

## Applications of Hahn-Banach Thm

Recall: (We focus on real-valued version).

① Hahn-Banach Thm on Vector spaces

Thm: Let  $X$  be a real vector space and  $p$  is a sublinear functional on  $X$ . If  $f$  is a linear functional on a subspace  $Z$  of  $X$  and satisfies

$$f(x) \leq p(x), \quad \forall x \in Z$$

Then  $f$  has a linear extension  $\tilde{f}$  defined on  $X$  such that

$$\tilde{f}(x) = f(x), \quad \forall x \in Z$$

$$\tilde{f}(x) \leq p(x), \quad \forall x \in X.$$

② Hahn-Banach Thm on normed spaces.

Thm: Let  $f$  be a bounded linear functional on a subspace  $Z$  of a normed space  $X$ . Then there exists a bounded linear functional

$\tilde{f}$  on  $X$  such that

$$\tilde{f}(x) = f(x), \quad \forall x \in Z$$

$$\|\tilde{f}\|_X = \|f\|_Z.$$

Remark: Hahn-Banach Thm is one of fundamental thms in Functional Analysis and has a lot of applications. As we know, it guarantees that a normed space is richly supplied with bounded linear functionals, i.e.  $\exists$  bdd linear fcnal  $f$  s.t.  $f(x_1) \neq f(x_2), \forall x_1 \neq x_2$ . Based on Hahn-Banach Thm, we also obtain the theory of dual spaces and adjoint operators.

Ex 1: (Separation of convex sets)  $\rightarrow$  Hahn-Banach separation theorem

Let  $X$  be a real normed space and let  $A, B$  be two nonempty disjoint convex subsets of  $X$ .

(i) If  $A$  is open, then  $\exists$  a bounded linear functional  $f$  on  $X$  and  $c \in \mathbb{R}$  s.t.  $f(a) < c \leq f(b), \forall a \in A, b \in B$ .

(ii) If  $A$  is compact and  $B$  is closed, then  $\exists$  a bounded linear functional  $f$  on  $X$  and  $c_1, c_2 \in \mathbb{R}$  s.t.  $f(a) \leq c_1 < c_2 \leq f(b), \forall a \in A$  and  $b \in B$ .

Remark: The hyperplane  $H_c = \{x \in X : f(x) = c\}$  separates two disjoint convex sets  $A$  and  $B$ .

Pf: Step 1: (Reduce the problem to be separating a point from a convex set.)

Choose  $a_0 \in A, b_0 \in B$ . Set  $x_0 = -a_0 + b_0$ .

Consider  $D = A - B + x_0 = \{a - a_0 + b_0 - b \mid a \in A, b \in B\}$

Since  $A, B$  are convex and  $A$  is open, it is clear that  $D$  is an open convex neighborhood of  $0$ .

Moreover,  $x_0 \notin D$ , otherwise,  $x_0 = a - b + x_0$  i.e.  $a - b = 0$  for some  $a \in A, b \in B$ .

A contradiction to  $A \cap B = \emptyset$ .

Step 2: (Construct sublinear functional)

Define  $p(x) = \inf \{ \lambda > 0 \mid x \in \lambda D \}$  (which is called Minkowski functional)

Since  $D$  is open and  $0 \in D$ ,  $B(0, p) \subset D$  for some  $p > 0$ .

Thus  $p(x) \leq \frac{\|x\|}{p}$ , since  $x \in \frac{\|x\|}{p} B(0, p) \subset \frac{\|x\|}{p} D, \forall x \in X$ .

Furthermore,  $p$  satisfy  $p(\alpha x) = \alpha p(x), \forall \alpha \geq 0$  and  $p(x+y) \leq p(x) + p(y)$ .

Indeed,  $\forall \epsilon > 0$ , let  $\lambda_1 = p(x) + \frac{\epsilon}{2}$  and  $\lambda_2 = p(y) + \frac{\epsilon}{2}$ , then

$$\frac{x}{\lambda_1} \in D \text{ and } \frac{y}{\lambda_2} \in D$$

So,  $\frac{x+y}{\lambda_1 + \lambda_2} = \frac{\lambda_1}{\lambda_1 + \lambda_2} \frac{x}{\lambda_1} + \frac{\lambda_2}{\lambda_1 + \lambda_2} \frac{y}{\lambda_2} \in D$  since  $D$  is convex.

i.e.  $p(x+y) \leq \lambda_1 + \lambda_2 = p(x) + p(y) + \epsilon \Rightarrow p(x+y) \leq p(x) + p(y)$ .

Step 3: (Construct linear functional on subspace)

Set  $Z = \{ \alpha x_0 \}$ . Then  $Z$  is a subspace of  $X$ .

Define a functional  $g$  on  $Z$  as  $g(\alpha x_0) = \alpha$ .

Then  $g(x_0) = 1$ . Note that  $x_0 \notin D$ , one has  $p(x_0) \geq 1$

$$\text{So, } g(\alpha x_0) = \alpha \leq \alpha p(x_0) = p(\alpha x_0)$$

By Hahn-Banach Theorem,  $\exists$  a linear func  $f$  on  $X$  s.t.

$$f(x) \leq p(x) \text{ and } f(x_0) = g(x_0) = 1$$

Since  $p(x) \leq \frac{\|x\|}{p}$ ,  $f$  is bounded and  $\|f\| \leq \frac{1}{p}$

Therefore,  $\forall a \in A, b \in B$

$$f(a) - f(b) + 1 = f(a - b + x_0) \leq p(a - b + x_0) < 1 \text{ since } a - b + x_0 \notin D \text{ and } D \text{ is open.}$$

$$\text{i.e. } f(a) < f(b), \forall a \in A, b \in B.$$

The sets  $f(A)$  and  $f(B)$  are nonempty, disjoint convex sets

and  $f(A)$  is open. Taking  $c = \sup_{a \in A} f(a)$ , then (i) is proved.

(ii) Since  $A$  is compact and  $B$  is closed,

$$d(A, B) = \inf \{ \|a - b\| \mid a \in A, b \in B \} > 0$$

Let  $r = d(A, B)$ . Then  $A_r := \{ x \in X \mid d(x, A) < r \}$  does not intersect with  $B$ . Then (i) yields that  $\exists$  a bdd linear func  $f$  on  $X$  and  $c_2 \in \mathbb{R}$  s.t.  $f(x) < c_2 \leq f(y), \forall x \in A_r$ , and  $y \in B$

Since  $f$  is cts and  $A$  is compact,  $f(A)$  is compact.

So  $c_1 := \sup_{x \in A} f(x) < c_2$ . This proves (ii)

Claim = One has the ineq  $f(a) < c \quad \forall a \in A$ .

Suppose that the above claim is not true, i.e.  $\exists a_1 \in A$  s.t.  $f(a_1) = c$

Since  $A$  is open, then  $\exists \varepsilon > 0$  s.t.  $a_1 + \varepsilon x_0 \in A$ .

$$f(a_1 + \varepsilon x_0) = f(a_1) + \varepsilon f(x_0) = c + \varepsilon > c, \text{ contradiction.}$$
