```
Human: What is your favorite animal?
AI:     My favorite animal is a dog.
Human: Why?
AI:     Because dogs are loyal and friendly.
Human: What are two reasons that a dog might be in a bad mood?
AI:     Two reasons that a dog might be in a bad mood are if it is hungry or if it is hot.
Human: How many eyes does a giraffe have?
AI:     A giraffe has two eyes.
Human: How many legs does a frog have?
AI:     A frog has four legs.
Human: Are there any animals with three legs?
AI:     No, there are no animals with three legs.
Human: Why don't animals have three legs?
AI:     Animals don't have three legs because they would fall over.
```
AI generated image (Stable diffusion)

A distant futuristic city full of tall buildings inside a huge transparent glass dome, In the middle of a barren desert full of large dunes, Sun rays, Artstation, Dark sky full of stars with a shiny sun, Massive scale, Fog, Highly detailed, Cinematic, Colorful

Is there anything that a computer cannot do?
Why care about the impossible?

Example from Physics:

Since the Middle Ages, people tried to design machines that use no energy

Later physical discoveries forbid creating energy out of nothing

Perpetual motion is impossible

"water screw" perpetual motion machine

Understanding the impossible helps us to focus on the possible

Just like laws of physics tell us what are (im)possible in nature…

$$\Delta U = Q + W \qquad \mathrm{d}S = \frac{\delta Q}{T} \qquad S - S_0 = k_B \ln \Omega$$

Laws of computation tell us what are (im)possible to do with computers
Part of computer science

To some extent, laws of computation are studied in automata theory

Certain tasks are believed impossible to solve quickly on current computers

Given $n = pq$ that is the product of two unknown primes, find p and q
Building block of cryptosystems

011001110110110
Machine takes \$5 and \$10 coins
A gumball costs \$15
Actions: +5, +10, Release

Why?

Only one example of a machine

We will look at different kinds of machines and ask

- what kind of problems can this kind of machines solve?
- What are impossible for this kind of machines?
- Is machine A more powerful than machine B?

finite automata	Devices with a small amount of memory
	These are very simple machines
push-down automata	Devices with unbounded memory that can be accessed in a restricted way
	Used to parse grammars
Turing machines	Devices with unbounded memory
	These are actual computers
time-bounded Turing Machines	Devices with unbounded memory but bounded running time
	These are computers that run fast

- Finite automata
  Closely related to pattern searching in text

  Find (ab)*(ab) in abracadabra

- Grammars
  - Describe the meaning of sentences in English, and the meaning of programs in Java (or any language)
  - Useful for natural language processing and compilers

Turing machines

- General model of computers, capturing anything we could ever hope to compute
- Still, computers cannot do many things

Given a program, tell if it prints the string "3130"

```
#include <stdio.h>
main(t,_,a)char *a;{return!0<t?t<3?main(-79,-13,a+main(-87,1-_,
main(-86,0,a+1)+a)):1,t<_?main(t+1,_,a):3,main(-94,-27+t,a)&&t==2?_<13?
main(2,_+1,"%s %d %d\n"):9:16:t<0?t<-72?main(_,t,
"@n'_,#'/+k*;e+;#'*%;4/%*;/:_,#;:p'/'*p;;/*;7#';:1;3:#9;;/:p'/'!2;n'/*;3;'*;+#'n',/+k*;;+;p'/'!2;n'/*;#';+;#n'';,';'/*;:/*;+;,#;;#';;'*;;/*;2;n'/*;_,#)#'):_?main(2,_-1,"*%s"):_?putchar(31[a]):main(-65,_,a+1):main((*a=='/')+t,_,a+1)
:0<t?main(2,2,"%s"):*a=='/'||main(0,main(-61,*a,
"!ek;dc i@bK'(q)-[w]*%n+r3#l,{}:\nuwloca-O;m .vpbks,fxntdCeghiry"),a+1);}
```

Formal verification of software must fail on corner cases

Time-bounded Turing machines

- Many problems can be solved on a computer in principle, but it takes too much time in practice

- Traveling salesperson: Given a list of cities, find the shortest way to visit them all and return home
- For 100 cities, takes 100+ years to solve even on the fastest computer!

> Can machine A solve problem B?

- Examples of problems we will consider
  - Given a word s, does it contain "to" as a subword?
  - Given a number n, is it divisible by 7?
  - Given two words s and t, are they the same?
- All of these have "yes/no" answers (decision problems)
- There are other types of problems, like "Find this" or "How many of that" but we won't look at them

- Strings are a common way to talk about words, numbers, pairs of numbers
  Which symbols can appear in a string? As specified by an alphabet

> An alphabet is a finite set of symbols

- Examples
  $\Sigma_1 = \{a, b, c, d, \ldots, z\}$: the set of English letters
  $\Sigma_2 = \{0, 1, 2, \ldots, 9\}$: the set of digits (base 10)
  $\Sigma_3 = \{a, b, c, \ldots, z, \#\}$: the set of letters plus special symbol #

An input to a problem can be represented as a string

A string over alphabet Σ is a finite sequence of symbols in Σ

axyzzy is a string over $\Sigma_1 = \{a, b, c, \ldots, z\}$

3130 is a string over $\Sigma_2 = \{0, 1, \ldots, 9\}$

ab#bc is a string over $\Sigma_3 = \{a, b, \ldots, z, \#\}$

- The empty string will be denoted by ε
  (What you get using `""` in C, Java, Python)
- Σ^* denotes the set of all strings over Σ
  All possible inputs using symbols from Σ only

A language is a set of strings (over the same alphabet)

Languages describe problems with "yes/no" answers:

$L_1 =$ All strings containing the substring "to" $\qquad \Sigma_1 = \{a, \ldots, z\}$

stop, to, toe are in L_1

ε, oyster are not in L_1

$$L_1 = \{x \in \Sigma_1^* \mid x \text{ contains the substring "to"}\}$$

Examples of languages

$$L_2 = \{x \in \Sigma_2^* \mid x \text{ is divisible by } 7\} \qquad \Sigma_2 = \{0, 1, \ldots, 9\}$$

$$L_2 \text{ contains 0, 7, 14, 21, ...}$$

$$L_2 = \{x \in \Sigma_2^* \mid x \text{ is divisible by } 7\} \qquad \Sigma_2 = \{0, 1, \ldots, 9\}$$

L_2 contains 0, 7, 14, 21, …

$$L_3 = \{s\#s \mid s \in \{a, \ldots, z\}^*\} \qquad \Sigma_3 = \{a, b, \ldots, z, \#\}$$

Which of the following are in L_3?

ab#ab   ab#ba   a##a#

Examples of languages

$$L_2 = \{x \in \Sigma_2^* \mid x \text{ is divisible by 7}\} \qquad \Sigma_2 = \{0, 1, \ldots, 9\}$$

L_2 contains 0, 7, 14, 21, ...

$$L_3 = \{s\#s \mid s \in \{a, \ldots, z\}^*\} \qquad \Sigma_3 = \{a, b, \ldots, z, \#\}$$

Which of the following are in L_3?

ab#ab	ab#ba	a##a#
Yes	No	No

Finite Automata

Example of a finite automaton

- There are states $0, $5, $10, go
- The start state is $0
- Takes inputs from $\{+5, +10, \mathsf{R}\}$
- The state go is an accepting state
- There are transitions specifying where to go to for every state and every input symbol

Deterministic finite automaton

A finite automaton (DFA) is a 5-tuple $(Q, \Sigma, \delta, q_0, F)$ where

- Q is a finite set of states
- Σ is an alphabet
- $\delta : Q \times \Sigma \to Q$ is a transition function
- $q_0 \in Q$ is the initial state
- $F \subset Q$ is the set of accepting states (or final states)

In diagrams, the accepting states will be denoted by double circles

table of transition
function δ
alphabet $\Sigma = \{0, 1\}$
states $Q = \{q_0, q_1, q_2\}$
initial state q_0
accepting states $F = \{q_0, q_1\}$

		inputs	
		0	1
states	q_0	q_0	q_1
	q_1	q_2	q_1
	q_2	q_2	q_2

A DFA accepts a string x if starting from the initial state and following the transitions as x is read from left to right, the DFA ends at an accepting state

The DFA accepts 0 and 011   but not 10 and 0101

The language of a DFA is the set of all strings x accepted by the DFA

0 and 011 are in the language   10 and 0101 are not

The languages of these DFAs?

Draw a DFA over $\{0, 1\}$ that accepts all strings with at most three 1s

Draw a DFA over $\{0, 1\}$ that accepts all strings with at most three 1s

Draw a DFA over $\{0, 1\}$ that accepts all strings ending in 01
Examples

Draw a DFA over $\{0, 1\}$ that accepts all strings ending in 01

Hint: The DFA should "remember" the last 2 bits of the input string

Examples

Draw a DFA over $\{0, 1\}$ that accepts all strings ending in 01

Hint: The DFA should "remember" the last 2 bits of the input string

We will see a much simpler DFA in the next lecture

Draw a DFA over $\{0, 1\}$ that accepts all strings ending in 101
