An opportunity to express our gratitude for late Professor Ka-Sing Lau.

Abstract:

The talk will present bounded variation (BV) and fractional Sobolev functional spaces, Besov critical exponents, and isoperimetric and Sobolev inequalities associated with fractional Laplacians on metric measure spaces. The main tool is the theory of heat semigroup-based Besov classes in Dirichlet Metric Measure Spaces that uses a Korevaar-Schoen space approach in a general framework of strongly local Dirichlet spaces with a heat kernel satisfying sub-Gaussian estimates. Under a weak Bakry-Emery curvature type condition, which is new in this setting, this BV class is identified with a heat semigroup-based Besov class. As a consequence of this identification, properties of BV functions and associated BV measures can be studied in detail. In particular, we prove co-area formulas, global Sobolev embeddings, and isoperimetric inequalities. It is shown that for nested fractals or their direct products, the BV class we define is dense in L^1 . The examples of the unbounded Vicsek set, unbounded Sierpinski gasket, and unbounded Sierpinski carpet are discussed. This is a joint work with Patricia Alonso-Ruiz, Fabrice Baudoin, Li Chen, Luke Rogers, and Nageswari Shanmugalingam.

Plan of the talk:

BV spaces on fractals with Dirichlet forms

Introduction: analysis on “fractafolds”*

Physics motivation

Group Theory and Complex Dynamics motivation

Heat Kernel Estimates and Dirichlet Forms

Spectral analysis

Elements of differential geometry

- ▶ *Strichartz: *A fractafold, a space that is locally modeled on a specified fractal, is the fractal equivalent of a manifold.*
 - ▶ *A “fractafold” is to a fractal what a manifold is to a Euclidean half-space.*

Let K be a fractal [F]. Then a *fractafold* \mathcal{F} based on K is a connected Hausdorff topological space such that every point x in \mathcal{F} has a neighborhood homeomorphic to a neighborhood in K . There is no generally agreed upon definition of “fractal”, other than “I know one when I see one”, but there are several well-defined classes of fractals, such as Kigami’s *p.c.f. (post-critically finite) self-similar fractals* [Ki1]. We are interested in this class of fractals because one can do analysis on them: under certain additional hypotheses, one can construct a Laplacian Δ on K and study properties of the spectrum of Δ . (Of course it should be emphasized here that the Laplacian is not uniquely determined by the topology of K , but rather depends on certain additional geometric structures, just as the Laplacian on a manifold depends on the choice of a Riemannian metric.) One of the purposes of introducing fractafolds in this context is that we may easily extend the Laplacian from K to \mathcal{F} , and thereby obtain a larger class of objects on which to do analysis ([B], [Ki1], [Ki2], [S2]).

sub-Gaussian Heat Kernel Estimates (sGHKE)

$$p_t(\mathbf{x}, \mathbf{y}) \sim \frac{1}{t^{d_f/d_w}} \exp\left(-c \frac{d(\mathbf{x}, \mathbf{y})^{\frac{d_w}{d_w-1}}}{t^{\frac{1}{d_w-1}}}\right) \quad (1)$$

$$\mathbf{distance} \sim (\mathbf{time})^{\frac{1}{d_w}}$$

d_f = Hausdorff dimension

$\frac{1}{\gamma} = d_w$ = “walk dimension” (γ =diffusion index)

$\frac{2d_f}{d_w} = d_s$ = “spectral dimension” (diffusion dimension)

First example: Sierpiński gasket; Kusuoka, Fukushima, Kigami, Barlow, Bass, Perkins (mid 1980'—)

$$1 = d_t = d_{mart} < d_{tH} = \frac{\ln 2}{\ln 3} + 1 < d_s < d_f = \frac{\ln 8}{\ln 3} < 2 < d_w$$

For Sierpinski carpets there exists a unique Dirichlet form and diffusion process due to [Barlow and Bass 1998, 1999] (see also [Barlow-Bass-Kumagai-T 2010])

Here $d_{tH} = \frac{\ln 2}{\ln 3} + 1$ is the **topological-Hausdorff dimension** of the Sierpinski carpet defined in Theorem 5.4 in:

[R.Balka, Z.Buczolich, M.Elekes. **A new fractal dimension: the topological Hausdorff dimension**. Adv. Math. 2015.]

Roughly speaking,

$$d_{tH} :=$$

$$1 + \inf \{ \text{Hausdorff dim. of boundaries of a base of open sets} \}$$

Barlow (Proceedings of SMS Montreal, 2011):

Given a regular fractal F , since L and M are given by the construction, one can calculate d_f easily. The constant ρ which gives d_w is somehow deeper, and seems to require some analysis on the set or its approximations. Loosely one can say that d_f is a ‘geometric’ constant, while d_w is an ‘analytic’ constant. One may guess that in some sense ρ or β are in general inaccessible by any purely geometric argument. (An exception is for trees, where one has $d_w = 1 + d_f$.)

Open questions:

On the Sierpinski carpet,

$$\kappa = d_W - d_f + d_{tH} - 1 = d_W - d_f + \frac{\log 2}{\log 3}$$

would give the best Hölder exponent for harmonic functions?
[*Strongly supported by numerical results: L.Rogers et al*]

Note that $(d_W - d_f)$ -Hölder continuity is classical:

BV and weak Bakry-Émery non-negative curvature

Definition

$BV(X) := KS^{\lambda_1^\#, 1}(X) = B^{1, \alpha_1^\#}(X)$ with $\alpha_1^\# = \frac{\lambda_1^\#}{d_W}$ the L^1 -Besov critical exponent, and for $f \in BV(X)$

$$\text{Var}(f) := \liminf_{r \rightarrow 0^+} \iint_{\Delta_r} \frac{|f(y) - f(x)|}{r^{\lambda_1^\#} \mu(B(x, r))} d\mu(y) d\mu(x).$$

Definition

We say that $(X, \mu, \mathcal{E}, \mathcal{F})$ satisfies the weak-Bakry-Émery non-negative curvature condition $wBE(\kappa)$ if there exist a constant $C > 0$ and a parameter $0 < \kappa < d_W$ such that for every $t > 0$, $g \in L^\infty(X, \mu)$ and $x, y \in X$,

$$|P_t g(x) - P_t g(y)| \leq C \frac{d(x, y)^\kappa}{t^{\kappa/d_W}} \|g\|_{L^\infty(X, \mu)}. \quad (2)$$

- ▶ If (X, d, μ) satisfies $wBE(\kappa)$ with $\kappa = \frac{d_W}{2}$, then the form \mathcal{E} admits a carré du champ operator, which means that $d_W = 2$ by [Kajino-Murugan 2019 Ann. Probab. 48, 2020]
- ▶ $\kappa \leq 1$ because $d(x, y)$ has to be essentially equivalent to a geodesic metric [Corollary 1.8, Theorem 2.11 Mathav Murugan JFA 2020]
- ▶ For nested fractals, p.c.f. with sGHKE (1)

$$\lambda_1^\# = \lambda_1^* = d_W \alpha_1^* = d_f$$

- ▶ For the Sierpinski carpet we conjecture

$$\lambda_1^\# = \lambda_1^* = d_f - d_{tH} + 1$$

where $d_{tH} = \frac{\ln 2}{\ln 3} + 1$ is the topological-Hausdorff dimension of the Sierpinski carpet

For the non-local fractional Laplacian $(-L)^\delta$ for some $0 < \delta < 1$ and the corresponding subordinated semigroup $P_t^{(\delta)}$ with generator $\mathbf{p}_t^{(\delta)}$

$$\|f\|_{\delta,p,\alpha} := \sup_{t>0} t^{-\alpha} \left(\int_X \int_X |f(x) - f(y)|^p \mathbf{p}_t^{(\delta)}(x, y) d\mu(y) d\mu(x) \right)^{1/p}.$$

If in addition P_t satisfies the weak Bakry-Émery estimate (2), then also the subordinated semigroup does: there is some $\kappa > 0$ such that for all $x, y \in X$ and $f \in L^\infty(X, \mu)$

$$|P_t^{(\delta)} f(x) - P_t^{(\delta)} f(y)| \leq C \frac{d(x, y)^\kappa}{t^{\frac{\kappa}{\delta d_W}}} \|f\|_{L^\infty(X, \mu)}, \quad (3)$$

When $\lambda_1^\# = d_W - \kappa$, then it is natural to define BV as the Korevaar-Schoen space $\text{KS}^{\lambda^\#, 1}(\mathbf{X})$, where, $\text{KS}^{\lambda, p}$ is the subspace of L^p determined by finiteness of the seminorm

$$\limsup_{r \rightarrow 0^+} \left(\int_{\mathbf{X}} \int_{\mathbf{B}(\mathbf{x}, r)} \frac{|f(\mathbf{x}) - f(\mathbf{y})|^p}{r^{\lambda p} \mu(\mathbf{B}(\mathbf{x}, r))} d\mu(\mathbf{y}) d\mu(\mathbf{x}) \right)^{1/p}, \quad (4)$$

and $\lambda_p^\#$ is the critical exponent defined as

$$\lambda_p^\# := \sup\{\lambda : \text{KS}^{\lambda, p}(\mathbf{X}) \text{ contains non-constant functions}\}. \quad (5)$$

The space $\text{KS}^{\lambda^\#, 1}$ enjoys many classical BV properties, including Sobolev embedding, isoperimetric inequalities, and a co-area formula, as well as an interpretation of the variation as a “BV measure”.

These properties will be established by comparing the seminorm (4) with the heat Besov seminorm for $\alpha = \lambda/(\delta d_W)$ and fixed $0 < \delta < 1$, and the corresponding critical exponents $\lambda_p^\#$ of the Korevaar-Schoen spaces and $\alpha_{\delta, p}^\#$ of the heat Besov spaces.

We need $\lambda_1^\# = \mathbf{d}_W - \kappa$ so that $\text{KS}^{\lambda_1^\#, 1}(\mathbf{X})$ is BV, and $\delta > \mathbf{1} - \frac{\kappa}{\mathbf{d}_W}$ to ensure this latter coincides with the critical heat Besov space.

Of particular interest is that this characterization is independent of the subordination parameter δ in the interval $(\lambda_1^\# / \mathbf{d}_W, \mathbf{1}) = (\mathbf{1} - \kappa / \mathbf{d}_W, \mathbf{1})$.

Intuitively, this result says that although being in BV appears to be a local property and was initially defined in terms of a local Dirichlet form and semigroup, we can recover it from the non-local fractional Laplacian operator and semigroup, as long as the latter it is not “too non-local”: $\delta > \lambda_1^\# / \mathbf{d}_W$.

This property of stability in the subordination parameter is consistent with the possibility of a non-trivial connection between the condition $\lambda_1^\# / \mathbf{d}_W = \mathbf{1} - \kappa / \mathbf{d}_W$ and the topological and metric structure of the space. We conjecture this quantity may depend not only on the Hausdorff and walk dimensions but also on the topological Hausdorff dimension.

Open question (Martin Barlow): Are there two fractals with the same values of d_f , d_w but different critical exponents α_1^* ?

Preliminary answer is positive if we compare the SC and

See also Lang and Plaut 2001.

Further examples of spaces to which our theory applies can be constructed by taking products of nested (sGHKE p.c.f.) fractals where the condition $\mathbf{wBE}(\kappa = \mathbf{d}_W - \mathbf{d}_f)$ is valid.

The n -fold product \mathbf{X}^n supports a heat kernel obtained by tensoring, the walk dimension remains \mathbf{d}_W on the product and $\mathbf{wBE}(\mathbf{d}_W - \mathbf{d}_f)$ is still true and the Hausdorff dimension is now $n\mathbf{d}_f$.

Theorem. If \mathbf{X} is a nested fractal, then for every $n \in \mathbb{N}$, the space $\mathbf{BV}(\mathbf{X}^n) = \mathbf{B}^{1, \mathbf{d}_f / \mathbf{d}_W}(\mathbf{X}^n)$ is dense in $\mathbf{L}^1(\mathbf{X}^n, \mu^{\otimes n})$ and our $\mathbf{wBE}(\kappa)$ Assumption is satisfied.

For **nested fractals** we do have $\kappa = d_W - d_f > 0$.

A set has finite perimeter if and only if it has finite boundary,
 $P(E) \sim \#(\partial E)$.

Theorem (research in progress)

$f \in \mathbf{BV}$ iff ∇f is a “vector valued Radon measure”.

This is understood in the distributional sense (Hinz, Rogers, Strichartz et al)

Corollary (research in progress)

1. on the Vicsek set, any BV function is \mathbb{R}^1 -**BV** along each geodesic path.
2. on the Sierpiński gasket, any **BV** function is discontinuous.

For Sierpinski carpets,

$$\alpha_1^* \geq (\mathbf{d}_f - \mathbf{d}_{tH} + 1)/\mathbf{d}_W, \quad (6)$$

However the Barlow-Bass theory only yields $\mathbf{wBE}(\kappa)$ for $\kappa = \mathbf{d}_W - \mathbf{d}_f$, not for

$$\kappa = \mathbf{d}_W - \mathbf{d}_f + \mathbf{d}_{tH} - 1.$$

We believe equality holds in (6) for α_1^* and post an open question about the weak Bakry-Émery estimate at criticality.

Note that, if $1 < \mathbf{d}_S = 2 \frac{\mathbf{d}_f}{\mathbf{d}_W} < 2$, proving $\mathbf{wBE}(\kappa)$ for $\kappa > \mathbf{d}_W - \mathbf{d}_f$ would involve improving the Hölder continuity estimates for harmonic functions in [BB89, BB99, Ba98], strongly supported by numerical calculations in [L.Rogers et al].

Conjecture: for generalized Sierpinski carpets

$$\alpha_1^* = (\mathbf{d}_f - \mathbf{d}_{tH} + 1)/\mathbf{d}_W$$

and the condition $\mathbf{wBE}(\kappa)$ is valid for some $\kappa > (\mathbf{d}_W - \mathbf{d}_f)_+$.

Why do we care?

Many reasons, including

We take a model of foamy space-time structure described by self-similar fractals. We study the propagation of a scalar field on such a background and we show that for almost any initial conditions the renormalization group equations lead to an effective highly symmetric metric at large scale.

Fig. 1. The first two iterations of a 2-dimensional 3-fractal.

Fig. 5. The plane of 2-parameter homogeneous metrics on the Sierpinski gasket. The hyperbole $\alpha = -\beta/(\beta + 1)$ separates the domain of euclidean metrics from minkowskian metrics and corresponds - except at the origin - to 1-dimensional metrics. M_1, M_2, M_3 denote unstable minkowskian fixed geometries while E corresponds to the stable euclidean fixed point. The unstable fixed points $0_1, 0_2$ and 0_3 associated to 0-dimensional geometries are located at the origin and at infinity on the (α, β) coordinates axis. The six straight lines are subsets invariant with respect to the recursion relation but repulsive in the region where they are dashed. The first points of two sequences of iterations are drawn. Note that for one of them the 10th point ($\alpha = -56.4, \beta = -52.5$) is outside the frame of the figure.

(Received 13 May 2005; published 20 October 2005)

We measure the spectral dimension of universes emerging from nonperturbative quantum gravity, defined through state sums of causal triangulated geometries. While four dimensional on large scales, the quantum universe appears two dimensional at short distances. We conclude that quantum gravity may be “self-renormalizing” at the Planck scale, by virtue of a mechanism of dynamical dimensional reduction.

Fractal space-times under the microscope: a renormalization group view on Monte Carlo data

Martin Reuter and Frank Saueressig

*Institute of Physics, University of Mainz,
Staudingerweg 7, D-55099 Mainz, Germany*

E-mail: reuter@thep.physik.uni-mainz.de,
saueressig@thep.physik.uni-mainz.de

ABSTRACT: The emergence of fractal features in the microscopic structure of space-time is a common theme in many approaches to quantum gravity. In this work we carry out a detailed renormalization group study of the spectral dimension d_s and walk dimension d_w associated with the effective space-times of asymptotically safe Quantum Einstein Gravity (QEG). We discover three scaling regimes where these generalized dimensions are approximately constant for an extended range of length scales: a classical regime where $d_s = d$, $d_w = 2$, a semi-classical regime where $d_s = 2d/(2+d)$, $d_w = 2+d$, and the UV-fixed point regime where $d_s = d/2$, $d_w = 4$. On the length scales covered by three-dimensional Monte Carlo simulations, the resulting spectral dimension is shown to be in very good agreement with the data. This comparison also provides a natural explanation for the apparent puzzle between the short distance behavior of the spectral dimension reported from Causal Dynamical Triangulations (CDT), Euclidean Dynamical Triangulations (EDT), and Asymptotic Safety.

Presented by Étienne Ghys

Abstract

We present relations between growth, growth of diameters and the rate of vanishing of the spectral gap in Schreier graphs of automaton groups. In particular, we introduce a series of examples, called Hanoi Towers groups since they model the well known Hanoi Towers Problem, that illustrate some of the possible types of behavior. *To cite this article:* R. Grigorchuk, Z. Šunić, *C. R. Acad. Sci. Paris, Ser. I* 344 (2006).

Tours de Hanoï

Pour les articles homonymes, voir [Hanoï \(homonymie\)](#).

Les tours de Hanoï (originellement, **la tour d'Hanoï**^a) sont un **jeu de réflexion** imaginé par le **mathématicien** français Édouard Lucas, et consistant à déplacer des disques de diamètres différents d'une tour de « départ » à une tour d'« arrivée » en passant par une tour « intermédiaire »,

Modèle d'une tour de Hanoï (avec ^[a] huit disques).

Heat Kernel Estimates and Dirichlet Forms (Intro 3)

$$p_t(x, y) \sim \frac{1}{t^{d_f/d_w}} \exp\left(-c \frac{d(x, y)^{\frac{d_w}{d_w-1}}}{t^{\frac{1}{d_w-1}}}\right)$$

$$\mathbf{distance} \sim (\mathbf{time})^{\frac{1}{d_w}}$$

d_f = Hausdorff dimension

$\frac{1}{\gamma} = d_w$ = “walk dimension” (γ =diffusion index)

$\frac{2d_f}{d_w} = d_s$ = “spectral dimension” (diffusion dimension)

First example: Sierpiński gasket; Kusuoka, Fukushima, Kigami, Barlow, Bass, Perkins (mid 1980'—)

Stability Theorem (Barlow, Bass, Kumagai (2006))

Under natural assumptions on the MMD (geodesic Metric Measure space with a regular symmetric conservative Dirichlet form), the sub-Gaussian **heat kernel estimates are stable under rough isometries**, *i.e.* under maps that preserve distance and energy up to scalar factors.

Gromov-Hausdorff + energy

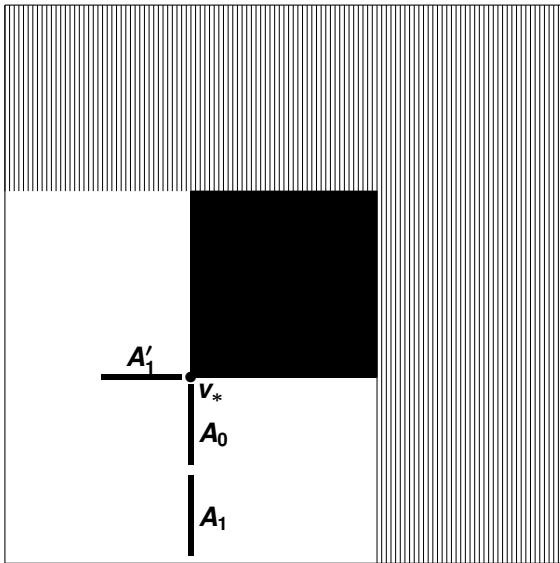

Theorem. (Barlow, Bass, Kumagai, T. (1989–2010).) On any generalized Sierpiński carpet there exists a unique, up to a scalar multiple, local regular Dirichlet form that is invariant under the local isometries.

Therefore there is a unique symmetric Markov process and **a unique Laplacian.**

Moreover, the Markov process is strong Feller and its transition density satisfies sub-Gaussian heat kernel estimates.

Main difficulties: If it is not a cube in \mathbb{R}^n , then

- ▶ $d_S < d_f, d_w > 2$
- ▶ the energy measure and the Hausdorff measure are mutually singular;
- ▶ the domain of the Laplacian is not an algebra;
- ▶ if $d(\mathbf{x}, \mathbf{y})$ is the shortest path metric, then $d(\mathbf{x}, \cdot)$ is not in the domain of the Dirichlet form (not of finite energy) and so methods of Differential geometry seem to be not applicable;
- ▶ Lipschitz functions are not of finite energy;
- ▶ in fact, we can not compute any functions of finite energy;
- ▶ Fourier and complex analysis methods seem to be not applicable.

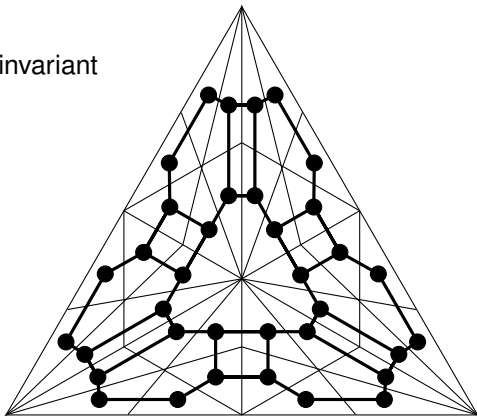

The half-face A_1 corresponds to a “slide move”, and the half-face A'_1 corresponds to a “corner move”, analogues of the “corner” and “knight’s” moves in [BB89].

However, it seems the uniqueness can fail in some natural settings, such as repeated barycentric subdivisions.

Theorem (Kelleher, Panzo, Brzoska, T.). The dual triangular and edge graphs have reciprocal resistance scaling factors $\rho = 1/\rho^T$ with $5/4 < \rho < 3/2$.

Conjecture. The reflection-invariant Dirichlet form is not unique.

BARLOW–BASS RESISTANCE ESTIMATES FOR HEXACARPET

Spectral analysis (Intro 4)

Theorem. (Derfel, Grabner, Vogl; T.; Kajino (2007–2011)) For a large class of **finitely ramified symmetric fractals**, which includes the Sierpiński gaskets, and may include the Sierpiński carpets, the spectral zeta function

$$\zeta(\mathbf{s}) = \sum \lambda_j^{\mathbf{s}/2}$$

has a meromorphic continuation from the half-plane $\mathbf{Re}(\mathbf{s}) > \mathbf{d}_S$ to \mathbb{C} . Moreover, all the poles and residues are computable from the geometric data of the fractal. Here λ_j are the eigenvalues of the unique symmetric Laplacian.

- ▶ Example: $\zeta(\mathbf{s})$ is the Riemann zeta function up to a trivial factor in the case when our fractal is $[0, 1]$.
- ▶ In more complicated situations, such as the Sierpiński gasket, there are infinitely many non-real poles, which can be called complex spectral dimensions, and are related to oscillations in the spectrum.

$$d_s = \frac{\log 9}{\log 5}$$

$$d_R = \frac{\log 4}{\log 5}$$

Poles (white circles) of the spectral zeta function of the Sierpiński gasket.

A part of an infinite Sierpiński gasket.

Figure: An illustration to the computation of the spectrum on the infinite Sierpiński gasket. The curved lines show the graph of the function $\mathfrak{R}(\cdot)$.

Theorem. (T. 1998, Quint 2009) On the Barlow-Perkins infinite Sierpiński fractafold the spectrum of the Laplacian consists of a **dense set of eigenvalues $\mathfrak{R}^{-1}(\Sigma_0)$ of infinite multiplicity** and a **singularly continuous component of spectral multiplicity one supported on $\mathfrak{R}^{-1}(\mathcal{J}_R)$.**

The Tree Fractafold.

An eigenfunction on the Tree Fractafold.

Theorem. (Strichartz, T. 2010) The Laplacian on the periodic triangular lattice finitely ramified Sierpiński fractal field consists of absolutely continuous spectrum and pure point spectrum. The **absolutely continuous spectrum** is $\mathfrak{R}^{-1}[0, \frac{16}{3}]$. The **pure point spectrum** consists of two infinite series of eigenvalues of infinite multiplicity. The spectral resolution is given in the main theorem.

Can we define harmonic differential forms, a de Rham complex, and obtain a version of de Rham's theorem?

Standard self-similar carpet \mathbf{S}_a
with $\mathbf{a} = (\frac{1}{3}, \frac{1}{3}, \frac{1}{3}, \dots)$

Non self-similar carpet \mathbf{S}_a
with $\mathbf{a} = (\frac{1}{3}, \frac{1}{5}, \frac{1}{7}, \dots)$

Proposition

(Mackay/Tyson/Wildrick'13) If $\mathbf{a} \in \mathbb{I}^2$ then \mathbf{S}_a has positive two dim Lebesgue measure and "all classical-type Sobolev inequalities".

Theorem (Hinz/T. '15)

1-dim Hodge-Helmholtz composition holds (despite that $\dim_H = 2$).

Theorem (Hinz/T. '17)

If $\mathbf{a} \in \mathbb{I}^2$, $\lim_{n \rightarrow \infty} \frac{a_1 \cdots a_{n-1}}{a_n} = 0$ then $\text{dom}(\text{curl}^*) = \{0\}$ and $(\text{curl}, \mathbf{C}^1)$ is not closable.

Luminy: Analysis on fractals and networks, and applications March 18-22, 2024

CIRM Luminy – Event N° 2950

please let me know if you'd like to attend and give a talk

7th Cornell Conference on Analysis, Probability, and Mathematical Physics on Fractals: June 4–8, 2022

In Memory of [Professor Robert Strichartz](#)

We will be dedicating the entire conference to Professor Strichartz. A special session will be scheduled during the conference for all to attend and reflect on their thoughts and memories of Bob. Bob is appreciated and recognized for his organizing of the Fractals Conference Community in 2002. He will be profoundly missed by family, friends, colleagues, and most of all, the students he mentored and influenced throughout his career.

A message from the Cornell Department of Mathematics Chair, Tara Holm:

Dear friends,

I am sad to share that our colleague and friend Professor Robert Strichartz died yesterday, 19 December 2021, after a long illness. He was 78.
