Undecidability of PCP (optional)

Undecidability of PCP

$$\text{PCP} = \{\langle T \rangle \mid T \text{ is a collection of tiles contains a top-bottom match}\}$$

The language PCP is undecidable

We will show that

If PCP can be decided, so can A_{TM}

We will only discuss the main idea, omitting details

Undecidability of PCP

$$\begin{array}{lcl} \langle M \rangle & \longmapsto & T \text{ (collection of tiles)} \\ M \text{ accepts } w & \Longleftrightarrow & T \text{ contains a match} \end{array}$$

Idea: Matches represent accepting history

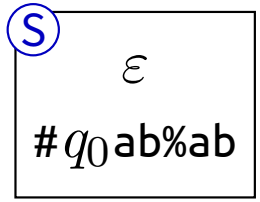
$$\#\, q_0\, \mathsf{ab\%ab\#x}\, q_1\, \mathsf{b\%ab\#...\#xx\%x}\, q_{\mathsf{a}}\, \mathsf{x\#}$$
$$\#\, q_0\, \mathsf{ab\%ab\#x}\, q_1\, \mathsf{b\%ab\#...\#xx\%x}\, q_{\mathsf{a}}\, \mathsf{x\#}$$

ε	$\#\, q_0\, \mathsf{a}$	b	a	$\%$	a	b	$\#$	$\mathsf{x}\, q_1\, \%$	$\cdots$
$\#\, q_0\, \mathsf{ab\%ab}$	$\#\, \mathsf{x}\, q_1$	b	a	$\%$	a	b	$\#$	$\mathsf{x\%}\, q_2$	

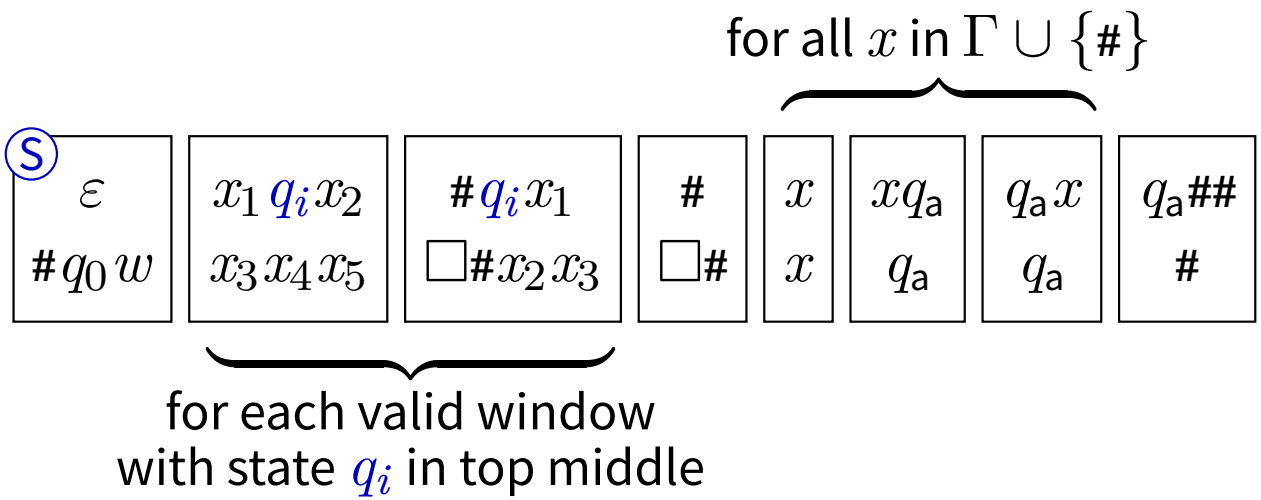
Undecidability of PCP

$$\begin{array}{lcl} \langle M \rangle & \longmapsto & T \text{ (collection of tiles)} \\ M \text{ accepts } w & \Longleftrightarrow & T \text{ contains a match} \end{array}$$

We will assume that the following tile is forced to be the starting tile:



On input $\langle M, w \rangle$, we construct these tiles for PCP



Undecidability of PCP

tile type	purpose
	represents initial configuration
	represents valid transitions between configurations
	adds blank spaces before # if necessary
	matching completes if computation accepts

Undecidability of PCP

Once the accepting state symbol occurs, the last two tiles can “eat up” the rest of the symbols

#xx%xq_ax#xx%xq_a#...#q_a##

#xx%xq_ax#xx%xq_a#...#q_a##

x	xq_a	$q_a x$	q_a##
x	q_a	q_a	#

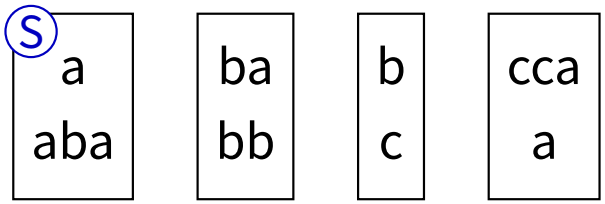
Undecidability of PCP

If M rejects on input w, then q_{rej} appears on the bottom at some point, but it cannot be matched on top

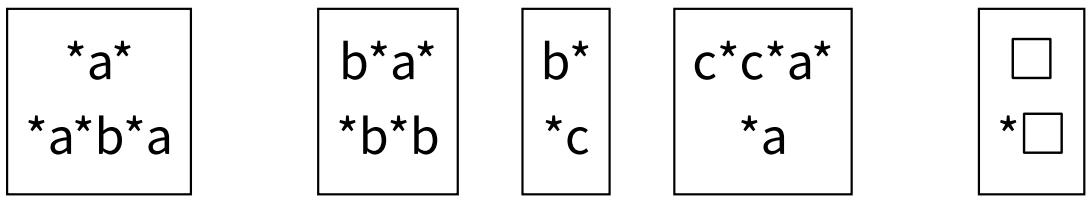
If M loops on w, then matching goes on forever

Getting rid of the starting tile

We assumed that one tile is marked as the starting tile



We can simulate this assumption by changing tiles a bit

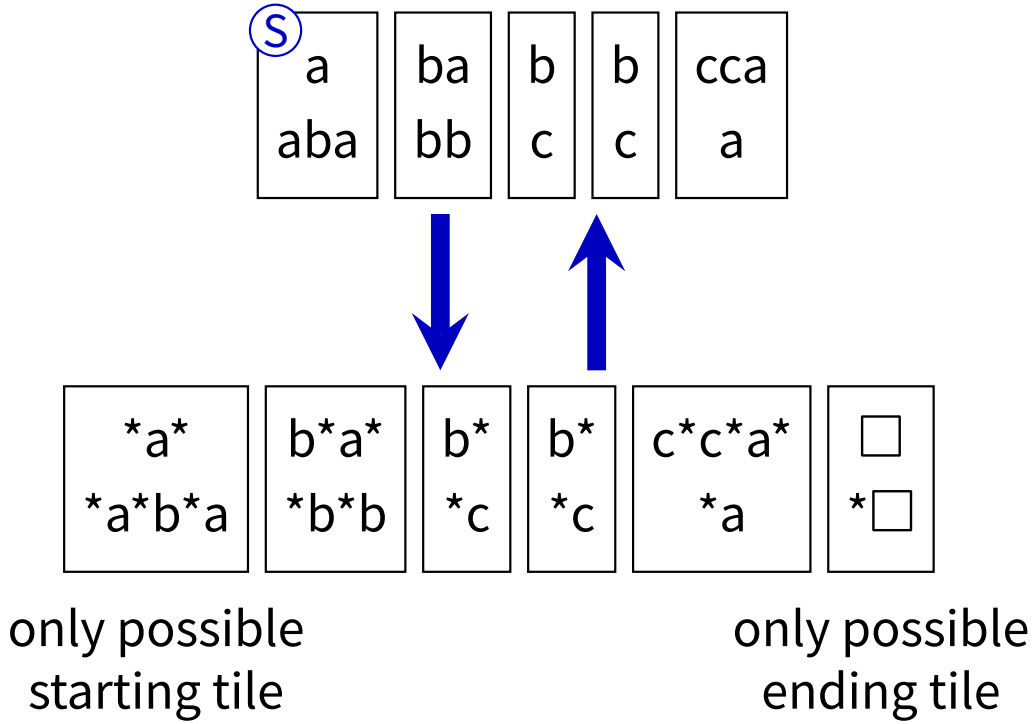


“starting tile” begins with *

“middle tiles”

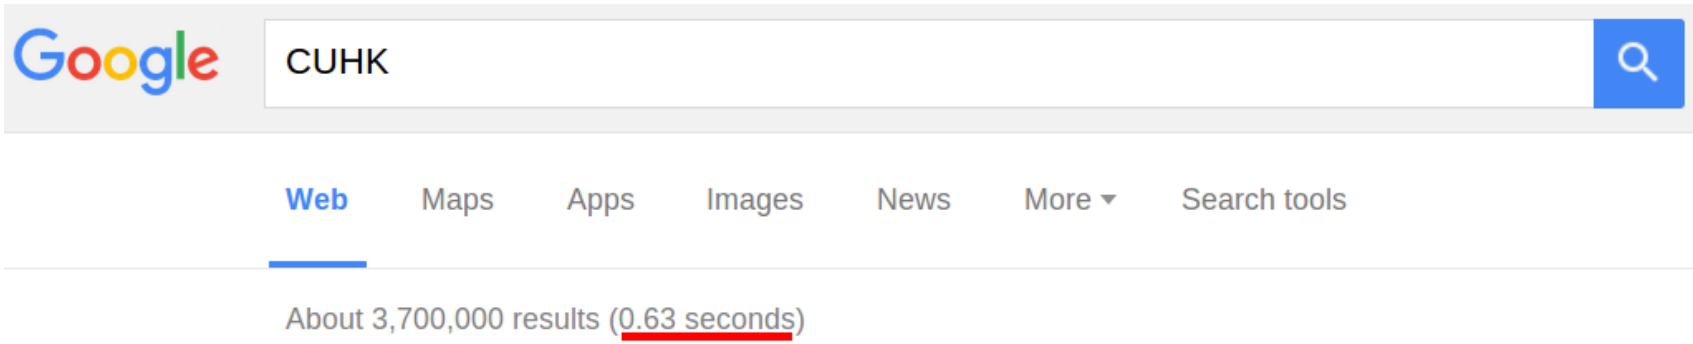
“ending tiles”

Getting rid of the starting tile



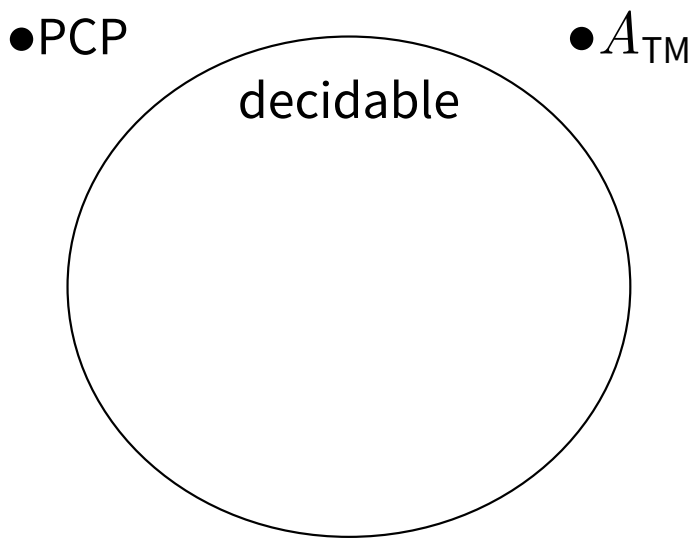
Polynomial time

Running time



We don’t want to just solve a problem, we want to solve it quickly

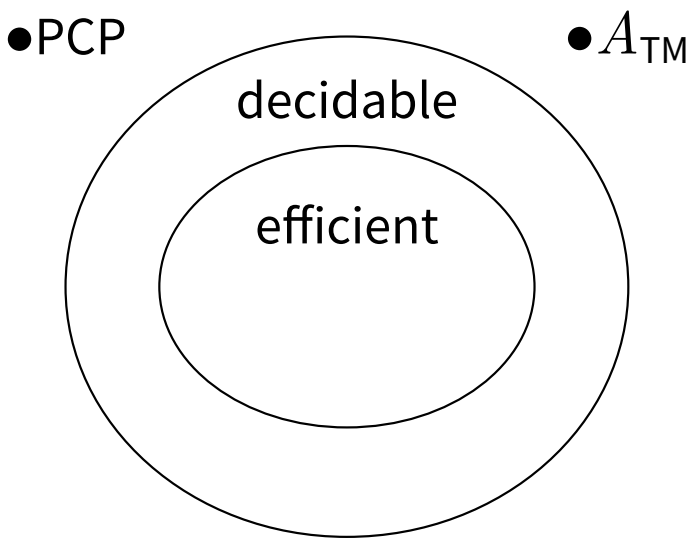
Efficiency



Undecidable problems:
We cannot find solutions in any finite amount of time

Decidable problems:
We can solve them, but it may take a very long time

Efficiency



The running time depends on the input

For longer inputs, we should allow more time

Efficiency is measured as a function of input size

Running time

The running time of a Turing machine M is the function $t_M(n)$:

$t_M(n) =$ maximum number of steps that M takes on any input of length n

Example: $L = \{w\#w \mid w \in \{\mathtt{a}, \mathtt{b}\}^*\}$

M: On input x, until you reach #	$O(n)$ times
Read and cross of first a or b before #	$O(n)$ steps
Read and cross off first a or b after #	
If mismatch, reject	
If all symbols except # are crossed off, accept	$O(n)$ steps
running time:	$O(n^2)$

Another example

$$L = \{\texttt{0}^n\texttt{1}^n \mid n \geqslant 0\}$$

M: On input x,	
Check that the input is of the form $\texttt{0}^*\texttt{1}^*$	$O(n)$ steps
Until everything is crossed off:	$O(n)$ times
Cross off the leftmost $\texttt{0}$	$O(n)$ steps
Cross off the following $\texttt{1}$	
If everything is crossed off, accept	$O(n)$ steps
running time:	$O(n^2)$

A faster way

$$L = \{\texttt{0}^n\texttt{1}^n \mid n \geqslant 0\}$$

M: On input x,	
Check that the input is of the form $\texttt{0}^*\texttt{1}^*$	$O(n)$ steps
Until everything is crossed off:	$O(\log n)$ times
Find parity of number of 0s	$O(n)$ steps
Find parity of number of 1s	
If the parities don't match, reject	
Cross off every other 0 and every other 1	
If everything is crossed off, accept	$O(n)$ steps
running time:	$O(n \log n)$

Running time vs model

What if we have a two-tape Turing machine?

$$L = \{\texttt{0}^n\texttt{1}^n \mid n \geqslant 0\}$$

M: On input x,	
Check that the input is of the form $\texttt{0}^*\texttt{1}^*$	$O(n)$ steps
Copy $\texttt{0}^*$ part of input to second tape	$O(n)$ steps
Until $\square$ is reached:	$\Big\}$ $O(n)$ steps
Cross off next $\texttt{1}$ from first tape	
Cross off next $\texttt{0}$ from second tape	
If both tapes reach $\square$ simultaneously, accept	$O(n)$ steps
running time:	$O(n)$

Running time vs model

How about a Java program?

$L = \{0^n 1^n \mid n \geqslant 0\}$

```
M(int[] x) {
  n = x.len;
  if (n % 2 == 0) reject();
  for (i = 0; i < n/2; i++) {
    if (x[i] != 0) reject();
    if (x[n-i+1] != 1) reject();
  }
  accept();
}
```

running time: $O(n)$

Running time can change depending on the model

1-tape TM	2-tape TM	Java
$O(n \log n)$	$O(n)$	$O(n)$

Measuring running time

What does it mean when we say

This algorithm runs in time T

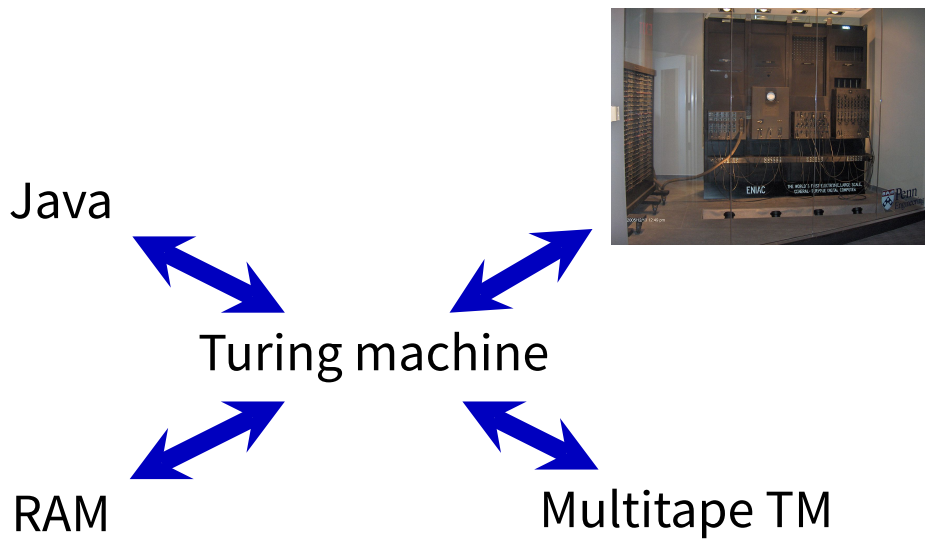
One "time unit" in

Java	Random access machine	Turing machine
`if (x > 0)` `  y = 5*y + x;`	`write r3`	$\delta(q_3, \mathtt{a}) = (q_7, \mathtt{b}, R)$

all mean different things!

Efficiency and the Church–Turing thesis

Church–Turing thesis says all these have the same computing power…



…without considering running time

Cobham–Edmonds thesis

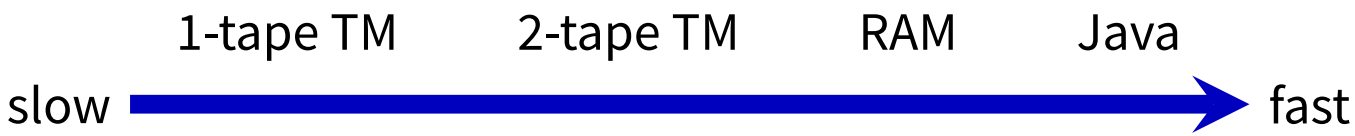
An extension to Church–Turing thesis, stating

For any realistic models of computation M_1 and M_2
M_1 can be simulated on M_2 with at most polynomial slowdown

So any task that takes time $t(n)$ on M_1 can be done in time (say) $O(t^3)$ on M_2

Efficient simulation

The running time of a program depends on the model of computation

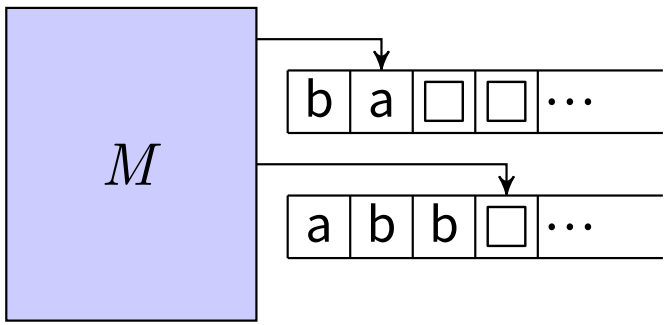


But if you ignore polynomial overhead, the difference is irrelevant

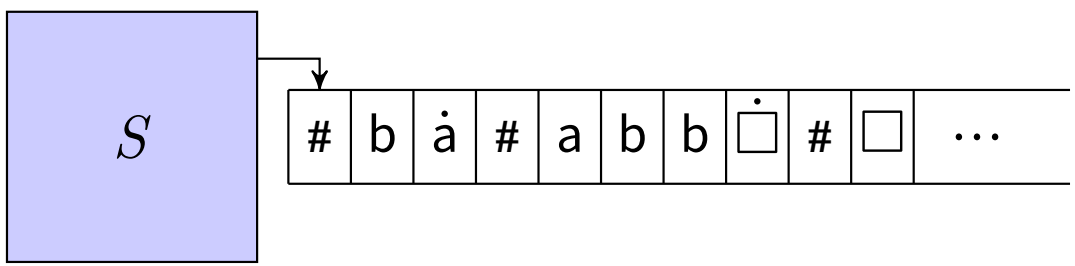
Every reasonable model of computation can be simulated efficiently on any other

Example of efficient simulation

Recall simulating two tapes on a single tape



$$\Gamma = \{\mathsf{a}, \mathsf{b}, \square\}$$

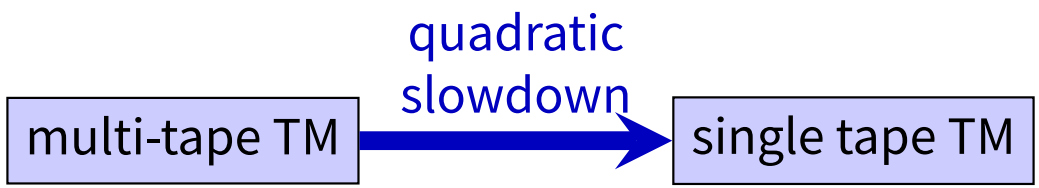


$$\Gamma = \{\mathsf{a}, \mathsf{b}, \square, \dot{\mathsf{a}}, \dot{\mathsf{b}}, \dot{\square}, \#\}$$

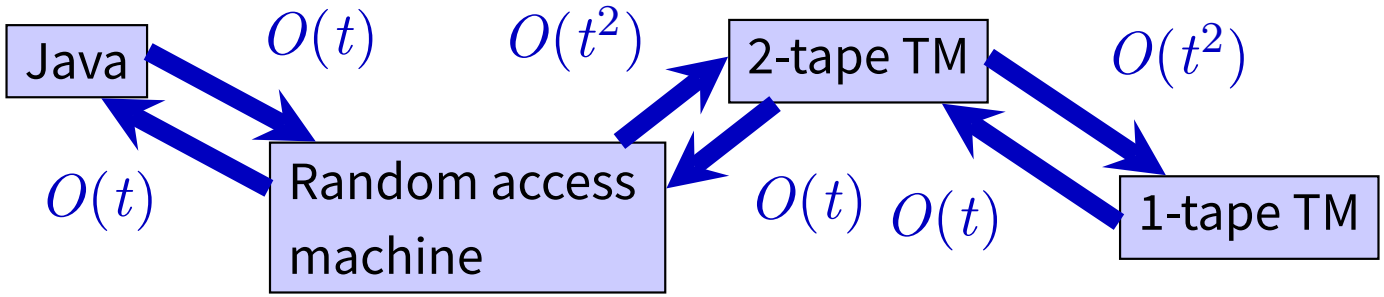
Running time of simulation

Each move of the multitape TM might require traversing the whole single tape

1 step of 2-tape TM	$\Rightarrow$	$O(s)$ steps of single tape TM
		$s =$ right most cell ever visited
after t steps	$\Rightarrow$	$s \leqslant 2t + O(1)$
t steps of 2-tape	$\Rightarrow$	$O(ts) = O(t^2)$ single tape steps



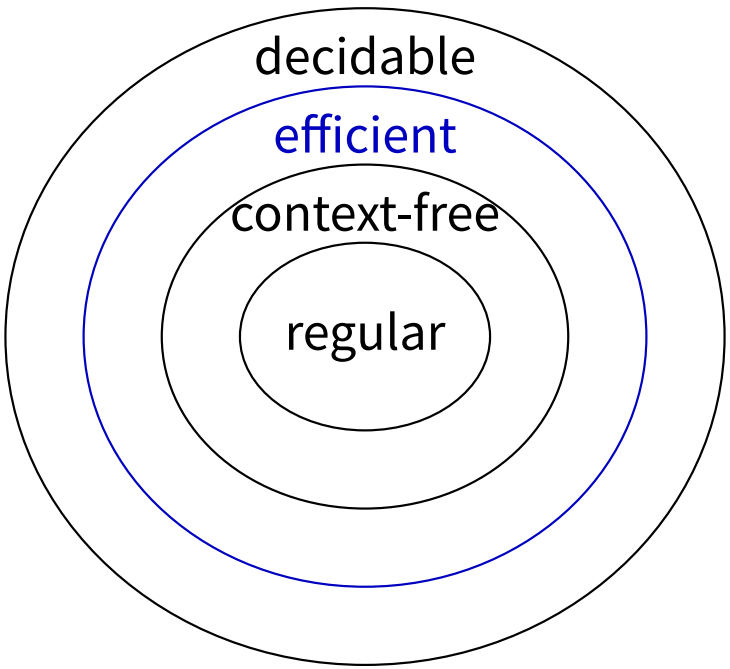
Simulation slowdown



Cobham–Edmonds thesis:

M_1 can be simulated on M_2 with at most polynomial slowdown

The class P



P is the class of languages that can be decided on a TM with polynomial running time

By Cobham–Edmonds thesis, they can also be decided by any realistic model of computation
e.g. Java, RAM, multitape TM

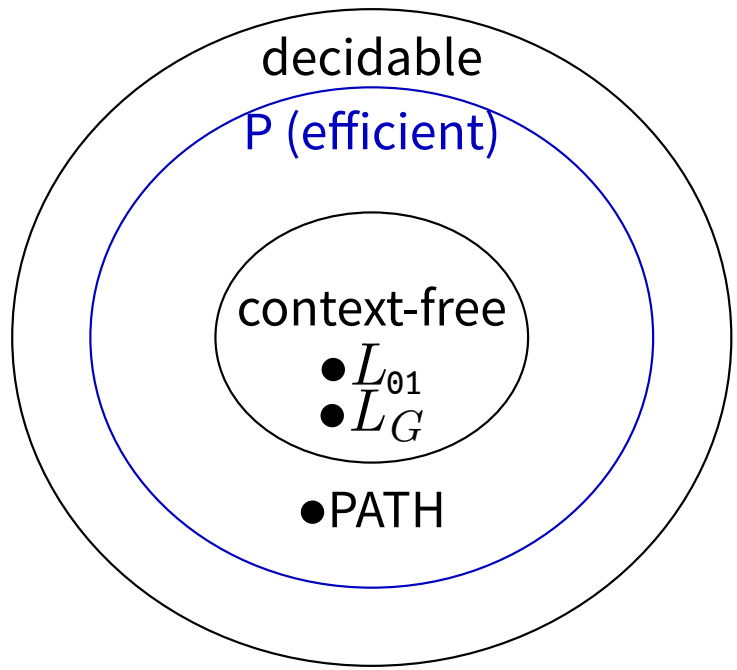
Examples of languages in P

P is the class of languages that are decidable in polynomial time (in the input length)

$$L_{\mathtt{01}} = \{\mathtt{0}^n\mathtt{1} \mid n \geqslant 0\}$$

$$L_G = \{w \mid \text{CFG } G \text{ generates } w\}$$

$$\text{PATH} = \{\langle G, s, t\rangle \mid \text{Graph } G \text{ has a path from node } s \text{ to node } t\}$$



Context-free languages in polynomial time

Let L be a context-free language, and G be a CFG for L in Chomsky Normal Form

CYK algorithm:

If there is a production $A \to x_i$

Put A in table cell $T[i, 1]$

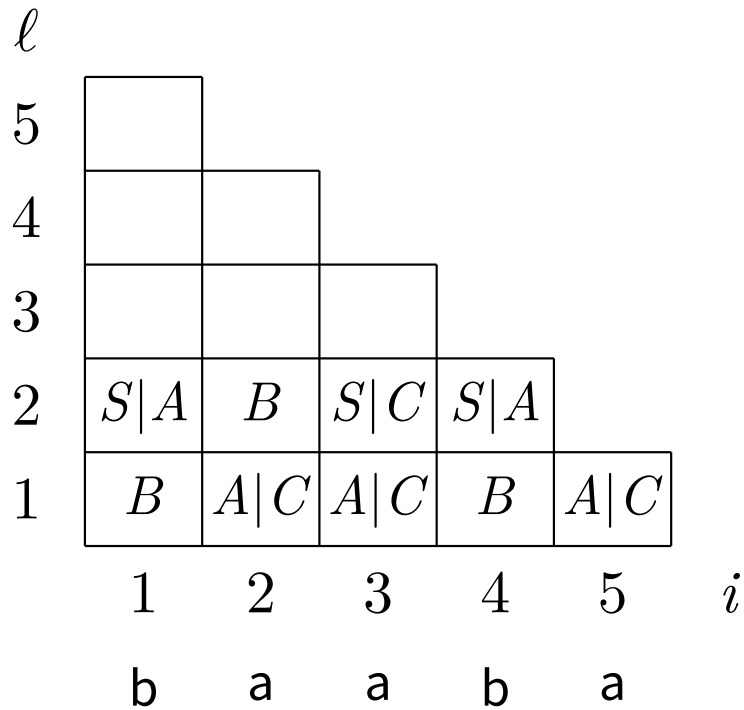
For cells $T[i, \ell]$

If there is a production $A \to BC$

where B is in cell $T[i, j]$

and C is in cell $T[i + j, \ell - j]$

Put A in cell $T[i, \ell]$



On input x of length n, running time is $O(n^3)$

PATH in polynomial time

$$\text{PATH} = \{\langle G, s, t\rangle \mid \text{Graph } G \text{ has a path from node } s \text{ to node } t\}$$

G has n vertices, m edges

$M =$ On input $\langle G, s, t\rangle$
- where G is a graph with nodes s and t
- Place a mark on node s
- Repeat until no additional nodes are marked: — $O(n)$ times
  - Scan the edges of G. — $O(m)$ steps
  - If some edge has both marked and unmarked endpoints
    - Mark the unmarked endpoint
- If t is marked, accept

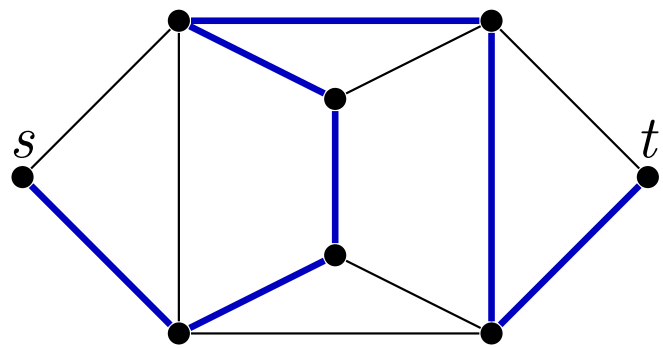
---

running time: $O(mn)$

Hamiltonian paths

A Hamiltonian path in G is a path that visits every node exactly once

$$\text{HAMPATH} = \{\langle G, s, t\rangle \mid \text{Graph } G \text{ has a Hamiltonian path from node } s \text{ to node } t\}$$



We don't know if HAMPATH is in P, and we believe it is not
