CSCI3610: Special Exercise Set 3

Problem 1. If we run the activity-selection algorithm taught in the class on the following input:
$S = \{[1, 10], [2, 22], [3, 23], [20, 30], [25, 45], [40, 50], [47, 62], [48, 63], [60, 70]\}$
what is the set of intervals returned?

Problem 2. The following is another greedy algorithm for the activity selection problem. Initialize an empty T, and then repeat the following steps until S is empty:

- (Step 1) Add to T the interval I with the shortest length.
- (Step 2) Remove from S the interval I, and all the intervals overlapping with I.

Finally, return T as the answer.

Prove: the above algorithm does not always return an optimal solution.

Problem 3 (0-1 Knapsack). Suppose that there are n gold bricks, where the i-th piece weighs p_i bounds and is worth d_i dollars. Given a positive integer W, our goal is to find a set S of gold bricks such that

- the total weight of the bricks in S is at most W, and
- the total value of the bricks in S is maximized (among all the sets S satisfying the first condition).

Assuming $d_1 \geq d_2 \geq ... \geq d_n$, let us consider the following greedy algorithm:

1. $S = \emptyset$
2. **for** $i = 1$ to n
3. **if** $p_i \leq W$ **then**
4. add p_i to S; $W \leftarrow W - p_i$

Prove: the above algorithm does not guarantee finding the desired set S.
