Computer Organization & Design

Lecture 03: Arithmetic Instructions

Bei Yu

CSE Department, CUHK

byu@cse.cuhk.edu.hk

(Textbook: Chapters 2.1 – 2.7)

2024 Spring

- ① Introduction
- ② Arithmetic & Logical Instructions
- ③ Data Transfer Instructions

Introduction

RISC-V

- An open standard instruction set architecture (ISA)
- A clean break from the earlier MIPS-inspired designs
- Modular ISA organization
- Open standards, numerous proprietary and open-source cores
- Managed by RISC-V Foundation

Specification of RISC-V

- Allow / Encourage custom extension
- Emphasize flexibility
- Standard extensions
 - I (Integer-related extension)
 - M (Standard integer multiply and divide extension)
 - A (Atomic extension)
 - F (Floating-point extension)
 - D (double-precision extension)
 - C (Compressed instruction extension)
 - G (General purpose extension, including IMAFD)
- G extension in RV32I encodes in 32-bit, C extension encodes in 16-bit
- User / Supervisor / Machine level

Notice

Our Labs will focus on **RV32I**

Table: RV32I Unprivileged Integer Register

Register Name	ABI Name	Description
x0	zero	Hard-Wired Zero
x1	ra	Return Address
x2	sp	Stack Pointer
x3	gp	Global Pointer
x4	tp	Thread Pointer
x5	t0	Temporary/Alternate Link Register
x6-x7	t1-t2	Temporary Register
x8	s0/fp	Saved Register (Frame Pointer)
x9	s1	Saved Register
x10-x11	a0-a1	Function Argument/Return Value Registers
x12-x17	a2-a7	Function Argument Registers
x18-x27	s2-s11	Saved Registers
x28-x31	t3-t6	Temporary Registers

Return pointer ra/x1

Used to save the subroutine / function return addresses. Before a subroutine call is performed, x1 is explicitly set to the subroutine return address which is usually $pc + 4$.

Stack pointer sp/x2

Use to hold the base address of the stack. Stack base address must align to 4-bytes, if not, a load / store alignment fault may arise.

Global pointer $gp/x3$

Data is allocated to the memory when it is globally declared in an application. RISC-V places all the global variables in a particular area which is pointed by $gp/x3$. Hold the base address of the location where the global variables reside.

Argument register $x10-x17$

In RISC-V, 8 argument registers ($x10$ to $x17$) are used to pass arguments in a subroutine / function. Before a subroutine call is made, the arguments to the subroutine are copied to the argument registers. The stack is used in case the number of arguments exceeds 8.

opcode 7-bits, opcode that specifies the operation

rs1 5-bits, register file address of the first source operand

rs2 5-bits, register file address of the second source operand

rd 5-bits, register file address of the result's destination

imm 12-bits / 20-bits, immediate number field

funct 3-bits / 10-bits, function code augmenting the opcode

Four RV32I Encodes

- Immediate Encoding Variants, *e.g., slti, addi, lui, and etc.*
- Integer Computational Instructions, *e.g., sll, sub, or, and etc.*
- Control Transfer Instructions, *e.g., jal, jalr, beq, and etc.*
- Load and Store Instructions, *e.g., lb, ld, sh, and etc.*

Notice

We will be detailed in Lab 1-1

Arithmetic & Logical Instructions

- RISC-V assembly language arithmetic statement

```
add    t0, a1, a2  
sub    t0, a1, a2
```

- Each arithmetic instruction performs **one** operation
- Each specifies exactly three operands that are all contained in the datapath's register file (t0, s1, s2)

```
destination = source1 op source2
```

- Instruction Format (**R** format)

0x0 / 0x40	0xc	0xb	0	0x5	0x33
------------	-----	-----	---	-----	------

- Small constants are often used in typical assembly code directly

Possible approaches?

- put “typical constants” in memory and load them
- create hard-wired registers (like `zero`) for constants like 1
- have special instructions that contain constants

```
addi sp, sp, 4      # sp = sp + 4  
slti t0, s2, 15    # t0 = 1 if s2 < 15
```

- Machine format (I format)
- The constant is kept inside the instruction itself!
- Immediate format limits values to the range -2^{11} to $+2^{11} - 1$

```
1  .globl _start
2
3  .text
4  _start:
5      li a1, 20
6      li a2, 23
7      add t0, a1, a2
8      sub t1, a1, a2
```

RARS example: $t0 = 0x2b$, $t1 = 0xffffffd$

- We'd also like to be able to load a 32 bit constant into a register
- For this we must use two instructions
- ① A new “load upper immediate” instruction (U-type format, load top 20-bits)

```
lui t0, 1010 1010 1010 1010 1010b
```

- ② Then must get the lower order bits right, use (I-type format, update low 12-bits)

```
ori t0, t0, 101010101010b
```

Aside: How About Larger Constants?

- We'd also like to be able to load a 32 bit constant into a register
 - For this we must use two instructions
- ① A new “load upper immediate” instruction (U-type format, load top 20-bits)

```
lui t0, 1010 1010 1010 1010 1010b
```

- ② Then must get the lower order bits right, use (I-type format, update low 12-bits)

```
ori t0, t0, 101010101010b
```

10101010101010101010	000000000000
----------------------	--------------

00000000000000000000	101010101010
----------------------	--------------

10101010101010101010	101010101010
----------------------	--------------

- Need operations to **pack** and **unpack** 8-bit characters into 32-bit words
- Shifts move all the bits in a word left or right

```
slli t2, s0, 8    # t2 = s0 << 8 bits  
srli t2, s0, 8    # t2 = s0 >> 8 bits
```

- Instruction Format (**I** format)
- Such shifts are called **logical** because they fill with **zeros**
- Notice that a 5-bit shamt field is enough to shift a 32-bit value $2^5 - 1$ or **31 bit positions**

```
1  .globl _start
2
3  .text
4  _start:
5      li a1, 20
6      li a2, 23
7      slli t0, a1, 2
8      srli t1, a2, 1
```

RARS example: $t0 = 0x50$, $t1 = 0x0b$

There are a number of **bit-wise** logical operations in the RISC-V ISA

R Format

```
and t0, t1, t2    # t0 = t1 & t2  
or  t0, t1, t2    # t0 = t1 | t2  
xor t0, t1, t2    # t0 = t1 & (not t2) + (not t1) & t2
```

I Format

```
andi t0, t1, 0xFF00    # t0 = t1 & 0xff00  
ori  t0, t1, 0xFF00    # t0 = t1 | 0xff00
```

```
1  .globl _start
2
3  .text
4  _start:
5      li a1, 20
6      li a2, 23
7      and t0, a1, a2
8      or t1, a1, a2
9      xor t2, a1, a2
10     andi t3, a1, 0x12
11     ori t4, a2, 0x21
```

RARS example: t0 = 0x14, t1 = 0x17, t2 = 0x03, t3 = 0x10, t4 = 37

Data Transfer Instructions

- Two basic **data transfer** instructions for accessing memory

```
lw  t0, 4(s3)  # load word from memory  
sw  t0, 8(s3)  # store word to memory
```

- The data is loaded into (**lw**) or stored from (**sw**) a register in the register file – a 5 bit address
- The memory address – a 32 bit address – is formed by adding the contents of the base address register to the offset value
- A 12-bit field in RV32I meaning access is limited to memory locations within a region from **-2 KB to 2 KB** of the address in the base register

```
1  .globl _start
2
3  .data
4  a: .word 1 2 3 4 5 # .word = 32 bits
5
6  .text
7  _start:
8      la a1, a
9      lw t0, 0(a1)
10     lw t1, 4(a1)
11     lw t2, 8(a1)
12     lw t3, 12(a1)
13     lw t4, 16(a1)
14     addi t4, t4, 1
15     sw t4, 20(a1)
16     lw t5, 20(a1)
```

RARS example: $t0 = 0x01$, $t1 = 0x02$, $t2 = 0x03$, $t3 = 0x04$, $t4 = 0x06$, $t5 = 0x06$

Load/Store Instruction Format (I format):

lw t0, 24(s3)

0x18	0x13	0x2	0x5	0x3
------	------	-----	-----	-----

Load/Store Instruction Format (I format):

$$24_{10} + s3 =$$

$$\begin{array}{r}
 \dots 0001\ 1000 \\
 + \dots 1001\ 0100 \\
 \hline
 \dots 1010\ 1100 = \\
 \qquad\qquad 0x120040ac
 \end{array}$$

- Since 8-bit bytes are so useful, most architectures address individual **bytes** in memory
- **Alignment restriction** – the memory address of a word must be on natural word boundaries (a multiple of 4 in RV32I)
- **Big Endian**: leftmost byte is word address
 - IBM 360/370, Motorola 68k, **MIPS**, Sparc, HP PA
- **Little Endian**: rightmost byte is word address
 - RISC-V, Intel 80x86, DEC Vax, DEC Alpha (Windows NT)

RISC-V provides special instructions to move bytes

```
lb    t0, 1(s3)    # load byte from memory  
sb    t0, 6(s3)    # store byte to memory
```

- What 8 bits get loaded and stored?
- **Load byte (lb)** places the byte from memory in the **rightmost** 8 bits to the destination register; **signed-extension**
- **Store byte (sb)** takes the byte from the **rightmost** 8 bits of a register and writes it to a byte in memory

EX-1:

Given following code sequence and memory state:

```

add   s3, zero, zero
lb    t0, 1(s3)
sb    t0, 6(s3)

```

- 1 What value is left in `t0`?
- 2 What word is changed in Memory and to what?
- 3 What if the machine was **Big Endian**?

Memory	
0x 0 0 0 0 0 0 0 0	24
0x 0 0 0 0 0 0 0 0	20
0x 0 0 0 0 0 0 0 0	16
0x 1 0 0 0 0 0 1 0	12
0x 0 1 0 0 0 4 0 2	8
0x F F F F F F F F	4
0x 0 0 9 0 1 2 A 0	0
Data	Word Address (Decimal)
