepsilon$' follows a plasma-like dispersion with an extremely low plasma frequency and damping rate. This dielectric response is linear with bias fields larger than 2.5 kV/mm. Additionally, after a step increase of the electric field, the transient current changes sign and is opposite to the applied field. These two properties rule out electrochemical effects as well as carrier trapping/de-trapping as the source of the negative dielectric constant. More importantly, this latter feature verifies that the static dielectric function, $\varepsilon$'(k, $\omega$=0), is negative. Furthermore, measurements on cold pressed (solid) pellets of the nanoparticles demonstrate that the effect is not due to rearrangement or large scale motion of the particles. In fact, the data suggests that the negative static $\varepsilon$' is correlated to the interfacial conductivity of the nanoparticles.

**D16 12 Scaling Behavior of Dielectric Switching in Nano-assemblies*** FENG CHEN, JASON SHULMAN, STEPHEN TSUI, YUYI XUE, C. W. CHU,† *Texas Center for Superconductivity, University of Houston, Houston, TX 77204-5002* Recently, we have reported a field-induced sign-switch of dielectric constant ($\varepsilon$') for urea-coated $Ba_{0.8}Rb_{0.4}Ti_O(C_2O_4)_2$ nano-particles (U-BRTOCO) in silicone oil and demonstrated that the observed negative $\varepsilon$' is an intrinsic property of the nanoparticle assemblies A systematic study has been subsequently carried out on the switching of $\varepsilon$' under a bias field for U-BRTOCO and other nano-particle assemblies under different conditions. The switching frequency ($\omega_c$) is found to be closely related to the zero-frequency electrical conductivity ($\sigma$(0)) of the assemblies. Such a scaling behavior for different nano-assemblies under various conditions gives us strong insight of the origin of the negative $\varepsilon$'. The possible models such as plasma and 2D electron-gas (2DEG) are compared.

*We thank Prof. W. J. Wen for supplying U-BRTOCO samples.

**17:18**

**D16 13 Magnetic resonances in nano-scale metamaterials*** ZHAO HAO, ALEX LIDDLE, MICHAEL MARTIN, *Lawrence Berkeley National Laboratory* We have designed, fabricated, and optically measured several different kinds of nano-scale metamaterials. We make use e-beam nano-lithography technology at LBNL's Center for X-Ray Optics for fabricating these structures on extremely thin SiN substrates so that they are close to free-standing. Optical properties were measured as a function of incidence angle and polarization. We directly observe a strong magnetic resonance consistent with a negative magnetic permeability in our samples at mid- and near-IR optical frequencies. We will discuss the results in comparison with detailed simulations, and will discuss the electric dipole or quadrupole resonances observed in the samples. Finally, we will report on our progress towards constructing a fully negative index of refraction meta-material.

**D17 1 High Spatial and Temporal Resolution Optical Probes of Ferroelectric Thin Films*** HONGZHOU MA, JEREMY LEVY, *Department of Physics and Astronomy, University of Pittsburgh* MIKE D. BIEGALSKI, DARRELL G. SCHLOM, SUSAN TROLIER-MCKINSTRY, *Department of Materials Science and Engineering, the Pennsylvania State University* WON-JEONG KIM, JAMES S. HORWITZ, *Naval Research Laboratory* Optical probes can provide unique insight into the local ferroelectric properties of thin films. We will describe two techniques that provide sensitive measures of domain structure and dynamics with high spatial and/or temporal resolution: (1) confocal scanning optical microscopy (CSOM), which measures in-plane domain structure of ferroelectric films, and (2) GHz apertureless near-field scanning optical microscopy (GHz-ANSOM) which probes ferroelectric domain dynamics with high spatial resolution ( $<$ 50 nm) and temporal resolution ( $\sim$ ps). The electro-optic effect, measured using CSOM on strained $SrTiO_3$ films, shows clear hysteresis at room temperature, indicating the existence of ferroelectric domains below the diffraction limit. The microwave dynamics of such nanoscale domains can be revealed using GHz-ANSOM.

**D17 2 Domains and Hysteresis Loops in Ferroelectric Thin Films with Metallic and Semiconductor Electrodes** A.M. BRATKOVSKY, *Hewlett-Packard Labs, Palo Alto, California 94304* A.P. LEVANYUK, *UA Madrid, Spain* Detailed thermodynamic description of the ferroelectric (FE) thin films with metallic and semiconductor electrodes is presented. We show that imperfect screening by the electrodes results in uncompensated depolarizing field and leads to a tilt of the hysteresis loops, as observed experimentally. We solve for the domain instability analytically

and find a simple criterion for stability of homogeneously polarized state in thin films with realistic metallic electrodes. In most cases the film breaks into domains, and they can exist in near cubic (perovskite) ferroelectrics down to ''atomic'' thicknesses (one unit cell thick). Domain structures under bias voltage are investigated. In the case of semiconductor electrodes the screening is poor at small values of polarization $P$ and highly nonlinear at larger $P$ close to a spontaneous polarization in the bulk. This formally allows for the ''Batra-like'' jumpwise transition at lowering temperature, which is not observed since it is preempted by domain instability. Additional boundary conditions [1] modify the above behavior, but mainly for a homogeneous state. The unusual phase behavior in cases of symmetric and asymmetric boundary conditions is discussed together with available experimental data. [1] A. M. Bratkovsky and A. P. Levanyuk, Phys. Rev. Lett. **94**, 107601 (2005) and to be published.

**D17 3 Domain Structures in Nano-Toroids and Ultra-Thin Single Crystals.***
MARTY GREGG, *Queen's University Belfast*

Rationalisation of the formation of domain structures, in ferroics of limited dimensions, has been a topic of interest since the 1940's [1], with early work, specifically in ferroelectrics, in the 1950's [2]. Experimental studies at that time primarily involved domain investigations using optical microscopy, on samples down to the order of hundreds of microns. More modern studies, extending domain research into the thin and ultrathin film regime [3], suggest that our understanding of certain aspects of domain behaviour remain relatively unchanged, despite the intervening decades. This might imply that reduction of scales into the nanometre range will not reveal anything new or interesting in ferroelectric domain research. In this talk, we hope to illustrate that this is not the case. We describe results from two recent research programmes on the characterisation of ferroelectric domain structures in single crystal $BaTiO_3$ (BTO) using Scanning Transmission Electron Microscopy. In both studies sample preparation was performed using a Focused Ion Beam Microscope (FIB). In the first study, the domain periodicity has been measured as a function of thickness of parallel-walled BTO slabs from several hundred nanometres down to $\sim$ 50nm. Early work [2] suggested that the domain width should vary as the square root of slab thickness, and this is consistent with our data. However, we find, in plotting data from several works on different ferroelectric materials, with differing surface boundary conditions, across six decades in thickness, that all data lie on the it same parent function, with the itsame constants of proportionality. This is totally unexpected, as the proportionality constants should be material and surface boundary state dependent. We suspect that this reveals fundamental aspects in the physics of ferroelectric domain formation that will be discussed. The second study was motivated by modelling done in 1994 by Gorbatsevich and Kopaev [4] and more recently by Fu and Bellaiche [5] and Naumov, Bellaiche and Fu [6]. Here, the influence of depolarization fields at ferroelectric surfaces were found to create polarization vortex structures when the ferroelectrics were sufficiently small. In toroidal shapes, Gorbatsevich and Kopaev even envisioned ordering of the vortices to produce nanoscale ferroelectric 'solenoids'. We have used the FIB to make toroidal structures and have characterized their domain morphologies. At the time of writing, only conventional domain behaviour has been observed down to scales of the order of $\sim$ 100nm. However, results on smaller scales to be performed over the next few months will be described, as well as the novel imaging techniques we intend to use to probe for the ferroelectric vortices. [1] C. **D17 4 Three perimeter effects in ferroelectric nanostructures**
ANDREAS RUEDIGER, FRANK PETER, RAINER WASER, *Center of Nanoelectronic Systems for Information Technology, Research Center Juelich, Germany* HYSTERETIC OXIDES TEAM, As the lateral size of ferroelectric nanoislands is now well below 50 nm, the question of size effects becomes increasingly relevant. Three independent techniques provided data of pronounced ferroelectric features along the perimeter: impedance spectroscopy [1], piezoelectric force microscopy [2] and pyroelectric current sensing [3]. However, as we can show, all three observations are related to the measurement technique that interferes with the lateral confinement and still there is no direct evidence of a lateral size effect in ferroelectric nanostructures. We discuss some scenarios of further downscaling and possible consequences. [1]M.Dawber, D.J. Jung, J.F. Scott, Perimeter effect in very small ferroelectrics,Appl. Phys. Lett. 82, 436 (2003) [2 ]F. **D17 5 Static Field Anisotropies in Composition-Graded Ferroics** J.V. MANTESE, A.L. MICHELI, N.W. SCHUBRING, *Delphi Research Laboratories* R.W. HAYES, G. SRINIVASAN, *Oakland University* S.P. ALPAY, *University of Connecticut* Compositionally graded ferroelectrics and ferrites are formed as the dielectric and inductive analogues of semiconductor junction devices. The internal, or ''built-in,'' ferroic fields are intrinsic to the

structures and are determined from ferroelectric hysteresis and ferromagnetic resonance microscopy. The dynamic response of the ferroelectric and magnetic analysis graded ferroic devices (GFD's) is determined from quasi-static analysis in terms of the spatially dependent order parameters, the polarization and magnetization, respectively; yielding values for the internal ferroic fields consistent with experimental observations. Our results are extended to the general class of ferroic and other ''smart'' materials via a spatially dependent free energy potential.

**D17 6 Geometry Conditions Affecting Piezoresponse Force Microscopy** FRANK PETER, BERND REICHENBERG, ANDREAS RÜDIGER, KRZYSZTOF SZOT, RAINER WASER, Piezoresponse force microscopy provides valuable insight into the inverse lateral and vertical piezoelectric effect on the nanoscale. When examining ferroelectric grains as opposed to continuous thin films, the measured response is substantially influenced by the topography. Furthermore, a lateral piezoresponse exists in axially symmetric samples. An analysis of the piezoelectric tensor of the material and the radially symmetric electric field applied by the cantilever shows that the lateral as well as the vertical piezoresponse depends on more than one piezoelectric coefficient. This results in an increase of the unexpected lateral response near the perimeter of a grain. Due to the geometry of the cantilever this enhancement is only visible on certain sides of a grain. As a result of a mechanical crosstalk, a part of the lateral signal at the cantilever can be observed in the vertical response.

**16:06**

**D17 7 Calculations of anomalies in properties of relaxor ferroelectric films** MAYA GLINCHUK, EVGENIY ELISEEV, *Institute for Problems of Materials Science, NAS, Kiev, Ukraine* For the first time, we have calculated the properties of thin relaxor ferroelectric films in a framework of random field theory allowing for a misfit strain between the film and a substrate via surface piezoelectric effect, that causes a built-in electric field in the strained films. We demonstrate that this misfit-induced electric field, as well as the random electric fields created by randomly distributed electric dipoles and charged defects, lead to a smearing of ferroelectric phase transition, namely, they wash out a dielectric susceptibility maximum and a spontaneous polarization temperature dependence. As an example, a dependence of an order parameter and the dielectric susceptibility on the film thickness, temperature, and random fields distribution function was obtained. For the first time, we have shown that a frequency dispersion of susceptibility temperature maximum in relaxor thin films obeys modified Vogel-Fulcher law. In the proposed modified Vogel-Fulcher law the freezing temperature and activation energy depend on the film thickness, namely, freezing temperature decreases and activation energy increases with film thickness decrease. The obtained results quantitatively agree with the available experimental data for $PbMg_{1/3}Nb_{2/3}O_3$ relaxor thin films.

**D17 8 Charge pumping and ferroelectricity in the disordered one-dimensional system** CHYH-HONG CHERN, SHIGEKI ONODA, *Spin Superstructure Project, ERATO, and Department of Applied Physics, University of Tokyo, 7-3-1, Hongo, Tokyo 113-8656, Japan* SHUICHI MURAKAMI, NAOTO NAGAOSA, *CREST and Department of Applied Physics, University of Tokyo, 7-3-1, Hongo, Tokyo 113-8656, Japan* We consider the adiabatic charge pumping in the isolated disorder system in one dimension. Different from the Thouless charge pumping, the system has no gap even though all the states are localized, i.e., Anderson Localization. The charge pumping can be done by making a loop adiabatically in the 2- dimensional parameter space $\vec{Q} = (Q_1, Q_2)$ of the Hamiltonian. It is because there are many $\delta$-function- like fluxes distributing over the parameter space with random strength, in sharp contrast to the single $\delta$-function in the pure case. This provides a new and more efficient way of charge pumping. On the other hand, we also consider the situation when system is connected with leads, in which the weakly disordered ferroelectrics will be formulated in the Landauer-Buttiker formalism. In this case, the ''vortex'' structure emerges in the parameter space, which is the origin of the charge transfer for one lead to the other. The vortex core corresponds to the perfect transmittance which can be explained as a resonance tunneling. The time required for the adiabatic charge transfer is also estimated.

**SESSION D18: FOCUS SESSION: CARBON NANOTUBES: SYNTHESIS AND GROWTH II**

**D18 2 Seeded Growth of Single-Walled Carbon Nanotubes from Open-ended SWNT Substrates*** MYUNG JONG KIM, ERIK HAROZ, HONGWEI SHAN, NOLAN NICHILAS, CARTER KITTRELL, *CNL, Rice University* ROBERT WHEELER, TIA BENSON-TOLLE, *Air Force Research Laboratory* YEONWOONG JUNG, DAVID LUZZI, *Dept. of Materials Science and Engineering, University of Pennsylvania* T.J. WAINERDI, *CNL, Rice University and CNI* HOWARD SCHMIDT, ROBERT HAUGE, RICHARD SMALLEY, *CNL, Rice University* We prepared nanoscopically flat open-ended SWNT substrates from SWNT spun fibers by using the focused ion beam cutting technique followed by various etching and clean-

ing schemes or alternatively from vertically aligned SWNT film by flipping over. Deposited catalyst was docked to the open ends of SWNTs, and carbon feedstocks were catalyzed into continued single-walled carbon nanotube growth resembling 1D molecular epitaxy in both the cold wall furnace and the hot wall furnace setups. The data obtained from Raman spectroscopy indicates that the (n, m) structure of the newly grown SWNT was cloned from that of the pre-existing SWNT substrate. Such results lead us to believe that this method will provide us with a means of chirality-controlled SWNTs growth on a macroscopic scale using a fairy general and scalable setup in the future.

**D18 3 Position-Controlled, Rapid Growth of Single-walled Carbon Nanotubes*** D. STYERS-BARNETT, Z. LIU, C. M. ROULEAU, H. CUI, D. B. GEOHEGAN, *Oak Ridge National Lab, Oak Ridge, Tennessee 37831-6031* A. A. PURETZKY, *Department of Materials Science and Engineering, University of Tennessee, Knoxville* 'Fast-heating' chemical vapor deposition (CVD) is a proven approach for the growth of long individual single-walled carbon nanotubes (SWCNTs). However, obtaining insights into how fast a carbon nanotube can grow is still of scientific and technical importance. Here, we describe a new CVD technique to synthesize SWCNTs using laser irradiation as the heat source. By adjusting the laser conditions, the heating time can be precisely controlled. Additionally, using a laser provides localization of the thermal energy, allowing position controlled growth. Temperature profiles of the substrate, measured by fast, in situ optical pyrometry, show controlled heating to CVD temperatures in a few seconds. Growth rate, yield, and diameter distribution of SWCNTs vary dramatically depending on catalysts, feedstock gases, and heating profile parameters, indicating this laser-CVD technique may provide local control over growth conditions and may pave a way for investigating the growth mechanism of 'fast-heating' carbon nanotubes.

**D18 4 Effect of Catalyst Particle Size on CVD Growth of Single-Walled Carbon Nanotubes.** A. HARUTYUNYAN, *Honda Research Institute* E. MORA, J-W. YOO, *Department of Physics The Ohio State University* T. TOKUNE, *Honda Research Institute* A.J. EPSTEIN, *Department of Physics The Ohio State University* HONDA RESEARCH INSTITUTE COLLABORATION, THE OHIO STATE UNIVERSITY COLLABORATION, A series of Fe catalysts with different mean diameter supported on alumina with different molar ratios were studied before and after SWNTs growth by using magnetic and Raman measurements to follow changes on catalyst particle size and its relationship with diameter of grown tubes. After the growth, based on blocking temperature values and Langevin function analysis, it was determined that for all catalysts, an increase and redistribution of particle size occurred. This is explained in terms of particle agglomeration, due to carbon-induced liquefaction accompanied with an increase in catalyst mobility. The free path of supported Fe particles was estimated to be $>$ 2.1nm. For big particles no correlation between catalyst size and nanotube diameter was observed. Analysis of the intensity of Breit-Wigner-Fano line contribution in the Raman G-band revealed that big catalyst particles are more selective to tubes chiralities, and more favorable to the growth of particular metallic tubes.

**D18 5 New empirical potentials between iron nanoparticles and oxide substrates*** AIQIN JIANG, NEHA AWASTHI, ALEKSEY KOLMOGOROV, *Duke University* KIM BOLTON, *Goteborg University, Sweden* ELENA MORA, *Ohio State University* TOSHIO TOKUNE, AVETIK HARUTYUNYAN, *Honda Research Institute, USA* STEFANO CURTAROLO, *Duke University* Interaction of iron catalyst nanoparticles with a substrate may influence nucleation and growth mechanism of carbon nantobutes (CNT) by shifting the melting temperature of the supported iron particles. To account for this effect we have used ab initio calculations to develop empirical potentials between iron nanoparticles and oxide substrates. Simulations have been performed on $Fe/Al_2O_3$ system with $Al_2O_3$ substrate fully relaxed. We have demonstrated that the surface rearrangement effects are significant but can be naturally incorporated into a simple Morse potential, which describes the total nanoparticle-substrate binding. The influence of different substrate surface terminations and positions of Fe layers on the strength of binding are discussed. Potentials for Fe and other oxide substrates are also being evaluated.

**D18 6 Phase diagrams for Fe-C nanoparticles: A Molecular Dynamics Study*** NEHA AWASTHI, AIQIN JIANG, ALEKSEY KOLMOGOROV, *Duke University (USA)* FENG DING, *Rice University (USA)* KIM BOLTON, *Goteborg University (Sweden)* ELENA MORA, *Ohio State University (USA)* TOSHIO TOKUNE, AVETIK HARUTYUNYAN, *Honda Research Institute (USA)* STEFANO CURTAROLO, *Duke University (USA)* Fe nanoparticles are widely used as catalysts for carbon nanotube growth. In order to better understand the melting and phase transition properties of these nanoparticles, molecular dynamics (MD) simulations are performed to determine the melting point of Fe-C nanoparticles ( $\sim$ 1- 4 nm size) as a function of size and carbon concentration. The temperature dependence of the total energy and the Lindemann index characterize the melting of nanoparticles. For free (unsupported) Fe-C clusters, it is observed that the eutectic point (in the phase diagram) shifts with nanoparticle size. We have investigated how the presence of a substrate affects the melting process of the Fe-C nanoparticles.

**D18 7 Carbon Nanotube Growth Under Applied Pressure: Mechanical Energy Output and Control of Film Structure** A.J. HART, A. SLOCUM, *Dept. of Mechanical Engr., MIT* We measure the force which can be exerted by a film of vertically-aligned carbon nanotubes (CNTs) as it grows by thermal CVD. The thickness of the film measured after a growth duration of 15 minutes decreases in an approximately linear fashion with the logarithm of pressure which is applied by placing a tungsten weight on the substrate prior to growth. With increasing pressure, the internal structure of the film changes from well-aligned, to less-aligned with bending and possible single-mode buckling of the CNTs, to predominately collapsed in an ''accordion'' pattern having a spa-

tial wavelength of 0.1-1 $\mu$m. While the mechanical energy exerted is significantly less than major energetic steps in the growth reaction, a growing CNT film can lift tens of thousands of times its own weight. The equivalent volumetric energy density of $2.4\times 10^4$ J/m$^3$ is comparable to muscle. We utilize this principle to fabricate CNT structures which grow to conform to the shape of an etched silicon template, which is clamped against the growth substrate. This technique surpasses traditional methods using two-dimensional catalyst patterns, as it enables fabrication of CNT structures having arbitrarily sloped surfaces, and does not require catalyst patterning. CNT films and structures having controlled density and conformation, such as fabricated by changing the pressure applied during growth, will be useful for applications including electrochemical energy storage and fluid filtration, and as scaffolds for biological materials.

**15:54**

**D18 8 Laser Irradiation Pretreatment Effects on Catalyst-Coated Silicon and Subsequent CVD Nanotube Growth*** C.M. ROULEAU, G. ERES, H. CUI, D.B. GEOHEGAN, *Condensed Matter Sciences Div., Oak Ridge National Laboratory* I.N. IVANOV, A.A. PURETZKY, *Dept. of Mat. Sci. and Engr., Univ. of Tennessee* Developing methods for directed growth of nanotube arrays is important for many nanotube-based applications. Although we are currently growing mm-lengths of vertically-aligned nanotube arrays (VANTAs) from e-beam evaporated catalyst films, further enhancement of length, rate, and density are desired. One promising approach is catalyst modification using laser irradiation. Results are presented on the effects of pulsed KrF laser irradiation prior to chemical vapor deposition of VANTAs. Under typical conditions, a single laser shot was directed at a catalyst coated Si wafer to produce a well-defined laser affected zone. Fluences that ranged from 0.5 to 1.5 J/cm$^2$ were employed. In-situ videography was used to study VANTA growth rate in, and adjacent to, the laser affected zone. Atomic force microscopy was used to characterize catalyst surfaces prior to, and following, laser irradiation. The results show that the growth rates for VANTAs within the affected region improved remarkably. The efficacy of this technique in producing changes in VANTA length are shown.

**D18 9 Large-Scale 'Surface-Programmed Assembly' of Carbon Nanotube-Based Biosensors*** DONG JOON LEE, BYUNG YANG LEE, JIWOON IM, MINBAEK LEE, SEUNGHUN HONG, *School of Physics, Seoul National University, Seoul, Korea* The unique electrical properties of single-wall carbon nanotubes (swCNT) have generated a huge amount of research on nanoelectronic devices and nanosensors. However, a lack of mass-production method of such devices has been holding back their practical applications. Herein, we present a method to assemble a large scale array of swCNT-based biosensors. In this method, self-assembled monolayer patterns direct the 'selective assembly' and 'alignment' of swCNTs onto substrates in the swCNT solution without relying on any externals forces. Using this method combined with microfabrication, we successfully demonstrated the fabrication of 256 x 256 swCNT-junction array on transparent glass substrates. Furthermore, by immobilizing glucose oxidase or L-glutamate oxidase on the CNT junctions, we fabricated swCNT-based biosensors for real-time detection of glucose or L-glutamate, respectively.

**D18 10 A biomimetic functionalization approach to integration of carbon nanoutbes into biological systems** XING CHEN, UN CHONG TAM, CAROLYN BERTOZZI, ALEX ZETTL, *Departments of Chemistry and Physics, University of California, Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory* Due to their remarkable structural, electrical, and mechanical properties, carbon nanotubes (CNTs) have potential applications in biology ranging from imaging and tissue engineering. To realize these applications, however, new strategies for controlling the interaction between CNTs and biological systems such as proteins and cells are required. Here we describe a biomimetic approach to functionalize CNTs and therefore render them biocompatibility in order to facilitate their integration into biological systems. CNTs were coated with synthetic gycopolymers that mimic cell surface mucin gycoproteins. The functionalized CNTs were soluble in water, resisted non-specific protein binding and bound specifically to biomolecules. The coated CNTs could then be integrated onto mammalian cell surface by virtue of glycan-receptor interactions. Furthermore, the functionalized CNTs are non-toxic to cells. This strategy offers new opportunities for development of biosensor to probe biological processes. References: 1. X. Chen, G. S. Lee, A. Zettl, C. R. Bertozzi, Angewandte Chemie-International Edition **43**, 6111 (2004). 2. X. Chen, U. C. Tam, J. L. Czlapanski, G. S. Lee, D. Rabuka, A. Zettl, C. R. Bertozzi, submitted.

**16:30**

**D18 11 Temperature stability of ferritin as a catalyst for Carbon nanotube growth** RICHARD VANFLEET, MARK ESTY, ROBERT DAVIS, *Brigham Young University* In Carbon nanotubes grown with thermal CVD the distribution of tube diameters is dependant upon the growth catalyst. Use of biologically derived catalysts particles have been explored with the hope of narrower diameter distributions resulting from the tight distribution of catalyst particle diameters. Ferritin is the iron storage system in biological systems and consists of a protein shell with an iron hydroxide core. Previous use of catalyst particles generated from ferritin has not consistently resulted in narrow nanotube size distributions. To explore this inconsistency we have studied the particle distribution and temperature stability of surface deposited ferritin on various substrates by TEM. The effects of common substrates (Carbon, $SiO_2$ and $Si_3N_4$) on particle densities will be reported. We removed the protein shell with either a low temperature oxygen plasma or a high temperature anneal. With plasma removal of the protein shell the initial particle size and spacing distribution can be maintained at temperatures up to 600 C.

**16:42**

**D18 12 The Effect of Atomic Hydrogen on the Growth of Single-Walled Carbon Nanotubes** ROBERT HAUGE, *Department of Chemistry and Carbon Nanotechnology Laboratory, Rice University* YA-QIONG XU, *Department of Electrical and Computer Engineering and Carbon Nanotechnology Laboratory, Rice University* KUNAL SHAH, *Department of Chemistry and Carbon Nanotechnology Laboratory, Rice Univeristy* MYUNG KIM, *Department of Physics and Carbon Nanotechnology Laboratory,*

*Rice University* RICHARD SMALLEY,* *Department of Chemistry and Carbon Nanotechnology Laboratory, Rice University* The role of atomic hydrogen generated in situ with a hot filament has been studied with respect its effects on single-walled carbon nanotube (SWNT) etching and growth. SWNT growth has been studied for both random new surface growth and organized new vertical growth of SWNTs. Its effects on continued growth of SWNT seeds will also be reported. Comparisons will be made to previous studies of SWNT growth in the presence of atomic hydrogen.

**D18 13 Ultra-high-yield growth of vertical single-walled carbon nanotubes** GUANGYU ZHANG, DAVID MANN, LI ZHANG, *Stanford University* ALI JAVEY, YIMING LI, ERHAN YENILMEZ, QIAN WANG, HONGJIE DAI, *Stanford University* JAMES MCVITTIE COLLABORATION, YOSHIO NISHI COLLABORATION, JAMES GIBBONS COLLABORATION, An oxygen-assisted hydrocarbon chemical vapor deposition method is developed to afford large-scale, highly reproducible, ultra-high-yield growth of vertical single-walled carbon nanotubes. It is revealed that reactive hydrogen species, inevitable in hydrocarbon-based growth, are damaging to the formation of sp2-like SWNTs in a diameter-dependent manner. The addition of oxygen scavenges H species and provides a powerful control over the C/H ratio to favor SWNT growth. The revelation of the roles played by hydrogen and oxygen leads to a unified and universal optimum-growth condition for SWNTs. Further, a versatile method is developed to form V-SWNT films on any substrate, lifting a major substrate-type limitation for aligned SWNTs.

**D18 15 In situ Optical Monitoring and Modeling of Vertically-Aligned Carbon Nanotube Array Growth During Chemical Vapor Deposition*** A. A. PURETZKY, D. B. GEOHEGAN, H. CUI, G. ERES, I. N. IVANOV, *Condensed Matter Sciences Division, Oak Ridge National Laboratory, and Dep. of Mat. Sci. and Eng., Univ. of Tennessee* A detailed experimental study of vertically aligned carbon nanotube array (VANTAs) growth by chemical vapor deposition (CVD) based on time-resolved reflectivity and direct remote microscope imaging as a diagnostic to measure and control the length of VANTAs in situ was performed. The VANTA growth was investigated between 500 [r]C and 900 [r]C on Si substrates with different evaporated multilayer catalysts and different feedstock gases. Nanotube lengths were controlled by rapid evacuation of the chamber. A kinetic model was developed to explain the observed growth kinetics, to discuss the main processes responsible for the growth of VANTAs, and to predict optimal growth conditions for single-wall carbon nanotube (SWNT) arrays. High quality VANTAs containing SWNTs were synthesized and characterized using Raman Spectroscopy.

*This research was sponsored by the U.S. Department of Energy under contract DE-AC05-00OR22725 with the Oak Ridge National Laboratory, managed by UT-Battelle.

## SESSION D19: FOCUS SESSION: SEMICONDUCTOR SPIN INJECTION AND DETECTION

**14:30**

**D19 1 Onsager relations and the detection of current-induced spins by Ferromagnetic contacts** INANC ADAGIDELI, *University of British Columbia* The recent prediction of intrinsic spin Hall currents raised many questions about methods of detection. We focus on the theoretical issues related to the detection of spin currents and accumulations via ferromagnetic contacts. Along the way, based on Onsager-like relations for the conductance, we show the unfeasibility of detecting spin current from a non-magnetic conductor in a two probe geometry within linear response. It is nevertheless possible to detect spin current in a four probe geometry, in which the spin current flowing into the ferromagnet leads to a potential difference between the Hall contacts. We calculate the Hall conductivity and compare this effect to the Anomalous Hall effect. Work done in collaboration with G.E.W. Bauer and B.I. Halperin

**14:42**

**D19 2 Low temperature annealing and spin injection in Fe/AlGaAs Spin-LEDs** A.T. HANBICKI, G. KIOSEOGLOU, R. GOSWAMI, T.J. ZEGA, C.H. LI, R.M. STROUD, G. SPANOS, B.T. JONKER, *Naval Research Laboratory* With the Fe/AlGaAs/GaAs spin-LED system, it is now routine to obtain electron spin polarizations of up to 32% in the GaAs quantum well. Because the nature of the interface between a magnetic contact and a semiconductor is expected to influence the spin-injection efficiency we have undertaken an annealing study to isolate the role of the Fe/AlGaAs interface on the overall spin injection efficiency. Optimized annealing can improve the measured spin polarization, therefore multiple pieces of a single sample can be annealed to generate a systematic dataset. Enhancement in polarization is seen with anneals as low as 175°C, and the maximum increase in po-

larization occurs for anneals above 200°C. Upon annealing, there is a net gain in measured spin polarizations of 8 to 10 percentage points independent of the starting value. Details on changes in parameters affected by annealing such as the magnetization, polarization, I-V characteristics, and interface structure will be presented. The role of the interface on changes in these parameters will be discussed. This work was supported by the DARPA SpinS program and ONR.

**14:54**

**D19 3 Spin Injection from Fe and FeGa into side-emitting GaAs spin LEDs** G. KIOSEOGLOU, O.M.J VAN 'T ERVE, A.T. HANBICKI, C.H. LI, B.T. JONKER, *Naval Research Laboratory, Washington DC* Most of the spin LEDs used as spin detectors are of the surface type. In this type of LEDs, using Fe as spin polarized source, electron spin polarizations up to 40 % have been reported. Since Fe has its magnetization easy axis in the substrate plane, a large magnetic field B (2.5 tesla) along the surface normal is required to saturate the magnetization. A side-emission geometry, on the other hand, enables magnetic switching fields of $\sim$ 100 Oe, a much more practical range for applications. We present a study of electrical spin injection from Fe and FeGa into side-emitting GaAs spin LEDs in which the applied magnetic field is parallel to electroluminescence emitted from the cleaved side. Several samples with different quantum well (QW) widths were investigated. The optical polarization for the 100Å QW spin LED is zero, as expected due to hole spin orientation. For wider QWs, the confinement energy diminishes and the magnetic field rather than the confinement defines the quantization axis. An optical circular polarization P = 6 % is measured for the 1000 Å QW LED which corresponds to an electron spin polarization of 12 %. The non-volatile character of the side-emitting spin LED will be also discussed using FeGa as a spin injector. This work was supported by DARPA and ONR.

**D19 4 Atomic structure of the interface between Fe and AlGaAs and its impact on spin transport** THOMAS ZEGA, AUBREY HANBICKI, STEVEN ERWIN, IGOR ZUTIC,* GEORGE KIOSEOGLOU, CONNIE LI, BEREND JONKER, RHONDA STROUD, *Materials Science and Technology Division, Naval Research Laboratory, Washington, D.C. 20375* We combined density-functional theory (DFT) with experimental- and simulated- transmission-electron-microscope (TEM) imaging to determine the atomic structure of the interface between Fe and AlGaAs in light-emitting diodes (LEDs) used to investigate the transport of spin-polarized electrons. We show that a 44% increase in the spin-injection efficiency occurs after a low-temperature anneal, which produces an interface consisting of a single atomic plane of alternating Fe and As atoms. Our results provide the structural information required to develop accurate models of charge transport and spin injection at complex interfaces between dissimilar materials.

**D19 5 Resonant X-Ray Emission investigation of Fe/GaAs Spin Devices** JESSICA MCCHESNEY, *Montana State Universit and ALS* C. ADELMANN, *University of Minnesota* PER-ANDERS GLANS, K.E. SMITH, *Boston University* The ability to produced spin polarized electrons has important consequences to electronics, as we know it. One such spintronics system is Fe on GaAs. Fluorescence measurements, using synchrotron radiation, were used to probe the electronic structure of the Fe at the interface of a working device structure. These ferromagnetic-semiconductor heterostructures were grown via molecular beam epitaxity. Absorption spectroscopy (NEXAFS) and energy-resolved fluorescence (RIXS) both on and off resonance were done on the Fe L-edge. Subtle differences between samples with differing degrees of spin polarization were observed. These differences are discussed in terms of bonding at the interface. Supported by ONR and DOE.

**D19 6 Molecular Beam Epitaxy of $Fe_3Ga/Ga_{1-x}Al_xAs$ Heterostructures: Growth, Properties and Spin Transport** C. J. PALMSTRØM, C. ADELMANN, X. LOU, S. K. SRIVASTAVA, P. A. CROWELL, *University of Minnesota* Single crystal $Fe_3Ga$ thin films have been grown on $Ga_{1-x}Al_xAs$ (001) by molecular beam epitaxy. The films are found to be pseudomorphic on $Ga_{1-x}Al_xAs$ and grow in a tetragonally-distorted Heusler-like $D0_3$ crystal structure. The $Fe_3Ga$ films are ferromagnetic above room temperature with a saturation magnetization of 1200 emu/cm$^3$. They exhibit a perpendicular magnetic anisotropy due to the strain-induced tetragonal distortion. Rutherford backscattering spectrometry finds no interfacial reactions of $Fe_3Ga/GaAs$ heterostructures, suggesting that $Fe_3Ga$ is thermally stable on GaAs. Spin injection from $Fe_3Ga$ into GaAs has been assessed by using $Fe_3Ga/Ga_{1-x}Al_xAs$ spin light-emitting diode (LED) structures. A steady-state spin polarization of 20% is obtained at 2K. The bias dependence of spin injection is found to be very similar to that of $Fe/Ga_{1-x}Al_xAs$ spin LEDs [1]. This work was supported in part by ONR and NSF-MRSEC. [1] C. Adelmann itet al., Phys. Rev. B **71**, 121301 (2005).

**D19 7 Imaging Spin Injection and Accumulation in Lateral Ferromagnet/Semiconductor Devices.***
PAUL A. CROWELL, *University of Minnesota*

We have directly imaged electrical spin injection and accumulation in the GaAs channel of a lateral spin transport device.† The ferromagnetic source and drain tunnel-barrier contacts at each end of the channel are epitaxial Fe Schottky barriers separated by a distance of 300 $\mu$m, which is much longer than the spin diffusion length. Emission of majority-spin electrons from the Fe source contact is observed using scanning Kerr microscopy. A majority spin polarization in the channel is also detected near the drain electrode, and we show that this accumulation is due to a spin current flowing away from the drain, against the unpolarized incident electron current. This result implies that the transmission of electrons through the forward-biased Schottky barrier is spin-sensitive. This is confirmed by demonstrating that the electrical

conductance of the device can be modulated by controlling the spin orientation of optically injected electrons flowing through the drain. These experiments are conducted in a geometry sensitive only to spin precession and allow for detailed modeling of spin transport in the channel. We show how this approach can be used to detect the spin accumulation at the drain electrode using purely electrical means. †S. A. Crooker *et al.*, Science **309**, 2191 (2005).

**D19 8 Electrical Detection of Spin Accumulation at a Ferromagnet-Semiconductor Interface** X. LOU, C. ADELMANN, *University of Minnesota* M. FURIS, S.A. CROOKER, *Los Alamos National Laboratory* C.J. PALMSTRØM, P.A. CROWELL, *University of Minnesota* We report a direct electrical transport measurement of spin accumulation in epitaxial Fe/GaAs heterostructures. This result is obtained in lateral transport devices consisting of two Fe Schottky tunnel barriers at the opposite ends of a lightly *n*- doped GaAs channel. Polarized spin accumulates near the forward- biased GaAs/Fe Schottky interface, resulting in an additional voltage that is observed between the channel and the ferromagnetic drain contact. We establish that the spin accumulation, which can also be observed with Kerr microscopy, occurs when unpolarized electrons are incident on the interface. The voltage due to the electron spin accumulation is suppressed in a small transverse magnetic field as a result of precession. The width of the voltage peak is determined by a combination of spin diffusion and relaxation and can be modeled accurately using parameters determined from transport and optical experiments. These results demonstrate that Fe/GaAs Schottky barriers can be used as electrical spin detectors as well as injectors. This work was supported by DARPA, ONR, NSF- MRSEC, and LANL.

**D19 9 Scanning Kerr Rotation Microscopy of Lateral Spin Transport Devices** M. FURIS, D.L. SMITH, S.A. CROOKER, *Los Alamos National Laboratory, New Mexico* X. LOU, C. ADELMANN, C.J. PALMSTRØM, P.A. CROWELL, *University of Minnesota, Minneapolis* Scanning Kerr-rotation microscopy is employed to image electrical spin injection and accumulation in the GaAs channel of lateral spin transport devices having ferromagnetic Fe/GaAs Schottky barrier source and drain contacts [1]. Because electrically-injected spins are initially oriented in the $xy$ sample plane ($S_0 \| \hat{x}$), we measure the Kerr rotation ($\theta_K \propto S_z$) as a function of small in- plane magnetic field ($B_y$). We specifically investigate how these ''Hanle curves'' vary across a series of devices with systematically increasing electron density $n_e$ in the n-type GaAs channel ($2 \times 10^{16}\ \mathrm{cm}^{-3} < n_e < 3 \times 10^{17}\ \mathrm{cm}^{-3}$). The width of the Hanle curves near the source contact increases with $n_e$, reflecting the decreasing electron spin lifetime. The amplitude of the Hanle curves (a measure of the spin polarization) decays on a lengthscale related to the $n_e$-dependent spin diffusion constant, lifetime, and mobility. [1] S.A. Crooker, M. Furis, X. Lou, C. Adelmann, D.L. Smith, C.J. Palmstrøm, P.A. Crowell, Science **309**, 2191 (2005).

**D19 10 Complete non-equilibrium spin polarization of electrons in degenerate semiconductors** A. G. PETUKHOV, *Physics Department, South Dakota School of Mines and Technology, Rapid City, SD* V. V. OSIPOV, V. N. SMELYANSKIY, *NASA Ames Research Center, Moffett Field, CA* We show that spin polarization of electrons in nonmagnetic degenerate semiconductors near specially tailored forward- biased ferromagnet-semiconductor junctions can achieve 100%. This effect is realized even at moderate spin polarization of the interfacial contact resistance. Our conclusions are based on detailed analysis of non-linear spin diffusion equation with realistic boundary conditions. The effect of complete spin extraction occurs at relatively strong electric fields and arises from a reduction of spin penetration length due to the drift of electrons from a semiconductor towards the spin- selective tunnel junction. We further demonstrate that non- equilibrium electrons in thin nonmagnetic semiconductor layers can be almost fully spin polarized by means of simultaneous electrical spin injection and extraction. The complete spin polarization is achieved if the thin layer is placed between two ferromagnetic metal contacts with moderate spin injection coefficients and antiparallel magnetizations. The sign of the spin polarization is determined by the direction of the current. Applications of this effect in spintronics and quantum information processing are discussed.

**D19 11 Ballistic spin injection spectroscopy of a (Ga,Mn)As spin Esaki diode** MAKOTO KOHDA, *Laboratory for Nanoelectronics and Spintronics, RIEC, Tohoku Univ. Japan* TOMOHIRO KITA, *Semiconductor Spintronics Project, ERATO, JST, and Laboratory for Nanoelectronics and Spintronics, RIEC, Tohoku Univ., Japan* YUZO OHNO, *Laboratory for Nanoelectronics and Spintronics, RIEC, Tohoku Univ., and CREST, JST, Japan* FUMIHIRO MATSUKURA, HIDEO OHNO, *Laboratory for Nanoelectronics and Spintronics, RIEC, Tohoku Univ. and Semiconductor Spintronics Project, ERATO, JST, Japan* A p-type ferromagnetic semiconductor (Ga,Mn)As is one of the promising materials for spin injector by interband tunneling [1]. In this work, we investigated injection of spin-polarized electrons in a (Ga,Mn)As/n$^+$-GaAs Esaki diode (ED) by using a three-terminal device integrating a (Ga,Mn)As ED and a light emitting diode (LED), which allows us to apply bias voltages to the ED and LED independently. Electroluminescence polarization ($P_{\mathrm{EL}}$) from the LED was measured under the Faraday configuration as a function of bias voltages. The maximum $P_{\mathrm{EL}}$ of 32.4% was observed when the valence electrons near the Fermi energy of (Ga,Mn)As are ballistically injected into the LED. The experimental results proved high spin polarization of valence electrons ( $>$ 85%) for 100 meV below the Fermi energy of (Ga,Mn)As. [1] M. Kohda et al., Jpn. J. Appl. Phys. **D19 12 Electrical Spin Injection into Two Dimensional Electron Gas.*** JONGHWA EOM, *Department of Physics, Sejong University, Korea* HYUN CHEOL KOO, DONGHWA JUNG, HYUNJUNG YI, JOONYEON CHANG, JAE BEOM KO, SUKHEE HAN, *Nano Device Research Center, Korea Institute of Science and Technology, Korea* While electrical spin injection has been observed in a variety of metal films, the signal of the electrical spin injection into semiconductors has been hardly observed. We have overcome the difficulties of spin injection by developing a well-controlled interface treatment between the ferromagnetic films and the InAs semiconductor surface. We have found the evidence of electrical spin injection and accumulation in permalloy(Py)/InAs 2DEG/permalloy(Py) lateral devices. Ferromagnetic metal electrodes with different aspect ratio being separated by various separations were fabricated on top of the InAs 2DEG channels. Our multi-terminal geometry allows us to measure non-local spin valve effect as well as local spin valve effect. In the non-local spin valve measurement, we were able to completely isolate the spin valve signal from other spurious effects and observed clear spin accumulation signals. Based on the spin accumulation signal depending on the channel length, we have evaluated the spin relaxation length in the InAs based 2DEG.

**D20 2 Ferroelectricity induced by acentric spin-density waves in YMn2O5** GRAEME R. BLAKE, *ISIS Facility, Rutherford Appleton Laboratory* LAURENT C. CHAPON, *ISIS Facility, Rutherford Appleton Laboratory, UK* PAOLO G. RADAELLI, *ISIS Facility, Rutherford Appleton Laboratory, UK* S. PARK, *Rutgers University, USA* S-W. CHEONG, *Rutgers University, USA* The commensurate and incommensurate magnetic structures of the magnetoelectric system $YMn_2O_5$, as determined from neutron diffraction, were found to be spin-density waves lacking a global center of symmetry. We propose a model, based on a simple magneto-elastic coupling to the lattice, which enables us to predict the polarization based entirely on the observed magnetic structure. Our data accurately reproduce the temperature-dependence of the spontaneous polarization, in particular its sign reversal at the commensurate-incommensurate transition.

**D20 3 X-ray and neutron scattering studies of the magnetoelectric $DyMn_2O_5$** V. KIRYUKHIN, A. BORISSOV, S-W. CHEONG, *Rutgers University* W. RATCLIFF II, S.-H. LEE, *NIST* Magnetic phase diagram of magnetoelectric $DyMn_2O_5$ is established using neutron and magnetic x-ray scattering. The magnetic origin of the complex dielectric anomalies in this material is revealed. New diffraction peaks arising due to structural distortion at low temperatures are found and analyzed in the framework of the existing models of the ferroelectric state. Effects of an applied electric field on the magnetic structure are discussed.

**15:06**

**D20 4 Structural anomalies at the magnetic and ferroelectric transitions in $RMn_2O_5$*** B. LORENZ, C.R. DELA CRUZ, F. YEN, Y.Y. SUN, C.W. CHU,† *Dept. of Physics, University of Houston* S. PARK, S-W. CHEONG, *Dept. of Physics and Astronomy and RCEM, Rutgers University* Multiferroic $RMn_2O_5$ (R =rare earth, Y), have attracted significant attention because of their magneto-electric properties giving rise to complex phase diagrams and novel phenomena such as magnetic control of ferroelectric polarization and giant magneto-dielectric effects. In understanding their ferroelectricity and magneto-electric properties the magneto-elastic lattice distortions at the phase transitions are assumed to play a key role. Such distortions are difficult to detect by x-ray or neutron scattering experiments due to the limited resolution. Employing high-precision capacitance dilatometry, we show the existence of distinct, anisotropic lattice anomalies in $RMn_2O_5$ (R=Ho, Tb, Dy) at all magnetic and ferroelectric phase transitions as function of temperature and magnetic fields. These data provide unambiguous evidence for strong magneto-elastic coupling in multiferroic $RMn_2O_5$.

**D20 5 The Pressure Effect on the Ferroelectricity in Multiferroic $R$Mn$_2$O$_5$ ($R$=Tb, Dy, Ho)** CLARINA DELA CRUZ, BERND LORENZ, CHING-WU CHU, *Dept. of Physics and TCSUH, University of Houston* SOON YONG PARK, SANG-WOOK CHEONG, *Dept. of Physics and Astronomy and RCEM, Rutgers University* MARIN GOSPODINOV, *Inst. of Solid State Physics, Bulgarian Academy of Sciences* The effect of isotropic pressure (**P**) up to 1.7 GPa on the magnetic and ferroelectric phase diagram of $R$Mn$_2$O$_5$ ($R$=Tb, Dy, Ho) is investigated. Distinctive anomalies of the *b*-axis dielectric constant identifying the critical temperatures for the various magnetic and ferroelectric transitions are monitored as a function of **P** and the temperature-pressure phase diagram of multiferroic $R$Mn$_2$O$_5$ was constructed. The magnetic and ferroelectric orders are stabilized under pressure and their respective onset temperatures increase with **P**. Most notably, the step-like change of the dielectric constant at lower temperatures ($T_{C2}$) that is associated with a drop in the ferroelectric polarization is suddenly quenched upon passing a critical pressure. These results suggest that above the critical pressure the ferroelectric polarization is restored below $T_{C2}$ and the ferroelectric phase in RMn$_2$O$_5$ is stabilized and extends to the lowest temperatures. *also at LBNL, Berkeley and HKUST, Hong Kong

**15:30**

**D20 6 High Magnetic Field Investigations of Multiferroic RMn2O5 (R=Tb, Dy, Bi, and Y)** KEE HOON KIM, S. Y. HAAM, J. W. KIM, Y. S. OH, *Seoul National University* N. HUR, S. PARK, S.-W. CHEONG, *Rutgers University* P. A. SHARMA, N. HARRISON, A. MIGLIORI, *NHMFL, Los Alamos National Laboratory* We have systematically investigated electric/magnetic phase diagram of a series of multiferroic crystals RMn2O5 (R =Tb, Dy, Bi, and Y) from dielectric constant, electric polarization, and magnetization measurements under intense magnetic fields up to 45 tesla by use of various static and pulsed magnets. Comparative studies of the phase diagram reveal several unprecedented findings: (1) phase evolution of the incommensurate antiferromagnetic Mn d spin ordering and related magneto-dielectric effects up to 33 T, (2) a new high field phase coupled to an incommensurate Mn d spin ordering appearing around 20 T, (3) phase evolution coupled to rare earth f-spin ordering and resultant polarization changes, and (4) significant modification of phase boundaries due to strong d-f spin interaction. Based on the determined electric/magnetic phase diagram, we also discuss how dielectric constant and polarization can be dependent on the commensurate and incommensurate magnetic phases under magnetic field to result in the observed large magneto-dielectric effects.

**D20 7 Phonon anisotropy in $ZnCr_2O_4$ from first principles** CRAIG J. FENNIE, *RutgersUniversity* KARIN M. RABE, The geometrically frustrated spinel $ZnCr_2O_4$ undergoes a cubic-to-tetragonal structural transition simultaneously as it enters a Neel state at $T_c$=12.5K. A recent experiment[1] using infrared spectroscopy measured a large splitting of an optical phonon frequency at $T_c$; it was argued that this splitting was due to a direct spin-phonon coupling. Here, we describe a first-principles study of the zone-center optical phonons in metrically cubic $ZnCr_2O_4$, with the LSDA+U as implemented in VASP. For selected collinear magnetically ordered structures, the influence of magnetic order on the phonon frequencies is identified, confirming the recent experimental results. The origin of this large phonon anisotropy will be discussed.

**D20 8 IR phonons induced by the helical magnetic order in multiferroic $TbMn_2O_5$*** ROLANDO VALDES AGUILAR, A. SUSHKOV, H.D. DREW, *University of Maryland. College Park, MD 20742* S.W. CHEONG, *Rutgers University. Piscataway, NJ 08854* The interplay between magnetic order and the lattice in multiferroic crystals has produced such interesting phenomena as polarization reversal and change of dielectric properties with magnetic fields[1]. Ferroelectricity in the multiferroic materials $REMn_2O_5$ (RE = rare earth) is thought to originate from a helical antiferromagnetic order. In order to study this possiblity we have made an infrared study of $TbMn_2O_5$. We find that several IR phonons show correlations with the distinct magnetic and dielectric phase transitions. Of special interest is the phonon spectrum for light polarization along the b axis where a mode at $\sim$ 706 $cm^{-1}$ exists only in the commensurate magnetic phase with **k** = (1/2,0,1/4) in the temperature range of 24-33 K. Possible scenarios for this phonon are: (1) the appearance of zone-folded modes; (2) the activation of previously silent modes due to the reduction of crystal symmetry. These scenarios are discussed in terms of the spin-lattice coupling in this class of materials.

**D20 9 Microwave dielectric constant measurements of multiferroic $TbMn_2O_5$*** SAMUEL LOFLAND, *Rowan University* A SUSHKOV, *University of Maryland* H.D. DREW, *University of Maryland* S.W. CHEONG, *Rutgers University* We have measured the temperature dependence of the dielectric constant of $TbMn_2O_5$ by a cavity perturbation technique at frequencies between 2 and 13 GHz. There are three anomalous features seen in the quasistatic dielectric constant as a function of termperature below the onset of magnetic ordering ( $\sim$ 38 K); however at microwave frequencies, the enhancement in the dielectric constant is significantly reduced. In fact, by 13 GHz, the anomalies have nearly disappeared. Each anomaly has its own characteristic relaxation frequency, with the ones at higher and lower temperature being in the GHz range and the intermediate one being in the MHz. We discuss these results in terms of magnetoelectric domains.

**D20 10 Phonon coupling to the Tb spin in multiferroic TbMn2O5*** YOUNG-NOH YOON, A.B. SUSHKOV, R. VALDES AGUILAR, H.D. DREW, *MRSEC, University of Maryland* N. HUR, S.W. CHEONG, *Rutgers University* TbMn2O5 is a representative of a group of multiferroic materials where ferroelectricity is induced by spiral magnetic ordering at low temperatures. These materials demonstrate several weak structural and magnetic transitions reflecting complex interplay between magnetic order and the lattice. Phonons serve as a probe of lattice changes and, via spin- phonon coupling, of magnetic ordering. We measured the reflectivity spectra in a- and b-polarizations of an orthorhombic single crystal. The Tb-dominating phonons are ac-

tive in both polarizations but only b-polarization shows a magnetic shift below 24 K where Tb moments start to order. We made lattice dynamics calculations using popular GULP program to understand why a particular infrared phonon is strongly coupled to spin ordering.

**D20 11 Temperature depending studies of multiferroic $TbMnO_3$ by spectral ellipsometry and Raman scattering** ILKA MAHNS, *Institute of Applied Physics, University of Hamburg, Germany* M. BASTJAN, R. RAUER, G. NEUBER, B. SCHULZ, S. MUELLER, A. RUSYDI, M. RUEBHAUSEN, *e 11, D-20355 Hamburg, Germany* D. N. ARGYRIOU, *Hahn-Meitner Institute, Germany* M. KIM, H. BARATH, S.L. COOPER, *Dept. of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign* $TbMnO_3$ has been studied in order to understand the orbital, structural, and magnetic structure as a function of temperature by Raman scattering and spectral ellipsometry. We present optical spectra, in which anomalies can be observed above and below the Néel temperature of 41 K. Below $T_N$, $TbMnO_3$ develops a complex magnetic structural phase. Another characteristic temperature of this material is $T_F = 28$ K. Below this temperature, $TbMnO_3$ develops a multiferroic state. From the ellipsometry data, we find a rearrangement of the spectral weight at 41 K. Raman scattering with an excitation energy of 1.91 eV shows Jahn-Teller mode changes below $T_N$. Below $T_F$ we also detected a new ferroelectric mode at 128 $cm^{-1}$. In the ellipsometry data as well as in the Raman spectra we identify another critical temperature at $T^* \sim 150$ K. From our observations we can conclude that there is a strong coupling between the electronic and lattice degrees of freedom, which influence both the formation of the multiferroic state and the Jahn-Teller-distortions.

**16:42**

**D20 12 Investigation of coupling between antiferromagnetic and ferroelectric orders in $TbMnO_3$ using magnetic field dependent Raman scattering** HARINI BARATH, MINJUNG KIM, S.L. COOPER, *Dept. of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, Urbana, Illinois 61801* I. MAHNS, M. RUEBHAUSEN, *Institut fur Angewandte Physik, Univeristat Hamburg, Jungiusstrasse 11, D-20355 Hamburg, Germany* D.N. ARGYRIOU, *Hahn-Meitner Institut, Glienicker Str. 100, D-15109 Berlin, Germany* $TbMnO_3$ is an antiferromagnetic insulator with a distorted orthorhombic perovskite structure and a Néel temperature at $T_N = 41$K. $TbMnO_3$ is of particular interest because it is one of the few materials that exhibits not just a co-existence, but a strong coupling between antiferromagnetic and ferroelectric order, as evidenced by a para- to ferro- electric transition below T = 28K. In this talk, we discuss magnetic field dependent Raman scattering measurements of $TbMnO_3$ – both for magnetic fields oriented along various crystallographic directions and as a function of temperature through the ferroelectric and Néel transitions - the goal of which is to investigate the magnetic-ferroelectric coupling mechanism in this interesting material.

**16:54**

**D20 13 Dielectric properties of $TbMnO_3$ and $La(Sr,Ca)_{0.3}MnO_3$ – evidence for spectral weight changes up to 20 eV.** S. MÜLLER, M. RUBHAUSEN, R. RAUER, A. RUSYDI, M. BASTJAN, G. NEUBER, S. DASTJANI-FAHARANI, B. SCHULZ, S. SINGER, A. LICHTENSTEIN, *Universität Hamburg* D. ARGYRIOU, *Hahn-Meitner Institut, Berlin* K. DÖRR, *IFW, Dresden* In order to analyze changes in the kinetic energy that occur at the transition into the magnetic state we have performed ellipsometry measurements (0.5-5.5 eV) and reflectance measurements (4 – 20 eV) covering in total a spectral range between 05 and 20 eV. First, we evaluate thermal difference reflectance spectra and find changes at the transition into the magnetic state for both undoped TbMnO3 and doped La(SrCa)MnO3 exceeding energies up to 20 eV. We find distinct changes at the magnetic transitions for energies around 2 eV, 4 eV, 8 eV, 12 eV, and 18 eV. We attribute the first two transitions to Mn d-d high-spin and Op-Mnd charge transfer transitions. The transition at 18 eV is most likely connected to the O2s to O2p transition, whereas the origin of the transitions at 8 and 12 eV remain to be discussed.

**17:06**

**D20 14 The role of lattice distortions in magnetoelectrics** TURAB LOOKMAN, AVADH SAXENA, *Los Alamos National Lab* The orthorhombic magnetoelectrics, such as RMnO3, R=Tb,Dy,Gd, exhibit lattice modulations as measured by diffraction. Symmetry analysis predicts a shuffle based transition associated with the magnetoelectric state. We include coupling of the shuffle modes to polarization and incoommensurate magnetization within a Landau free energy framework. We explore the possible role of strain in recently observed pressure effects in some of the materials. In addition, using strain we model the orthorhombic to monoclinic structural transition in certain doped materials. We attempt to connect the free energy coefficients to avaliable structural and thermodynamic data.

**D20 15 Field induced linear magneto-elastic coupling in multiferroic $TbMnO_3$** NADIR ALIOUANE, DIMITRI ARGYRIOU, *Hahn-Meitner-Institut, Glienicker Str. 100, Berlin D-14109* J. STREMPFER, I. ZEGKINOGLOU, *Max-Planck-Institut fur Festkorperforschung,Heisenbergstrasse 1, 70569 Stuttgart, Germany* M. V. ZIMMERMAN, *HASYLAB at Deutsches Elektronen-Synchrotron DESY, Notkestr. 85, 22603 Hamburg, Germany* We have used in-field neutron and X-ray single crystal diffraction to measure the incommensurability $\delta$ of the crystal and magnetic structure of multiferroic $TbMnO_3$. We show that the flop in the electric polarization at the critical field $H_C$, for field $H$ along the $a-$ and $b-$ axis coincides with a 1st order transition to a commensurate phase with propagation vector $\kappa = (0,\frac{1}{4},0)$. In-field X-ray diffraction measurements show that the quadratic magneto-elastic coupling breaks down with applied field as shown by the observation of the 1st harmonic lattice reflections above and below $H_C$. This indicates that magnetic field induces a linear magneto-elastic coupling. We argue that the commensurate phase can be described by an ordering of Mn-O-Mn bond angles.

**D21 1 Phase behavior of standing disks in 2D** KUN ZHAO, *Princeton University* CHRISTOPHER HARRISON, *Schlumberger-Doll Research Center* MATTHEW SULLIVAN, *Princeton University* THOMAS MASON, *University of California- Los Angeles* DAVID HUSE, WILLIAM RUSSEL, *Princeton University* PAUL CHAIKIN, *New York University* We use photolithography to fabricate plate-like colloidal PMMA disks (diameter$\sim$ 5.3micron, thickness$\sim$ 0.8micron). Using an electric field normal to the cover slip, we can get a monolayer of disks standing on their edges. The system resembles a 2D set of colloidal rectangles. We study the phase behavior of this system and find that there is K-T transition from isotropic to nematic (quasi-smectic). Between these two phases, we find a regime where tetratic correlations are longer range than nematic. By studying the disclinations and domain walls, we suggest that the tetratic phase is driven by the nearby nematic and exists on a length scale larger than the nematic domain wall spacing but smaller than the inter-disclination distance.

**D21 2 Attraction between charged silica spheres at a water-air interface*** PENGER TONG, WEI CHEN, *Department of Physics, Hong Kong University of Science & Technology* SUSHENG TAN, WARREN T. FORD, *Department of Chemistry, Oklahoma State University* Charged colloidal particles at aqueous interfaces are found to experience attractive interactions but the origin of such attraction is not well understood. Here we report an experimental study of attractive interactions between micron- sized charged silica spheres at a water-air interface. Atomic force microscopy is used to examine the charge distribution of the silica surface. Digital video microscopy is used to measure the equilibrium pair potential between the interfacial silica spheres over varying salt concentrations in the aqueous phase. It is found that the measured interaction potential U (r) has an energy barrier with height $\sim 0.15k_BT$ at large particle separation r. For smaller separations, U(r) has an attractive well of order $0.3k_BT$. At even smaller separations, the usual Coulomb repulsion dominates. The experimental observation can be explained in terms of a balance between the screened Coulomb repulsion and unscreened dipole interactions.

*Work supported in part by the Research Grants Council of Hong Kong SAR under Grant No.

**14:54**
**D21 3 Like-charge attraction originated from intrinsic charge inhomogeneity** YI ZHOU, ZHOUSHEN HUANG, TAI KAI NG, *Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, HongKong* We study attractions between charged colloidal spheres in a solution and at a water-air interface. Both intrinsic inhomogeneous charge distribution and induced charge fluctuations may result in like-charge attraction. The intrinsic inhomogeneous charge distribution comes from the inhomogeneous surfaces of colloidal spheres, characterized by the number of patchy domains, while charge fluctuations occur in a homogenous background of charges. As the number of patchy domains increases, it will change from the intrinsic charge inhomogeneity to the induced charge fluctuation case. This crossover is studied theoretically and the results are compared with the recent experiments on polystyrene and silicon particles. A simple mechanism is presented to explain the enhancement of the attraction between two charged colloidal particles when they are suspended near a wall.

**15:06**
**D21 4 Attraction between charged colloidal spheres at oil-water interface** CHUAN ZENG, HUGO BISSIG, ANTHONY DINSMORE, *Department of Physics, University of Massachusetts Amherst* The behavior of micron-sized, charged-stabilized colloidal spheres confined at oil-water interface was studied using microscopy. Aggregates of colloidal particles were observed, suggesting an attractive capillary force arising from electrostatic stress on the interface. We report measurements of a long-range attraction between carboxyl-modified polystyrene spheres (radius $\sim$ 1 micron) at the interface between 1,1,1-trifluoroheptan-2-ol and water using image analysis and particle tracking. The interaction between two isolated spheres was measured and compared to recent theoretical models. We also measured the interaction of single particles with large clusters as well as the interactions between clusters. We found acceleration due to the capillary attraction and a complex angular dependence owing to the anisotropy of the meniscus around a cluster. We acknowledge support from NASA through the Fluid Physics program (NRA 02-OBPR-03-C).

**15:18**
**D21 5 The elasticity of nanoparticle networks on liquid droplets** YOUNG-HSYANG CHEN, HSUAN-YI CHEN, *Department of Physics, National Central University, Taiwan* ALEX LEVINE, *Department of Chemistry and Biochemistry, University of California, Los Angeles, California* Inspired by recent experiments on the formation of linked nanoparticle networks [A.D. Dinsmore et al Science, **298**, 1006, (2002)] on the surface of oil-in-water droplets, we study the modification of the droplet surface elasticity due to the formation of a percolating network of linked nanoparticles. What coverage of nanoparticles is required to modify the elasticity of the droplet? Using Brownian dynamics simulations to model the DLCA (diffusion limited cluster aggregation) of nanoparticles on the surface we construct these networks and monitor the appearance of an elastic contribution due to the nanoparticles at a critical nanoparticle area density. This transition is a type of rigidity percolation on a compact surface.

**15:30**
**D21 6 Crystalline Particle Packings on Spheres*** YAPING JING, *Iowa State University* ALEX TRAVESSET, *Iowa State University and Ames lab* The problem of packing particles on spheres appears in several soft condensed matter systems such as the building of PMMA cages (Pickering emulsions or colloidosomes), the micropatterning of colloidal particles relevant for photonic crystals or the geometric strucures of Clathrin cages responsible for the vesicular transport of cargo in cells, just to name a few. In this talk we show how the structural and mechanical properties of spherical crystals can be described analytically from continuum elastic models and discuss how the results are extended to describe other geometries as well.

*funded by NSF-DMR-0426597

**15:42**

**D21 7 A 3d View of Spherical Crystals and Grain Boundary Scars** MARK BOWICK, *Syracuse University* THOMAS EINERT, PETER LIPOWSKY, JORG SCHILLING, ANDREAS BAUSCH, *Technical University of Munich* We present an experimental system suitable for producing spherical crystals and for observing the distribution of lattice defects (disclinations and dislocations) on a significant fraction (50%) of the sphere. The introduction of fluorescently labeled particles enables us to determine the location and orientation of grain boundary scars. We find that the total number of scars and the number of excess dislocations per scar agree with theoretical predictions and that the geometrical centers of the scars are roughly positioned at the vertices of an icosahedron.

**15:54**

**D21 8 Formation of nanoparticle-coated liquid metal droplets and measurement of their electronic properties.*** KAN DU, C. KNUTSON, RUI HONG, M. TUOMINEN, T. EMRICK, T. RUSSELL, A. DINSMORE, *University of Massachusetts Amherst* We form stable droplets of molten metal, investigate their stability, and demonstrate their potential for forming electronic devices. Droplets of liquid Ga, 0.1-100 microns in diameter, were stabilized by surfactants and by insulating, conducting, and semiconducting nanoparticles. We investigate electronic transport through the nanoparticle-coated droplets. Here we use silica, gold and CdSe nanoparticles which spontaneously form a layer on the droplets. A few droplets form junctions between two platinum wires; we apply a bias voltage to the wires and measure the current before and after evaporation of the solvent. Improved understanding of the electrical characteristics may allow inexpensive assembly of a large number of devices with controlled size, symmetry and function. We acknowledge support from the Center for UMass/Industry Research on Polymers (CUMIRP).

*Center for UMass/Industry Research on Polymers (CUMIRP)

**16:06**

**D21 9 Controlled Three-Dimensional Assembly of Colloidal Particles Using Optical Trapping** C.R. KNUTSON, J. PLEWA, *Arryx, Inc.* Optical trapping has become a widespread and valuable tool to assist researchers in the positioning of colloidal particles in solution. However, unless an additional potential acts on the particle, it freely diffuses from this position once the trap is removed. Previous researchers have used colloidal particles suspended in a gelatin to provide mechanical stability once the trap has been removed. We demonstrate that the van der Waals potential combined with Holographic Optical Trapping (HOT) can be used to build three-dimensional structures consisting of dozens of colloidal spheres. Particles are first positioned using HOT. An electrolyte solution is then flowed into the sample cell which screens the Coulomb repulsion and allows the van der Waals potential to affix the particles in place. We demonstrate that this technique can be used to build controlled three-dimensional structures formed on a substrate and in solution. Furthermore, many of these structures can be removed from solution without the aid of critical point drying or polymer fixation. This technique might provide a new route towards the assembly of photonic crystals and biotechnology devices.

**16:18**

**D21 10 MR Colloid Self-Assembly in Confined Geometries** PATRICK DOYLE, RAMIN HAGHGOOIE, *MIT* The characteristic length scales found in microfluidic devices have been shrinking drastically over the past several years. As a result it is becoming increasingly important to study the effects of this tight confinement. We have used the Brownian Dynamics simulation technique to study the self-assembly of magnetorheological (MR) colloids under confinement. To compliment these simulations, we have used particle tracking to study micron-sized colloids assembling in fluidic channels. For quasi-two dimensional systems, we report a seemingly contradictory response of the system to confinement between parallel hard walls. In contrast to previous circular geometries, we see re-entrant melting with respect to changing channel width and not with respect to field strength. As the channel height is increased (in the range of a few particle diameters), we observe oscillations in the mean cluster spacing with respect to gap height. These oscillations and the transition to the large gap scaling regime will be discussed.

**16:30**

**D21 11 Confocal Microscopy of Hard Sphere Crystal Growth** MATTHEW SULLIVAN, *Princeton University / Schlumberger-Doll Research* KUN ZHAO, ANDREW HOLLINGSWORTH, P.M. CHAIKIN, *Princeton University / New York University* WILLIAM B. RUSSEL, *Princeton University* Classical crystal growth is determined by the competition between chemical potential differences and surface tension. We use confocal microscopy to measure three dimensional crystal growth in a density matched suspension of PMMA-PHSA colloidal particles. The crystal is nucleated from a surface template that forces growth of face-centered-cubic crystals. The growing crystal surface is rough on the scale of several particle diameters, but the average growth rate is well described by the classical Wilson-Frenkel growth law. The local growth rate does depend on the roughness of the surface, however, and this growth rate variation provides a measure of interfacial surface tension.

**16:42**

**D21 12 Simulated Crystallite Melting Kinetics in Two Dimensions** D. W. BLAIR, J. R. SAVAGE, A. D. DINSMORE, J. MACHTA, R. A. GUYER, *University of Massachusetts at Amherst* A. J. LEVINE, *University of California, Los Angeles* We report on results of numerical simulations of the melting of two-dimensional crystallites. Recent experiments in colloidal systems demonstrate that colloidal crystallites undergo a two-stage melting process. Initially large crystallites melt at a constant rate until reaching a critical size at which there is a dramatic increase in the melting rate. Throughout the initial melting stage the crystallite interior maintains bond orientational order; this order is abruptly lost at the critical size. Using Brownian dynamics simulations of particles interacting via a variety of short-range central potentials, we find that in two dimensions small crystallites generically melt in two-stages characterized by a sudden increase in melting rate that coincides with an abrupt loss of bond orientational order. The critical size, particle number $\mathcal{O}(20)$, is in agreement with experimental data and appears insensitive to details of the short-range interparticle potential. We discuss a possible mechanism for this change in melting dynamics at a critical crystallite size. This work is supported in part by NSF (DMR-0242402) and NASA (NAG8-1659).

**16:54**

**D21 13 Influence of hydrodynamic coupling on pair-diffusion in a quasi-one-dimensional colloid system*** BINHUA LIN, XINLIANG XU, STUART RICE, *University of Chicago* HAIM DIAMANT, *Tel Aviv University* The effect of hydrodynamic interaction on the separation dependence of the center of mass and relative pair diffusion coefficients of colloid particles in a quasi-one-dimensional system, including the influence of proximate walls, has been calculated using the method of reflections. There is excellent agreement between the theoretical predictions and the experimental data. We show that the separation dependence of the relative pair diffusion coefficient has oscillatory structure on the scale length of the correlation length in the system, and we directly relate that oscillatory structure to the pair correlation function of the system.

*This research was supported by grants from the NSF (CHE-0241133, CTS-021774).

**D21 14 Short-time dynamics of a Brownian particle** BRANIMIR LUKIC, *Ecole Polytechnique Federale de Lausanne (EPFL), Switzerland* SYLVIA JENEY, ZELJKO SVIBEN, *EPFL Lausanne* CHRISTIAN TISCHER, *EMBL Heidelberg, Germany* ERNST-LUDWIG FLORIN, *Center for Nonlinear Dynamics, University of Texas, Austin* ANDRZEJ J. KULIK, LASZLO FORRO, *EPFL Lausanne* We record the thermal position fluctuations of a *single* micron- sized sphere immersed in a fluid by optical trapping interferometry with nanometer spatial and microsecond temporal resolution. On the shortest time scales investigated, the sphere's inertia has a small, but measurable, effect. We find, in accord with the theory of Brownian motion including hydrodynamic memory effects, that the transition from ballistic to diffusive motion is delayed to significantly longer times than predicted by the standard Langevin equation. This delay is a consequence of the inertia of the fluid. When the particle is confined by a harmonic potential with a depth on the order of $k_BT$, we find that these inertial effects determine the particle's motion at the similar time scale as the potential. Surprisingly, we don't observe the free diffusive behavior in such confined system.

**17:18**

**D21 15 Transport of nanoparticles in a temperature gradient** SHAWN PUTNAM, DAVID CAHILL, Thermodiffusion, mass transport in a temperature gradient, is commonly characterized by either the thermodiffusion coefficient $D_T$ or the Soret coefficient $S_T$; e.g., at low particle concentration $c$, the particle flux of a colloidal suspension subjected to a temperature gradient $\nabla T$ is $\mathbf{J} = -cD_T\nabla T - D_c\nabla c$, where $D_c$ is the diffusion coefficient and the Soret coefficient is $S_T = D_T/D_c$. We present our measured $D_T$ data for aqueous suspensions of charged polystyrene spheres, alumina nanoparticles, and globular proteins of lysozyme. Special emphasis is given to our published work on charged polystyrene spheres with different surface functionalities. For example, in solutions with large concentrations of monovalent salts, $\gtrsim$ 100 mM, $D_T$ for 26 nm spheres with carboxyl functionality can be varied within the range $-0.9 \times 10^{-7}$ cm$^2$ s$^{-1}$ K$^{-1}$ $< D_T <$ $1.5 \times 10^{-7}$ cm$^2$ s$^{-1}$ K$^{-1}$ by changing the ionic species in solution; in this case $D_T$ is the product of the electrophoretic mobility $\mu_E$ and the Seebeck coefficient of the electrolyte $S_e = (Q_C^* - Q_A^*)/2eT$, $D_T = -S_e\mu_E$, where $Q_C^*$ and $Q_A^*$ are the single ion heats of transport of the cationic and anionic species respectively. On the contrary, in low ionic strength solutions of LiCl, $\lesssim$ 5 mM, $D_T$ for the 26nm carboxyl spheres is negative, independent of particle concentration, and independent of the Debye length; $D_T = -0.73 \pm 0.05 \times 10^{-7}$ cm$^2$ s$^{-1}$ K$^{-1}$. The temperature dependence of $D_T$ is also discussed with results from our current work with polystyrene spheres, alumina nanoparticles, and protein solutions of lysozyme.

**D22 1 Magnetization reversal process and domain wall resistance in a water drop shape ring** D.C. CHEN, *Department of Material Science and Engineering, National Chiao Tung University* D.P. CHIANG, *Ming Hsin University of Science and Technology* Y.D. YAO, *Institute of Physics, Academia Sinica* Patterned permalloy (Ni80-Fe20) materials have been fabricated by e-beam lithography in the shape of water drop ring. A tip is intentionally added into ring as geometrical defects to interrupt the continuity of magnetization reversal process, in order to create domain wall. Image from Magnetic force microscopy (MFM) with real- time external field confirmed this domain structure. As a result of magneto- resistance (MR) measurement, the ratio of MR is about $0.137 \sim 0.233\%$ and $0.23 \sim 0.71\%$ at sweeping angles of samples and sweeping external field, respectively. The ratio of the change in the electric resistance which is measured by I-V curve is just about the value of domain wall MR ratio which is measured by sweeping angles and external field. In summary, we have successfully demonstrated that the domain wall motion along the direction of perimeter in a ferromagnetic ring at its onion state; and the critical field to form onion state is near 200 Oe and the lowest field which can still drag the domain wall is between 100 and 50 Oe.

**14:42**

**D22 2 Arrays of Ultrasmall Nanoscopic Ferromagnetic Rings*** DEEPAK SINGH, *Dept. of Physics, UMASS* HONGQI XIANG, *Dept. of Polymer science and Engineering, UMASS* ROBERT KROTKOV, *Dept. of Physics, UMASS* TING XU, *Dept. of Polymer Science and Engineering, UMASS* QIJUN XIAO, *Dept. of Physics, UMASS* THOMAS RUSSELL, *Dept. of Polymer Science and Engineering, UMASS* MARK TUOMINEN, *Dept. of Physics, UMASS* There has been a considerable amount of recent interest in the magnetic properties of ultrasmall ferromagnetic rings. This is largely motivated by the unique stability of the vortex state of magnetization and its relevance in future data storage elements. In this work, we discuss experimental research on ultra small cobalt nano rings. We fabricate arrays of ultra small rings using a technique involving self-assembled diblock copolymer templates, glancing angle evaporation and ion beam etching. The nanoscopic rings have an outer diameter of 13 nm and inner diameter of 5 nm. The magnetization properties of these arrays are measured in both parallel and perpendicular field orientations in SQUID magnetometer. We compare these measurements to analytical calculations

for different magnetic configurations that take into account the competition between exchange energy, Zeeman energy and magnetostatic energy. Based on analytical calculation and magnetic measurement we find that for such ultrasmall ring structures vortex states are the dominant remanent magnetic states.

**D22 3 Reversal mechanism of patterned ferromagnetic elements*** YIMEI ZHU, J.W. LAU, V.V. VOLKOV, *Brookhaven National Lab* CFN TEAM, Understanding of magnetization reversal dynamics in patterned ferromagnetic elements, or building blocks, is crucial to the development of modern magnetic storage media and spintronic devices. Using state-of-the-art, field-emission transmission electron microscope (TEM) equipped with a custom-made objective lens (the only one of its kind in the world) that allows high-resolution magnetic imaging and electron holography, we study the reversal mechanism and hysteresis behavior of patterned rings, squares, and ellipses with different aspect ratios of Permalloy and Co thin-films. By quantitative analysis of the local magnetization, we measure magnetic properties and shape effect of individual elements, and compare experimental observations with theoretical calculations. We explain why a parent state of the elements, isolated or in an array environment, can result in different low-energy ground states, depending on the switching rate, and how the energy barrier to the vortex nucleation can be measured. New results using a magnetic force microscope built into a TEM stage to locally induce magnetic field gradient and to change magnetic polarization of the elements to study element-element interaction and magnetic reversal will be also reported.

**D22 4 Magnetic nanorings and manipulation of nanowires.**
C.L. CHIEN, *Johns Hopkins University*

The properties of nanoscale entities, such as nanorings and nanowires, and the response of such entities to external fields are dictated by their geometrical shapes and sizes, which can be manipulated by fabrication. We have developed a method for fabricating a large number of nanorings ($10^{10}$) of different sizes in the range of 100 nm and ring cross sections. During magnetic reversal, both the vortex state and the rotating onion state appear with different proportions, which depend on the ring diameter, ring cross section, and the profile of the ring cross section. In the case of nanowires in suspension, the large aspect ratio of the nanowires can be exploited for manipulation despite extremely small Reynolds numbers of $10^{-5}$. Using AC electric field applied to microelectrodes, both magnetic and non-magnetic nanowires can be efficiently assembled into desired patterns. We also demonstrate rotation of nanowires with precisely controlled rotation speed and chirality, as well as an electrically driven nanowire micromotor a few [**micron**] in size. In collaboration with F. Q. Zhu, D. L. Fan, O. Tchernyshyov, R. C. Cammarata (Johns Hopkins University) and X. C. Zhu and J. G. Zhu (Carnegie-Mellon University).

**D22 5 Bistability and controllable magnetic switching of 100-nm asymmetric ferromagnetic nanorings** F.Q. ZHU, GIA-WEI CHERN, OLEG TCHERNYSHYOV, C.L. CHIEN, *Johns Hopkins University* Nanorings can acquire the vortex state with flux closure and zero stray field. We have developed a method for fabricating a large number of nanorings over a macroscopic area. However, for 100-nm nanorings, the nanorings can acquire both the rotating onion state and the vortex state during magnetic reversal with comparable probability. In this work, we report the fabrication and properties of asymmetric nanorings, whose thickness and width vary along the circumference. In contrast to symmetric nanorings, the percentage of vortex formation in asymmetric nanorings can be controlled by the direction of the magnetic field. When the field is along the asymmetry axis, nearly every nanoring can acquire the vortex state. The introduction of asymmetry in the nanorings allows full vortex formation without losing the virtue of small dimension, high stability and high areal density. We have also developed a theoretical model to calculate the dependence of domain wall energy on the local width and thickness of the nanorings to account for the enhancement of vortex state in asymmetric nanorings.

**D22 6 Self-Assembled Cobalt Nanodots along $Al_2O_3$ (0001) step edges*** JORGE ESPINOSA, DAVID LEDERMAN, *Dept of Physics, West Virginia University* Ultrathin films of Co with thicknesses of 0.80 monolayers (ML) and 0.20 ML were grown on Al $_2O_3$ (0001) via molecular beam epitaxy at room temperature. itIn situ non-contact atomic force microscopy images obtained after annealing the 0.80 ML film in-situ at 400 °C revealed the formation of nano-dots distributed randomly on the sapphire surface with an average diameter of approximately 18 nm and a height of 0.4 nm. The annealing of the 0.20 ML film showed the formation of nanodots with diameters of 16 nm for the film annealed at 500 °C and 28 nm for an annealing temperature of 500 °C. In general, the nanodots increase their sizes with the annealing temperature and they move towards the top of the sapphire step edges, indicating a certain degree of self organization.

**D22 7 Interaction effects in heterostructures of nanoscale magnetic particles and magnetic thin films** JENS MUELLER, STEPHAN VON MOLNAR, *Florida State University* YUZO OHNO, HIDEO OHNO, *Tohoku University, Sendai, Japan* Elongated magnetic nanoparticles attract continuing attention because of potential technological applications. STM assisted CVD is an

advantageous fabrication technique for exact positioning of individual Fe particles (diameter 5 – 20 nm) on different substrate materials. A first step towards an application of these small and local magnetic flux sources to intentionally influence and investigate other materials is to study structures of magnetic particles grown onto an underlying magnetic film. This enhances interaction effects between adjacent particles. Also, the particles alter the magnetic domain structure of the thin film making the transport properties of the latter sensitive to the magnetization state of the particles grown on top leading to a distinct switching effect in the magnetoresistance that persists up to room temperature. The interaction effects in such magnetic particles/thin-film heterostructures are further investigated in a device with a single magnetic nanoparticle and an underlying film of the concentrated magnetic semiconductor EuS. The magnetic interaction of this system can be tuned by sweeping the temperature through $T_C$ of EuS. We discuss the heterostructure's magnetization behavior in terms of different magnetic interaction strengths.

**16:18**

**D22 8 Perpendicular Anisotropy in Cobalt-nanodots on Rutile TiO2(110)*** N. WIDJAJA, *University of Tennessee* JIANDI ZHANG, *Florida International University* C.G. ZHOU, *ORNL* MINGHU PAN, *University of Tennessee and ORNL* E.W. PLUMMER, *University of Tennessee* J. SHEN, *ORNL* We report the structural and magnetic properties of self-assembled Co-nanodots on rutile $TiO_2$(110) substrates. Co-dots with different coverage density were prepared inside a UHV chamber (base pressure $< 1x10^{-10}$ Torr) by thermally evaporating Co-source on the well ordered rutile $TiO_2$(110) surface. The size of the Co-dots can be tuned by changing the coverage density and the dose rate of Co independently. The in-situ STM imaging indicates that the size of the Co-dots ranges from 0.5 nm to 1 nm. The magnetization of the systems was measured ex-situ using a Quantum Design SQUID magnetometer after they were capped with NaCl. The magnetization as a function of field measured at various temperatures for $2 < T < 250$K reveals significant perpendicular anisotropy. The origin of the anisotropy is explained in terms of the competition between magnetocrystalline anisotropy and shape anisotropy of the nanodots.

*The work was supported by NSF-DMR0346826 and ORAU faculty summer research program. ORNL is managed by UT-Battelle, LLC, for the U.S. Dept. of Energy under contract DE-AC05-00OR22725.

**D22 10 ''Live'' Surface Ferromagnetism in Fe Dot Multilayers on Cu(111)*** MARIA TORIJA, *Univ. of Tenn. Knoxville/ Oak Ridge National Laboratory* AN PING LI, CHARLES GUAN, *Oak Ridge National Laboratory* WARD PLUMMER, JIAN SHEN, *Univ. of Tenn. Knoxville/ Oak Ridge National Laboratory* We investigate the crossover behavior from two-dimensional (2D) to three dimensional (3D) in multilayers of magnetic nanodots grown by stacking 2D Fe nanodot assemblies on Cu(111) single crystal substrate with a Cu spacing layer. Using in-situ magneto-optical Kerr effect, we have observed a striking ferromagnetic to spin-glass phase transition with increasing number of Fe dot layers. The topmost layer of the Fe dots survives the phase transition and remains ferromagnetic. This unusual surface ferromagnetism is likely caused by a stronger surface state-mediated intralayer dot coupling which is stronger than the interlayer dot coupling, as confirmed by the fact that the critical temperature of the surface ferromagnetism is considerably higher than that of the bulk spin glass phase in the system.

*Supported by ORNL, managed by UT-Batelle, LLC for the U.S. Departament of Energy (Contract No. DE-AC05-00OR227525) and by the U.S. National Science Foundation (Contract DMR 0105232)

**D22 11 Fabrication and magnetism of sub-100 nm exchange-biased magnetic dot arrays and porous networks.*** CHANG-PENG LI, IGOR V. ROSHCHIN, ZHI-PAN LI, IVAN K. SCHULLER, *Physics Dept., UCSD, La Jolla, CA, USA* Studies of exchange bias (EB) at nanoscale, when the structure size is comparable to magnetic domain sizes, can offer new insights for the mechanism of EB. For these studies, sub-100 nm ferromagnetic (Ni)-antiferromagnetic ($FeF_2$) dots and porous network bilayers are fabricated using self-assembled porous alumina masks. The size and periodicity of the nanopatterns are controlled by anodization conditions and pore widening time. Magnetization of the field cooled dots and networks is measured at 10 K by SQUID magnetometry and magneto-optical Kerr effect (MOKE), respectively. For the dots, the EB field is found to decrease as the dot diameter decreases. For example, with Ni/$FeF_2$ dot diameter decreasing from 98 nm to 52 nm, the EB field decreases from 640 Oe to 240 Oe. For networks with the constant pore periodicity, an increase in pore diameter from 50 nm to 70 nm results in a decrease of EB field from 150 Oe to 90 Oe. The results suggest that the EB decreases as the magnetic structure size decreases, regardless of its actual shape.

**D22 12 Domain walls resistance study in magnetic thin films by means of thickness modulation*** WEI-LI LEE, *Department of Physics and Astronomy, Johns Hopkins Univ.* F.Q. ZHU, V. THAMPY, C.L. CHIEN, The manner with which the magnetic domain wall (DW) affects the transport properties of a ferromagnet remains an interesting but difficult topic. Experimental extraction of magnetoresistance (MR) of DWs is challenging because of other dominating contributions especially the anisotropic magnetoresistance (AMR). We have explored one way to extract DW resistance by creating structures with built-in thickness modula-

tion (THM). By capitalizing on the thickness dependence of coercivity, the domain size and hence the number of DWs can be controlled through the period of THM. In a previous work, we used lithography to pattern a 50 nm thick Co film, 5$\mu$m in width and 60$\mu$m in length. We then used a focused ion beam to create grooves transverse to its length with depth $\sim$ 8 nm and period $\sim$ 500 nm. Magnetic force microscopy reveals an induced magnetic anisotropy along the groove direction. By applying magnetic field along various directions and taking in account the AMR contributions, we have deduced that the DW resistance in Co is positive with a value of $\sim$ 29.3 m$\Omega$ corresponding to $\sim$ 0.14% MR. In the present work, the structure is prepared in different way and geometry so that current parallel to walls and current perpendicular to walls DW resistance can be both obtained from the experiment. The latest results and comparison with theoretical models will be discussed.

**D22 13 Ferromagnetic Nanocrystals of Antiferromagnetic FeGe** C.G. ZENG, MARIA VARELA, PAUL KENT, MARKUS EISENBACH, GEORGE MALCOLM STOCKS, MARIA TORIJA, JIAN SHEN, HANNO WEITERING, Epitaxial nanocrystals of FeGe have been stabilized on Ge(111). The nanocrystals assume a quasi one-dimensional shape as they grow exclusively along the $< 11^{-}0 >$ direction of the Ge(111) substrate, culminating in the monoclinic modification of FeGe. The uni-directional growth results from a close match between the Ge-atom spacing along $< 1\bar{1}0 >$ Ge and monoclinic b-axis of FeGe. Whereas monoclinic FeGe is antiferromagnetic in the bulk, the nanocrystals are surpisingly strong ferromagnets below $\sim$ 200 K with an average magnetic moment of 0.8 $\mu_B$ per Fe atom. Density functional calculations demonstrate that volume ferromagnetism is stabilized predominantly by compressive strain normal to the growth direction of the nanocrystals.

## SESSION D23: FOCUS SESSION: MAG.THY I / SPIN STRUCTURES AND DYNAMICS

**Monday Afternoon, 13 March 2006; 320, Baltimore Convention Center at 14:30**
**Dale Koelling, Department of Energy, presiding**

*Invited Papers*

**14:30**

**D23 1 Decoherence in Quantum Spin Systems.**
VIATCHESLAV V. DOBROVITSKI, *Ames Laboratory and Iowa State University, Ames IA 50011*

Understanding decoherence of quantum spin systems strongly coupled to a bath of environmental spins (spin bath) is important for many areas of physics, such as spintronics, quantum computing, nuclear and electronic magnetic resonance. Decoherence is a complex non-equilibrium many-body phenomenon, and for many interesting situations, exact numerical simulations are needed. We have developed highly efficient and accurate numerical techniques of solving the time-dependent Schrödinger equation for quantum many-spin systems. We used these techniques to directly model the evolution of the central spin system and its environment. I will demonstrate usefulness of this approach for several experimentally and theoretically important cases, where the many-body correlations between the system and the bath are particularly important. I will present, among others, our studies of the NMR spin echo of Si:dopant systems, and our investigation of decoherence by a spin bath in the regime of quantum chaos. Moreover, I will present our results on decoherence of an electron spin by a bath of nuclear spins in a quantum dot, which has been recently studied in experiments, and discuss novel numerical approaches based on techniques borrowed from quantum optics. This work was supported by US DOE, and NSA, ARDA and ARO.

**D23 2 Analysis of Density Matrix Off Diagonal Correlations for NMR Spin Echoes in Dipolar Solids** JOHN CHALLIS, VADIM OGANEYSAN, *Yale University* The experiments done by Barrett et al.* have established that repeated pi pulses can slow longitudinal relaxation in a dipolar solid. This result clearly lies outside any independent spin approximation, and so off diagonal terms in the density matrix cannot be neglected. We have calculated the size and correlations of these terms as a first step in diagnosing the mechanism behind the slow decay. *Dementyev et al. Phys. Rev. B 68, 153302 (2003)

**15:18**

**D23 3 Forces on spins in a field gradient: apparent spin relaxation** YULIN CHANG, MARK CONRADI, *Washington University* A magnetic field gradient exerts opposite forces on spin magnetic moments oriented up and down. The result is to partially segregate spins by orientation, with more spins-up at one end of the sample and more spins-down at the other. This apparent relaxation, involving only sorting and no flipping of spins, may be dominant in systems of high diffusivity and long $T_1$. The sorting mechanism competes with a well-known distinct, true $T_1$ mechanism driven by diffusion through field gradients. The results of our calculations and numerical solutions of the Bloch-Torrey equations, modified to include the force term, will be presented in detail.

**15:30**

**D23 4 Finite temperature modeling of magnetization processes in exchange-coupled films** R. H. KODAMA, *Univ. of Illinois at Chicago* A. E. BERKOWITZ, *Univ. of California, San Diego* Recent experimental studies by Berkowitz, et al. [PRB **72**, 134428 (2005)] have explored the effect of setting the exchange anisotropy of ferromagnetic / antiferromagnetic bilayers (FM/AFM) such as Co / (Ni,Co)O by deposition in a magnetic field at temperatures well below the $T_N$ or blocking temperature of the AFM

material. Two remarkable effects inspired this theoretical study: (1) the magnitude and direction of unidirectional anisotropy is modified by changing the applied magnetic field during deposition of the FM overlayer, and (2) there is a ''latent period'' after deposition is complete, during which the unidirectional anisotropy is modified by changing the field. We set out to determine if these effects could be understood using orthodox models of exchange anisotropy (invoking uncompensated interfacial moments on an ensemble of AFM grains) carried to an unprecedented level of detail. Finite interactions between FM- FM, AFM-AFM, and FM-AFM grains allow modeling of domain processes in both FM and AFM films. Finite temperature is included in a novel way, using a detailed analysis of the spin system's energy surface to determine sets of activation barriers and final states for low-energy collective modes. Results indicate that some of the observed effects can indeed be simulated in this way, although some of the experimental results are more consistent with a slow, interfacial redox reaction that changes the magnetic state of the interface.

**D23 5 First Principles Approach to the Magnetic Structure of Realistic Models of Nanoparticles*** G. MALCOLM STOCKS, AURELIAN RUSANU, DON NICHOLSON, MARKUS EISENBACH, *Oak Ridge National Laboratory* YANG WANG, *Pittsburgh Supercomputer Center* SAM FAULKNER, *Florida Atlantic University* Magnetic nanostructures are of great interest because of their potential applications in a wide range of technologies - data storage, magneto-electronics, permanent magnets, smart drug delivery, etc. Unfortunately magnetic nanostructures present substantial theoretical challenges due to the need to treat the electronic interactions quantum mechanically whilst dealing with a, still, large number of atoms – e.g., a 5nm cube of Fe contains $\sim$ 12,000 atoms, 4,000 of which are in the surface and subsurface layers. Here, we discuss a new implementation of the itab initio order-N Locally Self-consistent Multiple Scattering (LSMS) method that is capable of treating tens of thousands of atoms. We will present scaling data that show the performance of the code both in the real space mode of the original method and in the k-space mode based on screened structure constants and sparse matrix solvers. Illustrative results will be shown for a BCC Fe-nanoparticle embedded in a stoichiometric B2-FeAl binary alloy, a magnetic nanostructure model containing 16,000 atoms.

*The research of GMS, DMCN, ME, and AR is sponsored by DOE-OS, BES-DMEP under contract number DE-AC05-00OR22725 with UT-Battelle LLC.

**15:54**

**D23 6 Electronic and Magnetic Structure of Fe Nanoparticle Embedded in FeAl*** YANG WANG, *Pittsburgh Supercomputing Center* G. MALCOLM STOCKS, AURELIAN RUSANU, DON M.C. NICHOLSON, MARKUS EISENBACH, *Oak Ridge National Laboratory* J.S. FAULKNER, *Florida Atlantic University* Magnetic nanostructures are of great scientific interest because of their potential applications in a wide range of technologies - data storage, magneto-electronics, permanent magnets, smart drug delivery, etc. Unfortunately magnetic nanostructures present substantial theoretical challenges due to the need to treat the electronic interactions quantum mechanically whilst dealing with a, still, large number of atoms. In this presentation, we discuss our recent studies of magnetic nanoparticles using the Locally Self-consistent Multiple Scattering (LSMS) method, an order-N itab initio method capable of treating tens of thousands of atoms. In particular, we show results for a Fe nanoparticle embedded in a stoichiometric B2-FeAl binary alloy. The Fe nanoparticle, has the shape of a BCC Wigner-Seitz cell, contains 4,409 Fe atoms, and measures about 5 nm across the diagonal corners. Including the surrounding matrix the calculation involves 16,000 atoms. We show results for the moment and charge distribution within nanoparticle, on the facets, and in the FeAl matrix.

*The research of GMS, DMCN, ME, and AR is sponsored by DOE-OS, BES-DMEP under contract number DE-AC05-00OR22725 with UT-Battelle LLC. Calculations were performed at PSC, NERSC and ORNL-CCS.

**16:06**

**D23 7 Density functional calculations of the magnetic structure of FePt nano-particles** P.R.C. KENT, *University of Tennessee, TN* D.M.C. NICHOLSON, *Metals and Ceramics Division, Oak Ridge National Laboratory* M. EISENBACH, *Metals and Ceramics Division, Oak Ridge National Laboratory* T.C. SCHULTHESS, *Computer Science and Mathematics Division, Oak Ridge National Laboratory* The spin moment distribution in magnetic nano-particles is both scientifically interesting and technologically relevant. Here, we discuss the magnetic structure of FePt nano-particles, as determined by projector-augmented wave (PAW) and locally self-consistent multiple scattering (LSMS) local density calculations on nano-particles up to 3nm in size. The magnetic structure changes as a function of nano-particle size, composition, and chemical order, encompassing both ferromagnetic and anti-ferromagnetic tendencies. This behavior will be described and related to charge redistribution, structural relaxation, and local coordination. This work was enabled by computational resources of the Center for Computational Sciences at Oak Ridge National Laboratory and is supported by the Division of Scientific User Facilities and the Division of Materials Science and Engineering, U. S. Department of Energy.

**16:18**

**D23 8 Spin dynamics of a magnetic anti-vortex** HAO WANG, C.E. CAMPBELL, *University of Minnesota* We report the study of the spin dynamics of a magnetic anti-vortex in a submicron, asteroid shaped permalloy particle using micromagnetic simulations. A gyrotropic mode was found when a shifted anti-vortex core spirals back to the center of the asteroid. Azimuthal spin wave modes with in-plane wave vectors around the center have been excited using an in-plane pulsed field. The simultaneously excited gyrotropic mode causes a splitting of degenerate azimuthal modes. Radial spin wave modes with in-plane wave vectors along radial directions of the asteroid were excited by an out-of-plane pulsed field, which is created by a current surrounding the asteroid. The size dependence of dynamic modes has been systematically studied. The frequency of the gyrotropic mode increases with the thickness of the asteroid, but decreases with its size. The frequencies of both azimuthal and radial spin wave modes decrease with the thickness of the asteroid, and also decrease with the size of the asteroid, as may be expected by simple physical arguments.

**16:30**

**D23 9 Conductance and spin-flip of molecular magnets in a time-dependent magnetic field.*** ANH NGO, SERGIO E. ULLOA, *Ohio University* The properties of single molecular magnets and clusters with high spin, such as the Mn- or Fe-acetates, have been under intense study in recent years. The signature of magnetization tunneling on the conductance of films obtained by scanning tunneling microscopy (STM) has been recently studied theoretically [1]. We present here the effects of finite bias voltage and

temperature on the STM conductance using a model for tunneling among different magnetic states. The system consists of a single molecule magnet between two conducting leads (the substrate and the STM tip). Because of the spin-phonon interaction and finite bias voltage, a time-dependent magnetic field produces tunneling to different magnetic states even away from the fully resonant condition. We use an approximation to reduce the original $(2s + 1)$-level dynamical problem to a four-level sequence for the $s$-spin system. The differential conductance exhibits stepwise behavior with increasing longitudinal field that deviates substantially for increasing bias voltage and finite temperature. Analysis of the conductance vs. field and bias yields information on the spin-flip mechanisms. [1] G.-H. Kim and T.-S. Kim, Phys. Rev. Lett. 92, 137203 (2004).

**D23 10 Spin Anisotropy Effects in Dimer Single Molecule Magnets*** DMITRI EFREMOV, *Technische Universitaet Dresden, Germany* RICHARD KLEMM, *Kansas State University* We present a model of equal spin $s_1$ dimer single molecule magnets. The spins within each dimer interact via the Heisenberg and the most general set of four quadratic anisotropic spin interactions with respective strengths $J$ and $\{J_j\}$, and with the magnetic induction **B**. For antiferromagnetic Heisenberg couplings ($J < 0$) and weak anisotropy interactions ($|J_j/J| \ll 1$), the low temperature $T$ magnetization $\boldsymbol{M}(\boldsymbol{B})$ exhibits $2s_1$ steps, the height and midpoint slope of the $s$th step differing from their isotropic limits by corrections of $\mathcal{O}(J_j/J)^2$, but the position occurring at the energy level-crossing magnetic induction $B^{\rm lc}_{s,s_1}(\theta,\phi)$, where $\theta,\phi$ define the direction of $\boldsymbol{B}$. We solve the model exactly for $s_1 = 1/2$, 1, and 5/2. For weakly anisotropic dimers, the Hartree approximation yields analytic formulas for $\boldsymbol{M}(\boldsymbol{B})$ and $C_V(\boldsymbol{B})$ at arbitrary $s_1$ that accurately fit the exact solutions at sufficiently low $T$ or large $B$. Low-$T$ formulas for the inelastic neutron scattering $S(\boldsymbol{q},\omega)$ and the EPR $\chi(\omega)$ in an extended Hartree approximation are given. Our results are discussed with regard to existing experiments on $s_1 = 5/2$ $Fe_2$ dimers, suggesting further experiments on single crystals of these and some $s_1 = 9/2$ $[Mn_4]_2$ dimers are warranted.

**14:30**

**D25 1 Multiscale Simulation Studies of the Self-Association of Poly(ethylene oxide)-Tethered Fullerenes.** GRANT SMITH, *University of Utah*

I will discuss our multiscale molecular simulation studies of the aggregation of PEO-tethered C-60 fullerenes in water. Our simulations reveal that adjustment of the attachment pattern and molecular weight of the PEO ligands provides exquisite control of the morphology of the self-associating nanostructures formed through a balance of strong fullerene-fullerene attraction, moderately attractive fullerene-PEO interactions and repulsive steric interactions between the PEO ligands. I will also discuss results of our investigations of the influence of external fields (electrical and shear) on the morphology of the self-assembled fullerene nanostructures in bulk aqueous solution as well as results of simulation studies of the self-association of PEO-tethered fullerenes at air-water interfaces.

**D25 2 Polymer Models of Interphase Chromosomes*** JOSHUA MARTIN, JANÉ KONDEV, *Martin A. Fisher School of Physics* DEBRA BRESSEN, JAMES HABER, *Rosenstiel Center & Dept. of Bio., Brandeis Univ., Waltham MA 02454* Experiments during interphase, the growth phase of the cell cycle in eukaryotic cells, have shown that parts of chromosomes are tethered to the nuclear periphery[1]. Using a simple polymer model of interphase chromosomes that includes tethering, we compute the probability distribution for the distance between two marked points on the chromosome. These calculations are inspired by recent experiments with two or more fluorescent markers placed along the chromosome[2]. We demonstrate how experiments of this kind, in conjunction with simpe polymer models, can be used to systematically dissect the spatial organization of interphase chromosomes in the nucleus of living cells. This comparison of theory with experiments has lead to the conclusion that the structure of chromosome III in yeast is consistent with a 10nm-fiber model of chromatin. [1]Wallace F. Marshall. **D25 3 Dynamics of Adsorption-Desorption of Linear Polymer Chains to Spherical Nanoparticles: A Monte Carlo Investigation*** PETER J. DIONNE, CATALIN R. PICU, *Mechanical, Aerospace and Nuclear Engineering* RAHMI OZISIK, *Materials Science and Engineering, Rensselaer Polytechnic Institute* Dynamics of attachment/detachment processes of chains to/from spherical fillers in a polymer nanocomposite is investigated by means of numerical simulations using a chemistry-specific model for the polymer. The effects of chain length, chain-to-filler distance, filler radius, and polymer-particle interaction energy on the attachment/detachment processes are studied. It is found that the time a chain is in contact with a filler scales with the number of attached beads as expected from Rouse behavior. A deviation from Rouse behavior is observed at long attachment times where a plateau value in the number of attached beads is observed. This deviation was found to depend on the relative size of the chain and adsorption volume but was not related to entanglement effects. Changing the polymer-particle interaction energy from repulsive to attractive slows down the detachment process. An average characteristic detachment time was calculated as a function of polymer-particle interaction energy that follows an Arrhenius equation, where the activation energy is proportional to the polymer-particle interaction energy.

**D25 4 Manipulating assembly of nanoparticles by polymer tethers** ZHENLI ZHANG, MARK HORSCH, CHRISTOPHER IACOVELLA, SHARON GLOTZER, A major challenge in nanoscience and nanotechnology is the ability to control and guide the self-assembly of nano building blocks into target structures in a predictable way. In this talk, we use molecular simulation to show how polymer tethers can be used to manipulate the assembly of nanoparticles into various one-dimensional, two-dimensional, and three-dimensional structures. We present results on the self-assembly of polymer-tethered nanospheres, nanorods, and more exotic shapes, and present temperature versus concentration phase diagrams for the nanosphere and nanorod systems. For polymer-tethered nanorods we predict tetragonally perforated lamellar and honeycomb phases, which have been observed experimentally but have not been predicted by any previous theory. We also predict a new phase—a racemic mixture of hexagonally ordered chiral cylinders that self-assemble from these achiral building blocks. For the system of polymer-tethered nanospheres we predict that in contrast to flexible amphiphiles, the nanospheres are locally ordered and there is an increase in the local ordering with an increase in concentration or relative nanoparticle diameter. [1] Zhang, Mark A. Horsch, Monica H. Lamm, and Sharon C. Glotzer, itNano Lett., 3(10), 1341-1346, 2003. [2] Mark A. Horsch, Zhenli Zhang and Sharon C. Glotzer, itPhys. Rev. Lett., 95(5), 056106, 2005. [3] Christopher R. Iacovella, Mark A. Horsch, Zhenli Zhang and Sharon C. Glotzer, itLangmuir, 21(21), 9488, 2005.

**15:42**

**D25 5 Phase behavior and clustering of nanoparticles with approximate polymer interactions** ANDREW RAHEDI, FRANCIS STARR, *Wesleyan University* In nanoparticle polymer composite (NPC) materials, the clustering or dispersion of the nanoparticles strongly influences the material properties. The purpose of this study is to better understand the factors that influence nanoparticle clustering as a step towards developing more efficient simulation approaches. To understand the clustering of nanoparticles in an NPC, we simulate both pure nanoparticles and nanoparticles with approximate polymer interactions and compare our results with simulations that include explicit polymer interactions. We find that pure nanoparticles without polymeric interactions undergo ordinary phase separation. Thus the previously observed lack of nanoparticle phase separation in an NPC is due to interactions with the polymer matrix; this interaction includes short-range attractions due to monomer interactions and long-range repulsions due to the excluded volume of the chains. We approximate this interaction by including a Yukawa potential as a weak long-ranged repulsion acting between nanoparticles. Since the simulation of an NPC is computationally expensive due to the polymer-polymer interactions, this approach improves the efficiency of our simulations and enables us to study the thermodynamic properties over a much broader range of conditions.

**15:54**

**D25 6 Stable Bicontinuous Polymer Blend Films by Jamming Nanoparticles at the Interface** RUSSELL J. COMPOSTO, HYUN-JOONG CHUNG, *MSE and LRSM, U. of Pennsylvania* KOHJI OHNO, TAKESHI FUKUDA, *ICR, Kyoto U.* Polymer blends containing nanoparticles (NP) are attractive functional material for optoelectronic devices, chemical sensors, and nanoreactors. Because structure governs performances of these devices, a self-regulating, stable structure is highly desirable for many applications. Adding surface-modified silica NP to dPMMA:SAN (50:50) films (550 nm), we demonstrate that directed interfacial segregation of NP stabilize either three dimensional (3D) interpenetrating or 2D discrete structures at high and low volume fractions of NP, respectively. A simple interfacial energy argument provides a general guideline for predicting whether the NP are directed into one phase or to the interface between phases. If NP partition into one phase, the structural evolution slows down, but phase coarsening continues resulting in a roughened film [Europhys. Lett. (2004) **68**, 219]. However, if NP are driven to the interface between phases, phase coarsening ceases when NP jamming occurs at the interface. The final morphology and domain size can be predicted from the volume fraction of NP, film thickness, and NP size [Nano Lett. (2005) **5**, 1878]. These studies show that wetting and domain coarsening in polymer blend films can be controlled by the judicial addition of surface modified NP.

**16:06**

**D25 7 Directed self-assembly of nanoscale building blocks through coded bonding potentials** JASON J. BENKOSKI, RONALD L. JONES, JACK F. DOUGLAS, ALAMGIR KARIM, *National Institute of Standards and Technology* Herein we investigate the competition among the forces that drive the assembly of nanoscale building blocks, the results of which lay the groundwork for complex, hierarchichal topologies like those seen in Nature. We observed the self assembly of various nanoscale building blocks at the interface between water and a photocrosslinkable oil (dodecanediol dimethacrylate, DMA). While both liquids have a low viscosity at room temperature, DMA can be flash cured with UV light in the presence of a photoinitiator to produce a solid in less than 1 s. Such crosslinking allows one to obtain a ''snapshot'' of the self-assembly process for particles that segregate to the oil/water interface. Among the particles investigated were 400 nm

PMMA latex spheres, 10 nm quantum dots, multi-walled carbon nanotubes, and colloidosomes. Micrographs of each experiment were then captured using either an atomic force microscope (AFM) or light optical microscope (LOM). The agglomerates formed by this process were typically either globular or fractal-like in appearance. By comparing with theory and simulation, we argue that the geometry of the aggregates is coded directly in the particles through the symmetry of the bonding potentials.

**16:18**

**D25 8 Selective trapping nanoparticles on an adaptive, topographic surface** SHU YANG, YING ZHANG, SHUHUI QIN, *Materials Sci. and Eng., Univ. of Pennsylvania* JOHN A. TAYLOR, JOANNA AIZENBERG, *Bell Labs, Lucent Technologies* Control of interfacial properties, such as wettability, adhesion, and friction, is of great importance for both fundamental science and practical applications. One of the major challenges is how to spatially control the molecular recognition in different regions of surface and interface. Here, we report selective trapping and repelling of particles at different locations of a topographic substrate. It is achieved by tuning surface from highly hydrophobic to superhydrophilic within a narrow temperature window ( $= sim 10°C$). A thin layer ( $\sim$ 10 nm) of thermoresponsive polymer brushes from poly(N-isopropylacrylamide) (PNIPA) were ''grafted from'' the tips or everywhere on the micropost arrays (1 micron in diameter, 10 micron tall and 1 micron pitch), using surface- initiated atom transfer radical polymerization (ATRP). PNIPA has a lower critical solution temperature (LCST) of 32°C in water and becomes increasingly hydrophobic when heated from room temperature to 40°C. Above 40°C, the surface is highly hydrophobic (contact angle of 120-135 degree) on the microposts, which repels the hydrophilic silica particles. At room temperature, the surface becomes superhydrophilic (contact angle $<$ 10 degrees). The silica particles are found selectively trapped either on the tips, the bottom, or homogeneously along the microposts, depending on the particle size (900 nm vs. 90 nm), type of brushes (single vs. binary brushes), and the grafting location of PNIPA.

**16:30**

**D25 9 Wetting of polymer thin films with nanoparticles** IGAL SZLEIFER, *Purdue University* We theoretically study the ability of nanoparticles to induce wetting of polymer thin films on flat solid surfaces. Our studies show that there is an entropically driven attraction between the nanoparticles and the surface. The strength and range of the attraction depends upon the polymer melt molecular weight and the nanoparticles size. When the nanoparticles are mixed with the polymer melt and the film is put in contact with the surface, a very large number of nanoparticles adsorb on the surface, lowering the surface tension and enabling the wetting of the surface by the polymer melt. If the surface is modified with a grafted polymer layer of the same type as the polymer melt, nanoparticle adsorption on the surface is reduced for intermediate tethered polymers surface coverage. For high grafted surface coverage we predict a large adsorption of nanoparticle on the tip of the brush. As a result we find that nanoparticle induces wetting of polymer thin films on bare surfaces and on surfaces with grafted polymers at high surface coverage. These are the two regimes where experiments have shown that polymer thin films do not wet the surfaces. The predictions of the theory will be put in the context of available experimental observations.

**D25 10 The Effects of Supercritical $CO_2$ and Nanoparticles on Metallization of Polymer Thin Films*** B. KUGLER, *Jericho High School* F. SHAIKH, *Half Hollow Hills West* J. ROSENGARD, *Half Hollow Hills East* R. HOLZER, *Rambam Mestiva* J. JEROME, T. KOGA, M. RAFAILOVICH, J. SOKOLOV, *Stony Brook Univerisity* Thin films of Poly (methyl methacrylate), Polystyrene (PS), and Ethylene Vinyl Acetate (EVA) were metallized by vapor deposition of chromium (Cr). The surface morphology was analyzed using atomic force microscopy and correlated to the interfacial width between the polymer and metallized layers. The results showed that in all cases exposure of the substrates to supercritical $CO_2$ resulted in doubling the interfacial width between the metal and polymer. This was in turn manifested by a reduction of the RMS roughness and surface contact angles. Metallization of films containing nanoparticles was also performed. The results showed that the addition of POSS-PMMA particles dramatically reduced the RMS roughness for PMMA and EVA while increasing it for PS. Addition of Au nanoparticles decreased the roughness for EVA and PS. X-ray reflectivity indicated that the Au nanoparticles segregated to the surface thereby providing a wetting layer for the Cr. A model to explain these effects based or preferential surface segregation of nanoparticles for films exposed to supercritical fluids will be represented.

**D25 11 Optimal Confinement for Internal Polymer Binding** NAM-KYUNG LEE, *Department of Physics/Sejong University* CAMERON ABRAMS, *Department of Chemical and Biological Engineering/Drexel University* ALBERT JOHNER, *Institut Charles Sadron* Internal binding between specific groups dilute along a polymer chain plays a paramount role in many technological and biological systems. Against common intuition, we show that the interplay between excluded volume correlations and hydrodynamic interactions can produce an optimal confinement where the binding is fastest. Similarly there is an optimal osmotic pressure for the binding rate of a chain immersed in a solution of (non-binding) spectator chains. When internal binding leads to higher order vertices as in self-assembly, confinement can set the same kinetic rate for the formation of several low order vertices.

**D26 1 Probing Nucleosome Remodeling by Unzipping Single DNA Molecules.**
MICHELLE WANG, *Cornell University*

At the core of eukaryotic chromatin is the nucleosome, which consists of 147 bp of DNA wrapped 1.65 turns around an octamer of histone proteins. Even this lowest level of genomic compaction presents a strong barrier to DNA-binding cellular factors that are required for essential processes such as transcription, DNA replication, recombination and repair. Chromatin remodeling enzymes use the energy of ATP hydrolysis to regulate accessibility of the genetic code by altering chromatin structure. While remodeling enzymes have been the subject of extensive research in recent years, their precise mechanism remains unclear. In order to probe the structure of individual nucleosomes and their remodeling, we assembled a histone octamer onto a DNA segment containing a strong nucleosome positioning sequence. As the DNA double helix was unzipped through the nucleosome using a feedback-enhanced optical trap, the presence of the nucleosome was detected as a series of dramatic increases in the tension in the DNA, followed by sudden tension reductions. Analysis of the unzipping force throughout the disruption accurately revealed the spatial location and fine structure of the nucleosome to near base pair precision. Using this approach, we investigate how remodeling enzymes may alter the location and structure of a nucleosome.

**D26 2 Binding Study of T7 Gene 2.5 Protein to Single- and Double−Stranded DNA from Single Molecule Stretching**
LEILA SHOKRI, *Department of Physics, Northeastern University* BORIANA MARINTCHEVA, *Department of Biological Chemistry and Molecular Pharmacology, Harvard Medical School* CHARLES C. RICHARDSON, *Department of Biological Chemistry and Molecular Pharmacology, Harvard Medical School* MARK C. WILLIAMS, *Department of Physics, Northeastern University* Bacteriophage T7 gene 2.5 protein binds preferentially to single-stranded DNA. This property is essential for its role in DNA replication, recombination, and repair. We present the first quantitative study of the thermodynamics and kinetics of equilibrium and non-equilibrium DNA helix destabilization in the presence of gp2.5 and a deletion mutant lacking 26 C-terminal amino acids that binds with higher affinity to ssDNA (gp2.5-delta26C). Our measured force-extension curves of lambda-DNA in the presence of these proteins suggest strong cooperative binding. By measuring the DNA melting force as a function of time and pulling rate, we obtained binding site size and the association constants of these proteins to ssDNA and dsDNA, over a range of salt and protein concentrations. The results are used to characterize the electrostatic interactions that determine the DNA-protein binding in each case.

**D26 3 Dynamics of Protein-DNA Interactions probed with Laser Temperature-Jump and Time-Resolved FRET Measurements.** SERGUEI KUZNETSOV, *UIC* PAULA VIVAS, *UIC* SAWAKO SUGIMURA, *Yale* DONALD CROTHERS, *Yale* ANJUM ANSARI, *UIC* In many protein-DNA complexes, the DNA is often bent or sharply kinked. In order to elucidate the energetics of the binding mechanism it is necessary to study the dynamics of the binding and bending of DNA. Previous kinetics measurements failed to resolve DNA bending on the millisecond time-scales of stopped-flow techniques. Here we report measurements on the binding of IHF, an architectural protein from itE. coli, to its native H' substrate end-labeled with FRET pair to monitor the DNA bending. Stopped-flow measurements show relaxation kinetics that become concentration independent at high IHF concentrations, suggesting that under these conditions, the DNA bending becomes rate-limiting. To test this interpretation, we use a laser temperature-jump to perturb the IHF-H' complex, and to probe the dynamics with submillisecond time-resolution. These measurements support a sequential model for DNA binding and bending to IHF. The time-scales for DNA bending, when in complex with the protein, are not inconsistent with thermal fluctuations that can spontaneously bend DNA.

**D26 4 Inferring the itin vivo looping properties of DNA.** JOSE VILAR, *Memorial Sloan-Kettering Cancer Center* LEONOR SAIZ, *Memorial Sloan-Kettering Cancer Center* MIGUEL RUBI, *University of Barcelona* The free energy of looping DNA by proteins and protein complexes determines to what extent distal DNA sites can affect each other [1]. We inferred its itin vivo value through a combined computational-experimental approach for different lengths of the loop [2] and found that, in addition to the intrinsic periodicity of the DNA double helix, the free energy has an oscillatory component with about half the helical period. Moreover, the oscillations have such an amplitude that the effects of regulatory molecules become strongly dependent on their precise DNA positioning and yet easily tunable by their cooperative interactions. These unexpected results can confer to the physical properties of DNA a more prominent role at shaping the properties of gene regulation than previously thought. [1] J.M.G. Vilar and L. Saiz, Current Opinion in Genetics & Development, 15, 136-144 (2005). [2] L. Saiz, J.M. Rubi, and J.M.G. Vilar, Proc. Natl. Acad. Sci. USA, 102, 17642-17645 (2005).

**D26 5 DNA kept under tension reveals mechanochemical properties of protein reaction pathways.**
GIJS WUITE, *Vrije Universiteit Amsterdam*

The genetic information of an organism is encoded in the base pair sequence of its DNA. Many specialized proteins are involved in handling DNA, preserving and processing the vast amounts of information on the DNA. In order to do this swiftly and correctly these proteins have to move quickly and accurately along and/or around the DNA. Using model systems such as restriction enzymes and abundant bacterial gene regulators such as H-NS we try to understand the physics (forces, energies, mechanochemistry) behind such DNA processing. We are currently performing single molecule experiments on (non-)specific protein-DNA interactions in general and the organization of the bacterial nucleoid in particular. The experiments aim to elucidate the induced-fit reaction, substrate binding and DNA hydrolysis. Moreover, we are studying the relation between DNA configuration and association rates. The results of these model systems are generalized and though to be applicable to many DNA-protein interactions.

**D26 6 A Model for Folding and Aggregation in RNA Secondary Structures*** VISHWESHA GUTTAL, RALF BUNDSCHUH, *The Ohio State University* We study the statistical mechanics of RNA secondary structures designed to have an attraction between two different types of structures as a model system for heteropolymer aggregation. The competition between the branching entropy of the secondary structure and the energy gained by pairing drives the RNA to undergo a '*temperature independent*' second order phase transition from a molten to an *aggregated phase*. The aggregated phase thus obtained has a macroscopically large number of contacts between different RNAs. The partition function scaling exponent for this phase is $\theta \approx 1/2$ and the crossover exponent of the phase transition is $\nu \approx 5/3$. The relevance of these calculations to the aggregation of biological molecules is discussed.

*RB is supported by the NSF through grant no. DMR-0404615.

**D26 7 Mechanism of gene-regulating proteins diffusion along DNA: hopping vs. sliding** YAN MEI WANG, *Physics Department, Princeton University* EDWARD COX, *Molecular Biology Department, Princeton University* ROBERT AUSTIN, *Physics Department, Princeton University* It has been a long controversy as whether non-energy-driven proteins diffuse along DNA in the form of hopping or sliding. In the hopping model, the protein jumps on and off DNA frequently while diffusing, switching between 1D and 3D diffusions, and in the sliding model the protein diffuses along DNA basepair by basepair, staying in continuous contact with the DNA. We have investigated the diffusion mechanisms of LacI repressor protein along nonspecific sequences of DNA using single molecule imaging measurements. By studying the standard deviation (SD) of the diffusing LacIs point spread functions, we observed that the SD values in both the longitudinal and transverse directions to DNA elongation to be significantly higher than what can be accounted for by the sliding model. We will show that the large SD values agree with the hopping model.

**16:42**
**D26 8 Protein jamming on DNA** ZEBA WUNDERLICH, *Harvard* MICHAEL SLUTSKY, MEHRAN KARDAR, LEONID MIRNY, *MIT* The mechanisms by which DNA-binding proteins find their sites on DNA have been the subject of intensive research in biophysics. Most theoretical models consider proteins searching naked DNA for their binding sites. In the cell, however, myriads of proteins and protein complexes (*e.g.* nucleosomes) are constantly binding DNA. What is the effect of DNA-bound proteins and nucleosomes on the rate of protein-DNA association and dissociation? Here we study how a protein finds its site on DNA, and how long it stays on its site, considering DNA that is bound by other proteins. The process of association and dissociation is modeled by rounds of 3D diffusion and 1D sliding. We assume that proteins bound to DNA act as reflecting boundaries and obstruct sliding of other proteins. We demonstrate that if the density of proteins on the DNA is above a critical level, a protein's mobility on DNA is significantly reduced, leading to jamming. We find that proteins bound to DNA in the proximity of the specific site can (i) significantly increase the time it takes for the protein to find its site, and (ii) simultaneously increase the time a protein spends on its site. The increase in the residence time of a protein on its site can have important biological implications. Our results are consistent with recent experiments on p53 and the organization of nucleosomes in yeast promoters. The structures of eukaryotic enhancers also suggest that jamming may play a role in the assembly of protein complexes on DNA.

**D26 9 Single-molecule Study of Nucleocapsid Protein Chaperoned DNA Hairpin Structural Dynamics** YINING ZENG, *Department of Chemistry and Biochemistry, University of Texas at Austin* GONZALO COSA, *Department of Chemistry, McGill University* HSIAO-WEI LIU, CHRISTY LANDES, DMITRII MAKAROV, PAUL BARBARA, *Department of Chemistry and Biochemistry, University of Texas at Austin* KARIN MUSIER-FORSYTH, *Department of Chemistry, University of Minnesota* In HIV-1 reverse transcription, the nucleocapsid protein, NC, induces secondary structure fluctuations in the transactivation response (TAR) region of DNA and RNA hairpins. Time resolved single-molecule fluorescence resonance energy transfer was used to study NC chaperoned secondary fluctuations of DNA hairpins. The experiments reveal that the NC induced secondary fluctuations are limited to the terminal stems, and the mechanism for the fluctuations is complex. The dynamic processes occur over a wide time range, i.e. $\sim$ 5 to $>$ 250 milliseconds and involve long-lived inter-

mediates. The dynamic role of DNA loop regions and NC binding/dissociation events are discussed.

**17:06**
**D26 10 Mechanism of Nucleic Acid Chaperone Function of Retroviral Nuceleocapsid (NC) Proteins** IOULIA ROUZINA, MY-NUONG VO, KRISTEN STEWART, KARIN MUSIER-FORSYTH, MARGARETA CRUCEANU, MARK WILLIAMS, *Northeastern University* U OF M TEAM, NORTHEASTERN TEAM, Recent studies have highlighted two main activities of HIV-1 NC protein contributing to its function as a universal nucleic acid chaperone. Firstly, it is the ability of NC to weakly destabilize all nucleic acid,(NA), secondary structures, thus resolving the kinetic traps for NA refolding, while leaving the annealed state stable. Secondly, it is the ability of NC to aggregate NA, facilitating the nucleation step of bi-molecular annealing by increasing the local NA concentration. In this work we use single molecule DNA stretching and gel-based annealing assays to characterize these two chaperone activities of NC by using various HIV-1 NC mutants and several other retroviral NC proteins. Our results suggest that two NC functions are associated with its zinc fingers and cationic residues, respectively. NC proteins from other retroviruses have similar activities, although expressed to a different degree. Thus, NA aggregating ability improves, and NA duplex destabilizing activity decreases in the sequence: MLV NC, HIV NC, RSV NC. In contrast, HTLV NC protein works very differently from other NC proteins, and similarly to typical single stranded NA binding proteins. These features of retroviral NCs co-evolved with the structure of their genomes.

**D26 11 Fis protein induced λF-DNA bending observed by single-pair fluorescence resonance energy transfer** FU CHI-CHENG, *Institute of Atomic and Molecular Science, Academia Sinica,Taipei, Taiwan* FANN WUNSHAIN, *Institute of Atomic and Molecular Science, Academia Sinica,Taipei, Taiwan* YUAN HANNA S., *Institute of Molecular Biology, Academia Sinica,Taipei, Taiwan* Fis, a site-specific DNA binding protein, regulates many biological processes including recombination, transcription, and replication in E.coli. Fis induced DNA bending plays an important role in regulating these functions and bending angle range from ~ 50[r] to 95 [r] dependent on the DNA sequence. For instance, the average bending angle of λF-DNA (26 bp, 8.8nm long, contained λF binding site on the center) measured by gel mobility shift assays was ~ 94 [r]. But the traditional method cannot provide information about the dynamics and the angle distribution. In this study, λF-DNA was labeled with donor (Alexa Fluor 546) and acceptor (Alexa Fluor 647) dyes on its two 5' ends and the donor-acceptor distances were measured using single-pair fluorescence resonance energy transfer (sp-FRET) with and without the present of Fis protein. Combing with structure information of Fis-DNA complex, the sp-FRET results are used to estimate the protein induced DNA bending angle distribution and dynamics.

**D27 1 Linear scaling techniques for the solution of the time-dependent Schrödinger equation.***
SUXING HU, *Los Alamos National Laboratory*

An efficient, accurate solution of the time-dependent linear/nonlinear Schrödinger equation (TDSE) is required for a wide variety of problems in physics and chemistry. These include the dynamics of atoms and molecules in intense/ultrashort external fields, time-dependent approaches to atomic collisions, the dynamics of ultracold media such as Bose-Einstein Condensates and plasmas, and the behavior of materials under extreme conditions. Various techniques have been developed for this purpose. We shall describe a new approach in which the Finite Element Discrete Variable Representation (FEDVR) is combined with the Real-Space Product (RSP) algorithm to generate a highly effective procedure (RSP-FEDVR) for solving the TDSE on supercomputers. Emphasis will be placed on the complete formalism and the implementation of parallelization within the Message-Passing-Interface (MPI) scheme on large, distributed-memory supercomputer clusters. Its superior performance will be illustrated by a number of three-/four-dimensional problems, in comparison to the conventional finite-difference (FD) methods.

*In collaboration with Barry I. Schneider (NSF) and Lee A. Collins (LANL).

**D27 2 Solution of the Time-Dependent Schroedinger Equation using a Real Space Product Finite Element Discrete Variable Representation (RSPFEDVR)** BARRY SCHNEIDER, *National Science Foundation* LEE COLLINS, SUXING HU, *Los Alamos National Laboratory* A novel approach to the solution of the time-dependent Schroedinger equation using a RSPFEDVR method is described. The method is applied in both a second and fourth order version. In this talk we describe the essential features of the approach and compare the method as to its accuracy and efficiency in a number of model problems. The method may be transparently and efficiently parallelized using MPI as a consequence of the structure of the RSPFEDVR propagator which leads to a minimal number of communications at each step in the propagtion.

**15:18**
**D27 3 A Nonlinear Finite Difference Scheme for the Time-Dependent Schrodinger Equation*** RONALD MICKENS, In general, the time-dependent Schrodinger equation (TDSE) cannot be explicitly solved for an arbitrary boundary and/or initial value

problem. One resolution of this difficulty is to construct discrete models of this equation and use them to calculate numerical solutions. We consider the case of the TDSE, in one space dimension, and demonstrate that a nonlinear finite difference scheme can be formulated. We study its various limiting forms and compare their mathematical properties with those of the corresponding ordinary and partial differential equations. A formal solution is presented for the fully discrete TDSE. We discuss the basis of this nonlinear discretization within the framework of the nonstandard finite difference methodology created by Mickens [1] and the work of Bhattacharya [2]. [1] R. E. Mickens, Nonstandard Finite Difference Models of Differential Equations (World Scientific, Singapore, 1994). [2] M. C. Bhattacharya, Applied Mathematical Modeling 10 (1986), 68-70.

**D27 5 Quantum Computation for Quantum Chemistry.** ALAN ASPURU-GUZIK, *UC Berkeley*

The calculation time for the energy of atoms and molecules scales exponentially with system size on a classical computer, but polynomially using quantum algorithms. We demonstrate that such algorithms can be applied to problems of chemical interest using modest numbers of quantum bits. Calculations of the $H_2O$ and LiH molecular ground-state energies have been carried out on a quantum computer simulator using a recursive phase estimation algorithm. The recursive algorithm reduces the number of quantum bits required for the read-out register from approximately twenty to four. Mappings of the molecular wave function to the quantum bits are described. An adiabatic method for the preparation of a good approximate ground-state wave function is described and demonstrated for stretched $H_2$. The number of quantum bits required scales linearly with the number of basis functions used and the number of gates required grows polynomially with the number of quantum bits.

**D27 6 The ''Inverse Band Structure ( IBS) Approach'' for designer nanostructures and designer impurities in semiconductors.** ALEX ZUNGER, S. DUDIY, *NREL* While in standard computational physics and chemistry one first defines the molecular or crystalline structure and then computes the ensuing electronic structure and properties, we adopt a reverse approach in which we search for the atomic configuration having a prescribed target property. Using either Simulated Annealing or Genetic Algorithms as search strategies we determine the configuration of groups of Nitrogen atoms having either the deepest or the shallowest level in the GaP gap, or the highest/lowest oscillator-strength for optical absorption. Similar approaches are used to determine the extremal band gaps of alloys and the configuration of Mn atoms in GaAs having the highest Curie temperature. This approach allows one to scan a large number of configurations of e.g, alloys in search of the optimal one with a desired property.If the property is readily calculable, the IBS search is done on-the-fly. If its difficult to calculate ( e.g, Tc of ferromagnets), we first do a cluster expansion,then IBS search. Work supported by DOE-SC-BES-DMS under NREL contract AC3699GO10377.

**D27 7 A Real-Space Genetic Algorithm for Crystal Structure Determination** LUKE ABRAHAM, MATT PROBERT, *University of York* There has been much interest in using genetic algorithms for determining the ground-state structure of clusters [1] and nanowires [2], and more recently silicon surfaces [3]. We present a real-space encoded genetic algorithm which is suitable not only for surface structure calculations, but also for bulk crystal structure determination. This algorithm makes use of a novel crossover technique in the generation of offspring. The method is also suitable as a polymorph search, and is flexible enough that population members can have different supercells. We will present results from a variety of empirical and *ab initio* systems, where all calculations have been performed using the CASTEP [4] code.

**D27 8 Traveling the configurational space of binary alloys*** G. TRIMARCHI, S. V. BARABASH, A. ZUNGER, *National Renewable Energy Lab., Golden CO 80401* Binary $A_{1-x}B_x$ alloys can exist in any of the $2^N$ possible configurations on a periodic lattice of $N$ sites. In many areas of the alloy theory one needs to

search all lattice configuration. Such a problem arises, for example, when the $T = 0$ ground state configurations are sought, or in problems of materials design, where it is desirable to scan all the configurations to find the configuration $\sigma^*$ that has specific property. This task is complicated by (i) the huge computational demand for large $N$ and (ii) by the possibility that the $P(\sigma)$ is sensitive to the cell shape. In this talk we present a new computational approach for defining and searching the configurational space, that is based on (i) the exhaustive *enumeration* of the ''Inequivalent Cell Shapes,'' and, for a given cell shape on (ii) the *sampling* of the related ''Same-Shape-Structures'' via a Genetic Algorithm. We apply this procedure to few ground state problems in semiconductor and metal alloys: For $(AC)_x(BC)_{1-x}$ tetrahedral semiconductor alloys we predict the lattice configurations of minimum bond-bending and bond-stretching strain both in free-floating bulk and under the epitaxial strain. We show that the chalcopyrite structure remains a ground state even under epitaxy. For Au-Pd alloy modelled with the mixed basis cluster expansion Hamiltonian, we determine the ground state structures and compare the convex hull to the one found previously by the direct enumeration approach.

**D27 9 Simulating Charged Systems with the Geometric Cluster Algorithm** STEPHEN BARR, ERIK LUIJTEN, *University of Illinois at Urbana-Champaign* The recently introduced generalized geometric cluster algorithm (GCA) for colloidal suspensions [J. Liu and E. Luijten, Phys. Rev. Lett.**92**, 035504 (2004)] is extended to systems with electrostatic interactions. The Ewald summation is used to determine the pair potentials. However, the resulting pair potentials cannot be used directly in the GCA because the long range nature of the electrostatic potential causes all particles to be included in a cluster. In our new method, the cluster size is therefore controlled by using only the real-space part of the potential during cluster construction, then accepting or rejecting the cluster move based on the part of the internal energy that is computed in Fourier space. Although the resulting algorithm is, in contrast with the original approach, no longer rejection-free, it is possible to perform collective nonlocal moves while maintaining a significant acceptance ratio. The method is particularly beneficial for systems containing components with large size asymmetries, such as suspensions of charged colloids in the presence of salt.

**17:06**

**D27 10 Multi-physics/scale simulations using particles** PETROS KOUMOUTSAKOS, *ETH Zurich* Particle simulations of continuum and discrete phenomena can be formulated by following the motion of interacting particles that carry the physical properties of the systems that is being approximated (continuum) or modeled (discrete) by the particles. We identify the common computational characteristics of particle methods and emphasize their key properties that enable the formulation of a novel, systematic framework for multiscale simulations, that can be applicable to the simulation of diverse physical problems. We present novel multiresolution particle methods for continuum (fluid/solid) simulations, using adaptive mesh refinement and wavelets, by relaxing the grid-free character of particle methods and discuss the coupling of scales in continuum-atomistic flow simulations.

**17:18**

**D27 11 Algorithmic Refinements for Multicanonical System Measurements** DAVID YEVICK, TAO LU, DEREK DUMAS, MICHAEL REIMER, WITOLD BARDYSZEWSKI, BRETT HAMILTON, *University of Waterloo* We have adapted, to our knowledge for the first time, multicanonical sampling and its Wang-Landau extension to the analysis of the statistics of communication systems, and by extension, arbitrary stochastic physical systems.[D. Yevick, ''A First Course in Computational Physics and Object Oriented Programming with C++'', Cambridge University Press, Ch. 22 and references] Subsequently, we applied the technique experimentally with and without a novel biasing procedure for the intermediate pdf distributions that significantly enhances the statistics in selected regions of system variables. [T. Lu, D. Yevick et. al.**,** IEEE Photon. Technol. Lett, **17**, 1420 (2005) and to be published]. Here we additionally discuss procedures that (1) bias the statistical samples by raising the estimated pdf to a power (2) combine intermediate results in a manner identical to that employed in importance sampling (3) incorporate non-uniform Markov chain displacements and (4) interpolate the histogram and pdf values during iterations. These significantly impact experiments with a restricted number of samples.[D. Yevick et. al., submitted to J. Opt. Soc. Am. A]

**SESSION D28: BLOCK COPOLYMER THIN FILMS**

**D28 1 Tuning Surface Interactions to Control Thin Film Block Copolymer Orientation** ALAMGIR KARIM, RONALD JONES, DUANGRUT JULTHONGPIPUT, MICHAEL FASOLKA, ERIC AMIS, *Polymers Division, NIST* SUSHIL SATIJA, *Center for Neutron Research, NIST* SUSHIL SATIJA COLLABORATION, We tune polymer-substrate surface interactions in order to control the orientation and ordering of diblock copolymers of polystyrene – polymethylmethacrylate (PS-b-PMMA) ultrathin films. To this end we utilize UV to alter the surface energy of a SAM coated substrate and anneal spin coated thin films of high molecular weight (approx. 50kDa) PS-b-PMMA. We have previously utilized a combinatorial approach of substrate surface energy vs. diblock film thickness to map out the distribution of surface topography measured by optical microscopy (such as island and hole formation regions), and observed a switch in symmetry of topography with surface energy variation across a ''neutral'' region. In the present work, we report results pertaining to the neutral surface energy substrate conditions. We utilize AFM, neutron reflection, SEM and TEM to characterize the morphology of ordered structures on the controlled surface energy substrates. The advantage of the present work is the relative ease of surface energy control with UV and the tunability of surface energy to potentially match neutral boundary conditions for a broad set of block copolymers with different chemical blocks components.

**14:42**

**D28 2 Internal and Interface Structure in Diblock Copolymer Brushes** MARK D. FOSTER, BULENT AKGUN, GOKCE UGUR, WILLIAM J. BRITTAIN, *Maurice Morton Institute of Polymer Science, The University of Akron, Akron, OH 44325* XUEFA LI, DONG RYEOL LEE, JIN WANG, *Experimental Facilities Division, Argonne National Laboratory, Argonne, IL 60439* Internal and surface structure of polystyrene-*b*-polyacrylate diblock copolymer brushes have been studied using grazing-incidence small-angle X-ray scattering (GISAXS) and atomic force microscopy (AFM). Polystyrene-*b*-polyacrylate or polyacrylate-*b*-polystyrene brushes were synthesized using atom transfer radical polymerization. Poly (methylacrylate) or poly (*n*-butyl acrylate) is used as the acrylate block. Each as-deposited diblock brush show an internal lateral structure with a spacing comparable to the thickness of the top layer of the brush on the order of 10 nm. After a brush is treated with a selective solvent which is a good or theta solvent for the bottom block and poor solvent for the top block, Bragg rods appear in GISAXS pattern. The lateral spacing corresponding to the Bragg rods is on the order of the total thicknesses of the brushes. This lateral correlation is also detected by the power spectral density analysis of the AFM measurements of the samples' surfaces using tapping mode imaging. The Bragg rods disappear upon heating to 80 [r]C and this behavior does not depend on which polyacrylate block was used.

**14:54**

**D28 3 Internal Morphology of Diblock Copolymer Brushes Determined by Neutron Reflectivity.** BULENT AKGUN, WILLIAM J. BRITTAIN, MARK D. FOSTER, *Maurice Morton Institute of Polymer Science, The University of Akron, Akron, OH 44325* CHARLES F. MAJKRZAK, *National Institute of Standards and Technology, Gaithersburg, Maryland 20899* Although diblock copolymer brushes (BCB) have been extensively studied in recent years, their internal structure is still unknown. To elucidate the interface width and internal structure of BCBs, neutron reflectivity (NR) has been used. BCBs of deuterated polystyrene (dPS) and poly(methyl acrylate) (PMA) with dPS adjacent to the surface (d-PS-*b*-PMA) or with PMA adjacent to the surface (PMA-*b*-dPS) and having different thicknesses were synthesized using atom transfer radical polymerization. In ultrathin BCBs a gradient in composition perpendicular to the surface extends essentially through the entire thickness of the brush. The interface width, defined as the full-width at half-maximum of a Gaussian function needed to represent the broadening of the step interface profile, is found to be smaller for PMA-*b*-dPS than for dPS-*b*-PMA brushes. The interface width for a film spun from untethered chains of dPS-b-PMA has been measured and the results compared with those for the BCBs. BCBs have been measured in both good solvent and poor solvent vapors with NR and the concentration profiles and extent of swelling determined.

**15:06**

**D28 4 Resonant X-Ray Scattering in Block Copolymer Thin Films** JUSTIN VIRGILI, *University of California, Berkeley* JEFFREY KORTRIGHT, *Lawrence Berkeley National Laboratory* NITASH BALSARA, RACHEL SEGALMAN, *University of California, Berkeley* Resonant x-ray scattering in a transmission geometry is reported in block copolymer films for the first time. By tuning soft x-rays to the carbon $\pi^*$-$\pi^*$ bonds in a poly(styrene-b-isoprene) (PS-PI) diblock copolymer thin film, the scattering intensity is enhanced, thereby overcoming the small scattering volume inherent to a thin film geometry. This technique provides an alternative polymer thin film characterization technique to GISAXS that shares the same benefit of averaging over large sample areas (100's $\mu$m x 100's $\mu$m). The characterization of large sample areas is not readily accessible via real-space characterization techniques, such as TEM and AFM, and is of growing importance to applications such as optoelectronic devices. We will demonstrate the use of the resonant x-ray scattering technique in thin films of PS-PI and will demonstrate the effects block copolymer composition and film thickness on the observed scattering profiles. We will also compare our results from resonant x-ray scattering to TEM and AFM data.

**15:18**

**D28 5 The development of order in ultra-thin PS-PMMA diblock copolymer films.** WARD LOPES, HAI QIAN, GENE MAZENKO, HEINRICH JAEGER, *James Franck Institute, The University of Chicago* Knowledge of how two dimensional systems order is important for techniques like hierarchical self-assembly or diblock copolymer lithography. The applicability of these techniques can be limited by the defects which influence the late stage of ordering. Further, one would like to know whether or not the qualitative features of ordering depend only on the symmetry of the system. We address these concerns by studying the growth of order in weakly-segregated, cylindrical-phase, PS-PMMA diblock copolymer films. Our samples have smectic (striped) symmetry and form a single layer of half-cylinders with more than $10^5$ repeat spacings. We have found qualitative differences between our results and results reported on strongly segregated cylindrical-phase diblock copolymer films(1). We find, for example, that the number of dislocations and disclinations are approximately equal and that grain boundaries persist for long times. We are using time lapse atomic force microscopy to track disclination dipole, tripole, and quadrupole annihilations and will report on the relative frequency of each. We will compare our results with numerical simulations of the Swift-Hohenberg Model. (1) Harrison et. al. Science, **290**, 1558 (2000); Harrison et. al. Phys. Rev. E, **66**, 11706 (2002).

**15:30**

**D28 6 Thickness Dependent Packing Symmetries of Spherical-Domain Block Copolymer Multilayers** G.E. STEIN, E. COCHRAN, G.H. FREDRICKSON, E.J. KRAMER, *UCSB* X. LI, J. WANG, *ANL* The packing of spherical block copolymer domains confined to a thin film is investigated with grazing-incidence small angle x-ray scattering. Whereas the equilibrium structure of a monolayer is hexagonal (HEX), and that of the bulk is body-centered cubic (BCC), we find a remarkably complex transition from 2D to 3D packing as a function of film thickness. Films 1-3 layers of spheres thick have close-packed hexagonal symmetry. At four layers the hexagonal symmetry breaks to form an orthorhombic phase, characterized by a second-to-first nearest-neighbor distance ratio $a_1/a_2 = 1.08$ with an angle $\phi = 57°$ between $\vec{a}_1$ and $\vec{a}_2$. As the number of layers is increased from 4 to 23, $a_1/a_2$ increases monotonically to 1.17, and $\phi$ decreases monotonically to 54.2°, a structure similar to the stacking of BCC (110) planes. From measurements above and below the polymer critical angle, we determine that all phases are uniform throughout the depth of the film. These results are interpreted in the context of a Landau-type theory, using SCFT calculations to demonstrate the competition between the packing preferred in the bulk with that at the interfaces.

**15:42**

**D28 7 Effect of chain architecture and surface energies on the microdomain orientation in block copolymer films** V. KHANNA, E. J. KRAMER, E. W. COCHRAN, G. H. FREDRICKSON, *UCSB* X. LI, J. WANG, *Argonne National Lab* S. F. HAHN, *Dow Chemical Company* We investigate the effect of surface energy and chain architecture on the orientation of microdomains in relatively thick films ( 600nm) of lamellar and cylindrical block copolymers of poly(vinylcyclohexane)(C) and poly(ethylene)(E). The E block has 26 ethyl branches per 1000 backbone carbon atoms. Melt surface energies of the C and E blocks are 22.3 and 20.9 $mJ/m^2$, respectively. GISAXS, SFM and cross sectional TEM show that cylindrical and lamellar CEC triblock copolymers orient their microdomains normal to the surface through the film thickness. However, a lamellar CE diblock prefers a parallel orientation of the sheets with an E surface. Moreover, a cylindrical CEBC triblock copolymer where the EB block has 125 ethyl branches per 1000 backbone carbon atoms leads to EB cylinders that always orient parallel to the surface. In this case the lower surface energy EB block dominates the surface. Self-consistent field theory calculations allow us to interpret the experimental results in terms of the entropic cost of forming a wetting layer comprised entirely of looping blocks. Thus in triblock copolymers, parallel orientations are only stabilized when the surface energy of the midblock is low enough to compensate for this conformational penalty, which is absent in diblock copolymers.

**15:54**

**D28 8 Symmetry Breaking In Block Copolymer Thin Films** ERIC COCHRAN, *Iowa State University* KIRILL KATSOV, GILA STEIN, ED KRAMER, GLENN FREDRICKSON, *University of California, Santa Barbara* Recent experiments by Stein and Kramer show that thin films of poly(styrene-b-vinylpyridine) diblock copolymer undergo a discontinuous transformation from hexagonally-close packed spheres to a Fmmm orthorhombic packing as the thickness of the film is increased; beyond the hcp-Fmmm transition, the unit cell deforms to asymptotically approach bcc symmetry, which is preferred in the bulk system. We use a Landau-type theory to construct various scenarios of symmetry-breaking in this system. High resolution SCFT calculations show the nature of the competition between the preferred packing in the bulk and that at the interface. We conclude that character of the transition from thin-film to bulk behavior may be either continuous or discontinuous, depending on the bulk properties of the block copolymer and the surface energy.

**16:06**

**D28 9 Ion Complexation in Salt Containing Block Copolymer Thin Films** MATTHEW MISNER, *University of Massachusetts* SEUNG HYUN KIM, *Inha University* LING YANG, *University of Massachusetts* THOMAS RUSSELL, *University of Massachusetts* Ion complexation within cylinder-forming PS-b-PEO thin films was investigated, where added salts bound the PEO block as the minor component. Small amounts of added salts, on the order a few ions per chain, show large effects on the ordering and orientation of the copolymer films during solvent annealing, a process where we have shown a large degree of long-range lateral order can be obtained. The orientation of the cylindrical microdomains was found to strongly depend on salt concentration and the nature of the counter ion. Furthermore, with the addition of relatively large amounts of salts, we observed that the copolymer microdomains remained ordered at a high degree of swelling and an extremely large amount of lateral spatial correlations of the cylindrical microdomains was found in the swollen state, as observed by grazing incidence small angle scattering. By using gold or cobalt salts, well-organized patterns of nanoparticles were generated in the copolymer microdomains after the reduction of the corresponding salts.

**16:18**

**D28 10 Homopolymer Penetration on Crosslinked Copolymer Mat** DU YEOL RYU, *Yonsei University* JIA-YU WANG, *UMASS-Amherst* ERIC DROCKENMULLER, *UCSB* KRISTOPHER LAVERY, *UMASS-Amherst* CRAIG HAWKER, *UCSB* THOMAS RUSSELL, *UMASS-Amherst* UMASS-AMHERST COLLABORATION, UCSB COLLABORATION, Ultra-thin films of benzocyclobutene (BCB)-functionalized random copolymers of styrene and methyl methacrylate were thermally-crosslinked on a substrate, but applicable to other systems, with a controlled thickness. Contact angles measured in nano scale describe that over the critical minimum thickness ( 5.5nm) interfacial interaction of crosslinked random copolymer is well balanced. Neutron Reflectivity has been used to investigate in terms of the penetration of the polymer into crosslinked random copolymer P(S-r-BCB-r-MMA). Thus, to evaluate the critical minimum thickness which is at least required to control over the microdomain orientation of the PS- PMMA block copolymer systematically, deuterated PMMA was spin coated on crosslinked random copolymer controlled with various thickness from 1 to 10 nm. The neutron scattering length densities (SLD) of crosslinked random copolymer are increased with decreasing thickness, which means that the SLD contribution of d-PMMA to BCB layer is getting bigger because thin BCB layer is not enough to cover the SiOx.

**16:30**

**D28 11 Enhanced order in thinfilms of Pluronic (A-B-A) and Brij (A-B) block copolymers blended with poly(acrylic acid)*** VIJAY R. TIRUMALA, BRYAN D. VOGT, HAE-JEONG LEE, ERIC K. LIN, *Polymers Div., NIST* JAMES J. WATKINS, *Polymer Science & Engr. Dept., UMass-Amherst* Pluronic ($PEO_m$-$PPO_n$-$PEO_m$) and Brij ($PEO_m$-$PE_n$) based block copolymer films have recently been used as sacrificial templates for the fabrication of mesoporous low-*k* thinfilms. We have found that the addition of a low molecular weight third component homopolymer exhibiting strong interactions with one of the blocks enhances the local and long-range order of both Pluronic and Brij templates in the melt. In this work, small-angle neutron scattering and x-ray reflectivity were used to investigate the microstructure of block copolymer/poly(acrylic acid) blend templates. In templates where PEO serves as a majority phase, both scattering and reflectivity measurements show that addition of PAA decreases the interfacial width and strengthens domain segregation. In templates with PEO as the minority phase, addition of PAA can induce an order-order transition. Tuning the microphase morphology of block copolymer thinfilms using a low-molecular weight homopolymer additive has many implications for methods that use block copolymer melts as sacrificial templates.

**16:42**

**D28 12 Ordering transition of block copolymer films under compressed CO2** ABRAHAM ARCEO, PETER F. GREEN, *University of Michigan* It is well-known that a bulk, symmetric, A-b-B diblock copolymer forms a lamellar morphology, with period L, below an order- disorder transition temperature (TODT), for XN $<$ 10.5; X is the Flory-Huggins interaction parameter and N is the degree of polymerization of the copolymer. The ordering temperatures of poly(styrene-b-methyl methacrylate) (PS-b-PMMA) thin film diblock copolymers of thickness ca. 2L, supported by SiOx/Si substrates, in vacuum environments, are shown to increase beyond the bulk, having unusually large shifts of the transition temperature with small changes of XN. We find that in compressed $CO_2$ environments, these films are ordered at temperatures where the films are disordered in vacuum (or air) environments. This latter observation is of particular significance because small molecule diluents, including compressed $CO_2$, are known to decrease the TODT of the bulk (enhanced miscibility). We will discuss these results in light of the thin film compressibility and preferential sorption of the individual blocks at the experimental conditions.

**16:54**

**D28 13 Self-Organization of PS-b-PFOMA Block Copolymer Aggregates in Thin Films** YUAN LI,*LUCIANA MELI,†KEITH JOHNSTON, *Graduate Program of Materials Science and Engineering, Department of Chemical Engineering, The University of Texas at Austin* KWON LIM, *Division of Image and Information Engineering, Pukyong National University, Korea* PETER GREEN, *Department of Materials Science and Engineering, The University of Michigan* SFM, STEM and XPS were employed to study the morphologies of polystyrene-b-poly(1,1',2,2'-tetrahydroperflurooctyl methacrylate) (PS-b-PFOMA) films. The copolymer was dissolved in the co-solvent mixture of Freon 113 and toluene. Upon spin-casting on Si/SiOx substrate, PS-b-PFOMA was found to self-organize into spherical aggregates, where the cores of the spheres were composed primarily of PFOMA and the matrix was composed by PS. However, exposing the films to supercritical $CO_2$ led to a reversed morphology, where spheres of PS were embedded in the matrix of PFOMA. In addition, the degree of ordering was improved in sc-$CO_2$ and the domain size was tuned by adjusting sc-$CO_2$ density. The results were discussed based on the effects of sc-$CO_2$ on the interfacial tension and the relative PS-PFOMA interactions.

**D28 14 Scaling of Domain Spacing of Block Copolymers Dilated by High-Pressure Carbon Dioxide** TIMOTHY FRANCIS, BRYAN VOGT, XIAOHUI WANG, JAMES WATKINS, DEPARTMENT OF CHEMICAL ENGINEERING, UNIVERSITY OF MASSACHUSETTS COLLABORATION, POLYMERS DIVISION, NATIONAL INSTITUTE OF STANDARDS AND TECHNOLOGY COLLABORATION, POLYMER SCIENCE AND ENGINEERING DEPARTMENT, UNIVERSITY OF MASSACHUSETTS COLLABORATION, The dependence of the interdomain spacing on the sorbed solvent volume fraction of microphase separated poly(styrene-*b*-dimethyl siloxane) in the high concentration limit was probed using high-pressure carbon dioxide as the diluent. Domain spacing was measured using itin situ small angle neutron scattering, both isothermally and at constant polymer volume fraction. The results indicate that high-pressure $CO_2$ behaves similarly to a selective liquid solvent and that d-spacing is strongly influenced by solvent selectivity, which is a function of temperature for this system. The data also show that the d-spacing as a function of solvent volume fraction cannot be described by the traditional power law scaling that does not account for solvent selectivity, but collapse to a line when scaled by a swelling asymmetry factor. Data measured at constant polymer volume fraction are in good agreement with previously reported findings, and show that the interdomain spacing exhibits power law scaling with the temperature dependent interaction parameter.

**17:18**

**D28 15 Amphiphilic Block Copolymers in Condensed Carbon Dioxide** WILLIAM EDMONDS, *Department of Chemical Engineering and Materials Science, University of Minnesota* TIMOTHY LODGE, MARC HILLMYER, *University of Minnesota* Condensed carbon dioxide represents a promising ''green'' solvent alternative on the basis of its abundance and modest critical conditions. Amphiphilic block copolymers offer the potential of enhancing the versatility and usefulness of this solvent through the formation of micelles. Our goal is to understand and define the parameters that control aggregate shape and dimensions in solution; these parameters include copolymer volume fraction and solvent density. We will present dynamic light scattering and solubility data for a series of polybutadiene-*b*-poly(hexafluoropropylene oxide) and polylactide-*b*-poly(hexafluoropropylene oxide) copolymers. At modest pressures ( $<$ 500 bar), these materials are readily soluble. In addition, initial measurements suggest the formation of non-spherical micelles in solution.

**D29 1 Processivity of helicase-induced DNA strand separation** M. D. BETTERTON, *University of Colorado* F. JULICHER, *Max Planck Institute for the Physics of Complex Systems* Helicases are molecular motors which unwind double-stranded nucleic acids (dsNA) in cells. Many helicases move with directional bias on single-stranded nucleic acids (ssNA), and couple their directional translocation to strand separation. A simple model of the coupling between translocation and unwinding uses an interaction potential between the helicase and the ss-ds junction which can capture both 'passive' and 'active' mechanisms of NA unwinding. A passive helicase relies on fluctuations which open the dsNA base pairs to advance while its presence on the strand inhibits NA closing. An active helicase directly destabilizes dsNA base pairs where it is bound, thus accelerating the opening rate. Here, we take into account the effects of helicase detachment from the NA strand corresponding to a limited processivity. The average helicase attachment time then depends on the form of the interaction potential.

For a passive helicase the mean attachment time does not change between ss translocation and ds unwinding, while for an active helicase in general a decrease in attachment time occurs during unwinding as compared to ss translocation.

**D29 3 Twirling of Actin by Myosins II and V** JOHN F. BEAUSANG, *Phyiscs Dept.* HARRY W. SHROEDER, *Biochemistry and Mol. Biophysics* JAMES A. GILMOUR, *Dept of Bioengineering* YALE E. GOLDMAN,* *Pennsylvania Muscle Institute* A polarized total internal reflectance fluorescence microscope was used to measure the 3D orientation of single rhodamine molecules with 40 ms time resolution (Forkey et al., itNature 422:399, 2003). We modified this setup by adding excitation polarizations at $\pm$ 45° relative to the optical axis of the microscope, thus enabling us to uniquely monitor 1/4 of the probe's angular phase space (previously 1/8). Phase shifts in the optics were compensated with an adjustable waveplate. Using actin filaments sparsely labeled with tetramethylrhodamine at Cys-374, the increased range of discernable angles was used to determine the handedness of filament rotation about its axis in a gliding filament assay. During translocation by Myosin II or V, approximately half of the observed actin filaments exhibit a 'twirling' helical path of rotation around the filament axis. Myosin II and V consistently induce a left-handed twirling motion (opposite to the long-pitch helix of actin) with pitch of 1.0 $\pm$ 0.2 $\mu$m for myosin II and 1.5 $\pm$ 0.1 $\mu$mfor myosin V. Several factors may be the cause of this twirling including: the direction of the force vector between actin and myosin, the distribution of myosin binding sites on actin, and cooperation between myosins translocating an individual actin filament. Supported by NIH grant AR26846 and NSF grant DMR04-25780.

**D29 4 Synthetic Motors and Nanomachines.**
AMAR FLOOD, *Department of Chemistry, Indiana University*

A bistable and palindromically-constituted [3]rotaxane incorporating two mechanically-mobile rings interlocked around a linear dumbbell component, has been designed to operate like the sarcomeres of skeletal muscle. Contraction and extension occurs when the inter-ring distance of the two rings switch, ideally, between 4.2 and 1.4 nm upon redox stimulation either chemically or electrochemically in the solution phase. When the mobile rings of these artificial molecular muscles are bound onto the tops of gold-coated, micron-scale cantilever beams, their controllable nanometer motions have a chance to be amplified along the long axis of each cantilever. It turns out that $\sim$ 6 billion of the self-assembled [3]rotaxanes can bend the cantilevers in a bistable manner concomitant with the cycled addition of redox agents. The extent of bending is commensurate with 10's of pN of force per [3]rotaxane. Recent studies on a set of ''single-shot'' control [2]rotaxanes have provided additional evidence for the origins of the force generation as it arises from a molecule-based electrostatic repulsion energy of about 10 kcal/mol at 300 K. These findings will be presented in terms of the underlying thermodynamics and kinetics that have been utilized extensively to direct the design and synthesis of artificial molecular machines and which may also serve as a guide for the rational design of unidirectional molecular motors.

**D29 5 Track Switching and Crossing by Microtubule Motors.** JENNIFER ROSS, KAREN WALLACE, HENRY SHUMAN, ERIKA HOLZBAUR, YALE GOLDMAN, *Pennsylvania Muscle Institute, University of Pennsylvania* Cytoskeletal filaments in cells form a network of crossing tracks for motor proteins carrying vesicular and protein cargoes. The ability to pass through, switch, or dissociate at such intersections is relevant to the motor's ability to effectively navigate in the cell and deliver goods to the appropriate location. We have formed an itin vitro system of crossed microtubules to study the outcome of kinesin motors and dynein-dynactin complexes when they encounter an intersection. Micro-tubules were flowed into the sample chamber from two orthogonal directions and aligned with the flow direction when they attached to glass cover slips via biotin-streptavidin. The first flow direction defined the microtubules closest to the glass surface. Using total internal reflection fluorescence (TIRF) microscopy, we visualized single GFP-kinesin motors and dynein-dynactin-GFP complexes during processive motility at 1 mM ATP. Both dynein and kinesin can switch microtubules, pass by an intersection, or dissociate. Using optical trapping, we placed 1 $\mu$m polymer beads decorated with multiple motors to simulate a large cargo encountering an intersection at 1 mM ATP. Beads are more likely to pause at the intersection at high motor number and can pass and switch as the motor concentration is titrated down. The differences between kinesin and dynein could inform of the ability of these motors to navigate the cell, both separately and in coordination. Supported by NIH grant AR51174.

**D29 6 Collective dynamics of molecular motors pulling on fluid membranes*** JAUME CASADEMUNT, *Universitat de Barcelona* OTGER CAMPAS, *Universitat de Barcelona / Institut Curie* YARIV KAFRI, *Institut Curie / Technion, Haifa* KONSTANTIN B. ZELDOVICH, *Harvard University* JEAN-FRANCOIS JOANNY, *Institut Curie* The collective dynamics of $N$ weakly coupled processive molecular motors when an external force is exerted on the first one, are considered theoretically. We show, using a discrete lattice model, that the velocity-force curves strongly depend on the effective dynamic interactions between motors and differ significantly from the mean field prediction. They become essentially independent of $N$ when this number is large enough. For strongly biased motors such as kinesin, this may occur for $N$ as small as 5. The study of a two-state model shows that the existence of internal states can induce effective interactions. Several analytical predictions are discussed and checked numerically both for the discrete lattice model and the two-state model with Langevin dynamics. Typically, motors cooperate constructively so that the collective stall force and the mean velocity are larger than the mean field expectations. The implications on the interpretation of previous experiments on membrane tubes pulled by collective motors and possible design of new experiments are discussed.

**D29 7 Entropic pulling: how Hsp70 chaperones translocate proteins through membrane pores** PAOLO DE LOS RIOS, *Ecole Polytechnique Federale de Lausanne - EPFL* ANAT BENZVI, *Northwestern University* OLGA SLUTSKY, ABDUSSALAM AZEM, *Tel Aviv University* PIERRE GOLOUBINOFF, *University of Lausanne* Hsp70s are highly conserved ATPase molecular chaperones mediating the translocation of proteins across membranes and the active unfolding and disassembly of stress-induced protein aggregates. Here, we introduce a mechanism named itentropic pulling, based on entropy loss due to excluded volume effects, by which Hsp70 molecules can convert the energy of ATP hydrolysis into a force capable to drive the translocation of polypeptides into mitochondria. Entropic pulling represents a possible solution to the long-standing debate between the itpower-stroke and the itBrownian ratchet models for Hsp70-mediated protein translocation across membranes. Moreover, in a very different context devoid of membrane and components of the import pore, the same physical principles apply to the forceful unfolding, solubilization and assisted native refolding of stable protein aggregates by individual Hsp70 molecules, thus providing a unifying mechanism for the different Hsp70 functions.

**D29 8 Biological motors: Conventional and Unconventional Myosins.***
YALE E. GOLDMAN, *University of Pennsylvania*

Molecular motors are smart, soft machines that regulate their dynamics and energy consumption for efficient tuning to their cell-biological role and mechanics of their cargo. The efficiency is derived partly from harnessing the chaotic thermal fluctuations nano-scale machines experience, rather than struggle against them. Reciprocal coupling between the enzymatic chemistry, structural changes, and mechanical steps is expected from the thermodynamics of an energy-transducing nano-machine. Strong evidence for this bidirectional coupling exists for muscle (conventional) myosin and unconventional myosins. The structural dynamics of myosin leading to translocation along actin are detectable by Optical Trap Mechanical Nanometry (OTNM), Single-Molecule Fluorescence Polarization Microscopy (SMFPM), Fluorescence Imaging at One Nanometer Accuracy (FIONA) and various combinations of these methods. We are in an Acronym Rich Environment (ARE). Progress and puzzles make this a lively research area.

**D29 9 A single polymer Brownian motor** MATTHEW DOWNTON, *Simon Fraser University* MARTIN ZUCKERMANN, *Simon Fraser University* ERIN CRAIG, *University of Oregon* MICHAEL PLISCHKE, *Simon Fraser University* HEINER LINKE, *University of Oregon* We study a polymer chain in a flashing ratchet potential to determine how the mechanism of this Brownian motor system is affected by the presence of internal degrees of freedom. Each monomer is acted upon by a 1D asymmetric, piecewise linear potential of spatial period $L$ comparable to the radius of gyration of the polymer. We characterize the average motor velocity as a function of $L$, $T_{\mathrm{off}}$, and $N$ to determine optimal parameter ranges, and we evaluate motor performance in terms of finite dispersion, Peclet number, rectification efficiency, stall-force, and transportation of a load against a viscous drag. We find that the polymer motor performs qualitatively better than a single particle in a flashing ratchet: with increasing $N$, the polymer loses velocity much more slowly than expected in the absence of internal degrees of freedom, and the motor stall force increases linearly with $N$. To understand these cooperative aspects of motor operation, we analyze relevant Rouse modes. The experimental feasibility is analyzed and the parameters of the model are scaled to those of $\lambda$-DNA. Finally, in the context of experimental realization, we present initial modeling results for a 2D flashing ratchet constructed using an electrode array.

**D29 10 Imaging and Manipulation of Nanocars by STM** A.J. OSGOOD, Y. SHIRAI, Y. ZHAO, J.M. TOUR, K.F. KELLY, *Rice University* The nanocar molecule - four fullerene wheels connected by rotating alkyne axles to a central chassis - is the first molecule designed and fabricated specifically for nanoscale manipulation. We have investigated the imaging and manipulation of the nanocar molecule on Au(111) by variable-temperature STM.

From the observed movement of the nanocars, we can show that their motion is due to rolling, not sliding, across the gold surface. Additionally, we have begun to explore the conditions for nanoscale rolling in a number of other molecules built from our set of ''molecular tinker toys'' with an eye towards remote manipulation and increased system complexity.

**17:18**

**D29 11 Physical mechanism of the nuclear pore transport.** A. ZILMAN, S. DI TALIA, M. MAGNASCO, M. ROUT, B. CHAIT, *Rockefeller University* Functioning of eukaryotic cells depends on precise regulation of the transport of proteins in and out of the nucleus. All the transport in an out of the nucleus proceeds through the nuclear pore complex (NPC). NPC is an efficient transport device, which transports proteins between the nucleus and the cytoplasm in milliseconds time. NPC is highly selective, only allowing efficient passage of the molecules bound to the transporter proteins. Although, one GTP is used per transported cargo, the process of translocation through the pore is passive and does not involve active energy consumption. The key component in the NPC function is the attractive interaction between the transporter proteins, and the flexible filaments, lining the internal surface of the pore. We model the transport through the NPC as diffusion in an effective potential due to attachments to the flexible filaments. Using analytical theory and computer simulations, we explain known functional features of the NPC, in terms of its basic physical properties.

## SESSION D30: MULTIPHASE POLYMER MATERIALS

**D30 1 Phonon Propagation in Dry and Wet Polystyrene Opals** GEORGE FYTAS, *Max Planck Institute for Polymer Research, P. O. Box 3148, 55128 Mainz, Germany and FO.R.T.H P.O.Box 1527 71110 Heraklion,Greece* WEI CHENG, JIAN JUN WANG, ULRICH JONAS, *Max Planck Institute for Polymer Research, P. O. Box 3148, 55128 Mainz, Germany* The phononic properties of fabricated soft opals consisting of closely packed spherical submicrometer polystyrene particles were investigated by Brillouin light scattering in the GHz frequency range. In air, the numerous modes found in the dry opal are theoretically identified as the particle eigenmodes using the two elastic constants for the bulk polystyrene. The line shape of the low-frequency modes can be utilized as an index of the particle size polydispersity and a sensitive probe for monitoring the latex film formation. Unlike for the dry opal, the study of the propagation of acoustic waves in the infiltrated (by silicon oil) opal for wave vector $k_{||}$ parallel to the fcc (111) planes of the slab has revealed two modes: an effective medium mode with linear dispersion over the examined $k_{||}$ range and a second mode the dispersion of which depends on the direction of $k_{||}$ relatively to the symmetry lines of the Brillouin zone. The experimental dispersion will be compared with phononic band structure calculations.

**14:42**

**D30 2 Kinetics of phase separation in a dilute short-ranged square-well system: a molecular dynamics study** HONGJUN LIU, *Department of Chemical and Biological Engineering, Rensselaer Polytechnic Institute, Troy, NY 12180* SHEKHAR GARDE, SANAT KUMAR, We report on a molecular simulation study of the phase separation in a dilute short-ranged square-well system. The phase diagram of model displays solid-fluid equilibrium, with a metastable fluid-fluid separation. Equilibrium fluid configuration are quenched along the isochore at a sequence of temperatures and followed during the time evolution. We present the clear evidence of the metastable fluid-fluid separation, of the homogeneous crystallization and of the kinetically arrested gel. We also discuss the relevance of our simulation to the ''crystallization slot.''

**14:54**

**D30 3 Styrene-Hydroxystyrene Gradient and Block Copolymers: Comparisions of Behavior as Compatibilizers of Immiscible, Crystallizable Polymer Blends and in the Neat and Solution States.** JUNGKI KIM, JOHN M. TORKELSON, *Northwestern University, Evanston, IL 60208* Styrene-hydroxystyrene (S-SOH) gradient and block copolymers are made by semi-batch nitroxide-mediated controlled radical polymerization of styrene and acetoxystyrene followed by hydrolysis of the acetoxystyrene repeat units to SOH. These copolymers are investigated as compatibilizers for polystyrene (PS)/polycaprolactone (PCL) blends made by melt mixing; the hydroxyl groups on the SOH units undergo attractive hydrogen-bonding interactions with the ester groups on PCL. Gradient copolymers of a wide composition range are effective compatibilizers of PS/PCL blends, with the dispersed phase (PCL) domain size being a function of gradient copolymer composition. Block copolymers are also effective compatibilizers, resulting in very small dispersed-phase domain sizes ( $\sim$ 200 nm average diameter). In addition, block copolymer addition has major effects on the crystallizability of the PCL domains; in contrast, only small effects on PCL crystallizability are observed upon addition of gradient copolymer to the blend. The different effects of block and graft copolymers are likely due to greater hydrogen bonding of the PCL with the block copolymer, which impedes crystallization. The properties of the block and gradient copolymers in the neat state and their micellization in solvent and in homopolymer will also be discussed.

**15:06**

**D30 4 An off-lattice Wang-Landau simulation of the coil-globule and solid-liquid transitions of flexible homopolymers.** DREW PARSONS, DAVID WILLIAMS, *Australian National University* The temperature-independent Wang-Landau Monte Carlo approach is implemented for an off-lattice model of flexible homopolymers and applied to the study of the coil-globule and solidification transitions. Transition temperatures are calculated and the thermodynamic limit of the two transitions is compared. We address the issue of obtaining crystal structure in the low energy solid globules, and raise the question of whether a glass-like state rather than crystalline is a correct description of the solid state.

**15:18**

**D30 5 Exploring the Effects of Deuteration on Polymer Blends** MICHAEL TAMBASCO, JANE LIPSON, *Dartmouth College* JULIA HIGGINS, *Imperial College* Deuterium labeling is a requirement of neutron scattering experiments, but the extent to which the H-D switch affects the thermodynamic properties of the

mixture under investigation has not been widely examined. In order to explore this, we apply a simple lattice theory to the analysis of a fairly complete set of experimental data on blends of polystyrene(PS)/polybutadiene(PB), in which all permutations of PS, dPS, PB, and dPB are of interest. Available data include cloud point curves, neutron scattering intensities, and pressure-volume-temperature surfaces. In this talk we discuss what we have learned regarding the consequences of deuterium substitution on the properties of this blend, and draw some broader conclusions.

**15:30**

**D30 6 Coarse-Grained Simulations of PEO/PMMA Blends** PRAVEEN DEPA, CHUNXIA CHEN, JANNA MARANAS, *Pennsylvania State University* Coarse-graining involves mapping successive atoms along a polymer chain to larger coarse-grained beads, which are then simulated using conventional molecular dynamics techniques. The interaction between the coarse-grained [CG] beads is parameterized so as to reproduce static properties observed in the underlying atomistic simulations. We extend this methodology to blends by developing CG models for poly(ethylene oxide) [PEO], poly(methylmethacrylate) (PMMA) and PEO/PMMA blends. In the case of PEO, six united atoms were mapped to a CG bead with the center at every other oxygen atom and for PMMA, each monomer was replaced with two CG beads, one centered along the main chain and the other centered at the ester-oxygen on the side group. The CG models reproduce static properties for both components. Dynamic properties evolve correctly if rescaled by a constant factor, specific to each component. The CG model is then used to simulate larger system for longer times such that whole chain dynamics can be accessed and compared to local dynamics.

**15:42**

**D30 7 Relationship between Fluctuation and Stress Relaxation in a Block Copolymer Melt** AMISH PATEL, NITASH BALSARA, *Department of Chemical Engineering, University of California, Berkeley* SURESH NARAYANAN, ALEC SANDY, *Argonne National Laboratory* SIMON MOCHRIE, *Department of Physics, Yale University* BRUCE GARETZ, *Othmer Department of Chemical & Biological Sciences & Engineering, Polytechnic University* HIROSHI WATANABE, *Institute for Chemical Research, Kyoto University* The relationship between microscopic fluctuation relaxation and macroscopic stress relaxation was explored in a disordered block copolymer melt containing disordered micelles. Experiments conducted near the order-to-disorder transition, show that the fluctuation relaxation time, measured by X-ray photon correlation spectroscopy is larger than the terminal stress relaxation time, measured by rheology, by factors as large as 100. These observations are in qualitative agreement with predictions of the Fredrickson-Larson theory. The lack of quantitative agreement suggests the need for a comprehensive theory that predicts stress relaxation in systems with complex free energy landscapes, such as those containing micelles and disordered fluctuations.

**15:54**

**D30 8 Self-consistent field theoretic calculations of stress in diblock** PANAGIOTIS MANIADIS, KIM O. RASMUSSEN, TURAB LOOKMAN, EDWARD M. KOBER, *Theoretical Division, Los Alamos National Laboratory* The elastic properties of diblock copolymers are studied using self-consistent field theoretical calculations. Our starting point is the approach of Fredrickson (J. Chem. Phys. 117, 6810, 2002) in which microscopic expressions of the elastic energy and stress of polymer chains are self-consistently incorporated into the free energy expression for a homopolymer. We extend this theory to phase separating diblock copolymers and calculate numerically the complete stress tensor in the presence of external strain. Our numerical method can be easily generalized to multi-block copolymers, and our method can be used to study the elastic properties of phase separating polymer materials in general.

**16:06**

**D30 9 Coarse-Grained Modeling of the Mechanical Properties of Entangled Polymer Systems** BRIAN PASQUINI, FERNANDO ESCOBEDO, YONG L. JOO, *Cornell University* The complexity of entangled polymer interactions is a promising area for simulation studies to build upon polymer physics theories; however, it is necessary to use a coarse-grained approach to simulate the dynamic response of large polymer systems. Such studies have been done by treating the entanglement interactions as a set of entanglement points, which serve as the ends for the coarse-grained simulation unit. One method from literature (Smith and Termonia) formulates the free energy of an entanglement network based exclusively on neighboring entanglement points and uses temporary bonds which break as the simulation progresses. Another method (Terzis, Theodorou and Stroeks) treats the coarse-grained units as delocalized polymer density clouds, and formulates an expression for the free energy based on local polymer density. The first method has been extended to three dimensions for direct comparison to the second in tensile strain experiments. These models also show promise to understanding microstructure effects on mechanical properties in materials such as spider silk.

**16:18**

**D30 10 Flame Retardant Homopolymer and Polymer Blend Composites** MIRIAM RAFAILOVICH, MAYU SI, JONATHAN SOKOLOV, *Department of Materials Science and Engineering, Stony Brook University, Stony Brook, NY 11794* TOHRU ARAKI, HARALD ADE, *Department of Physics, University of North Carolina* DANIEL HEFTER, *DRS High School, Woodmere, NY* ARYEH SOKOLOV, *Queens College, Flushing, NY* We investigated the flame retardant performance of homopolymer, EVA, PMMA, PP, and PS, and polymer blends, PS/PMMA, PC/SAN, with organoclay and conventional flame retardant agents such as decabromodiphenyl ether (DB) and phosphorus compounds. These materials were characterized by TEM, STXM, LOI and UL 94 V-0. TEM and STXM photographs show that the addition of organoclays into polymer blends drastically slows down the phase separation and accelerates the decompose of bromine compounds during the combustion. Further, UL 94 V-0 results indicate that PS/PMMA blend with DB can not achieve self-extinguishing in the absence of clay. The amounts of flame retardants and clay used were varied to try to achieve the optimal formula to pass UL 94 V-0. The synergism of clay and flame retardant agents were completely studied by various measurements, time dependence burning (TEM, Ion Chromatography), GC-MS, and cone calorimeter.

**16:30**

**D30 11 Ellipsometry studies of nanofilled polymer thin films.** UFUK KARABIYIK, ALAN ESKER, *Department of Chemistry (0212), Virginia Tech Blacksburg, VA 24061* Thermal properties of polymer thin films and polymer/nanofiller blends are crucial and expected to be different from their corresponding bulk properties because of the large surface area/volume ratio and the greater fractional free volume in confined geometries. Langmuir-

Blodgett thin films of trisilanolphenyl-POSS (TPP) and poly(t-butyl acrylate) (PtBA) blends were prepared by Y-type deposition. The films have been characterized by x-ray reflectivity and ellipsometry. Ellipsometry is able to measure thermally induced structural changes and can be used to monitor surface glass transition temperatures as well as layer deformation in multilayer thin films. The results show that TPP depresses the glass transition temperature(Tg) of PtBA LB-films like a plasticizer at low TPP concentrations less than 3 wt. percent TPP and that Tg increases for TPP concentrations greater than 3 wt. percent. A speculative mechanism for this cross-over is an increase in TPP aggregation that pins PtBA chains leading to lower chain mobility at higher wt. percent TPP.

**16:42**

**D30 12 Charge dissipation measurement on the surface of polymeric materials using modified surface potential electric force microscopy** MICHAEL REAGAN, SERGEI LYUKSYUTOV, IVAN DOLOG, ROBERT MALLIK, *The University of Akron, OH* SHANE JUHL, RICHARD VAIA, MICHAEL DURSTOCK, JOHN FERGUSON, *AF Research Laboratory, WPAFB OH* The AFMEN technique when combined with surface potential electric force microscopy (SP-EFM) reveals the pattern of electric charge build-up and dissipation in polymeric and organic materials. This information can be used to develop an adequate description of nanoconductivity in these materials. The description includes effects due to local electric field variations and charge transport mechanisms. Charge evolution was estimated by measuring electric currents using AFM. In addition to the SP-EFM and AFM work outlined above, we also use Inelastic Electron Tunneling Spectroscopy (IETS) to characterize the electronic and vibrational properties of polymer and composite materials. IETS has been used in the past by one of the authors to investigate ultra-thin (roughly 1 nm) polymer films, including PMMA. The films were deposited either by spin coating from or by plasma polymerization. This work is being extended to study the adsorption of spin-coated PMMA on photovoltaic materials such as CdS. Temperature dependent current-voltage and conductance voltage data obtained from tunnel diodes containing CdS/PMMA heterolayers can be used to determine the conduction mechanisms in these layers.

**16:54**

**D30 13 Preparation and Characterization of a Superparamagnetic Polymer Nanocomposite** N. BRENNER, R. ISSEROFF, *Lawrence High School, Cedarhurst, NY* M. RAFAILOVICH, G. RUDOMEN, R. GAMBINO, S.S. LIANG, D. SUNIL, M. SI, L. COLLAZO, N. PERNODET, X. FANG, $Fe(CO)_5$ decomposition produced ferro- and superparamagnetic polymer nanocomposites. $Fe(CO)_5$ and Cloisite 20A clay were combined in a closed vial for 12 hours, then opened to air for 2 hours. Mössbauer analysis indicated formation of $Fe_2O_3$ on clay; mass analysis indicated 12% Fe in clay. A Brabender mixed $Fe_2O_3$/clays with PMMA and EVA at ratios by mass of 9:4:36 and 1:1:4 respectively ($Fe(CO)_5$:clay:polymer). TEM displayed $Fe_2O_3$ nanoparticles, $3.3 \pm 0.8$ nm in diameter, adsorbed on exfoliated clay platelet surfaces in polymer matrices. VSM data indicated superparamagnetism with moments of 510.3 emu/$g_{(Fe2O3)}$ (PMMA) and 8.46 emu/$g_{(Fe2O3)}$ (EVA). DMA showed 37% decreased dynamic modulus (EVA) and 11% (PMMA) due to $Fe_2O_3$. TGA indicated PMMA stability to $400^oC$ (9.3% mass residual) and EVA to $435^oC$ (11% mass residual). Cell adhesion tests showed $Fe_2O_3$/clay enhanced proliferation, promising applications in bone implants.

**17:06**

**D30 14 Molecular Simulation of the intercrystalline region in isotactic polypropylene** VIKRAM KUPPA, GREGORY C. RUTLEDGE, *Massachusetts Institute of Technology* Monte Carlo (MC) computer simulations are used to study the crystal-amorphous interlamellar phase in semi-crystalline isotactic polypropylene. This represents the first such study of the detailed atomic level structure of the interlamellar phase for a polymer with side groups. The polymer is modeled using a united atom force-field model. Replica exchange in energy space is required in addition to local conformation and topology altering MC moves to achieve effective sampling of phase space. The simulations reveal the temperature dependence of structural features such as mass and energy density profiles as well as population distributions of tails, loops and bridges associated with the fold surface. These results for polypropylene are compared and contrasted with previous results for the prototypical linear polymer, polyethylene, in order to study the effect of architectural complexity on structure and properties of semi-crystalline polymers

**17:18**

**D30 15 Phase Transition Behavior of Isotactic Polypropylene Crystallized from a Homogeneous Melt*** XIAOFENG CHEN, SANAT K. KUMAR, *Chemical and Biological Engineering* RAHMI OZISIK, *Materials Science and Engineering, Rensselaer Polytechnic Institute* The equilibrium melting behavior of helical structures in isotactic polypropylene (iPP) was studied by a Monte Carlo simulation. It was found that the melting of iPP helical structure was an exponential process at high temperatures ($T > 470$ K), whereas it becomes highly stretched at low temperatures ($T < 400$ K). An estimate of the melting temperature was obtained from a novel application of the second moment of the waiting time distribution for helix melting as described by Odagaki (T. Odagaki, itPhys. Rev. Lett. **1995**, 75, 3701). The calculated melting temperature was approximately 455 K, which is in surprisingly good agreement with experimental values. A second transition temperature was also observed at a lower temperature ($T \sim 390$ K), which we can not explain by equilibrium considerations. We suggest that at this temperature, once a helix forms, it does not melt within the time scale studied.

*This material is based upon work supported by the National Science Foundation under Grant 0310596.

**D31 1 Enhanced Raman Scattering from Individual Semiconductor Nanocones and Nanowires*** LINYOU CAO, BAHRAM NABET, JONATHAN SPANIER, *Drexel University* DREXEL UNIVERSITY TEAM, We report strong enhancement ( $\sim 10^3$) of the spontaneous Raman scattering from individual silicon nanowires and nanocones as compared with bulk Si. The observed en-

hancement is diameter ($d$), excitation-wavelength ($\lambda_{laser}$), and incident polarization state-dependent, and is explained in terms of a resonant behavior involving incident electromagnetic radiation and the structural dielectric cross-section. The variation of the Raman enhancement with $d$, $\lambda_{laser}$ and polarization is shown to be in good agreement with model calculations of scattering from an infinite dielectric cylinder.

**D31 2 Magic structures of H-passivated ⟨110⟩ silicon nanowires** TZU-LIANG CHAN, *Ames Laboratory and Physics Department, Iowa State University* CRISTIAN V. CIOBANU, *Division of Engineering, Colorado School of Mines* FENG-CHUAN CHUANG, NING LU, CAI-ZHUANG WANG, KAI-MING HO, *US. DOE Ames Laboratory and Physics Department, Iowa State University* We report a genetic algorithm approach combined with ab initio calculations to determine the structure of hydrogenated ⟨110⟩ Si nanowires. As the number of atoms per length increases, we find that the cross section of the nanowire evolves from chains of six-atom rings, to fused pairs of such chains, to hexagons bounded by {001} and {111} facets. Our calculations predict that hexagonal wires become stable starting at about 1.2 nm diameter, which is consistent with recent experimental reports of nanowires with diameters of about 3 nm.

**14:54**

**D31 3 Field Emission of Silicon Nanowires** BAOQUING ZENG, *Boston College, MA* GUANGYONG XIONG, *Boston College, MA* SHUO CHEN, *Boston College, MA* SUNG-HO JO, *Boston College, MA* WENZHONG WANG, *Boston College, MA* DEZHI WANG, *Boston College, MA* ZHIFENG REN, *Boston College, MA* Field emission of silicon nanowires (SiNWs), which were grown by chemical vapor deposition method with Au catalyst at a temperature of 480 C from silane, has been investigated. To obtain a current density of 1 mA/cm2, an electric field of 5.5 V/um is needed with a turn-on electric field of 2.9 V/um for a current density of 0.01 mA/cm2, which are the best ever reported values. The NWs were studied by scanning electron microscopy (SEM) and transmission electron microcopy (TEM). SEM showed that the length of the wires is about 100 um with diameters of around 100 nm. High-resolution TEM showed that the nanowires have high crystallinity. The low growth temperature makes the process applicable to glass substrates that are used as the backing of large area flat panel displays.

**15:06**

**D31 4 Growth of Pure and Long Silicon Nanowires on Table Salt Support** GUANGYONG XIONG, SHUO CHEN, BAOQIN ZENG, WENZHONG WANG, DEZHI WANG, ZHIFENG REN, *Boston College* REN'S GROUP TEAM, Table salt was found to be a very good support for the growth of silicon (Si) nanowires in large quantity by a simple thermal decomposition of diluted silane gas in argon and hydrogen gases at less than $500^{o}$C. Hydrogen gold tetrachloride was uniformly mixed into the salt and decomposed into gold nanoparticles at the growth temperature and acted as the catalyst particles to start the growth of Si nanowires. The scanning electron microscope images showed that the as-grown Si nanowires are about 50-100 nm in diameter and up to 200 micrometers long. X-ray diffraction patterns showed that the salt was completely removed by water rinse. The transmission electron microscope studies showed that these Si nanowires are highly crystallized single crystals with an amorphous silicon layer of less than a few nanometers.

**15:18**

**D31 5 Fabrication of single-crystal Si nanowires by ultrahigh vacuum magnetron sputtering.** J. W. KNEPPER, X. W. ZHAO, F. Y. YANG, *The Ohio State University* Semiconductor nanowires have attracted great interests due to the intriguing fundamental science and technological application they provide. Many semiconductor materials have been made into single crystal nanowires with superior crystal quality and high mobility. Among them, silicon is particularly interesting because silicon is the foundation of modern electronic technology. A majority of the nanowire synthesis used laser-assisted catalyst growth or chemical vapor deposition. Here we reported a different approach to the fabrication of semiconductor nanowires using ultrahigh vacuum magnetron sputtering. Using thin Au layers as catalyst via vopor-liquid-solid mechanism, single crystal Si nanowires have been grown on Si substrates at a temperature of $\sim$ 700[r]C. Electron microscopy revealed that most Si nanowires grew epitaxially on Si(111) surfaces. Si nanowires are perpendicular to the Si(111) surface with a Si/Au alloy sphere on the top of the nanowires. The growth of Si nanowires on Si wafers with other orientations and amorphous silicon oxide layers was also observed, but with much less probability. The diameter of the Si nanowires is about 200 nm using Au layers as catalyst. The nanowire diameter can be controlled to smaller size by patterning the Au layers into small dots to reduce the catalyst size. Si nanowires fabricated by ultrahigh vacuum sputter at a base pressure of 10-10 torr are high purity and can be easily doped to desirable carrier concentration.

**15:30**

**D31 6 Structures of Si and Ge nanowires in the sub-nanometer range** HELIO CHACHAM, RICARDO KAGIMURA, RICARDO W. NUNES, *Departamento de fisica, Universidade Federal de Minas Gerais, Brazil* We report [1] *ab initio* and tight-binding calculations of several structures of pristine Si and Ge nanowires with diameters D between 0.5 and 5.0 nm. For nanowires with D $<$ 2 nm, the calculations are performed in the framework of Kohn-Sham density functional theory, within the generalized-gradient approximation. Total-energy differences are converged to within 10 meV/atom. For nanowires with D $>$ 2 nm, an order-N density-matrix tight-binding methodology (DMTB) is employed. We consider nanowires based on the diamond structure, high-density bulk structures, and fullerene-like structures. Our calculations indicate a transition from $sp^3$ geometries to structures based on denser bulk phases and fullerene-like structures, for diameters smaller than $\sim$ 1.2 nm. We show that a continuum model is able to reproduce quantitatively this transition. According to the model, the transition originates from the larger surface energy density of the $sp^3$ wires as compared to those of the denser wires. We also find that diamond-structure nanowires are unstable for diameters smaller than 1 nm, undergoing considerable structural transformations towards amorphous-like wires. For diameters between 0.8 nm and 1 nm, filled-fullerene wires are the most stable. For even smaller diameters ( $\sim$ 0.5nm), we find that a simple hexagonal structure is particularly stable for both Si and Ge. [1] R. Kagimura, R. W. Nunes, and H. Chacham, Phys. Rev. Lett. 95, 115502 (2005)

**15:42**

**D31 7 Physics and Applications of Ge/Si Core/Shell Nanowires** JIE XIANG, WEI LU, YONGJIE HU, YUE WU, HAO YAN, CHARLES LIEBER, *Department of Chemistry and Division of Engineering and Applied Sciences, Harvard University* We recently reported hole-gas formation and ballistic transport through 1D modes in band-structure engineered Ge/Si core/shell nanowire heterostructures at cryogenic temperatures, opening up a new platform to study low-dimensional transport phenomena and applications such as high performance room temperature field effect transistors. In this talk we report studies of single Ge/Si nanowire field effect transistors employing high-k dielectrics with top gate geometry. The clean hole-gas system and enhanced gate coupling from the high-k dielectric allow clear identification of discrete 1D subbands, as well as the observation of superconductivity proximity effect with superconducting contacts. Room temperature FET characteristics exhibit the best performance achieved in nanowire FETs, and the calculated intrinsic delay as a function of gate length for these nanowire FETs shows a clear scaling advantage over planar Si MOSFETs. Studies investigating the effect of novel gate structures to control ambipolar behavior and threshold voltage will also be discussed.

**15:54**

**D31 8 What are new when Si nanowires get small: magic numbers and square shape*** RUQIAN WU, *Department of physics and astronomy, UCI, CA* Through systematic density functional studies, we found the existence of ''magic numbers'' for Si nanowires grown along the $< 100 >$ axis. Strikingly, Si nanowires prefer the sharp square cross-section with corner atoms when the diameter is smaller than 1.7 nm. This is promoted by two facts: (1) the presence of the corner atoms permits formation of benign reconstruction pattern to maximally saturate the dangling bonds; and (2) the corner atoms develop pairs and strongly interact with each other across nanowires.

**D31 9 Effect of surface roughness, defects and phonon scattering on electron current through silicon nanowires*** ALEXEI SVIZHENKO, PAUL LEU, KYEONGJAE CHO, *Department of Mechanical Engineering, Stanford University, Stanford, CA, 94305* Silicon nanowires (SiNW) can become an important building block of nanoscale devices and circuits. Many experimental groups have fabricated SiNWs and measured their current-voltage characteristics. While electron current was found to be very high by some measurements, it is also highly sensitive to chemical modification of NW surfaces. It is therefore important to understand the detailed mechanisms of electron transport in the presence of external factors (e.g., surface roughness, surface defects, dopants, or phonon scattering) and estimate the current carrying capacity of SiNW. In this talk we will discuss our theoretical calculations of current-voltage characteristics of SiNW based on non-equilibrium Greens function (NEGF) equations using an $sp^3d^5s^*$ tight-binding Hamiltonian. We will focus on the effect of surface roughness, random defects and inelastic electron-phonon scattering on electron transport.

**D31 10 Scanning Probe Microscopy of Semiconducting Nanowires*** A.C. BLESZYNSKI, R.M. WESTERVELT, *Dept. of Physics, Harvard University* F.A. ZWANENBURG, L.P. KOUWENHOVEN, *Kavli Institute of Nanoscience, Delft University of Technology* A.L. ROEST, E.P.A.M BAKKERS, *Philips Research Laboratories* We have used a liquid-He cooled scanning probe microscope (SPM) with a conducting tip to image electrical conduction through InAs nanowires. The charged SPM tip is scanned above the nanowire and the resulting change in nanowire conductance is recorded to form the image. These conductance images are used to study the behavior of electrons in the nanowire on a local scale. For example, the images reveal barriers to conduction at the contacts as well as sections of the wire that act as quantum dots. At 4K the wires exhibit Coulomb blockade oscillations in conductance versus backgate voltage that are indicative of multiple quantum dots in series. The images reveal the location of the quantum dots along the wire and the tip voltage can tune their charge state. The nanowires, grown catalytically from small gold particles, have diameters between 50 and 100 nm. Ti/Al source and drain contacts with a spacing of 1 to 2 $\mu$m were defined using e-beam lithography.

*This work was supported at Harvard and at Delft, by the NSEC grant NSF PHY-01-17795.

**D31 11 Tunable supercurrent through semiconductor nanowires** JORDEN VAN DAM, *Delft University of Technology* YONG-JOO DOH, *Delft University of Technology* AARNOUD ROEST, *Philips Research* ERIK BAKKERS, *Philips Research* SILVANO DE FRANCESCHI, *TASC-INFM, Trieste, Italy* LEO KOUWENHOVEN, *Delft University of Technology* We have developed a high-yield approach to the fabrication of nanoscale superconductor-semiconductor hybrid devices [1]. The devices are assembled from InAs semiconductor nanowires with diameters ranging from 30-130 nm, individually contacted by aluminum-based superconductor electrodes. Below 1 Kelvin, the high transparency of the contacts enables proximity-induced superconductivity. A supercurrent flows though the nanowire that can be tuned by a global gate acting on the electron density. Furthermore, we have used top-gates in order to make tunable barriers in InAs nanowires. By creating two closely spaced barriers in an InAs nanowire, we can define a Quantum Dot (QD) with tunable coupling. This enables us to study a tunable QD connected to superconducting leads. In these devices the supercurrent can be controlled by only a small change in gate voltage. If the QD is tuned at a charge degeneracy point, a supercurrent can flow through the QD. However, away from charge degeneracy the supercurrent is blocked due to coulomb blockade. [1] Y.-J. Doh, J.A. van Dam, et al., Science 309, 272 (2005)

**16:42**

**D31 12 Bandstructure Effects in Unstructured AlGaAs Nanowires** NEERAV KHARCHE, CLEMENS HEITZINGER, GERHARD KLIMECK, *Purdue University* MATHIEU LUISIER, *ETH Zurich, Switzerland* TIMOTHY BOYKIN, *Univ. Alabama in Huntsville* Atomic scale alloy disorders can have profound effects on the bandstructure and charge transport through nanowires. With decreasing diameters down to nanometer scales, alloy disorder can no longer be treated in an average manner using the virtual crystal approximation (VCA). Our zone unfolding algorithm along with supercell calculations can be used to treat alloy disorders even to atomic scales. We calculate bandstructures and transmission coef-

ficients of AlGaAs random alloy nanowires with diameters ranging from 2nm to 6nm. Using the nanoelectronic modeling tool (NEMO3D), eigenstates of the alloy nanowire supercell are calculated with the 20-band sp3d5s* spin model. Small cell bandstructures are then projected out of the supercell eigenstates. Transmission coefficients are calculated with an atomistic NEGF simulation of the alloy wire embedded between two ideal reservoirs. These projected bandstructures and transmission coefficients both show reduced bandgaps and noisy behavior and provide significant insight into the physics of charge transport.

**16:54**

**D31 13 Ground states of a novel AlAs quantum wire** TRINANJAN DATTA, ERICA W. CARLSON, *Department of Physics, Purdue University* Using abelian bosonization and renormalization group, we analyze the ground states of a recently fabricated novel AlAs quantum wire [Moser et al, Appl. Phys. Lett. (2005)]. There are two degenerate lowest energy bands, separated by half an umklapp vector. This bandstructure arrangement leads to four Fermi points and umklapp-induced pair processes, independent of filling. The ground states are different from those of a conventional quantum wire, where acquiring four Fermi points requires occupying two successive bands, leading to a CDW instability via density reorganization. Such an instability is forbidden in the AlAs wire, which may help stabilize other exotic gapped ground states.

**17:06**

**D31 14 Electrical Detection of Oscillations in Micro- and Nano-Cantilevers** GAYATRI KESKAR, JAY GAILLARD, RASVAN CIOCAN, MALCOLM SKOVE, APPARAO RAO, *Clemson University* Electrical Detection of Oscillations in Micro- and Nano- Cantilevers We described a fully electrical actuation and detection method for measuring mechanical oscillations in ambient conditions for two systems: Si-based micro- and multi-walled carbon nanotube (MWNT) based nano-cantilevers. In our studies, a cantilever is either a silicon microstructure shaped like a diving board, or a cantilevered MWNT. The cantilever is placed parallel to and within 1-10 $\mu$m from a counter electrode and is forced into resonance by applying an ac voltage ($V_{ac}$) with a dc offset ($V_{dc}$) on the counter electrode under ambient conditions. We measure the magnitude and phase of the electrical signal due to the charge induced on the cantilever. The signal showing the resonance frequency of the cantilever is best measured at harmonics of $V_{ac}$. A model describing the response of our electrical actuation and detection of resonance oscillations will be presented.

**17:18**

**D31 15 Position-dependent deflection (PPD) of a nanobeam: a new method to determine the Young's modulus of nanoscale matter** N. DUARTE, *Dept. of Electrical Engr., The Pennsylvania State University* QIHUA XIONG, *Dept. of Physics, The Pennsylvania State University* TADIGADAPA SRINIVAS, *Dept. of Electrical Engr., The Pennsylvania State University* PETER EKLUND, *Dept. of Physics, The Pennsylvania State University* In this approach, a nanowire beam is fixed at two ends and an AFM is used to apply a force F(x) where x locates the position along the beam and the beam deflection $\delta z(x)$ is measured simultaneously. This situation is realized by placing a nanobeam over a trench fabricated on a Silicon substrate via photolithography followed by metal evaporation, lift-off and $XeF_2$ etching. The AFM tip force-distance curve is first obtained from experiments on the rigid substrate. The slope of the AFM force-distance obtained when the tip contacts the beam is then measured and the Young's modulus Y is obtained from the change in slope using the Euler-Bernoulli (E-B) equation. The beam dimensions are also required: the beam height and length via AFM and the beam width and length by SEM. We believe this method can be used in any other nano-beam systems to measure the Young's modulus. Results for rectangular ZnS beams ( $\sim$ 100nm x 100 nm x 5$\mu$m long) will be presented that demonstrate the potential for this method. Values for Y lower than reported for the bulk are obtained (i.e. Y(nano) $\sim$ 70% Y(bulk)). This work was supported, in part, by NSF-NIRT DMR-0304178

**D32 1 The effect of polytype on energy gap in SiC nano-clusters** XIHONG PENG, AZAR ALIZADEH, NITIN BHATE, LARRY ROWLAND, *GE Global Research, Niskayuna, NY 12309* SAROJ NAYAK, SANAT KUMAR, *Departments of Physics and Chemical Engineering, Rensselaer Polytechnic Institute, Troy, NY 12810* The size dependence of energy gap is perhaps the most remarkable aspect of quantum confinements in low dimensional systems. Numerous models have been proposed to describe the quantum confined electronic states in Si, CdSe, etc, providing a precise description of the bandgap as a function of nano-crystal dimensions. Recently, ab-initio studies of energy gap in cubic SiC nanoparticles as a function of both size and surface composition have been reported. SiC is a remarkable semiconductor with over 200 different crystal structures (polytypes) due to different stacking orders. The always-indirect band gap of bulk SiC varies substantially among the different polytypes (2.4 eV for 3C-SiC to 3.3 eV for 2H-SiC). We have investigated the effect of polytypism on the size-dependency of energy gap in SiC nano-clusters using ab-initio calculations. For clusters smaller than 1 nm, all SiC polytypes show identical energy gap-size dependencies. For SiC nanoparticles larger than 1 nm, the effect of crystal structure becomes apparent approaching the bulk values.

**14:42**

**D32 2 Structural and electronic properties of InP nanowires: role of surface dangling bonds on nanowire facets** TORU AKIYAMA, KOHJI NAKAMURA, TOMONORI ITO, *Department of Physics Engineering, Mie University* InP nanowires are one of intriguing targets in the sources and detectors in fiber optic communications and high-speed electronic applications. In spite of this technological importance, however, understanding of atomic structures and electronic properties of InP nanowires still remain unclear. Here, we present first principles pseudopotential calculations that clarify structural stability and electronic properties of InP nanowires vertically grown on InP(111) substrates. Our calculations with diameter less than 23 Å demonstrate that the nanowires with zinc blende structure are less favorable than those with wurtzite structure, in which the surface dangling bonds on nanowire facets are found to be crucial to determine the stability. An analysis of the nanowire cohesive energy based on the number

of the dangling bonds predicts that the nanowires are bistable forming both wurtzite and zinc blende structures at large diameter around 120 Å, which leads to the exhibition of polytypes being consistent with experiments. In addition, the calculated Kohn-Sham energy bands for stable wurtzite nanowires show that the surface dangling bond states determine the band character and the gap energy for the nanowires with diameter less than 9 Å while the gap energy of nanowires with diameter larger than 14 Å is dependent on only the nanowire size.

**14:54**

**D32 3 Atomistic Simulations of Long-Range Strain and Close-Range Electronic Structure in Self-Assembled Quantum Dot Systems.** GERHARD KLIMECK, *Network for Computational Nanotechnology, Purdue University, W. Lafayette, IN 47907* SHAIKH AHMED, MAREK KORKUSINISKI, SEUNGWON LEE, FAISAL SAIED, *Network for Computational Nanotechnology, Purdue University, W. Lafayette, IN 47907* The electronic structure in self-assembled quantum dots depends on the detailed quantum dot configuration inside the embedding matrix and the nearest neighbor quantum dots through electronic and strain interactions. However, realistic determination of strain requires a large computational domain. To tackle this problem for an embedded InAs quantum dot NEMO-3D uses the atomistic VFF Keating model containing up to 64 million atoms. Interatomic distance changes obtained are used to influence the sp3d5s* tight-binding electronic Hamiltonian with 21 million atoms. Targeted eigenstates with correct symmetry are found reliably even in such large systems. Our investigations show a dramatic dependence of the dot states on the size of the strain domain and the boundary conditions. NEMO-3D is also used to study the electronic states in coupled quantum dots in stacks of 2 and 7 dots. There is an interesting interplay between strain induced and size induced state distributions.

**15:06**

**D32 4 Numerical modeling InAs/GaAs quantum ring capacitance spectroscopy using non-parabolic approximation.** IGOR FILIKHIN, VLADIMIR SUSLOV, BRANISLAV VLAHOVIC, *North Carolina Central University* Direct observation for discrete energy spectra of InAs/GaAs quantum dots (QD) and rings (QR) is possible by capacitance-voltage (CV) end far infrared (FIR) spectroscopy [1]. Existing theoretical explanations of experimental data are limited by the parabolic potential model [1,2] and infinite confinement, which they are using. In present work a single subband model for InAs/GaAs QD(QR) is used. The finite confinement band-gap potential is estimated by the band gap difference of InAs quantum object and GaAs substrate [3]. The non-parabolic approximation is defined by electron effective mass dependence on the confinement energy according to the Kane formula. The 3D confined energy problem is solved numerically by the finite element method. Obtained results for single electron levels are in good agreement with the CV spectroscopy. The calculations also reproduce experimental value for the energy-gate-voltage conversion coefficient equal to 7. Our estimation for the magnitude of the electron effective mass agrees with experimental data. The results are compared with the parabolic potential model calculations. [1] A. Lorke, et al., PRL **84** 2223 (2000). [2] A. Emperador, et al., PR B. **62** 4573 (2000). [3] I. Filikhin et al., Modelling Simul. Mater. Sci. Eng. **12** 1121 (2004).

**D32 5 A charge patching method calculation of a quantum dot/quantum well nanosystem.*** JOSHUA SCHRIER, LIN-WANG WANG, *Computational Research Division, Lawrence Berkeley National Laboratory* First principles density functional calculations typically involve finding self-consistent solution to the Kohn-Sham equations, scaling with the cube of system size. To study large systems, such as semiconductor nanocrystals, an approximate ab initio potential may be constructed by patching together local charge motifs determined from self-consistent calculations on small prototype systems, and the eigenvalues determined using the folded spectrum method for a few band-edge states. In this talk, I will discuss the recent applications of this method to CdS/CdSe/CdS colloidal quantum dot quantum wells. Results on the effect of core, well, and shell thicknesses on the wavefunction and optical properties will be discussed. We find the conduction band wavefunction to be significantly less confined to the CdSe quantum well layer than predicted by k.p theory, and discuss the implications of this result on the theoretical interpretation of recent time-resolved Faraday rotation experiments. We will also briefly discuss the extensions of this approach to the explicit treatment of surface ligand effects and transition-metal doped nanocrystals.

**D32 6 Discrete size series of CdSe quantum dots: A combined computational and experimental investigation** MIN YU, GAYANATH FERNANDO, RONGFU LI, FOTIOS PAPADIMITRAKOPOULOS, NING SHI, RAMAMURTHY RAMPRASAD, Ab initio computational studies were performed for CdSe nanocrystals over a wide range of sizes in conjunction with recent experimental work. Substantial relaxations and coordination of surface atoms were found to play a crucial role in determining the nanocrystal stability and optical properties. While optimally (three-fold ) coordinated surface atoms resulted in stable closed-shell structures with large optical gaps, sub-optimal coordination gave rise to lower stability and negligible optical gaps. These computations are in qualitative agreement with recent chemical etching experiments suggesting that closed shell nanocrystals contribute strongly to photoluminescence quantum yield while clusters with non-optimal surface coordination do not.

**D32 7 Excitonic absorption of million-atom (In,Ga)As/GaAs self-assembled quantum dots*** GUSTAVO A. NARVAEZ, ALEX ZUNGER, *National Renewable Energy Laboratory, Golden, Colorado 80401* We calculate the optical absorption spectra of (In,Ga)As/GaAs self-assembled quantum dots by adopting an atomistic pseudopotential approach to calculate the single-particle electron and hole confined states of the dot followed by a calculation of the neutral exciton $X^0$ states $|\Psi^{(\nu)}(X^0)\rangle$ based on the configuration-interaction approach. We predict three types of *allowed* transitions that would be naively expected to be forbidden. (i) Transitions involving low-lying electron and hole states that are forbidden in simple effective mass models (e.g. $1S$-$2S$, $1S$-$1P$) become allowed by virtue of single-particle band-mixing. (ii) Transitions involving a deep hole state, with a mixture of heavy-hole and light-hole character, and an electron in the lowest state are found to have oscillator strengths that are comparable in magnitude to those of the expected allowed transitions. Thus,

simple models based on single-band envelope functions cannot predict these transitions. (iii) Transitions whose intensity is large due to many-body borrowing of oscillator strength from allowed transitions. The transitions in (i) and (ii) appear, respectively, as low-energy and high-energy satellites of the allowed *P-P* transitions, as observed in PLE.

**D32 8 Optimized Configuration Interaction Method for Electronic Excitations in Nanostructures*** CLAUDIA TROPAREVSKY, *Oak Ridge National Laboratory and National Renewable Energy Laboratory* ALBERTO FRANCESCHETTI, *National Renewable Energy Laboratory* The Configuration Interaction (CI) method has been widely used to calculate electronic excitations in semiconductor nanostructures. The main drawbacks of this method are its slow convergence with the number of configurations and the difficulty to select a-priori the most relevant configurations. Here we report a new approach for the selection of the CI basis set: For a given number $N_C$ of configurations, we use heuristic search methods to find the set of $N_C$ configurations that minimizes the excited-state energy of the nanostructure. We demonstrate this method for single excitons and biexcitons in CdSe quantum dots. We show that the best configurations not only are different from what one would expect based on the single-particle energy ladder, but also, they often do not correspond to the configurations that have the largest contribution to the full CI wave function. We also show that a few (less than 100) optimized configurations provide excitation energies with accuracy comparable to much larger (10,000 or more) non-optimized configuration basis sets.

**D32 9 Molecular models for nanoporous amorphous carbons via a novel monte carlo algorithm** AMIT KUMAR, RAUL LOBO, NORMAN WAGNER, *Center for Mol. & Eng. Thermodynamics, Dept. of Chem. Eng. Univ. of Delaware, Newark, DE 19711* Nanoporous carbons (NPCs) are interesting amorphous phases of carbon that can exhibit very favorable gas permeation selectivity, which is an area of research. However, computational studies of such amorphous, nonequilibrium phases are hindered by the lack of a robust method to generate candidate molecular structures that validate against the known properties of such materials. A new monte carlo algorithm has been developed to create structural models for amorphous carbons. The simulation method mimics the experimental preparation of nanoporous carbons (NPC) by pyrolysis from polyfurfuryl alcohol as a guideline. The resulting molecular structures exhibits properties that compare favorably to those observed experimentally for real NPCs. These atomistic NPC models are approaching a realistic representation of NPCs used for gas separations and as such, are being used to study the diffusion of small gas molecules in these materials. Comparisons are made to other methods in the literature and possible improvements are discussed.

**D32 10 Solvophobic Solvation Forces between Nanoparticles: Size, Shape, and Solvent Effects** YONG QIN, KRISTEN A. FICHTHORN, *The Pennsylvania State University* The hydrophobic effect is an important phenomenon that can play a central role in biological and colloidal systems. Although hydrophobic hydration has been extensively studied, this is just a specialized case of the more general phenomenon of ''solvophobic solvation,'' which can occur in a wide variety of applications involving solutes in non-aqueous solutions, including colloid and polymer suspensions and assemblies. We report results from molecular-dynamics simulations of solvophobic nanoparticles immersed in n-decane liquid. Analogous to aqueous systems, we observe dewetting in the inter-particle region and attractive solvation forces when the particle separation becomes smaller than a critical value. We show that the critical separation can be affected by particle size and shape, and, in contrast to predictions by theories of hydrophobic hydration; it can be larger for small particles than for large ones. The complex size and shape dependence of solvophobic inter-particle forces allows new prospects for creating selective nonaqueous colloidal assemblies.

**D32 11 The Formation of Haeckelite Structures Induced by Vacancy Defects in Graphene Layers of Carbon Nanotube** GUN-DO LEE, *Seoul National University* C.Z. WANG, *Iowa State University* EUIJOON YOON, NONG-MOON HWANG, *Seoul National University* K.M. HO, *Iowa State University* SEOUL NATIONAL UNIVERSITY COLLABORATION, IOWA STATE UNIVERSITY COLLABORATION, The formation of haeckelite structures induced by vacancy defects in graphene layers of carbon nanotube are investigated by tight-binding molecular dynamics (TBMD) simulations and by first principles total energy calculations. It is observed in the TBMD simulations that two single vacancies coalesce into a 5-8-5 double vacancy at the temperature of 3,000 K, and it is further reconstructed into a new defect structure, the 555-777 defect, by the Stone-Wales type transformation at higher temperatures. First principles calculations confirm that the 555-777 defect is energetically much more stable than two separated single vacancies, and the energy of the 555-777 defect is also slightly lower than that of the 5-8-5 double vacancy. In TBMD simulation, it is also found that the four single vacancies reconstruct into two collective 555-777 defects which is the unit for the hexagonal haeckelite structure proposed by Terrones et al. [Phys. Rev. Lett. **84**, 1716 (2000)]

**D32 12 Viscoelastic Properties of Model Polymer Nanocomposites** JAMES THOMIN, SUCHIRA SEN, PAWEL KEBLINSKI, SANAT KUMAR, *Rensselaer Polytechnic Institute* The study of the dynamics of polymers in the presence of nano-scale particles is not only of fundamental interest but is also key to developing the tools necessary to engineer polymer nanocomposite materials. In this work, we investigate the effect of nanoscopic filler particles on the viscoelastic behavior of a model polymer melt. Molecular Dynamics simulations of bead-spring polymer systems containing roughly spherical nano-filler particles were performed. Equilibrium and non-equilibrium methods were used to determine the stress relaxation and shear-dependent viscosity of both the neat melt and filled systems. We will discuss the results of these simulations, as well as an interesting correlation between certain structural quantities and the observed mechanical reinforcement.

**D33 1 Tribochemical studies at the nanometer scale: synergisms of mechanical and chemical forces.***
J. THOMAS DICKINSON, *Washington State University*

The manipulation of matter on small size scales dominates a number of potential applications in nanoscience and nanotechnology. The forces and potentials available to break and reestablish bonds between ions, atoms, and molecules becomes greatly expanded when we consider combining stimuli. Our efforts on combining (mechanical + chemical) or (mechanical + radiative) stimulation aims at understanding the resulting synergisms in, for example, dissolution and/or deposition of material. We show that we can measure the kinetics of chemical mechanical wear (e.g., polishing) with a single asperity (the tip of an Atomic Force Microscope) on substrates of single crystals, amorphous materials such as silicate glasses,polymers, crystalline silicon, and on polycrystalline oxides, nitrides, and carbides in controlled chemical media. We find that although the mechanics are relatively straight forward to model, the itdependence on the applied normal force, the applied stress, the solution composition, the solution temperature, the duration time of the wear experiment, and the relative velocity of the AFM tip and substrate can be complex. With care, we have been able to properly measure and model the tribochemical wear on model systems. We present these studies and include new results on technologically interesting materials such as single crystal Si(100). We also present results on the use of an AFM tip to localize layer-by-layer growth of single crystals of inorganic carbonates, sulfates, and phosphates in saturated aqueous solutions.

**D33 2 Elucidation of the Atomic-Scale mechanisms of Friction in Model SAMs and DLC films*** JUDITH HARRISON, PAUL MIKULSKI, GUANGTU GAO, KEVIN VAN WORKUM, J. DAVID SCHALL, GINGER CHATEAUNEUF, *US Naval Academy* The development of micron-sized devices for terrestrial and space applications has prompted the need for protection of the surfaces of these devices. Amorphous carbon films, diamondlike carbon, and SAMs are all possible candidates for the passivation and lubrication of these devices. The fundamental problem associated with controlling friction is a lack of understanding of the underlying atomic-scale processes that govern it. Over the past several years, we have performed extensive molecular dynamics simulations aimed at understanding the atomic-scale mechanisms of friction. We have examined the contact forces present at the interface of a tip and SAMs during sliding. Compression- and shear-induced polymerization have also been modeled in SAMs. In addition, we have done simulations that analyzed the tribological properties of amorphous carbon films with various compositions and of diamondlike carbon films. Some of our recent results will be discussed.
