

SUDOKU Codes, a class of non-linear iteratively decodable codes

Jossy Sayir

UNIVERSITY OF CAMBRIDGE
Department of Engineering

Chinese University of Hong Kong, 21 October 2014

Outline

- ▶ SUDOKU as channel codes
- ▶ Efficient decoding / encoding of SUDOKU
- ▶ Density Evolution
- ▶ Rate of SUDOKU codes

Coding by SUDOKU

Wikipedia “The Mathematics of SUDOKU”

There are $M = 6,670,903,752,021,072,936,960$ valid SUDOKU grids.

Background

Literature

- ▶ **P. Farrell**, “Sudoku Codes: a Tutorial” (Ambleside 2009) - looked at **distance properties** of SUDOKU codes
 - ▶ **T. Moon & al.**, **BP** and **Sinkhorn** for SUDOKU solving (2006, 2009) - algorithms to solve SUDOKU puzzles (**not** SUDOKU as codes)
-
- ▶ use in lectures since 2006 to illustrate BP decoding
 - ▶ invaluable **didactic tool** to illustrate the use of **factor graphs**, **trellis decoding**, **arithmetic decoding** and other techniques
 - ▶ 2 student projects in 2013/14 and strong student interest
 - ▶ **Proxy for the study of non-linear codes with local constraints**

Non-linear Codes

Theory

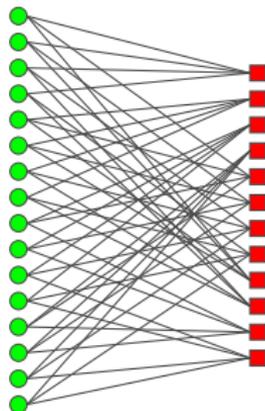

- ▶ Used in achievability proofs (fixed-composition codes, typical sequence arguments, etc.)
- ▶ No practical encoders, decoders, etc.

Applications

- ▶ Simple constrained sequences (e.g. for magnetic recording)
- ▶ Other constraints, e.g., low Peak-to-Average Power Ratio (PAPR), can translate into non-linear constraints

My work on SUDOKU codes

- ▶ Efficient decoding
- ▶ Efficient encoding
- ▶ Density Evolution
- ▶ Rate of the code

My work on SUDOKU codes

- ▶ Efficient decoding
- ▶ Efficient encoding
- ▶ Density Evolution
- ▶ Rate of the code

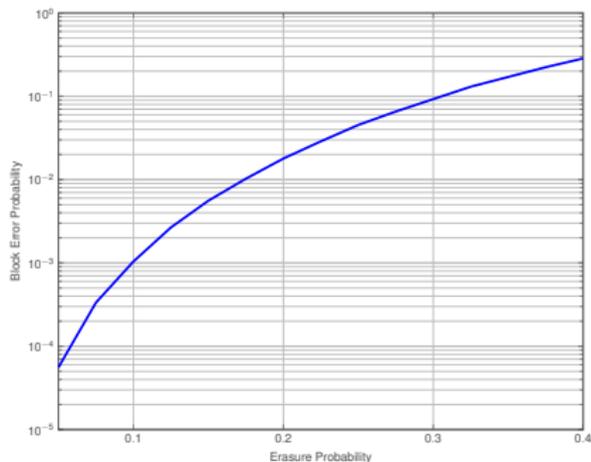

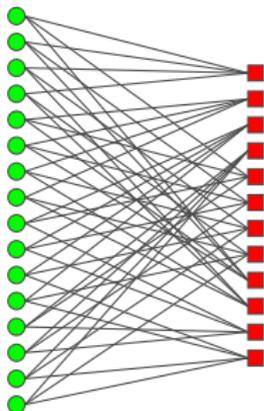

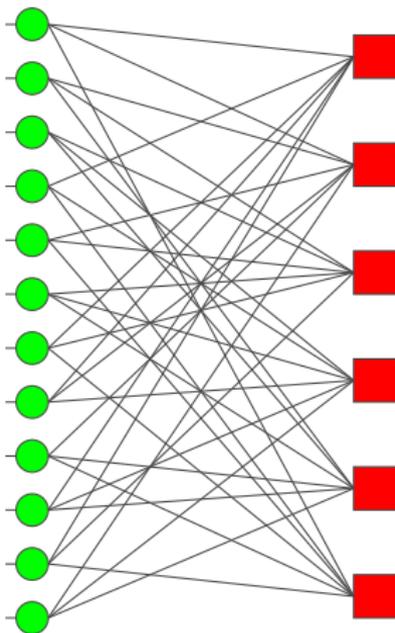

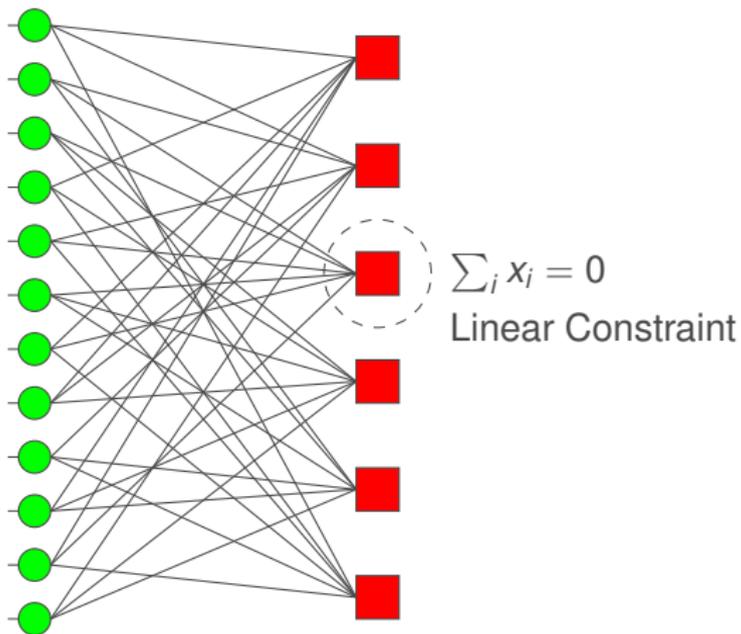

Figure : Classic 9x9 SUDOKU simulated performance averaged over 49 codewords

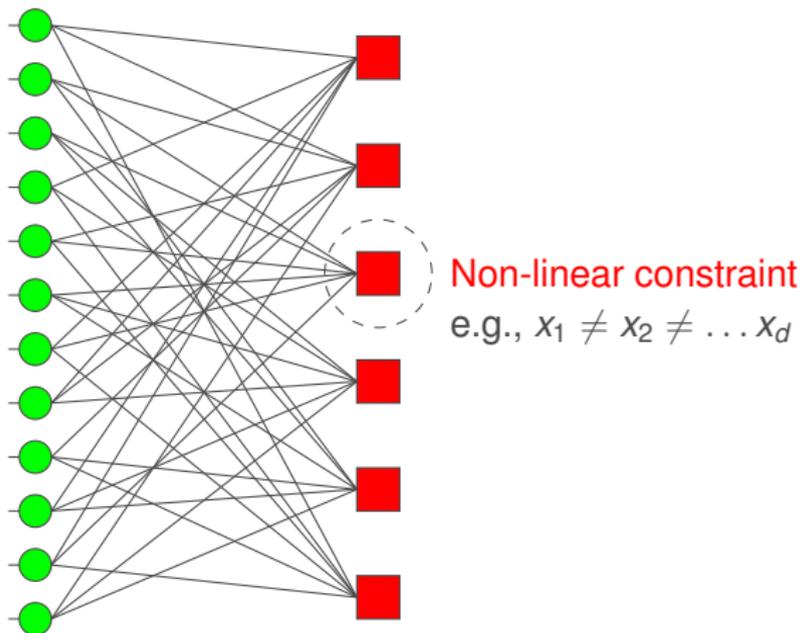

Local constraints: factor graphs

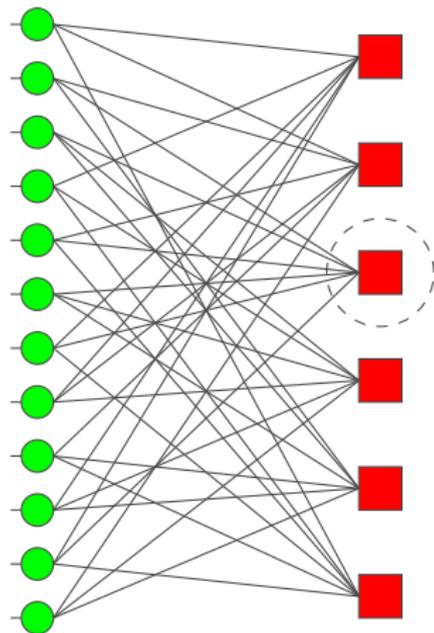

Local constraints: factor graphs

Local constraints: factor graphs

Local constraints: factor graphs

Non-linear constraint

e.g., $x_1 \neq x_2 \neq \dots x_d$

q : alphabet size

d : node degree

if $q = d$, $\{x_1, \dots, x_q\} \in \mathcal{S}_q$

SUDOKU (permutation) constraint

Belief propagation for permutation constraints

- ▶ Messages are q -ary probability mass functions
- ▶ Variable nodes: product of incoming probabilities
- ▶ Constraint nodes:

$$P(X_i = k | m_{v \sim i \rightarrow c}) = \sum_{i' \neq i} \prod_{k' \neq k} P(X_{i'} = k' | m_{v_{i'} \rightarrow c})$$

- ▶ Let \mathbf{P} be the matrix of incoming messages to a constraint node, i.e., p_{ik} is the probability that the variable corresponding to the i -th message takes on value k

Constraint Node Computation: Permanents

Augustin-Louis Cauchy

- ▶ Permanent of a matrix,

$$\text{per} \begin{bmatrix} a & b & c \\ d & e & f \\ g & h & i \end{bmatrix} = a(ei + hf) + b(di + gf) + c(dh + ge),$$

same as a determinant except all “+”

- ▶ For a constraint node,

$$m_{c \rightarrow vi} = \frac{1}{\text{per } \mathbf{P}} [\text{per}(\mathbf{P}_{\sim i1}), \text{per}(\mathbf{P}_{\sim i2}), \dots, \text{per}(\mathbf{P}_{\sim iq})],$$

where $\mathbf{P}_{\sim ij}$ denotes the matrix \mathbf{P} with its i -th row and j -th column removed

Complexity of the constraint node operation

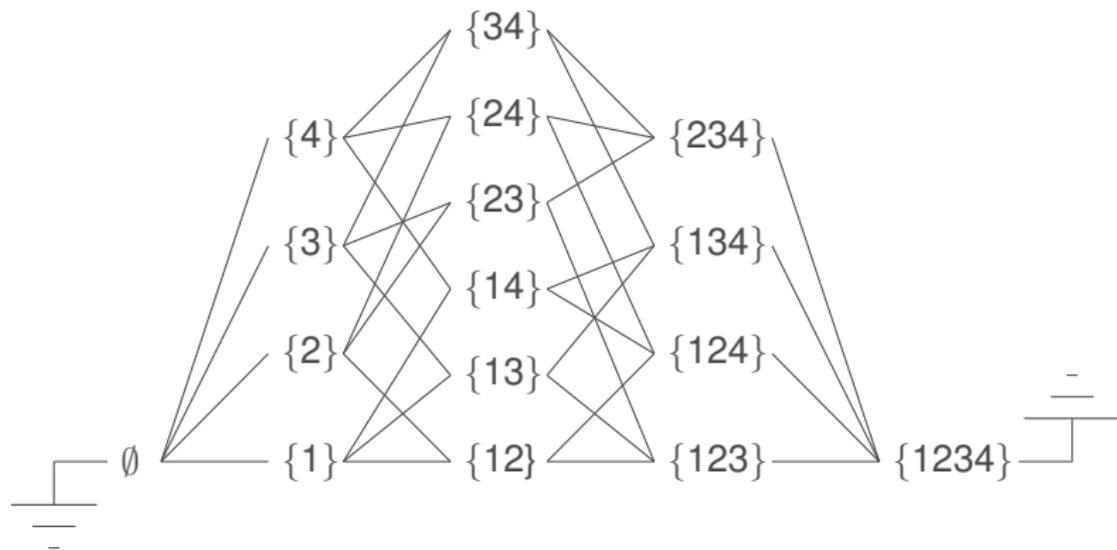

- ▶ Each constraint node at each iteration requires the computation of a permanent
- ▶ Brute force computation: sum of $q!$ products of q factors, i.e.,

Alphabet Size q	Multiplications $(q - 1) \times q!$	Additions $q! - 1$
4	72	23
9	2'903'040	362'879
16	3.14×10^{14}	2.09×10^{13}

- ▶ *From Wikipedia:* The permanent is more difficult to compute than the determinant. Gaussian elimination **cannot** be used to compute the permanent. Computing the permanent of a 0-1 matrix (matrix whose entries are 0 or 1) is $\#P$ -complete. $FP = \#P$ is stronger than $P = NP$. When the **entries of A are nonnegative**, however, the permanent can be **computed approximately in probabilistic polynomial time**, up to an error of ϵM , where M is the value of the permanent and $\epsilon > 0$ is arbitrary.¹

¹Jerrum, M.; Sinclair, A.; Vigoda, E. (2004), "A polynomial-time approximation algorithm for the permanent of a matrix with nonnegative entries", Journal of the ACM

Trellis-based permanent computation

- ▶ Forward multiply and add yields the permanent
- ▶ Full BCJR yields the subpermanents we need
- ▶ thanks Gottfried Lechner

Trellis-based **erasure** decoding

$$\mathbf{T}_{\text{in}} = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 0 \\ 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 \end{bmatrix}$$

7	3,200,400	0.1571

Asymptotic Analysis

Density Evolution

Non-linear codes with local constraints vs. linear (LDPC) codes

- ▶ Concentration of the error performance
- ▶ Convergence to a cycle-free case
- ▶ Simplification by restriction to the all-one (all zero) codeword

SUDOKU constraints for the q -ary Erasure channel

- ▶ Messages = subsets of $\{1, \dots, q\}$
- ▶ Some interesting symmetries

Symmetries of the SUDOKU decoder

Proposition

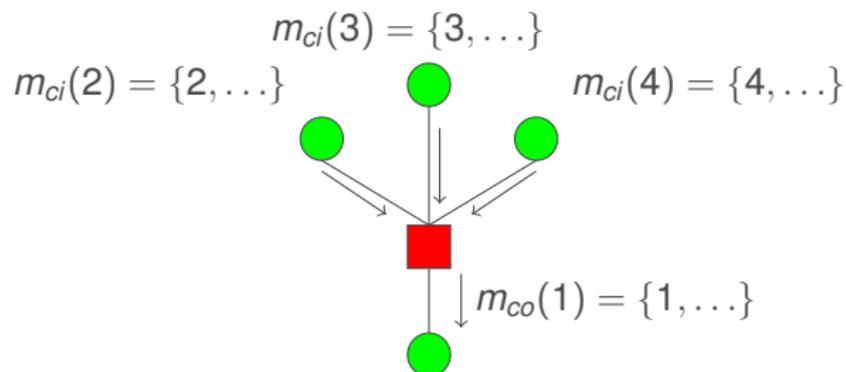

All operations symmetric under alphabet and edge permutations

Proposition

The probability distribution of the **cardinalities** of messages $\#m$ at iteration k is a sufficient statistic for the probability distribution of the actual messages

- ▶ $P_k(\#m)$ is a sufficient statistic for $P_{k+1}(\#m)$
- ▶ $P_k(\#m)$ is a sufficient statistic for the block error probability at iteration k

Rate as blocklength $N \rightarrow \infty$

The rate of a SUDOKU-type code for $N \rightarrow \infty$ is currently unknown. The quantity defined below may give an indication of what the true rate might be.

Definition

For a constraint-regular factor graph with constraint degree d_c equal to the alphabet size q , and variable degree distribution $\lambda(x)$, the “cycle-free rate” of a code with SUDOKU type constraints is

$$R_{cf} = \frac{\log_q((q-1)!)}{q-1}$$

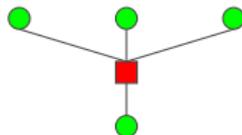

Rate as blocklength $N \rightarrow \infty$

The rate of a SUDOKU-type code for $N \rightarrow \infty$ is currently unknown. The quantity defined below may give an indication of what the true rate might be.

Definition

For a constraint-regular factor graph with constraint degree d_c equal to the alphabet size q , and variable degree distribution $\lambda(x)$, the “cycle-free rate” of a code with SUDOKU type constraints is

$$R_{cf} = \frac{\log_q((q-1)!)}{q-1}$$

$$\frac{\log(q!)}{q}$$

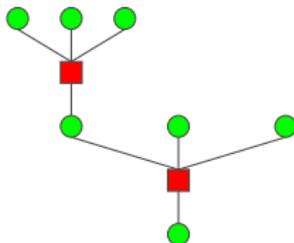

Rate as blocklength $N \rightarrow \infty$

The rate of a SUDOKU-type code for $N \rightarrow \infty$ is currently unknown. The quantity defined below may give an indication of what the true rate might be.

Definition

For a constraint-regular factor graph with constraint degree d_c equal to the alphabet size q , and variable degree distribution $\lambda(x)$, the “cycle-free rate” of a code with SUDOKU type constraints is

$$R_{cf} = \frac{\log_q((q-1)!)}{q-1}$$

$$\frac{\log(q!) + \log((q-1)!)}{q + (q-1)}$$

Pascal Vontobel's Bethe approximation of the partition function of the factor graph

Rate

$$R = \max \left\{ 0, \frac{d_v}{q} \log_2(q!) - (d_v - 1) \log_2 q \right\}$$
$$\approx \max \left\{ 0, \log_2 \left(\frac{q(2\pi q)^{d_v/(2q)}}{e^{d_v}} \right) \right\}$$

$R = 0$ for $d_v = 3$ and $q < 12$

Conclusion

- ▶ I calculated using density evolution an erasure threshold for $d_v = 3$ and $q = 3, \dots, 8$, but Pascal proved that there are in fact no codewords for these dimensions (or, as he put it more precisely, sub-exponentially many codewords)
- ▶ Asymptotic analysis seems stuck between a combinatorial explosion and the requirement to go to higher alphabets
- ▶ Study specific structures like the diagonal SUDOKU, devise encoding methods and analyse performance
- ▶ Non-linear codes with local constraints are fun: they test the limit of our abilities, pose interesting problems, and the brand name “SUDOKU” seems to attract good students
- ▶ **Current student project:** linear codes with added non-linear constraints for joint synchronisation and coding
