Chinese University of Hong Kong

Graph  $G$

A **clique** is a subset of vertices that are **pairwise adjacent**

$\{1, 4\}$ ,  $\{2, 3, 4\}$ ,  $\{1\}$  are cliques

An **independent set** is a subset of vertices that are **pairwise non-adjacent**

$\{1, 2\}$ ,  $\{1, 3\}$ ,  $\{4\}$  are independent sets

A **vertex cover** is a set of vertices that **touches (covers) all edges**

$\{2, 4\}$ ,  $\{3, 4\}$ ,  $\{1, 2, 3\}$  are vertex covers

# These problems

CLIQUE =  $\{\langle G, k \rangle \mid \text{Graph } G \text{ has a clique of } k \text{ vertices}\}$

INDEPENDENT-SET =  $\{\langle G, k \rangle \mid \text{Graph } G \text{ has}$   
an independent set of  $k$  vertices}

VERTEX-COVER =  $\{\langle G, k \rangle \mid \text{Graph } G \text{ has}$   
a vertex cover of  $k$  vertices}

What do these problems **have in common?**

1. Given a candidate solution, we can quickly check if it is valid
2. We don't know how to solve these problems quickly

# Checking solutions quickly

If someone told us a candidate solution, we can quickly **verify** if it is valid

Example: Is  $\langle G, 5 \rangle \in \text{CLIQUE?}$

Candidate solution:  $\{1, 5, 9, 12, 14\}$

# The class NP

A **verifier** for  $L$  is a Turing machine  $V$  such that

$$x \in L \iff V \text{ accepts } \langle x, s \rangle \text{ for some } s$$

$s$  is a **candidate solution** for  $x$

We say  $V$  runs in **polynomial time** if on every input  $x$ , it runs in time polynomial in  $|x|$  (for every  $s$ )

NP is the class of all languages that have polynomial-time verifiers

## Example

$V =$  On input  $\langle G, k, C \rangle$ , where  $C$  is a set of vertices in  $G$

If  $C$  has size  $k$  and all edges between vertices  $C$  are present in  $G$   
accept

Otherwise reject

Running time:  $O(k^2)$

Therefore CLIQUE is in NP

# P versus NP

P is contained in NP

because the verifier can ignore the candidate solution

Intuitively, **finding** solutions can only be harder than **verifying** them

IS = INDEPENDENT-SET

VC = VERTEX-COVER

We will talk about SAT in the next lecture

# Millennium prize problems

In 2000, Clay Math Institute gave 7 problems for the 21st century

- P versus NP (computer science)
- Hodge conjecture
- Poincaré conjecture (Perelman 2006)
- Riemann hypothesis (Hilbert's 8th problem)
- Yang–Mills existence and mass gap
- Navier–Stokes existence and smoothness
- Birch and Swinnerton-Dyer conjecture

# P versus NP

Is P equal to NP?

We don't know. But one reason to believe  $P \neq NP$  is that intuitively, **searching** for a solution is harder than verifying its correctness

For example, solving homework problems (searching for solutions) is harder than **grading** (verifying the candidate solution is correct)

# Searching versus verifying

## Mathematician:

Given a mathematical claim, come up with a proof for it

## Scientist:

Given a collection of data on some phenomenon, find a theory explaining it

## Engineer:

Given a set of constraints (on cost, physical laws, etc), come up with a design (of an engine, bridge, etc) which meets them

## Detective:

Given the crime scene, find “who’s done it”

# P and NP

P = languages that can be decided on TM in **polynomial time** (admit efficient algorithms)

NP = languages whose solutions can be **verified** on a TM in polynomial time (solutions can be **checked** efficiently)

We believe  $P \neq NP$ , but we are not sure

## Evidence that NP is bigger than P

CLIQUE =  $\{\langle G, k \rangle \mid G \text{ is a graph having a clique of } k \text{ vertices}\}$

IS =  $\{\langle G, k \rangle \mid G \text{ is a graph having}$   
an independent set of  $k$  vertices}

VC =  $\{\langle G, k \rangle \mid G \text{ is a graph having}$   
a vertex cover of  $k$  vertices}

What do they have in common?

- These (and many others) are in NP
- No efficient algorithms are known for solving any of them

# Naive algorithm for solving CLIQUE

$\text{CLIQUE} = \{ \langle G, k \rangle \mid G \text{ is a graph having a clique of } k \text{ vertices} \}$

**Turing machine  $M$ : On input  $\langle G, k \rangle$**

For all subsets  $S$  of vertices of size  $k$

If every pair  $u \in S, v \in S, u \neq v$  are adjacent

accept

else reject

Example:

Graph  $G$

input:	$\langle G, 3 \rangle$			
subsets:	$\{123\}$	$\{124\}$	$\{134\}$	$\{234\}$
All edges in $S$ ?	No	No	No	Yes

# Running time analysis

CLIQUE =  $\{\langle G, k \rangle \mid G \text{ is a graph having a clique of } k \text{ vertices}\}$

$M$ : On input  $\langle G, k \rangle$ :

For all subsets  $S$  of vertices of size  $k$       $\binom{n}{k}$  subsets

    If every pair  $u, v \in S$  are adjacent      $k^2$  pairs

        accept

    else reject

---

running time:  $k^2 \binom{n}{k}$   
 $\geq 2^n$  when  $k = n/2$

# Equivalence of certain NP languages

We strongly suspect that problems like CLIQUE, SAT, etc require roughly  $2^n$  time to solve

We do not know how to prove this, but we can prove that

If **any one** of them can be solved efficiently,  
then **all of them** can be solved efficiently

# Equivalence of some NP languages

Next lecture:

All problems such as CLIQUE, SAT, IS, VC are **as hard as** one another

Moreover, they are at least as hard as any problem in NP
